Leaves stalked, ovate. Flowers capitate or whorled. Calyx entirely clothed with hairs curved upwards. Flower-stalks rough with deflexed hairs.—Common in watery places throughout Europe. This is the most variable species of the whole. It is often purplish; always more or less hairy, and in general remarkably so; the hairs of the *stem*, *branches*, and *flower-stalks* all curved downward, those of the *foot-stalks*, *leaves*, and especially those which clothe the *calyx*, all turned forward or upward. The direction of the pubescence never varies, though its quantity is extremely variable. We have a wild specimen, which to the naked eye looks nearly as smooth as the *odorata* last described, but which is, indeed, minutely hairy, especially the *calyx* and *stalks*. The root that bore this, being transplanted into a neighbouring garden, produced, the following year, a plant as hairy as any variety we have seen. The smell of the present species is likewise changeable. In general it is pungent and aromatic, much like Spear Mint, but sometimes acquires the flavour of Pepper Mint, or of Camphor, and occasionally a very sweet odour, like Frankincense Thyme, very lasting in specimens seventy years old, and which is now and then found in the, usually fetid, *M. arvensis*. The *stems* are upright, mostly branched, in the manner of *M. odorata*. *Leaves* stalked, ovate, rather acute, but sometimes blunt, serrated, very variable in size; their veins strong and parallel. *Flowers* purplish; in the first variety, α , capitate, like those of *odorata*, with one or two dense, distant, stalked, axillary whorls below; in β , so many whorls terminate the stem or branches as to form a bluntish spike, still accompanied by a distant whorl, or rather a pair of stalked axillary heads, underneath; this has been made a species by most authors, but it has all the essential characters of α , into which we have observed it to change, even in a wild state, according to changes in the moisture of the soil; this is the *palustris* of Sole, t. 6; his *paludosa*, t. 22, has the whorls sessile, and more numerous, so as more nearly to resemble a properly whorled mint, which plants of this kind, from Mr. Sole, have completely become in our garden; in γ , which like α varies in size, hairiness, colour, and flavour, the inflorescence is entirely whorled throughout. It is not without repeated observations on these plants in their wild state, and long cultivation of them in two different gardens, one wet, the other dry, that we have been decided in considering these different forms of inflorescence, in the *M. hirsuta*, as constituting no specific distinction. We have indeed specimens which shew the change from α to γ . This is a point nevertheless which theoretical botanists find difficult to allow, and which nothing but great experience can establish. See a similar instance mentioned at the end of our 12th species.

15. *M. acutifolia*. Fragrant Sharp-leaved Mint. Fl. Brit. n. 7. Engl. Bot. t. 2415. (*M. verticillata*; Mill. Dict. ed. 8. n. 17.)—Flowers whorled. Leaves ovato-lanceolate, tapering at each end. Calyx hairy all over. Hairs of the flower-stalks spreading.—The only specimen we have ever seen, was gathered by Rand, at the side of the river Medway, in Kent. Miller says the plant grew between Rochester and Chatham, where Mr. Sowerby has sought it in vain. We doubt its being distinct from *M. hirsuta*, but the much more spreading hairs of the *flower-stalks*, first induced us to think it more than a variety. The very sweet scent, like frankincense thyme, agrees with a variety above-mentioned of *hirsuta*, nor perhaps can the tapering bases of the *leaves* be thought of more importance, as the foliage of the

latter species is acknowledged to vary much. The *whorls* are all quite sessile. *Calyx* clothed with ascending hairs, especially at the base, by which this plant is essentially distinguished from *rubra*, n. 17, while the hairy *flower-stalks* distinguish it from the following.

16. *M. canadensis*. Canadian Mint. Linn. Sp. Pl. 806. Ait. Hort. Kew. n. 13.—Flowers whorled. Leaves ovato-lanceolate, tapering at each end. Footstalks twice as long as the whorls. Calyx hairy all over. Flower-stalks quite smooth.—Gathered in Canada by Kalm. It was sent in 1801, by the late Mr. Masson, to Kew garden, where it lives in the open air, flowering in July. No figure of this species has yet appeared. It is more nearly allied to our *acutifolia*, than to the *arvensis*, with which Linnæus compares it. The long slender *footstalks*, sharply serrated and more lanceolate *leaves*, and the perfectly smooth and naked *flower-stalks*, are its discriminating characters. The *calyx* is hairy all over, with more erect hairs than in *arvensis*. The *whorls* are accompanied by long linear *bractæas*.

This should seem to be *M. borealis* of Michaux. Boreal-Amer. v. 2. 2; while his *tenuis* appears to be our small American variety of *viridis*, mentioned under that species; but having seen no specimens, we decline a positive reference to his work.

17. *M. rubra*. Tall Red Mint. Tr. of L. Soc. v. 5. 205. Engl. Bot. t. 1413. (*M. fativa*; Sole Menth. t. 21. *M. verticillata*; Raii Syn. 232. Riv. Monop. Irr. t. 48. f. 1. *M. fativa rubra*; Ger. em. 680. *M. pratensis*; Sole Menth. t. 17. (See Tr. of L. Soc. v. 5. 275.)—Flowers whorled. Leaves ovate. Stem upright, zigzag. Flower-stalks and lower part of the calyx very smooth; teeth hairy. Found about ditches, wet hedges, and the borders of rivers, not unfrequently, in England. Foreign writers seem unacquainted with this, which is the tallest and handsomest of our Mints, rising to the height of four, five, or six feet, with a red, wavy, usually smooth *stem*, bearing few and short branches. *Leaves* ovate, stalked, of a dark shining green, often very broad, with strong serratures; the upper ones small and short. *Whorls* numerous, stalked, of many large purplish-red *flowers*, with linear fringed *bractæas*. *Calyx* tubular, dotted with numerous resinous points, quite smooth, like the *flower-stalks*, except the teeth, which are always more or less furnished with upright hairs. The whole plant has a strong aromatic scent, especially in a dry soil. We have seen it kept in country gardens, and called Heart Mint, from its supposed cordial qualities. The Rev. Mr. Williams has observed this species in Shropshire, acquiring the peculiar scent of *M. arvensis*, of which we know no other instance.

18. *M. gentilis*. Bushy Red Mint. Linn. Sp. Pl. 805. Engl. Bot. t. 2118. (*M. rubra*; Sole Menth. t. 18. *M. rivalis* α ; ibid. t. 20. *M. variegata*; ibid. t. 19. *M. arvensis verticillata* varicolor; Morif. sect. 11. t. 7. f. 5.)—Flowers whorled. Leaves ovate. Stem very much branched and spreading. Flower-stalks and base of the calyx smooth.—In watery waste places, but not common. We have it from North Wales, Shropshire, and Somersetshire. Linnæus says it grows in the south of Europe, and Dr. Sibthorp found what he took for this species, and judged to be the $\epsilon\lambda\lambda\upsilon\sigma\mu\omicron\varsigma$ $\alpha\gamma\chi\epsilon\iota\omicron\varsigma$ of Dioscorides, frequent among stubble in Greece, at the end of autumn; but there being no specimen in his herbarium, we cannot be certain of what he intended. This differs widely from the last in having a low, bushy, much-branched *stem*. The whole plant is rather hairy, and on a dry soil pleasantly aromatic. *Leaves* paler, less shining, and more elongated than in *rubra*, as well as more uniform in shape; their veins whitish underneath.

neath. *Whorls* not quite sessile. *Bracts* lanceolate, various in size. *Flower-stalks* round, purple, for the most part very smooth. Upper part of the *calyx* more or less rough, with ascending hairs; base smooth; the whole sprinkled with resinous dots. *Corolla* pale purple, generally a long as the *filaments*. The variety with blotches of yellow on the *leaves*, (Sole's t. 10, figured also in Morison,) when cultivated in a dry gravelly soil, is much improved in scent, and undergoes other changes; the *whorls* often become elevated on long leafy stalks, and the *flower-stalks* rough with deflexed hairs.

19. *M. gracilis*. Narrow-leaved Mint. Sole Menth. t. 16. Fl. Brit. n. 10. (*M. gentilis*; Engl. Bot. t. 449. Sole Menth. t. 15. *M. hortensis verticillata*, ocyimi odore; Morif. feët. 11. t. 7. f. 1.)—Flowers whorled. Leaves lanceolate, nearly sessile. Stem much branched, erect. Flower-stalks and base of the calyx very smooth.—On commons and waste ground, chiefly in watery places. The variety smelling like Basil, *gentilis* of Sole, is said by that author to be "frequent in ditches and waste places, near towns and villages, but scarcely wild." We have seen it in gardens only, where it is sometimes kept for its scent, resembling Basil, or the perfume of the Muscat Grape; but this flavour is not so constant in the living plant, nor so permanent in the dry one, as many others met with in this genus. The ordinary *M. gracilis* has the strong lasting scent of *viridis*, not of the finest kind. The whole *herb* is a little hairy. Stem erect, twelve or eighteen inches high, much branched about the middle, leafy, rough, and reddish. Leaves uniform, lanceolate, acute, sharply serrated, tapering much at the base, but hardly stalked, bright green, slightly clothed with short hairs. *Whorls* generally sessile, with lanceolate hairy *bracts*. *Flower-stalks* round, purple, uniformly and perfectly smooth. *Calyx* tubular, somewhat bell-shaped, purple, with resinous dots; very smooth and naked at the base; furrowed upwards, and clothed towards the top, especially its taper-teeth, with white upright hairs. *Corolla* purplish, bearded at the extremity, longer than the *filaments*.—The Basil-scented variety has deflexed *leaves*; the lower ones ovate; the floral ones often so small, that it assumes the aspect of a spiked mint. Had we not found it by culture extremely variable in these characters, while the *flowers* constantly agree with the true *gracilis*, we might have been tempted to consider this variety a distinct species.

20. *M. arvensis*. Corn Mint. Linn. Sp. Pl. 806. Hudf. 253. Fl. Brit. n. 11. Engl. Bot. t. 219. Sole Menth. t. 12. Ehrh. Pl. Off. 416. Fl. Dan. t. 512. (*M. arvensis verticillata procumbens*; Morif. feët. 11. t. 7. f. 5. *Calamintha aquatica*; Ger. em. 684. *M. procox*; Sole Menth. t. 13.)—Flowers whorled. Leaves ovate. Stem much branched, diffuse. Calyx bell-shaped, clothed all over with horizontal hairs.—Frequent in corn-fields where water stagnates in winter, especially on a sandy or gravelly soil. It is often a troublesome weed, because of the widely-creeping nature of the *root*, and its turgid fleshy shoots, well calculated to retain life in a soil that fluctuates as to humidity. The *stems* are mostly diffuse, and much branched. *Leaves* ovate, inclining to elliptical, obtuse, pale, clothed with rather rigid prominent hairs. *Flower-stalks* shortish, round, generally smooth, sometimes furnished with a few spreading, or slightly deflexed, hairs. *Calyx* shorter, more bell-shaped, and more broadly toothed than in any of the foregoing, and essentially characterised by being clothed all over with horizontally spreading hairs. *Flowers* reddish-lilac, externally hairy.

This species is readily known by its peculiar scent, justly compared to that of blue mouldy cheese, and which Haller

lays he could not endure. The dried specimens strongly retain it. The neat, elliptical, *brother-leaves* of Mr. Sole's *procox*, and its earlier time of flowering, indicate somewhat of a specific difference, but culture and repeated observations have not confirmed it. *M. arvensis*, Jacq. Austr. t. 53. Winkl. n. 10, is with great probability identified by the latter author to be a variety of *arvensis*. Mr. Which has sent us from Mr. Richards's Garden an almost unbranched specimen of *arvensis*, very like Jacquin's figure; but having been no Austrian specimen, we could not bring on the subject. The hairs of the *calyx* and *flower-stalks*, which nobody has properly described, and which is the matter in dispute. Jacquin's plate bears a great resemblance to the *procox*. A variety of *arvensis*, with the flavour of Basil, is the *gentilis* of Mill. Dict. ed. 8. t. 15.

21. *M. argyrea*. Rugged Field Mint. Sol. Menth. t. 14. Engl. Bot. t. 212. (*M. arvensis*; Fl. Brit. t. 24. Tr. of Linn. Soc. v. 5. 213. 216.)—Flowers whorled. Leaves somewhat heart-shaped, strongly serrated, rugose. Stems erect. Calyx bell-shaped, clothed all over with horizontal hairs.—Observed by Mr. Sole in corn-fields and neglected-gardens in Somersetshire. Mr. Barrer finds it very common in Sullex. We have been induced, in the 30th vol. of Engl. Bot. to agree with Mr. Sole in separating this plant from *arvensis*, on account of its upright stem, and roundish-heart-shaped, rugged, dark, strongly serrated leaves, which give it a peculiarly coarse and harsh aspect; all which marks our cultivated and abundantly increasing specimens have now retained for thirteen years without the least variation. The parts of the *flower*, and the scent of the whole *herb*, accord entirely with the *arvensis*.

22. *M. Pulegium*. Common Penny-royal. Linn. Sp. Pl. 807. Woodv. Med. Bot. t. 171. Sole Menth. t. 23. Engl. Bot. t. 1026. (*Pulegium*; Fuchf. Hill. 193. Riv. Monop. Irr. t. 23. f. 1. Brunf. Herb. v. 1. 227. *P. regium*; Ger. em. 671.)—Flowers whorled. Leaves ovate. Stem prostrate. Flower-stalks downy. Calyx hairy all over, with fringed teeth.—Native of watery places in various parts of Europe. This is much smaller than any of the preceding, and is known by its prostrate stems; small, downy, stalked, ovate, reflexed leaves, sparingly serrated; and numerous dense whorls of purplish, sometimes white, flowers, without *bracts*. The *flower-stalks* are always densely clothed with fine short prominent hairs or down. *Calyx* less densely clothed, either with hairs of the same length, or, as is most commonly the case, with longer and more bristly hairs, a little ascending; its teeth fringed with bristles; its mouth closed with hairs. *Corolla* twice the length of the calyx, very hairy externally, shorter than the *filaments*. The broadest segment of the *corolla* is decidedly cloven, as it ought to be in *Mentha*. Some botanists thought they found it otherwise, and on that ground were disposed to separate *Pulegium* as a genus.

The flavour of Penny-royal is peculiarly strong, resembling *Thymus Nepeta*, Fl. Brit., but not confined to these plants. Some *Curile* and *Saturja* have the same scent.

Some old authors distinguished from this the *Mentha aquatica*, *pulegium mas diela*; Tournef. Inil. 190. *Pulegium latifolium alterum*; Bauh. Pin. 222. P. mas; Ger. em. 671.—This is said to differ in having an erect stem. We have carefully examined a specimen in Sherard's herbarium, and have been inclined to make it a distinct species, the leaves being broad and nearly smooth, and the hairs of the *calyx* rather more long and bristly than in any British varieties of *Pulegium*. Still as we perceive gradations among the latter, we prefer leaving the matter as we find it, till living specimens fall in our way. About the following we have less doubt.

MENTHA.

23. *M. tomentosa*. Downy Penny-royal. (*M. aquatica tomentosa minima*; Tourn. Inst. 190. *Pulegium tomentosum minimum*; Bocc. Sic. 40. t. 41. f. 2.)—Flowers whorled. Leaves ovate, hairy. Stem ascending. Flower-stalks densely clothed with horizontal hairs. Calyx covered with long loosely-spreading hairs.—Native of Sicily. We have it from Algiers, sent by the late Monf. Broussonet. Its appearance is altogether much more hairy or shaggy than any variety of *Pulegium*; the mouth of the calyx is entirely clothed with wool rather than hair, and the hairy covering of the flower-stalks is remarkable for its great length and density. If these marks be accidental, we know no other instance of the kind among *Mentha*, yet we confess them rather differences in degree, than in direction, of the pubescence.

24. *M. cervina*. Hyssop-leaved Mint. Linn. Sp. Pl. 807. Willd. n. 21. (*M. n. 222*; Hall. Hist. v. 1. 98. *Pulegium angustifolium*; Moris. sect. 11. t. 7. f. 7. Riv. Monop. Irr. t. 23. f. 2. Ger. em. 672.)—Flowers whorled. Bractæas palmate. Leaves linear. Calyx and flower-stalks smooth.—Native of the south of France. A most distinct and remarkable species. The whole plant is smooth, larger than *Pulegium*, with which it nearly agrees in flavour and qualities. Stem ascending, slightly quadrangular, not much branched. Leaves sessile, linear, keeled, nearly or quite entire; their under side copiously dotted. Whorls large, dense, many-flowered, each accompanied by a pair of broad, rigid, ribbed, palmate bractæas. Calyx tubular, ribbed, with short spinous teeth. Corolla twice as long as the calyx. Stamens prominent.

Two Linnæan species remain to be noticed. These are—*M. exigua*; Linn. Sp. Pl. 806 Sm. Plant. Ic. ex Herb. Linn. t. 38. This is shewn in Tr. of Linn. Soc. v. 3. 18, to be the same plant as *Cunila pulegioides* of Linnæus, and is therefore struck out of the present genus.

M. perilloides. Linn. Syft. Veg. ed. 13. 445. (*Ocimum frutescens*; Linn. Sp. Pl. 832.)—This is indeed distinct from *Perilla ocymoides*, with which some have been disposed to confound it; but so little like a *Mentha*, that it does not concern our present subject; neither is the original specimen sufficient to determine its genus. S.

MENTHA canariensis plumosa. See BYSTROPOGON.

MENTHA, in Gardening, comprehends plants of the hardy herbaceous perennial kind, of which the species cultivated are, the spear-mint (*M. viridis*); the round-leaved mint (*M. rotundifolia*); the curled mint (*M. crispa*); the pepper-mint (*M. piperita*); the red mint (*M. gentilis*); the penny-royal (*M. pulegium*); and the hyssop-leaved mint, or upright penny-royal (*M. cervina*.)

From the first kind not being so hot to the taste as peppermint, and having a more agreeable flavour than most of the other sorts, it is generally preferred for culinary and other purposes. The leaves and tops are used in spring salads, and eaten as sauce with lamb, and, when dried, in soups, &c.

There are several varieties of it, as, the broad-leaved; the narrow-leaved; the curled-leaved; the variegated-leaved; the silver-striped-leaved; and the gold-striped-leaved.

The fourth species, in its external appearance, corresponds with the first sort, for which it may easily be mistaken; but in that the stem is taller, the leaves have scarcely any petioles, and are narrower in proportion to their length, the spikes are longer and composed of more whorls.

In the fifth sort there is a variety with the scent of basil; the orange-scented mint; the gold-striped orange mint; the yellow-orange mint; and the reddish-orange mint.

And the sixth species varies with a white flower, and with

the stems erect, nearly a foot high: the leaves longer and narrower: the whorls of flowers much larger, the stamens longer than the corolla: this is Spanish penny-royal, which has almost superseded the other sort; the stems being more erect, it is easier to tie in bunches, and it comes earlier to flower, and has a brighter appearance,

In the seventh sort there is a variety with white flowers, growing taller than the common one with purple flowers, which is by some preferred to the sixth sort for medicinal use, and called Hart's penny-royal.

Method of Culture in the Mint Kind.—All these plants may be increased with facility by young offset plants or shoots, or by parting their roots, and planting them out in the spring, or by planting cuttings during any of the summer months in a moist soil. After the cuttings are planted, when the season is dry, they should be often watered until they have taken root; when they require no further care, but to be kept clean from weeds. The best method is to plant them in beds about four feet wide, allowing a path about two feet broad between them, to water, weed, and cut the plants; being set four or five inches or more distant in the rows, as the plants spread much at their roots; on which account the beds should not stand longer than three years before planting them again, as by that time the roots become so closely matted, as to rot and decay each other when they are suffered to stand longer.

With regard to the general culture it is that of clearing them from weeds in spring and summer, cutting down all the remaining stalks annually in autumn; removing all weeds; digging the alleys, and spreading a little of the earth over the beds. Plantations thus formed will afford several cuttings every summer, when only wanted young for use, for culinary purposes; but when for drying to keep in winter, or green for distilling or medicinal use, the plants should generally be suffered to stand until nearly full grown, and they are just coming into flower; which being then cut down close, the roots send up another crop fit for cutting again in the beginning of autumn, or towards Michaelmas; each general cutting being always made as close to the ground as it possibly can be done.

Method of forcing Mint on Hot-beds.—Where it is much wanted for salads in the winter and early spring seasons, a hot-bed should be made for this purpose, any time after November till the spring, about two feet thick of dung, covering it with garden frames and glasses, or with mats on arched sticks, which should then be earthed over with rich mould, six inches thick; when a quantity of roots should be taken up from a bed and planted pretty close together upon the surface of the bed, moulding them over an inch deep with fine earth, putting on the lights, or other coverings, keeping them close in the nights and in bad weather, but admitting fresh air in mild weather. The plants soon come up, when fresh air should be admitted in fine weather, and moderate waterings should be given, and they will soon be ready to have their young green tops gathered for use. When the plants are two or three inches high, they are ready for being cropped, after which they presently break out again, and fresh shoots rise from the bottom; so that the same bed furnishes fresh supplies a long time; two beds, made at different times, being generally sufficient for the whole winter use. In this way mint may be obtained young and green from the time that in the natural ground it goes off in autumn until it comes in again in the spring season.

Young mint shoots may also be procured by planting some roots thick in large pots, and placing them in a hot-house,

house, as they quickly shoot and furnish plants of young green mint in such situations.

Where this practice is much attended to, small fresh plantations should be made annually in the open ground for the purpose of furnishing a sufficiency of roots, proper for taking up at forcing time without disturbing those of the principal crops.

Method of Culture in the Penny-yeal Kind.—These may be increased in the same manner as above, and also by their creeping stems, which should be cut off and planted out in fresh beds, allowing at least a foot distance every way. The young shoots planted in the spring in the same way also take root like the other sorts. The proper time for this work is in the early autumn, that the plants may be well rooted before winter.

It is found that in this way the plants are much stronger, and produce larger crops than when planted out in the spring. When the roots remain so close as is generally the case, they are apt to rot in the winter season. They succeed best in a moist strong soil.

It may be noticed that some of the species and varieties may be introduced in the borders and other parts of pleasure grounds, for ornament and variety with good effect.

MENTHA, in the *Materia Medica*. Several species of this genus have some claims on our notice under this head. The *Mentha piperita*, or "pepper-mint," has a more penetrating smell than any of the other mints, and a much stronger and warmer taste, pungent like pepper, sinking as it were into the tongue, and followed by a sensation of coldness. By maceration, or infusion, it readily and strongly impregnates both water and spirit with its virtue. On distillation with water, it yields a considerable quantity of essential oil of a pale greenish-yellow colour, growing of a darker colour by age, very light, subtle, possessing in a high degree the specific smell and penetrating pungency of pepper-mint. According to Dr. Cullen, rectification is particularly necessary and proper for this essential oil. What has been called essence of pepper-mint is, in his opinion, no other than the rectified oil, dissolved in spirit of wine. Rectified spirit, drawn with a gentle heat from the tincture made in that menstruum, brings over little of the virtue of the herb, nearly all its pungency and warmth remaining concentrated in the extract. This plant, it is observed, yields camphor. Its stomachic, antispasmodic, and carminative qualities render it useful in stultent colics, hysterical affections, retchings, and other dyspeptic symptoms, acting as a cordial, and often producing immediate relief. Its officinal preparations are an essential oil, a simple water, and a spirit. The water is prepared by pouring on, *e. g.* a pound and half of pepper-mint, so much water, that, after the distillation, a sufficiency may remain to prevent empyreuma; and distilling over a gallon. The spirit of pepper-mint is obtained by macerating, for 24 hours, a pound and half of pepper-mint dried in a gallon of proof spirit, with water sufficient to prevent empyreuma, and distilling a gallon by a gentle fire.

Mentha viridis, or *sativa*, "spear-mint," is not so warm to the taste as pepper-mint, but having a more agreeable flavour, it is preferred for culinary uses, and more generally cultivated in our gardens. Many virtues are ascribed by the ancients to mint, but the particular species is not ascertained. This, however, is of no great importance in a medical view, as the virtues of all reside in the aromatic flavour, which is common to the whole genus. On drying, the leaves lose about three-fourths of their weight, without suffering much loss of their smell or taste; nor is the smell soon dissipated by moderate warmth, or impaired on keep-

ing. Cold water, by maceration for six or eight hours on the dry herb, and warm water in a shorter time, become richly impregnated with its flavour. By distillation, a pound and a half of the dry leaves communicate a strong impregnation to a gallon of water. the distilled water proves rather more elegant, if drawn from the fresh plant in the proportion of ten pints from three pounds. Along with the aqueous fluid an essential oil distils, of a pale yellowish colour, changing to a red, in quantity near one ounce from ten pounds of the fresh herb in flower, smelling and tasting strongly of the mint, but somewhat less agreeable than the herb itself. Dry mint, digested in rectified spirit, either in the cold or with a gentle warmth, gives out readily its peculiar taste and smell, without imparting the grosser and more ungrateful matter, though the digestion be long continued. The tincture appears by day-light of a fine dark green, by candle-light of a dark red colour: a tincture extracted from the remaining mint by fresh spirit, appears in both lights green: the colour of both tinctures changes, in keeping, to a brown. On gentle distillation, with proof spirit, the spirituous portion which rises at first discovers little flavour of the mint; but as soon as the watery part begins to distil, the virtues of the mint come over plentifully with it. Hence the spiritus menthæ sativæ, P. L., which is prepared by drawing off a gallon of proof spirit from a pound and a half of the dried plant, proves strongly impregnated with the mint.

To spear-mint are to be ascribed the same medicinal qualities which we have noticed of pepper-mint; but the different preparations of the former, though more pleasant, are perhaps less efficacious. It contains much essential oil, but of an odour somewhat less agreeable than that of lavender or marjoram. It is therefore less employed as a cephalic; but it acts very powerfully on the parts to which it is immediately applied, and therefore considerably on the stomach, invigorating all its functions. It acts especially as an antispasmodic, and therefore relieves pains and cholick depending upon spasm. It will also stop vomiting, depending upon such a cause; but there are many cases of vomiting in which it is of no service: and in these cases, anywise depending upon inflammatory irritation in the stomach itself, or in other parts of the body, it aggravates the disease, and increases the vomiting. Practitioners have thought, and we think justly, that the infusion of mint in warm water agrees better with the stomach than the distilled water, which is often somewhat empyreumatic.

Lewis observes, that it is said by some to prevent the coagulation of milk; and hence it has been recommended to be used along with milk diets, and even in cataplasms and fomentations for resolving coagulated milk in the breasts. Upon experiment, the curd of milk, digested in a strong infusion of mint, could not be perceived to be any otherwise affected than by common water; but milk, in which mint leaves were set to macerate, did not coagulate near so soon as an equal quantity of the same milk kept by itself.

The officinal preparations of spear-mint are an essential oil, a conserve, a simple water, and a spirit. Lewis M. M. Cullen M. M. Woodville Med. Bot.

The spear-mint water, aqua menthæ viridis of the London Pharmacopeia, is prepared by pouring on a pound and half of spear-mint so much water, that, after the distillation, enough may remain to prevent empyreuma; and distilling over a gallon. The spirit, spiritus menthæ viridis, is obtained by macerating, for 24 hours, a pound and half of dried spear-mint in a gallon of proof spirit, with water sufficient to prevent empyreuma, and distilling a gallon by a gentle fire.

Menba Pulegium, "Penny-royal mint," has a warm pungent flavour, somewhat similar to mint, but more acrid, and less agreeable both in smell and taste. Its active principle is an essential oil, of a more volatile nature than that of mint, coming over hastily with water at the beginning of the distillation, and rising also in great part with highly-rectified spirit; in taste very pungent, and of a strong smell; when newly drawn, of a yellowish colour, with a cast of green; by age turning brownish.

The pulegium certainly possesses the general properties of the other mints: it is supposed, however, to be of less efficacy as a stomachic, but more useful as a carminative and emmenagogue, and is more commonly employed in hysterical affections. We are told by Boyle, and others, that it has been successfully used in the whooping-cough; but the chief purpose to which it has long been administered is promoting the uterine evacuation. With this intention, Haller recommends an infusion of the herb with steel, in white wine, which he never knew to fail of success. However, in the opinion of Dr. Cullen, mint is in every respect a more effectual remedy than penny-royal; and nothing but the neglect of all attempts to establish principles could have made physicians think of this as a peculiar medicine different from the other species: and conformably to this remark, it may be observed, that this plant is less frequently used now than formerly.

Its official preparations are a simple water, a spirit, and an essential oil. Lewis M. M. Cullen M. M. Woodville Med. Bot.

Aqua pulegii, "Penny-royal water," is prepared by pouring on a pound and half of penny-royal so much water, that, after distillation, enough may remain to prevent empyreuma, and distilling over a gallon. The "spirit of penny-royal" is obtained by macerating, for 24 hours, a pound and half of dried penny-royal in a gallon of proof spirit, with water sufficient to prevent empyreuma, and distilling a gallon by a gentle fire. The water which distils over with the oils of pepper-mint, spear-mint, and penny-royal, is to be kept for use. Lond. Pharmac. 1809.

MENTI LEVATOR, in *Anatomy*, a small muscle in the chin. It is described with the muscles of the lower lip, in the article DEGLUTITION.

MENTOLE, in *Geography*, a town of the island of Ceylon, on the west coast; 80 miles W.N.W. of Trincomaly. N. lat. $9^{\circ} 1'$. E. long. $80^{\circ} 3'$.

MENTON, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; 6 miles N.E. of Monaco. The place contains 3289, and the canton 4383 inhabitants, on a territory of 60 kilometres, in 4 communes.

MENTOS, a town of Louisiana, on the Akanfas; 150 miles S.W. of New Madrid. N. lat. $35^{\circ} 27'$. W. long. $92^{\circ} 40'$.

MENTUM, in *Anatomy*, the lower part of the face, beneath the mouth; which we otherwise distinguish by the name of *chin*.

MENTZ, or MAYENCE, *Archbishopric of*, in *Geography*, formerly an electoral principality of Germany, in which, besides corn, are breeds of cattle, fine garden fruits, and excellent wines, particularly those Rhenish wines that are furnished by the Rheingau; good salt is also manufactured here, and it has here and there iron mines. In the Mentz portion of the Berg-Strazza is found plenty of almonds, chestnuts, and fiberds. The lower part of the Eichsfeld yields corn in sufficient abundance, together with large quantities of flax and tobacco. The principal rivers are the Rhine, the Maine, the Jaxt, and the Lahn. In the whole

of the electoral countries of Mentz, comprehended within this circle, were 41 cities and 21 boroughs. Eichsfeld is now annexed to the kingdom of Westphalia. In the upper Eichsfeld are manufactures of serge and linen; and in the lower, tobacco and flax are cultivated. In the archbishopric are some woollen and other manufactures; and a considerable trade is carried on in wines. From Berg-Strazza are exported almonds, chestnuts, nuts, and nut-wood. The countries lying on the Rhine and on the Maine have, ever since the Reformation, been subject to the elector of Mentz, and maintained their attachment to the Roman Catholic faith. It was in the year 751 that the bishopric of Mentz was fully established as an archbishopric, which was first administered by S. Boniface; and with the archbishopric, the first in Germany, the dignity of elector was inseparably connected. In 1802, at the settlement of the indemnities, in consequence of the ascendancy gained by the French in Germany, all that part of the diocese which lay on the right of the Maine, was given to the prince of Nassau-Usingen, except the bailiwick of Aschaffenburg. It was then determined that the electoral title should from that time be elector of Aschaffenburg, and count of Wetzlar; that he should still continue arch-chancellor of the empire, and hold his office at Ratisbon, with some abbies, and other indemnities, so as to yield an annual revenue of a million of florins. His jurisdiction, as metropolitan of the German church, was to extend all over Germany, except the Prussian states.

MENTZ, or *Mayence*, formerly capital of the above-mentioned electorate and archbishopric of Germany, but by the treaty of Campo Formio, 1797, a city of France, chief place of a district, and capital of the department of Mont-Tonnerre, situated at the conflux of the Rhine and Maine; bearing in Latin the appellation of "Moguntium." It was considered as a barrier fortress of the empire. The city is large and populous, but consists, for the most part, of narrow streets and old-fashioned houses, intermixed with some fine buildings, a considerable palace, and a magnificent cathedral. Before the revolution, it contained seven parish churches, six monasteries, and five nunneries, with a charter-house and two other nunneries near the city, and also six hospitals. The university was founded by Charlemagne in 800, and established in 1482 by the archbishop Diether. It has undergone many revolutions, and frequently changed its masters, until in 1792 it was taken by the French; but in the following year it was retaken. By the peace between the emperor and the French it was surrendered to the latter, who took possession of it. The number of inhabitants is reckoned at 21,400, and those of its canton 21,615, in two communes. N. lat. $49^{\circ} 58'$. E. long. $8^{\circ} 14'$.

MENTZELIA, in *Botany*, named by Plumier in honour of Dr. Christian Mentzel, Counsellor and Physician to the Elector of Brandenburg, who published, in 1682, in folio, an Index of the names of plants in various languages, accompanied by a small catalogue of rare plants, with plates. He wrote also some papers in the Ephemerides Acad. Nat. Curios. on geological subjects, and died in 1701, aged 79. Plum. Gen. 40. Linn. Gen. 270. Schreb. 360. Willd. Sp. Pl. v. 2. 1175. Mart. Mill. Dict. v. 3. Jacq. Amer. 164. Ait. Hort. Kew. ed. 2. v. 3. 302. Juss. 321. Lamarck Illust. t. 425.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagraceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, spreading, deciduous, of five, lanceolate, concave, pointed leaves. *Cor.* Petals five, obovate, pointed, spreading, a little longer than the calyx. *Stam.* Filaments numerous (about thirty), the length of the calyx, erect, the outer ones membranous in the upper part; others roundish. *Pist.* Germen inferior, cylindrical,

cylindrical, long; style thread-shaped, as long as the stamens; stigma simple, obtuse. *Peric.* Capsule cylindrical, long, of one cell, three-valved at top. *Seeds* about six, oblong, angulated.

Eff. Cl. Calyx of five leaves. Petals five. Capsule inferior, cylindrical, many-seeded.

1. *M. aspera*. Linn. Sp. Pl. 735. (*M. foliis et fructibus asperis*; Plum. Ic. 167. t. 174 f. 1.)—Stem branched. Flowers axillary. Petals notched, obtuse.—A native of South America, and the West Indies, very common among the bushes in all the dry savannahs about Kingston, Jamaica. It flowers in the gardens during July and August. *Root* annual. Whole herb clothed with rigid, partly hooked bristles. *Stem* round, branched, leafy. *Leaves* on longish stalks, oblong, somewhat hastate, acute, unequally and coarsely serrated. *Flowers* axillary, solitary, nearly sessile, yellow. The germen and calyx very bristly.

2. *M. hispida*. Willd. n. 2. (*M. aspera*; Cavan. Ic. v. 1. 51. t. 70.)—Stem forked. Flowers solitary, at the forks of the stem. Petals entire, acutely pointed.—A native of Mexico. This differs from the last in having the leaves more ovate, flowers principally from the forks of the stem, with a much shorter and ovate germen, and longer leaves of the calyx. Willdeow also points out the above difference of the petals.

This genus is very nearly allied in habit as well as character to *Loosa* (see that article); indeed so much are they alike, that we greatly suspect they must be one genus, for which *Mentzelia*, being the oldest name, ought to remain, and the other ambiguous appellation would be happily superseded.

MENU, in *Biography*, is the name of a very celebrated law-giver among the Hindoos. Sir William Jones translated his code from the original Sanscrit; and it is in the hands of the public, under the title of "Institutes of Hindoo Law, or the Ordinances of Menu." The work comprises, in 12 chapters and 2685 verses, the Indian system of duties, religious and civil, and is held in the greatest reverence by all classes of Hindoos; so much so, that should a series of Brahmans omit, for three generations, the reading of Menu, their sacerdotal class would, as they assert, be forfeited. They must, however, explain it only to their pupils of the three highest classes: and to ensure a greater degree of reverence for its sanctity, it is understood that a Brahman, duly pious, would not, on any consideration, read it on a forbidden day of the moon, or until after the performance of certain ceremonies prescribed in the code. The learned translator, from internal evidence, ascribes the date of the Institutes, in their present form, to a period so far back as 880 years before Christ. Whether Menu, or Menus in the nominative, and Menos in an oblique case, was the same personage with Minos, he leaves others to determine; but he evidently inclines to that opinion, though, with his characteristic modesty, he forbears any pointed expression of it. He recognises a strong resemblance, though obscured and faded by time, between the Menu of the Hindoos, with his divine bull, or the emblem of abstract justice, and the Mneues of Egypt, with his companion or symbol Apis: and though he duly guards himself and his readers against the delusions of etymological conjecture, he relates Minos and Mneues, or Mneuis, to be merely Greek terminations, and that the crude nouu is composed of the same radical letters in Greek and Sanscrit. "And if," he continues in his preface, "Minos, the son of Jupiter, whom the Cretans, from national vanity, might have made a native of their own island, was really the same person with Menu, the son of Brahma, we have the good fortune to restore, by means of

Indian literature, the most celebrated system of heathen jurisprudence." The fables of the Hindoos, as to the antiquity and origin of the laws of Menu, are in their usual style of extravagance. They firmly believe them to have been promulgated in the beginning of time by Menu, son or grandson of Brahma, or, in plain language, the first of created beings; and not the eldest only, but the host of legislators.

Menu is highly honoured by name in the Veda itself, where it is declared, that "whatever Menu pronounced was a medicine for the soul itself;" and it is asserted by a high authority among the Hindoos, "that Menu held the first rank among legislators, because he had expressed in his code the whole sense of the Veda; that no code was approved, which contradicted Menu; that other *astras*, and treatises on grammar or logic, retained splendour only so long as Menu, who taught the way to just wealth, to virtue, and to final happiness, was not seen in competition with them." It has been also authoritatively asserted, that "the Veda, with its *Angas*, or the six compositions deduced from it, the revealed system of medicine, the *Puranas*, or sacred histories, and the code of MENU, were four works of supreme authority, which ought never to be shaken by arguments merely human." It is the general opinion of the Pandits, that Brahma taught his laws to Menu in 100,000 verses, which Menu explained to the world in the very words of the book translated by Sir William Jones. It was afterwards abridged to 12,000 verses, and subsequently to 4000; but at present they consist only of 2685 verses. Of the numerous glosses or comments on Menu, that of Cullucá Bhatta is most highly commended by Sir William Jones, who has implicitly followed his text and interpretation.

The work, as presented to the European reader by Sir William Jones, contains abundance of curious matter, extremely interesting both to speculative lawyers and to antiquaries; with many beauties, and with many blemishes, which cannot be justified or palliated. It is a system of despotism and priestcraft, both indeed limited by law, but artfully conspiring to give mutual support, though with mutual checks: it abounds with strange conceits in metaphysics and natural philosophy, with idle superstitions, and with a scheme of theology most obscurely figurative, and consequently liable to dangerous misconceptions; with minute and childish formalities; with ceremonies generally absurd, and often ridiculous. The punishments denounced are partial and fanciful; for some crimes dreadfully cruel, for others reprehensibly slight: and the morals even, though rigid enough on the whole, are, in one or two instances, (as in the case of light oaths and of pious perjury,) unaccountably relaxed. Nevertheless, a spirit of sublime devotion, of benevolence to mankind, and of amiable tenderness to all sentient creatures, pervades the whole work. Some doubt, however, has been entertained with regard to the sublimity of the devotion, and the amiable tenderness of feeling, ascribed by Sir William Jones to this specimen of the Hindoo writings; and it has been alleged, that the general character of the devotion of the Hindoos is that of a debasing superstition, and that their tenderness for animals is chiefly superstition and weakness, derived from their doctrine of transmigration. The style of it has a certain austere majesty that sounds like the language of legislation, and extorts a respectful awe. The sentiments of independence on all beings but God, and the harsh admonitions, even to kings, are truly noble. Whatever opinion, in short, may be formed of Menu and his laws, in a country happily enlightened by sound philosophy and the only true revelation, it ought to be remembered that those laws are actually revered as the

word of the Most High, by nations of great importance to the political and commercial interests of Europe, and particularly by many millions of Hindoo subjects, whose well directed industry adds largely to the wealth of Britain, and who ask no more in return than protection for their persons and places of abode, justice in their temporal concerns, indulgence to the prejudices of their old religion, and the benefit of those laws which they have been taught to believe sacred, and which alone they can possibly comprehend. See Preface to Sir William Jones's translation of the "Institutes of Menu," in his Works, vol. vii. p. 75, &c. 8vo. (See GENTOO.) For an extended account of its incomparable translator, see our article JONES, Sir WILLIAM.

The Hindoos have, however, seven holy persons distinguished by the common denomination of Menu, whose names we shall presently give; but the first and last only demand any particular notice. The name is derived from the Sanscrit root *men*, or *man*, to understand or think; and it signifies, as all the Pandits agree, *intelligent*, particularly in the doctrines of the Veda, or a thinking being: hence *menes*, *mens*, and *mind*, also *man*, both in Gothic and English. If in the first Menu we recognise Adam, our great progenitor; so in the seventh we find Noah, the great restorer of our species. Here follow their names: 1. Swayambhuva, meaning the son of the Self-existent; a name applied by different sects to the peculiar object of their adoration. 2. Swarochesha. 3. Uttama. 4. Tamasa. 5. Raivata. 6. Chakusha. 7. Satyavrata. In the time of the last, the general deluge occurred. See MATSYAVATARA and ILA, also SWAYAMBHUVA and SATYAVRATA.

Although seven Menus are usually referred to in Hindoo books, that precise number is not always given. In the tenth lecture of the Gita, (see MAHABARAT,) "the four Menus" are mentioned; and fourteen are spoken of in the Siva-purana. It seems, indeed, a generic term for *wisdom*. Mr. Wilford (As. Res. vol. v.) thinks it likely that the seven Menus, the seven Brahmadicas, and the seven Rishis, (see RISHI,) are the same, and make only so many individuals, first called Brahmadicas, or children of Brahma, created for the purpose of supplying the world with inhabitants. Having fulfilled this mission, they became sovereigns, or Menus, who, when far advanced in years, withdrew from the world to solitary places to prepare for death; as, according to the Puranas, was the general practice of mankind in the early ages; and became Rishis, or holy penitents, who, by their salutary counsels and the example of their austerities, pointed out the paths of virtue and rectitude to mankind. There are still much confusion and contradiction in the accounts of the person and characters of these holy persons, of whom many particulars occur in Moor's Hindoo Pantheon.

MENUET, Fr., MINUET, Engl., the name of a musical movement in triple time of three crotchets or three quavers in a bar, which is the guide to a graceful dance in the slowest time of any movement that is danced off the stage at public or private balls, since the *louvre* has totally lost its favour.

The minuet, according to Brossard, had its origin in Poitou. The melody of the minuet is usually divided into two parts, or strains, consisting of eight bars each, of which the first ends on the fifth of the key, and the second on the key note.

There is so much dignity and grace in this dance, that it is to be lamented it has ceased to be a part of education, and to be discontinued at private balls and assemblies where elegance and decorum used to be observed. In learning the steps and figure of the minuet, other things necessary in

polished society used to be taught; such as the bow, the curtsy, the entrance into a room and departure from it with ease and grace, the presenting to or receiving from a superior; indeed the whole carriage of the person used to be regulated in learning the minuet, in a manner not, as we can discover, included in the Scotch step or Irish lilt, the cotillon, or the waltz. Those who never had the courage or intention to exhibit their persons in a ball-room, public or private, have been discovered to have learned to dance by standing still or walking in the street, as a peasant discovers himself to have been drilled in the same situations.

MENUF, or MENOUF, in *Geography*, a town of Egypt, and chief place of a district, seated near a canal, which was formerly navigable, but has ceased to be so in consequence of a dyke raised for restraining the inundations of the Nile in that branch of it which runs to Damietta. The canal surrounds the walls of the town from S. to W. The houses are mean and the streets narrow and crooked; nor has it many remains of antiquity. In its vicinity are no gardens, so that it is supplied with fruit and vegetables from a distance; but the land is well cultivated and produces wheat, barley, maize, lentils and lupines. The cultivation of maize from seed-time to harvest occupies 70 or 80 days. The animals employed in husbandry are oxen, buffaloes, camels, asses, and a few horses. Menuf, during the inundation, is surrounded with water, but it does not long continue. It is sheltered from the S., and being open to the N. and N.W., it is kept moderately cool. The number of inhabitants is about 5000; 22 miles N.N.W. of Cairo.

MENUFIE, or MENOUFIE, the district of which Menuf is the capital, on the S. part of the Delta, between the E. and W. branches of the Nile.

MENUGAT, a town of Asiatic Turkey, in the province of Caramania, on a river of the same name, which runs into the gulf of Satalia; 21 miles W. of Alanieh.

MENYANTHES, in *Botany*, according to Linnæus, is derived from *μην*, a month, and *ανθος*, a flower, because the plant continues in blossom about that period of time. *M. trifoliata* is undoubtedly the *μινυανθεις* of Theophrastus and *Minyanthes* of Pliny, because those authors describe it as having ternate leaves and ornamental flowers. Buckbean. Linn. Gen. 82. Schreb. 107. Willd. Sp. Pl. v. 1. 810. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 225. Prod. Fl. Græc. p. 1. 128. Ait. Hort. Kew. ed. 2. v. 1. 312. Tournef. t. 15. Juss. 98. Lamarck Illustr. t. 100. Gærtn. t. 114. Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Precie*, Linn. *Lysimachie*, Juss. *Gentiane*, Ventenat.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-cleft, erect, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrically funnel-shaped, short; limb cloven below the middle into five, spreading, recurved, obtuse, more or less hairy segments. *Stam.* Filaments five, awl-shaped, short; anthers acute, cloven at the base, erect. *Pist.* Germen superior, conical; style cylindrical, exactly as long as the corolla; stigma cloven, compressed. *Peric.* Capsule ovate, enveloped by the calyx, of one cell. *Seeds* numerous, ovate, small.

Ess. Ch. Corolla hairy. Stigma cloven. Capsule of one cell.

1. *M. nymphæoides*. Fringed Buckbean. Lesser Yellow Water Lily. Linn. Sp. Pl. 207. Engl. Bot. t. 217. Fl. Dan. t. 339.—Leaves heart shaped, entire, waved. Corolla ciliated. Found occasionally in rivers and lakes, though by no means so common a plant with us as in the still canals of Holland. It flowers from June to August. *Root* perennial, long and stringy. *Stems* very long, round, bearing leaves and flowers towards their summits. *Leaves* opposite, simple,

simple, on stalks, floating, heart-shaped or roundish, wavy, smooth. *Flowers* axillary, crowded together, on stalks, expanding at noon, of a golden colour, fringed at the margin. Dr. Smith observes, that the leaves of this plant, like those of the *Nymphaea*, perspire so quickly as to become dry in a few hours, though at first so succulent. Some authors have thought from the corolla being ciliated, not hairy, that *M. nymphaeoides* should be referred to another genus. But as Justien, whose authority upon such a point is very great, has not separated this from *M. trifoliata*, and as *M. indica* and *ovata* seem to connect the two, we think with Dr. Smith they may safely remain as they are.

2. *M. ovata*. Oval-leaved Buckbean. Linn. Suppl. 133. Willd. n. 2. (*M. capensis*; Thunb. Prod. 34. Villaria *ovata*; Vent. Choix de Plantes, t. 9.)—Leaves ovate, on long stalks. Stem panicled. An aquatic of the Cape, flowering in May and June. Linnæus observes that this species has the habit of an *Alisma*, but the flower of a *Menyanthes*. Root fibrous. Stems few, about two feet high and the thickness of a quill, straight, cylindrical, sometimes naked and like straws, more frequently furnished with three or four leaves, simple, smooth, bright green. Leaves obtuse, generally quite entire, nerved, smooth, of a bright green colour and bitter flavour. Flowers on stalks, bracted, of a fine yellow or citron colour, without smell.

3. *M. indica*. Indian Buckbean. Linn. Sp. Pl. 207. Bot. Mag. t. 658.—Leaves heart-shaped, somewhat notched. Flowers on simple stalks. Corolla internally hairy. Native of the Cape, flowering nearly through the summer. Root fibrous. Stems floating, branched. Leaves peltate, bright green on one side, dark russet on the other. Flowers forming a lax umbel, placed on the stem just below the leaf, of a bright yellow colour, looking as if covered with silver froth.

4. *M. cristata*. Crested Buckbean, or Antara-Jamara of the Telingas. Roxb. Coromandel. v. 3. t. 105.—Leaves heart-shaped, wavy. Flowers on simple stalks. Corolla with an elevated crested rib.—A native of banks, or pools of fresh water, in the East Indies, where it floats, often not reaching the bottom with its roots. Flowering time the wet and cold season.—Roots annual, fibrous. Stems numerous, much spreading. Leaves on short stalks, smooth; green above with a purplish tinge. Flowers in a loose umbel, not hairy, of a pure white colour, about an inch in diameter. Rheede describes the last species as having ten stamens. We suspect the present, which has also ten, though five are imperfect, is what sir William Jones described in his select Indian plants, calling it *Cumuda*, or deluge of the water, which seems to be a general name for beautiful aquatic flowers.

5. *M. exaltata*. Tall Buckbean. Soland. MSS. and Herb. Banks. Ait. Hort. Kew. ed. 2. v. 1. 312. Bot. Mag. t. 1029.—Leaves roundish-heart-shaped, somewhat peltate, slightly crenate. Stem panicled. A native of New South Wales, where it was discovered by sir Joseph Banks. It flowers from November to February, being kept in a cistern near the glass in a bark-stove. This is a larger plant than any of the preceding, with a tall, panicled, many-flowered stem. The leaves are heart-shaped, veiny and wavy. Flowers deep yellow, their petals toothed at the edge, and bearded on the upper side at the base. Dr. Sims remarks that it is nearly allied to *M. ovata*, and should immediately precede that species.

6. *M. trifoliata*. Common Buckbean, or Marsh Trefoil. Linn. Sp. Pl. 208. Engl. Bot. t. 495. Curt. Lond. fasc. 4. t. 17.—Leaves ternate. Corolla extremely hairy on the upper side. This elegant plant is common in boggy, marshy

situations, and flowers in June or July. Root perennial, formed of spreading scyons, black. Stem leafy, spreading horizontally, branched. Leaves ternate, on stalks, toothed and slightly folded at the edge. Flowers in spikes, bracted, on stalks, of a beautiful flesh-colour, hairy and very thickly set on the upper side with fleshy obtuse fibres. Style prominent. The whole herb is bitter, powerfully inducing perspiration. Dr. Smith remarks that "an infusion of it was long ago recommended for the rheumatism, and has been a popular medicine in England. It has also been given for the gout, scurvy, ague, catarrh and dropsy, a formidable list of disorders: if it has any right to such celebrity, it must act as a powerful tonic."

7. *M. hydrophyllum*. Water-leaf Buckbean. Loureir. Cochine. 105. Mart. Mill. Dict. v. 3.—Leaves heart-shaped, entire. Flowers axillary, crowded together. A native of swamps in Cochinchina. This plant is considered by the authors above quoted as forming a connecting link between *Menyanthes* and *Hydrophyllum*. The stem is thread-shaped and creeping. Leaves smooth, on stalks, scattered, few in number. Flowers white, on long stalks.

MENYANTHES Trifoliata, Water-trefoil, or Buck-bean, in the *Materia Medica*. The whole plant is so extremely bitter, that in some countries it is used for hops in the preparation of malt-liquor; and yet Linnæus observes, that the poorer people in Lapland make a bread of the powdered roots mixed with meal, acknowledging at the same time that it is a very unpalatable food. The blackness manifested by adding a solution of green vitriol to the juice, or to a strong infusion of the leaves of buckbean, is a sufficient test of its astringency; while a drachm of the powdered leaves seldom fails to open the body, or produce vomiting; so that in common with the tonic properties of a bitter, it seems farther to possess a considerable share of medicinal activity: we can therefore more easily credit the reports of its success in a great number of chronic diseases mentioned by various authors, as scurvy, dropsy, jaundice, asthma, periodical headaches, intermittents, hypochondriasis, cachexia, obstructions of the meninges, rheumatism, scrophula, worms, gout. Dr. Boerhaave was relieved in the last mentioned complaint by drinking the juice mixed with whey; and Dr. Alston tells us, that "this plant had remarkable effects in the gout, in keeping off 'the paroxysms;' but adds, "though not to the patient's advantage."

In confirmation of the good effects of water trefoil in dropsies, we are told that sheep, when forced to eat it, are cured of the rot (*oves tabidæ*); yet as we have but few and imperfect proofs of its diuretic powers, this fact will be considered of little weight.

Bergius confines the uses of this plant to scorbutus, leucophlegmatia, arthritis, rheumatismus, cacochætes, and this specification is still farther contracted by later writers on the materia medica. In Lewis's Mat. Med. (by Mr. Aikin) it is said, that the leaves of buckbean "have of late years come into common use as an alterative and aperient, in impurities of the humours, and some hydropic and rheumatic cases;" and as an active and eccoprotic bitter, we should suppose them not ill adapted to supply the want of bile in the *primæ viæ*, and thus infer their use in protracted jaundice, and other biliary obstructions. Dr. Cullen has "had several instances of their good effects in some cutaneous diseases of the herpetic and seemingly cancerous kind."

The leaves may be given in powder from ℞i to ℞ij for a dose two or three times a day, but a strong infusion of them is perhaps preferable, and with delicate stomachs it may be necessary to conjoin a grateful aromatic: they impart their properties both to watery and spirituous menstrua, and an extract

extract is ordered to be prepared from them in the Ph. Dan. p. 171. "Efficax et frequentis commodique usus." Murray. Lewis Mat. Med. Cullen Mat. Med. Woodville Med. Bot.

MENZABANO, in *Geography*, a town of Italy, on the river Mincio, famous for a battle fought here between the French and the Austrians, on the 28th of December 1801, in which, after a very obstinate and sanguinary contest, the former were victorious, and took 8000 prisoners.

MENZALE, called by Strabo (lib. xvii.) and the Arabian authors *Tanis* (which see), a large lake, separated from the Mediterranean, to which it is parallel, by a slip of land, about 60 miles in length and from 2 to 12 in breadth; filled and occasionally overflowed by the waters of the Nile. During the inundation the water is fresh, and becomes salt as the river returns into its bed; a circumstance which was observed in the time of the caliphs. The Nile, says the geographer of Nubia, overflowing its banks at the summer solstice, the canals which discharge themselves into lake Tanis, render its waters fresh; and the sea, flowing into it, in its turn, makes them salt. In this lake are islands with buildings in them like barns; but they are only accessible in boats. About 1200 boats, each of which pays annually 40 livres to the Pacha's renter, are constantly employed in fishing on the lake. The quality of the water gives to the fish a white flesh and a fine delicate flavour. They supply Damietta at a cheap rate. As the lake has several communications with the Nile and the Mediterranean, and being full of islands, reeds, herbs, and insects, it is abundantly stocked with fish. Two thousand persons are annually employed in the fishery, and thousands of birds constantly feed upon the fish without occasioning any perceptible diminution. The waters are covered with wild geese, ducks, teals, plovers, and ibises; and various other birds of large size and beautiful plumage. The islands in this lake are for the most part uninhabited, except Matarieh; and of course are uncultivated. Menzalé communicates with the sea by two mouths, *viz.* Dibé and Eumené Fareggi, which are the Mendesian and Tanitic mouths of the ancients; each mouth is shut towards the sea with a bar or bank, forming the part of a circle. The tongue of land, separating the lake from the sea, extends, with only four interruptions in its whole length, from Damietta to Tineh. The length of the lake from N.W. to S.E. is 43,000 fathoms, and its breadth from 12,000 to 26,000.—Also, a town of Egypt, situated near the lake to which it gives name; 20 miles S.S.E. of Damietta. N. lat. $31^{\circ} 3'$. E. long. 32° .

MENZALINSK, a town of Russia, in the government of Upha; 132 miles W.N.W. of Upha. N. lat. $55^{\circ} 16'$. E. long. $52^{\circ} 14'$.

MENZIESIA, in *Botany*, so named many years ago, by the writer of this, in the *Plantarum Icones ex Herb. Linn. fasc. 3*, in honour of his much-valued friend Mr. Archibald Menzies, F. L. S. This gentleman, in his voyage round the world with captain Vancouver, collected many rare and non-descript plants, particularly on the western coasts of New Holland and of North America. He also discovered, near Dusky bay in New Zealand, the richest collection of *Jungermannia* that was ever, perhaps, made by any one person.—Sm. Plant. Ic. 56. Willd. Sp. Pl. v. 2. 355. Michaux Boreal-Amer. v. 1. 235. Juss. in Annal. du Mus. v. 1. 55. Ait. Hort. Kew. ed. 2. v. 2. 360. Swartz Tr. of Linn. Soc. v. 10. 375. Engl. Bot. v. 35. 2469. Lamarck Dict. v. 4. 115. Illustr. t. 285. Class and order, *Obandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, more or

less deeply four or five-cleft, permanent. *Cor.* of one petal, inflated, nearly ovate, deciduous; its limb spreading, in four or five small, spreading, equal segments. *Stam.* Filaments eight or ten, thread-shaped, equal, shorter than the corolla, inserted into the receptacle; anthers erect, oblong, simple, two-lobed at the base, opening by two pores at the top. *Pist.* Germen superior, roundish-oblong, furrowed; style angular, erect, rather longer than the filaments; stigma obtuse, with four or five small lobes. *Peric.* Capsules elliptic-oblong, with four or five furrows, and as many valves and cells, opening from the top downward, the partitions double, formed of the inflexed margins of the valves. *Seeds* numerous, small, oblong, more or less pointed, affixed to the ribs of the large central column.

Ess. Ch. Calyx of one leaf, four or five-cleft. Corolla of one petal, inflated. Filaments inserted into the receptacle. Capsule superior, of four or five cells, the partitions from the inflexed margins of the valves.

1. *M. ferruginea*. Rusty-flowered Menziesia. Sm. Plant. Ic. t. 56.—Calyx very slightly four-lobed. Leaves obovato-lanceolate, finely serrated; smooth beneath.—Gathered by Mr. Menzies, very copiously, in 1787 and 1788, on the west coast of North America. The stem is shrubby, two or three feet high, determinately branched, spreading, round, smooth, the pale bark scaling off in long strips; branches leafy, hairy when young, springing from the same buds as the flowers, the scales composing which are ovate and fringed. Leaves alternate, crowded towards the tops of the branches, stalked, spreading, obovate, inclining to lanceolate, one and a half or two inches long, three-fourths of an inch broad, obtuse, tipped with a gland, finely serrated, fringed, membranous, flat, veiny; green and besprinkled with white depressed hairs above; pale and smooth beneath, except a few hairs, or flat narrow scales, on the ribs; deciduous. Footstalks short, winged. Stipules none. Flowers from the buds of the last season, five or more together, on simple stalks, about an inch long, covered with viscid hairs, and drooping. Calyx small and flat, very slightly four-lobed, or rather waved at the edge, fringed. Corolla ovate, one-third of an inch long, the border four-cleft, slightly expanded, altogether (as appears by Mr. Menzies's drawing and description) of a rusty hue. Stamens eight. Capsule smooth, dark brown externally, pale within.

2. *M. globularis*. Pale-flowered Menziesia. Salisb. Parad. t. 44. Ait. Hort. Kew. n. 1. (*M. Smithii*; Michaux Boreal-Amer. v. 1. 235.)—Calyx in four rounded lobes. Leaves obovate, nearly entire; glaucous and downy beneath.—Native of South Carolina, according to Salisbury and Lyon. Of this we know nothing but from the works quoted, by which it appears to differ from the foregoing, besides the above specific characters, in having a more globose corolla, pale yellow with red streaks. The flowers are octandrous and four-cleft, as in *M. ferruginea*. Michaux mistook this for the original species; and having no information of the specific name, gave one of his own. The above writers copy his error of the press.

3. *M. polifolia*. Irish Menziesia. Juss. in Ann. du Mus. v. 1. 55. Ait. n. 2. (*Erica Daboecii*; Sm. Fl. Brit. 420. Engl. Bot. t. 35. Willd. Sp. Pl. v. 2. 383. *Andromeda Daboecia*; Linn. Syst. Veg. ed. 13. 338.)—Calyx in four deep segments. Flowers racemose. Leaves ovate; very densely downy and snow-white beneath.—Native of hills in Spain and Ireland, on a boggy soil. Mr. Lambert found it abundant on Croagh Patrick in the county of Mayo, and Dr. Wade in the district of Cunnemara, county of Galway. In gardens it is often cultivated for ornament, amongst American and other flowering shrubs which thrive in bog earth,

earth, flowering from June to September. The *stems* are shrubby, bushy, a foot and a half high, with many upright, simple, leafy branches, at length decumbent and spreading. *Leaves* numerous, stalked, generally alternate, now and then opposite, or three together, ovate, entire, slightly revolute; dark green, shining, and somewhat hairy above; snow-white, with dense cottony down beneath, their smooth red rib vanishing about the middle. There are axillary tufts of numerous small leaves besides. *Flowers* four-cleft, octandrous, large, purplish-red, ovate, with four obtuse angles, drooping in a long, loose, inclining, bracteated cluster; the stalks and calyx red, hairy, and viscid. *Capsule* small and roundish, with partitions from the inflexed margin of the valves, which is never the case with a real *Andromeda*. Hence this plant was retained in *Erica* in Fl. Brit. according to the original opinion of Linnæus, who was chiefly led by number in the parts of fructification. M. de Jussieu however, who always much approved this genus of *Menziesia*, has reinforced it with the present species, as Dr. Swartz has done with the two following.

4. *M. cerulea*. Scottish *Menziesia*. Swartz Tr. of Linn. Soc. v. 10. 377. t. 30. f. A. Engl. Bot. t. 2469. (*Andromeda cærulea*; Linn. Sp. Pl. 563. Fl. Lapp. ed. 2. 133. t. 1. f. 5. Lapl. Tour. v. 1. 272. Fl. Dan. t. 57. A. *taxifolia*; Pall. Ross. v. 1. p. 2. 54. t. 72. f. 2. *Erica cærulea*; Willd. Sp. Pl. v. 2. 393.)—Calyx in five deep acute segments. Corolla ovate. Flower-stalks terminal, aggregate, simple. Leaves scattered, numerous, linear, obtuse, finely serrated.—Native of turfy stony mountainous heaths in Lapland, Norway, some part of Siberia, and also in the most northern parts of America. It has lately been discovered at Avienore in Strathspey, as well as in the remote western isles of Shiant. This is a more humble *shrub* than the last, with the habit of an *Empetrum*, and distinguished from all the foregoing species, by its narrow crowded *leaves*, like those of a heath, moderately spreading in every direction. They are almost linear, about half an inch long, rather shining above, finely toothed at the edge: their rib downy underneath. *Flower-stalks* four or five at the top of some of the branches, at first perfectly terminal, but the branch gradually shoots beyond them; each is about an inch and a half long, simple, rough with red glandular hairs, drooping gracefully at the top, and bearing one large ovate *flower* of a pale blueish or livid red; the *calyx* in five deep acute segments. On turning to Pallas's *Flora Rossica*, we find he did not alter the specific name to *taxifolia*, from want of understanding the true meaning of *cerulea*, but because the *corolla* occasionally varies to flesh-colour or to white; but these changes are frequent, and do not authorize such a measure.

5. *M. empetriformis*. Bell-flowered *Menziesia*. Sm. Tr. of Linn. Soc. v. 10. 380.—Calyx in five deep obtuse segments. Corolla bell-shaped. Flower-stalks terminal, aggregate, simple. Leaves scattered, linear, obtuse, finely serrated; concave beneath.—Gathered by Mr. Menzies on the west coast of North America, near Nootka Sound. A much taller plant than the last, with less crowded *leaves*, which are concave beneath, with a smooth rib; their upper surface shining; the margin fringed with bristly serratures. The *flower-stalks* are crowded in like manner about the tops of the branches, but in greater number. *Calyx* not above half so long, with five blunt, thin-edged, deep, convex segments. *Corolla* smaller, bell-shaped, with five spreading, ovate, marginal segments, and not contracted at the mouth. *Capsule* almost globular, dark brown, besprinkled with resinous dots.

6. *M. bryantia*. Mossy *Menziesia*. Swartz Tr. of Linn. Soc. v. 10. 378. t. 30. f. B. (*Andromeda bryantha*; Linn.

Mant. 238. A. *Bryanthus*; Pall. Ross. v. 1. p. 2. 57. t. 73. f. 1. *Bryanthus*; Gmel. Sib. v. 4. 133. t. 57. f. 3. *Erica bryantha*; Willd. Sp. Pl. v. 2. 386.)—Calyx in four deep acute segments. Corolla bell-shaped, in four deep segments. Flower-stalks terminal, corymbose. Leaves scattered, elliptic-oblong, toothed; convex beneath.—Gathered by Steller, on mossy rocks in Kamtschatka, flowering in July. This elegant little *shrub* is much smaller than any of the rest, clothing the ground with its long trailing branching *stems*; and the small, oblong, numerous *leaves* give it a moss-like aspect. The *flowers* grow four or five together in a small, corymbose, bracteated cluster, on a long terminal stalk. The *calyx* and *stamens* are red. *Corolla* white, divided below the middle into four segments. Pallas says it has sometimes five or six divisions, and that the *stamens* are equal to them in number; but he must mean that they are twice as numerous, which indeed his figure expresses, and which is the case in the whole genus. The *capsule* is nearly globular, with four furrows. We have seen no specimen.

These are all the species of *Menziesia* hitherto established. Willdenow suggests, Sp. Pl. v. 2. 610, that the *Andromeda odandra*, Swartz Ind. Occ. 840, may belong to this genus; but Swartz describes the corolla as permanent, and though he does not describe the fruit, in a manner to assist us in this enquiry, we must presume he did not overlook this plant of his own, while seeking for *Menziesia* amongst *Andromeda*.

MENZIL, in *Geography*, a town of Africa, in the kingdom of Tunis, anciently called "Zæta;" 4 miles S.S.W. of Sufa.

MENZINI, BENEDETTO, in *Biography*, an eminent Italian poet, was born at Florence of indigent parents in 1646. He was taken at an early period into the house of Gianvincenzo Salviati, who gave him the means of cultivating his talents. He was soon distinguished for eloquence, and opened a school of rhetoric. By the advice of the celebrated Redi he turned his efforts to Italian poetry, and in 1674 published a volume of poems, dedicated to the grand duke Cosmo III., and in 1679 he published a treatise, entitled "Costruzione irregolare della Lingua Toscana," and in the following year he appeared before the public with a volume of lyric poems, by which he obtained great reputation. In 1685 he accepted an invitation from queen Christina of Sweden, then resident at Rome, who gave him a very favourable reception, and admitted him into her academy. He had now leisure to pursue his studies, but the death of the queen in 1689 obliged him to seek a maintenance by writing for other persons, particularly sermons for the clergy who were unable to compose their own discourses. He at length received from pope Innocent XII. an office in the church of St. Angelo, in Peschiera; and in 1701 he was nominated coadjutor in the chair of eloquence at the college of the Sapienza at Rome. He died, according to one account, in 1704, but according to another in 1708. He wrote almost every kind of Italian poetry, but in anacreontic songs, in pastoral sonnets, elegies, and sacred hymns, he has few equals, and perhaps no superior; and in Italian satires none can compare with him. All the works of Menzini were collected and published at Florence, in four volumes, in the year 1731. Of these the first contains his lyric poems: the second his miscellaneous pieces: the third his Italian prose; and the fourth his Latin compositions. He was a member of the academy Della Crusca, and his works have been considered as belonging to the golden age of the language.

MEOLA, in *Geography*, a town of Italy, in the Trevisan; 11 miles E. of Treviso.

MEPHITIS, or MEPHITICAL *Exhalation*, denotes a poisonous

poisonous and noxious steam issuing out of the earth. See DAMP, *Mephitic Air*, and AZOTE. See also EFFLUVIA, and GROTTO *del Cani*.

MEPHITIS, in *Mythology*, is a name given to Juno, because she is supposed to preside over stinking exhalations, or corrupted and noxious air; and hence it was used to signify such noxious air itself. Servius, upon the passage in Virgil (*Æn.* vii) "Sævamque exhalat opaca Mephitim," says, that this goddess may possibly be Juno taken for the air, because it is by means of the air that bad smells are communicated. According to Scaliger, the word is Etruscan, and derived from the Syrians, with whom it signified any stinking smell. Juno had a temple among the Hirpines under this appellation.

MEPPEL, in *Geography*, a town of Holland, in the department of Overissel, seated on the Walt Aa; 24 miles W. of Covorden.

MEPPEN, a town and fortress of Germany, in the bishopric of Munster, at the conflux of the Hase and Embs; 52 miles N. of Munster. N. lat. 52° 43'. E. long. 7° 26'.

MEQUINENZA, a town of Spain, in the kingdom of Aragon, at the conflux of the Segre, the Cinea, and the Ebro; anciently called "Ostogesa" and "Istosa;" defended by a castle, and once the see of a bishop; 16 miles S.S.W. of Lerida.

MEQUINEZ, an imperial city of Morocco, greatly embellished and enlarged by Muley Ishmael, and the metropolis of the north. It is situated at the extremity of Beni-Hassen, 80 leagues N. of Morocco, and 20 leagues E. of Sallee and the sea. Maknassa, the founder of this city, built it at the bottom of a valley, but Muley Ishmael made it much larger, by building on the plain to the west. The city is surrounded by vallies and eminences highly cultivated, ornamented with gardens, and plantations of olive-trees, and watered by a variety of streams, so that the fruits and vegetables are of an excellent flavour. The winter is disagreeable on account of the quantity of mud which then accumulates in the city and its environs, because the streets are not paved, and the soil is clay. Mequinez is encompassed with walls: and the palace is fortified with two bastions, in which was formerly some small artillery. The Brebes have often conspired against the tyranny of its rulers; and on the western side are still seen some walls of circumvallation, six feet in height, which were probably only intrenchments for the infantry, as the attacks of the Brebes were sudden and momentary incursions, which did not require any long defence. In Mequinez, as well as in Morocco, there is a quarter walled in and guarded for the Jews. The houses are handsomer here than in that of Morocco; the Jews are more numerous, and derive greater profit from their industry, because the Moors of Mequinez are richer, and as they are nearer, they have greater intercourse with Europe than those of the Southern provinces. Contiguous to the quarter of the Jews, is another, inclosed with walls, but now in ruins, called the Negro town, built by Muley Ishmael for the families of his black soldiers; but of this the walls only remain. At the extremity of the city, on the S.E. side, is the emperor's palace, which is a very extensive building, including several gardens, well laid out and watered by abundant streams. In the centre is a large garden, surrounded by a spacious gallery supported by columns, which maintains a communication between the apartments. Those of the women are large, and terminate in a common chamber, built on a causeway that divides the great garden, where the women may look out at the window through an iron lattice. In passing from one apartment to another, we meet at intervals with regular courts, paved with squares of black and

white marble. In the middle of these courts is a marble basin, on which is raised a round shell; in the centre of this is a fountain that plays into the basin. There are many other fountains that supply water for the numerous ablutions of the Mahometans. At Mequinez, as well as at Fez, they make a kind of glazed tiles, similar to what we call Dutch tiles, of various colours; which are used to pave their rooms and face their walls, and give to their houses an air of neatness and coolness, not occurring in other towns of the empire. The Moors of Mequinez are much more affable and engaging than those of the southern provinces; and the women are extremely handsome, being very fair, with fine black eyes, and beautiful teeth. They are sometimes seen walking on the terrace; but when a Moor appears, they immediately retire. At Mequinez, as well as at Morocco, there is a hospital, or convent, of Spanish Recollects, founded more than 100 years ago by the munificence of the kings of Spain, for the benefit and spiritual comfort of the Christian captives. These convents are much respected in the country, both for the exemplary lives of the fathers, and the service they render to the poor, whom they supply with medicines gratis; 35 miles S.W. of Fez. N. lat. 33° 56'. W. long. 5° 50'.

MER, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Blois; 9 miles N.E. of Blois. The place contains 4300, and the canton 10,623 inhabitants, on a territory of 172½ kilometres, in 12 communes. N. lat. 47° 42'. E. long. 1° 35'.

MER.—*Oyster le Mer*. See OUSTER.

MERA, in *Geography*, a town of Spain, in Galicia, near the sea-coast; 3 miles E. of Corunna.

MERA, in *Hindoo Mythology*, is the fabled wife of Haimavat and mother of Uma, a name and form of Parvati, thus incarnated to become the wife of Siva, and parent, or reputed parent, of Kartikya. (See KARTIKYA.) The stories connected with this fable are very numerous, filling many books in great esteem among the Hindoos. In the thirtieth and following sections of the first kanda, or book, of the Ramayana, it is detailed in a very poetical style how the "great Haimavat, sovereign of mountains, the grand magazine of metallic substances, had two daughters of incomparable beauty, by his wife Mera." Their names were Ganga and Uma. The first (the river Ganges) was yielded in marriage to all the celestials, at their earnest solicitation. Her younger sister, remaining a virgin, became a devotee of extraordinary rigidity, and was at length espoused by Siva, whose frigidity was, however, such as to require much address, on the part of the celestials, to animate him to the due pitch of passion; his nuptials and the consequent production of Kartikya being of great moment. On this occasion it was that Kama, the god of love, artfully placing the beautiful Uma before Siva, while in the graceful act of gathering flowers wherewith to decorate his emblem, the Linga had the audacity to launch an arrow at the dreaded deity. Siva, enraged, reduced Kama to ashes (or, according to some legends, to a mental essence) by a beam of fire, darted from his central eye. This fable is noticed in the article KAMA, and is as often alluded to in Hindoo books as any perhaps in the whole range of their mythological extravagance. In the Siva-purana, the parents of Parvati in this incarnation are named Himachala and Mahina, in other works Himalaya and Mena. (See MENA.) The name of the father, in all cases, being derived from a Sanscrit word meaning snow. Mera is said to be daughter of the mountain Meru; a most fruitful source of mythological tales of wonder and extravagance. See MERU.

MERAB,

MERAB, in *Geography*, a town of Arabia, in the province of Nedjed; 100 miles N. of Yamama.

—Also, a town of Persia, in Khorasan; 45 miles N.E. of Meshed.

MERACOBIN, a town of Africa, in the kingdom of Adel, on the coast of the Indian sea. N. lat. 8° 10'. E. long. 49° 14'.

MERAN, a town of the Tyrol, of which it was formerly the capital, at the conflux of the Adige and Passer, containing six churches and convents; two miles S.S.E. of Tyrol. N. lat. 46° 38'. E. long. 11° 24'.

MERAT, a town of Hindoostan, in the country of Delhi; 40 miles N. of Delhi. N. lat. 29° 20'. E. long. 78° 6'.

MERATE, a town of Italy, in the department of the Serio; 9 miles W. of Bergamo.

MERATTE, a town of Algiers; 15 miles N. of Tagademt.

MERAUDABAD, or MOORADABAD, a town of Hindoostan, in Oude, once large with a mint, but now decayed; 20 miles N.E. of Sumbul.

MERBAT, a town of Arabia, in the province of Hadramaut, which, as well as Ilafch, is only known for the traffic which the inhabitants carry on in incense produced in that neighbourhood; 32 miles N. of Dafar.

MERBES LE-CHATEAU, a town of France, in the department of Jenappe, and chief place of a canton, in the district of Charleroy. The place contains 661, and the canton 6382 inhabitants, on a territory of 122½ kilometres, in 17 communes.

MERCADAL, the chief town of the Terminos Mercadal in the island of Minorca, situated nearly in the middle of the island on the great road between Mahon and Ciudadella. Its streets are narrow, winding, ill paved and worse repaired. The public edifices consist of the old parish church, which is decaying, and a new one. Its situation is the least salubrious in the whole island. During the extreme heat, the inhabitants are afflicted with obdurate fevers; water is scarce, as the great public cistern is often dry during the summer. The territory of this place is about 5½ leagues in length, and 4½ in breadth. In the same district, about four leagues from Mercadal, is Ferarias, where the English have constructed barracks for 200 soldiers. The territory of Ferarias is five leagues in length and two in breadth. Few of the occupiers are husbandmen, the greater number being employed in hunting, as game is very abundant.

MERCARA, a city of Hindoostan, and residence of the rajah of Coorga; 55 miles W. of Seringapatam.

MERCATI, MICHAEL, in *Biography*, a physician and naturalist, the son of Peter Mercati, a physician of St. Miniato, in Tuscany, was born in April, 1541. After having finished his scholastic education at his native place, he was sent to Pisa, and placed under the tuition of Cesalpini, from whom he derived his taste for the study of nature. Having received his degree of doctor in philosophy and medicine in that university, he went to Rome, where he soon became known to the pope, Pius V., who appointed him superintendent of the botanical garden of the Vatican, at the age of twenty-six. In the following year he obtained the esteem of Ferdinand I., the grand duke of Tuscany, who raised him to the rank of nobility; and soon afterwards the same dignity was conferred upon him by the senate of Rome. He was in great favour with pope Gregory XIII., who honoured him with an appointment about his person, and with his full confidence, as did also his successor Sixtus V., who conferred upon him the honourable office of apostolical protonotary, and sent him into Poland with cardinal Aldo-

brandini, that he might enjoy the opportunity of increasing his collections in natural history. During this journey he greatly enriched his mineralogical cabinet, which he had already commenced at Rome. The same cardinal, when elected pope in 1592, under the title of Clem. VIII., nominated Mercati his first physician, and had in consequence higher honours to bestow upon him, when this able physician died, in 1593, in the fifty-third year of his age. His character in private life was universally esteemed, and the respect of the most distinguished persons of Rome followed him to his grave.

Mercati wrote in Italian, at the request of his patron pope Gregory, a work "On the Plague, and the Corruption of the Air, on the Gout, and on Palsy," which was printed at Rome, in 1576, in 4to: and likewise a "Dissertation on the Obelisks of Rome," printed in 1580, 4to. But he is principally remembered for his description of the subjects of natural history, particularly of mineralogy, contained in the museum of the Vatican, which was formed under the auspices of Gregory XIII. and Sixtus V. and was afterwards totally dispersed. He was about to prepare engravings of the principal subjects, when his disease, which terminated his life, interrupted his progress. His manuscript came into the hands of Carlo Dati of Florence, where it remained till the time of Clement XI., who purchased it, and caused it to be splendidly edited by Lancisi, his first physician, in 1717, under the title of "Metallotheca, opus posthumum Autoritate et Munificentia Clementis XI. Pont. Max. à tenebris in lucem educitum; operâ & stud. J. M. Lancisi Archiat. Prat. illustratum." folio. An "Appendix ad Metallothecam" was published in 1719. Eloy Dict. Hist. de la Méd. Gen. Biog.

MERCATOR, GERARD, an eminent Flemish geographer and mathematician, was born at Ruremond, in the year 1512. After he had attained a good degree of classical learning, he studied philosophy at Bois-le-Duc, and removed from thence to Louvain, where he was admitted to the degree of M.A. His studies now laid so full hold of him, that he frequently forgot the usual periods for refreshment and sleep. At the age of twenty-four he married, and then began to learn the art of engraving. His first production in this way was a description and map of the Holy Land, which he published in 1537, when he was only twenty five years of age. In the year 1541 he made a terrestrial globe, which proved the means of introducing him to the patronage of the emperor Charles V., for whom he executed maps, globes, and a collection of other mathematical instruments. This business was the means of obtaining for him an appointment in the emperor's household. About the same time the duke of Juliers and Cleves made him his cosmographer. In 1551, Mercator produced his celestial globe, which was accompanied with a short treatise on the use of that instrument. He now left Louvain, and settled at Duisburg, where he published, at different periods, descriptions and maps of the World, Europe, Germany, France, and the British islands; these he afterwards collected together into an Atlas, to which he prefixed a treatise "On the Creation and Construction of the World." His method of laying down maps, &c. is a projection of the surface of the earth on a plane. (See MAP.) In 1568, Mercator published his "Chronologia" from the beginning of the world to that year, and immediately he gave the public a corrected edition of "The Geographical Tables of Ptolemy." He died of a paralytic stroke in 1594 at a very advanced age, and in the midst of his useful labours, at the same time projecting new works for the improvement of the science of geography. He was author of several other works besides those already noticed.

Of these the principal are as follow, 1. "Ratio scribendarum Literarum Latinarum, quas Italicas cursoriasque vocant:" 2. "De usu Annuli Astronomici:" 3. "Harmonia Evangelistarum." He had a son named Bartholomew, who wrote notes on John Sacrobosc's treatise "De Sphæra Mundi," when he was very young, as he died at the age of eighteen.

MERCATOR, NICHOLAS, an eminent astronomer and mathematician, was born in Danish Holstein about the year 1640. He received an excellent education, and his turn for mathematical studies introduced him to public regard and esteem in his country, and facilitated his correspondence with those persons who were eminent in the same sciences, in Denmark, Italy, and England. Receiving an invitation to visit this country, he came, and was so well pleased with the reception he met with, that he spent the remainder of his life in England. He was, soon after his arrival, elected a fellow of the Royal Society, and applied himself very diligently to the improvement of the sciences, but he has been charged with having borrowed the inventions of others, and adopting them as his own; and it appeared upon some occasions that he was not endowed with a very liberal mind in scientific communications. Thus, it had been observed before him, that there was an analogy between a scale of logarithmic tangents and Wright's protraction of the nautical meridian line, which consisted of the sines of the secants, though it did not appear by whom this analogy was first discovered. It seemed, however, that it was first published and introduced into the practice of navigation by Mr. Henry Bond, who mentions this property in an edition of Norwood's "Epitome of Navigation" printed about the year 1645, and he treated of it more fully in an edition of Gunter's works, printed in 1653, where he teaches, from this property, to resolve all cases of Mercator's sailing by the logarithmic tangents, independently of the table of meridional parts. This analogy had been only found to be nearly true by trials, but not demonstrated to be a mathematical property. Such demonstration was probably first discovered by Mercator, who, desirous of making the most advantage of this and another invention in navigation, invited, by a paper in the Philosophical Transactions for June 1666, the public to enter into a wager with him on his ability to prove the truth or falsehood of the supposed analogy. This proposal, not very reputable to a man of science and literature, was not taken up by any one, and Mercator reserved his demonstration: he, however, distinguished himself by many valuable pieces on philosophical and mathematical subjects. Of these we may mention "Cosmographia, five Descriptio Cæli et Terræ in Circulos, &c.:" "Rationes Mathematicæ subductæ Anno 1653:" "Hypothesis Astronomica nova et consensus ejus cum Observationibus:" "Logarithmotechnia, five methodus construendi Logarithmos, &c.:" "Institutionum Astronomicarum Libri duo." He published also some papers in the Philosophical Transactions.

MERCATOR'S *Chart*, or *Projection*, is a sea-chart, or projection of the surface of the earth in plano.

For the construction, use, advantages, &c. of which, see *Mercator's CHART*.

MERCATOR'S *Sailing*, is that performed loxodromically, by means of Mercator's charts. See *Mercator's SAILING*.

MERCATORUM FESTUM, among the Romans, a festival kept by the mercantile people on the ides, or 15th of May, in honour of Mercury, to whom they sacrificed a sow; then sprinkling themselves with the water of a fountain, called aqua Mercuri, they prayed the god to prosper their trade.

MERCATUS, or MERCADO, LOUIS, in *Biography*, an eminent physician of the 16th century, was born at Valla-

dolid, in Spain, where he became a medical teacher, and obtained such reputation, as led to wealth and honourable appointments. He was first physician to Philip II. during a period of twenty years; and on the death of that prince, in 1598, was nominated to the same office by his son and successor, Philip III. Mercado lived to the age of 86; but the latter years of his life were rendered painful by the affliction of a stone in the bladder. He was author of a considerable number of works relative to medicine and surgery, written in a better Latin style than most of those composed by the writers of Spain; nevertheless, they are chiefly borrowed from the ancients, and contain nothing that is original. The whole were collected, and printed in three volumes, folio, in 1605, and have been several times reprinted. Eloy Dict. Hist.

MERCED, LA, in *Geography*, a town of New Navarre; 90 miles S.W. of Casa Grande.—Also, a town of Chili; 50 miles S.S.W. of St. Yago.

MERCER, a county of Pennsylvania, bounded N. by Crawford, E. by Venango, S.E. by Butler, S. by Beaver, and W. by Ohio state; about 40 miles long, and 27 broad; containing about 642,000 acres, and 3220 inhabitants.—Also, a county of Kentucky, adjoining Woodford, Shelby, and Madison counties: it contains 9242 inhabitants, of whom 2169 are slaves. The chief town is Harrodsburg.

MERCHAB, or MERHAB, a fortress of Syria, in the pachalic of Tripoli, on the coast of the Mediterranean, built by the Franks, and long possessed by the knights of St. John; 8 miles N. of Tortosa.

MERCHANT, MERCATOR, is one who buys and trades in any thing: and as merchandize includes all goods and wares exposed to sale in fairs or markets, so the word merchant formerly extended to all sorts of traders, buyers, and sellers. But every one that buys and sells is not at this day under the denomination of a merchant; only those who traffic in the way of commerce, by importation or exportation, or carry on business by way of barter or exchange, and who make it their living to buy and sell, by a continued assiduity, or frequent negotiation in the mystery of merchandizing, are esteemed merchants. Those who buy goods, to reduce them by their own art or industry into other forms than they are of, and then to sell them, are artificers, and not merchants. Bankers, and such as deal by exchange, are properly called merchants. Lex. Mercat. on Merch. Com. 23.

The mercantile profession is esteemed noble, and independent. In France, by two arrears of Louis XIV., the one of 1669, the other of 1701, the nobility are allowed to trade, both by land and sea, without derogating from their nobility: and we have frequent instances of merchants ennobled in that country, in regard to the utility of their commerce, and the manufactures they have set up. In Bretagne, even a retail trader does not derogate from nobility.

When the nobles of that province are disposed for commerce, they let their nobility sleep; that is, they do not lose it, but only cease to enjoy the privileges of their noblesse while their commerce continues; and re-assume it on their giving over trade, without any letters or instruments of rehabilitation.

In republics, trading is still more valued; but no where more than in England, where the younger sons and brothers of the best families are frequently bred up to merchandize. Add to this, that many of the Italian princes are the principal merchants of their states; and think it no discredit to make their palaces serve as warehouses; and that many of the kings of Asia, and most of those of the coast of Africa and

and Guinea, traffic with the Europeans; sometimes by their families, and sometimes in person.

There are companies of merchants in London for carrying on considerable joint-trade to foreign parts. See COMPANY.

Besides these companies, there are other merchants who are distinguished by the country to which they trade; as Dutch merchants; West India merchants; Canary and Portugal merchants; Italian merchants, who trade to Leghorn, Venice, &c.; French and Spanish merchants.

The law of England, as a commercial country, pays a very particular regard to foreign merchants, in innumerable instances. Thus it is provided by Magna Charta, c. 30, that all merchants, unless beforehand publicly prohibited, shall have safe conduct to depart from, to come into, or tarry in, and to go through England, for the exercise of merchandise, without any unreasonable imposts, except in time of war: and if a war breaks out between us and their country, they shall be attached, if in England, without harm of body or goods, till the king, or his chief justice, be informed how our merchants are treated in the land with which we are at war; and if our's are secure in that land, they shall be secure in our's. Upon which Montesquieu remarks, with admiration, that the English have made the protection of foreign merchants one of the articles of their national liberty: and also, that the English know better than any other people upon earth, how to value at the same time these three great advantages, religion, liberty, and commerce. In this respect their disposition is very different from the genius of the Roman people; who, in their manners, their constitution, and even in their laws, treated commerce as a dishonourable employment, and prohibited the exercise of it to persons of birth, rank, or fortune; and equally different from the bigotry of the canonists, who looked on trade as inconsistent with Christianity, and determined at the council of Meli, under pope Urban II. A.D. 1090, that it was impossible, with a safe conscience, to exercise any traffic, or follow the profession of the law. See COMMERCE.

If a difference arise between the king and any foreign state, alien merchants are to have forty days notice, or longer time, to sell their effects and leave the kingdom. 27 Ed. III. stat. 2. cap. 17.

The principal qualifications requisite for the profession of a merchant, are, 1. To know how to keep books single or double, viz. journals, ledgers, and others. 2. To draw invoices, contracts, charter-parties, policies of assurance, bills of exchange, letters missive, &c. 3. To know the relations between the money, weights, and measures, of several countries. 4. To know the places where the several kinds of merchandise are manufactured, in what manner made, what the materials composed of, and whence; the preparation the materials require before they are wrought; and the merchandises afterwards. 5. The lengths and breadths of stuffs, as silks, wools, hairs, linens, &c.; and the regulations of the places where they are manufactured; and their different prices at different seasons. 6. The dyeing and the ingredients for the formation of the different colours. 7. The merchandises that abound or are more rare, in one country than another; their kinds and qualities; and the manner of trafficking in them to the best advantage, whether by land, by sea, or river. 8. The commodities permitted or prohibited, both for the import and export of a state. 9. The price of exchange, according to the course of several places, and what it is that raises or lowers it. 10. The duties to be paid, both at the import and export of wares, according to the usage of the place, the tariffs, regulations, &c. 11. The

manner of packing, bailing, and tunning merchandises, to keep them either in magazines, or in voyages, &c. 12. On what terms a merchant vessel may be freighted and insured. 13. The goodness and value of every thing requisite for the construction or refitting of vessels, the prices of woods, cordage, masts, anchors, sails, and other necessaries. 14. The wages ordinarily given captains, officers, and sailors; and the manner of contracting with them. 15. The foreign languages, which may be reduced to four principal ones; viz. the Spanish, used almost through all the East, particularly on the coast of Africa, from the Canaries to the Cape of Good Hope; the Italian, used throughout the coasts of the Mediterranean, and many places of the Levant; the Teutonic, or German, used throughout most countries of the North; and the French, which is now become almost universally current. 16. The consular jurisdiction, the laws, customs, companies, colonies, chambers of insurance, consulates in the several countries; and, in general, all the ordinances, regulations, and policies, relating to commerce.

MERCHANT Court, or Court-Merchant, a kind of judicatory power, vested in merchants, chosen for that purpose, in several parts of Europe: in order to decide and determine, in a summary way, all differences and litigations among themselves and their dependents.

The affairs of merchants are accompanied with such a variety of circumstances, such new and unusual contingencies, which change and differ in every age, with a multitude of niceties and punctilios; and those again altering, as the customs and usages of countries and states do alter, that it has been found impracticable to make any laws that could extend to all cases: and our law itself does tacitly acknowledge its own imperfection in this case, by allowing the custom of merchants to pass as a kind of law in cases of difficulty. See CUSTOM of Merchants.

MERCHANT, Tenant per Statute. See TENANT.

MERCHENLAGE, MERCIORUM Lex, was the law of the people here called the Mercians. Camden, in his Britannia, says, that in the year 1016 this kingdom was divided into three parts; whereof the West Saxons had one, governing it by the laws called West Saxonlage, which contained these nine shires, viz. Kent, Sussex, Surrey, Berks, Hampshire, Wilts, Somerset, Dorset, and Devon; the Danes had the second, containing fifteen shires, i. e. York, Derby, Nottingham, Leicester, Lincoln, Northampton, Bedford, Bucks, Hertford, Essex, Middlesex, Norfolk, Suffolk, Cambridge, and Huntingdon, which was governed by the laws called Danelage; and the third part was in possession of the Mercians, whose laws were called Merchenlage, and contained eight shires, Gloucester, Worcester, Hereford, Warwick, Oxford, Chester, Salop, Stafford; from which three, king William I. chose the best, and with the other laws ordained them to be the laws of the kingdom. Camd. Brit. p. 94. See COMMON Law.

MERCIER, BARTHOLOMEW, in Biography, known under the name of the abbé St. Leger, was born at Lyons in 1784. He entered into the religious society of St. Genevieve, of which he became librarian. Louis XV. gave him the abbey of St. Leger of Soissons, of which he was deprived and reduced to indigence in the revolution. He died in 1799. Mercier was a man of erudition, and one of the first bibliographers in Europe. His works are, 1. "Letters on the Bibliography of Debure," 8vo.; 2. "Letters on the true Author of the Political Testament of Cardinal Richelieu;" 3. "Supplement to Marchand's History of Printing," 4to.; 4. "Let-

ter concerning the Maid of Orleans;" 5. "Dissertation on the Author of the Book on the Imitation of Jesus Christ (Kempis);" 6. "Notice of a rare Book, entitled 'Pedis Admirandæ,' by J. d'Artis;" 7. "On the Letters attributed to Pope Ganganelli;" 8. "Letters on different rare Editions of the 15th Century;" 8vo. 9. "Library of Romances," translated from the Greek, 2 vols. &c. He was concerned in the *Journal de Trevoux*, and the *Magazine Encyclopédique*.

MERCHET. See MARCHET and BOROUGH-*Englisb*.

MERCKLEIN, GEORGE ABRAHAM, in *Biography*, a learned physician, and son of a physician of the same name, was born at Weissemburg, in Franconia, in November 1644. His early education was conducted by his father; but he was afterwards sent to the universities of Nuremberg and Wittemberg, and thence to that of Padua, which was then in the highest reputation; he returned, however, to Altorf, where he took his doctor's degree in 1670. He succeeded his father, in 1683, in the office of physician to the Teutonic order of the house of Nuremberg, and was subsequently appointed first physician to two princes palatine, who were grand masters of this order. He passed a life of great activity, and is said to have brought on a consumption by the extreme ardour with which he pursued his occupations, which terminated his life in April 1702, at the age of fifty-eight. Mercklein was admitted a member of the Academy Naturæ Curioforum, under the title of Chiron I., and communicated many memoirs on medical subjects, which were published in their *Ephemeries*. He was also author and editor of the following works. "Tractatio Medica curiosa de ortu et occasu Transfusionis sanguinis," Nuremberg, 1679, 1715, in which he gives a history of this invention, and expresses forcibly his disapprobation of the practice, which he calls cruel and dangerous. "Josephi Pandolphini à Monte Martiano Tractatus de Ventositatis Spinæ, sævissimo Morbo," *ibid.* 1674. "Lindenius renovatus," an augmented edition of the work of J. Ant. Vander Linden, "De Scriptis Medicis," in two volumes 4to., 1686, and "Sylloge Casuum Medicorum Incantationi vulgò adscribi solitorum, maximèque præ cæteris memorabilium," *ibid.* 1698, 1715, 4to.: a curious subject, but treated with too little discrimination between real and supposititious facts. *Eloy Dict. Hist. Gen. Biog.*

MERCŒUR, in *Geography*, a town of France, in the department of the Correze, and chief place of a canton, in the district of Tulle; 18 miles S. of Tulle. The place contains 825, and the canton 6971 inhabitants, on a territory of 225 kilometres, in 11 communes.

MERCURIAL, something that consists of, or bears a relation to mercury, or quicksilver.

We say also, a mercurial person, to denote a person of a brisk, volatile complexion; such persons being supposed by astrologers to be under the more immediate influence of the planet Mercury. We say, mercurial fumes, mercurial spirits, &c. with reference to the mineral mercury.

MERCURIAL *Level*. See LEVEL.

MERCURIAL *Medicines*. See MERCURIALS.

MERCURIAL *Phosphorus, Pump, Salivation, Thermometer*. See the substantives.

MERCURIAL *Unguents, Frictions, &c.* See SALIVATION.

MERCURIAL *Waters*. See WATER.

MERCURIALS, medicines composed or prepared of mercury, or quicksilver. See MERCURY in the *Materia Medica*.

MERCURIALI, GIROLAMO, in *Biography*, a learned and eminent physician, was born at Forli, in Romagna, in September 1530. The places at which he received his edu-

cation are not accurately known, but probably were Bologna and Padua, at the latter of which he is said to have received his doctor's degree; but some assert, that he graduated at Venice in 1555. He settled in the practice of his profession at his native town, and at the age of 32 was delegated on some public business to pope Pius IV., at Rome. He evinced so much talent, and acquired so much esteem at the pontifical court, especially with cardinal Alexander Farnese, that he was honoured with the citizenship of Rome, and was strongly invited to reside there. The opportunities which the public libraries and collections of antiquities in that metropolis presented for the pursuit of his favourite studies, led him to accept the invitation; and during his abode there, he not only employed himself in his professional concerns, but studied the classical literature, and the monuments of antiquity with great ardour. The result of these researches was a learned and elegant work, which acquired him much celebrity in the literary world, and which was first published at Venice in 1569, under the title of "De Arte Gymnasticâ Libri sex," 4to. It was many times reprinted. It is rather to be regarded as a philological than a medical performance; since, while it throws much light on the private life and customs of the ancients, its reasonings and precepts are almost wholly derived from their schools. The reputation of this work brought him an invitation, in the same year, to the first medical chair in the university of Padua, which he accepted, and was successor to Anthony Francanzano, a man of such high reputation, that he had been called the Esculapius of his age. The character of Mercuriali, however, was not diminished by the splendour of that of his predecessor, and his fame soon extended throughout Europe. In 1573 he was called to Vienna by the emperor Maximilian II., to consult respecting a severe illness under which that personage laboured; and his treatment was so successful, that he returned loaded with valuable presents, and honoured with the dignities of a knight and count palatine. He had fulfilled the duties of his professorial office during the period of eighteen years, and his stipend had been gradually augmented to a greater sum than had ever been allotted to a medical chair, when, in 1587, he removed to Bologna, where he was attended by a numerous audience. This removal has been partly attributed to a degree of dissatisfaction or self-accusation, in consequence of an error of judgment, which had been committed by him and Capivaccio, several years before, when they were called to Venice, in order to give their advice respecting a pestilential disorder, which prevailed in that city. On this occasion both he and his colleague seem to have fallen into the mistake of several medical theorists, of denying the reality of contagion; and their counsels were said to have been productive of extensive mischief. Nevertheless his reputation appears to have suffered little from this error; for he was invited by Ferdinand, the grand duke of Tuscany, to settle at Pisa in 1599, where he was ordered a stipend of eighteen hundred golden crowns, which was ultimately raised to two thousand. He had not resided long at Pisa, however, before the severe calculous affections, under which he laboured, rendered him incapable of attending to his professional and professorial duties, and he retired to his native town. He sunk under his disorder in 1606, and was interred, with great honours, in a chapel, which he had himself erected at Forli. He left a large property in money and effects, among which was a valuable collection of pictures; and he made a great number of charitable bequests.

Mercuriali was a voluminous writer, as the following catalogue of his works will evince. He was a learned commentator on Hippocrates, and edited a classified collection of his

his works. Like the learned of his age, however, he was bigoted to the doctrines of the ancients, and fond of hypothetical reasoning, to the disparagement of sound observation; and he thronged his pupils with the same erroneous principles. His first publication was a tract entitled "Nomothefaurus, seu Ratio lactandi Infantes." His second, the work "De Arte Gymnastica" before mentioned. 3. "Variarum Lectionum in Medicina Scripturis et aliis, Libri iv.," Venice 1571. 4. "De Morbis Cutaneis, et omnibus corporis humani Excrementis," ib. 1572. 5. "Tractatus de Maculis pelliteris et Hydrophobia," Basle, 1577. 6. "De Pestilentia in uniuersum, præsertim uero de Veneta et Patavina," Venice 1577. 7. "Hippocratis Opera Græce et Latine," ibid. 1578. 8. "De Morbis Muliebribus Prælectiones," Basle, 1582. 9. "De Morbis puerorum Tractatus locuple illumi," Venice, 1583. 10. "De Venenis et Morbis uenensibus," ibid. 1584. 11. "De Decoratione liber," ibid. 1585. 12. "Consultationes et Responsa Medicinalia." Four volumes were successively published in 1587, 1590, and 1597; and were republished together after his death. 13. "Tractatus de Compositione Medicamentorum, De Morbis oculorum et aurium," ibid. 1590. 14. "De Horum Generatione," 1597. 15. "Commentarii in Hippoc. Coi Prognostica, Prærbetica, &c." ibid. 1597. 16. "Medicina Præctica, seu, de cognoscendis, discernendis, et curandis omnibus humani corporis affectibus," Francfort, 1602, folio. All these works have been several times reprinted, and some of them were selected after his death, and printed together, under the title of "Opuscula aurea et selectiora," Venice, 1644, folio. Eloy Dict. Hist. de la Med. Gen. Biog.

MERCURIALIS, in *Botany*, is said to have been so named, in ancient times, after Mercury, its reputed discoverer. This etymology is at least as probable, if not so ingenious, as that preferred by Ambrosius, who says *Mercurialis* is properly *Muliercularis*, because it is used by young wenches (*mulierculus*) as a laxative, in fallads. If the Linnæan *Mercurialis* be intended, certainly a very small dose would be sufficient, if not dangerous, and we cannot but suspect a confusion of different plants under the name in question. A similar error respecting the English name, Mercury, has crept into our article **LINOZOSTIS**, without any communication with the writer of the present. The plant called English Mercury is *Chenopodium Bonus-Henricus*, an excellent pot-herb, very nearly akin to Spinach; whereas the *Mercurialis*, or Mercury, properly so denominated, is a virulent poison, from the use of which, by mistake for the former, the most dangerous consequences have followed, as Ray and others relate. Such an error is the more carefully to be guarded against, as this poisonous plant is by far the most common of the two. See **LINOZOSTIS** and **CHENOPODIUM**.—Linn. Gen. 527. Schreb. 695. Mart. Mill Dict. v. 3. Sm. Fl. Brit. 1083. Ait. Hort. Kew. ed. 1. v. 3. 408. Juss. 385. Lamarck Dict. v. 4. 116. Illustr. t. 820. Gært. t. 107.—Class and order, *Diocia Enneandria*. Nat. Ord. *Tricocceæ*, Linn. *Euphorbias*, Julf.

Gen. Ch. Male, *Cal.* Perianth in three deep, ovato-lanceolate, concave, spreading segments. *Cor.* none, except the calyx be so considered. *Stam.* Filaments from nine to twelve, capillary, straight, the length of the calyx; anthers formed of a pair of globose cells.

Female, *Cal.* Perianth as in the male. *Cor.* none. Nectary of two sharp awl shaped bodies, one at each side of the germen, and lodged in its furrow, but not always present. *Pist.* Germen superior, roundish, compressed, with a furrow at each side, hispid; styles two, reflexed, horn-like, hispid;

stigmas acute, reflexed. *Peric.* Capsule roundish, pouch-like, two-lobed, of two cells. *Seed* solitary, roundish.

Obs. *M. ambigua* is monoecious, and *M. annua* occasionally so. *M. afra*, mentioned by Schæffer, is *Hydrocotyle villosa*, a plant of a totally different nature.

Ess. Ch. Male, Calyx in three deep segments. Corolla none. Stamens from nine to twelve. Anthers of two globes.

Female, Calyx in three deep segments. Corolla none. Styles two. Capsule two-lobed, of two cells. Seeds solitary.

1. *M. perennis*. Perennial Mercury, or Dog's Mercury. —Linn. Sp. Pl. 1465. Curt. Lond. fasc. 2 t. 65. Mill. Illustr. t. 91. Fl. Dan t. 400. Engl. Bot. t. 1872. (Cynocrambe; Matth. Valgr. v. 2. 635. Camer. Epit. 998, 999. Fuchf. Hist. 444. Ger. em. 333.)—Stem quite simple. Leaves rough. Root creeping. Common and plentiful in bushy places throughout Europe, in the spring, flowering in April or May. The roots are perennial, creeping and matted together to a great extent. *Herb* fetid, dark green, roughish, 12 or 18 inches high, with a round unbranched stem, most leafy about the summit. Leaves opposite, stalked, ovate, acute, crenate, hairy, with membranous, reflexed, intrasoliateous stipules. Flowers green, always dioecious, in axillary, stalked, upright clusters. Capsule rough with hairs. When dried, the leaves often assume a blue tint, indicating the affinity of the genus to *Croton tinctorium*. This has been observed before, but we know of no experiments that have proved this plant useful in dyeing. That it is the *λυοζωστis* of Dioscorides, his description leaves no doubt, and he recommends it as a pot-herb, of a purgative quality. Possibly boiling, or the admixture of oily substances, may render it mild, and less dangerous.

2. *M. annua*. Annual, or French Mercury. Linn. Sp. Pl. 1465. Curt. Lond. fasc. 5. t. 68. Engl. Bot. t. 559. (M. mas et femina; Matth. Valgr. v. 2. 633, 634. Camer. Epit. 996, 997. Fuchf. Hist. 475, 476. Ger. em. 332. Dod. Pempt. 658.)—Stem cross-branched. Leaves ovate, smooth. Flowers racemose. Root fibrous. —Native of cultivated and waste ground, chiefly in the more temperate parts of Europe. It is common about London, Norwich, and some other towns, but not in the north of England; flowering in autumn. From the former it is readily distinguished by its fibrous annual root, and bushy stem. The whole herb moreover is smooth, of a deep shining green, smelling disagreeably, something like Elder. Leaves stalked, ovate, acute, serrated. Spikes much as in *M. perennis*, but there are no linear scales at each side of the germen, and the capsule is prickly or warty. A few male flowers are often found dispersed upon the female plant; and on the other hand, a few female ones upon the male now and then occur. The present species, like the former, is said to have been used as a pot-herb, and to be of an emollient quality. It is, we believe, the least virulent and dangerous of the two, but its nauseous flavour is not promising of any good property. The seeds are said by Lamarck to be very fattening to small birds, especially to the delicious Becafico, *Motacilla Ficedula*; which is not unlikely, considering the oily nature of several seeds in this natural order.

3. *M. ambigua*. Intermediate Mercury. Linn. Sp. Pl. 1465. Linn. fil. Dec. 1. 15. t. 8.—Stem cross-branched. Leaves ovate, nearly smooth. Flowers monoecious, in axillary tufts.—Native of Spain. Linnæus cultivated it in the Upsal garden, and found it constant from seed, yet its whole appearance is so like the last, that he was latterly disposed

to think it a variety. The *flowers* however are not spiked, but grow, male and female together, in little axillary tufts, each flower on a simple stalk, the males most numerous.

4. *M. elliptica*. Shrubby Mercury. Lamarck n. 4. (*M. lusitanica fruticosa*, amygdali folio; Tourn. Inst. 534. *M. tenuifolia fruticosa perennis*; Griseb. Lusit. 63.)—Stem cross-branched, shrubby. Leaves elliptical, crenate, smooth.—Native of Portugal. Gathered near Faro by the abbé Durand. We have seen it also in Tournefort's herbarium. This is undoubtedly a very distinct species, unknown to Linnæus. The shrubby perennial stem, and the much smaller, elliptical, obtuse, crenate, not serrated, leaves, at once distinguish it. The *flowers* are dioecious, axillary; the males in short, dense, solitary, stalked spikes; the females on single-flowered, simple, shorter stalks, two or three together. *Germs* smooth and even, accompanied at each side by a small, linear, whitish scale. The *leaves* and young twigs have often, in the dry plant, a reddish or purplish hue.

5. *M. longifolia*. Long-leaved Mercury. Lamarck n. 5.—Stem cross-branched. Leaves oblong, downy, green, with blunt serratures. Fruit woolly.—Described by Lamarck from the herbarium of Thouin. Its native country is unknown. The stem is about a foot high, branched, slender and weak, slightly downy. Leaves stalked, spreading, oblong or somewhat elliptical, about an inch and half long, and not above five or six lines broad, being of a much narrower shape than those of any other species. They are dark green, clothed on both sides with depressed hairs, which render them rather silky; the margin serrated, with short, blunt, glandular, curved teeth. *Footstalks* about three lines long, with a pair of lateral glands at the top, and a pair of short downy *stipules* at their base. *Flowers* axillary, greenish, dioecious; the males in solitary, slender, stalked spikes; females solitary, on simple short stalks. *Germs* and *capsule* hoary and woolly, accompanied by a slender scale at each side.

6. *M. tomentosa*. Downy Mercury. Linn. Sp. Pl. 1465. (*Phyllon arrhenogonon*, five mariticum; Ger. em. 333. f. 2; and *Ph. theligonon*, five feminificum; f. 3.)—Whole plant finely downy and hoary. Stem somewhat shrubby. Leaves oblong, more or less serrated.—Native of Spain and the south of France. Known from all the rest by its white hoary aspect, caused by the soft downy dense hairs which clothe every part. The stem is most branched in the male plant, the *flowers* of which grow in little round heads, either solitary, or several one above another, on simple, solitary, axillary stalks. The female *flowers* are axillary, solitary, on simple stalks, on a separate plant. Some female *flowers* nevertheless are occasionally interspersed on the former, as Gerard's cut, borrowed from Clusius, well expresses. The *leaves* of both are nearly sessile, oblong, acute, veiny, generally more or less serrated, though sometimes nearly entire. The ideas of the ancient botanists, from whence the above names originated, are truly absurd. They not only mistook the female plant for the male, on account of the shape of the capsule, in which they were pleased to find a certain anatomical resemblance; but they gratuitously supposed that the herb, on account of such resemblance, would be efficacious in procuring male children, while the real male plant was presumed to favour the generation of girls.

7. *M. indica*. Indian Mercury. Loureir. Cochinch. 628.—Stem shrubby, branched. Leaves alternate, lanceolate, smooth and naked. Styles three.—Native of Cochinchina, according to Loureiro, who says the fresh leaves, boiled in broth, have a mildly purging quality, without any

bad effects; and that the plant is called *Rau mai*, or *Luc mai*. The stem is shrubby, straight, six feet high, with round ascending branches. Leaves alternate, lanceolate, serrated, smooth and shining. *Flowers* dioecious, lateral, of the proper structure of a *Mercurialis*, except that the *germs* is said to be three-lobed, with three styles, which, as well as the alternate leaves, induces some suspicion respecting the genus. We have seen no specimen.

In the first edition of Sp. Pl. 1036, occurs a *Mercurialis procumbens*, not quoted by that name in any subsequent work of Linnæus. This however appears by the synonyms and his herbarium to be *Croton Ricinocarpus*, Sp. Pl. ed. 2. 1427. See CROTON, n. 90.

MERCURIALIS, in the *Materia Medica*, the species called French mercury, *Mercurialis annua*, with branched stalks, and smooth glossy leaves, grows wild in gardens and dung-hills. This plant is mucilaginous, and was formerly much employed as an emollient. It was eaten like spinach, and when used in considerable quantity it opens the bowels. Accordingly Tournefort informs us, that the French made a syrup of it, two ounces of which was given as a purge; and that they used it in clysters and pessaries mixing one part of honey with one and a half of juice. In England it is now disregarded. A cataplasm of the leaves has been recommended in pains of the limbs, in tumours, and even in ulcers, which it cleanses and disposes to heal. Poor people in country places use it as a cataplasm for the rheumatism, and even for the gout. There is another species, called cynorambe, and dog's mercury, *Mercurialis perennis*, which grows wild in woods and hedges: this, though more acceptable to the palate, as an cleraceous herb, than the foregoing, has lately been found to possess noxious qualities, and to act as a violent narcotic. (See Phil. Transf. N° 203.) In drying it turns blue, and steeped in water, it affords a fine deep blue colour; but which, Dr. Stokes says, is unhappily destructible both by acids and alkalies, and recoverable by no means that he hath been able to discover. Miller by Martyn.

MERCURIFICATION, in *Metallurgic Chemistry*, the obtaining the mercury from metallic minerals in its fluid form. See MERCURY in *Mixeralogy* and *Chemistry*.

MERCURIO, in *Geography*, a town of Corfica or Golo, and chief place of a canton, in the department of Corté. The canton contains 2378 inhabitants.

MERCURY, 8, in *Astronomy*, the smallest of the inferior planets, and the nearest to the sun.

The mean distance of Mercury from the sun is to that of our earth from the sun as 38710 to 100000: and his real distance from the sun 36,841,468 miles. The eccentricity 7955.4. The inclination of its orbit, that is, the angle formed by the plane of its orbit with the plane of the ecliptic, is 7 degrees, and the secular change of the inclination by the action of the other planets + 20.43. The diameter of Mercury, measured by Dr. Bradley in 1723, in its transit over the sun's disc, with a micrometer to Huygens's telescope of 120 feet long, was found to be 10'.75; hence its diameter at the mean distance of the earth will be 7".27. M. de la Larme, from the transit in 1753, found it to be 6'.5; and therefore it may be stated at 7'. Von Zach says, that the mean apparent diameter of Mercury is not so much as 7", probably little more than 5". Its real diameter to that of the earth is nearly as 0.4 to 1, or 3180 miles. The mean apparent diameter of the sun at Mercury is = 80'; the density of Mercury to that of the earth is as 2.5833 to 1; its quantity of matter to that of the earth as 0.16536 to 1, the quantities of matter in spherical bodies being as the cubes of their diameters and densities conjointly; the weights of equal bodies,

MERCURY.

or gravities, on the surfaces of Mercury and the Earth, are as 1.035; to 1, such weights varying as the diameters and densities conjointly: the place of the ascending node of Mercury in 1750 $1^{\circ} 15' 23'' 43''$; secular motion of the node $1^{\circ} 12' 10''$; the annual motion of the node by the action of the other planets — 8.98; the precession 50.25, and the motion in longitude 41.27. The place of the aphelion $8^{\circ} 14' 22''$; the mean place of the planet $5^{\circ} 11' 54''$; the motion of the aphelion in longitude in 100 years $1^{\circ} 34'$. The tropical revolution of Mercury $87^{\circ} 23' 14'' 33''$; the sidereal revolution $87^{\circ} 23' 15'' 44''$. For further particulars see DENSITY, DIAMETER, DISTANCE, EXCENTRICITY, and PLACES. As the intensities of light and heat, which the planets receive from the sun, vary inversely as the squares of their distances from the sun; and as the proportional distances of Mercury and the Earth are as 4 to 10, we shall have the inverse squares $\frac{10^2}{4^2}$ to 1, or 6.25 to 1 for the relative intensities of light and heat at Mercury and the Earth.

According to sir Isaac Newton, the heat and light of the sun on the surface of Mercury, are almost seven times as intense as on the surface of the earth in the middle of summer: which, as he found by experiments made for that purpose by a thermometer, is sufficient to make water boil. Such a degree of heat, therefore, must render Mercury uninhabitable to creatures of our constitution. And if bodies on its surface be not inflamed, and set on fire, it must be because their degree of density is proportionably greater than that of such bodies as with us. The revolution of Mercury round the sun, or his year, has been already stated; but his diurnal revolution, or the length of his day, is not yet determined; nor is it certain whether he has such a motion round his own axis or not.

What variety of weather or seasons it may be liable to, we are still at a loss to determine; as not knowing the inclination of his axis to the plane of his orbit.

Mercury changes its phases, like the moon, according to its several positions with regard to the sun and earth; except only that he never appears quite full, because his enlightened side is never turned directly towards us, but when he is so near the sun as to be lost to our sight in his beams. And as his enlightened side is always towards the sun, it is plain that he shines not by any light of his own; for if he did, he would constantly appear round. This planet, when viewed with Dr. Herschel's ten feet reflector, and with other telescopes, appeared much darker than any of the solar spots, and perfectly well defined; no irregularity of form having

been perceptible at the moment of contact; but the observation appears to have been intermitted at the instant of the approach of the planet to the sun's limb. Dr. Herschel could not perceive the slightest degree of ellipticity in the form of the planet's disc.

The situation of this planet proves evidently, that the hypothesis of Ptolemy is false: for Mercury is sometimes observed betwixt the earth and sun; and sometimes beyond the sun. But the earth is never found between Mercury and the sun; which however must happen, if the spheres of all the planets encompassed the earth, as a centre, according to the Ptolemaic scheme.

The diameter of the sun, viewed from Mercury, would appear between two and three times as big as it appears on our earth; that planet being so much nearer to him than we are, and therefore the sun's disc would appear seven times as large as to us. Mercury's greatest distance from the sun, with regard to us, never exceeds twenty-eight degrees twenty minutes (see ELONGATION); whence it is seldom visible, being commonly either lost in the sun's light, or, when the most remote from the sun, in the crepusculum. The best observations of this planet are those made when it is seen on the sun's disc; for, in its lower conjunction, it passes before the sun like a little spot, eclipsing a small part of his body, only observable with a telescope.

The node from which Mercury ascends northward above the ecliptic, is in the 15th degree of Taurus; the opposite in the 15th degree of Scorpio. The earth is in these points about the 6th of November, and 4th of May, new style; and when Mercury comes to either of his nodes at his inferior conjunction about these times, he will appear in this manner to pass over the disc of the sun. But in all other parts of his orbit, his conjunctions are invisible, because he either goes above or below the sun. The first observation of this kind was that of Cassendi, in November, 1631. Several subsequent observations of the like transits are collected in Du Hamel's Hist. of the Royal Acad. of Sciences, p. 470. ed. 2. See Dr. Halley's Accounts of the Transits of Mercury and Venus, in Phil. Trans. N^o 193. See TRANSIT.

To an inhabitant of Mercury, the solar spots will appear to traverse his disc sometimes in a right line from east to west, and sometimes elliptically. As the other planets are above Mercury, their phenomena will be nearly the same there as with us. Venus and the Earth, when in opposition to the sun, will shine with full orbs, and afford a noble light to that planet.

MERCURY.

MERCURY.

As a specimen of the use of the preceding tables, we shall give the following example from the Astronomy of Professor Vince, whose polite compliance with our wish to extract the preceding tables from his valuable work, demands our respectful acknowledgment.

To compute the Heliocentric Latitude and Longitude of Mercury, and Logarithm of his Distance from the Sun.—From Table I. of the epochs, take out the epochs of the mean longitude of the aphelion and node, for the given year, and place them in an horizontal line. But if the given year be not found in that table, take the nearest year preceding the given year, as an epoch, and take out as before; under which (Table II.) place the mean motion, in longitude, of the aphelion and node, answering to the number of years elapsed since the epoch to the given year.

Under these, write down (Table III.) the mean motions of the same, for the given day of the month.

Under these, write down (Table IV.) the mean motions of the same, for the given hours, minutes, and seconds.

Add together the numbers in the several columns, rejecting 12 S, or any multiple thereof, if they occur; and you get the mean longitude, places of the aphelion, and node for the given time.

Subtract the longitude of the aphelion from the mean longitude, and the remainder is the mean anomaly.

With the mean anomaly enter Table V., and take out the equation of the orbit, making proportion for the minutes

and seconds, if there be any, correcting the result of the proportion for second differences.

Apply the equation, with its proper sign, to the mean longitude, and you get the longitude on the orbit, from the mean equinox.

From the longitude of Mercury in his orbit, subtract the longitude of the node, and you get the argument, called the *argument of latitude*.

To the longitude on the orbit thus found, apply the reduction (Table VII.) with its proper sign, and you have the longitude upon the ecliptic, reckoned from the mean equinox.

To the longitude thus found, apply the nutation, or equation of the equinoxes in longitude with its proper sign, and you get the true longitude of Mercury on the ecliptic, from the true equinox.

With the argument of latitude enter Table VIII., and take out the heliocentric latitude, making proportion for the minutes and seconds, if necessary, correcting the result of the proportion for second differences, and this is the true heliocentric latitude of Mercury.

With the mean anomaly of Mercury enter Table VI., and take out the logarithm of the distance, making proportion for the minutes and seconds, if necessary.

With the argument of latitude enter Table VII., and in the column *Sub. Log.* take out the number, making proportion for minutes and seconds, if necessary; and subtracting it from the logarithm of the distance last found, you have the logarithm of the curtate distance.

Example.—What is the heliocentric Latitude and Longitude of Mercury on June 3, 1793, at 5^h 17' 19", mean Time at Greenwich, and the Logarithm of his Distance from the Sun?

MERCURY, in *Botany*, &c. See MERCURIALIS.

MERCURY, *English*. See CHENOPODIUM.

MERCURY is a metal of a silvery-white colour, and fluid at the usual temperature of the atmosphere. It is known under a variety of denominations: the common name among the ancients was *hydrargyrum*, q. d. water of silver. The moderns commonly call it *mercury*, from some supposed relation it bears to the planet of that name. In English it is

popularly called *quicksilver*, from its appearance. Many of the chemists call it *Proteus*, from the variety of forms, colours, &c. it passes through in their preparations.

§ 1. Ores of Mercury.

1. *Native Mercury*; *Gediegen queck-silber*, Wern.; *Mer-cure natif*, Haüy.

Its colour is that of silver.

MERCURY.

It is found as globules in the cells of other ores of mercury, and as large masses in druse cavities, &c.

When pure it is perfectly fluid; it feels very cold, and as if wet, but does not adhere to the finger. It has neither smell nor taste.

Its lustre is metallic splendid. Sp. gr. 13.568, Cavendish, Brissot; 13.581, Haüy; 13.600, Klapp.

Native mercury is generally pure, but sometimes it is amalgamated with some silver, though not sufficiently saturated to be referrible to the following species, into which a transition is thus formed.

There are only a few places where native mercury has been found in abundance, such as Idria, the Palatinate, and Spain; but in small quantities it occurs almost always together with cinnabar and other mercurial ores, in stetz-rocks, which appear to be subordinate to some coal formation. See the sequel of this article, and MIXTURE.

For the use, and chemical and physical properties of mercury, see the sequel of this article.

2. *Native Amalgam*; *Natürliches amalgam*, Wern.; *Mercur argentale*, Haüy.

Its colour varies between that of tin and silver.

It is seldom found massive; oftener disseminated, in superficial laminæ, and sometimes crystallized. The crystals hitherto observed are: 1. The regular octahedron with all its edges truncated, mentioned by Romé de l'Isle (*Mercur argentale émarginé*, Haüy, pl. 65, fig. 24.) 2. The rhomboidal or garnet dodecahedron (*Mercur argentale dodécaèdre*, Haüy, ib. fig. 25.) This occurs more frequently than the others, and is by Cordier considered as the primitive crystal. 3. The preceding truncated on the edges (*Mercur argentale triforme*, Haüy, ib. fig. 26.) Also the leucite crystal, or the double eight-sided pyramid, flatly acuminate on each extremity by four planes set on the alternate lateral edges, is mentioned among the modifications of this substance.

The crystals are never large, generally of the size of a small pea: they are usually imbedded, seldom several of them grouped together.

Externally it is shining and splendid, but less so than native mercury: lustre metallic. When scraped it becomes dull.

Fracture conchoidal. It is more or less soft, sometimes approaching to fluid; not particularly brittle. Spec. grav. 14.1192, as a mean of several experiments by Cordier.

Besides this pasty semifluid amalgam, there is a more solid variety, the fracture of which is more imperfectly flat conchoidal, sometimes passing into fine-grained uneven, and which, when pressed between the fingers, or cut with a knife, gives out a more creaking sound than the other variety.

Exposed to the fire the mercury is volatilized, and a button of silver remains.

The variety analysed by Heyer contained 74 parts of mercury and 25 of silver; that examined by Klaproth 64 parts of mercury and 36 of silver; lastly, Cordier found 72.5 of mercury and 27.5 of silver in the crystallized amalgam.

The native amalgam is of rare occurrence; it has been found at Salberg in Sweden, at Rosenau and Niederslana in Hungary, at Morsfeld in the Palatinate, and principally at Moschellandsberg and Stahlberg in Deuxponts, in a yellowish and reddish ferruginous clay, mixed with other mercurial ores, and accompanied with spathose iron, lithomarge, limestone, barytes, hornstone, iron pyrites, &c.

Nothing exact is known respecting the mode of its occurrence; but probably it is confined to beds in stetz mountains.

The more solid variety resembles silver, but may easily

be known by the property it possesses of whitening gold and copper when rubbed on them.

3. *Mercurial Horn-Ore*; *Quack-silber horn-ertz*, Wern.; *Mercurie muriate*, Haüy.

Its usual colour is ash-grey, more or less deep; it often passes into yellowish-grey and greyish-white, and also inclines to greenish-grey.

It is seldom found massive or disseminated; but generally in thin crusts formed by tubercular or small globular masses, which are often composed of minute crystals. The form of these crystals is generally a dodecahedron like that of zircon, or rectangular four-sided prism, acuminate by four planes set on the lateral edges. (*Mercurie muriaté dodécaèdre*, Haüy.) Besides this the following modifications are mentioned by authors: a rectangular four-sided prism, acuminate like the preceding by four planes, but which are set on the lateral planes; a six-sided prism bevelled at both extremities, the bevelling planes set on the two largest opposite lateral planes; and the octahedron with summits and edges truncated.

These crystals are always minute and irregular, often gibbous, whence the difficulty of determining their figure with exactness. Externally they are splendid, internally splendid with a complete diamond lustre, sometimes approaching metallic lustre.

It appears to be composed of fine-grained distinct concretions. It is generally faintly translucent, sometimes only on the edges; soft; may be cut with a knife, and is easily frangible.

Its specific gravity and other characters remain yet undetermined, on account of the smallness and scarcity of the fragments that have hitherto been found.

Before the blowpipe it is volatilized, without decomposition. It is soluble in water. Woulfe found it composed of 64 parts of sulphat of mercury, and 36 muriat of mercury; Kirwan of 70 parts of mercury, and 30 of muriatic and sulphuric acids.

The Horn mercury, the scarcest of all mercurial ores, was first discovered by Mr. Woulfe in the quicksilver mines of Moschellandsberg and Morsfeld, in ferruginous clayey sand-stone, accompanied with other ores of mercury, ochrey-brown iron-stone, malachite and blue copper ore, calcareous spar, lithomarge, &c. It has also been found at Idria, generally in the cavities of an indurated clay, and of slate-clay accompanied with crystallized cinnabar; at Horzowitz in Bohemia, with dark red cinnabar in a vein of brown iron-stone, and at Almaden in Spain.

4. *Mercurial Liver-Ore*; *Quack-silber-Leberertz*, Wern.; *Liver-coloured mercurial ore*, Atk. *Mercurie sulfuré bituminifere*, Haüy.

It is divided by Werner into compact and stony liver-ore.

a. *Compact*.—Its colour is intermediate between dark lead-grey and cochineal red.

Occurs massive and rarely disseminated. Internally it is glittering and glimmering, with semi-metallic lustre.

Fracture even, passing sometimes into fine-grained uneven, and imperfect large and flat conchoidal: fragments indeterminate angular, more or less blunt-edged; opaque. Streak thinning, and of a deep cochineal red colour. It is soft, may be cut with a knife, and is easily frangible. Specif. grav. 7.186—7.352, Kirwan; 7.937, Gellert.

b. *Stony*.—Its colour nearly the same as the preceding, only now and then more of the red observable on the principal fracture. It is found only massive. Its fracture in the direction of the laminæ is curved and thick stony; it is shining, and its lustre approaches the metallic; cross fracture

MERCURY.

even and compact, and but little shining or only glimmering. Fragments more or less flat. It is opaque, and uncommonly easily frangible.

The mercurial liver-ore affords upwards of 80 per cent. of pure mercury. Klaproth, who analysed the compact variety from Idria, obtained the following results :

Mercury	-	-	-	818
Sulphur	-	-	-	137.50
Charcoal	-	-	-	23
Silex	-	-	-	6.50
Alumina	-	-	-	5.50
Oxyds of copper	-	-	-	2
Copper	-	-	-	0.20
Water which served to form the sulphu- rated hydrogen gas, and other loss	}			7.30
				1000

This analysis, Klaproth adds, may serve to rectify the erroneous notions which have been adopted concerning the composition of this mixed mineral. By shewing that the sulphur is combined with the metal in the same proportion as in cinnabar, namely, as 1 to 6 in round numbers, we are taught how little foundation there is for the opinion of those who, like Sage and Kirwan, think that a part only of the mercury is in the state of sulphurated mercury, and that the other is in the state of a simple oxyd. If that were the case, the non-sulphurated part would certainly be soluble in the nitric acid; but experiment shews that this is not the case, because the acid cannot dissolve any part even when boiling, the mineral powder remaining unchanged at the bottom of the vessel. See Nichol's Journ. vol. 15. p. 231.

Both varieties of mercurial liver-ore occur together at Idria in Friaul, to which they appear exclusively to belong, though Spain, Siberia, and other places have been mentioned by authors among their localities. They are found in large masses, in and with slate-clay, and a kind of bituminous shale, and accompanied with cinnabar, and sometimes small quantities of native mercury and iron pyrites. Two ores of mercury, supposed to belong to the liver-ore, are at Idria distinguished by particular names. One is the *Brand-ertz*, which appears to be a kind of coarse coal impregnated with cinnabar; the blackish-grey variety contains only from 1 to 18 per cent., the red from 30 to 40 per cent. of mercury. The other is called *Corallen-ertz*, (bead or coral-ore); it consists of reddish-black oblong beads of the size of a large coffee bean, of a foliated structure, imbedded in a blackish bituminous shale, and also in sand-stone. The richest affords about 40 per cent. of mercury.

5. *Cinnabar*; *Zinnober*, Wern; *Mercure sulfuré*, Häuy.

This species may conveniently be subdivided into two varieties, viz dark red cinnabar and bright red cinnabar.

Dark red cinnabar; *Dunkel-rother zinnober*, Wern.

Its colour is cochineal red, which in some varieties inclines on one side to carmine red, on the other to lead grey.

It is found massive, disseminated, in superficial coatings and membranes, amorphous, cellular, dendritic, and crystallized.

Its primitive form is the regular hexahedral prism; integrant molecule, the triangular equilateral prism. The following, according to Werner, Emmerling, and Eistner, are the principal secondary forms: 1. The rhomboid rather flattened, truncated in the two diagonally opposite obtuse angles.

2. The six-sided table, formed by the increase of the truncating planes of the preceding figure. 3. The regular six-sided prism, either perfect or acuminate by three planes set on the alternate lateral planes. 4. The three-sided pyramid, either double or single, in which the angles are sometimes more or less deeply truncated. 5. The regular octohedron, sometimes terminating in an edge at the summit.

Häuy, on the other hand, has observed only two distinct modifications in the crystals of cinnabar; the one is the primitive form, or the regular six-sided prism (*Mercure sulfuré primitif*, pl. 65. fig. 27.), in which the divisions parallel with the lateral planes are very distinct; the other (*Merc. sulf. bifolterne*, fig. 28.) a similar short prism, with six marginal planes at each extremity placed alternately with regard to the lateral planes and to the planes of the other extremity.

These crystals, whose real form is often difficultly determinable, are generally small and very small; they are grouped together without order, generally lining the cavities of massive cinnabar. Externally they are splendid; internally both the crystallized and amorphous varieties are shining, which sometimes passes into glistening, and likewise into glimmering; with diamond lustre approaching to semi-metallic. The foliated varieties have the strongest lustre.

Fracture either more or less perfectly lamellar, the crystalline varieties with laminae sometimes rather curved; or fine-grained uneven, with a tendency to conchoidal. Fragments indeterminate angular, rather blunt-edged. The lamellar varieties present granular distinct concretions; sometimes there is a tendency to thick and straight lamellar distinct concretions.

Massive cinnabar is opaque, seldom translucent on the edges; but the crystals are sometimes translucent and even approach transparent.

It becomes shining in the streak, affording a scarlet red powder. It is soft and easily cut with the knife, and very heavy. Spec. gr. varies from 4.500 to 10.218, which latter was determined by Briffon on a pure crystal from Almaden: 7.710, Klapr. (the Japanese in grains): 8.116, Kl. (the massive from Neumärktel).

The constituent parts of dark red cinnabar, were found by Klaproth to be

	The Japanese.	From Neumärktel.
Mercury	-	84.50
Sulphur	-	14.75
		99.25
		99.25

Bright red cinnabar; *Hoekrother zinnober*, Wern.

Colour bright scarlet red. It is found massive, disseminated, and coating. Internally it is glimmering, of rather a pearly lustre; sometimes, especially on the cross fracture, it is dull; principal fracture between earthy and fibrous; cross fracture earthy, fine-grained; fragments indeterminate angular, blunt-edged. It is opaque. Streak scarlet red, shining. It is very soft, passing into friable; and foils. It is very heavy.

This sub-species, which is much scarcer than the preceding, is found in the quicksilver mines of the Palatinate, particularly at Wolfstein and at Deuxponte, where it is accompanied with brown iron-stone, iron-ochre, quartz, calcareous spar, and dark red cinnabar. The other localities assigned to light red cinnabar are not well authenticated.

Some authors, as Eistner, are said to have mistaken the red iron-

iron-ore, which is found with bright red cinnabar, for this latter variety; whence the other shades of red they mention are not applicable to the substance in question.

Werner adopts two distinct formations of cinnabar, contemporaneous with the mountains in which they occur in beds. These latter, in the older formations, consist of a kind of chlorite slate, quartz, &c.; in the newer, of slate clay, &c. It is also found in veins, the relative age of which is not ascertained. To the newer formation, which is far more abundant than the old, belong the repositories in the Palatinate, in Deuxponts, Spain, Idria, &c.; to the older, those of Hartenstein in Saxony, of Carinthia, &c. In veins it occurs at Horowitz in Bohemia, in Lower Hungary, &c., where it is accompanied with some other mercurial ores, with iron-stone, galena, and other geognostically related species, which, in this case, are always indications of venigenous origin. When occurring in beds, it is generally accompanied (besides with other ores of mercury) with compact lime-stone, calcareous spar, barytes, quartz, and sometimes traces of copper ores; the beds themselves are principally formed by slate clay, a kind of sand-stone, and rocks of a similar nature. Some of the older beds are found in clay slate mountains, and contain the cinnabar in contemporaneous small veins or trunks. The newer beds are supposed partly to belong to the coal-formation. Mohs.

The geognostic relations of the Japanese dark red cinnabar are not known. It is brought to us in small grains, being mostly fragments of flattened six-sided prisms, which partly contain finely disseminated iron pyrites, and are also found adhering to particles of a quartz substance.

The principal quicksilver mines in the Palatinate are at the following places, *viz.* Mörsfeld, where the cinnabar traverses quartz, which is often completely coloured by it; the native quicksilver, formerly found at this place, was so abundant, that, according to Ferber, it was observed in the very streets of the town: Spitzenberg near Mörsfeld, where cinnabar occurs mixed with brown iron-stone; also small veins of asphaltum are sometimes found here in the masses of cinnabar: Carlsgrück, which furnishes a mercurial sand ore, being cinnabar in a grey fine-grained and partly slaty sand-stone, mixed with more or less clay; also native mercury has sometimes been found here included in geodes of brown iron-stone: Wolfstein, where there is the mine *Theodors Erzluft*, in a mountain called the Königberg; it was formerly uncommonly rich in mercurial ores, such as the light red cinnabar both earthy and fibrous, which is almost exclusively found here, accompanied with brown iron-stone, &c.: at Potzberg, in the principality of Veldentz, cinnabar occurs in a kind of pudding-stone.

In the territory of Deuxponts, the most remarkable mine is that in the Schloßberg of Obermoschel or Moschellandsberg, where both cinnabar and native mercury are found in great abundance.

The quicksilver mines of Idria were discovered in 1497. The richest ores, according to Ferber's account, occur in a considerable bed of clay slate. The roof and hanging side of the veins consist of limestone; they are very much rent, and traversed by dykes or ridges of other calcareous rocks and of a hard clay slate, which produce slips and faults in the mercurial vein. The clay slate of Idria is generally soft at some depth under ground, but harder and more distinctly slaty towards the surface: its principal colour is black. This slate is traversed and penetrated in all directions by veins of cinnabar and disseminated native mercury, which are also found in nests. It is in the softer part

of the slate that the richer ores are generally found; they are firm, compact, and commonly marle-like, and when unmixed with other soft earthy substances, are susceptible of polish. These richer ores contain from 40 to 70 and even 80 pounds of quicksilver in the hundred weight.

The different rock-stones at Idria containing mercury are, 1. Grey and black lime-stone, improperly called horn-stone by the miners; it constitutes only the roof and sides of the slaty vein and the bars, which latter sometimes contain much disseminated cinnabar. 2. Varieties of clay of various colours, white, grey, yellow, red, and blackish, some pure others marly, and of various degrees of hardness: the blackish-grey variety yields from five to ten *per cent.* of quicksilver. 3. Grey clay slate, either pure or mixed with lime: it contains from two to three *per cent.* of quicksilver; the more its colour increases in depth the richer it becomes, so that the darkest, or blackish-grey variety, yields sometimes eight pounds in the hundred weight. 4. Black soft clay slate, called *Mildzeug*, of a more or less marly nature, and containing from ten to fifteen, and sometimes even from thirty to forty pounds in the hundred. 5. A black hard clay slate, called *Spiegel*, or looking-glass slate, on account of its shining surface: it sometimes produces from forty to fifty pounds in the hundred weight; but very little when purely argillaceous, and very hard. 6. Druses, or aggregations of calcareous, gypseous, and barytic crystals, which are sometimes found coated with cinnabar.

The following are the principal mercurial ores known at Idria: 1. Pure cinnabar, massive and crystallized. 2. Red ore, or impure cinnabar, of a tile-red colour, mixed with marle and pyrites; producing about thirty pounds in the hundred. 3. *Schnürl-erz*, or bead-ore, because the cinnabar traverses the matrix in small veins similar to strings of beads. 4. Mercurial liver-ore, a very rich ore, yielding from fifty to eighty pounds in the hundred weight. 5. Mercurial brand ore. 6. Coral ore, which contains from one to forty pounds. *Vide supra Mercurial liver-ore.*

The Spanish quicksilver mines are the most ancient we are acquainted with. Pliny informs us that no other cinnabar was made use of at Rome than that from Spain, particularly that of the *Regio Sifaponensis* in Bætica, which appears to have been the territory of the present Almaden. This latter name is of Saracenic origin, signifying the shaft or gallery of a mine. According to Theophrastus and Pliny's account, the cinnabar brought to Rome was a kind of sand; a term which is applicable to those small fragments of cinnabar mixed with quartz, which are still found in considerable quantity in the old mine de las Cuebas, near Almaden, from the size of a hazel-nut to that of a hemp-seed.

The prevailing mountain-rock at and near Almaden is a grey clay slate, traversed in many places by considerable beds of a breccia, which is composed of pieces of a similar clay slate, with white calcareous spots, and fragments of the same black bituminous shale, which is the usual concomitant of the quicksilver mines of Almaden. This breccia is here known under the name of *Fraileque*, on account of its prevailing colour, which resembles that of the habit of the Franciscan monks.

The most important mines are at the south side of Almaden, in the immediate neighbourhood of the town; there are six of them, running, within the space of about fifty fathoms, nearly from east to west: some of them, especially that of San Diego, deviate from this course, describing part of a large circle. Their dip is from sixty to upwards of eighty degrees; they frequently intersect each other, and are also traversed by the above-mentioned breccia and a black bitu-

MERCURY.

minous shale; but at a certain depth (such as in the mine Francisco, which is 100 fathoms deep), they generally continue their course without interruption. They are all very rich in ore: where the veins meet, particularly those of San Julian and San Diego, the repositories of ore are from four to five fathoms in thickness: these consist of a quartz, richly intermixed with cinnabar, yielding from twenty to thirty pounds in the hundred.

The other quicksilver mines belonging to the territory of Almaden are, 1. That of Almadenejos, where veins of quartz, from one to half a fathom in thickness, richly penetrated by cinnabar, traverse the grey clay slate above-mentioned. 2. That of Guadalperal, half a Spanish league N.W. from Almadenejos: this mine, which is very superficial, was wrought by the Romans. The rock it traverses is the same clay slate with that of Almaden, only that the breccia contains no fragments of the black bituminous shale, which is one of the component parts of that seen at Almaden. The ores of this mine consist of crystalline cinnabar, mostly in very narrow veins or trunks. 3. The mine de las Cuebas, about three English miles from Almaden, in the same direction with that of Guadalperal. The quicksilver ores are here found in short interrupted veins of quartz traversing bituminous shale.

For a complete account of the quicksilver mines of Almaden, see Hoppen sack über den Bergbau in Spanien. Weimar, 1796.

MERCURY, Assay and Analysis of the Ores of.—Mercury is frequently combined with silver and bismuth in the form of an amalgam. The mercury may be separated by distillation in a retort of iron, or of glass coated with sand and clay. The residuum, which is generally silver and bismuth, may be dissolved in nitric acid. When the solution is complete, a large quantity of water must be added, by which the greatest part of the bismuth will be separated in the state of subnitrat. If oxymuriatic gas be passed through the solution of silver and the remaining bismuth, the former will be precipitated in the state of muriat of silver, while the bismuth will be held in solution in the state of oxymuriat of bismuth. When the muriat of silver is separated, the bismuth may be precipitated by potash, and the oxyd collected and dried. The subnitrat of this metal first separated must be boiled with potash, to separate the nitric acid. This oxyd, being washed and dried, may be added to the other. For every 100 of this oxyd, allow 90 of the metal. The muriat of silver contains, in the 100, 77.77 of the metal.

A specimen of the native amalgam of silver and mercury, analysed by Klaproth, gave 64 mercury and 36 silver in the 100.

Should any gold be present, it will be left undissolved when the residual metals are taken up by the nitric acid.

Native cinnabar may be analysed by dissolving it in nitro-muriatic acid. The mercury will be dissolved in the state of oxymuriat of mercury, while the sulphur will be separated. If much heat be employed, some of the sulphur will be converted into sulphuric acid, and some of the mercury, in consequence, will be thrown down in the state of sulphat: the solution, therefore, must be made in the cold.

The sulphur being separated, washed, and dried, may be weighed.

The mercury may be separated in the metallic form by a clean piece of iron. This is almost the only instance in which a metal is precipitated by another in a state of purity, since iron does not in any degree combine with mercury. The mercury may also be thrown down by the green sulphat of iron. This ore, according to Klaproth, consists of

84.5 mercury, and 14.75 sulphur. The hepatic ore may be analysed by a process similar to the last. This, however, is apt to abound with other substances besides sulphur and mercury. A specimen from Idria was analysed by Klaproth, and the result is given under the article *Ores of Mercury*, supra.

The native muriat of mercury consists of a mixture of sulphuric and muriatic combined with the oxyd of mercury. This ore must be reduced to a fine powder, and mixed with twenty-four parts of water; oxymuriatic gas must then be passed through it for a length of time, till the whole of the powder be dissolved. The sulphuric acid may be precipitated by muriat of barytes. The mercury may be precipitated from the muriatic acid by a bright piece of iron.

The sulphat by this process becomes oxyfulphat of mercury. In the ore it may be considered as the sulphat: for every 100, therefore, of sulphat of barytes precipitated, allow 211.76 of sulphat of mercury in the ore. The rest may be considered muriat of mercury. For 100 of mercury allow 4 of oxygen, and 11.2 muriatic acid.

For the assay of mercurial ores in the dry way, let the specimen be pulverized, and accurately mixed with one-fourth its weight of quicklime, and an equal portion of iron filings, and then let it be pretty strongly ignited in an iron or earthen retort, as long as any mercury comes over into the receiver.

The modes of extracting the metal from the ores of mercury are very simple. Messrs. Aikin, in their valuable Dictionary of Chemistry and Mineralogy, have given an account of the process for this purpose at the mines of Deuxponte and of Idria, and also at Almaden in Spain. The former is the best and most scientific, and it is as follows: when the ore is brought out of the mine it is accurately sorted, those pieces being rejected which appear to be destitute of metal. The sorted ore, being pulverized, is mingled with one-fifth, more or less, according to the proportion of cinnabar contained in the ore, of quicklime powdered by exposure to the air. This mixture is then put into iron retorts, about forty or fifty in number, capable of holding about 60lbs. weight, which, thus charged, are fixed in a long furnace; a glass receiver is then attached to each retort, but not luted, and a gentle fire is applied in order to expel all the moisture: when this is effected, the juncture of the vessels is closely stopped with tempered clay, and a full red heat is applied for seven or eight hours, at the expiration of which time all the mercury will have been volatilized and condensed in the receiver. The common produce varies between six and ten ounces of metal from 100lbs. of the ore.

The process at Almaden is more rude and artificial: it is described by Messrs. Aikin (*ubi supra*); and to their account of it the reader, desirous of further information, is referred.

The conveyance of mercury from place to place requires, on account of its fluidity, extraordinary precautions. It is packed in the following manner. A fresh found sheep-skin, the hair of which has been taken off, is laid over a wooden bowl, and a quantity, from 50lbs. to 75lbs. of mercury is poured into it: the ends of the skin are then gathered up, and tied together with great care, thus forming a sort of bag in which the metal is inclosed: this bag is inclosed in a second skin, and the second in a third: and, lastly, these bags are put into very tight barrels, capable of holding from two to four of them, and in this state are brought into the market.

Chemical and Physical Properties of Mercury.—It is a white

MERCURY.

white metal resembling tin. Its specific gravity is 13.568. It is liquid at the greatest cold of this climate, but becomes solid at -39° , or 71° below the freezing point of water. It has frequently been reduced to the solid form in this country by the aid of freezing mixtures, and lately, by Mr. Letley, in the vacuum of the air-pump. In this state it possesses some of the characters of tin, as far as regards its appearance and malleability. It is said to undergo a rapid decrease of volume immediately before congelation, a property the reverse of what is observed in the freezing of water; and in the congelation of all bodies, the liquids of which are of greater specific gravity than their solids, will it not be found that solid mercury is of greater specific gravity than the liquid? The boiling point of mercury, or the temperature at which it assumes the elastic form, is 650° , or, as some say, 660° ; so that the number of degrees between its freezing and boiling points is 689° , or 699° . This property admits of its being distilled, which furnishes a simple method of separating it from substances which are not volatile. Hence we may conclude, that if our natural temperature were more than 650° , mercury would be presented to us in the form of a permanently elastic fluid: while, in a temperature less than -39° , it would be a solid malleable metal.

Mercury does not decompose water at any temperature, and hence it may be kept under that fluid without undergoing any change.

When exposed to the air it soon tarnishes, and becomes covered with a dark grey powder. If it be agitated with the fingers for a short time, they become soiled with the same powder. This substance is produced by the mercury combining with the oxygen of the atmosphere. It may be formed in greater quantity by a stronger agitation in contact with oxygen. This has been effected by putting a small quantity of mercury into a large bottle, and tying it to the spoke of a coach-wheel. The change of surface, from the motion of the wheel, induces the rapid oxydation of the mercury. The oxyd so obtained is the first or protoxyd of mercury, and was called by the old chemists *Ethiops per se*. If, according to Dalton, the atom of mercury be 167, hydrogen being 1, and oxygen 7, the protoxyd will be $\frac{167 \times 7}{7}$

$= \frac{100}{4}$, or four per cent. This is exactly what Fourcroy

makes it by experiment. In taking a general view of the combinations of mercury with other bodies, it would appear that Mr. Dalton has rated the atom of mercury too high. The analysis of the sulphuret appears to be the most perfect. It may with much confidence be admitted, that 85 of mercury combines with 15 of sulphur for the second

sulphuret. Hence we shall have $\frac{15}{85} = \frac{26}{147\frac{1}{2}}$. We

shall find, therefore, in treating of the other compounds, that it will be nearer the truth, to call the atom of mercury 147. This number will give the protoxyd 4.5 per cent. When mercury is dissolved in nitric acid with a boiling heat, and the oxyd precipitated by lime water, the precipitate will be formed of a yellow colour. This is in all probability the second

oxyd, which should be constituted as follows: $\frac{147 + 14}{14}$

$= \frac{100}{8.7}$, or 8.7 oxygen, and 81.3 mercury. Chenevix

makes it 10.7. It is likely, however, that as he expelled the acid by heat, the oxyd might absorb more oxygen, or the acid might not be all driven off.

The third oxyd of mercury may be formed by exposing the metal or the protoxyd in small quantity in a large glass matras, the neck being drawn out to a small point. When the mercury is heated in this vessel to a boiling heat, 650° , the smallness of the aperture does not admit of its escape as vapour, while it is completely exposed to the oxygen of the atmospheric air. By this means the mercury becomes converted into a red powder, which is the third oxyd. The same may also be procured by adding lime-water to a solution of the oxyduret of mercury (corrosive sublimate), when a beautiful red powder is precipitated, which is the oxyd in question. The proportions will be $\frac{147 + 21}{21} = \frac{100}{12.5}$ or 87.5 mercury, and 12.5 oxygen.

This oxyd is of a beautiful red colour: it possesses some of the qualities of an acid, inasmuch as it has a decided taste, is corrosive to the skin, and when heated with filings of tin or zinc, it causes them to inflame by yielding with facility its oxygen to them. Chenevix makes the proportions to be 85 mercury and 15 of oxygen, but for the reasons given in the second oxyd it is, doubtless, rated too high.

Mercury does not combine with carbon, hydrogen, or nitrogen, but it combines with sulphur and phosphorus.

When two parts of sulphur and one of mercury are rubbed together in a mortar, the mercury combines with a portion of sulphur. The whole mass appears of a black colour, and consists of the sulphuret of mercury mixed with an excess of sulphur. This substance was formerly called *Ethiops mineral*. If this mass be exposed to a heat sufficient to sublime the sulphur, the excess of the latter substance escapes, leaving behind a substance of a deep violet colour. If this heat be continued the sulphuret is sublimed, which, if collected by a proper vessel, will form a red cake, which, when reduced to powder and washed, constitutes the factitious cinnabar, known in the arts by the name of *Vermilion*. There appears to be two sulphurets of mercury, viz. cinnabar, and one containing less sulphur. The first will consist of 8 of sulphur and 92 of mercury, for $\frac{147 + 13}{13} = \frac{100}{7.1}$. The second sulphuret consists

of 15 sulphur and 85 mercury, from what has been before stated. The second sulphuret of mercury has a beautiful scarlet colour, for which it is esteemed in the arts as a pigment: it does not dissolve in water and is perfectly tasteless. It does not change on exposure to the air. When exposed to a strong heat the sulphur combines with oxygen, and burns with a blue flame. Iron has a stronger attraction for sulphur than mercury. Hence, if the red sulphuret be mixed with iron filings and introduced into a retort, the iron combines with the sulphur, and if the heat be sufficiently raised, the mercury comes over in a state of tolerable purity. This method is employed in the large way to separate mercury from native cinnabar.

A method of preparing artificial cinnabar has been discovered by Mr. Kirchoff. To 300 grains of mercury add 68 grains of sulphur, which being moistened with a solution of potash, must be rubbed together in a mortar which is not of metal. By this means the ethiops mineral is produced. To this substance 160 grains of potash, dissolved in its own weight of water, must be added. Let the mass now be transferred into a porcelain dish and heated over a chemical lamp, adding water from time to time to supply the loss by evaporation, in order to keep the solid ingredients covered.

MERCURY.

covered. During this process it should be constantly triturated with a glass pestil. At the end of two hours the colour will begin to change from black to brown, and soon passes through different shades to a red. As the mass assumes the form of jelly, the red colour increases in brightness, and soon acquires its maximum of tint, at which time it will be proper to withdraw the heat, otherwise the colour declines to a dirty brown. It is recommended, that after it has acquired a tolerable good colour, it should be exposed for a few days to a low and uniform temperature, by which means the colour gradually improves and ultimately becomes exquisite. If the cinnabar thus obtained be exposed to a strong heat, it becomes brown and ultimately of a violet colour. It is highly probable, that this violet-coloured sulphuret is the first sulphuret produced from the second, from some of the sulphur being volatilized.

Phosphorus does not easily combine with mercury. Pelletier, however, succeeded in uniting these bodies by distilling a mixture of red oxyd of mercury and phosphorus. He observed that the red oxyd assumed a black colour before it combined with the phosphorus. Dr. Thomson, partly from this fact and from his own experience, is of opinion, that it is not the metal which unites with the phosphorus, but the black oxyd. In reasoning from analogy we might be apt to doubt this fact. We know that when sulphur is heated with an oxyd of mercury, the oxygen of the latter combines with a portion of sulphur, and is carried off in the state of sulphurous acid gas. Then since phosphorus has a stronger attraction for oxygen than sulphur, it would seem likely that the mercury would be reduced to its metallic form before it combined with the phosphorus. This, however, is not a fair conclusion, since none of the compounds of phosphorus are volatile. The circumstance of sulphurous acid being elastic, is doubtless a strong reason why the metals in the metallic sulphurets are generally free from oxygen.

The phosphuret above alluded to is a solid of a black colour: its consistency is such as to be cut with a knife. When exposed to the air it exhales a vapour smelling like phosphorus.

Mercury combines with most of the metals forming alloys, which have been called amalgams. Many of these compounds are of great use in the arts.

Gold unites with mercury with such facility, that if a piece of pure gold be singly dipped into it, it comes out completely covered with mercury. When the gold is divided into small grains and heated red-hot, the mercury being heated near to its boiling point, the gold almost instantly dissolves. A considerable proportion of gold may be added in this way without materially altering its liquidity. If, however, this liquid amalgam be squeezed through sheep's leather, an alloy will be obtained of almost any degree of consistency. The amalgam of gold used for gilding is about the consistency of paste. The substance to be gilt, which is copper, brass, or silver, is first covered with mercury, in order to form a medium for covering the surface with the amalgam. When the surface of silver is clean, the mercury combines with it with great facility. Copper or brass do not take the mercury by the same mode of application. A dilute nitric acid is added to the mercury, by which a portion of the metal is dissolved. If a small quantity of this solution be applied to the brass or copper surface, the mercury becomes precipitated upon it, and is instantly made fit to receive the amalgam. A small quantity of the amalgam, more or less, according to the thickness of the gilding required, is laid upon the quicksilver surface, and

uniformly spread about with a brush. The substance is then held over a clean coke or charcoal fire, and thus alternately heated and brushed till all the mercury is evaporated, leaving the gold firmly and uniformly adhering to the surface.

Mercury does not combine easily with platina in masses. If, however, the precipitate from nitromuriatic acid by muriat of ammonia be exposed to a strong heat, the acid and oxygen are expelled, leaving pure platina in a state of minute division. If the mercury be mixed with this powder and heat applied, an alloy will be formed, from which an amalgam of any degree of consistency may be obtained by squeezing through leather. This amalgam may be employed for coating metals, such as silver, brass, and copper. The metallic precipitate of platina above-mentioned, might be obtained at little expence, probably not more than the price of silver. Vessels of copper might, therefore, be covered with platina without much increasing their intrinsic value.

We hope, therefore, that artists in this line will take the hint. Even if no other end should be gained than preventing the deleterious effects of copper, the object is worth attention.

Silver easily amalgamates with mercury. When the proportion is eight of mercury to one of silver, the mass is capable of assuming a crystalline form. The specific gravity of this compound is greater than an arithmetical mean, a proof of considerable affinity between the two metals. This amalgam, like the two last, may be employed to coat copper and brass with silver.

Copper is capable of combining with mercury. The alloy, however, is not of any use, and has been little examined.

Mercury does not combine with iron. This circumstance presents many advantages. Iron vessels are well calculated for conveying mercury from place to place, and iron retorts are well fitted for distilling that substance. There are some disadvantages in mercury not uniting with iron. If the surface of iron could be covered with mercury like copper, &c. it might be gilt with as much facility as those metals. Although it is generally considered as incapable of uniting with mercury, it is stated in Crell's Journal, that Mr. Vogel has succeeded by the following process. Take half an ounce of iron filings and one ounce of alum, and rub them together to a very fine powder; add to this from an ounce to an ounce and a half of mercury, and triturate till the amalgam begins to be formed; then pour in a little water, and continue the agitation for an hour: the alum is now to be dissolved out and the amalgam of iron will remain behind.

Tin combines easily with mercury. It is this alloy which constitutes the silvering of glass reflectors. A piece of tin-foil is first cut to the size of the glass plate to be silvered. This sheet is spread upon a smooth and perfectly flat stone, at first truly horizontal, but capable of being placed in an inclined position. The sheet of tin-foil is then covered with mercury, till the whole of the surface appears perfectly bright and liquid. The plate of glass, perfectly clean, is then laid upon the tin-foil. A number of weights are also laid upon the glass-plate, and the stone put into an inclined position by a lever, and held in that situation by temporary props. By this means the excess of mercury is squeezed out, and runs off by a groove in the edge of the stone. As much mercury is left with the tin-foil as will form a tolerably hard alloy.

Mercury unites with zinc in any proportion. This alloy is employed in a friable state for the purpose of laying on the

MERCURY.

the cushions of electric machines, which much increases their exciting power.

It is also employed in the process called *filioring*. An amalgam of the consistency of that used for gilding is applied, in a manner similar to the gilding amalgam, to the surface of copper. The mercury evaporates by heat, leaving the zinc behind. The latter, however, does not appear in its pure state, but combines a portion of copper, and by that means produces a fine yellow surface, little inferior to gold, but in fact it is nothing more than brass formed by the union of the copper with the zinc. This process is employed by the button-makers. Some sorts of buttons are first covered all over with this yellow coating. The upper surface of the button is afterwards really gilt.

Mercury is readily alloyed with lead, bismuth, and antimony: the second of these is frequently used to adulterate mercury. It may contain a considerable portion of bismuth without sensibly losing its liquidity.

Salts of Mercury.—The salts of mercury are generally distinguished by their nauseous taste. Those that constitute the greatest part are insoluble in water. They form several varieties from the oxyd of mercury, assuming different states of oxydation, and also from their aptness to exist in the state of sub and super-salts.

Sulphat of Mercury.—Sulphuric acid does not act upon mercury without the assistance of heat. The acid is then partly decomposed. An atom of oxygen is separated, which combines with the mercury. The acid flies off in the state of sulphurous acid. Indeed this is the best way of getting this gaseous acid in a state of purity. The oxyd of mercury unites with another portion of the acid, forming the sulphat of mercury which separates in the form of white powder. In this experiment the sulphuric acid should not be in excess, since in that case the super-sulphat of mercury would be obtained. This salt dissolves in 500 parts of water at 60°, and in 287 at 212°. On evaporation it affords small prismatic crystals. It is not changed by exposure to the air, but is decomposable by heat. According to the analysis of Foureroy, it is composed of 12 acid, 83 of the second oxyd of mercury, and 5 water. If we consider the atom of mercury 147, oxygen 7, and sulphuric acid 34, the atom of the second oxyd will be $147 + 2 \times 7 = 161$: then for the sulphat we have $\frac{161 + 34}{34} = \frac{100}{17.4}$, or 17.4 acid, and 82.6 of the second oxyd of mercury.

Super-sulphat of Mercury.—When an excess of sulphuric acid is boiled upon mercury, the oxyd combines with two atoms of acid, constituting the super-sulphat of mercury. It has a disagreeable acrid taste. It is not changed by exposure to the air. It changes vegetable blues to red. Foureroy says that when the acid amounts to $\frac{1}{2}$ th of its weight, it is soluble in 157 of cold, and 33 of boiling water, and observes that it is differently soluble with different proportions of acid. This is the first instance in which we have heard of the acid of a salt being so unlimited, and we cannot help doubting the accuracy of the above fact. In all the instances in which super-salts have been analysed, they have been found to contain a double dose of acid. Considering it therefore as such, we have $\frac{161 + 2 \times 34}{2 \times 34} =$

$\frac{100}{29.7}$, or 29.7 acid, and 70.3 base.

Vol. XXIII.

Super-oxyfulphat of Mercury.—This salt is described by Dr. Thomson as the oxyfulphat, but the proportion of acid given by the analysis of Messrs. Braucamp and Sigueira-Oliva, shews it to be a super-salt. When mercury is boiled with an excess of acid, and the heat continued longer than in the formation of the last salt, some of the excess is decomposed, giving another atom of oxygen to the mercury, while sulphurous acid gas is disengaged. The oxyd, therefore, combines with an excess of oxygen, and then this oxyd combines with an excess of acid, which constitutes the super-oxyfulphat. This salt is sparingly soluble in water, and affords small crystals of the shape of prisms.

According to the chemists above-named, it is composed of 31.8 acid, and 63.8 peroxyd, and 4.4 water. According to hypothesis it will consist as follows: $\frac{168 + 68}{78} =$

$\frac{100}{28.0}$, which gives 28.0 acid, and 71.1 peroxyd.

Oxyfulphat of Mercury.—The salt which has been called *Turbith mineral*, has been supposed to be a sub-oxyfulphat of mercury. If, however, we can depend upon the analysis of Braucamp and Sigueira-Oliva, we can only consider it an oxyfulphat. It is in the state of a yellow powder, and was formerly much used in medicine. It has, however, been laid aside on account of its extreme severity of operation. According to the above chemists it is composed of 15 acid, 84.7 peroxyd, and 0.3 water. If we consider it

as a sulphat, we shall have $\frac{168 + 34}{34} = \frac{100}{16.8}$, which

gives 16.8 acid, and 83.2 of the peroxyd. If such a salt exists as the sub-oxyfulphat, it will be found to consist

of 9.2 acid, and 90.8 peroxyd; for $\frac{168 \times 2 + 34}{34} =$

$\frac{100}{9.2}$. It does not appear likely that such a mistake could

be made in an analysis. The difference between the sub and the neutral salt is nearly six per cent of acid. It may, therefore, with some confidence be concluded, that *Turbith mineral* is the oxyfulphat of mercury, and not a sub-salt, as has been supposed.

Nitrat of Mercury.—When nitric acid of a mean strength is poured upon mercury, a brisk effervescence ensues, induced by the disengagement of nitrous gas. When the acid is much diluted, and the mixture kept cool by placing the vessel in a large mass of cold water, the solution goes on very slowly. By this means every atom of mercury decomposes an atom of nitric acid, taking an atom of oxygen, by which an atom of nitrous gas is evolved. The atom of oxyd so found unites with two atoms more of nitric acid, forming the salt in question. It will be proper to observe here, that there is a seeming anomaly as well in this as in most of the soluble nitrats, and in a great number of carbonats. Although we call them indiscriminately nitrats and carbonats, they are, strictly speaking, super-nitrats and super-carbonats. We may almost generally conclude, that those salts which have been called nitrats are super-nitrats; while those which have been denominated sub-nitrats will prove, on analysis, to be nitrats simply. We cannot, however, at present make this distinction without some further experiments.

When the above solution is carried to a certain extent, or the dilute solution evaporated, the salt very easily affords

T t crystals,

MERCURY.

crystals, which are in the form of four-sided pyramids, base to base.

When sulphuretted hydrogen is passed through a solution of nitrat of mercury, the hydrogen combines with the oxygen of the mercury, forming water, while the sulphur combines with the mercury, and falls down in the form of sulphuret.

A solution of muriat of tin added to this salt precipitates the mercury by combining with its oxygen. The crystals of nitrat of mercury detonate upon burning coals, and explode with phosphorus by the blow of a hammer. No analysis of this salt has been given by chemists, but from the weight of its constituent atoms it will be as follows:

$\frac{147 + 7 + 2 \times 19}{2 \times 19} = \frac{100}{19.3}$; which gives 19.3 of acid, and 80.7 of the protoxyd.

Oxynitrat of Mercury.—When mercury is dissolved in nitric acid with the assistance of heat, an atom of mercury decomposes two atoms of the acid, while two other atoms of acid unite with the oxyd so formed, constituting what is called the oxynitrat, but which is in fact a super-oxynitrat. If this action goes on with a little water the salt soon forms into a yellow crystalline mass, which shews a marked difference in the character of the two salts, arising from the base of this salt having a larger proportion of oxygen. If water be added in considerable quantity to the solution of this salt, a portion of it loses one atom of acid, and is converted into a yellowish powder, which falls to the bottom of the vessel. This has been improperly called a sub-oxynitrat. From the analysis it appears to be a nitrat.

On passing sulphuretted hydrogen gas through a solution of the oxynitrat, it becomes reduced to the nitrat, and is said, by Zaboada, to combine with sulphur. It is more likely, however, that the sulphur would be converted into sulphuric acid, and that the precipitate is a sulphat of mercury. When muriat of tin is added to a solution of this salt, instead of reducing it to the metallic form, which is the case with the nitrat, it reduces it merely to the state of the protoxyd, which combines with the muriatic acid to form muriat of mercury. Its components will be known from

the following analogy: $\frac{161 + 38}{38} = \frac{100}{19.1}$, which gives 19.1 of acid, and 80.9 of the second oxyd.

The salt which has been called sub-oxynitrat, but which from its analysis must be the oxynitrat, was formerly called *nitrous turbid*, from its resemblance to the sulphat. It has been analysed by Messrs. Braumcamp and Sigueira-Oliva, who make it to consist of 12 acid, and 88 second oxyd.

By treating this salt, as the oxynitrat simply, we shall see that the proportions by hypothesis agree nearly with the above analysis: for $\frac{161 + 19}{19} = \frac{100}{10.5}$, or 10.5 acid, and 89.5 of the second oxyd.

Besides the oxynitrat already described, which contains the second oxyd, a salt may be formed with the third oxyd, so that we have three salts formed with the three oxyds; namely, the nitrat, the oxynitrat, and, for the sake of distinction, the last might be called the hyper-oxynitrat. This last salt cannot be formed by boiling the nitric acid with mercury, but by directly dissolving the third oxyd in nitric acid. Muriat of soda causes no precipitation from a solution of this salt, since the oxyd is at a maximum of oxydation, and is all employed in forming the super-oxymuriat.

Muriat of Mercury.—Muriatic acid has no action upon mercury, but readily combines with its oxyds, forming with the first a muriat of mercury, and with the third or peroxyd an oxymuriat, or rather, as we shall shew, a super-oxymuriat. The old method of making the muriat was by triturating four parts of the oxymuriat with three parts of metallic mercury, till the latter totally disappeared. By this process the peroxyd in the oxymuriat gives up as much oxygen to the metal as makes the whole into the protoxyd, which, with the excess of acid in the oxymuriat, forms the whole into a simple muriat. The mass so produced is put into a matras capable of holding about four times the quantity of matter which is put into it. This being set in a sand bath, and the heat raised, the muriat of mercury sublimes into the upper part of the matras. The vessel is now broken, and the sublimed matter carefully selected. This, however, is frequently mixed with a little of the oxymuriat, which is to be separated by repeated sublimations, or by washing in water, the oxymuriat being soluble while the muriat is not so. It would appear that this method was invented long before the component parts of the salts were known. The metallic mercury added to the oxymuriat is much too little. If we consider the oxyd in the muriat as being the protoxyd, the metal ought to be to the oxymuriat as 294 to 212. If the running mercury were less there would be an excess of oxymuriat. This experiment is very important in shewing that the oxyd of mercury in the muriat is the protoxyd. If it were the second oxyd, 212 parts of the oxymuriat ought only to take up 73.5 of running mercury. The above process, however, shews that 212 of the oxymuriat takes up 159 of mercury, and still some of the oxy salt is found in excess after sublimation. Although in this process 212 parts of the oxymuriat, by trituration with 294 of mercury, would form 462 of the protoxyd; the acid in the oxymuriat will not be sufficient to form the whole into a muriat. The acid in 212 parts of the oxymuriat is 44, which will combine with 308 of the protoxyd, to form 352 of the muriat. This quantity ought to be sublimed, leaving behind 154 of the protoxyd. If, instead of employing 212 of the oxymuriat to 294 of mercury, we make their proportions as 212 to 192, we should get 352 parts of the muriat, as before; but the residuum will consist of 52 parts of the peroxyd. The Edinburgh form for calomel, or muriat of mercury, is four parts of corrosive sublimate (oxymuriat of mercury) to 3.5 of running mercury.

In the above proportions of 212 to 192, in which the residuum is 52 of peroxyd, the proportions reduced to their lowest terms, are 4 to 3.6; for $\frac{212}{192} = \frac{4}{3.6}$. If, however, this process were carried on with the greatest economy, 212 parts of the oxymuriat should be triturated with 294 of mercury, and 22 of real muriatic acid. The whole of the matter will, in this case, be sublimed in the state of muriat, which will be 528 parts, while in the common way only 352 of this salt is obtained.

Muriat of mercury may be formed in the humid way with much more convenience, and probably cheaper. This process was first proposed by Scheele. He dissolved the mercury in nitric acid, with heat, and then added to the solution a solution of muriat of soda. A precipitate was formed, which, when well washed with hot water, was the muriat of mercury, which has been called by the names of *calomel* and *mercurius dulcis*.

This process has been much improved by dissolving the mercury in a dilute nitric acid, without heat. In Scheele's process

MERCURY.

process the mercury was converted into the second oxyd, which, when the muriat of soda was added, about three-fourths of the muriat were formed, and one-fourth of oxymuriat of mercury. By dissolving the mercury slowly, nothing but the protoxyd is formed, and not the least proportion of oxymuriat will be left in the solution, after the muriat is precipitated.

The oxyd of mercury in the muriat, as we have before shewn, is the protoxyd, that of oxymuriat being the peroxyd; but the oxyd of the oxynitrat is, in all probability, the second oxyd. It will appear, therefore, from theory, and experience confirms it, that one part of the second oxyd in the nitrat gives up an atom of oxygen to the other part, and thus dividing the resulting salts into muriat and oxymuriat, the former being precipitated, while the latter remains dissolved in the liquid. This idea is strongly confirmed by experiment. If lime-water be added to the oxynitrat a yellow oxyd is precipitated, which is the second oxyd. If lime-water be added to the muriat precipitated from the oxynitrat, the black or first oxyd is obtained; but if the same be added to the liquor from whence the muriat has been precipitated, the red or third oxyd will fall down. If the mercury be dissolved in dilute nitric acid in the cold, the simple nitrat will always be formed, in which the oxyd is a protoxyd. The whole of this oxyd will combine with the muriat, when the muriat of soda is added to form the muriat of mercury. This is by far the most simple and safe process for making calomel. If the mercury be dissolved with heat, the oxyd of the nitrat will be the second oxyd, which constitutes the oxynitrat. When muriat of soda is added to this, one-half of the mercury combines with an extra atom of oxygen, at the same time the other loses an atom, reducing one-half to the protoxyd, and the other to the peroxyd; the former combines with the muriatic acid to form muriat of mercury, the other combines with another portion of acid to form the oxymuriat. This latter salt is then divided into a super and a salt, the former remaining in solution, the latter falling down with the muriat. Hence it will appear, that when the oxynitrat is used, we do not obtain a pure muriat. An improved method of subliming calomel has been invented, which may be considered a valuable discovery. Instead of subliming it into a cake, as in the old way, it is sublimed into water. By this means the salt is completely freed from any soluble matter. The muriat of mercury, when pure, is in the state of white powder. It is nearly insoluble in water, requiring 1152 parts of boiling water to dissolve 1 of this salt. By exposure to the air it becomes of a deeper colour. It sublimes at a heat less than that required to sublime the oxymuriat. Hence it happens, that the latter salt is always attached to the under side of the sublimed cake of the former, when the two salts are sublimed together. This affords the means of their separation, by detaching the oxymuriat and subliming again. When the muriat is mixed with water, and oxymuriatic gas passes through it, it is converted into oxymuriat of mercury. Nitric acid dissolves it with the disengagement of nitrous gas. The result becomes a mixture of oxymuriat and oxynitrat. The last fact furnishes an easy method of analysing the salt, and has been taken advantage of by Chenevix and Zaboada. When it is dissolved in nitric acid, nitrat of silver precipitates the muriatic acid. The former chemist by this means found 100 parts of the salt or calomel to consist of 11.5 parts of muriatic acid, and 88.5 protoxyd, or 79 of mercury, and 9.5 of oxygen. The latter chemist, from 100 grains of the salt, obtained 10.6 of acid; he then precipitated the mercury with muriat of tin, which amounted to 85 grains: the rest was oxygen, which was 5 per cent., very nearly agreeing with

that above given, which was 4.5 per cent. By the latter, therefore, we have 105 muriatic acid, and 89.5 of protoxyd of mercury. By hypothesis $\frac{147 + 7 + 22}{22} = \frac{100}{12.5}$. This gives 12.5 muriatic acid, and 87.5 of protoxyd.

Calomel nine times sublimed forms what some have called the "Mercurial Panacea."

Oxymuriat of Mercury—This salt is generally known by the name of *corrosive sublimate*. It has long been known for its dreadful effects on the animal system when taken on the stomach in too large a quantity, and as a medicine in moderate doses. It was understood by the alchemists, and has been tolerably well described by Albertus Magnus.

A great variety of processes has been invented for preparing it, most of which are complicated and uncertain. We shall, therefore, give the direct method only, which is simple and economical.

We have seen in the formation of the muriat of mercury, by triturating it with running mercury, that if the oxymuriat had not an extra dose of acid, as well as an extra dose of oxygen, the proportion of acid in the oxymuriat ought to be less than that in the muriat, because no addition of acid is employed with the running mercury. We must consider the salt in question, therefore, not as the oxymuriat of mercury, but the super-oxymuriat. It was some time ago assumed by Gay Lussac, as a principle, that in all salts in which the bases combined with an extra dose of oxygen, the acid was increased in a proportionate degree. The present salt and some others seem to countenance such an opinion, but the principle is far from being general. We have many instances of super-salts without an increase of oxygen in the base. There are also oxy-salts without an increase of acid. In the oxy-sulphats of mercury above treated, one of them has merely an excess of oxygen in the base of the salt. The other has both an excess of oxygen and an excess of acid, the first being a sulphat, and the second a super-oxy-sulphat. The oxy-sulphat of iron has no extra dose of acid; since the nitric acid alone, when too great a heat is not applied, is sufficient to convert the green sulphat into the red or oxy-sulphat. This salt, however, is frequently resolved into two distinct salts, *viz.* the super-oxy-sulphat and a sub-salt, a proof that an excess of base is as common to the oxy-salts as an excess of acid. The oxymuriat of mercury may be prepared by directly adding muriatic acid to the red or peroxyd of mercury. The solution affords crystals by evaporation. It may also be formed by passing oxymuriatic gas through a solution of the nitrat of mercury, or through a mixture of water with any of the oxyds of mercury, and then evaporating the solution to obtain the salt in crystals. In making the muriat by adding muriat of soda to the solution of oxynitrat of mercury, it has been shewn that the second oxyd is divided into the protoxyd and the peroxyd, the former combining with one atom of acid, forming the muriat, which falls down; the other portion combining with two atoms of acid, forming the salt in question, and remaining dissolved in the liquid. It would appear that this latter salt could not be formed if an excess of muriatic acid were not present, in order to give to the oxymuriat its double dose of acid. The solution of mercury in the nitric acid has generally an excess of acid, which disengages muriatic acid from the muriat of soda, to make up for this demand. It would be worth while to make the experiment with a saturated solution of nitrat of mercury, and with a neutral solution of muriat of soda. Would an oxymuriat of mercury, strictly speaking, be formed? Or would this salt be resolved into a sub-oxymuriat of mercury, and a super-oxymuriat? Experiment must decide.

MERCURY.

side this point. The oxymuriat of mercury has generally been employed in medicine and the arts in the state after sublimation. It is then a white semitransparent mass in needle-formed prismatic crystals. Its aggregation is very great, on which account it is scarcely soluble in cold water. If, however, it be rubbed in a mortar with boiling water, it dissolves nearly $\frac{1}{3}$ d of its weight. When cold, however, it does not retain more than $\frac{1}{7}$ th. The oxymuriat, therefore, made by sublimation, should not be attempted to be dissolved in cold water, because of its great aggregation.

When this salt is formed by evaporation, or when its crystals are formed in the humid way, it is more to be depended upon. These crystals will immediately dissolve in three or four parts of boiling water, and in about 20 of cold water. The form of the humid crystals is that of quadrangular prisms, rather rhomboidal. An analysis of this salt has been made by Chenevix, by Zaboada, and by Messrs. Braumcamp and Sigueira Oliva. The first makes it

18	Muriatic acid
82	Peroxyd, <i>i. e.</i> 69.7 mercury, and
—	12.3 oxygen.
100	

The second	19.5	Acid
	80.5	Peroxyd
	—	
	100	

The latter	18.8	Acid
	81.2	Peroxyd
	—	
	100	

We shall see from the following calculation, that this salt is super-oxymuriat of mercury; the acid 2×22 , the oxygen 3×7 , and the mercury 147; $\frac{147 + 21 + 44}{44} = \frac{100}{20.7}$, which gives 20.7 acid, and 79.3 of peroxyd.

The neutral oxysulphat would be $\frac{147 + 21 + 22}{22} = \frac{100}{11.6}$, or 11.6 acid, and 88.4 of peroxyd; so that the near agreement in the above analysis, and their great difference from this last state, leave no doubt of the salt in question being a super-salt.

It is frequently a matter of much importance to be able to detect the presence of this salt, particularly when it has been administered as a poison. The life of an individual sometimes depends upon the result of a chemical test, many of which are very ambiguous. How very necessary, therefore, it is to be able to detect the presence of very small portions of this substance by some method which will be so simple and certain as to be used by any individual. We shall here give the common methods which have been recommended by different chemists.

If the fluid containing the corrosive sublimate be colourless and clear, such as water, sulphuretted hydrogen gas passed through the fluid will change it to first a yellow colour, which gets deeper, and if the quantity of sublimate be considerable, it will become black. This gas may be obtained as follows. Heat a bar of iron to a bright red, and rub the

heated part with a roll of sulphur. A sulphuret of iron will be formed, which will fall off in drops. Let this substance be put into a common phial, to which a cork must be fitted, through which is passed a bended glass tube. Then to one part of the sulphuret of iron add one of sulphuric acid, and five of water. Insert the cork with its tube as quick as possible, and let the gas which escapes pass through the fluid supposed to contain the sublimate, which, if that substance be present, will change colour in a few minutes. It must be observed, that the same gas would give a yellow colour if the fluid contained arsenic. The latter, however, is more of a golden yellow, and remains permanent, while the former changes to a dark brown. Pure potash or lime water is an excellent test for the oxymuriat of mercury. When solutions of the above substances are dropped into a fluid containing the smallest portion of corrosive sublimate, the potash produces a bright orange coloured precipitate, which is the peroxyd of mercury. The lime water produces a similar precipitate, but rather more inclining to a brick-red colour.

A very sensible test for corrosive sublimate was some time ago proposed by Dr. Bostock of Liverpool, which was the muriat of tin. When a few drops of a solution of tin in muriatic acid are added to any fluid containing the smallest portion of oxymuriat of mercury, a very conspicuous milky whiteness instantly appears. This is occasioned by the oxyd of tin seizing the excess of oxygen in the oxymuriat of mercury, by which a quantity of the oxyd of tin, or rather, perhaps, the submuriat, is instantly set free, and at the same time the oxymuriat of mercury is converted into muriat, which is also precipitated. Hence this very conspicuous phenomenon arises from the joint precipitation of the above substances. Sensible as this may be, it is not to be relied upon, except in the hands of very accurate observers. When muriat of tin is dropped in water, it becomes milky by the precipitation of the submuriat of tin, even where no corrosive sublimate is present. Hence, if more water be present with the suspected matter, than will be calculated to keep the tin suspended, the result will be ambiguous and uncertain.

From what has been said of the properties of this salt, it will appear that any substance will form a test of salt which will either precipitate the oxyd, or deprive it of some of its oxygen. In the first case the high coloured red oxyd becomes very conspicuous: in the second, the oxymuriat of mercury is reduced to the state of muriat, which renders the fluid turbid and milky, from the insolubility of the latter substance.

The most satisfactory appearance of the presence of corrosive sublimate would be the mercury itself, since this salt is the only soluble muriat to be purchased in the shops. If the mercury be made to appear in its metallic state, it may almost be deemed impossible for it to have originated from any other substance than the oxymuriat of mercury. Fortunately we have it in our power to recommend a method to the public which will answer this purpose completely. It is so simple as to be practised by any person unacquainted with chemistry, and it is so sensible, at the same time, that it is impossible to say how minute a quantity of mercury can be detached.

It is founded upon the principle by which the precipitation of one metal by another, under the influence of electricity, takes place. In order to make the apparatus as simple as possible, we shall use, in lieu of a piece of gold wire, a common wedding ring, and when a piece of zinc wire cannot be had, a piece of iron wire will do very well. Let the zinc or iron wire be bent into the shape of a parallelogram about two inches long, and about the width of the gold ring. Let this consist of three sides, two long sides and one short side,

MERCURY.

side, that it may have the appearance of a fork or a flaple. Tye the ends of the wire to the ring with a bit of thread, so that the same may be opposite to each other, separated by the diameter of the ring. When this is done, the ring and the wire, when laid upon a flat surface, will touch the surface in two places; the ring in one place, and the short side of the parallelogram in another, the touching points being about two inches distant: then take a flat piece of window glass, or a small looking glass, and lay it in a horizontal position, so that any liquid dropped upon it may not run to any side. This being done, prepare a small quantity of dilute sulphuric or muriatic acid, about four of water to one of acid, and also get some of the liquid supposed to contain the corrosive sublimate. Let the dilute acid be dropped upon the plate, till it spreads to the breadth of about one inch and a half. Then, at about half an inch distance from it, let the suspected liquid be dropped, till the peripheries of the two circles join. After this, let the apparatus above described be so laid, that the iron wire may touch the dilute acid, and the gold ring the other liquid. If the latter contain corrosive sublimate, the ring will become covered with mercury on the part which touches the liquid. This appearance will be sooner in taking place, as the quantity of corrosive sublimate is greater. When the liquid contains two parts of this substance, the mercury will be very perceptible upon the ring in five minutes from the time of the connection being made.

Mr. Chenevix, in ascertaining that corrosive sublimate was not oxymuriat of mercury, but merely muriat of mercury highly oxydated, has discovered a salt which is truly the oxymuriat of this metal. By passing a current of oxymuriatic gas through water, in which there was some red oxyd of mercury, after a time the red oxyd became of a very dark brown colour, and part of it was dissolved. The liquor was then evaporated nearly to dryness, and a mixed salt was obtained, consisting partly of corrosive muriat, and partly of another salt which crystallized later than the former, and on being redissolved and crystallized appeared nearly pure. This salt, which has not been much examined, possesses the essential quality of an oxymuriat, in giving out vapours of oxymuriatic acid by the effusion of the sulphuric or any stronger acid.

Phosphat of Mercury.—Phosphoric acid does not act upon mercury, because of the great affinity of phosphorus for oxygen. This acid, however, combines with the oxyds of mercury, forming phosphat of mercury. The best method of forming this salt is by adding phosphat of soda in solution to nitrat of mercury: the phosphoric acid leaves the soda to combine with the oxyd of mercury; the compound falling down in the state of white powder. It should be observed, that if the phosphat of soda is not made from the acid which is obtained by burning phosphorus, the result will not be correct; since the acid obtained from bones is a super-phosphat of lime: and Mr. Dalton has lately found, that the substance at present used in medicine as phosphat of soda, is a triple salt, being a phosphat of soda and lime.

Phosphat of mercury becomes phosphorescent when rubbed in the dark. Like the phosphat of lead, it affords phosphorus by distillation with charcoal. It is said to answer as a substitute for some other mercurials in medicine. It appears from its analysis to be a super-oxyphosphat: this, however, does not appear plausible, from the manner of preparing it. If the nitrat of mercury be fully saturated with acid, the mercury cannot unite with more acid than will form a simple phosphat, except the phosphat of soda be a super-salt, or that the phosphat of mercury on its formation, be resolved into sub and super-salts; both of which

fall down together. If the solution of mercury employed in the preparation of the salt does not contain the second oxyd, the salt cannot be an oxy-salt, nor can any portion of it become so, but at the expence of two salts being formed; the one consisting of the acid united to the protoxyd, as in the case of forming the muriat; and the other consisting of the acid united with the peroxyd, forming an oxy-salt. There is at present so much ambiguity in the facts given of this salt, that we cannot be warranted at present in proposing any thing conclusive. The neutral phosphat with the protoxyd, if such a salt exist, will be as follows:

$$\frac{147 + 7 + 23}{23} = \frac{100}{13}, \text{ or } 13 \text{ acid, and } 87 \text{ base. The}$$

$$\text{oxyphosphat will be } \frac{147 + 21 + 23}{23} = \frac{100}{12}, \text{ or } 12 \text{ acid}$$

$$\text{and } 88 \text{ base. The super-oxyphosphat is } \frac{147 + 21 + 46}{46}$$

$$= \frac{100}{21.5}, \text{ or } 21.5 \text{ acid, and } 78.5 \text{ base. According to the}$$

analysis of Braumcamp and Sigueira, it consists of 28.5 acid, and 71.5 of the peroxyd. The sub-oxyphosphat of mercury, which in all probability may exist, will consist as

$$\text{follows: } \frac{(147 + 21) \cdot 2 + 23}{23} = \frac{100}{6.1}, \text{ or } 6.1 \text{ of acid, and}$$

3.9 of peroxyd.

Fluat of Mercury.—Fluoric acid has no action upon mercury. When an alkaline fluat is added to a solution of nitrat of mercury, an insoluble powder falls down, which is the fluat of mercury. Nothing more is known of this salt.

Borat of Mercury.—This salt may, like the last, be formed by adding borat of soda to nitrat of mercury, the boracic acid having no action upon the metal. It falls down in the form of insoluble powder, like the last salt.

Carbonat of Mercury.—Carbonic acid does not act upon mercury. This salt is formed by adding carbonat of potash to nitrat of mercury. The salt is precipitated in the state of powder of a white colour, and is known in medicine by the name white precipitate of mercury. According to the analysis of Bergman, it consists of 90.9 mercury, and 9.1 of

$$\text{oxygen and carbonic acid. By hypothesis it is } \frac{147 + 14 + 19}{19}$$

$$= \frac{100}{11}, \text{ or } 11 \text{ of acid, and } 89 \text{ of the second oxyd. When}$$

this salt is exposed to heat, the carbonic acid flies off, and leaves the yellow oxyd.

The precipitate formed by adding the carbonat of potash to oxynitrat of mercury is seldom a true carbonat. At the moment it is precipitated, it appears of a beautiful white; but upon shaking the mixture some carbonic acid escapes, and the precipitate assumes a yellowish hue. It is therefore certain, that the precipitate becomes ultimately a sub-carbonat. If it were to remain a carbonat, no carbonic acid ought to escape. The proportions under these circum-

$$\text{stances are } \frac{2 \cdot (147 + 14) + 19}{19} = \frac{100}{5.5}, \text{ or } 5.5 \text{ of car-}$$

bonic acid, and 94.5 of the yellow oxyd. The oxygen in this salt is 4.1 per cent. This, added to the acid, gives 9.6 of oxygen and acid together, which very nearly agrees with the analysis of Bergman above given. Hence it will appear that this was the salt which he analysed, and not the carbonat.

MERCURY.

nat. The sub-carbonat obtained from the nitrat, which gives the protoxyd, is perfectly white.

Acetat of Mercury.—The acetic acid does not act upon mercury; but it dissolves its oxyds, forming several species of salts. When a solution of the acetat of potash is added to a solution of the nitrat of mercury, the acetic acid combines with the protoxyd, and is precipitated in the form of flat scaly crystals, resembling boracic acid, which is the true acetat of mercury. If the oxynitrat be employed which contains the second oxyd, in all probability a change takes place similar to that in the formation of the muriat, by adding muriat of soda. The oxyd is equally divided into the prot and peroxyd, by which an acetat, with some sub-oxyacetat, is formed, while a super-oxyacetat will remain dissolved. This salt is insoluble in alcohol, and nearly so in water.

Oxyacetat.—This salt may be formed by dissolving the peroxyd in the acetic acid. When evaporated it does not crystallize, but forms a yellow coloured mass, which is deliquescent. When water is added to it, the salt is changed into a sub-oxyacetat, which precipitates in the state of a yellow powder, and a super-oxyacetat, which remains dissolved. When the oxyacetat is heated, the acetic acid deprives the mercury of some oxygen, and crystals of the acetat are formed.

Oxalat of Mercury.—Oxalic acid, as well as the other vegetable acids, has no action upon mercury. It combines with the oxyd of mercury, forming an oxalat which is nearly insoluble in water. This salt turns black by the action of light; and, according to the authority of Klaproth, it detonates when heated. Dr. Thomson thinks this salt a constituent of the fulminating mercury of Howard.

Tartrat of Mercury.—If tartrat of potash be added to a solution of nitrat of mercury, the tartrat of mercury will be precipitated in the state of white powder. It is changed to a yellow colour by exposure to light.

Citrat of Mercury.—This salt is scarcely soluble in water. It is decomposed by distillation; the oxyd being reduced by the carbon and hydrogen of the acid.

The *Succinat of Mercury* is slightly soluble.

The *Benzoat of Mercury* is insoluble in water: it sublimes by heat, and is decomposed by the sulphuric, nitric, and muriatic acids.

The *Malat* of this metal is an insoluble powder.

Prussiat of Mercury.—This salt may be formed by boiling the red oxyd of mercury with Prussian blue in water. It is soluble in water to a certain extent, and the solution affords crystals of a prismatic form. It is generally employed to get pure prussic acid, by distillation with sulphuric acid.

Arseniat of Mercury.—When arsenic acid and mercury are heated together in a retort, the mercury is oxydized, and oxyd of arsenic is volatilized, leaving the arseniat of mercury. This salt may also be formed by adding the arseniat of potash to nitrat of mercury in solution. The arseniat of mercury is precipitated in the form of yellow powder.

Molybdat of Mercury, with the protoxyd, is insoluble, but soluble with the peroxyd, which forms an oxymolybdat.

Chromat of Mercury is formed by an alkaline chromat with nitrat of mercury. It falls down in the state of powder of a purple colour. Several triple salts of mercury have been noticed by chemists.

Nitro-oxymercuriat of Mercury has been pointed out by Berthollet. It is formed by adding a solution of muriat of soda to oxynitrat of mercury. A salt is obtained by evaporation in rhomboidal crystals. May not this salt be merely a mixture of muriat of soda and super-oxymercuriat of mercury

crystallized together on account of the simularity of their form?

Oxymercuriat of Soda and Mercury.—This is no doubt the super-oxymercuriat of mercury crystallized with muriat of soda, since it is formed by adding four parts of super-oxymercuriat of mercury to one of muriat of soda.

Sub-oxymercuriat of Mercury and Ammonia.—When ammonia is poured upon the super-oxymercuriat of mercury, the ammonia takes up as much of the acid as leaves the remainder in a state of sub-salt. The two salts fall down together in the state of white powder. The analysis of Fourcroy shews it to consist of certain proportions of the two salts; which is 16 acid, 81 oxyd, and 3 of ammonia. This gives 14 of muriat of ammonia, and 86 of the sub-oxymercuriat of mercury.

This compound salt is soluble in muriatic acid. In this state it has been called *sal alembroth*. In modern nomenclature, it has been denominated the *ammoniaco-mercurial muriat*.

Tartrat of Potash and Mercury.—This salt is formed by boiling the oxyd of mercury with super-tartrat of potash. The oxyd of mercury takes the excess of acid from the super-tartrat to form a tartrat. By evaporation the two crystallize together.

Mercury combines with the sulphuret and super-sulphuret of hydrogen, forming black insoluble precipitates. The first is called hydro-sulphuret, and the second a hydrogurretted sulphuret.

Mercury is very valuable in the arts on account of some of its physical properties, principally for constructing barometers and thermometers.

For the first of these uses the mercury should be perfectly free from air, which it mechanically contains in common with other liquids, and which leaves it when the pressure of the atmosphere is removed. If, therefore, a barometer be made with mercury not freed from air, the column constituting the barometer will be depressed by the spring of the air which rises into the upper part of the tube.

In order to purify mercury for the use of barometers and thermometers, it should first be distilled in a retort of iron or Wedgewood ware. After this, however, it does not acquire its greatest degree of fluidity, nor does it appear perfectly bright. This is principally owing to its being mechanically mixed with some oxyd of mercury. This is completely removed by digesting it a little time with very dilute nitric acid. It becomes very brilliant and fluid. It must now be well washed with water, and the water dried up clean. After this it must be boiled in the tube it is intended to fill. If, while the tube is hot, it be placed, with the open end upwards, under the receiver of an air-pump, and is shaken frequently, a still greater quantity of air is set free, and the mercurial column will stand higher in consequence. We can have little dependence upon the absolute height of the barometer, where this precaution is not taken. See BAROMETER and THERMOMETER.

Mercury is extensively used in gilding, but has been productive of great mischief to the workmen, from their inhaling the vapour which must of necessity be formed.

We have already given some account of this process, sufficient to shew, that if the mercury, when it evaporates, could be forced into some channel, without coming near to the workman, and without mixing with the smoke of the chimney, its deleterious effects would not only be avoided, but the greatest part of the mercury would be saved, which would be of very great importance to the proprietors of such manufactures as employ gilding on a large scale.

We have long been in possession of the means of remedying

ing this evil, at an expence which would speedily be reimbursed by the saving of the mercury alone.

The furnace to produce the heat should be a common air-furnace, but so constructed as to contain a vessel of the nature, though not of the shape, of a muffle. Its form would be determined by the size and figure of the articles to be gilt. It should have such an opening in front, and be so spacious within, as just to allow the workman to turn the articles freely about during their exposure to evaporate the mercury. The upper part of the muffle should have a chimney connected with it of earthenware, of the same kind as that of the muffle. This chimney must pass some distance up the main chimney, in order to be heated for the purpose of rarefying the enclosed air, to cause a rapid current. The earthen chimney, being carried about a yard high, should now branch out of the main chimney, and be continued with an iron pipe to the height of about twenty feet. This iron pipe should communicate with the earthen tube, by a perpendicular branch from it, within about six feet of the bottom of the former, so that one part of the iron pipe ascends to the height of twenty feet, and the other descends about six feet into a cistern of water. By this means a current of air will constantly be entering the mouth of the muffle, which must of necessity carry with it the vapour of mercury, unmix'd with any other extraneous matter. The mercurial vapour will be condensed long before it reaches the top of the iron tube, and will fall into the cistern of water below. The water will prevent the oxydation of the mercury between the times of removing it.

Another advantage attending this apparatus, will be the uniform heat to which the evaporable surface will be exposed. The greatest heat of the fire will be much less in this contrivance, and consequently less annoying to the face and eyes of the workman. This evil, however, may be still made less, by interposing a screen of glass between the face and the fire.

MERCURY, or *Hydrargyrum*, in the *Materia Medica*. This fluid, supposed by the Greeks to be poisonous and corrosive, was introduced into medicine, by the Arabians, as an ingredient in external applications, against different cutaneous maladies. The practice was followed by some physicians in Europe towards the end of the thirteenth century; but was not established or looked upon in general to be safe, till about the beginning of the sixteenth, when the venereal distemper, then lately received from America, was found to yield to mercurial applications alone: and now also the internal use of mercury began to be ventured on, in this and in other diseases. Crude and fluid mercury taken internally produces no effect on the body; because the adhesion of its integrant parts to each other hinders their division and distribution, or solution, without which it cannot have any effect. In its crude state, therefore, it does nothing but load the stomach and intestines. It falls downwards by its weight, and goes out of the body with the feces, in the same state in which it entered. Hence some have been induced to give a pound or more in violent constipations, in order to open obstructions that had resisted the common methods of cure by purgatives, relaxants, and emollients. But the practice has been attended with no remarkable success.

Dr. Dover, in his "Physician's Legacy to his Country," having recommended crude mercury or quicksilver as a most beneficial medicine for several diseases, it had for some time a great run in London, which occasioned the writing a great many pamphlets for and against it. Dr. Cheyne also greatly recommends this medicine in his treatise, entitled "The Rational Method of curing Diseases."

The authors of the Medical Essays of Edinburgh assure

us, that though some they knew had taken an ounce or two of crude mercury each morning for several weeks, yet they were not apprized of any instance of its increasing any of the sensible evacuations; but they have been told, that some who used it thus, had passed some of it with their urine, and that the hands of others, taking this medicine, had tinged their snuff-boxes, &c.

But we have an account of the effects of crude mercury on a person who had the advice of his physician for the taking it, in a remarkable case, recorded in the Philosophical Transactions, about the time when Dr. Dover had brought it into such general use; and as the effects of it, in this case, may serve to caution people as to the use of it, it may be proper to give the substance of it, which is this: a person had long been subject to great difficulty in going to stool, for which he at length took several ounces of crude mercury at different times, but without relief. Upon the opening of the abdomen there issued out a great quantity of wind, before the stomach or guts were wounded. The stomach was empty, and its inner coat violently inflamed. The small guts were, in many places, fouled with a black powder, resembling æthiops mineral, and in several parts of them were found small globules of quicksilver. The black powder was doubtless the quicksilver altered into a sort of æthiops in the body. The colon was inflamed and distended, and contained six quarts of liquid excrement, among which was a great deal of crude mercury, and of the same black powder. This gut also was inflamed on the outside, and had formed an abscess where it adhered to the omentum; the other guts in contact with this part also shared this disorder. On the lower part of the colon the coats became schirrous, and the passage was very small. Some of the valves were also become schirrous, and obstructed the passage, and a small plum-stone was found buried in the villose coat of this intestine: This had also formed a small abscess, which discharged itself into the pelvis. What part of these symptoms was owing to the taking the quicksilver is easily seen, and such effects may be guarded against for the future, by observing the state of the patient before it is given. Phil. Transf. N^o 442. p. 295.

But when mercury is much divided, so that its molecules cannot again unite and form fluid mercury by the interposition of proper substances, it operates with great power, and extends its action through the whole habit. In these forms, whether taken internally, or introduced into the blood from external applications, it seems to liquefy all the juices of the body, and may be so managed as to promote excretion through all the emunctories. The salutary effects of mercurials have, in many cases, very little dependence on the quantity of sensible evacuation. Venereal maladies and chronical distempers, proceeding from a visciditv of the humours and obstructions of the small vessels, are often successfully cured by mercurials taken in such doses as not to produce any remarkable discharge: especially if assisted by diaphoretics, and a warm diluting regimen. In this view, camphor, and the resin or extract of gualiacum, are frequently joined to the mercury; and to the more active preparations, a little opium; which not only promotes the diaphoresis, but prevents the mercury from irritating the first passages, and running off by the grosser emunctories. Mercurials are always pernicious in the true scurvy, and in constitutions inclined to this disease, whose humours are disposed to a putrescent state; and a long continued use of mercury colliquates the whole mass of blood, and tends to weaken the nerves, so as to bring on tremors and paralyfes. Mercurials are destructive to insects, perhaps of every kind: they are sometimes given internally against worms; and Van
Helmont

MERCURY.

Helmolt says, that water in which mercury has lain some time, though insipid, will destroy worms; and Mr. Boyle seems to recommend it as an innocent and useful cosmetic. Works Abr. vol. iii. p. 345.

Although mercury in its native metallic state is a perfectly inert substance with respect to any operation on the animal system, it may be rendered active by some changes in its chemical state, or some addition to its substance. When rendered thus active, it seems to be a stimulus to every sensible and moving fibre of the body to which it is applied; and it is particularly a stimulus to every excretory of the system, to which it is externally or internally applied. Besides its noted effects upon the excretories of the saliva, it seems to operate upon the whole of those of the alimentary canal. It proves often diuretic; and Dr. Cullen says, that he has met with particular proofs of its reaching and acting upon the organs of perspiration. Whilst it is known to operate more upon certain excretions than upon others, it may be presumed, that when any tolerable quantity is thrown into the body, it is in part distributed over the whole; and therefore its medicinal effect is, that it is the most universal aperient and deobstruent known. Dr. Cullen, however, contends, in opposition to the common opinion, that the effects of its producing evacuations depend entirely upon the stimulus given to the excretories, and not at all to any change produced in the state of the fluids. Upon many occasions of mercury thrown into the body very largely, this author has found no difference in the appearance of the state of the blood drawn out of the veins. From the stimulus given by mercury to the whole system, he has always found the blood putting on the same appearance that it does in inflammatory diseases, nor has he observed any circumstance that implies any diminution of its ordinary consistence. Although it has been the common opinion, that mercury diminishes the consistence of the blood, and very much increases its fluidity, no evidence or proof of this as a fact, known to Dr. Cullen, has been produced; and he thinks, that it has been taken up upon mistaken facts, and supported by a theory which is without foundation. Upon the whole, our author concludes, that the chief effects of mercurial medicines are to be ascribed to their general stimulus of the system, and especially to their stimulating the various excretories of it. Concerning its medical effects in the disease to which it has been most generally and most efficaciously applied, we refer to the article *LUES VENEREA*. But the various operations of mercury are modified, in a very remarkable degree, by the different preparations of it which have been proposed and employed. In consequence of the changes which it undergoes by its numerous preparations, so that it is become one of the most considerable articles in the chemical pharmacy, and a remedy of the most extensive application, it is not only a powerful stimulant, but it enters into the circulation, quickens the vascular action, and excites powerfully the whole of the glandular system, increasing all the secretions and excretions. Hence it happens, that its various preparations produce different effects, operating sometimes as stimulants, astringents, cathartics, or emmenagogues, and locally as errhines; and hence it becomes useful in a great variety of diseases; such as febrile affections, spasms, cachectic diseases, glandular obstructions, and cutaneous eruptions. Since Paracelsus, counteracting ancient authority and practice, evinced that it might be exhibited internally, not only with safety, but with advantage, during a period of almost 300 years, experience has fully sanctioned its use; and as Mr. Pearson justly observes, "not one medicine besides, derived from the animal, vegetable, or mineral kingdom, has maintained its credit, with men actually em-

ployed in extensive practice, during a tenth part of that period." Although it is a medicine capable of being abused, to the disappointment of the patient, and to the injury of the constitution, yet under the direction of cautious and judicious practitioners, it may rank as one of the most useful of the articles of the *Materia Medica*.

The chemical changes which have been proposed, in order to render mercury active and useful, have been many and various; but Dr. Cullen, in his "*Materia Medica*," refers them to four heads; 1st, by being converted into vapour; 2dly, by calcination; 3dly, by triture with viscid fluids; and, 4thly, by being combined with acids of different kinds. The first mode of employing mercury, may perhaps (he says) be the best adapted to some local complaints; but its application to the whole body is attended with so much hazard and uncertainty in the administration, as hardly ever to be an eligible practice. The preparation by calcination is not, as had been formerly supposed, of any peculiar power or advantage; and is therefore as he believes, little employed in the present practice; this operation serving merely to put the mercury in a condition to be acted upon by the acids of the stomach, and the preparation not differing from others made by a combination with acids. The preparations by triture seem to be milder than those formed by a combination with acids; but imperfect triture renders the practitioner often uncertain in their use. The triture with unguinous substances gives the advantage of its being introduced by unctio upon the skin; and when it has been properly prepared, and is properly administered, it affords a mode of introducing mercury, which is often less liable to purging, and therefore more convenient than the employment of the saline preparations. These latter are different according to the acid employed.

Those made by the vegetable acid are milder and more manageable than those formed with any of the fossil acids. Of these, the combination with the muriatic acid, when the acid is in its full proportion to the mercury, as it is in the corrosive sublimate, is certainly more active and powerful than any other saline preparation. The use of it has been often convenient and effectual; but its operation is so different in men of different constitutions, that the employment of it requires much management and discretion. It is rendered much milder in the preparation of the *Mercurius dulcis*, which has given occasion to the frequent employment of this, which, according to Dr. Cullen, does not seem to be a very eligible preparation. It does not seem to be so readily diffusible in the system as many others, because it is more ready than many others to operate upon the intestines, and run off by stool. This may give it some advantages for its being combined with purgatives; but for that reason it is less fit for being employed to act upon the salivary glands, or upon the other excretions of the system. Dr. Duncan, in the "*Edinburgh New Dispensatory*," has given a table of official preparations of mercury, of which Mr. A. T. Todd has availed himself in the valuable "*London Dispensatory*," lately published. We shall take the liberty of inserting his table for the satisfaction of our medical readers, recommending the work itself to their perusal.

Official Preparations of Mercury.

- I. By distillation to purify the metal.
 1. Hydrargyrus purificatus. L. D.
- II. By trituration; (suboxidized).
 - a. With animal fat.
 2. Unguentum Hydrargyri fortius. L. Ung. Hydrargyri. D.
 3. Unguentum Hydrargyri. E.

MERCURY.

4. Unguentum Hydrargyri mitius. L. D.
5. Linimentum Hydrargyri. L.
6. Emplastrum Ammoniaci cum Hydrargyro. L. D.
Hydrargyri. L. E.
- b. With saccharine substances.
7. Pilule Hydrargyri. L. E. D.
- c. With carbonate of lime.
8. Hydrargyrus cum Creta. L. D.
- d. With carbonate of magnesia.
9. Hydrargyrum cum Magnesia. D.
11. By the action of heat and air: (oxidized).
10. Hydrargyri Oxydum rubrum. L. Oxydum Hydrargyri. D.
14. By the action of acids.
- a. With sulphuric acid; (suboxidized).
11. Subsulphas Hydrargyri flavus. E. Oxydum Hydrargyri sulphuricum. D.
- b. With nitric acid; (suboxidized).
12. Unguentum Hydrargyri nitrati. L. E. Unguentum Supernitratis Hydrargyri. D.
13. Unguentum Nitratis Hydrargyri mitius. E.
(oxidized).
14. Hydrargyri Nitrico-oxydum. L. Oxidum Hydrargyri rubrum per Acidum nitricum. E. Oxydum Hydrargyri nitricum. D.
15. Unguentum Hydrargyri nitrico-oxydi. L. Unguentum Oxidi Hydrargyri rubri. E. Unguentum Subnitratis Hydrargyri. D.
- c. With muriatic acid.
† sublimated; (oxidized).
16. Hydrargyri Submurias. L. E. Submurias Hydrargyri sublimatum. D.
17. Pilule Hydrargyri Submuriatis. L.
(oxidized and acidified).
18. Oxymurias Hydrargyri. L. Murias Hydrargyri. E. Murias Hydrargyri corrosivum. D.
19. Liquor Hydrargyri Oxymuriatis. L.
†† precipitated; (oxidized).
20. Submurias Hydrargyri præcipitatus. E. D.
- d. With acetic acid; (suboxidized).
21. Acetis Hydrargyri. E. Acetas Hydrargyri. D.
- V. By precipitation with earths and alkalies from acid solutions.
- a. By lime-water from the nitric solution; (suboxidized).
22. Hydrargyri Oxydum cinereum. L.
- b. By ammonia from the nitric solution; (suboxidized).
23. Oxydum Hydrargyri cinereum. E. Pulvis Hydrargyri cinereus. D.
- c. By ammonia from the muriatic solution; (oxidized).
24. Submurias Hydrargyri ammoniatum. D. Hydrargyrus Præcipitatus albus. L.
25. Unguentum Submuriatis Hydrargyri ammoniati. D. Ung. Hydrargyri Præcipitati albi. L.
- VI. Combined with sulphur.
- a. By trituration.
26. Sulphuretum Hydrargyri nigrum. E. D.
- b. Sublimated.
27. Hydrargyri Sulphuretum rubrum. L. D.

We shall here subjoin a more particular account of these different preparations, as they occur in the London, Edinburgh, and Dublin dispensaries, annexing to the modern names the appellations by which they have been distinguished in former, now superseded, nomenclatures.

Hydrargyrus purificatus. Argentum vivum purificatum, P. L. 1745.

Rub together 6lbs. of mercury, by weight, with 1lb. of iron filings, and distil the mercury from an iron retort, by

the application of heat to it. The E. D. directs four parts of mercury, and one part of filings of iron, to be rubbed together and distilled from an iron retort. The Dub. D. procures it by distilling off slowly 4lbs. from 6lbs. of mercury.

Hydrargyri Actus, acetite of mercury, is prepared, according to the E. D., by mixing 3 oz. of purified mercury with 4 oz. or a little more than may be necessary for dissolving the mercury, of diluted nitrous acid; and having dissolved 3 oz. of acetite of potash in boiling water, by adding to this solution, while hot, the former, and mixing them by agitation. When the mixture has been set aside to crystallize, the crystals are washed in a funnel with cold distilled water, and then dried with a gentle heat.

Hydrargyri Actus, acetate of mercury, is obtained, according to the directions of the Dub. D., by adding three fluid-ounces of diluted nitrous acid to 3 oz. of purified mercury, and digesting, when the effervescence ceases, upon hot sand, for the complete dissolution of the metal; then mixing this solution with eight pints of boiling distilled water in which 3 oz. of acetate of kali have been previously dissolved, and passing the mixture immediately through a double linen cloth: afterwards cooling it that crystals may be formed, washing these with cold distilled water, and drying them upon paper with a very gentle heat.

All the vessels in these two processes must be of glass.

The acetate of mercury is antisyphilitic, and alterative; but it is scarcely ever used, except as an active ingredient in Keyser's pills. In some cutaneous affections a solution of it, in the proportion of two grains in f.ʒii of rose water, is externally applied. The internal dose is 1 gr. night and morning.

Hydrargyri oxymurias, oxymuriate of mercury, *Hydrargyrus muriatus,* P. L. 1787, *Mercurius corrosivus sublimatus,* P. L. 1745, P. L. 1720, is prepared, according to the L. D. 1809, by boiling 2lbs. by weight of purified mercury with 30 oz. by weight of sulphuric acid in a glass vessel until the sulphate of mercury is left dry: then, rubbing this, when cold, with 4lbs. of dried muriate of soda, in an earthenware mortar, and afterwards subliming it in a glass cucurbit, gradually increasing the heat. The corrosive sublimate is denominated *Murias hydrargyri,* or muriate of mercury, in the E. D. and prepared much in the same manner. In the Dub. D. it is denominated *Murias hydrargyri corrosivum.* It is prepared by dissolving 2lbs. of purified mercury in 3lbs. of sulphuric acid, gradually increasing the heat until the matter becomes almost dry; when cold, rub it with 2½lbs. of dried muriate of soda in an earthenware mortar, and then sublime it, in a proper vessel, with a gradually increased heat. Mr. Chenevix found, that if a bit of copper be put into a solution of corrosive sublimate, a white powder usually falls to the bottom, and that powder is "calomel." When washed, it does not contain an atom of copper, nor of corrosive sublimate.

This salt is a powerful stimulant and alterative; and in large doses it is one of the most violent of the metallic poisons. It was formerly much extolled as an antisyphilitic; but Mr. Pearson observes, that even in checking the progress of the secondary symptoms, relieving venereal pains, and healing ulcers of the throat, it never confers permanent benefit.

It is said to be used with greater advantage in old ulcers, chronic rheumatism, and cutaneous diseases, particularly lepra. (See LEPROSY.) The sensible operation of this salt is by urine, but sometimes it occasions the most violent nausea, griping, and purging; in which cases it should be combined with opium; and during the use of it, it is necessary to take some mucilaginous fluid, in order to allay its irritation. It is also

MERCURY.

used as an external application. The dose is from $\frac{1}{8}$ th to $\frac{1}{4}$ th of a grain, twice a day, formed into a pill with a crumb of bread or extract of poppies. Van Swieten brought this salt into more general use for the cure of venereal maladies: he dissolves a grain of the sublimate in 2 oz. of proof spirit, but rectified spirit dissolves it more perfectly, and gives of this solution from one to two spoonfuls twice a day, continuing the medicine so long as any of the symptoms remain, with low diet, and plentiful dilution. There are many instances in the London Med. Obs. and Enq. of the success of this method.

Hydrargyri oxymuriatis Liquor, solution of oxymuriate of mercury, is prepared by dissolving eight grains of oxymuriate of mercury in fifteen fluid-ounces of distilled water, and adding to it a fluid-ounce of rectified spirit. This solution is directed (P. L. 1809) in order to facilitate the administration of divisions of the grain of this active medicine. Each fluid-drachm contains $\frac{1}{7}$ th of a grain of the salt. This may be given as an antisyphilitic in doses of from f.ʒfs to f.ʒij, in f.ʒij of linseed infusion, or water and syrup, and in more minute doses, when its effects as an alterative only are required. As a local application, this solution diluted with two parts of water forms an useful gargle in venereal sore-throat, and without dilution it serves as a gargle for breaking the abscess in cynanche tonsillarum, when suppuration takes place. Diluted with an equal quantity of water, it is employed as a wash against tetter and psoa; and very largely diluted, it may be used as an injection in gonorrhœa, or given in the form of enema, when the stomach will not bear it. This sublimate is a violent escharotic, and eats away proud flesh: half a drachm of it dissolved in a pint of lime-water turns it yellow; it is then called "phagedænic water," and is used to wash ulcerous and tetterous eruptions. A strong solution, made by boiling the same quantity of powdered sublimate with equal its weight of alum in a pint of common water, until half the liquor is wasted, is the "alluminous water" applied to the same purpose.

Hydrargyri submuriatis, submuriate of mercury, Calomelas, *Hydrargyrus muriatus mitis*, P. L. 1787, *Mercurius dulcis sublimatus*, P. L. 1745, *Aquila alba*, *Manna metallorum*, *Sublimatum dulce*, is prepared, according to P. L. 1809, by rubbing together 1lb. of oxymuriate of mercury with 9 oz. by weight of purified mercury, until the metallic globules disappear, then subliming, taking out the sublimed mass, pulverizing it, and subliming it in the same manner twice more successively; and, lastly, bringing it into the state of very fine powder, by the same process which is directed for the preparation of chalk. A very elegant and useful modification of this process has lately been adopted by Mr. Howard, chemist, who sublimes the submuriate into water, with the vapour of which it mixes as it arises in its gaseous form, and subsides at once as a fine impalpable precipitate to the bottom of the water. Formerly preparations of mercury analogous to this were distinguished according to the number of sublimations they had undergone. After three sublimations it was *mercurius dulcis*, after six, *calomelas*, and after eight, *panacea mercurialis*; but, according to Beaumè, a small portion of oxymuriate is formed by each of these repeated sublimations, probably from the absorption of oxygen by the heated preparation from the air of the vessels, and hence no advantage, but rather the contrary, must arise from an increased number of the operations. The Pharmacopœia of 1745 had six sublimations; that of 1787, as the directions seem to express it, five; and now they are reduced to three, which are, in fact, fully sufficient, especially with that subsequent application of water which the mode adopted for reducing it to a fine powder requires.

Hydrargyri submuriatis, five *Calomelas*, Edinb. D. Submuriate of mercury, or calomel; is obtained by rubbing together 4 oz. of muriate of mercury pulverized in a glass mortar with 3 oz. of purified mercury, in a glass mortar with a little water, to prevent the acrid powder from rising, until the mercury be extinguished; putting the dried powder in an oblong phial, one-third full, and subliming it in a sand-bath. When the sublimation is completed the phial is broken, and the red powder round its bottom, and the white at its neck, are rejected; the rest of the mass is sublimed, and reduced to a fine powder, which is, lastly, to be well washed with boiling distilled water.

Hydrargyri, Submuriatis sublimatum, five *Calomelas*, Dub. D. is prepared much in the same manner with that of the Lond. Pharmac. The final trituration and levigation are intended to separate any corrosive muriate that may have been formed; and in order to ascertain this, the Dublin college prescribes the following test; the sublimed matter is pulverized and repeatedly washed with distilled water, until the solution poured off, no longer lets any sediment fall on the addition of a few drops of carbonate of kali.

Calomel is the most useful and the most frequently employed of all the preparations of mercury. It is antisyphilitic, antispasmodic, alterative, deobstruent, purgative, and errhine. As a remedy in syphilis, it can be fully confided in, when its disposition to run off by the bowels is counteracted by opium; and in the same state of combination it is also found efficacious in several convulsive affections, as epilepsy, trismus, and tetanus; and in that species of spasmodic stricture which occurs in virulent gonorrhœa. As an alterative and deobstruent, it is employed with advantage in cutaneous eruptions, as lepra, scabies, and psoa, in which cases it is combined with antimonials and guaiacum; and in hepatitis, and glandular obstructions; in dropsies it assists the action of squill and foxglove; and as a purgative it may be employed with safety in almost every form of disease not attended with visceral inflammation, or where there are not great irritability and delicacy of habit. Calomel, however, does not act with certainty as a purgative even in large doses, and hence it is generally combined with scammony, jalap, or some other active cathartic. The usual dose to affect the habit and produce ptyalism is from gr. j to grs. ij, in a pill with opium, given night and morning; and from grs. iij to grs. viij act in general as a purgative: but in some complaints, as yellow fever and croup for example, in which it is supposed to exert a specific effect, this dose has been repeated every two or three hours, until upwards of 100 grains have been taken in a very short space of time.

On account of its insolubility and great specific gravity, it can be given only in the form of pills.

Hydrargyri Submuriatis precipitatus, precipitated submuriate of mercury, Edinb. is prepared by mixing 8 oz. of purified mercury with the same quantity of diluted nitrous acid, and towards the end of the effervescence digesting with a gentle heat, the vessel being frequently shaken; at the same time let 4½ oz. of the muriate of soda be dissolved in 8lbs. of boiling water; and to this let the other solution be added while it is warm, and let them be mixed very quickly together. After the precipitate has subsided, pour off the saline fluid, and wash the submuriate of mercury by frequent affusions of warm water, which are to be poured off each time after the precipitate subsides, until the water comes off tasteless.

Hydrargyri Submuriatis precipitatum is obtained by pouring five fluid-ounces of diluted nitrous acid on 7 oz. of purified mercury in a glass vessel, and at the termination of the effervescence digesting with a gentle heat for six hours, with frequent agitation. The heat should then be somewhat raised.

MERCURY.

raised that the solution may boil a little, which being poured off from the residual mercury, should be quickly mixed with 10lbs. of boiling water, in which 4 oz. of muriate of soda have been previously dissolved; the subsiding powder is washed with warm distilled water, as long as the fluid poured off from it yields a precipitate on the addition of a few drops of the solution of subcarbonate of kali; and lastly, it is to be dried. In reference to these processes of the two colleges, we may here note, that Mr. Murray has ascertained, that the quantity of mild muriate obtained from a solution of \mathfrak{zj} of mercury in the diluted nitric acid in the cold is a little more than \mathfrak{zj} ; while from the same quantity dissolved with the application of heat, the precipitate did not exceed \mathfrak{zfs} , while the liquor held dissolved much more corrosive muriate than the other. Hence it may be inferred, that the greatest proportion of pure mild muriate of mercury by precipitation may be obtained, by preparing the nitrat slowly, and without the aid of heat, which ought not to be employed in any part of the process.

The properties of this substance are essentially the same with those of common calomel, and therefore it may be regarded as superfluous.

Hydrargyrus precipitatus albus, white precipitated mercury, *Calx hydrargyri alba*, P. L. 1787, *Mercurius precipitatus albus*, P. L. 1745, is prepared, according to the directions of the London college, P. L. 1809, by first dissolving \mathfrak{zlb} . of muriate of ammonia, and then the same quantity of oxymuriate of mercury, in four pints of distilled water, and adding to it half a pint of the solution of subcarbonate of potash; then washing the precipitated powder until it becomes tasteless, and afterwards drying it.

Hydrargyri Submuriatis ammoniatum, ammoniated submuriate of mercury, Dub. is obtained by adding to the fluid which has been poured off from the precipitated submuriate of mercury a quantity of water of caustic ammonia sufficient to precipitate the whole of the metallic salt; then washing the precipitate with cold distilled water, and drying it upon bibulous paper. This preparation is only used, in combination with lard, as an ointment for the cure of the itch, and some other cutaneous eruptions. See *UNGUENTUM Hydrargyri precipitati albi*.

Hydrargyrus cum Creta, mercury with chalk, *Mercurius alkalizatus*, P. L. 1745, is prepared by rubbing together 3 oz. by weight of purified mercury with 5 oz. of prepared chalk, until the metallic globules disappear. As this preparation is milder than any other mercurial one, and does not so easily act upon the bowels, it is very much used by many practitioners. It appears to be slightly oxydized by the trituration, as it contains, according to Fourcroy, only $\frac{1}{85}$ of oxygen.

Hydrargyrus cum Creta, mercury with chalk, of the Dublin college, is prepared in the same manner as the mercury with magnesia, employing precipitated chalk instead of magnesia. This substance is alterative, and occasionally prescribed in tinea capitis, and other cutaneous affections; but it merits very little attention. The dose may be from 5 gr. to \mathfrak{zfs} , given twice a day, mixed in any viscid substances.

Hydrargyrus cum magnesia, mercury with magnesia, of the Dublin college, is prepared by triturating an ounce of mercury with the same quantity of manna in an earthen mortar, adding as many drops of water as will give to the mixture the thickness of syrup, and continuing the rubbing until the metallic globules disappear; then adding, whilst the trituration is continued, a drachm of magnesia, and after the whole is well mixed, a pint of hot water, agitating the mixture. When it has remained some time at rest, that the sediment may subside, decant from it the fluid, repeat the wash-

ing a second and a third time, that the whole of the manna may be removed; and add the remainder of the magnesia to the sediment, while it is still moist; and lastly, dry the powder upon bibulous paper. The addition of the manna in this and the former process is intended only to facilitate the oxydization of the mercury; and it is afterwards removed by the subsequent washings, so that the product remains a grey or black oxyd of mercury mixed with magnesia. This preparation is of no great importance.

Hydrargyri nitrico-oxydum, nitric oxyd of mercury, *Hydrargyrus nitratus ruber*, P. L. 1787, *Mercurius corrosivus ruber*, P. L. 1745, *Mercurius precipitatus corrosivus*, P. L. 1720, is prepared by the directions of the Lond. Pharm. by mixing in a glass vessel 3lbs. by weight of purified mercury, $1\frac{1}{2}$ lb. by weight of nitric acid, in two pints of distilled water, and boiling the mixture in a sand-bath until the mercury being dissolved and the water evaporated, a white mass remains. Rub this into powder, and put it into another shallow vessel, then apply a moderate heat, and raise the fire gradually until the red vapour ceases to arise. The component parts of this oxyd are, according to Fourcroy, mercury 92, and oxygen 8; according to Chenevix, mercury 85, oxygen 15.

Hydrargyri Oxydum rubrum per acidum nitricum, olim, *Mercurius precipitatus ruber*, Edmb. red oxyd of mercury by nitric acid, formerly red precipitate of mercury. Dissolve a pound of purified mercury in 16 oz. of diluted nitrous acid; and evaporate the solution over a gentle fire to a dry white mass, which being rubbed to a powder, is to be put into a glass cucurbit, and covered with a thick plate of glass: then adapt a capital to the vessel, and having placed it in a sand-bath, let the contained matter be roasted with a fire gradually raised until it passes into very red small scales.

Hydrargyri Oxydum nitricum, Dub. nitric oxyd of mercury. Mix 10 oz. of purified mercury, and ten fluid-ounces of diluted nitrous acid in a glass, and dissolve the mercury with a gradually raised heat: then increase the fire until the residuary matter in the bottom of the vessel be converted into red scales.

Nitric oxyd of mercury is stimulant and escharotic. It is merely used externally, when rubbed into a fine powder, as a stimulant to old sores, and for destroying fungus. As a powder, in the proportion of gr. fs. to grs. iv of sugar, it is blown into the eye to remove specks in the cornea; and formed into an ointment with lard, it is a useful application to ulcerations of the eye-lids, and to chancres. See *UNGUENTUM Hydrargyri nitrico-oxidi*.

Hydrargyri oxydum rubrum, red oxyd of mercury, *Hydrargyrus calcinatus*, P. L. 1787, *Mercurius calcinatus*, P. L. 1745, is prepared by pouring *e. g.* 1lb. by weight of purified mercury into a glass matras with a very narrow mouth and broad bottom: apply a heat of 600° to this vessel, without stopping it, until the mercury has changed into red scales; then reduce these to a very fine powder. The whole process may probably require an exposure of six weeks.

Hydrargyri oxydum, Dub. oxyd of mercury, is obtained by taking any quantity of purified mercury, and proceeding as in the last article.

According to Lavoisier 100 parts of this oxyd contain 7 of oxygen; Fourcroy makes the proportion of oxygen 8, and Chenevix, 15 parts.

This is a very active preparation of mercury, and has been employed by some eminent practitioners, *e. g.* John Hunter, as an internal remedy in syphilis. See *LUES VENEREA*. Its effects, however, are violent, so that it is now scarcely

MERCURY.

ever employed internally, or as an antisyphilitic. The dose may be gr. j combined with gr. ss of opium, in the form of pill, night and morning. It is chiefly used as an external stimulant and escharotic in the same cases as the nitric oxyd; being previously rubbed to a fine powder, and either sprinkled over the ulcers, or united with lard, and applied as an ointment.

Hydrargyri oxydum cinereum, grey oxyd of mercury, is formed, according to the instructions of the Lond. Pharm., by boiling an ounce of submuriate of mercury in a gallon of lime-water, constantly stirring until a grey oxyd of mercury is separated; wash this with distilled water, and then dry it. The same preparation of the Edinb. Disp. is formed of four parts of purified mercury, five parts of diluted nitrous acid, 15 parts of distilled water, and a sufficient quantity of water of carbonate of ammonia. Dissolve the mercury in the acid; add gradually the distilled water, then pour in as much water of carbonate of ammonia as may be sufficient for precipitating the whole of the oxyd of mercury, which is to be afterwards washed with pure water, and dried.

Hydrargyri Pulvis cinereus, Dubl. grey powder of mercury, is formed by dissolving 2 oz. of mercury in two fluid-ounces of diluted nitrous acid, in a slow heat, and diluting the solution with eight fluid-ounces of cold water; then dropping into it 1½ oz. of the water of carbonate of ammonia, or as much as may be sufficient for precipitating the whole of the metal, which is to be washed with boiling distilled water, until the fluid, poured off, yields no sediment, when water of sulphuret of ammonia is dropped into it: lastly, let the precipitate be dried. The constituents of the grey oxyd of mercury are supposed to be 96 parts of mercury, and 4 of oxygen, in 100 parts.

The grey oxyd of mercury, when well prepared, may be used as a substitute for the oxyd prepared by trituration; and as it is more likely to be always of an uniform strength, it may of course be more depended on than those preparations. It has been objected to for forming ointment, in order to serve the purposes of mercurial frictions (see *UNGUENTUM Oxydi hydrargyri cinerei*); but the objection may have been owing to the use of that form of preparation which contains the triple salt. It has been used with advantage for fumigation, both locally applied towards the healing of venereal ulcers, and, generally, to bring the habit under the influence of mercury, when it could not be introduced by the ordinary mode. The dose of this oxyd is from gr. i. to grs. iii. given in the form of pill twice a day.

Hydrargyri, Sulphuretum nigrum, olim, *Æthiops mineralis*, Edinb. Dubl. black sulphuret of mercury, formerly æthiops mineral. This is prepared by rubbing together equal weights of purified mercury and sublimed sulphur in a glass mortar with a glass pestle, until the globules of mercury altogether disappear. It may also be made with double the quantity of mercury.

This mercurial preparation is alterative and anthelmintic; it is chiefly employed against scrophulous swellings, and in cutaneous affections; and has been found useful as an antidote to ascarides. It must be long used to produce any sensible effects. The dose is from grs. v. to f. ʒss., given twice or three times a day. See *ÆTHIOPS Mineral*.

Hydrargyri sulphuretum rubrum, red sulphuret of mercury, *Hydrargyrus sulphuratus ruber*, P. L. 1787, *Cinnabaris factitia*, P. L. 1745, is prepared by melting 8 oz. of sublimed sulphur over the fire, and mixing in 40 oz. by weight, of purified mercury; and as soon as the mass begins to swell, removing the vessel from the fire, and covering it

with considerable force, to prevent inflammation; then rubbing the mass into powder and subliming.

Hydrargyri, Sulphuretum rubrum, Dubl. red sulphuret of mercury, is prepared as in the last process. Red sulphuret of mercury is alterative and deobstruent. It was formerly much used in cutaneous diseases, gouty and rheumatic affections, and in cases of worms, but it is now scarcely ever employed. It has been recommended for fumigations in syphilis; but on account of the sulphurous vapours it is less fit for this purpose than the grey oxyd. The dose for internal use is from grs. x. to ʒss. made into an electuary or bolus.

Hydrargyri Subsulphas flavus, olim, *Turpethum minerale*, Edinb. yellow sub sulphate of mercury, formerly, *Turbith mineral*, *Hydrargyrus vitriolatus*, P. L. 1787; also *Mercurius emeticus flavus*. For preparing it, take of purified mercury 4 oz.; sulphuric acid 6 oz.; put them into a glass cucurbit, placed in a sand-bath, and boil them to dryness; pulverize the white mass which is left at the bottom of the vessel, and throw it into boiling water; it will be immediately converted into a yellow powder, which is to be washed with frequent affusions of warm water.

Hydrargyri Oxydum sulphuricum, Dubl. sulphuric oxyd of mercury, is prepared by dissolving in a glass vessel 1 lb. of purified mercury, in 1½ lb. of sulphuric acid, with a sufficient degree of heat, and gradually raising the fire until the mass be completely dried. This, by the affusion of a large quantity of hot water, will immediately become yellow and fall into powder, which is to be well triturated with the water in an earthenware mortar. After pouring off the supernatant fluid, wash the powder with repeated affusions of hot distilled water, as long as any precipitate is produced in the decanted liquor on the addition of a few drops of water of subcarbonate of kali; and, lastly, dry it.

This preparation is emetic, discentient, alterative, and errhine; but as its operation is violent, it is seldom administered as an internal remedy. As an errhine, it has been useful in chronic ophthalmia, and diseases of the head; but in this case its acrimony should be sheathed by some bland powder, as starch, or liquorice-root powder, in the proportion of grs. v. to gr. i. of the subsulphat. In doses of gr. v. it operates as a very powerful emetic.

MERCURY, Coralline. See *ARCANUM Corallinum*.

MERCURY, Fulminating. This curious compound was discovered by Mr. Howard, who has given us the following process for preparing it. Dissolve 1.0 grains of mercury in 1½ ounce, by measure, of nitric acid, of the specific gravity of 1.3, with the assistance of heat. When this solution is cold, pour it upon two ounces, by measure, of alcohol: let this mixture be exposed to heat till an effervescence takes place, when the heat must be withdrawn. The effervescence continues with violence for some time, accompanied by the evolution of a dense white vapour, which Mr. Howard conceived to be the etherized nitrous gas combined with oxyd of mercury. During this process a white powder gradually subsides, which must be well washed, filtered, and dried on a sand-bath heated by steam, as a temperature a little higher would cause its explosion. The powder thus obtained is rather crystalline in its appearance. When it is heated to 368°, it explodes with great violence, producing a vivid flash of light, with but little heat. The same explosion takes place by the blow of a hammer, by an electric spark, and by flint and steel. The surface of the body on which it is exploded becomes always covered with a white film, which is the reduced mercury. This indicates that the oxygen of the oxyd has had some share in producing the effect. The explosion by means of a blow is so violent, as frequently to indent

violent the face of the hammer and the anvil. When concentrated sulphuric acid is added to fulminating mercury, it instantly explodes. The dilute acid decomposes it without explosion. A gaseous substance is given out, which consists of carbonic acid mixed with an inflammable gas, which burns with a greenish flame. A white powder is at the same time precipitated, which is the oxalat of mercury mixed with a little running mercury. The composition of fulminating mercury is, therefore, found to be oxalat of mercury combined with the etherized nitrous gas. This substance has been since examined by other chemists. Fourcroy is of opinion that it may be varied in its properties by varying the process. When heat is continued during the whole time of the effervescence, a substance is produced of a greenish colour, which detonates with less force, and emits a blue flame when laid on hot coals. In this case, Fourcroy supposes it to contain ammonia, and more of the vegetable matter of the alcohol. We have before noticed that the oxalat of mercury has the property of exploding with the blow of a hammer. Hence it would appear, that any substance holding oxygen with slight affinity, and at the same time combined with inflammable matter, particularly such as contains hydrogen, may constitute an explosive compound. It is said by Brugnatelli, that a nitrat of silver with excess of acid being heated with alcohol, affords a fulminating substance more violent in its effects than the substance in question. This no doubt arises from the oxygen of the silver giving up less of its specific caloric when it combines with that substance, and of course has more to give up when it combines with the inflammable matter derived from the alcohol. Notwithstanding the mystery so much talked of in the firing of gunpowder, it might no doubt be proved that the light and heat given out when the explosion takes place, is the difference between what would be afforded by the combustion of nitrogen, and the carbon and sulphur of the gunpowder. See *NITRIC Acid*.

M. Bayen was the first chemist who observed the fulminating property of the oxyds of mercury when heated with sulphur; and hence mixtures of this kind have been denominated "Bayen's fulminating mercury." The most powerful of these mixtures is thus prepared; to a solution of nitrat of mercury add lime-water, as long as any precipitate falls down; decant the clear liquor, and wash the pulverulent oxyd with repeated portions of water, after which dry it on a water bath, and then grind it carefully in a mortar, with $\frac{1}{3}$ th of its weight of flower of sulphur. This powder, when laid on a hot iron, explodes with considerable force, undoubtedly in consequence of the sudden oxydation of the mercury, and the rapid combustion of part of the sulphur; for if it is performed in a close vessel, to prevent the dissipation of the powder, the result of its decomposition will be a reddish violet-coloured sulphuret, similar to that procured in the usual manner. Aikin's Dict.

MERCURY, *Incalescent*. See INCALESCENT.

MERCURY, *Ointment of*. See UNGUENT.

MERCURY, *Pills of*. See PILLS.

MERCURY, *Plaster of*. See EMPLASTRUM and PLASTER.

MERCURY, or *Mercury of Bodies*, has been used by alchemists to denote the third of the principles or elements of natural bodies, called also spirit.

In this sense, mercury is defined the most subtle, light, volatile, penetrating, and active part of all bodies. See SPIRIT.

MERCURY of Life, *Mercurius vite*, may, according to Mr. Boyle, be moderated in its evacuating quality, by continually stirring it in a flat glazed earthen vessel, over a fire,

till it emits no fumes, and turns of a grey colour; and he thinks this is the *mercurius vite purgans* so often mentioned by Riverius. Boyle, Works abr. vol. 1. p. 74.

Mr. Godfrey observes, that what is called *mercurius vite*, prepared of sublimate mercury and antimony, has no mercury in it, but is the regulus part of the antimony, with the acid of the sublimate; and what remains is the mercury formed into cinnabar by the sulphur of the antimony. See ALGARDOT.

MERCURY of Metals, or of the *philosophers*, is a pure fluid substance in form of common running mercury, said to be found in all mercury, and capable of being extracted from the same.

The notion of mercury of metals is founded on the common system of the alchemists, that mercury or quicksilver is the basis or matter of all metals; and that metals are only mercury fixed by a certain sulphur.

Mr. Boyle assures us, he had a way of drawing a true running mercury, or quicksilver, from antimony.

MERCURY also serves as a title for books, and papers of news; so called from the heathen deity Mercury, supposed the messenger of the gods.

In the like sense, Mercury is always figuratively applied to persons who make it their business to collect news, or to run about and distribute it.

MERCURY, in *Heraldry*, denotes the purple colour in the coats of sovereign princes. See COLOUR.

MERCURY, in *Mythology*, the son of Jupiter and Maia. He was the god of merchandize, and therefore was sometimes painted with a wand in his left hand, and a bag of money in his right. He was also the god of eloquence, and the messenger of the gods; and, as such, concerned in all treaties of peace and alliance. He is pictured, therefore, with a herald's staff in his hand, entwined with two snakes; wings on his feet, to shew his speed; and a broad-brimmed beaver with wings. He had a general power delegated to him by Jupiter, of conducting the souls of men to their proper place, after their parting from the body; and re-conducting them to our world again, when there was any particular occasion for it. He was, moreover, the god of all gainful arts; whence the proverb *κωνίς έρμης*, i. e. *commune lucrum*; especially of things found by chance, the inventor of the lyre, and of the exercise of wrestling. He was the patron of thieves, having himself been expert that way; and the guide of travellers, for which reason he had statues four-square set up to him in cross-roads. (See TERMINUS.) There are several marks whereby Mercury may be known; among which we may reckon the lightness and agility of his person as the chief; but the most remarkable of his distinguishing attributes are his petasus, or winged cap; the talaria, or wings to his feet; and his wand, with two serpents about it, which they call his caduceus. Sometimes he is also represented with the chlamys, fastened over his shoulders on his breast, and floating behind him in the air. He is likewise distinguished by his sword, with which he killed Argus, called Harpé. As the form of Mercury seems to be all intended for lightness and dispatch, the ancients might borrow this idea of him from his planetary character: thus Lucan, Pharsal. i. v. 663, in speaking of Mercury as the guiding intelligence of a planet, marks the swiftness of its motion.

It has been said, and not without reason, that the Mercury of the Latins was the same deity with the Hermes of the Greeks, the Theutat of the Gauls, and the Thot or Thaut of the Egyptians, from whom some have thought they were derived. His name Hermes signified Interpreter,

or, according to Proclus, Messenger, or, if we trace it to a Celtic original, it was the same with *arines*, which signifies divination, a character which belonged by way of eminence to Mercury, who was distinguished by his knowledge and practice of this art. The Latin appellation was derived, according to Festus, from a term denoting merchants, or rather merchandize, *i. e. Mercurius a Mercibus*; and among the Celts he obtained the name of Merk-ur, on account of his introduction of traffic among them. Lactantius, the grammarian, reckons four of this name, and according to Cicero there were five. Banier allows of none but the ancient Mercury, the Thot, Thaut, or Taaustus of the Egyptians, and the Mercury, who, according to Hesiod, was the son of Jupiter and Maia. To this deity temples were built, and altars erected. There is no personage in profane antiquity more famous than the Egyptian Mercury. Being the soul of Osiris's counsel, he was employed as his agent in the most important offices; and during his absence in India, he assisted Isis, the queen, with his advice, and exerted himself with great assiduity and zeal in causing arts and commerce to flourish through the whole country of Egypt. As he was a proficient in various sciences, he communicated his knowledge to the Egyptians, and established among them a variety of institutions, which contributed to their reputation and prosperity. Such is the account which is given of him by Herodotus and Diodorus Siculus. The second Mercury, or the son of Jupiter and Maia, became famous among the Titan princes, and took possession of Italy, Gaul, Spain, and Mauritania in Africa. This prince is said to have travelled more than once into Egypt, in order to acquaint himself with the arts and sciences, the manners and customs, and particularly the theology and magic of that country. He was thus enabled, upon his return, to instruct his own subjects, and to acquire that high reputation for which he was distinguished, by exhibiting those qualities and performing those services, which we have above recited. After various contests with the other sons of Jupiter, by whom he was repeatedly vanquished, he is said to have retired into Egypt, where he died; though others say he ended his days in Spain, where his tomb was to be seen. Such, says Banier, is the history of Mercury, the Titan prince, which has been much disguised by the Greeks, and blended with several fables. Mercury was worshipped by the Gauls, as Cæsar informs us, but, as we learn from Kircher, (*Œd. Ægypt.*) in Egypt, where the priests consecrated to him the stork, the animal most renowned among them next to the ox. It was chiefly in the month of May that his festival was celebrated, and the most solemn parts of his worship were performed.

The learned Bochart (*Phaleg. l. i. c. 2.*) traces the history of Mercury to that of Canaan. Both, he says, were the sons of Jupiter, or Ammon, who was the same with Ham; one taking his name from *Mercatura*, merchandize, and Canaan, he says, had in Hebrew the same signification. As Canaan was the servant of his brethren, Mercury was the messenger of the gods. This deity had the charge of the highways, because the Phœnicians or Canaanites of the race of Canaan were great travellers, and settled colonies wherever they migrated. The wings of this god are the sails of the Phœnician vessels. He was the god of eloquence, and the inventor of letters, because the Phœnicians brought the use of them into the West. Others represent Mercury as the same with Moses, and compare the miraculous rod of that legislator to the caduceus of this god. Such is the opinion of Huetius.

This pagan divinity had two very distinct names and characters; the Egyptian, known by the title of Hermes,

a grave and venerable personage, who received divine honours on account of his useful and extensive talents for every thing that was conducive to the good of society: the Mercury of the Greeks, on the contrary, was a profligate character; the god of thieves, the intriguing messenger of Jupiter, and useful to him in all his amours. But to both these divinities is ascribed the invention of music and the lyre.

Among the various opinions of the several ancient writers who have mentioned this circumstance, and confined the invention to the Egyptian Mercury, that of Apollodorus is the most intelligible and probable. "The Nile," says this writer, "after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the shore a great number of dead animals of various kinds, and among the rest, a tortoise, the flesh of which being dried and waisted by the sun, nothing was left within the shell, but nerves and cartilages, and these being braced and contracted by desiccation, were rendered sonorous; Mercury, in walking along the banks of the Nile, happening to strike his foot against the shell of this tortoise, was so pleased with the sound it produced, that it suggested to him the first idea of a lyre, which he afterwards constructed in the form of a tortoise, and strung it with the dried sinews of dead animals."

Of the Grecian Mercury, Horace, Ode x. lib. 1. gives us the best part of his character:

"Thou god of wit, from Atlas sprung,
Who by persuasive power of tongue,
And graceful exercise, refin'd
The savage race of human kind,
Hail! winged messenger of Jove,
And all th' immortal powers above.
Sweet parent of the bending lyre,
Thy praise shall all its sounds inspire.

Artful and cunning to conceal
Whate'er in sportive theft you steal,
When from the god who gilds the pole,
E'en yet a boy, his herds you stole:
With angry voice the threaten'ing pow'r
Bad thee thy fraudulent prey restore,
But of his quiver too beguil'd,
Pleas'd with the theft, Apollo smil'd.

You were the wealthy Priam's guide,
When safe from Agamemnon's pride,
Through hostile camps, which round him spread
Their watchful fires, his way he sped.
Unspotted spirits you consign
To blissful seats and joys divine,
And, powerful with thy golden wand,
The light unbodied crowd command;
Thus grateful does thy office prove
To gods below, and gods above." Francis.

This ode contains the substance of a very long hymn to Mercury, attributed to Homer. See HERMES.

MERCURY Bay, in *Geography*, a bay on the N.E. coast of the northernmost of New Zealand, so called by lieutenant Cook, who anchored here in 1769, examined the adjoining country, and in November of the same year observed the transit of Mercury over the sun, from which planet it derived its name. Southward and northward of this bay, there are several islands, and a small island or rock in the middle of the entrance; within which island the depth of water no where exceeds nine fathoms. The best anchoring is in a sandy bay, which lies just within the south head, in five and four fathoms. This place is very convenient both for wooding and watering, and in the river there is an immense quantity of oysters

oysters and other shell-fish, whence it was called by Cook the "Oyster river." But for a ship that wants to stay here any time, the best and safest place is in the river at the head of the bay, which, from the number of mangrove trees about it, was called "Mangrove river." To sail into this river, the south shore must be kept all the way on board. The country on the east side of the river and bay is very barren; its only produce being fern, and a few other plants that will grow in a poor soil. The land on the N.W. side is covered with wood, and the soil being much more fertile, would, with proper cultivation, produce all the necessaries of life; it is not, however, so fertile as the land observed by our navigators to the southward; nor do the inhabitants, though numerous, make so good an appearance: they have no plantations; their canoes are mean, and without ornament; they sleep in the open air; and say, that Teratu, whose sovereignty they do not acknowledge, if he were to come among them, would kill them. This favoured an opinion of their being outlaws; though they had "Heppahs," or strong holds, to which they retired in time of imminent danger. On the shore, in several parts of the bay, were found great quantities of iron sand, which is brought down by every little rivulet of fresh water, that finds its way from the country; a circumstance which demonstrates that there is ore of that metal not far inland; nevertheless none of the inhabitants of this place, or any other part of the coast, observed by Cook and his companions, knew the use of iron, or set the least value upon it: all of them preferring the most worthless trifle, not only to a nail, but to any tool of that metal. Our navigators, before they left the bay, cut upon one of the trees near the wtering place, the ship's name and that of the commander, with the date of the year, and month when they were there; and after displaying the English colours, took a formal possession of it in the name of his Britannic majesty king George III. S. lat. 36° 47'. W. long. 184° 4'. Hawke's Voyages, vol. ii.

MERCURY Point, a cape on the E. coast of New Zealand, forming the N.E. point of Mercury bay.

MERCURY Isles, a cluster of small islands in the South Pacific ocean, near the E. coast of New Zealand, situated in a line, a little N.E. of Mercury Point.

MERCY, in *Ethics*, has the same general nature and sources as *compassion*, which see; and seems to differ from it only in this, that the object of it has forfeited his title to happiness, or the removal of misery, by some demerit, particularly against ourselves. Here, therefore, resentment on account of an injury done to ourselves, or what is called a just indignation against vice in general, interferes, and checks the otherwise natural course of our compassion, to as, in the unmerciful, entirely to put a stop to it. But in the merciful, the sources of compassion prevail over those of resentment and indignation; whence it appears, that the compassion required in acts of mercy is greater than in common acts of mere compassion; agreeably to which it is observable, that mercy is held in higher esteem than mere compassion. The mercy of God is that attribute of the divine nature, or that modification of benevolence, which respects the misery of mankind in connection with their offences and demerit; and the exercise of it makes provision for their relief by affording them the means of recovery, by repentance and reformation, so that they may become fit objects of pardon and favour.

MERCY, in *Law*. See MISERICORDIA.

MERCY, *Order of our Lady of*, was instituted, for the redemption of captives, as several writers affirm, by James I. king of Arragon, in 1218; but others, on better authority,

attribute the institution of the order to Peter Nolasque, a native of Mar des Saintes Puelles, a town in the diocese of St. Papoule, one league distant from Castellnaudary. The badge worn by the knights at their breast was a small shield per fess gules and or; in chief, a cross pattée argent; in base four pallets gules, for Arragon: the shield crowned with a ducal coronet.

MERCY, *Religious Order of*, is said to have been instituted and liberally endowed, for ladies, in 1261, by Mary du Secours, a woman of quality born at Barce lona: the ladies of this order wore at their breast a small shield of the arms of the order, exactly similar to that worn by the knights.

MERCY-Seat, in *Scripture History*. See *Ark of the Covenant*.

MERDDIN, in *Biography*, the son of Mervyn, a celebrated Welsh poet, who flourished about A. D. 560. He ranked with Merddin Emrys, and Taliesin, as the three principal Christian bards of Britain. Merddin is said to have slain his nephew in battle, on which account he secluded himself from society in a wood, whence he is called Merddin the Wild. Owen's Camb. Biog.

MERDESENGI. See MARDAC.

MERDIN, or MARDIN, in *Geography*, a fortified town of Asiatic Turkey, in the province of Diarbekir. It is situated at the top of a very lofty and rugged mountain, surrounded by a strong and lofty wall of hewn stone, and guarded by a strong fort on the summit of the mountain, furnished with a few cannon. This town is of a considerable size, and very populous. It is the see of a bishop, and the greater part of its inhabitants consists of Armenians, who are very industrious, and carry on several manufactures. They are hospitable and well disposed, enjoy a pure air, and in general appear ruddy and healthy. Many of the women are beautiful. Provisions, and particularly vegetables, are plentiful, good, and cheap; and they have also most kinds of fruits, of excellent quality, the climate being very hot in the vallies, and temperate on the mountains. It is the residence of a pacha, in whose train are 200 spahis and 500 janizaries. This town, which seems to have been called "Zibin" by Rauwolf, was taken and sacked by Timur Bec, but the fortrefs was invincible; 50 miles S. of Diarbekir. N. lat. 37° 19'. E. long. 40°.

MERDIVORÆ, from *merda*, dung, and *voro*, I devour, the *dung-eaters*, in *Natural History*, the name given by authors to several flies, which feed on excrements of different animals. Of these there are three kinds very common among us; 1. The coprophagos, which is of a dun colour, with a reddish head, and a white streak along the middle of it: 2. The red dung-fly, which has silvery wings, a red body, and black shoulders: and, 3. The green one, which is of a very glittering hue, and has silvery wings.

MERDOO, in *Geography*, a town on the N. coast of the island of Sumatra. N. lat. 5°. E. long. 96° 20'.

MERDRIGNAC, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Loudéac; 13 miles E. of Loudéac. The place contains 2134, and the canton 10,044 inhabitants, on a territory of 302½ kilometres, in nine communes.

MERË, a town of Norway, in the government of Drontheim; 68 miles N. of Drontheim.

MERE, a small market-town and parish, situated in the hundred of Mere, and county of Wilts, England. The parish is of an angular shape, and is bounded on two sides by the counties of Somerset and Dorset. Hence it is supposed to have derived its name. *Mere*, in the Saxon language, is often used to denote a boundary or land mark. The appearance of the town is that of a straggling village, the houses

houses being ill arranged and very indifferently built. In the middle of it stands a small cross or market-house, where a weekly market is held on Thursdays, and two fairs annually. According to the parliamentary returns of 1801, it contained 181 houses, and 381 inhabitants. A manufactory of bed-ticking and dowls is carried on here chiefly by the women. The church is an extensive edifice, ornamented at one end by a handsome tower. The living is vicarial, and in the gift of the dean of Salisbury. In the parsonage house was born Francis Potter, one of the most singular mechanical geniuses of his age.

On an eminence still called Castle-hill, immediately adjoining the town, formerly stood a castle, but few traces of its walls can now be discovered. Some encampments appear in this neighbourhood, one of which, called by Leland "White-shole-hill," is surrounded by a double trench, and was probably occupied by the Danish army, previous to some engagement with the celebrated Alfred.

About two miles N.W. of Mere is the parish of Stourton, in which is a noble seat, named Stourhead, the seat of sir R. C. Hoare, bart. This gentleman has distinguished himself in the literary annals of the present age, by the publication of some interesting and handsome works on the topography and antiquities of Great Britain. One of these, entitled "The History of Ancient Wiltshire," contains much new and curious information respecting the characteristics of encampments, barrows, stonehenge, &c. and a particular account of some singular excavations, called Penn-pitts, in this neighbourhood. Stourhead is justly noted among the handsome seats of this county; and though the house has no prominent architectural beauties, yet it is stored with choice pictures, with drawings, and an extensive and well selected library. The pleasure grounds, woods, and water, display many picturesque and sylvan beauties, and the whole demesne is highly impressive and interesting. See Britton's Beauties of Wiltshire.

MERECZ, a town of Lithuania, in the palatinate of Troki, at the conflux of the Merez and the Niemen; 28 miles N. of Grodno.

MEREDITH, CAPE, a cape among the Falkland islands, in the South Atlantic ocean, between port Stephen's and cape Orford.

MEREDITH, a township of America, in Strafford county, New Hampshire, on the S.W. side of lake Winipiscogee; 15 miles N. of Gelmantown, and nine S.E. of Plymouth; incorporated in 1768, and first called New Salem.—Also, a post-town in Delaware county, New York; 25 miles S. of Cooperstown.

MEREEGA, HAMMAM, *i. e.* the baths of Mereega, formerly the "Aquæ Calidæ Colonia," a town of Algiers, in the province of Tlemsan or Tremecen, situated half way betwixt the shelliff and the sea, eight miles E.N.E. of Maliana, and celebrated for its hot baths. The largest and the most frequented of them is a basin 12 feet square, and four deep: and the water, which bubbles up in a degree of heat scarcely supportable, after it has filled this cistern, passes on to a much smaller one used by the Jews, who are not permitted to bathe in company, or in the same place with the Mahometans. These baths were formerly covered, and had corridors surrounding the basins; but they now lie exposed to the weather, and are half filled with stones and rubbish. Nevertheless they are resorted to by a great concourse of people in the spring, which is the season of these waters; accounted very efficacious for curing the jaundice, rheumatic pains, and some of the most inveterate distempers. Higher up the hill is another bath, which being of too intense a heat for bathing, has its water con-

ducted through a long pipe into another chamber, where it is used in "Duccian," an operation similar in its nature and effect with pumping. Betwixt this and the lower bath are the ruins of an old Roman town equal to that of "Herba; and at a little distance from it are tombs and coffins of stone, of an unusual size; 24 miles S.E. of Shershell. Shaw's Travels.

MERENDERA, in *Botany*, a name given by the Spaniards to this plant and some that resemble it, and which may perhaps be tolerated, like a few others of barbarous origin, as being sufficiently harmonious. Ramond Bullet. Philomat. n. 47. 178. t. 12. f. 2. Redout. Liliac. v. 1. 25.—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronarie*, Linn. *Junci*, Juss.

Cal. Sheath of one leaf. *Cor.* of six petals, funnel-shaped, equal; claws erect, long and linear; borders elliptic-lanceolate, spreading. *Stam.* Filaments six, thread-shaped, equal, inserted into the claws of the petals, shorter than the limb, permanent; anthers terminal, erect, awl-shaped. *Pist.* Germen three-lobed, superior, somewhat stalked, oblong, acute; styles thread-shaped, the length of the stamens; stigmas simple. *Peric.* Capsule stalked, oblong, three-lobed, acute, of three valves and three cells, opening at their inner edge. *Seeds* several in each cell, obovate, stalked, ranged along the margins of each valve.

Est. Ch. Sheath of one valve. Petals six, with long claws. Anthers vertical. Capsule of three cells, opening at their inner edge. Seeds several.

1. *M. Bulbocodium*. Pyrenean Merendera. Redout. Liliac. t. 25. (*Bulbocodium vernum*; Desfort. Atlant. v. 1. 284, excluding the synonyms, according to Redouté, but the description does not entirely agree. *Colchicum montanum minus*, *versicolore flore*; Clus. Hist. v. 1. 201. Ger. em. 160.)—Found in the grassy pastures of the highest of the Pyrenean mountains, flowering at the commencement of autumn, and ripening seed in the following spring. *Root* an ovate bulb. *Stem* none. *Leaves* three or four, produced after the flower is past, radical, spreading, linear, acute, channelled, smooth, a span long. *Flower* solitary, radical, the size of a small *Crocus*, with purplish rose-coloured petals, white at their base, and yellow anthers. *Capsule* small, brown, elevated on a stalk two inches high.—We have copied from Redouté the quotation of Ramond. This plant might perhaps, without violence to nature, be referred to *Colchicum*.

MERETRIX, among the Romans. The meretrices were the better sort of courtezans, and differed much from the *prostitule*, or common prostitutes, who had bills or inscriptions, *tituli*, over their doors, and were ready at all times to entertain their customers, whereas the meretrices entertained none but at night.

The meretrices were distinguished from the matrons by their dress, being obliged to wear the *toga* and short tunics, like those of the men; whereas the matrons wore the *stola*, which was a garment that reached down to their feet, as did likewise their *palla*, or outer robe.

MERÉVILLE, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Corbeil; 10 miles from Estampes. The place contains 1307, and the canton 8012 inhabitants, on a territory of 240 kilometres, in 20 communes.

MERG, a town of Africa; 30 miles N. of Fez.

MERGANSEER, in *Ornithology*, the name of a large water-fowl, called in English the *goosander*, and by some authors the *harle*.

This is the *Mergus merganser* in the Linnæan system: the bill of the male of this species is about three inches

long, narrow, and finely serrated: the colour of the bill as well as of the irides is red; the head is large, and the feathers on the hind part long and loose; the colour black, finely glossed with green; the upper part of the neck the same; the lower part and under side of the body of a fine pale yellow; the upper part of the back and inner scapulars are black; the lower part of the back and tail are ash-coloured; the tail consists of eighteen feathers; the greater quill-feathers are black, the lesser white, some of which are edged with black; the coverts at the setting on of the wings are black; the rest white; and the legs of a deep orange colour. Pennant. See *Mergans*.

MERGEN, a word used by some of the chemical writers to express coral.

MERGENTHEIM, in *Geography*, a town of Germany, on the S. side of the Tauber; the residence of the grand master of the Teutonic order, and seat of the regency; 25 miles S.S.W. of Wurzburg. N. lat. $49^{\circ} 21'$. E. long. $9^{\circ} 27'$.

MERGER, in *Law*, is where a lesser estate in lands, &c. is drowned in the greater; as, if the fee comes to tenant for years or life, the particular estates are merged in the fee: but an estate tail cannot be merged in an estate fee; for no estate in tail can be extinct, by the accession of a greater estate to it. If a lessor, who had the fee, marries with the lessee for years, this is no merger, because he hath the inheritance in his own, and the lease in right of his wife. And where a man hath a term in his own right, and the inheritance descends to his wife, so that he hath a freehold in her right, the term is not merged or drowned.

MERGAN, in *Geography*, a town of Persia, in the province of Segestan; 32 miles S.S.W. of Kin.

MERGUEN HOTUN, a town of Chinese Tartary; 670 miles N.N.E. of Peking. N. lat. $49^{\circ} 12'$. E. long. $142^{\circ} 20'$.

MERGUI, a sea-port town of the kingdom of Siam, situated S. of Tavoy, on an island near the E. coast, with a harbour that is accounted one of the best in India. The sea near the coast being full of islands, is denominated by captain Forrest the Mergui Archipelago. N. lat. $12^{\circ} 6'$. E. long. $98^{\circ} 23'$.

MERGUS, in *Ornithology*, a genus of birds of the order Anseres. The trivial name of this genus is *Merganser*: the bill is toothed, slender, cylindrical, hooked at the point; nostrils small, oval, in the middle of the bill; feet four-toed, the outer toe longest. There are ten species, of which five are common to our country; the others are natives of Europe and America. The birds of this genus live on fish, and are very destructive in ponds.

Species.

CUCULLATUS, Crested Merganser. Crest globular, white on each side; body above brown, beneath white. It inhabits North America; and is 17 inches long; it builds near lakes, forming its nest of grass, and down plucked from its own breast; lays from four to six eggs. The bill and legs are black; irides golden; crest larger than the head, edged with black. The female is brown; crest less, ferruginous.

* **MERGANSER**, Goosander. Subcrested; white head; neck, upper part of the breast, and wings glossy-black; tail cinereous. It weighs about four pounds when full grown; its length is two feet four inches. It is found in Europe, Asia, and America. Sometimes the goosander visits our rivers and lakes in severe winters, but retires to the more northern latitudes to breed. It has been known to build on

trees, like the cormorant, but more frequently among rocks or floeces, and lays 13 eggs, which, with the bird itself, are eagerly devoured by the weazel. It swims with its head above the water; dives deep; remains a long time below, and rises at a considerable distance. Its flesh is rancid, though sometimes eaten. In quest of fish, it dives with great celerity, and holds its slippery prey with great security by means of its toothed bill, so admirably adapted to the purpose. Bill, legs, and irides red; greater quill-feathers black, lesser white.

* **CASTOR**, Dun-diver. Crested, emereous; head and upper part of the neck bay; chin, middle quill-feathers, and belly white. It weighs about two pounds and a half, measures twenty-five inches in length. Inhabits the same countries with the preceding. It has been regarded by some naturalists as the female of another species, but the labyrinth, or enlargement at the bottom of the wind-pipe, seems to others to prove it to be a male, and consequently a distinct species. Bill and irides red; belly sometimes flesh-colour.

* **SERRATOR**, Red-breasted Merganser. Crest pendent; breast variegated with reddish; collar white; tail-feathers brown, varied with cinereous. It inhabits the northern parts of Europe, Asia, and America; and is 21 inches long. The bill beneath and legs are red; feathers of the sides of the breast large, white, edged with black, covering the fore-part of the folded wings. In the *male* the hind-head is crested; head and upper part of the neck green. The *female* is scarcely crested at all; the head and beginning of the neck rufous. There are two other varieties distinguished by differences of colouring marks; the *second* above is black, beneath white; greater quill-feathers black; tail brown; variety of the *male*; the *third* is above black, beneath white; neck bay; wings with a transverse white stripe; greater quill-feathers and tail black; variety of the *female*.

IMPERIALIS, Imperial Goosander. Varied with black, brown, and grey; head smooth; first quill-feathers black; it has no wing-spot; bill and legs reddish-white. It inhabits Sardinia; is the size of a goose; and the tongue fringed.

* **ALBELLUS**, Smew or White Nun. Crest pendent; hind-head black; body white; back and temples black; wings variegated. Inhabits Europe and America; breeds in the Arctic regions, and is driven to the south only by severe weather. Bill and legs black; wing-spot white; oval spot from the bill surrounding the eyes, black, and two arched lines on each side near the beginning of the wings, black. Female, head smooth, grey; band across the eyes black, and under the eyes a white spot; body above blackish-brown, beneath white; upper part of the head bay; chin white.

* **MINUTUS**, Minute Merganser. Brown-ash, beneath and chin white; head and upper part of the neck ferruginous; wing-spot white before and behind. There is a variety having a smooth head; black back; belly white; bill and legs blood-red; first quill-feathers black; tail cinereous.

FURCIFER, Fork-tailed Merganser. Black; head smooth; hind-head, neck, vent, belly, and lateral tail-feathers white; front and cheeks pale brown; the tail is forked. Bill black; dirty-red at the sides; from the ears on each side, through the sides of the neck to the breast, there is a black band.

FUSCUS, Brown Merganser. Crested; brown, beneath white; chin and breast spotted with black; wings black with a white band. It is found in Hudson's bay, and is 17 inches long. Hind-head crested; behind the eyes a white

band extending to the nape; lower part of the crest black; breast blueish waved with whitish; legs yellowish.

CÆRULEUS, Blue Merganser. Crested; blue; crown and tail black; chin, belly, and spot on the wings white. It inhabits Hudson's bay, and is 14 inches long. The bill of this species is long and black; legs are blue. We shall now conclude this article with some general observations on the whole genus.

These birds, with few exceptions, are of a middle size, between that of a goose and of a duck. The edges of both mandibles are serrated, the tongue is thick, set with small bristles pointing backward; an happy contrivance for holding the slippery fishes which form their prey, and conducting it into the bird's throat. They swallow with an undistinguishable voracity, fishes, that are by far too large to enter entire into the stomach; and hence, while the one end is digesting in the œsophagus, the other often remains in the throat.

The head and back of the merganser are black, beautified with a gloss of green. The lower parts of the body are white, the breast tending to a pale yellow. The tail is grey, the eyes, feet, and part of the bill, are red. As this bird is obliged to search for its food by diving, it is capable of remaining a long time under water; and for this purpose, is furnished with a quantity of air, lodged in a cavity of its body, to serve the purpose of respiration while it remains below.

The mergansers, from their voracity, and their expertness in swimming, are perhaps the most destructive of all birds that plunder the waters; while their flesh, which is dry, and of a bad flavour, makes but a small compensation for the devastations which they commit.

Some of them build in trees; but the greater part in rocks, jutting over precipitous forelands. One or two species are said to have been found as high up the North seas as Iceland, but this is uncommon. In all the species, the female is of a smaller size than the male, and differs considerably in the distribution of her colours. Her head is red; and the mantle or back and neck-feathers grey. The white nun is the most beautiful of the whole tribe; the white plumage of the fore parts, and the black mantle that covers its back, are each perfect in their kind; the tuft of small detached feathers white upon the crown, but of a dark green shaded with purple upon the hind part, produces a very elegant effect; while to complete this modest and religious dress of the white nun, the lower part of the neck is half surrounded with a collar of long silky feathers like velvet.

MERCUS cirratus minor, in *Ornithology*, a name by which Gesner calls the *capo negro*, a species of duck, called in English the *tufted duck*.

MERIANA, and **MERIANELLA**, in *Botany*. See **ANTHOLYZA** and **WATSONIA**.

MERIANIA, named by Swartz in memory of Maria Sybilla Merian, daughter of a German engraver, who was born at Frankfort on the Maine, April 12th 1647, and was the wife of John Andrew Graff. This lady is celebrated for her zeal in the pursuit of natural history, especially in what relates to the metamorphoses of insects, and for her great skill in the use of the pencil. She published a work, of which there have been several editions, in folio or quarto, with plates, on European insects, and the plants they feed upon; but her most famous book, detailing the metamorphoses of Surinam insects, is a splendid folio, of which original coloured copies are very rare and valuable. Botany was with her a secondary object, nor are her delineations, however magnificent, always remarkable for accuracy. She

performed several voyages in pursuit of her favourite object. Sir Hans Sloane purchased what were supposed to be her original drawings on vellum, but the copy exhibited in the British Museum, has certainly marks of the graver, though it may have been coloured by her hand. She died at Amsterdam in 1717.—Swartz Ind. Occ. 823. Willd. Sp. Pl. v. 2. 600.—Clafs and order, *Decandria Monogynia*. Nat. Ord. *Calycantbema*, Linn. *Melastoma*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, campanulate, permanent, its margin in five, short, obtuse, membranous segments, each accompanied by a long, external tooth. *Cor.* Petals five, inserted below the throat of the calyx, ovate, somewhat leathery, spreading, deciduous. *Stam.* Filaments ten, fixed internally to the five-sided margin of the calyx, within the petals, broad at the base, bent in the upper part; anthers long, broadish, bent backward, pointed at the summit, opening there by two pores. *Pist.* Germen superior, roundish, five-sided, in the bottom of the calyx; style thick, club-shaped, bent downward; stigma obtuse. *Peric.* Capsule in the bottom of the bell-shaped calyx, covered by the calyx; but unconnected with it, naked above, roundish, five-sided, five-celled, five-valved; the partitions contrary to the valves. *Seeds* numerous, minute. *Recept.* crescent-shaped.

Eff. Ch. Calyx bell-shaped, five-cleft. Petals five, inserted into the calyx. Stamens declining. Capsule distinct, of five cells; the partitions contrary to the valves. Seeds numerous.

1. *M. leucantha*. White-flowered Meriania. Swartz Ind. Occ. 826. t. 15. f. a. (*Rhexia leucantha*; Swartz Prod. 61.)—Leaves oblong, shining. Flowers with two bracteas.—Native of the highest mountains of Jamaica, flowering in the summer and autumn.—This is a shining, elegant tree, whose straight trunk, covered with a smooth bark, is from 15 to 30 feet in height. Branches erect, roundish, smooth; smaller ones quadrangular, compressed, furrowed, brittle. Leaves opposite, crossing each other in pairs, ovate-oblong, pointed, three-nerved, toothed and cartilaginous at the margin, paler, and beautifully veined like net-work beneath; smooth on both sides; very shining, four or five inches long; on angulated smooth footstalks which are channelled above. Flower-stalks at the axils of the terminal leaves, opposite, solitary, remote, an inch and a half long, round, compressed, erect, single-flowered, smooth. Bracteas two, opposite, nearly sessile, ovate-lanceolate, pointed, entire, three-nerved, pale. Flowers large and handsome, white, or slightly flesh-coloured, inodorous, somewhat drooping.

2. *M. purpurea*. Purple Meriania. Swartz Ind. Occ. 829. t. 15. f. b. (*Rhexia purpurea*; Swartz Prod. 61.)—Leaves ovate-lanceolate. Flowers with four bracteas.—Grows in similar situations to the last, and flowers in autumn. The present species differs chiefly from *M. leucantha* in being considerably smaller, in having its leaves of a brownish-green, its smaller branches round, not quadrangular, and its flowers of a deep blood or purple colour, accompanied by four bracteas instead of two. The corolla in each species is as large as that of a single wild rose. We find the second species, in the herbarium of the younger Linnæus, marked *Wrightia superba*, and we recollect to have seen the same name at Sir Joseph Banks's, which, when the genus was established, ought to have been retained in justice to a very indefatigable collector and botanist who first sent the specimens to Europe, Dr. Wm. Wright, now of Edinburgh.

MERJAPOUR, in *Geography*, a town of Hindoostan, in Bahar; 28 miles S.S.W. of Bahar.

MERI-

MERIBASA, a river of Asiatic Turkey, which runs into the Mediterranean, near Adana.

MERICHSWAND, a fertile tract of Switzerland, in the canton of Lucerne, four miles long, and two broad, separated from the rest of the canton. In it is a parochial village near the Ruz.

MERIDA, an ancient town of Spain, in Estremadura, seated on an eminence, near the Guadiana. It was anciently large, populous, and flourishing, and much embellished by the Romans, so that it now only presents an image of its former grandeur and magnificence. This town became a colony under the emperor Augustus, and being peopled, after the war with the Cantabrians, with soldiers of the 5th and 10th legions, took the name of that prince, and was called "Emerita Augusta." (See AUGUSTA.) Writers differ about its extent; some assigning to it eight miles, and others six leagues of circumference. It was, however, the largest in Spain, under the Romans. Under the dominion of the Goths, it preserved its monuments; but when it was taken by the Moors, A.D. 713, it was very much ransacked and destroyed. From then it was retaken by Alphonso IX., king of Castile and Leon, in 1230; and from that period it has been always attached to the kingdom of Castile. It lies in that part of Spain which the Romans called Vetonia; but notwithstanding its former extent and populousness, the number of its present inhabitants scarcely amounts to 5000. Under the Gothic kings it was the see of an archbishop, and the seat of some provincial councils. The archiepiscopal see was removed to Compostella by pope Calixtus II., under king Alphonso VII., whilst this town was in the possession of the Moors. When it was retaken by Alphonso IX., he gave it to the military order of St. James, and it still belongs to this order. Merida took as arms the reverse of a medal struck under Augustus for commemorating its erection into a Roman colony; this is a gate of a town formed by two arches with two towers, and a semicircular enclosure, which extended from one to the other. It still affords considerable wrecks of its ancient magnificence under the Romans. Here they built superb bridges and magnificent temples; triumphal arches and beautiful aqueducts; here they raised edifices for public feasts and games; a circus, a theatre, and a naumachia. The vestiges of these grand public monuments are still visible; of which some are in and others out of the town. The baths are in a better state of preservation than most of the other monuments. In its vicinity are two large reservoirs of water, resembling lakes, called Albafera and Albuera. One is 90 feet long, and 51 deep, surrounded by thick walls, and ornamented with two beautiful towers; about a league from the town. The other is at the distance of two leagues; it is small, but the walls which contain the waters, and the great tower which serves as an aperture for air, are much finer. The environs of Merida are pleasant and fertile; abounding in wine, good fruits, and grain, with excellent pasture; nine leagues from Badajoz. N. lat. $38^{\circ} 48'$. W. long. $6^{\circ} 3'$.

MERIDA, the capital of Yucatan, in the audience of Mexico; lying near the N. side of the province between the gulfs of Mexico and Honduras; the residence of a governor, and see of a bishop; 130 miles N.E. of Campeachy. N. lat. $21^{\circ} 38'$. W. long. $90^{\circ} 36'$.—Also, a town of South America, in the government of Caraccas, founded in 1558 by John Rodriguez Suarez, under the name of Santiago de los Caballeros, and situated in a valley three leagues long, and about three quarters of a league wide in its broadest part. It is surrounded by three rivers, Mucujun, Albarregas, and Chama, neither of which is navigable. At some distance from the city are plantations of sugar, cacao, and

coffee. All the environs of Merida abound with fruits, maize, beans, peas, potatoes, cassada, wheat of the finest quality, barley, &c. Excellent meat is purchased here at a very moderate price. The climate is variable, so that every day it experiences the four seasons of the year. The west wind is particularly insalubrious; the rains are heavy, and fall through the year, but with peculiar violence from the month of March to November. This city is the see of a bishop and a chapter. It possesses a college and seminary for the education of ministers who conduct the Catholic worship; and for other classes of inhabitants. The orders of St. Dominic and of St. Augustin, and also of St. Clair, have each a convent; and besides the cathedral, they have several places of worship. The number of inhabitants at Merida amounts to 11,500, of all colours and of all classes. No class here disdains labour; the white are employed in agriculture, the rearing of cattle, and the offices of the ecclesiastical state. The people of colour fabricate different articles of cotton and wool. Merida is distant from Maracaibo 80 leagues to the S.; from Caraccas 140 leagues to the S.E., and from Varinas 25 leagues S.E. N. lat. $8^{\circ} 10'$. W. long. $73^{\circ} 45'$.

MERIDIAN, in *Astronomy*, a great circle of the sphere, passing through the zenith, nadir, and poles of the world, crossing the equinoctial at right angles, and dividing the sphere into two hemispheres, the one eastern, and the other western.

It is called meridian, from the Latin *meridies*, noon, or mid-day, because when the sun is in this circle, it is noon in those places situated under it.

MERIDIAN, in *Geography*, is a great circle, as P A Q D, (Plate 1. *Geography*, fig. 9.) passing through the poles of the earth P and Q: and any given place at Z. So that the plane of the terrestrial meridian is in the plane of the celestial one.

Hence, 1, as the meridian invests the whole earth, there are several places situated under the same meridian. And, 2, as it is noon-tide whenever the centre of the sun is in the meridian of the heavens; and as the meridian of the earth is in the plane of the former; it follows, that it is noon at the same time, in all places situate under the same meridian. 3. There are as many meridians on the earth as there are points conceived in the equator. In effect, the meridians always change, as you change the longitude of the place; and may be said to be infinite; each respective place from east to west having its respective meridian.

MERIDIAN, *Firß*, is that from which the rest are accounted, reckoning from west to east. The first meridian is the beginning of longitude.

The fixing of the first meridian is a matter merely arbitrary; and hence different persons, nations, and ages, have fixed it differently; whence some confusion has arisen in geography. The rule among the ancients was, to make it pass through the place farthest to the west that was known. But the moderns knowing that there is no such place in the earth as can be esteemed the most westerly, the way of computing the longitudes of places from one fixed point is much laid aside.

Ptolomy assumed the meridian that passes through the farthest of the Canary islands as his first meridian; that being the most western place of the world then known. After him, as more countries were discovered in that quarter, the first meridian was removed farther off. The Arabian geographers chose to fix the first meridian upon the utmost shore of the western ocean. Some fixed it to the island of St. Nicholas, near Cape Verd; Hondius to the isle of St. James; others to the island of Del Corvo, one of the

Azores; because on that island the magnetic needle, at that time, pointed directly north, without any variation; and it was not then known that the variation of the needle is itself subject to variation. The latest geographers, particularly the Dutch, have pitched on the Pike of Teneriffe; others on the isle of Palm, another of the Canaries; and, lastly, the French, by command of their king, on the island of Ferro, another of the Canaries.

But, without much regard to any of these rules, our geographers and map-makers frequently assume the meridian of the place where they live, or the capital of their country, for a first meridian; and thence reckon the longitudes of their places.

The astronomers in their calculations usually choose the meridian of the place where their observations are made, for their first meridian; as Ptolemy, at Alexandria; Tycho Brahe, at Uranibourg; Riccioli, at Bologna; Mr. Flamsteed, at the Royal Observatory at Greenwich; and the French, at the Observatory at Paris.

MERIDIAN of a Globe, or Sphere, is the brazen circle in which the globe hangs and turns. See **GLOBE**.

It is divided into four nineties, or three hundred and sixty degrees, beginning at the equinoctial: on it, each way, from the equinoctial, on the celestial globe, is counted the fourth and north declination of the sun or stars; and on the terrestrial globe, the latitude of places north and south. There are two points on this circle, called the *poles*; and a diameter, continued from thence through the centre of either globe, is called the axis of the earth, or heavens, on which they are supposed to turn round.

On the terrestrial globes there are usually thirty-six meridians drawn, one through every tenth degree of the equator, or through every tenth degree of longitude.

The uses of this circle are, to set the globes to any particular latitude, to shew the sun's or a star's declination, right ascension, greatest altitude, &c.

MERIDIAN Line, an arc, or part of the meridian of the place, terminated each way by the horizon.

Or, a meridian line is the intersection of the plane of the meridian of the place with the plane of the horizon, vulgarly called a *north and south line*, because its direction is from one pole towards the other.

The use of a meridian line in astronomy, geography, dialling, &c. is very great, and on its exactness all depends; whence infinite pains have been taken by divers astronomers to fix it to the utmost precision. M. Cassini has distinguished himself by a meridian line drawn on the pavement of the church of S. Petronio, at Bologna, the largest and most accurate in the world; being 120 feet in length. In the roof of this church, a thousand inches above the pavement, is a little hole, through which the sun's image, when in the meridian, falling upon the line, marks his progress all the year. When finished, M. Cassini, by a public writing, informed the mathematicians of Europe, of a new oracle of Apollo, or the sun, established in a temple, which might be consulted, with entire confidence, as to all difficulties in astronomy. See **GNOMON**.

To draw a Meridian Line.—Knowing the fourth quarter pretty nearly, observe the altitude FE (*Plate XVII. Astronomy, fig. 3.*) of some star on the eastern side thereof, not far from the meridian HZRN: then, keeping the quadrant firm on its axis, so as the plummet may still cut the same degree, only directing it to the western side of the meridian, wait till you find the star has the same altitude as before, *f, e.* Lastly, bisect the angle E C e, formed by the intersection of the two planes wherein the quadrant

is placed at the time of the two observations, by the right line H R. This H R is a meridian line.

Or thus: on the horizontal plane, from the same centre C (*fig. 4.*) describe several arcs of circles BA, *ba*, &c. and on the same centre, C, erect a style, or gnomon, perpendicular to the plane A C B, a foot or half a foot long. About the twenty-first of June, between the hours of nine and eleven in the morning, and between one and three in the afternoon, observe the points B, *b*, &c. A, *a*, wherein the shadow of the style terminates. Bisect the arcs A B, *ab*, &c. in D, *d*, &c. If then the same right line D E bisect all the arcs A B, *ab*, &c. it will be the meridian line sought.

As it is difficult to determine the extremity of the shadow exactly, it is best to have the style flat at top, and to drill a little hole, noting the lucid spot projected by it on the arcs A B and *ab*, instead of the extremity of the shadow. Otherwise the circles may be made with yellow, instead of black, &c.

A good meridian line for regulating clocks and watches may be had by the following method: make a round hole, almost a quarter of an inch in diameter, in a thin plate of metal; and fix the plate in the top of a fourth window in such a manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can guess; for then the plate will face the sun directly at noon on the equinoctial days. Let the sun shine freely through the hole into the room, previously darkened; and hang a plumb-line to the ceiling of the room, at least five or six feet from the window, in such a place as that the sun's rays, transmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the said place on the ceiling, take away the line. Having adjusted a sliding-bar to a dove-tail groove, in a piece of wood about eighteen inches long, and fixed a hook into the middle of the bar, nail the wood to the above-mentioned place in the ceiling, parallel to the side of the room in which the window is; the groove and bar being towards the floor. Then hang the plumb-line upon the hook in the bar, the weight or plummet reaching almost to the floor: when this is done, find the true solar time, and thereby regulate your clock or watch. Then, at the moment of next noon by the clock, when the sun shines, move the sliding-bar in the groove until the shadow of the plumb-line bisects the image of the sun on the floor, wall, or on a white screen placed on the north side of the line; the plummet, or weight at the end of the line, hanging freely in a pail of water, placed below it on the floor. By repeated corrections, on the following days, with the sun and clock, this method may be brought to a very great exactness. This meridian line will not only be sufficient for the regulation of clocks and watches, to the true mean time, by equation tables, but also for most astronomical purposes. Ferguson's *Lect. on select Subjects*, &c. *lect. x.*

Several authors have invented particular instruments and methods for the describing of meridian lines, or rather for determining equal altitudes of the sun in the eastern and western parts of the heavens; as Mr. Grey, Dr. Derham, &c. in the *Philosophical Transactions*. But as the former of the methods above delivered suffices for astronomical observations, and the latter for more ordinary occasions, we shall forbear to give any descriptions of them.

From what has been shewn, it is evident, that whenever the shadow of the style covers the meridian line, the centre of the sun is in the meridian; and, therefore, it is then noon. And hence the use of a meridian line in adjusting the motion of clocks, &c. to the sun.

Hence .

Hence also, if the meridian line be bisected by a right line O V, drawn perpendicularly through the point C, O V will be the intersection of the meridian, and first vertical; and, consequently, O will shew the east point, and V the west.

Lastly, if a style be erected perpendicularly in any other horizontal plane, and a signal be given when the shadow of the style covers the meridian line drawn in another plane, noting the apex, or extremity, of the shadow projected by the style, a line drawn from that point through that wherein the style is raised, will be a meridian line.

One meridian line being given, another may be drawn upon another horizontal plane by the following method: hang a thread with a plummet exactly over the south end of the meridian line given, and another thread with a plummet over the south end of the plane upon which the meridian line is to be drawn; let one person observe at noon the moment when the shadow of the first thread falls exactly upon the meridian given, and let another observer, at the same time, mark two distant points in the shadow of the second thread: a line drawn through those points is the meridian line required. By the same method may a meridian line be found upon a south wall, by making two points in the shadow of a thread hung at a little distance from it: if the meridians are near, he that observes the shadow of the first thread, may let the other know the moment it falls upon the meridian line, by saying *now*: if they are far distant, it should be done by the motion of the hand, because sound takes some time to pass from one place to another. The meridian line is the basis of astronomical observations: a meridian line being found, there may be placed over it a quadrant or sextant in such a manner, that though it be moved up or down to give it different elevations, in order to view through the sights of it the celestial bodies at their different altitudes; yet the plane of that side of the instrument upon which the degrees are marked shall continue all the while in the plane of the meridian. Of this kind is the mural arc in the royal observatory at Greenwich. See **MERIDIAN Altitude**.

MERIDIAN Line, on a dial, is a right line arising from the intersection of the meridian of the place with the plane of the dial. This is the line of twelve o'clock, and from hence the division of the hour-line begins.

MERIDIAN, Magnetical, is a great circle, passing through or by the magnetical poles; to which the magnetic needle, or needle of the mariner's compass, if not otherwise hindered, conforms itself.

MERIDIAN Altitude of the sun or stars is, their altitude when in the meridian of the place where they are observed. See **ALTITUDE**.

To take the Meridian Altitude of the Stars.—Astronomers make two principal kinds of observations of the stars, the one when they are in the meridian, and the other when in vertical circles.

For meridian observations there are two instruments principally used, the quadrant and gnomon.

To take the Meridian Altitude with a Quadrant.—If the position of the meridian be known, and the plane of an astronomical quadrant be placed in the meridian line, by means of the plumb-line suspended at the centre, the meridian altitudes of the stars, which are the principal observations whereon the whole art of astronomy is founded, may easily be determined.

The meridian altitude of a star may likewise be had by means of a pendulum-clock, if the exact time of the star's passage by the meridian be known. Now it must be observed, that the stars have the same altitude for a minute

before and after their passage by the meridian, if they be not in or near the zenith; but if they be, their altitudes must be taken every minute, when they are near the meridian; and then their greatest altitudes will be the meridian altitudes sought.

As to the manner of observing, it is found very difficult to place the vane of the quadrant in the meridian exact enough to take the meridian altitude of a star; for, unless there be a convenient place, and a wall, where the quadrant may be firmly fastened in the plane of the meridian, which is not easily had, we shall not have the true position of the meridian proper to observe the stars. It will be much easier, therefore, on several accounts, to use the portable quadrant, by which the altitude of the star may be observed a little before its passage over the meridian, every minute, till its greatest altitude be found. Here, though we have not the true position of the meridian by this means, yet we have the apparent meridian altitude of the star.

Though this method, in the general, be very good, and free from any sensible error; yet, in case a star passes by the meridian near the zenith, it proves somewhat defective: for in these kinds of observations, the inconvenient situation of the observer, the variation of the star's azimuth several degrees in a little time, the alteration of the instrument, and the difficulty of replacing it vertically, will prevent the observations being made oftener than in every four minutes; but in each minute the altitude varies about 15 minutes of a degree, so that there will be the difference of a degree in the star's altitude between each observation. In such cases, therefore, it will be better to have the true position of the meridian, or the exact time wherein the star passes the meridian, in order either to place the instrument in the meridian, or to observe the altitude of the star the moment it passes the meridian.

To find the Meridian Altitude of the Sun, &c. by a Gnomon, see **GNOMON**. By other means, see **ALTITUDE**.

MERIDIAN Telescope. See **TELESCOPE**.

To measure the Degrees of the Meridian, see **DEGREE**.

To observe the Transits or Passages of the heavenly Bodies across the Plane of the Meridian.—A meridian line being found, hang two threads with plummets exactly over it, at a little distance from one another, and they will be in the plane of the meridian: if you place your eye close to one of the threads in such a manner that you make it cover the other, and both appear as one thread; when a star is behind the threads, it is in the meridian. By the same method the sun may be viewed through a smoked glass; when the threads pass through his centre, he is in the meridian: but the best way of observing the sun, moon, stars, or planets, is through a telescope placed in the meridian, with two cross hairs, one of which is in a vertical, the other in a horizontal position; when the vertical hair passes through the centre of the sun, he is in the meridian.

MERIDIAN, from *Meridies*, the hour for sleeping, which was allowed to the ancient monks, in this and other countries, about noon, during the summer months.

MERIDIANI, in *Antiquity*, is a name which the Romans gave to a kind of gladiators, who entered the arena about noon, after the bestiarii (who fought in the morning against beasts) had finished. See **GLADIATOR**.

They were thus called from *meridies*, i. e. *noon*, the time when they exhibited their shows.

The meridiani were a sort of artless combatants, who fought man with man, sword in hand: hence Seneca takes occasion to observe, that the combats of the morning were full of humanity, compared with those which followed.

MERIDIONAL DISTANCE, in *Navigation*, the same with departure, or casting and wetting; being the difference of longitude between the meridian, under which the ship now is, and any other meridian, which she was under before.

MERIDIONAL Parts, Miles, or Minutes, are the parts by which the meridians in a Mercator's chart increase, as the parallels of latitude decrease.

The cosine of the latitude of any place being equal to the radius, or semidiameter, of that parallel; therefore, in the true sea-chart, or nautical planisphere, this radius being the radius of the equinoctial, or whole sine, of 90 degrees, the meridional parts at each degree of latitude must increase, as the secants of the arc contained between that latitude, and the equinoctial decrease.

In order to understand this, it is necessary to consider, 1. That the distance between any two meridians at the equator is to their distance in any parallel of latitude as radius is to the cosine of that latitude. Let P D F E (*Plate I. Navigation, fig. 8.*) represent the fourth part of a sphere; E being the centre, P the pole, E D the radius of the equator, A B the radius of a parallel of latitude: then each of the arcs P B D, P C d, will represent a quadrant of a meridian; D d an arc of the equator; and B C an arc of a parallel of latitude: D B expresses the latitude, and P B the complement of the latitude, whose right sine is B A. But the circumference of a circle, whose radius is E D, is to the circumference of a circle, whose radius is A B, and consequently like arcs D d, B C, intercepted between the same two meridians, as E D is to A B, *i. e.* as radius to the cosine of the latitude. Whence it is easy to construct a table shewing in what proportion the degrees of longitude diminish in every latitude. See such a table under article **DEGREE of Latitude**.

2. Any part of a parallel of latitude is to a like part of a meridian, as radius is to the secant of the latitude of that parallel. Let P D E (*Plate I. Navigation, fig. 9.*) represent a quadrant of a meridian, where P is the pole, and D E the radius of the equator; A B is the radius of a parallel of latitude, or the cosine of the latitude, whose sine is B F, and secant E C. Then E F : E B :: E D : E C; or cosine latitude: rad. : : rad.: secant of the latitude, in that parallel. Therefore, part of a parallel of latitude is to a like part of the equator as the radius is to the secant of the latitude to that parallel: consequently, since like parts of the meridian and equator are equal, as great circles, any part of a parallel of latitude is to a like

part of a meridian, as radius to the secant of the latitude to that parallel.

3. The distance of any parallel of latitude, A, from the equator, is expressed by the sum of the secants of all the arcs between the equator and that parallel. For, as radius to the secant of the latitude A, so is a diminished degree of longitude in the latitude A, or a degree of that parallel, to a degree of the meridian: but the degrees of latitude, or of the meridian, are to be lengthened in proportion as the degrees of longitude decrease: therefore, as radius to the secant of the latitude A, so is a natural degree of the meridian to a lengthened degree in the latitude A, radius being here as unity, and one natural degree as unity also: therefore, the length of a degree in any latitude is as the secant of that latitude, or may be expressed by that secant: but the distance of any parallel from the equator is the sum of all the successive arcs between the equator and that parallel: consequently, the distance of that parallel is expressed by the sum of the secants of all these arcs between the equator and that parallel of latitude: and, therefore, by the addition of the secants of small arcs, the distances of the parallels of latitude from the equator are obtained.

The tables, therefore, of meridional parts, in books of navigation, are to be made by a continual addition of secants, calculated in some books, as in sir Jonas Moor's Tables, Robertson's Navigation, &c. for every degree and minute of latitude; and these will serve either to make or graduate a Mercator's chart, or to work the Mercator's sailing.

Mr. Wright, to whom we are indebted for this excellent discovery, made his table for the division of the nautical meridian, or the table of meridional parts, as follows: the meridional parts for 1 minute he made equal to the secant of 1 minute; those of 2' equal to the sum of the secants of 1' and 2'; those of 3' equal to the sum of the secants of 1', 2', and 3'; those of 4' equal to the sum of the meridional parts of 3' and the secant of 4'; and so on by a constant addition of the secants: Mr. Oughtred, sir Jonas Moor, Dr. Wallis, Dr. Halley, and others, have endeavoured to find methods of constructing these tables with greater accuracy than by the addition of the secants to every minute. As the reader may not have immediate access to such a table, we have here annexed one, extracted from Robertson's "Elements of Navigation."

The following is a Table of meridional parts to every degree and minute of the quadrant, established on a supposition that the earth is a perfect sphere.

MERIDIONAL PARTS.

min.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	min.					
D. l.	78	79	80	81	82	83	84	85	86	87	88	89	D. l.

N.B. In this table D. l. stands for degree of lat. and M. P. for meridional parts. In using it, seek the degrees of latitude at the top or bottom, and the minutes in the right or left hand columns; and the corresponding meridional parts will stand right against the minutes, and in the column signed with the degree proposed.

Having the latitude of two places, to find the meridional miles or minutes between them; consider whether the places be one under the equinoctial, and the other wide of it; or the one on the one side of the equinoctial, and the other on the other; or whether they both lie on the same side.

If one place lie under the equator, the meridional minute next under the degree of latitude of the other place, is the meridional difference of latitude, or latitude enlarged. If one be in north, and the other in south latitude, the meridional minutes, corresponding to the two latitudes, added together, give the meridional minutes between them.

Both places lying towards the same pole, subtract the meridional parts answering to the less latitude from those of the greater, the remainder gives the meridional minutes. See SAILING.

In the Philosophical Transactions, No. 219, Dr. Halley has given a very curious paper relating to the division of the nautical meridian, by a quite different method from Mr. Wright's; and containing a method of performing the problems of sailing according to the true chart, by the help of Briggs's, or the common table of logarithmic tangents, without a table of meridional parts. Dr. Halley avails himself of a principle, first accidentally discovered by Mr. Henry Bond, and published about the year 1645, that the meridian line was analogous to a scale of logarithmic tangents of half the complements of the latitude. This analogy was first demonstrated by Mr. James Gregory, in his "Exercitationes Geometricæ," published in 1688, and more elegantly and concisely by Dr. Halley himself; who has also shewn (ubi supra) how to apply this analogy, by means of any system of logarithms, for computing the interval of the meridional parts answering to any two given latitudes. The reader may find this subject well illustrated by Mr. Robertson in his Elements of Navigation, book viii. p. 142, &c. See also Phil. Transf. vol. xlvi. p. 559, &c.

To find the meridional parts to any spheroid, with the same exactness as in a sphere.

Let the semi-diameter of the equator be to the distance of the focus of the generating ellipse from the centre, as m to 1. Let A represent the latitude for which the meridional parts are required, s the sine of the latitude, the radius being unit; find the arc B , whose sine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B , from the common tables; subtract this logarithmic tangent from 10.000000, or the logarithmic tangent of 45° : multiply the remainder by $\frac{7915.7044678978}{m}$, &c. and the product

subtracted from the meridional parts in the sphere, computed in the usual manner for the latitude A , will give the meridional parts expressed in minutes for the same latitude in the spheroid, provided it be oblate.

Example:—If $m : 1 :: 1000 : 22$, then the greatest difference of the meridional parts in the sphere and spheroid is 76.0929 minutes; in other cases it is found by multiplying the remainder above mentioned by 1174.078.

When the spheroid is oblong, the difference of the meridional parts in the sphere and spheroid, for the same

latitude, is then determined by a circular arc. Phil. Transf. No. 461. sect. 14. See also Maclaurin's Fluxions, art. 195—899.

Mr. Murdoch has solved this problem by infinite series, and has computed a table of meridional parts for an oblate spheroid, such as is mentioned in the foregoing example. See his treatise, intitled "Mercator's Sailing applied to the true Figure of the Earth," Lond. 1741, 4to. See the article DEGREE.

MERJEIAH, in *Geography*, a town of Algiers; 80 miles E. of Oran.

MERIGHI, LA SIGNORA, in *Biography*, was announced in Handel's advertisements, on his return from Italy in 1729, where he had been to engage singers, as "a woman of a very fine presence, an excellent actress, and a very good singer, with a counter-tenor voice." We find afterwards, however, that she was only engaged as second woman under the Strada.

MERJIAN, in *Geography*, a town of Persia, in the province of Kerman; 55 miles N. of Kabis.

MERIM, a large lake of S. America, in Paraguay, near the coast of the S. Atlantic ocean. At the S. end stands fort St. Miguel, and at its northern extremity fort Mangaveira. Parallel to it, and between it and the ocean, is another lake nearly as long. The forts command the extremities of the peninsula.

MERIMEG, or MARAMAG, a large river of Louisiana, which runs into the Mississippi, below the mouth of the Missouri.

MERINDAPILLY, a town of Hindoostan, in Baramaul; 25 miles N.W. of Darempoury.

MERINO-SHEEP, in *Agriculture*, a breed of fine-woolled sheep lately introduced from Spain, hence sometimes termed the *Spanish breed*. They are characterised by the males having horns, but the females being sometimes without them, by having white faces and legs, the latter rather long, the body not very perfect in shape, fine in the bone, some degree of throatiness, the pelt fine and clear. The weight, when fattened in some degree, in the rams about 17lbs., in the ewes 11lbs. the quarter. The wool is very fine. They are said to be hardy, and to have the property of fattening in a pretty expeditious manner. See MESTA, and SHEEP.

MERION, UPPER and LOWER, in *Geography*, two townships of America, in Montgomery county, Pennsylvania; the first has 993, and the latter 1422 inhabitants.

MERIONETHSHIRE, one of the counties of North Wales, is bounded on the W. by the extensive bay of Cardigan, which forms part of the Irish sea; on the N. by Denbighshire and Caernarvonshire; on the E. by Montgomeryshire; and on the S. by the river Dovey, which divides it from Cardiganshire. This county extends in length, from Beddgelert, near Snowdon, to Bwlch y Vedwen, on the confines of Montgomeryshire, 43 miles; in breadth, from Harlech to the extreme boundary of Llangollen parish, 38. It is called by the natives Meironydd, and is the only county in Wales which, with the addition of the word shire, still retains its ancient appellation. This name is said to be derived from Meirion, the son of Tibravn, and grandson of Cunedda, a distinguished British chieftain of the fifth century, who, having assisted the Welsh in rescuing their country from the depredations of a band of Irish marauders, received from them a large extent of territory as the reward of his services.

The early history of this county is equally as obscure as that of any other in Wales. That it was known to the Romans is evident from the many vestiges of their customs which are yet to be discovered in different parts of it. Of these the

MERIONETHSHIRE.

the principal are, the fortifications of Tommen-y-Bala, near Bala town; Caer-Gai, in the vicinity of Llanuwchllyn; Cefn-Carr, in the parish of Penul, and Tommen-y-Mur, near Fellinglog. The Roman road, denominated Sarn-Helen, can easily be traced from the fine station last mentioned, stretching itself towards Dinas Emrys, Caernarvonshire. From this road two branches appear to have struck off in this neighbourhood, one of which led to Conovium, and the other to Segontium. During the Saxon and Norman dynasties, history is nearly silent concerning Merionethshire, but the numerous fortifications which cover its hills plainly evince that it did not in these ages escape the ravages of war. At a later period it was the scene of many of the daring exploits of the celebrated Owen Glyndyr, who so vigorously espoused the cause of the unfortunate Richard II.

The general aspect of Merionethshire differs in some respects from that of the other counties in North Wales. For the most part it is extremely mountainous, but its mountains are less elevated, with the exception of a few points, than those of the adjacent county of Caernarvon. The highest hill, however, called Cader-Idris, is inferior in height only to Snowdon. This mountain, according to tradition, was so called from being the favourite seat of Idris, who was a great prince, poet, astronomer, and philosopher in ancient times. Its highest peak is said to be two thousand eight hundred and fifty feet above the level of the town of Dolgellau, which is situated near its base. The other principal eminences are Aren-Vowdhwy, Aren-Benllyn, Aren-nig, Moelwyn, Manod, &c.: these rear their lofty heads over a profusion of lower hills, which are intersected by some beautiful vallies, and are interspersed with woods, lakes, rivers, rivulets, and cataracts.

The principal river in this county is the Dee, which takes its rise from several springs on the declivity of the lofty Aren. These quickly uniting their streams enter the lake, called by the Welsh Llyn-tegid, and by the English Pimblemeer, and from thence flow through the beautiful vale of Ederion, towards Corwen, a little below which town it enters Denbighshire. The Dee, in its course through this county, forms several fine cataracts. That called Rhaiadrdu, or the Black-Cataract, from the colour of its waters, is situated in the vicinity of Dolgellau, and is a double fall about sixty feet in height, where the river dashes rapidly over a series of black rugged rocks, which are covered in many places with white lichens, and thus give a peculiar appearance to the scene. The other rivers of importance besides the Dee are the Maw or Mawddach, the Dovey or Duff, and the Glaslyn and Dwyrid, the two last of which form a junction, and passing Traeth-Mawr and Traeth-Bychan, empty their waters into the Irish sea. There is in this county a variety of lakes: the principal ones are Llyn-tegid near Bala, and Llyn-Tallyllyn at the southern foot of Cader Idris.

From the mountainous nature of Merionethshire it may naturally be supposed that it is not destined to reach any high degree of agricultural improvement. Mr. Davies, in his enlightened Survey of North Wales, estimates the number of acres in the whole county at 430,000, and states that out of these not above 146,000 acres are inclosed. The soil is various, but in general extremely poor. The hilly districts, where covered with soil, are in general too steep and rugged to admit of culture. By far the greater proportion of the low grounds consists of peat earth, forming bogs and turbaries. In some few places attempts have been made by different individuals to bring a part of these waste lands into cultivation, but their progress has by no means answered

their expectations, though some advantages have certainly been gained. The attention of the inhabitants therefore is chiefly directed to the rearing and feeding of cattle, sheep, and goats, of which a great number are exchanged for the commodities of more fertile, or more commercial districts. The cultivated spots lie chiefly on the sea-coast, and on the skirts of the county. In the vallies, and on the sides of the hills, in many parts there appear considerable plantations of wood, both natural and raised by art.

Notwithstanding the apparently favourable character of this county for the productions of the mineral kingdom, it is remarkable that few mines of any importance have been discovered in it. The district abounds indeed with numerous veins, both of lead and copper ore, but they are generally either so peculiarly placed, or so limited in extent, as to deprive the adventurer of any fair prospect of remuneration for the expence and trouble of opening them. Sulphat of copper, in particular, is found at Aberdyfo, and at Buddugr and Clogiau mines near Dolgellau. The two latter are the principal in Merionethshire, and perhaps the only ones which are wrought with any degree of spirit or profit. At Moel-Isfri, in the parish of Llanelyd, Pont-yr-avonddu, Buleh-y-plwm, and Craig-wen, near Dinas-mowddwy, are the chief veins of lead. The same metal also abounds at Melin, Illyw-y-pair, in the parish of Tywyn, and at Bryndinas, near Dyffryn-gwyn.

This county possesses no iron ores, and can only boast of one insulated white lime rock at Gwerclas, near Corwen, in which about 50,000 bushels are annually burnt. Merionethshire affords no coal, so that peat forms the chief article for fuel.

But if the practical miner does not discover here such exhaustless stores of useful metals as he might be led to expect upon a general view of the county, the scientific mineralogist will find ample materials for the illustration of his geological inquiries. The lofty mountain of Cader-Idris possesses numerous peculiarities, both of structure and composition; and affords several facts tending to support the Huttonian hypothesis. This eminence is the commencement of a chain of primitive mountains, which extend in a north-north-easterly direction towards the Arens and Arenig. It is extremely steep, and more craggy than the hills of secondary formation which surround it, and consists of siliceous porphyry, quartz, and feldspar, inclosed in a green paste, with siliceous schistose porphyry, intersected with veins of quartz and argillaceous porphyry in a mass, and a dark grey paste. Besides these species, some of the rocks likewise contain the component parts of granite and porphyry, together with the granitell in mass of Mr. Kirwan, composed of quartz and schorl. On the sides of the mountain lie a considerable quantity of stones, resembling lava; and hence some writers suppose it to have been at one time volcanic. But this supposition is unquestionably erroneous. The porous appearance of these stones has arisen from the circumstance of the feldspar which intersected the quartz having been decomposed. On the south side of the mountain, and near its apex, is a large lake, from which the rocks rise almost perpendicularly. On the north side is another lake: and at the summit is a mass of large stones, called Idris's chair. See Aikin's Tour in Wales.

In a level part of the county, called Towyn Meironydd, rises a very singular rock of immense size, and terminating in a conical form. Quartz constitutes the chief matrix of the lead and copper ores here. In some places several veins consist entirely of this mineral upon the surface. A line of dark coloured argillaceous limestone can be traced in a south-western direction, stretching through the whole extent of

the county to Cadair-Ddinmael, near Cerrig-Druidion. This lime is of little value, either as a cement or a manure.

Besides the Roman roads already mentioned, Merionethshire contains many interesting monuments of remote ages. Above Nannua, in the neighbourhood of Dolgellau, on a rocky eminence, is a vast collection of loose stones, which have evidently formed the rampart of a British post. The hill on which these stones are placed is emphatically denominated Moel-orthwm, or the hill of oppression. The remains of a castle, formerly of great strength and extent, occupy the top of the insulated rock near Towyn-Meirionydd, already noticed. It appears to have stretched longitudinally over the whole surface of the summit. One of the apartments, thirty feet in diameter, is excavated in the rock. In some parts, the lines of circumvallation consist of stones loosely piled on the edges of the precipices, but on other parts appear well built walls of squared stones, cemented with mortar composed of calcined shells and gravel. According to Mr. Pennant, this castle was anciently called Castle-bere, and was granted by Edward I. to the custody of Robert Fitzwalter. The same author likewise supposes, from its present name Teberri, that it may have been the fortrefs belonging to the last Llewellyn, which was taken only a short time previous to the final conquest of Wales by William de Valence, earl of Pembroke. This conjecture, however, is extremely questionable. St. Cadwan's stone, in the church-yard of Towyn, is traditionally reported to have been erected, in honour of that saint, in the sixth century. In the parish of Llanelltyd are the ruins of Cynmer-abbey, founded by two Welsh princes in 1198. On the mountain called Mikneint, near Rhyd-ar-Helen, stand some remarkable stone monuments, at least thirty in number. Each separate grave has four stones, one at each corner, resembling small square pillars, two or three feet high, and about nine inches broad. Tradition says they serve to commemorate some persons of note, who fell in the battle fought here between the men of Dyffryn-Ardwdwy, and some of Denbighshire. A considerable number of similar monuments are found likewise in the parish of Trawsfynudd. Several stone circles appear in the vicinity of these graves, the largest about fifty-two feet in diameter, and a vast carnedd, with two upright stones; also several smaller circles, the whole apparently surrounded by one of much greater circumference. Near Rhuw-goch is a small fort, in a singular position, on a circular isolated rock, resembling an artificial mount, between the hills, evidently intended for the defence of the pass. Some persons have supposed that this was of British construction, but the regularity of its facings, and the numerous coins which have been found in its neighbourhood, seem to imply that it was of Roman formation. Besides, in the inclosed country immediately adjacent, is a large encampment, undoubtedly the work of that illustrious people. This commands a variety of passes, which are defended by minor posts. At one extremity of the vale of Maentwrog is a large upright stone, called Maen-twrog, which is supposed to be the monument of a saint so named, who was contemporary with St. Beuno. The large artificial mount called Tomen-y-Bala, near the lake of Bala, is supposed to have been originally Roman, but afterwards to have been occupied by the Welsh during their conflicts with the English. Situated on an eminence fronting the town of Corwen, is the British post called Caer-Drewin, which consists of a circular wall, about a mile and a half in circumference, and is supposed by Mr. Pennant to have been one of those strong holds in which the Welsh secured their families and their property, in the event of an invasion. Lyttelton conjectures that Owen Gwynedd occupied this post, while Henry II. encamped on

the opposite side of the vale, from whence however he was forced to return to England in chagrin, without being able to strike a single blow. It was afterwards the retreat of the brave and heroic Owen Glyndwr, whose memory continues to be highly revered by the inhabitants of the surrounding district. Harlech castle has been already described under the word HARLECH. This county is not distinguished for its manufactures; but at Bala and Dolgellau, some strong cloths, druggets, kerfimeres, flannels, &c. are made. Bala is particularly noted for its stockings and wigs.

The political divisions of this county have varied at different periods. At present it comprehends five comots, or hundreds, *viz.* Ardwdwy, Penllyn, Estumaner, Edernion, and Talybont; 37 parishes, and seven market-towns; *viz.* Harlech, Bala, Dolgellau, Dinas-y-Mowddu, Corwen, Tywen or Towyn, and Barmouth. Harlech, the county-town, is but a poor place, though governed by a mayor. Barmouth is the only port in the county. Dolgellau is distinguished as the place where the summer assizes are held, and is perhaps the most thriving town in Merionethshire. Bala is likewise a thriving town. Dinas-Mowddu, although now a mean town, was anciently a fortified city, and the residence of a Welsh prince or chieftain. It is still a corporate town, with a mayor, alderman, recorder, and several burgesses. The mayor has the right of trying criminals, but of late years that privilege has not been put in practice. He still, however, retains all the insignia of his magisterial office. Besides these towns there is a variety of villages dispersed through different parts of the county. Of these, Festiniog and Mallwyd are remarkable for the beauty of their situations, and noble prospects which they command. Festiniog has been celebrated by several authors, but more especially by lord Lyttelton. The vale in which this stands has been compared to the celebrated vale of Tempe, and it must be confessed that few spots in this island can boast of such varied and romantic scenery.

According to the parliamentary return of 1801, this county contained 5980 houses, and 29,506 inhabitants, of whom 13,896 were males, and 15,610 females. The number engaged in agriculture was 10,308, and in commerce and manufactures 2711. Pennant's Tour in Wales. Carlisle's Topographical Dictionary of Wales. Aikin's Tour in Wales.

MERIS, *μερίς*, a part, in *Music*, an appellation given by Mr. Sauveur to the forty-third part of an octave. See Mem. Acad. Scienc. 1701.

MERISMA, in *Botany*, from *μερισμοεις*, a division, alluding to the divided or branched nature of this fungus.—Perf. Syn. 582.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. Branching, leathery, compressed, even; for the most part hairy at the top.

This genus consists of seven species in Perfoon, differing from *Clavaria* chiefly in their compressed dilated form, for the hairiness is avowedly not constant. Examples may be seen in

M. cristatum. Perf. n. 3. (*Clavaria laciniata*; Bull. t. 415. f. 1. Sowerb. t. 158.)—Somewhat decumbent, incrusting other plants, pale; its branches lacinated, tumid, rugose. Found in woods, running over every thing that comes in its way, like a stalactitical concretion, and throwing out variously dilated, sharply jagged, fan-like branches. The whole is of a pale whitish hue, and faint smell and taste.

M. fatidum. Perf. n. 7. (*Clavaria anthocephala*; Bull. t. 452. f. 1. Sowerb. t. 156)—Purplish-brown. Branches palmate, crowded, whitish and polished at their tips.—Not infrequent on the ground in fir woods. It is of a tough

woody texture, and about two inches high, of a nauseous scent when fresh. The whole is of a palmate figure, stalked, with many crowded, fan-like branches, various in diameter, whitish at their summits, which are abrupt and notched.

MERIT, in *Theology*, is used to signify the moral goodness of the actions of men, and the reward due to them.

The Romish schoolmen distinguish two kinds of merit towards God: the one of *congruity*, the other of *condignity*.

MERIT of *Congruity* is when there is no just proportion between the action and the reward; but he who bestows the reward supplies, by his goodness or liberality, what was wanting in the action. Such is the merit of a son towards his father: but this is only merit in an improper sense.

MERIT of *Condignity* is when there is an absolute equality and a just estimation between the action and the reward: as in the wages of a workman.

Those of the reformed religion disclaim all merit of condignity towards God; even their best works, they own, do not merit at his hands. Hence the doctrine of condign merits makes one of the great articles of controversy between the Romish and reformed churches.

MERIT, *Order of*, was instituted by Frederick, king of Prussia. The ensign of the order is a star of eight points enamelled blue, and edged with gold; on the centre the letters F.R. in a cypher; in each angle an eagle displayed fabule; on the upper two points, the regal crown of Prussia; on the reverse, in enamel, this motto, POUR LE MERITE. It is worn round the neck, pendent to a black ribbon, edged with silver.

MERIT, *Military Order of*, in Hesse Cassel, was instituted by the late landgrave. The badge is a gold star of eight points enamelled white; on the centre this motto, VIRTUTE ET FIDELITATE. It is worn at the button-hole, pendent to a blue ribbon, edged with silver.

MERIT, *Military, the Order of*, was instituted in France, in the year 1759, by Louis XV. in favour of those officers of his army who were Protestants. The marks of honour are the same with those of the order of *St. Louis*. The ensign of the order is also of the same form as that of *St. Louis*, with this difference, that on one side is "a sword in pale," within this motto, PRO VIRTUTE BELLICA: and on the reverse is a chaplet of laurel: within this inscription, LUD. XV. INSTITUIT, 1759.

MERKA, in *Geography*, a town of Prussia, in the palatinate of Culm; 10 miles N.N.E. of Thorn.

MERKENDORF, a town of Germany, in the margravate of Anspach; 7 miles S.E. of Anspach.

MERKET ISLANDS, a cluster of small islands in the Red sea, near the coast of Arabia. N. lat. 18° 10'.

MERKLIN, a town of Bohemia, in the circle of Pilsen; 15 miles S.S.W. of Pilsen.

MERLANGUS, in *Ichthyology*, a name given by Belonius and some other authors, to a small species of whiting, or *afellus mollis*, called by the Venetians *mollo*, and by some other nations the *capelon*. See *GADUS minutus*.—Also, the name of the common whiting, a species of *Gadus*; which see.

MERLENGO, in *Geography*, a town of Italy, in the department of the Mincio; 10 miles N. of Mantua.

MERLERA, a small island in the Mediterranean, four miles from cape Sidero, on the N. coast of Corfu.

MERLERAULT, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; 18 miles N.N.E. of Alençon. The place contains 1222, and the canton 8098 inhabitants, on a territory of 177½ kilometres, in 19 communes.

MERLIN, AMBROSE, in *Biography*, a British writer,

who flourished in the fifth century, was regarded as a prophet and magician. Strange stories are told of him by ancient writers, some of whom have assumed that he conveyed by enchantment the stupendous stones on Salisbury plain from Ireland. There are likewise certain extravagant predictions that pass under his name, printed at Paris in 1530. Near Caermarthen is a mount called Merlin's Hill, beneath which it is said the prophet was buried.

MERLIN, in *Ornithology*, the name of the yellow-legged falcon. See *FALCO Æfalon*.

MERLINGEN, in *Geography*, a town of Switzerland, in the canton of Bern; 7 miles S.E. of Thun.

MERLOM, a town of Hindoostan, in Dowlatabad; 12 miles S.E. of Bader.

MERLON, in *Fortification*, that part of the parapet, from fifteen to eighteen feet in length, which lies betwixt two embrasures.

The word comes from *merula*, or *merla*, which, in the corrupt Latin, was used for a battlement.

To flake out the merlons, measure from each end of the wall, twelve feet, there stick a stake, and plant other stakes at every intermediate eighteen feet: when this is done on the inside of the wall, let other stakes be planted on the outside, either directly opposite to the former, or in the line towards the place where the gun is more particularly intended to deliver its shot. Plant other stakes on the inside, one a foot distant on each side of the former, and this will leave spaces of two feet each for the inner opening of embrasures: then, on the outside, plant other stakes at five or six feet distance from the former ones, one on each side, and the spaces of ten or twelve feet will be marked out for the outside openings of the embrasures. In the direction of the pickets, which limit the inner and outer openings of the embrasures, let single rows of fascines be staked down across the wall, and these will be the sides of the embrasures: fill the intermediate spaces, or merlons, with rows or fascines laid lengthwise to the wall, and this will be the first floor of the merlon, which is to be picketed down, and the hollows filled with earth. Let other floors be raised in like manner, until the merlons are carried up to about five or six feet, or more if necessary; and on the top of each let a bed or floor of earth be laid of about eight or twelve inches thick.

MERLON, or *Mellon*, in *Geography*, a town of France, in the department of the Oise; seven miles S. of Clermont.

MERLUCIUS, *Gadus merluccius* of Linnæus, in *Ichthyology*, the name of a fish commonly called the *bake*, and by some authors the *afellus alter*.

It is a moderately large fish, growing to two feet or more in length, and resembling the common pike in figure, from whence it has its name, *merlucius*, *quasi maris lucius*, the *sea-pike*. See *GADUS Merluccius*.

MERMAID, or MERMAN, a sea-creature, frequently talked of, and supposed half human and half a fish.

However naturalists may doubt of the reality of *mermen*, or mermaids, if we might believe particular writers, there seems testimony enough to establish it. In the year 1187, as Larrey informs us, such a monster was fished up in the county of Suffolk, and kept by the governor for six months. It bore so near a conformity with man, that nothing seemed wanting to it besides speech. One day it took the opportunity of making its escape, and plunging into the sea, and was never more heard of. Hist. d'Angleterre, p. 1, p. 403.

In the year 1430, we are told, that, after an huge tempest, which broke down the dykes in Holland, and made way for the sea into the meadows, &c. some girls, of the town of Edam, in West-Friesland, going in a boat to milk their

cows, perceived a mermaid embarrassed in the mud with a very little water. They took it into their boat, and brought it with them to Edam, dressed it in women's apparel, and taught it to spin. It fed like one of them, but could never be brought to offer at speech. Some time after it was brought to Haerlem, where it lived for some years, though still shewing an inclination to the water. Parival relates that they had given it some notions of a deity, and that it made its reverences very devoutly whenever it passed by a crucifix. (Delices d'Hollande.) In the year 1560, near the island of Manar, on the western coast of the island of Ceylon, some fishermen are said to have brought up, at one draught of a net, seven mermen and maids; of which several Jesuits, and among the rest F. Hen. Henriques, and Dimas Bosquez, physician to the viceroy of Goa, are said to have been witnesses. And it is added, that the physician, who examined them with a great deal of care, and made dissections thereof, asserted that all the parts, both internal and external, were found perfectly conformable to those of men. See the Hist. de la Compagne de Jesus, p. ii. tom. iv. N^o 276, where the relation is given at length.

We have another account, as well attested, of a merman, near the great rock called Diamond, on the coast of Martinico. The persons who saw it gave in a precise description of it before a notary: they affirmed, that they saw it wipe its hands over its face, and even heard it blow its nose.

Another creature, of the same species, was caught in the Baltic, in the year 1531, and sent as a present to Sigismund king of Poland, with whom it lived three days, and was seen by all the court. And another very young one was taken near Rocca de Sintra, as related by Damian Goes.

The king of Portugal, and the grand-masser of the order of St. James, are said to have had a suit at law, to determine which party these monsters belonged to. See SEA-CÖW, and SIREN. See Pontoppidan's Nat. Hist. of Norway, vol. ii. p. 186, &c.

MERMEREDGIK, in *Geography*, a town of Asiatic Turkey, in Natolia; 44 miles E. of Smyrna.

MERO, a district of Tennessee, in America, on the banks of Cumberland river, comprehending seven counties and 32,178 inhabitants, of whom 8074 are slaves.

MERO Point, a point on the coast of Peru, in the South Pacific ocean, between cape Blanco to the S.W., and Tumber river to the N.E., on the S.E. side of Guayaquil bay. S. lat. 3^o 40'.

MERO Motu. See *Ex Mero*.

MEROCELE, from $\mu\epsilon\rho\sigma$, the thigh, and $\kappa\epsilon\lambda\eta$, a tumour, in *Surgery*, the crural or femoral rupture. See HERNIA.

MÉROLA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 42^o 6'. E. long. 14^o 55'.

MEROPE, a town of Peru, in the diocese of Truxillo; 12 miles N.W. of Lambayeque.

MEROPS, the Bee-eater, in *Natural History*, a genus of birds of the order Picæ: bill curved, quadrangular, compressed, carinate, pointed; nostrils small, at the base of the bill; tongue slender, the tip generally, jagged; feet gresatorial. There are twenty-six species. The birds of this genus, with a few exceptions, inhabit the old continent. Their general food is insects, and they are particularly fond of bees and wasps. They have no note beyond a whistle, and that far from an agreeable one. Like the king-fisher, they breed in holes in the banks of rivers.

Species.

* APIASTER. Back ferruginous; belly and tail blueish-green; two of the tail-feathers longer; chin pale yellow.

A variety occurs with the bill convex and uncarinated, and the toes unconnected at the last joint. Bill black; irids red; front blue-green; crown, hind-head, and neck bay; a black streak from the bill to the hind-head; tail wedged, the feathers edged within with cinereous; legs chestnut; claws reddish-black. This is one of the most elegant of the European birds, and, next to the roller and king-fisher, may be regarded as the most brilliant in point of colour. This bird is a native of the warmer parts of Europe, and of many parts both of Asia and Africa. It is rarely seen in the northern regions of Europe. In Greece, and among the islands of the Archipelago, it seems to be extremely common, and we are told by Belon, that in the island of Crete the inhabitants practise a curious mode of catching it by means of a cicada, fastened on a bent pin, or a fish hook, and tied to a long line; the insect is then thrown into the air, and flies with great rapidity, and the bee-eater, ever on the watch for insects, seeing the cicada, springs at it, and swallowing the bait, is thus taken by the Cretan boys. It has been seen in Sweden; and in the third volume of the Transactions of the Linnæan society, it is asserted that a flight of these birds, not less than twenty in number, was seen near Mattishall in Norfolk, in the month of June 1793, and again in the following October. They feed, on the wing, upon bees, gnats, flies, and other insects. Their nest is composed of moss, and the eggs, from five to seven, are perfectly white, and about the size of those of a hare. When the sun shines upon them, in their flight, they are a pleasing object, as they appear gilded. It is recorded by Kolben, the historian of the Cape of Good Hope, that bee-eaters guide the Hottentots to the honey, which the bees lay up in clefts of the rocks.

VIRIDIS, Indian Bee-eater. Green; band on the breast black; chin and tail blue; two of the tail-feathers longer. It inhabits Bengal, and is eight or nine inches in length. Bill and band across the eyes are black; legs are brown. There are four other varieties of this species: in the *second*, the body is longer, front blue; in the *third*, the chin is yellow; line on the sides of the head black; quill-feathers tipped with brown. It is found in Egypt. The bill is black, straight; tongue not jagged; legs flesh-colour; tail even; in the *fourth* variety, the chin and stripe beneath the eyes are blue; tail even; it is found in the Philippine islands; two middle tail-feathers are black; in the *fifth* and last variety, the front is of a pale yellow colour; chin blue, it inhabits India.

CONGENER, Yellow-headed Bee-eater. Yellowish; rump greenish; quill-feathers tipped with red; tail-feathers yellow at the base. Found in the southern parts of Europe. The band across the eyes is black; back and shoulders bay; lesser wing-coverts blueish, the greater are yellow; quill-feathers black; legs yellow. According to Gesner it is often seen in the neighbourhood of Strasburg.

SUPERCILIOSUS, Supercilious Bee-eater. Green, frontal line above and beneath the eyes white; chin yellowish; two of the tail-feathers longer. There is a variety of this species described as having a slenderer bill; an even tail, with a rump and tail of blue-green. It inhabits Madagascar, and is nearly a foot long. Bill and area of the eyes black; crown greenish-bay; the legs are brown, and claws black.

PHILIPPENSIS, Philippine Bee-eater. Green, beneath yellowish; rump blue; tail even. This, as its name imports, inhabits the Philippine islands, and is about eight or nine inches long. The bill and line through the eyes are black; legs and claws brown.

CINEREUS, Cinereous Bee-eater. Variegated red and yellow, beneath reddish-yellow; the two longest tail-feathers are red. Inhabits New Spain, and is between nine

and ten inches long. The bill is green; head, quill and lateral tail-feathers cinereous.

FLAVICANS, Yellow Bee-eater. Whitish; head varied with white and tawny; breast reddish; back yellow; rump, wings, and tail rufous; two middle tail-feathers very long. In Willughby's Ornithology this species is described as the second bird of Paradise of Aldrovandus. This naturalist says he observed it, in the year 1577, in the possession of a Roman knight of the name of Cavalieri. The head was nearly white, sprinkled with yellow, and gold-coloured spots; the eyes were luteous, with red eye-lashes; the bill between green and yellow, two fingers breadth long, and rather curved; the tongue red, longish, and sharp, not unlike that of a wood-pecker, and calculated for piercing; the breast reddish; the back, wings, and belly whitish, but the upper parts of the tips of the wings ferruginous; the upper part of the back yellowish, but becoming reddish or ferruginous at the rump; the tail-feathers were white at the base, but ferruginous for the remainder of their length, and the two middle feathers exceeded the others two palms in length. The wings in the figure of Aldrovandus appear very long in proportion to the bird, and the author says they measured five palms in length; the tail likewise, exclusively of the two middle feathers, appears of considerable length.

COROMANDUS, Coromandel Bee-eater. Yellowish; sides of the neck, wings, and tail yellow; wing-coverts, back, and rump waved blueish, ocular stripes black. Inhabits different parts of India and Coromandel, whence it derives its name. Bill and legs black; irid; pale rufous; chin greenish.

BRASILIENSIS, Brazilian Bee-eater. Varied brown and black; head, chin, lesser wing-coverts, and body beneath red; wings and tail blue. It is found, as its name imports, in Brasil; is about nine inches long; the bill, wings beneath, legs and claws yellow.

SUPERBUS, Superb Bee-eater. Front and rump blue; two middle tail-feathers longer. Bill blackish; quill-feathers edged with brown; lower half of the middle tail-feathers dark brown. The size of this splendid bird is nearly that of the common or European bee-eater.

BADIUS, Chestnut Bee-eater. Blue-green; head, neck, and shoulders chestnut coloured; tail-feathers above blue, beneath grey-brown; two middle tail-feathers longer pointed. There is a variety that has the wings and tail chestnut. It inhabits the isle of France. Bill black, band beneath the eyes brown; upper wing-coverts green, beneath tawny; quill-feathers beneath grey, four inner ones totally green; 13 middle ones tipped with black; tail-feathers grey at the inner edge; legs reddish; claws blackish.

CHRYSOCEPHALUS, Yellow-throated Bee-eater. Green-gold, beneath blue-green; head and neck tawny; chin yellow; two middle tail-feathers longer. It is found in different parts of Asia, and is about ten inches long. The front and eye-brows blue-green; upper tail-coverts green.

ANGOLENSIS, Angola Bee-eater. Glossy green-gold; band through the eyes cinereous, spotted with black; wings and wedged tail beneath cinereous; chin yellow; throat chestnut. It inhabits, as its name expresses, Angola, and is about five inches long. The bill and claws are black; legs cinereous; body beneath blueish.

ERYTHROCEPHALUS, Red-headed Bee-eater. Green, beneath yellowish; head and neck red; chin yellow; wings and even tail beneath cinereous. It is found in India, and is about six inches long. According to Brisson, the crown of the head and upper part of the neck are of a bright red; there is across the eyes a black streak; all the upper parts of the bird are of a fine green; the throat and under parts yellow, but slightly dashed, from the throat downwards,

with red; tail even at the end, and rather short; irides red; bill black; legs brown.

NUBIENSIS, Blue-headed Bee-eater. Blue green, beneath red; back, wings, and forked tail dirty red. It inhabits Nubia, and is ten inches long. The bill is black; great quill-feathers tipped with blueish-ash, the secondary are blackish; legs pale ash.

ERYTHROTERTUS, Red-winged Bee-eater. Olive, beneath whitish, chin yellow; wings and tail red, tipped with black. It was described by Buffon, from a specimen brought from Senegal by Adanson. Its total length was about six inches.

CAYANENSIS, Cayenne Bee-eater. Green; wings and tail rufous, the latter tipped with black. It is a native of Cayenne, from whence it derives its name. The bill is black; quill-feathers white at the base; the tail-feathers edged with black; legs yellowish.

SURINAMENSIS, Surinam Bee-eater. Variegated; head reddish; scrag greenish-yellow; quill-feathers greenish, varied with black and blue. An inhabitant of Surinam. The irides are chestnut and claws black.

NOVÆ ZEELANDIÆ, New Zealand Bee-eater. Glossy greenish-black; greater wing-coverts and tuft of curled feathers on each side the neck white; tail even, coverts blue. Is found in New Zealand; is about 11 inches long; sings well; is held sacred by the inhabitants; and the flesh is good. Legs and claws black; inside the mouth and tongue yellow, the latter tipped with black and beset with bristles; feathers of the neck lax, long, a little curled, with a longitudinal white streak through the shaft.

PHYGIUS, Embroidered Bee-eater. Black variegated with yellow. This beautiful species is the size of a thrush, and its black most elegantly variegated with bright and pale yellow; the sides of the head, round the eyes, are covered by a naked, yellow, granulated skin; the back and breast undulated by numerous pale or whitish-yellow crests, the tips of the black feathers being of that colour; the smaller wing-coverts are marked in a similar manner; the larger tipped with bright yellow, and the quill-feathers edged with the same colour, as are also the exterior tail-feathers; the bill is black, of a moderate length, and sharp-pointed; the legs are brown. It is a native of New Holland.

NIGER, Yellow-tufted Bee-eater. Black; a large tuft of feathers behind the wings and vent yellow; tail wedged, edged and tipped with white. Native of the Sandwich islands, where it is much esteemed on account of the tufts of yellow feathers beneath the wings, which are used in various ornamental articles of dress among the natives, and on that account Dr. Shaw says it might justify us in placing this species among a particular division of the genus *Certhia*. There are two other varieties, of which the *second* is known by having two middle tail-feathers uniform; and the *third* by its rufous flanks, and by its having all the tail-feathers uniform.

CARUNCULATUS, New Holland Bee-eater. Brown, belly yellow; wattles carunculate; tail wedged, tipped with white. It inhabits New Holland, and is described and figured in White's Voyage to New South Wales. It is somewhat of the size of a Mistle thrush, but much longer in proportion, measuring about fourteen inches. The feathers on the upper part of the head are longer than the rest, giving the appearance of a slight crest; the plumage of the bird is brown, the feathers long and pointed, and each feather has a white longitudinal streak; beneath the eye, on each side the head, beyond the base of the lower mandible, is a lengthened pendent wattle of an orange colour; the

middle of the belly is yellow, the tail wedge-shaped, like that of the magpie, and the feathers are tipped with white. The bill and legs are brown. In some individuals of this species a silvery streak appears beyond each side of the bill, and in the young birds the white streaks on the plumage terminate in a kind of dilated spot at the tip of each feather.

CORNICULATUS, Horned Bee-eater. Brown, head nakedish; body beneath and tips of the tail-feathers whitish; horn on the front obtuse. This is also an inhabitant of New Holland, and is described and figured by Mr. White. It is rather larger than a black-bird, the plumage above is brown, and beneath it is white; the head and upper part of the neck is sparingly covered with narrow white feathers, almost like hairs; but the fore-part of the neck and breast are furnished with long ones of a white colour with a dark middle streak, and pointed at the ends; its most remarkable feature is, that on the forehead, just at the base of the bill, there is a short blunt knob, about a quarter of an inch in height, and of a brownish colour; the tongue is nearly the length of the bill, and brittle at the end; the legs are dark brown.

GULARIS, Red-throated Bee-eater, and sometimes, from its colour, called the Black Bee-eater. Black; forehead and rump blue; belly spotted with blue; throat red. It inhabits Sierra Leona. In size it is rather smaller than the common bee-eater, and its prevailing colour is the finest velvet black; the forehead is of the richest blue, so also is the rump, surpassing that of the king-fisher; the throat is of a bright blood-red, the larger wing-coverts and middle quill-feathers bordered with bright ferruginous; the tail is even at the end; the bill and legs black.

RUFUS, Rufous Bee-eater. Quill-feathers brown, the outer edge rufous. Body beneath inclining to yellow; toes separated to the base; hind-claw longer. It is observed by Buffon, that as the toes in this species are not united, as in the rest of the genus, it seems to form as it were a connecting link, or shade, between the bee-eaters and the hoopoes.

MOLUCCENSIS, Molucca Bee-eater. Grey; orbits naked; cheeks black; tail subequal. It is a native of the Molucca islands, and is about 14 inches long. The bill is blackish, pervious, half covered with a membrane; tongue as long as the bill, fringed at the tip; some of the feathers of the cheeks are tipped with a silvery colour; legs dusky; outer toe connected with the middle one; hind-claw longer.

MONACHUS, Brown or Cowled Bee-eater. Described by Latham, white beneath, with black and somewhat downy head with raised crown. It is a large species, and a native of New Holland.

MALIMBICUS, Malimba Bee-eater. Sanguine rose coloured beneath, with black eye-stripe, white throat, and two lengthened tail-feathers. This is a native of Malimba, in Congo, Africa, where it continues only three months in the year; migrating in troops, flying with the swiftness of a swallow, feeding on insects, rarely perching on trees; nor on the ground any length of time.

MEROS, in *Ichthyology*, the name of a very large American fish, growing to five or six feet long, and called by the Brazilians *cugupu-guacu*. Its head is very large, and its mouth wide and toothless; its eyes have a black pupil and a yellow iris; it hath five fins, one running the whole length of the back and reaching nearly to the tail; the anterior part of this is narrow, and armed with small but sharp spines; the other part is broader, and sustained by softer rays; behind the anus is one like the hinder part of that on the back, and two others behind the gills, which are large and broad; the tail fin is very large and broad, and much more so at its extremity than at its origin; the scales are small; the head, back, and sides are of a brownish-grey;

and its belly white. It is accounted a well tasted fish. Ray. See *PERCA Guttata*.

MEROSAGLIA, in *Geography*, a town of the island of Corfica; 14 miles N.E. of Corte.

MEROVEUS, in *Biography*, king of France, or of the Franks, whose monarchy, at that time, was confined to both banks of the Lower Rhine, began his reign about the year 448. Little is known of his origin and descent, but the most probable opinion seems to be, that he was the younger of the two sons of Clodion, his predecessor, and that he obtained the crown of the Franks through the protection of Valentinian III., and his minister Aëtius. Attila supported the cause of his elder brother, and Meroveus was present as an ally of the Romans in the famous battle of Chalons, fought against that conqueror in 451. He afterwards probably extended his dominion in the provinces of Mentz and Rheims, to the banks of the Seine, and it has been said, that in consequence of his celebrity and renown, all the French kings of the first race bore the name of *Merovingian*, though others maintain that the appellation is older than this sovereign. He died about the year 456. Gibbon. Univer. Hist.

MEROVINGIAN CHARACTER, derives its name from Meroüce, the first king of France of that race, which reigned 333 years, from Pharamond to Charles Martel. This race is said by some to have terminated in Childeric III. A.D. 751. There are many MSS. in the French libraries still extant in this character. See *Speët. de la Nat.* vol. vii. p. 190.

MERRET, CHRISTOPHER, in *Biography*, a physician and naturalist, was born at Winchcombe, in Gloucestershire, in February 1614. He was educated at Oxford, being first entered at Gloucester hall, and subsequently removing to Oriel, and took the degree of M.D. in 1642, when he settled in London. He appears to have enjoyed a considerable share of practice in his profession, was a fellow of the College of Physicians, and one of the original members of the Philosophical Society, which after the restoration became the Royal Society. He died in 1695. Merret was a strenuous supporter of the exclusive rights of the college, and his first publication was "A Collection of Acts of Parliament, Charters, Trials at Law, and Judges' Opinions, concerning those Grants to the College of Physicians," 4to. 1660. This book became the basis of Dr. Goodall's History of the College, and it was followed, in 1669, by "A short View of the Frauds and Abuses committed by Apothecaries, in relation to Patients and Physicians." This publication involved him in an angry controversy with Henry Stubbe. He was known to the public, however, more reputationally as a naturalist, by the publication of his work, entitled "Pinax Rerum Naturalium Britannicarum, continens Vegetabilia, Animalia, et Fossilia in hac Insula reperta," Lond. 1667, 8vo. This, though a dry and incomplete catalogue, and abounding with errors, has the merit of being the first of the kind relating to this country, and was without doubt instrumental in promoting the study of natural history here. The botanical part is the fullest, consisting chiefly, however, of an alphabetical list, according to the Latin names. A great portion of his knowledge of plants was obtained through the medium of Thomas Willisel, a noted herbalist, whom he employed to travel through the kingdom for him during five summers. The zoological and mineral parts of his pinax are very meagre. Merret communicated several papers to the Royal Society, which are printed in the earlier volumes of the Philosophical Transactions; particularly an account of some experiments on vegetation; of the tin mines in Cornwall; of the art of refining; and some curious observations

vations relative to the fens of Lincolnshire. In 1662, he translated into English, Neri's work "De Arte Vitricaria." In 1686, an edition of the same work was published in Latin, with Merret's observations and notes; and subsequently a work was printed in German and French, comprehending all that had been written by Neri, Merret, and Kunckel, upon this art. Eloy Dict. Hist. Gen. Biog.

MERRIMACK, in *Geography*, a river of America, which is formed by the confluence of Pemigewasset and Winnipisaukee rivers in about N. lat. $43^{\circ} 26'$, and which pursues a southerly course through the state of New Hampshire, till it enters Massachusetts, and then turning easterly, passes into the ocean at Newbury-Port. It is navigable for vessels of burden about 20 miles from its mouth.

MERRIMACK, a township in Hillsborough county, New Hampshire, on the W. bank of Merrimack river; eight or ten miles S. of Amherst; containing 926 inhabitants.

MERRIMACHI, a river of America, which falls into the head of a bay of that name on the N.E. coast of the province of New Brunswick. From this river there is a communication with St. John's, partly by land, but principally by water carriage in canoes. The salmon fishery is carried on with success, and the cod-fishery is improving near the entrance of the bay.

MERRITCH, or **MERRICK**, a town of Hindostan, in the country of Viliapour, situated on the N. side of the Kistnah; 50 miles S.W. of Viliapour. N. lat. $16^{\circ} 58'$. E. long. $74^{\circ} 47'$.

MERRY, ROBERT, in *Biography*, was born in London, April 1755, and was descended in a right line from Sir Henry Merry, who was knighted by James I. at Whitehall. Mr. Merry's father was governor of the Hudson's Bay Company. His grandfather was a captain in the royal navy, and one of the elder brethren of the Trinity House; he established the commerce of the Hudson's Bay Company upon the plan which it now pursues. He made a voyage himself to Hudson's Bay, and discovered the island in the North seas, which still bears the name of Merry's island. He also made a voyage to the East Indies, and was, perhaps, the first Englishman who returned home over land; in which expedition he encountered inconceivable hardships. Mr. Merry's mother was the eldest daughter of the late lord chief justice Willes, who presided for many years with great ability in the court of Common Pleas, and was for some time first lord commissioner of the great seal. Mr. Merry was educated at Harrow, under Dr. Sumner. The celebrated Dr. Parr was his private tutor. From Harrow he went to Cambridge, and was entered of Christ's college. He left Cambridge without taking any degree, and was afterwards entered of Lincoln's Inn, but was never called to the bar. Upon the death of his father he bought a commission in the horse-guards, and was for several years adjutant and lieutenant to the first troop, commanded by Lord Lothian. Mr. Merry quitted the service and went abroad, where he remained nearly eight years; during which time he visited most of the principal towns of France, Switzerland, Italy, Germany, and Holland. At Florence he stayed a considerable time, enamoured (as it is said) of a lady of distinguished rank and beauty. Here he studied the Italian language, encouraged his favourite pursuit, poetry, and was elected a member of the academy Della Crusca; the name of which academy he afterwards used as a signature to many poems which were favourably received by the public, and which excited a great number of imitators. When Mr. Merry observed this, he dropped his fictitious character, and ever afterwards published in his own name.

Upon his marriage with Miss Branton, who performed in

his tragedy of Lorenzo, a prospect opened to him of living at his ease, by the joint production of that lady's talents, and his own pen; but unfortunately the pride of those relations upon whom he had most dependence was wounded by the alliance; and he was constrained, much against Mrs. Merry's inclination, to take her from the stage. This he did as soon as her engagement at the theatre expired, which was in the spring of 1792. They then visited the continent, and returned in the summer of 1793. They retired to America in 1796, and our author died suddenly at Baltimore, in Maryland, Dec. 24, 1798, of an apoplectic disorder, which proceeded, as is supposed, from a plethora, and the want of proper exercise. He was author of the following dramatic pieces, viz. "Ambitious Vengeance;" "Lorenzo;" "The Magician or Conjuror;" and "Fenelon," a serious drama. Monthly Magazine, Jan 1799.

MERRY'S Island, in *Geography*, an island in Hudson's Bay. N. lat. $61^{\circ} 52'$. W. long. $93^{\circ} 5'$.

MERRY-MEETING BAY, a bay of America, in Strafford county, New Hampshire, being the southernmost arm of lake Winnipisaukee. On its W. side stands Mount Major. —Also, a bay in Maine, formed by the junction of Androscoggin and Kennebeck rivers, opposite to the town of Woolwich, 20 miles from the sea.

MERS AGOLETA, a town of Algiers, near the sea-coast; six miles S.W. of Tneifs.

MERS il Kecer. See MAZALQUIVIR.

MERSA, EL, a town of Africa; 12 miles N.E. of Tunis.

MERSBURG, or **MORSBURG**, a town of the duchy of Baden, seated on the lake of Constance, containing a seminary for secular clergy, and a nunnery of the Dominicans; six miles N.E. of Constance. N. lat. $47^{\circ} 41'$. E. long. $9^{\circ} 14'$.

MERSCH, a town of France, in the department of the Forests, and chief place of a canton, in the district of Luxembourg. The place contains 1446, and the canton 8185 inhabitants, on a territory of $217\frac{1}{2}$ kilometres, in 15 communes.

MERSCHOWITZ, a town of Bohemia, in the circle of Leitmeritz; 14 miles W.S.W. of Leitmeritz.

MERSEA, a township of Upper Canada, in the county of Essex, seated on lake Erie, W. of Romney.

MERSEBURG, a principality of Saxony, encompassed by the circles of Leipsic and Thuringia, the principality of Querfurt, and duchy of Magdeburg. The soil is fertile, and well cultivated, producing wheat, millet, and flax, but wanting wood.—Also, the capital of the above-named principality, seated on the Saale. It contains within the liberties of the Chapter, the episcopal palace and cathedral; a gymnasium or foundation school, the chancery-house, the chapter-house, the curia or residences of the canons, and other buildings. It has also a parish church; and derives its chief subsistence from the strong beer that is brewed here and exported to different places; 16 miles W. of Leipsic. N. lat. $51^{\circ} 22'$. E. long. $14^{\circ} 6'$.

MERSENETI, a town of Asiatic Turkey, in Natolia; 10 miles S.E. of Milets.

MERSENNE, MARIN, in *Biography*, a learned French mathematician and philosopher, was born at Oyse, in the province of Maine, in the year 1588. He pursued his college studies at La Fleche, where he had as a fellow student the celebrated Des Cartes, with whom he contracted an intimacy and friendship that lasted during their lives. Here Mersenne rendered himself conspicuous for the diligence and rapid progress which he made in his various studies. From La Fleche he went to the university of Paris, where he paid

the

MERSENNE.

the utmost attention to the mathematical sciences; after which, he went through a theological course at the Sorbonne. When he had completed his studies, he entered himself at the convent of Minims near Paris, and took the vows in 1612, when he was only 24 years of age. In the following year he was ordained priest, and began to study the Hebrew language, of which he made himself a complete master. In 1615 he was sent to the convent of his order near Nevers, to fill the philosophical chair in that house; and he continued there, teaching philosophy, and afterwards theology, till the year 1619, when he was chosen superior of the convent. Upon the expiration of the term of his office, which was annual, he withdrew to Paris, where he spent the remainder of his life in study and literary converse, excepting such time as he devoted to short excursions into Italy, Germany, and the Netherlands. While at this great city, he was the chief friend and literary agent of Des Cartes, giving him advice and assistance upon all occasions, and informing him of every thing of a literary and philosophical kind that was going on in that city, and elsewhere. So highly did Des Cartes estimate the opinion of our philosopher, that he scarcely did any thing, without first consulting his friend. It has been reported, that when Des Cartes was about to found his system of philosophy upon the principle of a vacuum, he was informed by Mersenne, who had founded the Parisian philosophers upon it, that it would not be admitted, and immediately changed his system, and adopted the opposite doctrine of a plenum. Mersenne was much celebrated for possessing the peculiar talent of forming curious questions and problems; some of which, it afterwards appeared, he was unable to solve. To him has been ascribed the invention of the curve, well known by the name of the "cycloid," which instantly engaged the attention of mathematicians. Schooten, indeed, ascribes the invention to Des Cartes; but Torricelli, in the appendix, "De Dimensione Cycloidis," says, the curve was discovered and named by Galileo and others, about the year 1599, before Mersenne and Des Cartes could have made much progress in mathematical learning. Dr. Wallis, in the first volume of the London "Philosophical Transactions abridged," attempts to shew that it is a much older invention, and was known to Bovilli in the year 1500, and by cardinal Cusa a full half century before this. Mersenne died in the year 1648. The loss of him was deeply regretted by persons of all ranks who were acquainted with him, by whom he was as much beloved for the cheerful qualities of his heart, and his mild and amiable temper, as he was respected for his profound scientific knowledge. He was, while a resident at Paris, the very centre of communication between literary men of all countries; being there, what Mr. Collins was in England. He omitted no opportunity of engaging them to publish their works; and to Mersenne the world is indebted for several important discoveries, which would probably have been lost, but for his encouragement and patronage. His own works were numerous, and many of them highly important. The first which he published, of any magnitude, was entitled "Questiones celeberrimæ in Genesim, &c. cum accurata Textus Expheatione. In hoc Volumine Athei et Deilæ impugnantur et expugnantur." The other works of this philosopher are enumerated in the General Biography, to which our readers are referred.

In the musical writings of this diligent and ingenious ecclesiastic may be found the most minute and satisfactory account of the state of music in France, during the reign of Louis XIII., particularly in his "Harmonie Universelle," published at Paris in 1636, in folio; a work in which, through all the partiality to his country, want of taste, and

method, there are so many curious researches and ingenious and philosophical experiments, which have been of the greatest use to subsequent writers, particularly Kircher, as render the book extremely valuable. This work, corrected and enlarged, was translated into Latin, and published by the author in 1648, the year of his death, under the following title, "De Sonorum Natura, Causis et Effectibus." In his twenty-third proposition, liv. i., this author explains and describes twelve different kinds of music and movement, used in France during his time: these were motets, songs or airs, passacailles, pavans, allemandes, gaillards, voltes, courantes, farabandes, canaries, branles, and balets; of all which he gives examples in notes. But though most of these movements were the specific names of the dances then in vogue, the minuet, which, during the present century, has been in such general favour all over Europe, is never mentioned.

In the "Pref. generale," Mersenne speaks of Galileo's discoveries in harmonics; and in his liv. ii. "Des Consonances," of sympathetic vibrations. In other parts of his work he explains clearly the twelve keys major of practical music; and shews, for the first time perhaps, that there may be seventy-two keys, or six for each note, flat, natural, and sharp, major and minor. There is nothing in this good father's book which reflects more honour on his taste and penetration than his partiality for the violin, to which, in liv. iv. "Des Instrumens," prop. i. he gives the preference over all other instruments then in use, at a time when it was thought unworthy of being admitted into the concerts of other countries.

It is amusing, however, to see how contented mankind have ever been, in the most rude and uncultivated ages of the world, with their own talents and accomplishments. A singular instance of this mental comfort appears in Mersenne, chap. "De l'Embellissement des Chants," which he addresses "to posterity, that they may form some idea," says he, "of our manner of gracing and embellishing airs; as such advances have at no time been made in polishing and refining melody, as at present." In his treatise "De la Voix," where he explains the manner of running divisions and making shakes, he says, that "of all nations who study singing, and who run divisions in the throat, the French execute passages in the neatest manner: this even the Italians confess, who make a particular profession of singing. It is impossible," adds he, "to describe the beauty and sweetness of our vocal embellishments to such as have not heard them; for the purring of a stream, the meandering of a brook, or the warbling of a nightingale, is not half so mellifluous. And I find nothing in nature," continues this pious father, "that can give the least idea of these passages, which are far more ravishing than shakes or trills, for they are the very quintessence of music." (Liv. i. De la Voix, p. 40.) He afterwards observes, that no traces are to be found in the writers of music among the ancient Greeks, that this ingenious and voluptuous people ever had "des fredons & des passages comme nous autres:" trills and divisions in their music, like us.

One proposition in this book (xxxiv.) is to inquire whether the French method of singing is the best of all possible methods? and determines in the affirmative, not only with respect to this proposition, but affirms that of all those he had heard sing in neighbouring countries, as in Spain, Germany, Flanders, and Italy, he had met with none who sung so agreeably as the French. "There may," says he, "be now and then a miraculous performer in other countries, but I speak here in general."

He mentions recitative as a thing little practised in France,
for

for want of courage. The Italians, he observes, had succeeded in this species of singing, which Giacomo Peri had invented at Florence the beginning of the century. Here he speaks of several musical dramas in Italy, but does not call them operas. (Liv. vi. L'Art de bien Chanter.) A book with the same title was published at Paris, by Bacilly, 1668.

The *fi*, to express the seventh of the key, does not seem to have been in use at this time in France; as Merfennus in his solmifation has never introduced it, repeating the *mi*, in the key of C, for E and B.

MERSEY, in *Geography*, a navigable river of England, flows from the east to the west, and forms, in the greater part of its course, a natural boundary between the counties of Lancaller and Chester. Its whole extent is about fifty miles; thirty-five of which are navigable, from Liverpool to the mouth of the river Irwell, for vessels of considerable burthen. The Mersey derives its origin from the junction of the rivers Etherow and Goyt, where it assumes the present name, and in its course receives the streams of the Tame, the Bullen, the Irwell, and the Weever. Opposite Warington in Lancashire, where it meets the tide-water, the Mersey is only forty yards wide; but at Runcorn-gap, where it communicates with the Grand-trunk, and duke of Bridgewater's canals, its width is three hundred yards: below the gap, it extends itself into a grand estuary of three miles in width, and receives the navigable river Weever from Northwich and Frodham. In its course northward from Runcorn, it gradually diminishes for six miles, and opposite Liverpool is only three-quarters of a mile wide; but it forms a fine channel, at least ten fathoms deep at low water, and is very commodious for shipping. About five miles farther, measuring by the Cheshire coast, it falls into the Irish sea, by two or three different channels, which are much incommoded by sands; but the passage is rendered secure by means of various land-marks, buoys, and light-houses, and the excellent system of pilotage established by the Liverpool merchants. Lysons's *Magna Britannia*, vol. ii.

MERSIG, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Sarrebruck. The place contains 1832, and the canton 6421 inhabitants, in 20 communes.

MERTAQUE, a town of New Spain, in the province of Honduras, which produces cochineal.

MERTENSIA, in *Botany*, a genus of the Submersed *Algae*, commonly termed Sea-weeds, named by the celebrated Thunberg, in honour of Professor F. C. Mertens, of Bremen, a man of the most amiable character, highly distinguished by his knowledge of this tribe of vegetables in particular. A treatise illustrating this genus was published by Dr. Roth, in Schrader's *New Journal* for 1807. A *Mertensia* had indeed previously appeared, from the pen of Professor Willdenow, in the *Stockholm Transactions* for 1804, belonging to the order of Ferns; but that being reduced to another genus, (see *GLEICHENIA*), the present is established; and as far as any opinion can be formed of so unsettled a tribe, it seems to be tolerably distinct from all that have already been adopted. Roth, in *Schrad. New Journ.* v. 2. fasc. i. 11. t. 1. f. B.—Class and order, *Cryptogamia Algae*. Nat. Ord. *Algae*, Linn. Jussl.

Ess. Ch. Frond internally jointed. Seeds dispersed in the coats of cluttered inflated vesicles.

1. *M. lumbriculis*. Roth as above. (*Ulva lumbricalis*; Linn. *Mant.* 311. *Syst. Veg.* ed. 14. 972. Thunb. *Prod.* 180.) Gathered by Koenig, as well as by Thunberg, upon submarine rocks at the Cape of Good Hope. The root consists of many slender entangled fibres, attaching themselves

to shells and stones. *Fronds* several, three or four inches high, cylindrical, blackish, tapering at the base, determinately branched, the thickness of a crow's quill, or more, greenish-yellow, or purplish, composed of a thickish coriaceous coat; internally spongy, and interrupted by very frequent transverse reticulated partitions, which are scarcely discoverable at the outside. *Fructification* generally axillary, rarely lateral, consisting of numerous crowded, obovate, or oblong, vesicles, proceeding from a slightly elevated fleshy base, or *receptacle*. Each of these is jointed internally like the frond, but their coat is rather thinner and more pellucid, bulging very numerous, scattered, roundish-oval, crystalline *seeds*. The specimens in the herbarium of Linnæus justify his description of the fructification being terminal, but Roth asserts that it becomes so only by accidental injuries to the frond. The internal partitions are considered by this great cryptogamist of a spurious nature, as originating from cellular substance only, which dilates into a transverse web or net. The *seeds* are dispersed under the external cuticle, exactly as in real *Ulva*, though confined to the above-mentioned vesicular excrescences, which however seem materially different from branches, nor do they appear ever to be extended into such.

MERTHYR TYDVIL, or *Tudfyl*, in *Geography*, a large and populous market-town, situated in the cwmwd of Senghennydd, cantref of Brehinol, now the hundred of Caerphilly, and county of Glamorgan, South Wales. It is a place of great antiquity, and is said to derive its name from Tydvil, the daughter of Brechan, prince of Brecknockshire, who was murdered here, along with her father and brother, Rhun Dremrudd, by a party of Saxon marauders, about the close of the fifth century. Tydvil was the wife of Cyngin, son of Cadell, prince of the vale royal and part of Powys, and is reckoned among the number of the ancient British saints. After her death, the Saxons having been expelled by the prowess of her nephew, Nevydd, a church was erected and dedicated to her at this place, and called the church of Merthyr Tydvil, which in Welsh signifies "the Martyr Tydvil."

From this period, nothing occurs deserving of notice relative to Merthyr Tydvil, till about the year 1620, when it was distinguished for its zeal in the cause of non-conformity. Though then trivial in extent and political importance, it was nevertheless a sort of hot-bed, which contributed in no small degree to engender and keep alive, for more than a century, those religious dissensions, the effects of which still continue visible in the separation of the greater proportion of the inhabitants of Wales from the established church. In 1755 a new era commenced in the history of this place. The extensive and valuable mines in its immediate vicinity had hitherto attracted but little notice. At this time, however, Mr. Bacon particularly directed his attention towards them; and having obtained a lease of a district, extending about eight miles in length, and four in breadth, at the moderate rent of 200*l.* per annum, immediately began operations, and erected extensive works for the smelting and forging of iron. This gentleman continued increasing his establishment till the year 1783, when he deemed it proper to let out the greater part of his property to Mr. Crawshay, and the remainder to Mr. Hill: at the same time, he reserved to himself a certain tonnage on all the iron manufactured above a specified quantity. The new proprietors soon augmented the works; and the part belonging to Mr. Crawshay, at Cyfartha, are now by far the largest in this kingdom, and probably in Europe. He employs no fewer than 1500 men, at an average of 30 shillings a week per man. The weekly wages paid for labour amount to 1500 pounds.

The.

The average of iron produced from these works is from 180 to 200 tons a week. Six furnaces and two rolling-mills are employed. For procuring blast for the furnaces and working the mills, there are four steam-engines; one of fifty, one of forty, one of twelve, and one of seven horse power. The first engine is connected with the four upper blast-furnaces, to which is a water-engine annexed of nearly the same power. The machinery of this establishment is truly gigantic; and that part of it worked by water is curious, and certainly highly powerful. The great water-wheel is a most extraordinary piece of mechanism: it was constructed under the superintendance of Watkin George, and measures 50 feet in diameter. W. George was then a carpenter employed about the works: he was afterwards taken into partnership, and received 20,000*l.* to give up his share. Besides these works, and those of Mr. Hill, there are two others at Pendarren and Dowlais; the former producing about 140 tons of iron weekly, and the latter about three fourth-parts of that quantity. The total number of smelting-furnaces near this town is seventeen, *viz.* Dowlais four, Pendarren three, Plymouth (Mr. Hill) four, and Cyfartha six.

No fact can better illustrate the magic influence of trade on the condition of a country, than the rapid change which has been effected at Merthyr Tydvil and its neighbourhood. Forty years ago, this town was an inconsiderable village, and contained only a few hundred inhabitants; whereas, by the sole operation of its iron-works, it has risen to be by far the largest and most populous town in Wales. The inhabitants of this parish were estimated at 7705, in 1801; but the population is conjectured to amount to 10,000 persons. In 1803 the money raised for the poor rates, at 6*s.* 6*d.* in the pound, was 1453*l.* 17*s.* 10½*d.* The streets in general are close and confined, and have no proper outlets behind the houses. Considerable improvements, however, have already been made within these last five or six years. Such streets as have been built since that period are much better arranged, and wider than those which were erected earlier. At Pendarren is a large and elegant house, surrounded by beautiful gardens and pleasure-grounds, belonging to Mr. Homfray. The parish church, rebuilt in 1806, is a large and handsome building; and besides it, there is a spacious chapel built by Mr. Crawshaw. The meeting-houses for dissenters of different sects are about eleven in number: three Baptists, two Presbyterian, two Independents, two in the Wesley connection, and two in that of Whitfield. A theatre has been lately erected here. There is likewise a philosophical society here, as well as a printing-house, and a book-seller. The inhabitants of this town are chiefly Welsh, and the language spoken in it almost entirely so. Less immorality prevails than might be expected in a place where the population consists chiefly of the lower orders. This is partly owing to the circumstance of the iron-masters and clergymen being usually magistrates for the county, and partly to the effect of religious instruction. These magistrates have the power of nominating the requisite number of constables, and must submit all their proceedings to the quarter and great sessions. A court of conscience, for the recovery of small debts, has been instituted here by act of parliament, within these three years. This town has three market-places, which are well supplied twice every week, on Wednesdays and Saturdays. It has likewise several fairs during the year. The weighty and valuable productions of Merthyr Tydvil find an easy conveyance to the sea, by means of a canal which extends hence to Penarth harbour, in the Bristol channel, being navigable as far as Cardiff for vessels of 300 tons, and above that town for barges of 100 tons. This canal, begun about 22 years ago, was completed in 1798.

At the Cyfartha works, where it terminates, it is 568 feet above the level of the sea; which elevation is effected by means of about 40 locks. A new tram road runs nearly by its side, through its whole course, extending altogether 26 miles in length.

Besides its iron ores, the neighbourhood of this town is abundantly productive of other minerals useful in the arts, and consequently subservient to the convenience and happiness of man. Coal, so indispensably necessary in the manufacture of the iron, is supplied in immense quantities, and of excellent quality. Good mill-stones and stones for paving are likewise abundant; and in the lime-stone rocks are found beds of black and variegated marble, not inferior to any in the kingdom.

About two miles from the town, on the summit of a lofty mountain, is situated a very ancient market-place, where weekly markets have now been held for upwards of 800 years, during the summer season, from the 14th of May till the 14th October. This singular market is still much frequented. Several fairs are likewise held here for cattle, though the houses in the place do not exceed six in number.

Morlais castle stands about three miles to the north-west. It is situated on the summit of a hill, about half a mile from the ancient road over the mountains from Cardiff to Brecknock, overlooking a ravine of great depth, in the bottom of which runs a branch of Taff Vechan river. The area of this castle forms an irregular pentagon, defended on the south and east sides by a very large and deep trench cut in the solid rock. On the north and west sides it is rendered sufficiently strong, by the bold and rugged precipices which overhang the dingle. The whole of this castle is now in ruins. It was built by Ivor Petit, or Ivor Bach, the son of Cedevor, who was no less distinguished for his valour than for the uncommon smallness of his stature. Malkin's Scenery, Antiquities, and Biography of South Wales, 2 vols. 8vo. 1807. Carlisle's Topographical Dictionary of Wales, 1 vol. 4to. 1811.

MERTOLA, a town of Portugal, in Alentejo, seated on the Guadiana, containing about 2400 inhabitants; 24 miles S.S.E. of Beja. N. lat. 37° 36'. W. long. 7° 37'.

MERTON, a village in the west half-hundred of Brixton, in the county of Surrey, England, is situated on the Epsom road, nine miles distant from London. It contained in the year 1801, according to the return then made to parliament, 151 houses, occupied by 813 persons. The manor, which before the Conquest was the property of earl Harold, and was afterwards held by the crown, was granted by Henry I. to Gilbert Norman, sheriff of Surrey, who, in the year 1115, built a convent for canons regular of the order of St. Austin. The establishment was patronised by the king and his queen Matilda. In 1130, Merton abbey, as it was then called, was built with stone; and in 1136 the canons entered on the possession of it. The benefactions to it were numerous and ample. In the year 1236 a parliament was held at the abbey, wherein were enacted the statutes which take their name from that place. In this house also was concluded the peace between Henry III. and the dauphin of France. The abbey was surrendered in 1538; and the site was afterwards granted to the newly-established monastery at Shene. After the dissolution, it was leased out to private persons; and during the civil war of Charles I. it appears to have been used as a garrison. At present there is no other vestige of the abbey than the east window of a chapel of crumbling stone, which seems, from its style, to have been built in the fifteenth century. The walls which surround the premises, including a space of about 60 acres,

are nearly entire. The site has long been occupied by two extensive manufactories for printing calicoes; and a copper mill is also established here.

The parish church of Merton was built, early in the twelfth century, by Gilbert Norman, the founder of the abbey. It is constructed of flints, and consists of a nave and chancel; and at the west end is a low spire. From the style of architecture, it is presumed to be the original structure, which has undergone but little alteration. In the chancel window are some remains of painted glass; and against the north wall of the church is a large picture of Christ bearing the cross.

Merton-Place, the seat of the late admiral Nelson, is in this parish; as is Cannon-hill, the villa of William Mollison, esq. Sir Richard Hotham had a seat here, which was purchased by — Graves, esq. Lysons's *Environ's of London*, vol. i.

MERTVOI KULTUCK, a bay at the north extremity of the Caspian sea. N. lat. 46°.

MERTZA, a small island in the north part of the gulf of Bothnia. N. lat. 65° 27'. E. long. 22° 9'.

MERTZBACH, a town of the duchy of Wurzburg; 6 miles N.N.E. of Ebern.

MERU, a town of France, in the department of the Oise, and chief place of a canton, in the district of Beauvais; 12 miles S.S.E. of Beauvais. The place contains 1800. and the canton 7131 inhabitants, on a territory of 165 kilometres, in 20 communes.

MERU, a very celebrated mountain, in the mythological fables of the Hindoos. The word in Sanscrit signifies an *axis*, or *centre*; and hence, perhaps, it has been applied to the north pole, which, being deemed the most elevated region, led the poets to describe Meru as the highest mountain in the world. It is also, by way of pre-eminence, called *Sū-merū*, denoting its fairness or beauty. In the 15th chapter of the first book of the Mahabarat, it is thus described: "There is a fair and stately mountain, and its name is *Mēroo*; a most exalted mass of glory, reflecting the sunny rays from the splendid surface of its gilded horns. It is clothed in gold, and is the respected haunt of deus and gandharvas (deities and celestial choristers). It is inconceivable, and not to be encompassed by sinful man; and it is guarded by dreadful serpents. Many celestial medicinal plants adorn its sides; and it stands, piercing the heavens with its aspiring summit, a mighty hill, inaccessible even by the human mind. It is adorned with trees and pleasant streams, and resoundeth with the delightful songs of various birds." (Gita, p. 146.) The above is the introduction to the story of the Kurmavata, given by the learned translator in a note on the Gita. (See *KURMAVATARA* and *BRACHMANS*.) This may be deemed sufficiently extravagant; but it is tame, compared with some of the ravings of Hindoo mystics, who find, in the contemplation of this mysterious mountain, types and symbols of every thing in and out of nature. Here follows a specimen of the *Brahmanda Purana*, taken from Mr. Wilford's dissertation on the Sacred Isles in the West, in vol. viii. of the Asiatic Researches. "Meru is the sacred and primeval *Linga*, and the earth beneath is the mysterious *Yoni*, open like the *Padma* or *Lotos*. The convexity in the centre is the *Os tinea*, or navel of *Vishnu*; and the Hindoos often represent the physiological mysteries of their religion by the emblem of the *Lotos*, where the whole flower signifies both the earth and the two principles of fecundation; the germ is both *Meru* and the *Linga*; the petal and filaments are the mountains which encircle *Meru*, and are also the type of the *Yoni*; the four leaves of the calyx are the four vast regions towards the

cardinal points; and the leaves of the plant are the different islands in the ocean round *Jambu*." At the end of this ingenious essay are curious plates, representing *Meru* under the fanciful semblance of a *lotos*, and other geographical extravaganzas of the Hindoo Puranas, or poetical fables. "Brahma, Indra, and all the gods, declare that 'his largest of mountains is a form consisting of jewels of unnumbered colours; the abode of various tribes; like gold; like the dawning morn, resplendent, with a thousand petals; like a thousand water-pots, with a thousand leaves. Within it is adorned with the self-moving cars of the gods, all beautiful; in its petals are the abodes of the gods, like heaven; in its thousand petals they dwell with their consorts. There resides above *Brahma*, god of gods, with four faces. There in the east is *Indra*, for ever to be praised; the lord of wealth, with a thousand eyes, the destroyer of towns.'" (See *INDRA*.) On this *Olympia* of the Hindoos are all the gods assembled in their magnificent palaces, under different designations. *Kailasa* is the paradise of *Siva*. (See *KAILASA*.) *Meru* is the grand-father of the river *Ganges*, as noticed under *MERA*, the name of his daughter. Under the articles *LINGA*, *LOTOS*, and *YONI*, some mention is made of this wonderful mountain; and the reader, desirous of farther accounts of it, and of mysticisms connected with it, is referred to vol. viii. of the Asiatic Researches, and to *Moor's Hindoo Pantheon*.

MERVILLE, MICHAEL GUYOT DE, in *Biography*, a French writer, was born at Versailles in 1696. After travelling through various countries, he settled as a bookseller at the Hague, where he published a literary journal. His affairs becoming embarrassed, he went to Switzerland, and drowned himself in the lake of Geneva in 1765. He wrote, 1. *Voyage Historique*, 2 vols. 12mo. 2. *Several Comedies*, &c. published at Paris, in 3 vols. 12mo.

MERVILLE, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Hazebrouck; 15 miles W. of Lille. The place contains 5302. and the canton 16,608 inhabitants, on a territory of 60 kilometres, in 5 communes.

MERUIT QUANTUM, in *Law*. See *QUANTUM*.

MERULA, GEORGE, in *Biography*, a critic and historian, one of the revivers of ancient literature, was a native of Alessandria in Italy. He acquired the rudiments of Latin and Greek under able preceptors, was soon distinguished for his classical attainments, and passed the greatest part of his life in teaching the languages and rhetoric at Venice, Milan, and Pavia. He died at Milan, at an advanced age, in 1494. He was celebrated as an original writer, and as an editor and commentator. Under the patronage of Lewis Sforza he wrote "*Antiquitates Vicecomitum, five de Gestis ducum Mediolanensium*," of which the first decade was published in his life time, and four books of the second decade were given in the 25th vol. of the "*Scriptores Rerum Ital.*" He also composed a description of *Montferrat*, and of the eruption of mount *Vesuvius*, and a small historical tract entitled "*Bellum Scodrense*," descriptive of the siege of *Scutari* by the Turks in 1474. He was the first who gave an edition of the four Latin writers on agriculture, *viz.* *Cato*, *Varro*, *Columella*, and *Palladius*, with notes, 1472. In the same year he gave the first edition of the "*Comedies of Plautus*." He likewise either first published or illustrated "*Juvenal*;" "*Martial*;" "*Ausonius*," and the "*Declamations*" of *Quintilian*. He translated from the Greek, the lives of *Trajan*, *Nerva*, and *Adrian*. To him the world is indebted for the discovery of many ancient MSS. in the monastery of *Bobbio* in 1494. *Gen. Biog.*

MERULA, PAUL, was born at Dordrecht, in Holland, in

the year 1558. He acquired in his own country a profound knowledge of law, history, and polite literature, and then travelled for improvement into France, Italy, Germany, and England. On his return he was appointed to succeed the famous Lipsius as professor of history at Leyden, an office which he held for fifteen years. He died in 1607; leaving behind him several learned works, as "The Fragments of Ennius, with a Commentary;" "Eutropius;" "The Lives of Erasmus and Junius;" "Cosmographia," a work on ancient geography: "A Treatise on Law;" "A Treatise on Hunting, with the Laws respecting it;" the two last are in the Dutch language. After his death his works were collected and published under the title of "P. Merulæ Opera varia posthuma," 1684.

MERULA, CLAUDIO, DA CORREGGIO, (a small town in the state of Modena,) organist of the church of St. Marc at Venice in the time of Zarlino, and one of the interlocutors in the "Ragionamento primo" of his "Dimost. Harm." where he is called "il gentilissimo M. Claudio Merula, suavissimo organista del suo tempo"—the sweetest organist of his time. He had been maestro di cappella to the duke of Parma, and published "Toccate," or preludes for the organ, engraved on copper plates. The first book of his "Cantionum sacrarum" appeared at Venice in 1578, in 4to.; after this he published masses, psalms, motets, magnificats, madrigals in three, four, and five parts.

Claudio Merula was one of the first who attempted dramatic music. In 1574, he composed a theatrical piece at Venice, which was performed in the grand council chamber, for the entertainment of Henry III. of France, when he returned from Poland on the death of his brother, Charles IX. This piece was called a tragedy, and was probably declaimed, with madrigals and chorusses intermixed.

MERULA, TARQUINIO, *il Cavalier*, a whimsical composer of Bergamo; in the tenth vol. of whose works, printed at Venice in 1655, most of his instrumental movements are composed on a ground-bass, which soon after became a common practice with Stradella, Purcell, and others. This master was a church composer, and a madrigalists; but his favourite style seems to have been the burlesque: in his cantata of Curtius for a bass voice, published in 1638, the poet, after advising Curtius against so rash a step, tells him, that though he may easily find his way to the bottom of the gulph into which he was about to plunge, yet, he adds, *quanto al ritornare, sarà un difficile passo*; to which last word a division of six bars, of sixteen semiquavers in each, is given, in the course of which, the finger is carried from D on the sixth space in the bass, down to the abyss of double C. There is another division of seven bars at the last close, in which the passages are echoed, piano, and the trill of the times in iterations of the same note, in semiquavers, is written twice at full length.

The cavalier Merula's compositions are almost all so tintured with caprice and buffoonery, as to render them more singular and new at least than those of his contemporaries. In his "Libro secondo della Musiche concertate," published in 1635, he has published a three-part song, with ritornels for two violins and a bass, sopra la ciaccona, with his cantata of "Curzio precipitato." Among other capricious things in this publication, there is a Canzonetta spirituale sopra la Nanna, or Lullaby, consisting of only these two notes in the bass:

He has composed a learned fugue in four parts, on the declension of *Hic, hæc, hoc*; and another upon *Quis vel qui*:

nominativo qui, quæ, quod, &c. This last consists of several movements which are supported with vivacity, and imitations of the cant and flammering of school-boys in repeating their grammatical lesson. The single vocal airs of this period by Merula and others, which we have examined, in order to trace the progress of Italian melody, *ab ovo*, are dull, monotonous, and inelegant. Imagination, as yet, was too much fettered by canto fermo, canon, fugue, and ecclesiastical modes, to attempt the use of her wings.

MERULA, in *Ichthyology*, a species of *Labrus*; which see.

MERULA *Fluviatilis*, a name given by Schoneveldt, and some other writers, to the common tench. See CYPRINUS *Tinca*.

MERULA, in *Ornithology*, the *Black-bird*, a species of *Turdus*, of which there are several varieties. See TURDUS *Merula*, &c. For other species of *Merula*, see ALAUDA, CORVUS, GRACULA, LANIUS, MUSCICAPA, ORIOLUS, PARADISEA, STURNUS, and TANAGRA.

MERULA *Aquatica*, the name of a bird called the *water-ouzel* in English. See STURNUS *Cinclus*.

MERULA *Saxatilis*. See TURDUS *Saxatilis*, LANIUS *Infustus*, and CORVUS *Caryocatactes*.

MERULIUS, in *Botany*, a name of far-fetched etymology and meaning; adopted by Haller, for the genus which now retains it, from John Baubin, who in his *Historia* v. 3. 807, mentions some fungi as called by the name of *Merulius* or *Metulius*, from *Meta*, a pillar or boundary-post with a round top, which their shape resembles. Such fungi, no doubt, are numerous, belonging to various genera; but the idea is less suitable to our present *Merulii*, than to most others.—Hall. Hist. v. 3. 150. Perf. Syn. 488. (Cantherellus; Juss. 4. Lamarck Illust. t. 883.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. Cap fleshy or membranous. Receptacle veiny, with superficial swelling plaits.

Perfoon defines 25 species of this very well-marked genus, whose fructifying membrane resembles the gills of an *Agaricus* in appearance only, being totally distinct in nature. Its surface is perfectly continuous, but pinched up, as it were, into simple or branched tumid plaits.—The genus is divided into three sections; 1st, the true *Cantherelli*, which have an entire, rather cup-shaped cap, with or without stalk, and consist of 20 species; 2d, *Serpula*, four species, which spread indeterminately, fructifying on the upper side, and have no stalk; 3d, *Gomphus*, one species, of a club-like but truncated shape, which we think might be referred to the first section.

Examples of the first section are,

M. *Cantharellus*. Common Chanterelle. Perf. n. 1. (M. n. 2326; Hall. Hist. v. 3. 150. Agaricus Cantharellus; Linn. Sp. Pl. 1639. Hudf. 609. Fl. Dan. t. 264. Bull. t. 505. f. 1. Sowerb. t. 46. Bolt. t. 62. A. n. 73; Schæff. t. 82, and n. 95. t. 206. Fungus angulosus, et velut in laciniis dissectus; Vaill. Paris. 60. t. 11. f. 14, 15.)—Clustered, deep yellow all over. Cap fleshy, smooth, depressed.—Very frequent in fir woods. It varies in the breadth of its top, from one to near three inches, and is entirely of the colour of yolk of egg, with an agreeable scent like a plum or apricot, especially when drying. This fungus is eaten in many countries, and seems to be no otherwise unwholesome, than as its toughness renders it indigestible. Haller reports the flavour to be excellent, though somewhat acrid, and says he had often eaten this *Merulius* dressed in meat broth, without any bad effects.

M. *nigripes*. Black-stalked Chanterelle. Perf. n. 3. (Agaricus cantharelloides; Bull. t. 505. f. 2.)—Cap funnel-shaped, yellowish. Stalk elongated, black, and footy.

—Native of France. Perfoon seems to have adopted it from Bulliard. The taller, more slender, black *stalk*, and more excavated top of the *cap*, seem the principal marks of distinction between this and the first species, of which Mr. Sowerby esteems it a variety only.

M. luteifera. Yellowish-stalked Chanterelle. Perf. n. 4. (Agaricus cantharelloides; Sowerb. t. 47. Helvella cantharelloides; Bull. t. 473. f. 3.)—Cap umbilicated, smooth; yellowish brown above; red lish ash-coloured beneath. Stalk yellow, hollow.—Not uncommon in woods in autumn, according to Perfoon, but it seems to have been first observed in England by Mr. Sowerby, Nov. 1794, in Peckham wood. This is clearly distinguished by its hollow pale-yellow *stalk*, and the reddish buff of its fructifying membrane, contrasted with the light brown of the upper surface.

M. cornucopioides. Cornucopiæ Chanterelle. Perf. n. 8. (Peziza cornucopioides; Linn. Sp. Pl. 1650. Sowerb. t. 74. Bull. t. 150. Bolt. t. 103. Elvela, n. 17. Schæff. t. 165, and n. 18. t. 166.)—Cluttered, blackish, trumpet-shaped, with a wavy reflexed margin; the upper surface scaly; fructifying membrane blueish, with obsolete plaits.—Common in woods in autumn. Distinguished by its invertedly conical trumpet-like shape, with scarcely any *stalk*, the central hollow of the *cap* running down the middle, almost to the root, so as to form a funnel, the outside of which is really the under side of the *cap*, and bears a blueish powder, presumed to be the seed. The plaits of this part are in general sufficiently obvious to mark the genus, though often evanescent. An essential difference exists between this fungus and *Peziza*, the latter producing its seeds from the strongly-coloured upper side of the *cap*, or cup.

M. retirugus. Reticulated Sessile Chanterelle. Perf. n. 16. (Helvella retiruga; Bull. t. 498. f. 1.)—Sessile, vertical, roundish, thin and membranous; smooth and pale grey above; ash-coloured, with radiating reticulated plaits beneath.—This pretty species was found in France by Richard, growing parasitically upon mosses and other plants, affixed by its smooth upper side. The margin is entire when young, but subsequently torn or lobed. The *stalk* is wanting in this, and two or three others of the first section, and Perfoon seems doubtful whether they ought not to range in the next. Their membranous nature, and determinate form, with the presence of a proper upper surface, surely justify their remaining where he has placed them.

The second section (which is Perfoon's third, as he divides the former into two, because some have a central stalk, and others a lateral one, or none at all) comprises four species, whose shape is quite indeterminate, the whole fungus being reversed, or laid on its back, without any stalk, and almost without any upper surface. The fructification is rare, or tardily produced. The most remarkable is

M. destruens. Dry-rot Merulius. Perf. n. 21. (Boletus lachrymans; Wulf. in Jacq. Misc. Austr. v. 2. 111. t. 8. f. 2. Dickf. Crypt. fasc. 1. 18. Sowerb. t. 113.)—Widely spreading, indeterminate, yellowish-red, with a white downy edge. Plaits widely reticulated. The nature of this formidable fungus has not been known till within a few years, though its effects have been but too notorious in countries where much fir wood is used for building. The plant insinuates itself in the form of a fine web, like a sort of mouldiness, amongst the timbers or wooden walls of a house, which it speedily and effectually destroys, so that in Sweden, where houses of fir are common, their unexpected downfall is by no means unfrequent. Mr. Sowerby informs us of this pest having lately attacked some ships in the British navy, concerning which he has been consulted by the navy commis-

sioners. The cure for this evil is the admission of air into all such structures, which is fatal to the growth of the plant. Where this vegetable thrives, it meets with a check to its increase by walls or otherwise, it thickens greatly, and produces a sort of orange-coloured honey-comb structure, containing the *seeds*, and discharging large drops of fluid here and there, as expressed in Mr. Sowerby's plate, justly commended by Perfoon.

M. vasinator, Perf. n. 22, seems very nearly akin to the last.

The third section consists of only one species,

M. clavatus. Club-shaped Chanterelle. Perf. n. 25. (Clavaria truncata; Schmid. Ic. t. 60.)—Club-shaped, abrupt, solid, with lateral plaits.—Found in grassy places in Germany, generally growing in tufts. The colour is violet, dull purple, or brownish. The shape is that of a *Clavaria*, either simple or branched; the top abrupt and flat, evidently, though narrow, analogous to the usual upper surface of the *cap* of a *Merulius*; the sides of the club-shaped body below being plaited or veiny, like the fructifying part of the other species.

MERY, JOHN, in *Biography*, a distinguished anatomist and surgeon, was born at Vavau, in Berry, where his father practised surgery, in January 1645. From his earliest years he displayed an exclusive attachment to the profession of his father, and at the age of eighteen went to the great hospital at Paris, the Hôtel Dieu, where he pursued the study with extraordinary ardour. So earnest, indeed, was he in this pursuit, that whenever he could procure a body, he conveyed it to his bed-room, and passed the night in dissection. In 1681 he was promoted to the office of queen's surgeon; and in 1683 he was appointed surgeon-major to the invalids, at the instance of M. de Louvois, who justly estimated his zeal and talents. In the following year, when the king of Portugal applied to Louis XIV. to send a surgeon to Lisbon to attend upon the queen, he was sent post to that capital; but the queen died before his arrival. Both the courts of Spain and Portugal attempted, by very advantageous offers, to induce him to remain in the peninsula, but he declined them, and returned to Paris. He was now, 1684, received into the Academy of Sciences; and he was soon afterwards sent on a journey to England, by order of the court; but the object of this mission was never made public. He was also chosen by the monarch to attend upon the duke of Burgundy, then a child. Attendance on a court, however, as Fontenelle remarks, was not less irksome to him at home, than in Spain or Portugal, and he returned as soon as it was in his power to the hospital of invalids, and to the dissecting room.

He lived in retirement from all society, as far as it was possible, shutting himself in his closet as soon as he had performed the ordinary duties of his office, which he transacted very methodically: he was not seen even by his family, except at his hours of repast; and declined all solicitations to engage in private practice, except for the service of a few friends. In 1700 he was appointed first surgeon to the Hôtel Dieu, which gratified his utmost ambition, and afforded him abundant opportunities of gratifying his zeal in the pursuit of knowledge, for which he voluntarily sacrificed all considerations of rank and emolument. His high reputation for anatomical knowledge brought many requests from foreigners to give lectures upon that subject; which, however, he declined. But he procured for the students of the Hôtel Dieu the erection of a theatre, in which they might obtain a regular course of anatomy, instead of the casual instructions which they had hitherto received; and he expected no additional

tional recompence for his increased trouble. It was a great part of the labour of his life to form an anatomical museum, which at length he rendered extremely curious and complete. For this purpose, he secluded himself in the most minute and patient dissections; and no man surpassed him in the accuracy with which he investigated facts relative to the construction of the human body. Nevertheless, he justly entertained a very humble opinion of the extent of information, which the knife of the anatomist can bring before the mind, in regard to the minute operations of the animal economy; and was accustomed to say ingenuously, "we anatomists are like the porters of Paris, who are well acquainted with all its streets, as well as its lanes and alleys, but know nothing of what passes within the houses." From the steady occupation of the investigation of facts, he was not in the habit of inventing theories, and did not readily admit the reasonings of others; at the same time, he did not easily renounce his own, when he thought them well founded on observation. Being little used, likewise, to the forms of polite conversation, he stated his views with great plainness, and used no ceremony in contradicting opinions and assertions, which he thought absurd or unfounded in fact; whence he sometimes gave offence at the meetings of the Academy without intending it. In his moral habits he was extremely regular, and always had a high sense of religion. He was married, and had several children. About the age of seventy-five, he suddenly lost the use of his legs, without any other indisposition; but from that time his health and strength began to be impaired, and he died in 1722, in his seventy-seventh year.

In addition to a great number of valuable communications, which were printed in the Memoirs of the Academy of Sciences, Mery published the following works separately. 1. "Description de l'Oreille de l'Homme," Paris, 1681, which was annexed to Laney's work "De l'Âme sensitive," by which he anticipated Duverney, who was known to have been long employed on the same subject. 2. "Observations sur la Manière de Tailler dans les deux Sexes, pour l'Extraction de la Pierre, pratiquée par Frère Jacques," *ibid.* 1700, 12mo. This is a very scientific and candid discussion of that celebrated empiric's method of cutting for the stone, the general principle of which he approves, while he points out many mischiefs in his operations, occasioned by his ignorance of anatomy, and the rudeness of his instruments. 3. "Nouveau Systeme de la Circulation du Sang, par le trou ovale, dans le Fœtus humain, avec les Reponses aux Objections de M. M. Duverney, Sauvry, Verheyen, Sylvestre, et Buissiere," *ibid.* 1700, 12mo. The controversy upon this question was carried on with ardour. Mery controverted the received opinion, that part of the blood passes from the right to the left ventricle, through the foramen ovale, and maintained that its passage was in the opposite direction; and, therefore, that the greater part of the blood in the fœtus circulated through the lungs, and the smaller portion through the rest of the body. It is singular, as Senac remarks, in his treatise on the heart, that Mery, who was in error, had the greater number of partizans; but Duverney and the rest defended the question ill. 4. His last work, "Problèmes de Physique," *ibid.* 1711, 4to., relates to the connection of the fœtus with the mother, and its nutrition, which he maintains, in opposition to Falconet, to be effected by means of the maternal blood alone, and not by any lacteous fluid, produced in the uterus for that purpose. Eloy Dict. Hist. de la Med. Fontenelle, *Eloges des Acad.* Gen. Biog.

MERY-*fur-Seine*, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in

the district of Arcis-*sur-Aube*; 15 miles N.W. of Troyes. The place contains 1164, and the canton 9849 inhabitants, on a territory of 330 kilometres, in 26 communes. N. lat. 48° 30'. E. long. 3° 58'.

MERYTA, in *Botany*, from *μυρτα*, to collect in clusters, alluding to the situation of the flowers. Forst. Gen. t. 60. Just. 442. Lamarck Illustr. t. 803. Class and order, *Dinizia Triandria*. Nat. Ord. uncertain.

Gen. Ch. Male flowers aggregate in close heads. Cal. Perianth in three deep, ovate, acute segments. Cor. none. Stam. Filaments three, capillary, the length of the calyx; anthers oblong, with four furrows.

Female flowers not discovered.

1. *M. lanceolata*. Forst. Prod. 92.—Native of the Society isles.—The male flowers are represented in an hemispherical, lateral, sessile head. This is all the information extant respecting the genus in question; except that we find, by a note of the younger Linnæus, that sir J. Banks and Dr. Solander had likewise described it as new, by the name of *Nesfa*.

MERZAPOUR, in *Geography*, a town of Bengal; 15 miles N.N.W. of Moorshedabad.—Also, a town of Hindoostan, in the country of Benares, seated on the Ganges; 24 miles W.S.W. of Benares. N. lat. 25° 10'. E. long. 82° 50'.

MERZBERG, a town of Silesia, in the county of Glatz, which has a silver mine; 10 miles S. of Glatz.

MERZIFOUR, a town of Asiatic Turkey, in Natolia; 30 miles S. of Samfun.

MES, a river of Persia, which runs into the Tab, near Ragian.

MESA, CHRISTOVAL DE, in *Biography*, a Spanish poet, who lived five years in habits of intimacy with Tasso. He is the author of three heroic poems. 1. "Las Navas de Tolosa," 1598, upon the great victory won at Madrid by Alonzo VIII. over the Moors. 2. "La Restauracion de Espana," 1607, of which Pelayo is the hero. 3. "El Patron de Espana," 1612, in honour of Santiago. Besides these works he published some smaller pieces, as a tragedy upon Pompey, and a translation of the whole of Virgil; and he left in MS. a version of the Iliad. Gen. Biog.

MESA, in *Geography*, a river of Russia, which discharges itself in the Tazovskaia gulf, N. lat. 68° 12'. E. long. 79° 14'.

MESA, La, the southernmost of four isles in the Pacific ocean, near each other, and E. of the Sandwich isles. N. lat. 10°. W. long. 137° 10'.

MES-AIR, or MEZAIR, in the *Manege*, is a manege half *terra a terra*, and half *corvet*: so that the mezaire is higher than the action of the former, and lower than that of the latter. In this action use the same aids as in working upon curvets. Give the aids of the leg with delicacy, and no stronger than is just necessary to carry your horse forward. Remember when you close your legs to make him go forward, to push with the outward in such a degree as to keep your horse confined, and to assist the other in driving him forward; as it is not necessary to lay so much stress on the inner leg, because that serves only to guide the horse, and make him cover and embrace the ground that lies before him. Berengier's Horsemanship, vol. ii. p. 116.

MESANA, in *Geography*, a town of Hindoostan, in Guzerat; 35 miles N. of Amedabad.

MESANGE of Buffon, in *Ornithology*. See MOTACILLA and PARUS.

MESANGIA, the name of a bird common in France and Italy; it is of the size and shape of the *ficedula*,

and differs from it very little, except the having a black spot upon the head. This seems to be the *melancoryphos* of the ancients, who supposed, as many do at this time, that the scedula changed into this bird. The scedula, or fig-eater, comes into the gardens in France only at the time when the figs, which are its proper food, are ripe: these it devours in an insatiable manner, and, as soon as it has done with them, goes away again. Soon after this the *mesangia* or black-cap appears, and is supposed to be the same bird, with the addition of this beautiful ornament. The ancients were very fond of this imaginary change of one bird into another; and Aristotle tells us, that the upupa is the same bird with the cuckoo, only changed in the colour and disposition of its feathers. Æschylus tells us in the same manner, according to the opinion of his times, that the cuckoo sings all the summer, and after that disappears; and that soon afterwards it comes again in a new form, with a plume upon its head, and is called the *upupa*.

MESARAIC, in *Anatomy*, a term applied to the blood-vessels, glands, &c. of the mesentery.

MESAYEH, in *Geography*, a town of the Arabian Irak, on the Euphrates; 50 miles S.S.W. of Bagdad.

MESAZONTES, *μεσάζοντες*, officers under the emperors of Constantinople. See MEDIATOR.

MESCHEDIZAR, in *Geography*. See MEDSHETISAR.

MESCHETWIND, a town of Bavaria, in the principality of Bamberg; seven miles S.W. of Forcheim.

MESCHID, a town of the Arabian Irak, near a large lake called "Rahemat," which communicates by a canal with the Euphrates. This is the place in which Ali, Mahomet's cousin and friend, and one of his successors, is said to have been interred; and his tomb is annually visited by a multitude of Persian pilgrims, who deem it a part of devotion equal to the pilgrimage to Mecca; 90 miles S. of Bagdad. N. lat. $32^{\circ} 5'$. E. long. $43^{\circ} 34'$.

MESCHID-Huffain, a town of the Arabian Irak, situated on a canal which passes from the Euphrates to the lake Rahemat; 53 miles S.S.W. of Bagdad. N. lat. $32^{\circ} 36'$. E. long. $43^{\circ} 29'$.

MESCHID, or *Maschid*, a city of Persia, in the province of Khorasan. Abas I. raised this place, which was small and called "Tus," to eminence, by erecting a magnificent mosque in honour of an Imam who was buried there, and which drew together a great number of pilgrims. This town has a manufacture of beautiful pottery, and also a manufacture of skins. In time of peace caravans pass continually through this town from Bucharia, Balk, Candahar, Hindooftan, and all parts of Persia. N. lat. $37^{\circ} 35'$. E. long. $57'$.

MESCHIDABAD, a town of Asiatic Turkey, in Nalolia; 25 miles S.S.W. of Amafreh.

MESCHIQUEJOS, a town of South America, in the province of Carthagenia; ten miles S. of Mompox.

MESCINZUNGH, a town of Thibet; 30 miles W. of Tankia.

MESCOLANZA, Ital. mixture: as *mescolanza dell' antica e moderna*, a mixture of ancient and modern music.

MESE, in *Geography*, a small island in the East Indian sea. N. lat. $6^{\circ} 55'$. E. long. $131^{\circ} 50'$.

Mesé, in the *Ancient Greek Music*, the name of the most acute sound of the second tetrachord. It implies *mean*: as it was in the middle of the great system, and an octave above the *proslambanomenos*.

Euclid calls mese the found by which all other sounds are regulated. And Aristotle, in his 36th problem, sect. 19, says, that all the tones of a scale are accommodated or tuned to the mesé. See *MUSIC of the Ancients*.

MESLEMBRIA, or *Mesolium*, in *Geography*, a town of European Turkey, in Romania, at the mouth of a river which runs into the Black sea; formerly a bishop's see; 16 miles E.N.E. of Burgas. N. lat. $42^{\circ} 38'$. E. long. $27^{\circ} 47'$.

MESEMBRYANTHEMUM, in *Botany*, a vast genus of succulent plants, formerly known by the name of *Ficoidea*, from its affinity to the Indian Fig, or *Castus*. Breynius first named it *Mesembryanthemum*, meaning to express its flowers expanding at mid-day, which is true of many of the species, but not of all. Dillenius therefore, by altering one letter in the orthography, had recourse to another etymology, from *μεσος*, the middle, *εμβρυον*, an embryo, and *αθος*, a flower; because the embryo (meaning the germen) is in the middle of the flower; which indeed, as that author most truly remarks, is the case with innumerable plants besides, but not exactly as in the present genus. He observes that the flower does not altogether stand on the top of the fruit, but is perforated, as it were, by the latter, whilst it so closely adheres to the middle, as not to be separable from it without laceration. We confess our predilection for the original idea of Breynius, which if not strictly applicable to all the species, one or more of which are night-scented flowers, is strikingly apposite to the generality, whose resplendent and radiating petals seem to welcome, as well as to emulate, the noon-tide sun, folding themselves up as it withdraws. Fig-Marigold.—Dill. Elth. 225. Linn. Gen. 252. Schreb. 340. Willd. Sp. Pl. v. 2. 1025. Mart. Mill. Dict. v. 3. Ant. Hort. Kew. ed. 2. v. 3. 212. Juss. 317. Lamarek Dict. v. 2. 474. Illustr. t. 438. Gærtn. t. 126.—Class and order, *Icosandria Pentagynia*. Nat. Ord. *Succulenta*, Linn. *Ficoidea*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, in five acute, spreading, permanent segments. Cor. Petals numerous, linear-lanceolate, in many rows, rather longer than the calyx, slightly united into a tube by their claws. Stam. Filaments numerous, capillary, the length of the calyx, inserted into its fleshy part within the petals; anthers incumbent. Pist. Germen inferior, with five obtuse angles; styles generally five, sometimes four or ten, awl-shaped, spreading; stigmas simple. Peric. Capsule fleshy, roundish, marked with rays at the summit, the cells and valves each answering to the styles in number. Seeds numerous, roundish, affixed to the central column.

Ess. Ch. Calyx five-cleft. Petals numerous, linear, cohering at the base. Capsule fleshy, inferior, with many seeds.

Fifty species of *Mesembryanthemum* are defined in the 14th ed. of *Syst. Veg.* disposed in three sections, distinguished by the flowers being white, red, or yellow. Thunberg in his *Prodromus* has but 72; Willdenow mentions 86; but the new edition of the *Hortus Kewensis* enumerates 175. The labours of Mr. Haworth, who has published, in an octavo volume, an ample Monograph of the present genus, and who has, for many years, investigated and cultivated all the species he could procure, has thrown great light upon the subject, though we are not able to follow him in all that he describes, for want of having seen them so completely. They are almost exclusively the productions of the arid sands of the Cape of Good Hope; a very few only being found in New Holland, and New Zealand, or in the south of Europe. We shall therefore mention the native countries of such only of those we are about to particularize, as are found in other places, though even these are often likewise natives of the Cape; as the *crystallinum* and *nodiflorum*. There they are all at home. Their peculiarly succulent nature, like that of Aloes, is calculated to resist the

MESEMBRYANTHEMUM.

the burning sun and long-continued drought of that climate, their cuticle allowing of very slow perspiration, though of ready absorption; so that however exhausted they may be, they revive from the slightest shower. This wonderful provision of nature exists only in the living plant. When killed by momentary immersion in hot water, these succulent plants dry nearly as quick as any others. The horticulturists of Europe are best acquainted with the numerous perennial species of the genus before us. There have indeed been some annual ones raised here, but we have reason to think there are many almost entirely unknown. Some of these bear very curiously-constructed capsules, which expand by moisture, contrary to the nature of capsules in general, that their seeds may be dispersed in the wet season, when alone they would, in such a country, have any chance of germinating. (See Sm. *Introductio ad Botanicam*, 277. f. 178.)—We shall mention a few species of each of the 13 sections into which this genus is distributed in *Hort. Kew.*

1. *Stemless*; *inversely conical, or obovate, or more rarely spherical, the leaves being extremely abrupt, and united even to their summits, the flowers solitary.* Seven species in *Hort. Kew.*

M. minutum. Tiny Fig-Marigold. Ait. n. 1. Sims in *Curt. Mag.* t. 1376.—Smooth, glaucous, spotless, nearly globose, umbilicated. Bases of the petals forming a tube nearly as long as the borders.—This singular plant appears a congeries of glaucous balls, each about the size of a small gooseberry, hollowed out at the top, from whence springs a rose-coloured, sessile, solitary flower, larger than a daisy, with yellow stigmas, and a pale tubular base, composed of the united claws of the petals, by which it is elevated much above the calyx. This species blossoms from the middle of November to near Christmas, after which it must be kept without water through the winter, being preserved from frost.—Six more of this curious section are described by Mr. Haworth, and in *Hort. Kew.*, all sent from the Cape at different times by the late Mr. Francis Masson. See MASSON.

2. *Nearly stemless, with a perennial root.* Thirty-eight species.

M. calamiforme. Quill-leaved Fig-Marigold. Linn. Sp. Pl. 690. Willd. n. 20. Ait. n. 16. Dill. Elth. 239. t. 186. f. 228. (*Ficoides capensis humilis, capæ folio, flore stramineo*; Bradley Succ. Pl. t. 19.)—Leaves nearly cylindrical, acute, glaucous, finely dotted; flattened just above their base. Styles eight.—The numerous upright or ascending leaves, about a finger's length, compose dense glaucous tufts. Flowers large, of a brilliant white with pale lemon-coloured stamens, each on a very short, solitary, slightly leafy, stalk, not so tall as the leaves. This is one of the oldest inhabitants of our gardens. Bradley published it in 1717.

M. felinum. Cat-chap Fig-Marigold. Haworth n. 35. Willd. n. 11. Ait. n. 29. (*M. ringens* ♂; Linn. Sp. Pl. 698. *M. rictum felinum representans*; Dill. Elth. 240. t. 187. f. 230. *Ficoides afra, folio triangulari cusiformi crasso brevi, &c.*; Mart. Dec. t. 30.)—Stem none. Leaves glaucous, fringed with vertical taper-pointed teeth; cartilaginous at the extremity.—This has been long known in England, and thrives well in the dry stove, flowering for some time during autumn. It is distinguished by the idea which its opposite leaves, fringed with long vertical hooked teeth, convey of the widely-gaping mouth of a cat. The flowers are sessile, large, lemon-coloured, opening in the afternoon, and closing at night.

M. tigrinum, and caninum are nearly akin to this; and the latter was confounded with it by Linnæus.

M. præpingue. Soft Tongue Fig-Marigold. Ait. n. 38. (*M. heterophyllum*; Andr. Repof. t. 540.)—Leaves tongue-shaped, very tender; the younger ones finely fringed, incurved at the point.—This flowered at Mr. Lambert's, at Boyton. The herbage is peculiarly succulent and tender, of a grass green, and shining. Flowers large, yellow, on shortish stalks. Capsule closed when dry, expanding with moisture, as in some annual species above-mentioned, and, as it appears by the account in Andrews, (which, if we mistake not, came from the pen of the late excellent Mr. George Jackson, see JACKSONIA), in many perennial ones; perhaps in all the genus.

M. dolabriforme. Hatchet-leaved Fig-Marigold. Linn. Sp. Pl. 699. Ait. n. 45. Curt. Mag. t. 32. (*M. folio dolabriformi*; Dill. Elth. 248. t. 191. t. 237. *Ficoides capensis humilis, foliis cornua referentibus, petals luteis, noctiflora*; Bradl. Succ. Pl. t. 10.)—Stem short. Leaves compressed, with a very prominent dilated keel, and a cylindrical base.—Although the growth of this species be very slow, it has always more or less of a decided thick woody much-branched stem, so that few students would seek it in this section. The leaves are very peculiarly formed, as above described, and are the only instance of the hatchet shape; see Sm. *Intr. to Bot.* 171. f. 98. The flowers are plentifully produced, yellow, on longish, solitary, terminal stalks, and expand in the evening and night only.

3. *Stems prostrate. Leaves clustered, elongated. Petals yellow, either on both sides, or on the upper one only.* Five species.

M. loreum. Leathery-stalked Fig-Marigold. Linn. Sp. Pl. 694. Willd. n. 48. Ait. n. 46. Dill. Elth. 264. t. 200. f. 255.—Leaves semicylindrical, somewhat triangular, elongated, recurved, rather glaucous, in round tufts. Stems lax, roundish, slender, whitish. Flowers axillary.—Though this has been generally cultivated in England for above 80 years, nothing is recorded of its blooming. Willdenow however describes the flowers as very rarely produced in the collection of Engelbert Gother, each on a short axillary stalk, from the lower leaves of the branch, with a purple corolla, and whitish stamens. The plant is known by its long trailing twine-like shoots, bearing several little tufts or knots of leaves, and generally dependent over the edges of the garden-pot.

4. *Leaves very long, alternate, closely crowded into tufts. Stem decumbent when old. Petals very narrow, fringed from the base to the middle.* Three species.

M. capitatum. Short Dagger-leaved Fig-Marigold. Haworth. Ait. n. 52. (*M. pugioniforme*; Linn. Sp. Pl. 699. Willd. n. 80. *M. pugioniforme, flore amplo stramineo*; Dill. Elth. 280. t. 210. f. 269. *Ficoides capensis, caryophylli folio, flore aureo specioso*; Bradl. Succ. Pl. t. 14.)—"Leaves awl-shaped, triangular with equal sides, glaucous. Membranes of the calyx pale. Petals yellow, as long as the calyx; the outer ones purplish. Styles bristle-shaped, straight."—A fine large branching species, distinguished by the great size of its flowers, which are nearly as broad as the palm of the hand, of a brilliant straw-colour, purplish underneath, opening in sun-shine only. The leaves are numerous, curved, three or four inches long. This is the original *M. pugioniforme*, and we do not well understand why that name should be transferred to another species, which it seems is so called in a French work on Succulent Plants, t. 72, and which has more compressed leaves, the membranes of the calyx brown, petals entirely straw-coloured, shorter than the calyx, and linear-lanceolate expanded styles.

MESEMBRYANTHEMUM.

5. *Leaves flat, often somewhat keeled beneath. Stems often decumbent or prostrate, widely spreading. Seventeen species.*

M. crystallinum. Ice-plant. Linn. Sp. Pl. 688. Willd. n. 25. Ait. n. 54. (*M. crystallinum*, *plantagina folio undulato*; Dill. Elth. 231. t. 180. f. 221. *Ficoides africana*, *folio plantagine undulato*, *micis argenteis asperis*; Bradd. Succ. Pl. t. 48.)—Leaves alternate, ovate, waved, papillary. Flowers sessile. Segments of the calyx ovate, broad.—Linneus, not without reason, doubted whether this species came from Africa. Thunberg, however, found it at the Cape of Good Hope. The late Dr. J. Sibthorp gathered it about Athens. In gardens the plant has long been known, as a tender annual, much admired for appearing as if frosted over; or encrusted with sugar. This appearance is caused by innumerable little bladders in the cuticle, filled with limpid juice. To the touch the whole herb is cold, and remarkably flaccid. Its stem spreads widely on the ground, in a rank mode of growth, bearing numerous broad undulated leaves, and copious, nearly sessile, flowers, of a pale rose or flesh-colour. The fruit is dark purple.

M. pinnatifidum. Jagged-leaved Fig-Marigold. Linn. Suppl. 260. Willd. n. 23. Ait. n. 55. Curt. Mag. t. 67.—Leaves oblong, pinnatifid, papillary. Flowers axillary, on longish stalks.—This also is an annual, whose seeds, sent by Thunberg from the Cape, vegetated in the Upsal garden. The pinnatifid leaves, and small yellow long-stalked flowers, are its characteristics.

M. cordifolium. Heart-leaved Fig-Marigold. Linn. Suppl. 260. Willd. n. 24. Ait. n. 65. Sm. Spicil. t. 6. Jacq. Ic. Rar. t. 487.—Leaves stalked, papillary, heart-shaped or ovate. Stem round. Calyx often four-cleft.—Soon after the first introduction of this species, it was common in every green-house, but is now rather neglected. The stems are shrubby, though long and trailing. Leaves darkish green. Flowers small, deep crimson. It is readily propagated by cuttings.

6. *Leaves linear; the younger ones channelled above, convex beneath. Branches often somewhat shrubby. Root mostly perennial; rarely annual. Seventeen species.*

M. nodiflorum. Neapolitan Fig-Marigold. Linn. Sp. Pl. 687. Willd. n. 56. Ait. n. 71. (*Kali floridum repens Neapolitanum*; Column. Ecphr. t. 73.)—Leaves alternate, nearly cylindrical, obtuse; fringed at the base.—Native of the sea-coasts of the south of Europe, and north of Africa. Root annual. Stem branched from the bottom, spreading, covered, like the leaves, with pellucid watery vesicles, as in *M. crystallinum*, but rather less glaucous. Flowers lateral or axillary, sessile, solitary, small and unornamental, with narrow white petals and yellow stamens. The segments of the calyx are oblong, obtuse, leafy, very unequal in size.

M. viridiflorum. Green-flowered Fig-Marigold. Willd. n. 51. Ait. n. 74. Curt. Mag. t. 326.—Leaves semi-cylindrical, hairy, somewhat papillary. Calyx hairy. Petals capillary. Stem tumid. Branches diffuse.—A shrubby species, singular in having green petals, which are very copious, and as narrow as a fine thread. The herbage is downy all over, slightly glaucous and papillary. It blooms from July to September, and is readily increased by cuttings. Mr. Masson sent this from the Cape in 1774.

7. *Evening-flowering; with slender, shrubby, hard, greatly defoliated stems; nearly cylindrical undotted leaves; a four-cleft calyx; fragrant flowers, white on their upper side; roots much swelled with age, having very few fibres. Two species.*

M. noctiflorum. Night-flowering Fig-Marigold. Linn. Sp. Pl. 689. Willd. n. 41. Ait. n. 88. *M. noctiflorum*. flore intus candido, extus phœniceo, odoratissimo; Dill.

Elth. 273. t. 206. f. 262.)—Leaves remote, obscurely semicylindrical, distinct, glaucous. Bark white—Highly desirable for the sake of its flowers, whose scent in an evening is like the Scarlet *Craffula*, or the finest Bergamot Pear. The stem is shrubby, pale, upright, round, cross-branched at the top. Flowers on longish stalks, from the ends or forks of the branches, with a thick pear-shaped germen, and short four-cleft calyx, much exceeded by the numerous pale petals, whose under side is either red or yellow.

M. stramineum. Straw-coloured Sweet Fig-Marigold. Haworth. Ait. n. 89. (*M. noctiflorum* β ; Linn. Sp. Pl. 689) Willd. n. 41. *M. noctiflorum*, flore intus candido, extus stramineo, odoratissimo; Dill. Elth. 274. t. 206. f. 263.)—Leaves remote, nearly cylindrical, distinct, rather glaucous. Bark grey.—Mr. Haworth agrees with Dillenius, who strenuously insisted on this being specifically distinct from the last, of which most writers make it a variety. The flowers are larger, very white above, pale yellow beneath. They expand only in an evening, like the last, and smell like the Dame's Violet, or Rocket (*Heesperis*).

8. *Flowers generally reddish. Branches shrubby, smooth. Leaves triangular and compressed (except M. laeve, Ait. n. 93), naked, with straight points. Thirty-nine species.*

M. spectabile. Showy Fig-Marigold. Haworth Me-
seembry. 385. Willd. n. 73. Ait. n. 98. Curt. Mag. t. 396.—Leaves crowded, triangular, elongated, glaucous, somewhat curved. Stem woody, ascending.—Introduced by Mr. Masson in 1787. Its fine large crimson flowers, produced all summer long, render this one of the most desirable, nor is it difficult of culture. Mr. Curtis observes that the leaves, which are very glaucous, and often tinged with red, sometimes acquire a prominent tooth or appendage on their upper side near the point.

M. acinaciforme. Scimitar-leaved Fig-Marigold. Linn. Sp. Pl. 695. Willd. n. 83. Ait. n. 116. Andr. Repos. t. 580, not 508. (*M. acinaciforme*, flore amplexissimo purpureo; Dill. Elth. 282. t. 211. f. 270, and t. 212. f. 271.)—Leaves scimitar-shaped, dotless, combined at their base; their margins minutely undulated and rough. Petals lanceolate.—One of the first species brought to Europe, and one of the largest and most ornamental when it flowers, which unfortunately is but of rare occurrence. Andrews says this was accomplished by Mr. Trimmer of Brentford, by training the branches up against the glass, and watering the plant very sparingly. The leaves are numerous, three inches long, very glaucous. Flowers terminal, solitary, as broad as the hand, formed of innumerable recurved bluntish petals, of a fine crimson, with white filaments and yellow anthers.

M. edule. Eatable Fig-Marigold. Hottentot's Fig. Linn. Sp. Pl. 695. Willd. n. 85. Ait. n. 119 (*M. falcatum majus*, flore amplo luteo; Dill. Elth. 283. t. 212. f. 272.)—Leaves with three equal sides, dotless, somewhat channelled; tapering at each end; keel finely serrated. Angles of the branches smooth and entire.—This is said to have been one of the Cape plants, brought from Holland by the first Earl of Portland. It rarely flowers here, and not till the plant is old and woody. It nearly vies with the last in size, but the flowers are yellow. The fruit is reported to be eaten at the Cape, both by the Hottentots and the Dutch settlers.—The colour of this flower is an exception to the character of the section, but its close affinity to some of the other species has superseded that one particular mark.

9. *Flowers yellow, orange, or scarlet. Stems rather shrubby, often erect. Leaves triangular, for the most part very short. Twelve species.*

M. aureum.

MESEMBRYANTHEMUM.

M. aurum. Golden-flowered Fig-Marigold. Linn. Syft. Nat. ed. 10. v. 2. 1060. Willd. n. 75. Ait. n. 136. Curt. Mag. t. 262.—Leaves triangular, somewhat cylindrical, dotted, distinct. Petals orange. Styles deep purple.—A bushy species, long cultivated here, and easily increased, known by its rather large orange-coloured *corolla*, pale yellow *stamens*, and five purple *styles*, spreading like a star. The *leaves* are glaucous, tumid between their angles, about one inch and a half long. So great a similarity between the species of this section exists in the form of their *leaves*, that botanists are obliged to recur to the colours of the parts of fructification, which experience proves, in this case, to be constant. The *aurum* blossoms from February to May, being one of the earliest of its genus.

M. tenuifolium. Slender-leaved Fig-Marigold. Linn. Sp. Pl. 693. Willd. n. 45. Ait. n. 140. (*M. tenuifolium procumbens*, flore coccineo; Dill. Elth. 264. t. 201. f. 256.)—Leaves femicylindrical, awl-shaped, slightly compressed, green, smooth, longer than the joints of the branches. Petals scarlet. Stems decumbent.—Cultivated at Chelsea in 1700. Its procumbent habit, and slender scarcely glaucous *foliage*, mark this species. The *flowers* are plentiful about Midsummer, rather large, of a light brilliant scarlet, each lasting several days.

10. *Leaves more or less hooked at their points, distinct (without thickened sheaths) at the base. Petals reddish. Stems somewhat shrubby, very rarely creeping.* Ten species.

M. tuberosum. Tuberous-rooted Fig-Marigold. Linn. Sp. Pl. 693. Willd. n. 44. Ait. n. 146. (*M. fruticescens*, radice ingenti tuberosa; Dill. Elth. 275. t. 207. f. 264.)—Leaves bluntly triangular, compressed, minutely papillary; recurved at the ends. Root tuberous, very large.—Brought from the Cape at the beginning of the last century. The root consists of several large ovate knobs, almost like those of a *Dahlia*. Stems woody, variously branched and curved. *Leaves* about an inch long, convex above. *Flowers* small, dull red, in terminal dichotomous panicles, whose permanent stalks often become spinous.

The *flowers* in this section are among the least beautiful of the genus.

11. *Leaves triangular, strongly united, so as to be perfoliate; their sheaths fleshy; their tips hooked. Stems hard, woody. Flowers mostly white, rarely reddish.* Twelve species.

M. perfoliatum. Great Perfoliate Fig-Marigold. Ait. n. 152. (*M. uncinatum* β ; Linn. Sp. Pl. 692. Willd. n. 79. *M. perfoliatum*, foliis majoribus triacanthis; Dill. Elth. 251. t. 193. f. 240.)—Leaves strongly united at the base, pointed, dotted; their keel three-toothed at the summit.—A bushy plant, of rather slow growth, remarkable for two sharp teeth, besides the terminal one, at the back of its strongly perfoliate *leaves*. The *flowers* are purple, not frequent, produced after Midsummer.

M. uncinatum α of Linnæus and Willdenow, Dill. f. 239, differs in its smaller size, and having but one tooth below the point of the *leaves*.

M. umbellatum. Umbel-flowered Fig-Marigold. Linn. Sp. Pl. 689. Willd. n. 42. Ait. n. 162. (*M. fruticescens*, floribus albis umbellatis; Dill. Elth. 276. t. 208. f. 266. *Ficoides africana erecta teretifolia*, floribus albis umbellatis; Herm. Parad. 166. t. 166. Bœadl. Succ. Pl. dec. 4. 12. t. 44, not 34.)—Leaves rather glaucous, rough with minute dots, remote, elongated, slender; their points recurved; their sheaths greatly thickened upwards.—This, according to Hermann, was early plentiful in the gardens of Holland. The *stem* is often two feet high. *Leaves* two inches long, spreading, channelled above, bearing axillary tufts of smaller

ones. *Flowers* white, about as big as a daisy, many together in a forked umbel-like *panicle*, not a real umbel.

12. *Stems shrubby, their branches more or less rough.* Five species.

M. micans. Glittering Fig-Marigold. Linn. Sp. Pl. 696. Willd. n. 54. Ait. n. 163. Curt. Mag. t. 448. (*M. micans*, flore phœniceo, filamentis atris; Dill. Elth. 292. t. 215. f. 282.)—Leaves femicylindrical, blantish, papillary, slightly recurved. Segments of the calyx rather pointed. Petals acute.—An old inhabitant of our greenhouses, distinguished by its glittering, glaucous, often purplish, *leaves* and *branches*, and the very rich orange scarlet of its *flowers*, which however are not so lasting as beautiful. The dark purple *stamens* form a striking contrast with the *corolla*.

Mr. Haworth's *M. speciosum*, Ait. n. 164, seems to us but a variety of this, with blunter *petals* whose claws are green.

13. *Branches, or leaves, or the tips of the leaves, more or less bipid.* Eight species.

M. bipidum. Purple Bristly Fig-Marigold. Linn. Sp. Pl. 691. Willd. n. 61. Ait. n. 168. Mill. Ic. t. 176. f. 3. (*M. pilosum micans*, flore saturantèr purpureo; Dill. Elth. 289. t. 214. f. 277, 278.)—Leaves cylindrical, blunt, papillary, without hairs, as well as the calyx. Stamens longer than the pistils. Branches very hairy.—Common in greenhouses, flowering most part of the year. The very bristly *stem* and *branches*; thick, deflexed, blunt *leaves*, and large *flowers*, of a shining violet purple, distinguish the present from all we have hitherto noticed.

Linnæus made several varieties of this, which are the *floribundum*, *friatum*, and perhaps *hirtellum*, Ait. n. 169, 171, and 170, all nearly akin, but we mean not to say they are one species. The citation of Willdenow under the *floribundum* in *Hort. Kew.* should be *M. bipidum* β .

M. barbatum. Trailing Bearded Fig-Marigold. Linn. Sp. Pl. 691. Willd. n. 63. Ait. n. 173. Curt. Mag. t. 70. (*M. radiatum*, ramulis prolixis recumbentibus; Dill. Elth. 245. t. 190. f. 234.)—Leaves remote, somewhat ovate, tumid, papillary; flatish above; tipped with five radiating bristles. Branches slender, smooth, straggling. Calyx five-cleft.—Very common in greenhouses, and even in the garret windows of many a humble collector. The radiating bristles at the end of the tumid *leaves* are remarkable, and are but about five in this species. The *flowers* appear in July, and are of a rich violet purple. Linnæus by mistake quotes Miller's t. 176. f. 3, for the present plant, instead of the *M. bipidum*. Willdenow has it under both.

M. densum. Dwarf Bearded Fig-Marigold. Haworth. Ait. n. 175. Curt. Mag. t. 1220. (*M. barbatum* γ ; Linn. Sp. Pl. 691. Willd. n. 63. *M. radiatum humile*, foliis majoribus; Dill. Elth. 248. t. 190. f. 236.)—Stem very short. Leaves densely crowded, femicylindrical, papillary, tipped with many radiating bristles; their base somewhat fringed. Calyx six-cleft, very hairy, as well as the flower-stalks.—Dillenius says this was plentiful with him, but he never remembered its blooming. Mr. Haworth kept it 21 years without seeing a flower. We perfectly agree with Dr. Sims that this gentleman has shewn his judgment in separating this, as well as his *bisutum*, Dill. f. 235, from the *barbatum*, under which Linnæus had confounded them all. The *flower* of the *densum* is twice as large as that of either of the others, with conspicuous yellow *anthers*; and the white membranous itary bristles, at the end of each leaf, are very striking.

MESEMBRYANTHEMUM, in *Gardening*, comprehends plants of the succulent flowery exotic kinds, of which the species cultivated are, the diamond fig marigold, or ice plant (*M. crystal-*

MESEMBRYANTHEMUM.

orysallinum); the pinnated fig marigold (*M. pinnatifidum*); the plane-leaved fig marigold (*M. tripolium*); the small-flowered fig marigold (*M. caducum*); the angular-flaked fig marigold (*M. populifolium*); the jointed fig marigold (*M. geniculiflorum*); the night-flowering fig marigold (*M. noctiflorum*); the shining fig marigold (*M. splendens*); the umbrella-leaved fig marigold (*M. umbellatum*); the horse-leek-leaved fig marigold (*M. expansum*); the quill-leaved fig marigold (*M. calamiforme*); the daisy-flowered fig marigold (*M. bellidiflorum*); the delta-leaved fig marigold (*M. deltoidea*); the bearded fig marigold (*M. barbatum*); the brittle fig marigold (*M. hispidum*); the hairy-flaked fig marigold (*M. villosum*); the rugged fig marigold (*M. scabrum*); the creeping fig marigold (*M. reptans*); the hook-leaved fig marigold (*M. uncinatum*); the thorny fig marigold (*M. spinosum*); the tuberous-rooted fig marigold (*M. tuberosum*); the slender-leaved fig marigold (*M. tenuifolium*); the upright-shrubby fig marigold (*M. stipulaceum*); the thick-leaved fig marigold (*M. crassifolium*); the pickle-leaved fig marigold (*M. falcatum*); the clustered fig marigold (*M. glomeratum*); the two-coloured fig marigold (*M. bicolorum*); the ferrate-leaved fig marigold (*M. ferratum*); the glittering fig marigold (*M. micans*); the spit-leaved fig marigold (*M. veruculatum*); the glaucous-leaved fig marigold (*M. glaucum*); the horned fig marigold (*M. corniculatum*); the ringent fig marigold (*M. ringens*); the hatchet-leaved fig marigold (*M. dolabriforme*); the various-leaved fig marigold (*M. difforme*); the white fig marigold (*M. albidum*); the tongue-leaved fig marigold (*M. linguiforme*); the dagger-leaved fig marigold (*M. pugioniforme*); the twisted-leaved fig marigold (*M. tortuosum*); the notch-flowered fig marigold (*M. emarginatum*); and the bracteated fig marigold (*M. bracteatum*).

In the seventh species there is a variety in which the flowers are somewhat larger, and of a very pale yellow on the outside.

The thirteenth sort has different varieties; as the great delta-leaved, and the small delta-leaved marigold.

The fourteenth species has also several varieties; as the shrubby, bearded, the small dwarf-bearded, and the great dwarf-bearded.

And in the fifteenth kind there are different varieties; as the purple-flowered, the pale-flowered, and the stripe-flowered.

The nineteenth species likewise affords different varieties.

It may be noticed, that the twenty-sixth species is very variable, assuming different appearances, according to its treatment, and the different stages of its growth: its very numerous beautiful purple flowers, covering the whole plant, and produced every season, make it a valuable species in all cases.

The twenty-ninth species varies with paler and smaller flowers.

And the thirtieth varies with shorter and more manifestly three-sided leaves and fewer flowers.

The thirty-second species has a variety which throws out many procumbent branches, tough at the lower part, but not properly woody, herbaceous at the upper part, about three inches in length, round or slightly angular, jointed at short intervals, with bluntly triangular leaves, from which other leaves spring in bundles, of the same form but shorter; the root-leaves and those at the base of the branches remarkably long: the leaves bend like the horns of kine, whence the trivial name.

In the thirty-third species there is a variety which is entirely sessile, of a whitish glaucous colour, with the leaves

pale at the base, with frequent round whitish dots, especially towards the end; they are shorter than those of the original, more recumbent, less triquetrous, but with a rounder back, and more frequent, longer incurved prickles, terminated by slender harmless spicule, which are sometimes white, sometimes reddish: the leaves have a white line at the end, which is continued towards the back: there is first a flower in the middle, and afterwards several come out successively at the sides, all sessile. This is called *Cat-chap marigold*.

Mr. Haworth has two other varieties; the *Tiger-chap fig marigold*, which is stemless in all the stages of its growth; being more succulent and gross than the following: the leaves are rather shorter, beset with much longer hairs on the sides, and having numerous whitish spots: the flowers are sessile, yellow, and large; and the *Mouse-chap fig marigold*, in which the branches in very old plants are some inches long, and numerous, forming a fine tufted plant; the flowers small and of a yellow colour.

The thirty-seventh species has several varieties.

In the first the leaves are wide and compressed about the edge; the flowers somewhat large, with blunt petals, scattered and not numerous, with scarcely any peduncle; one plant has several heads, from each of which are produced clusters of leaves in pairs, disposed like those of the Tongue-aloes, but with the edges not horizontal but oblique; there are generally three or four pairs of these leaves; they are broad and thick, flat above, pillowed below, bright green, smooth and shining, sometimes blunt, sometimes a little pointed, generally in the shape of a shoemaker's knife; the younger leaves in this and the other varieties, are folded together and obliquely inserted into each other; the flowers come out successively in August and September from the axils, beginning with the lowest; they are subsessile, large, yellow, somewhat paler than in the following variety, shining in the sun; petals somewhat blunter, entire, or sometimes cut here and there.

The *Broad tongue-leaved* variety has thick leaves, flat above, convex beneath, with the margins thicker and less upright than in the preceding, smooth and shining, pale green, especially towards the base, when held up to the light appearing to be composed of innumerable vesicles; three or four pairs of these leaves lie in the same inclined plane; these are sometimes flatter and blunt at the end, sometimes very much cut at the edge; from the lower pair first, and then from the next, a short peduncle arises, obtusely triquetrous, bearing a large flower of a shining golden colour, with many stamens, having oblong golden anthers.

The *Narrow tongued-leaved* variety is very like the preceding, but the petals have a slight tinge of red on the outside; the older leaves are more reflex; the younger ones, which are closer and more luxuriant, are somewhat twisted in and excavated, and are of a fuller green colour, the fruit is smaller and softer, not elevated, but rather depressed, roundish, and commonly streaked with eleven angles; it is generally eleven-celled; the cells being the same in number as there are horns of the style, which are depressed at the bottom of the flower under the stamens, and are curled and wrinkled; the petals in two or three rows, almost of the same length, of a shining yellow colour.

There is another variety, which is distinguished from the others by the leaves being longer and more erect; the peduncles of the flowers longer; the capsules less globular, commonly divided into nine cells; the calycine segments four, three longer and narrower, one shorter and broader, with a membranaceous margin; the flowers have a double or triple row of petals, shining in the sun with the splendour

of gold; the stamens numerous, with oblong saffron-coloured anthers.

Method of Culture.—Those of the annual and biennial kinds may be increased by sowing the seeds in the early spring months on a fresh hot-bed, covered with sandy earth, or in pots of fine sandy mould. And when the plants have attained a few inches in growth they may be planted on fresh hot-beds, or in pots plunged in them, to bring them forward; and as soon as they have taken root, they should have very little water; when of sufficiently large size, each should be planted in a small pot, filled with light fresh earth, but not rich, plunging them into a hot-bed of tan, shading them in the heat of the day until they have taken new root, when they should have plenty of fresh air. About the beginning of summer some of the plants may be inured to the open air, and afterwards be turned out of the pots, and planted with balls of earth about them in a warm border, where they often thrive and spread, but are not very productive of flowers in this way. Some mult also be continued in pots, and removed to the shelves of the stove, where they flower more plentifully.

The only culture which they afterwards require is, for those in the pots to have frequent slight waterings in dry weather, and the others to be kept clean, and their branches permitted to spread upon the surface of the ground.

All the perennial sorts may be readily increased by cuttings planted during the summer months. Those having shrubby stalks and branches, readily take root when planted out in beds or in pots of light sandy soil, covered with mats or glasses; in the latter case, being shaded when the sun is warm. The cuttings of these sorts need not be cut from the plant more than five or six days before they are planted, during which time they should be laid in a dry room, not too much exposed to the sun, that the parts which are separated from the old plants may heal over and dry, otherwise they are apt to rot. They may then be planted at about three inches distance from each other, the earth being pressed very close to them, and none of their leaves buried in the ground, as from their abounding in moisture, when they are covered with the earth, it is apt to cause them to rot, which often destroys the cuttings. When they are taken from the old plants, they should therefore be divested of their lower leaves, so as to allow a naked stalk of sufficient length for being planted in the earth.

Those in pots may be plunged in a hot-bed, or in a warm border, due shade and shelter being given, and slight waterings in dry weather. When they have stricken good roots, they should be removed with balls of earth into other separate small pots of light sandy mould, being placed in a shady situation, a very slight watering being given to settle the earth about them. After they become well rooted, they may be removed, so as to have more sun; when they may be kept till autumn, being watered very slightly twice a week in summer and once afterwards, care being taken to prevent their roots shooting through the pots, by shifting them two or three times in the summer season in order to pare them off.

In the autumn and winter they should be protected in the greenhouse.

The cuttings of the more succulent sorts should be left to heal over a much longer time, being a little freed from leaves, and covered with glasses to prevent the wet. They should have less water, and be removed less frequently. They succeed well in an airy glass case during the winter, when screened from frosts and severe weather.

And such sorts as do not afford cuttings, may be increased by planting and managing the bottom side-heads or off-sets

in the above manner. They may likewise be increased by seeds or cuttings readily in the stove department.

The only culture necessary afterwards is, merely to give water frequently in small quantities in summer, and very sparingly in winter, shifting the plants occasionally into larger pots.

These are mostly plants which afford a fine variety in greenhouse collections, and among other potted plants of similar growths.

MESEMMA, or BOUSEMMA, in *Geography*, a town of Africa, in the kingdom of Fez, inhabited by Arabs.

MESENTERIC, in *Anatomy*, from mesentery, an epithet used in describing parts connected with the mesentery. There are a superior and inferior mesenteric artery, branches of the abdominal aorta (see ARTERY): a superior and inferior mesenteric vein joining the vena portarum. (See LIVER.) The glands connected with the lacteals and with the absorbents of the large intestine, are called mesenteric, and the same term is applied to the nerves of the intestines.

MESENTERICA, in *Botany*, a genus of the fungus tribe, so called by Tode, from its resemblance to the human mesentery—Perf. Syn. 706. Tode Fung. Mecklenb. fasc. 1. 7.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. — Creeping, gelatinous, veiny; the ramifications of the veins joined by a thin membrane.

1. *M. lutea*. Perf. n. 1. (*M. tremelloides* α , lutea; Tode fasc. 1. 7. t. 2. f. 12.)—Lemon-coloured, or of a golden yellow.—Found after rain in the spring, sometimes in autumn, upon rotten wood, spreading to the breadth of two or three inches, like a fine veiny web, of a yellow colour, more or less deep; sometimes greenish. The margin at length swells, and assumes a bright yellow hue; whence Tode concluded that part to be the seat of the fructification. The whole is so delicate, that if exposed for twelve hours to a warm air, it decays entirely, leaving nothing but a few very minute scales.

2. *M. caerulea*. Perf. n. 2. (*M. tremelloides* β , caerulea; Tode fasc. 1. 8.)—Entirely of a glaucous blue.—Found once only, in September, on a half-rotten board. Tode.

3. *M. argentea*. Perf. n. 3. (*Corallo-fungus argenteus*, omenti forma; Vaill. Paris. 41. t. 8. f. 1.)—White, very broad; the margin tumid and downy. On old boards or poils in cellars, spreading from a little soft and tender tuft, as white as snow, into a membrane from four to twenty-four inches in extent, full of beautifully branching veins, and fringed at the margin. After some time, the whole turns reddish and decays.

MESENTERIUM, MESENTERY, in *Anatomy*, the process of peritoneum, by which the small intestine is retained in its position in the abdomen. See INTESTINE.

MESERCAN, in *Geography*, a town of Persia, in Chufistai; 36 miles S.S.E. of Sulter.

MESERJEEN, a town of Algiers; 5 miles S.W. of Oran.

MESERITSCH, or MESERIZCZ, a town of Moravia, in the circle of Prerau; 30 miles E. of Olmutz. N. lat. 49° 26'. E. long. 18° 2'.

MESERITSCH, GREAT, a town of Moravia, in the circle of Iglau; 18 miles W. of Olmutz. N. lat. 49° 23'. E. long. 15° 55'.

MESERITZ, a town of the duchy of Warsaw; 40 miles W. of Posen.

MESEWITZ, a town of Prussia, in the palatinate of Culm; 21 miles E.S.E. of Culm.

MESHES of *Nets*, the openings or interstices between the threads.

MESHTA,

MESITA, in *Geography*, a town of Egypt, on the left bank of the Nile; 7 miles N. of Tahta.

MESIANO, the name of two towns of Naples, in Calabria Ultra; one six miles N. E. of Bovà, and the other three miles N. of it.

MESINAN, a town of Persia, in the province of Mazanderan; 50 miles S. of Allabad.

MESIRE, a name given by Avicenna to a dilemma-ture of the liver, attended with a sense of heaviness, tumour, inflammation, and pungent pain, and always with thirst, a dry mouth, and a parched black tongue.

MESITICUM, among the Romans, a toll paid for a place to sell goods in the forum.

MESKOUTEEN, **HAMMAM**, *i. e.* the *silent or enchanted baths*, celebrated baths of Algiers, in the province of Constantina, situated on a low ground, surrounded with mountains. The water furnished by several fountains is intensely hot, and falls afterwards into the river Ze-nati. Other baths at a small distance are, comparatively, intensely cold; and still farther, nearer the banks of the Ze-nati, are the ruins of a few houses, built probably for the convenience of persons who came thither for the benefit of the waters; 36 miles E. of Constantina. Shaw's Travels.

MESLAY, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Laval. The place contains 1173, and the canton 10,154 inhabitants, on a territory of 245 kilometres, in 14 communes.

MESLE-SUR-SARTHE, a town of France, in the department of the Orne, and chief place of a canton, in the district of Alençon. The place contains 648, and the canton 9,364 inhabitants, on a territory of 157½ kilometres, in 20 communes.

MESLIN-CORN, in *Agriculture*, a term applied to wheat and rye produced in a state of mixture.

MESMARCHURES, in the *Manege*. See **PASTERN**.

MESMES, **CLAUDE DE**, *Count d'Arcaux*, in *Biography*, an eminent French negociator, descended from an illustrious family, was trained from an early period of life to public business, and was appointed counsellor of state in the year 1623. In 1627 he was sent as ambassador to Venice, in which quality he visited Rome, Mantua, Florence, and Turin. He next passed into Germany, where he held conferences with most of the princes of the empire. Soon after this he was dispatched upon public business to the more northern kingdoms of Poland, Denmark, and Sweden. In every undertaking he obtained a high character for probity as well as talents, and thus acquired an almost unlimited confidence with the foreign ministers, with whom he treated. This enabled him to act with considerable effect as plenipotentiary, from his court, at the general peace, concluded, in 1648, at Munster and Osnaburg. He did not confine himself wholly to the affairs of the state, but also maintained a regular correspondence with men of letters, of whom he was the friend and protector. He died at Paris in 1650. Moreri.

MESMES, **JOHN ANTONY DE**, *Count d'Arcaux*, and a nephew of the preceding, passed through a similar course of public employments with his uncle. He was appointed ambassador extraordinary to Venice from 1671 to 1674, and in the following year was one of the plenipotentiaries at the peace of Nimeguen. Some time after this he was ambassador in Holland, where he effected the truce with Spain by which Luxembourg was ceded to France. In 1689 he was the French ambassador to James II. while in Ireland. In 1692 he went out in the same quality to Sweden, and was very useful in settling the preliminaries of the peace of Ryf-wick. He died in 1709, at Paris, at the age of sixty-nine,

having passed an active and very useful life in the service of his country. A collection of his "Letters and Negotiations" was published in 1752, in six volumes 12mo. Moreri.

MESN, or **MESNE**, a term in *Law*, signifying him who is lord of a manor, and so hath tenants holding of him; yet he himself holds of a superior lord.

All the land in the kingdom is supposed to be holden, mediately or immediately of the king; who is styled the lord "paramount," or above all. Such tenants as hold under the king immediately, when they granted out portions of their lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and, thus, partaking of a middle nature, were called *mesne*, or middle lords. So that if the king granted a manor to A, and he granted a portion of the land to B, now B was said to hold of A, and A of the king; or, in other words, B held his lands immediately of A, but mediately of the king. The king was therefore styled lord paramount; A was both tenant and lord, or was a *mesne* lord; and B was called tenant "paravail," or the lowest tenant; being he, who was supposed to make "avail," or profit of the land. It is in this manner all the lands of the kingdom are holden, which are in the hands of subjects. Bl. Com. b. ii.

The word is properly derived from *mesne*, *quasi minor natus*; because his tenure is derived from another, from whom he holds; or perhaps *mesne* is the same as *mean* or middle between two extremes, either in time or dignity.

MESN also denotes a writ, which lieth where there is lord *mesne* and tenant; and lies, when upon a subinfeudation the *mesne* or middle lord suffers his under-tenant, or tenant *paravail*, to be distrained upon by the lord paramount, for the rent due to him from the *mesne* lord. F. N. B. 135.

This is in the nature of a writ of right; and in this case the tenant shall have judgment to be acquitted or indemnified by the *mesne* lord; and if he makes default therein, or does not appear originally to the tenant's writ, he shall be forejudged of his *mesnalty*, and the tenant shall hold immediately of the lord paramount himself.

MESN, or *Mesne process*. See **PROCESS**.

MESNA, in *Geography, a city of Africa, capital of Begarmee; 170 miles S. of Bornou. N. lat. 17. E. long. 22° 12'.*

MESNAGER, **NICHOLAS**, in *Biography*, an able negociator, was born at Rouen, in 1658, of a rich commercial family. He was sent by Louis XIV. to Spain on some important missions relative to the commerce of the Indies, and afterwards to Holland; on which occasions he gave so much satisfaction as to be created a chevalier of the order of St. Michael, with patents of nobility. In 1711 he signed the preliminary treaty of peace between France and England at London, and he was next employed with the abbé Polignac as plenipotentiary at Utrecht. He died at Paris in 1714. His memoirs have been printed. Moreri.

MESNARDIERE, **HIPPOLYTUS JULIUS PILET DELA**, a French poet, was born at Loudun in 1610, and died in 1663. He was a member of the French Academy, and patronized by cardinal Richelieu. His works are, 1. "A Treatise on Melancholy," 8vo.; 2. "Poetique," 4to.; 3. "The Tragedies of Alvide and La Pucelle de Orleans;" 4. "A Collection of Poems," &c.; 5. "Relations of War," &c. Moreri.

MESNEVY, or **MASNAVI**, in *Oriental Literature*, is a very celebrated work in the Persian language. The author is Jelal ud Din; Rumi is often added to his name, denoting that he was of Lower Asia. He died in 1262, and was buried in a monastery founded by him in the city of Konyeh

(Iconium) for an order of Dervishes. His work is the most esteemed of that numerous class of writings containing the doctrines of Sufism, (see *SUFĪ*) or emblematical theology, and for several centuries his tomb was visited by his devout countrymen, who consider his works as the effect of inspiration, and inferior only to the Koran. As well as religion and morality, the *Mesnevy* comprises also history and politics. The following character of it is taken from the last volume of sir William Jones's works. "So extraordinary a book as the *Mesnavi* was never, perhaps, composed by man. It abounds with beauties and blemishes equally great; with gross obscenity and pure ethics; with exquisite strains of poetry and flat puerilities; with wit and pleasantries mixed with dull jests; with ridicule on all established religions, and a vein of sublime piety. It is like a wild country in a fine climate, overspread with rich flowers and with the odour of beasts. I know of no writer to whom the *Maulavi* can justly be compared, except Chaucer or Shakspeare." The term *Maulavi*, here used, is usually applied to this great writer, denoting his literary reputation. Commentaries on his works, and abridgments, translations, and imitations of them, are very numerous in the different dialects of the East. See *MYSTICAL Poetry*.

MESNOI, in *Geography*, an island of Russia, in the straits of Vaigatskoi, N. lat. $70^{\circ} 4'$. E. long. $60^{\circ} 14'$.

MESOGHOROS, *μεσοχορος*, among the ancients. The *mesochori* were musicians who presided in concerts, and by beating a desk in a regular manner with their feet, directed the measure of the music. For this purpose in the theatre they wore wooden clogs on their feet, that they might be better heard, which were called by the Greeks *crupedia*.

MESOGHORUS, among the Romans, was also used for a person in public assemblies, appointed to give the signal for acclamation at the proper time, that all might join in it at once.

MESOCOLON, in *Anatomy*, the peritoneum connecting the colon in its situation. See *INTESTINE*.

MESOCUROS, *μεσοκουρος*, in *Antiquity*, an actress in tragedies, who had the middle part of her head shaven: but others think that *mesocuros* signifies a girl or very young woman.

MESODMES, or **MESOMEDES**, in *Biography*, a Greek lyric poet and musician, to whom the hymn to Nemesis, the last of the three hymns published in Dr. Fell's Oxford edit. of Aratus, with the original music, has been ascribed. It is not satisfactorily settled who this *Mesomedes* was, or at what time he lived. See *MUSIC of the Ancient Greeks*, for conjectures on the subject.

MESOGASTER, **MESOGASTRION**, in *Anatomy*, a name sometimes given to the lesser omentum. See *EPIPLOON*.

MESOGLOSSI, a name given by some writers to the muscles of the tongue, more usually called by anatomists the *genioglossi*.

MESOIDE, in the *Greek Music*, a kind of melopœia, the notes of which were confined to the two middle strings of the *meson* tetrachord.

MESOIDES, mean sounds, or sounds taken in the middle of the system. See *MELOPEIA*.

MESOLA, or **MEZOLA**, in *Geography*, a town of Italy, in the department of the Lower Po, near the coast of the Adriatic, on an island formed by a branch of the Po; 30 miles E.N.E. of Ferrara.

MESOLABE, **MESOLABIUM**, a mathematical instrument, invented by the ancients for finding two mean proportionals mechanically, which they could not come at geometrically. See *PROPORTIONAL*.

It consists of three parallelograms, moving in groove to certain interfections. Its figure is described by Eutocius, in his commentary on Archimedes.

MESO-LOGARITHM, a term used by Kepler to signify the logarithms of the co-sines and co-tangents; the former of which lord Napier calls *antilogarithms*, and the latter *differentiales*.

These are also called *artificial sines and tangents*.

MESON, in the *Ancient Greek Music*, is the name given to the second tetrachord from the bottom, and it was likewise the name by which the four strings of that tetrachord were distinguished: as the first string was called *hypate-meson*, the second *parhypate-meson*, the third *lichanos-meson*, or *meson-diatonos*, and the fourth *mesê*. *Meson* is the genitive case plural of *mesê*, mean or middle; because the *meson* tetrachord is the middle between the first and third tetrachord, or rather because the string or found *mesê* gives the name to the whole tetrachord, of which it is the highest note. See *Plate of the Greek Diagram*.

MESONYCTICUM, Lat., *μεσονυκτικον*, Gr., a midnight hymn in the Greek church.

MESO-PLEURII, derived from *μεσος*, middle, and *πλευρον*, rib, in *Anatomy*, the intercostal muscles.

MESO-PLEURII is sometimes also used for the intermediate spaces between the costæ, or ribs.

MESOPOTAMIA, in *Ancient Geography*, an extensive province of Asia, the Greek name of which denotes "between the rivers," and on this account Strabo says, "ἐν κείνῃ Μεσσηνίᾳ τῆς Εὐφράτης καὶ τοῦ Τίγριος;" that it was situated between the Euphrates and the Tigris. In Scripture this country is called "Aram," and "Aramæa." But as *Aram* also signifies Syria, it is denominated "Aram Naharaim," or the Syria of the rivers. This province, which inclines from the S.E. to the N.W., commenced at N. lat. $33^{\circ} 20'$, and terminated near N. lat. $37^{\circ} 30'$. Towards the south it extended as far as the bend formed by the Jordan at Cunaxa, and to the wall of Semiramis which separated it from *Mesene*. Towards the north, it comprehended part of *Taurus* and the *Mesius*, which lay between the Euphrates and the Tigris. The modern name, given by the Arabs to this part, is of the same import with the ancient appellation; they call it "isle," or in their language, "Al-Dgézera." In this northern part is found *Osrhoëne*, which seems to have been the same place with *Arthemusia*. The northern part of *Mesopotamia* is occupied by chains of mountains passing from N.W. to S.E., in the situation of the rivers. The central parts of these mountains were called "Singaræ montes." The principal rivers were *Chaboras* (Al Kabour), which commenced at *Charræ* (Harran), E. of the mountains, and discharged itself into the Euphrates at *Circesium* (Kirkisieh) (see *CHABOR*); the *Mygdonius* (Hanali), the source of which was near *Nisibis*, and its termination in the *Chaboras*. (See *MYGDONIUS*.) The principal towns, in the eastern part along the Tigris and near it, are *Nisibis* (Nisibin), *Bezabde* (Zabda), *Singora* (Sindja), *Labbana* on the Tigris (Mosul), *Hatru* (Harder), and *Apamea-Mesenes*. At some distance to the south, upon the Tigris and on the borders of *Mesopotamia*, was the town of *Antiochia*, near which commenced the wall that passed from the Tigris to the Euphrates, under the name of "Murus Mediæ," or "Semiramidis." In the western part were *Edeffa*, called also *Callin-Rhæ* (Orfa), *Charræ* (Harran), *Nicephorium* (Racca), *Circesium* at the mouth of the *Chaboras*, *Anatho* (Anah), *Neharda* (Hadith Unnour) upon the right of the Euphrates. There are several other towns of less importance, which our limits will not allow us to mention. According to Strabo, this country was fertile in vines,

vines, and afforded abundance of good wine. According to Ptolemy, Mesopotamia had on the north a part of Armenia, on the west the Euphrates, on the side of Syria, on the east the Tigris, on the borders of Assyria, and on the south the Euphrates which joined the Tigris. Mesopotamia was a satrapy under the king of Syria. See SYRIA.

MESOPYCNI, *μεσopycni*, in the *Ancient Music*, was an appellation given to such chords as formed the middle notes of the staff. There were five mesopycni in the scale. See PYCNI and STRISEM.

MESOREC PUM, in *Anatomy*, the process of peritoneum attached to the sigmoid flexure of the colon, and upper part of the rectum. See INTESTINE.

MESORO, in *Ichthyology*, a name given by Salvian to that fish which we call the butterfly-fish, the blennius or blennius of other authors.

MESON is also used by the Italians for the fish commonly called the *uranolescope*, or *star-gazer*.

MESOTHENAR, in *Anatomy*, a name given by Winslow to a muscle of the thumb. It includes the adductor pollicis, and a part of the flexor brevis. See ADDUCTOR and FLEXOR.

MESOTYPE, in *Mineralogy*. See ZFOHITE.

MESPILEUS LAPIS, in *Natural History*, a name given to some species of the echinite, from their resemblance to the ripe fruit of a medlar. This was a name given them before they were much known, and they were some time afterwards called, from their five lines on the surface, *pentaxoche*.

MESPILUS, in *Botany*. *μσπιλον* of the Greeks, the Medlar-Tree. Linn. Gen. 251. Schreb. 339. Willd. Sp. Pl. v. 2. 1010. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 2. v. 3. 205. Sm. Fl. Brit. 520. Juss. 335. Lamarck Dict. v. 4. 437. Illustr. t. 436. Michaux Boreal-Amer. v. 1. 291. Gært. t. 87. (*Cratægus*; Linn. Gen. 250. Schreb. 338. Willd. Sp. Pl. v. 2. 1000. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2 v. 3. 200. Juss. 335. Lamarck Illustr. t. 433. Michaux Boreal-Amer. v. 1. 287. —Class and order, *Icosandria Pentagynia*. Sm. Intr. 427. Nat. Ord. *Pomacæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, concave, in five deep, spreading, permanent segments. *Cor.* Petals five, roundish, concave, with short claws, inserted into the calyx. *Stam.* Filaments about twenty, awl-shaped, inserted into the calyx, not longer than the corolla; anthers simple, roundish. *Pist.* Germen inferior; styles from two to five, (occasionally solitary,) simple, erect; stigmas capitate. *Peric.* Berry roundish, umbelicated, crowned with the closed calyx, but almost perforated in the centre. *Seeds* equal in number to the styles, bony, gibbous at the outer side, each with two kernels.

Ess. Ch. Calyx five-cleft. Petals five. Berry inferior. Seeds two to five, with two kernels.

Botanists have differed concerning the limits of this genus. The *Cratægus* of Linnæus is distinguished from his *Mespilus* solely by the former having but two styles, and occasionally, on the same tree, some flowers with but one; while the latter has five. *Sorbus* is supposed to differ from both in having three styles and as many seeds. Linnæus was well aware of the close relationship between all the three genera, and hints that there is scarcely any sufficient distinction between them. He adds however that "the leaves in *Sorbus* are usually pinnate, in *Cratægus* angular, in *Mespilus* undivided." This would indeed be a character in the habit too important to be overlooked, but unfortunately it is not founded in fact. *M. tanacetifolia* has not merely angular, but pinnatifid leaves, with the fructification of a per-

fect *Mespilus*, and is so naturally allied to the Hawthorn, *Cratægus Oxyacantha* of Linnæus, that nothing ought to distinguish them. As to *Sorbus*, the *domestica* is shown in *Engl. Bot.* v. 5. 152, to be a complete *Pyrus*, both by number and structure of all the parts; nor can the *anupuris* or the *hybrida* (more properly *pinnatifida*) be separated from it, as the number of their styles and cells is variable, though the coats of the latter are rather more cartilaginous than in the *domestica*. Other acknowledged species of *Pyrus* indeed have pinnate or pinnatifid leaves. (See *PYRUS*.) The writer of the present article therefore sees no reason to abrogate what is settled in the *Flora Britannica*, though Willdenow, not having seen that work till he got as far as *Tetradynamia*, has not adopted this correction; and the authors of the new edition of the *Hortus Kewensis* in general follow him, where they themselves have not particularly studied any subject. Hence five of the fourteen species of *Cratægus* in the last-mentioned work are defined with five styles or five seeds, one with three and another with four; a sufficient evidence of their being *Mespili*, in spite of their more or less angular foliage. It is scarcely necessary to observe that the fruit of these two supposed genera is exactly of the same nature. We now follow Linnæus and Gærtner in calling it a *bacca*, or berry, because it is found most convenient to restrict the term *drupa* to pulpy fruits with a solitary nut.

The number of styles is so ill calculated for a generic distinction in this case, that we cannot take advantage of it even to divide *Mespilus* into any tolerably natural sections. The form of the leaves, whether undivided, lobed, or pinnatifid, might serve better. None of this genus is known to have really pinnate leaves.

The species of *Cratægus* are nineteen in Willdenow, of *Mespilus* six; in all twenty-five. They are all either *trees* or *shrubs*, with very hard wood, often thorny; and they have stalked, alternate, almost always deciduous, leaves. Their flowers are corymbose, sometimes solitary; white with an occasional tint of red. Fruit mealy, red or yellow, seldom eatable. The whole genus is very patient of cold, partly American, partly European and Alpine, well calculated and much used for the adorning of shrubberies in this climate. It is remarkable that none of them have been published in that useful and deservedly popular work, the Botanical Magazine.

We shall indicate a few of the most valuable.

M. coccinea. Great American Hawthorn. (*Mespilus apii* folio virginiana, spinis horrida, fructu amplo coccineo; Pluk. Phyt. t. 46. f. 4. *Cratægus coccinea*; Linn. Sp. Pl. 682. Willd. n. 1. Ait. n. 1.)—Thorny. Leaves ovate, with angular incisions, serrated, smooth; heart-shaped at the base. Footstalks and calyx glandular. Styles five.—Native of Virginia and Canada. Cultivated by bishop Compton at Fulham in 1683. This is a spreading tree, with broad light green leaves, strong thorns, large white copious flowers, which appear in May, and scarlet fruit, as big as a small damson. Linnæus and Willdenow cite under this, synonyms of Miller (*l. t.* 179.) and the *Hort. Angl. t.* 13, which belong to *Mespilus cordata*, their *Cratægus*, n. 2.

M. parvifolia. Small-leaved Hawthorn. (*M. Xanthocarpus*; Linn. Suppl. 254. *Cratægus parvifolia*; Willd. n. 8. Ait. n. 7.)—Thorny. Leaves somewhat wedge-shaped, crenate, cut. Flowers nearly solitary. Segments of the calyx leafy, cut and serrated, as long as the fruit. Styles five.—Native of Virginia. Cultivated here in the time of bishop Compton. We are indebted to Messrs. Lee and Kennedy for a knowledge of this species, for Willdenow quotes a heap of erroneous synonyms, amongst others the

MESPILUS.

the *Cratægus tomentosa*, Linn. Sp. Pl. 682. The present shrub is remarkable for its stout, rigid habit; straight dark thorns, often two inches in length; small leaves, about an inch long, more or less downy; rather large flowers, mostly solitary, at the end of each short lateral shoot, with a long, leafy, green calyx. The fruit is said to be pale yellow, dotted with little black warts, and containing five seeds.

M. Oxyacantha. Common Hawthorn, White-thorn, or May. Gært. v. 2. 43. t. 87. Sm. Fl. Brit. 529. (*Cratægus Oxyacantha*; Linn. Sp. Pl. 683. Fl. Dan. t. 634. Bulliard. t. 333, with the flowers of *Prunus spinosa*! C. monogyna; Jacq. Austr. t. 292. *Oxyacanthus*; Ger. em. 1327.)—Thorny. Leaves obtuse, deeply three-cleft, serrated, smooth. Styles one or two.—Native of dry, open, stony countries in all parts of Europe, flowering in May or June. In the rich deep soil of Marshland it is particularly luxuriant, and the blossoms, usually white, assume there a pink hue. Double and rose-coloured varieties are often cultivated, as well as one with yellow, not scarlet, fruit. This tree is one of the greatest ornaments of our parks and hedges.

M. odoratissima. Downy Oriental Hawthorn. Andr. Repof. t. 590. (*M. tanacetifolia* β; Sm. Prod. Fl. Græc. Sibth. v. 1. 342.)—Thorny. Leaves deeply five-cleft, jagged; very downy on both sides. Styles five.—Native of the Levant. In Greece, and the fourth-western part of the Crimea. Cultivated by Messrs. Lee and Kennedy for some years past. Rather stouter than the Common Hawthorn, and distinguished by its very soft deep-cut leaves, larger highly fragrant flowers, and globular scarlet fruit, as big as a small gooseberry. Mr. Lambert discovered, by Pallas's herbarium, that this is the *Cratægus orientalis* mentioned by that intelligent traveller; see the English edition of his Travels, v. 2. 174. and 181.

M. tanacetifolia. Tansey-leaved Hawthorn. Sm. Exot. Bot. v. 2. 51. t. 85. Ait. Hort. Kew. ed. 2. v. 3. 206. Andr. Repof. t. 591. (*M. orientalis*, *tanacetifolia villosa*, magno fructu pentagono e viridi flavescente; Tourn. Cor. 44. Voy. v. 2. 171. t. 172.)—Thorny. Leaves obtuse, pinnatifid, cut; downy on both sides. Styles five. Bractæas permanent.—Native of all the high mountains of Greece. A very desirable shrub for plantations, on account of its large highly-scented corymbose flowers, and yellow fruit, which resembles a small apple, and has the scent of one. By culture and grafting, it promises to become an acquisition to our tables. From the description in Dioscorides of his *μεισμαλον*, “a spinous tree with leaves like hawthorn, fruit like a little apple, sweet, with three hard seeds,” this should seem, as the number of seeds varies, to be the present; while his *μεισμαλον επιρον*, from Italy, “a tree like an apple tree, but with smaller leaves, and a round eatable fruit, with a broad depression, slightly astringent, and long in ripening,” can only be our common garden *Mespilus germanica*. Tournefort did not observe the thorns of the *M. tanacetifolia*, but he describes the eagerness with which his Armenian companions collected and ate the fruit, and he mentions the trees as of the size of oaks. He notices also our preceding *M. odoratissima*, as distinguished by its red fruit, varying in size, rather acid, and more agreeable than that of the *tanacetifolia*.

M. Azarolus. Neapolitan Medlar or Azarole. (*M. Aronia veterum*; Bauh. Hist. v. 1. 67. *M. prima*; Matth. Valgr. v. 1. 229. *M. n. 13*; Duham. Arb. v. 2. 16. t. 5. (*Cratægus Azarolus*; Linn. Sp. Pl. 683. Willd. n. 19. Ait. n. 14. Andr. Repof. t. 579.)—Somewhat thorny. Leaves obtuse, nearly smooth, in three or five entire-edged segments. Styles two.—Native of Italy, the south of France, and Carniola; rare in our gardens. It is

akin to the two last, but the leaves are smoother, entire at the edges, and the styles but two; though Scopoli says the fruit has five cells, which caused him to refer this species to *Pyrus*. We have no doubt that the number of the styles and cells is the same, and therefore this perhaps affords another example of the variableness of that number. The fruit is said to be austere in flavour, and hence Matthioli found a difference between his plant and the *μεισμαλον* of Dioscorides, which, as they had never seen the true one, he, and other botanists of his time, took this to be; nor were they very wide of the mark. When cultivated, the Azarole is spoken of as an agreeable fruit. We have never heard of its ripening in England, nor does the tree often blossom.—The old wooden cut of Matthioli, used again by Duhamel, is by far the best representation of this species; that in Ger. em. 1454 is more like the *Oxyacantha*.

M. germanica. Common, or Dutch Medlar. Linn. Sp. Pl. 684. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 1523. Pallas Ross. v. 1. p. 1. 29. t. 13. f. 1. (*M. altera*; Matth. Valgr. v. 1. 230. *M. sativa*; Ger. em. 1453.)—Thorns none. Leaves lanceolate, somewhat downy. Flowers solitary, sessile, terminal. Styles five.—Native of the warmer parts of Europe. Common in gardens, for the sake of its fruit, which is not eatable till it becomes quite mellow, and is almost as variable in size and flavour as any other. The leaves are a span long, most downy beneath, dark green above, a little serrated at the top. Flowers the largest of the genus, white, as broad as a crown piece. Fruit broad, depressed, brown when ripe.

M. grandiflora. Large-flowered Barren Medlar. Sm. Exot. Bot. v. 1. 33. t. 18. Ait. n. 5.—Thorns none. Leaves elliptic-oblong, slightly downy, unequally serrated. Flowers nearly solitary, terminal. Styles three.—Cultivated in Chelsea garden by Mr. J. Fairbairn, who is unacquainted with its native country. The tree much resembles the *M. germanica*, but the leaves are strongly serrated, and more elliptical. Flowers white, scentless, almost as big as those of the *germanica*, and much exceeding those of all the other species, *tanacetifolia* approaching them most nearly in this respect. They grow mostly solitary, rarely two together, at the ends of small lateral branches. Styles never more than three; often but two. Fruit small, reddish, with little pulp, rarely perfected in England.

M. japonica. Japan Medlar, or Lequat. Thunb. Jap. 206. Willd. n. 2. Ait. n. 2. Banks. Ic. Kæmpf. t. 18. Vent. Malmaif. t. 19. (Bywa; Kæmpf. Amœn. 800.)—Leaves obovate, acute, serrated; downy beneath. Clusters aggregate, terminal. Styles five.—Native of Japan; hardy with us, flowering in spring and autumn, and often ripening its fruit, which is globular, an inch in diameter, yellow, not bad eating. Thunberg says this is a very large tree in its native country. The leaves are rigid, a foot long, evergreen, smooth, and shining on the upper side, white or rusty beneath. Flowers very numerous, white, on rusty stalks.—This plant remained for some time in our stores without flowering, and was taken for a *Volkameria*.

MESPILUS, in Gardening, comprehends plants of the deciduous tree flowering shrubby and evergreen kinds, of which the species cultivated are; the Dutch or common medlar (*M. germanica*); the arbutus-leaved mespilus (*M. arbutifolia*); the alpine mespilus (*M. amelanchier*); the baitard quince, or mespilus (*M. chamæ-mespilus*); the snowy mespilus (*M. canadensis*); the dwarf mespilus (*M. cotoneaster*); the quince-leaved mespilus (*M. tomentosa*); and the evergreen thorn or mespilus (*M. pyracantha*).

In the first sort it is observed, that the wild tree differs from the cultivated one in having more slender, strigose, thorny

thorny branches, and much smaller leaves, flowers, and fruits.

And there are two varieties, the narrow-leaved and the broad-leaved; the first growing to a large tree, rising with a straighter stem, and the branches growing more upright than those of the Dutch medlar; the leaves are narrower and not serrate, the flowers smaller, and the fruit shaped like a pear. This is a native of Sicily.

The latter never rises with an upright trunk, but sends out crooked deformed branches at a small height from the ground, the leaves are very large, entire, and downy on their under side: the flowers very large, as also the fruit, which is rounder, and approaches nearer to the shape of an apple: this, bearing the largest fruit, is now generally cultivated; but there is one with smaller fruit, called the Nottingham medlar, of a much quicker and more poignant taste. There are also other varieties in the fruit, which are now little attended to by the cultivators of this fruit.

The second species varies with red, with black, and with white fruit.

Method of Culture.—They are all easily raised by seeds, layers, grafting and budding; but it is the best practice to raise the medlar kinds principally by grafting or budding, in order to continue the sorts.

When they are raised in the first method, the seeds should be sown in autumn, in a bed of common earth, as they usually lie a year, or more, before they germinate, as in the haw and holly-berries, &c.

As soon as the plants appear they should be watered frequently in dry weather; and in the autumn or spring following, the largest be thinned out and planted in nursery rows, two feet by one asunder; and in another year all the rest may be set out in the same manner; and in three or four years they will be proper for being planted out in the garden or shrubbery grounds.

But in the second mode the young branches should be laid down in the autumn in the common method; and they will be properly rooted by the autumn following, when they should be planted out in nursery-rows in the same way as the seedlings.

And the two last methods should be performed on the stems or stalks of the larger medlar kinds, or sometimes upon those of the white thorn, raised from seed as above; but the pear-stock is to be preferred for the common medlars, when intended as fruit trees. The operations are performed in the usual way, low in the stocks to form dwarfs; and for half or full standards, training the first shoot for a stem, or the stock may be let form a stem, and then be wrought at from about three or four to five or six feet in height. See **BEDDING and GRAFTING.**

Those plants intended for fruit-trees, whether dwarfs, half or full standards, in training, should, for dwarfs, have the first shoots from the graft or bud headed down short in spring, if necessary, in order to force out a proper supply of bottom branches, which must be trained as other dwarf fruit-trees, either for standard-dwarfs or espaliers. When for half or full standards, and wrought low in the stocks, the first shoot of each should be trained for a stem, topping it afterwards at the proper height to force out lateral shoots to form the head; but when wrought high in the stock, the first shoots may either be shortened or suffered to grow, as may seem most proper, according to the natural disposition of the leading shoot, in respect to its furnishing lateral branches. After this training for the first year or two, to give the trees their first proper formation, there should not be any further general shortening of the branches, practising it only occasionally to particular shoots, to procure more wood, when

necessary, to fill vacancies, to reduce any irregular growth, or to cut off dead parts. But in other respects the branches should be principally left at full length, and the standards left to assume nearly their own natural way of branching. See **PRUNING and TRAINING.**

These plants are all hardy, succeeding in any common soil and situation.

It may be noticed that the first sort and varieties are cultivated as fruit trees, principally as standards, but sometimes as espaliers for variety; and are often introduced into the shrubbery plantations. All the other species are proper for ornament in shrubbery or other plantations, where they effect a fine variety by their different foliage and flowers, as well as their fruit in autumn and winter, which remains long on the branches. They should be disposed—the deciduous kinds principally in assemblage with others of that sort, and the ever-green kind also chiefly with those of their own kind, arranging each sort according to its height of growth; but the last sort, being agreeably ornamental, both as an ever-green and in its numerous clusters of fine red berries in winter, should have a conspicuous situation. From its being of a rather slender growth, it is however commonly trained against walls or the fronts of houses, for the support of its flexible branches, as well as to exhibit its berries more ornamentally. It may however be trained as a standard shrub, like the other sorts, in the open shrubbery; in which case it should be generally trained with short single stems, and be permitted to branch out upwards into spreading heads, which have a good effect.

MESS, in *Sea Language*, denotes a particular company of the officers or crew of a ship, who eat, drink, and associate together, whence *mess-mate*, denoting one of these with respect to another.

Mess, in *Military Language*. The principal military mess in Great Britain is kept, and provided for in the extraordinaries of the army, at the Horse-guards. This mess consists of the field officers in waiting, of the life and foot guards, officers in the king's life and foot guards; officer of the queen's guard and tilt picket, and adjutant of the battalion of foot guards that mounts. The colonel of the foot guards is allowed to invite three visitors. Two breakfasts are likewise provided every morning, one for the guard coming on, and one for the guard going off, together with a supper every night.

MESSA, in *Geography*, a town of Morocco, situated on the river Sus, not far from the foot of the Atlas. It is large, divided into three parts, and surrounded with walls. In its vicinity is a mosque, containing the bones of a whale, which the superstitious inhabitants consider as those of the whale which swallowed Jonah; 165 miles S.W. of Morocco. N. lat. 29 56'.

MESSA, *Messe*, plural. Ital.; *Messe*, *Messes*, plu. Fr., the title given in the Romish liturgy to the high mass in music, consisting of the *Kyrie*, *Cbrijle*, *Credo*, *Sandus*, and *Agnus Dei*. These portions of the church service have been set in the style of our cathedral services by every great composer in Catholic countries, ever since the laws of counterpoint were settled, that is, from the latter end of the 15th century to the present time. For common occasions the mass is set for the choral establishment, accompanied only by the organ: in these, solo verses are seldom introduced; but for festivals, in Italy, the composition is more elaborate and secular, when an additional band and singers of the first class are employed. Alessandro Scarlatti, Leo, Pergolesi, Durante, Perez, Jomelli, Sacchini, &c. have composed masses, which will be regarded by true judges of composition as master-pieces of the art.

MESSA Bassa, silent mass whispered by the priest during a musical performance.

MESSE de Capella, in the *Italian Music*, is used for masses sung by their grand chorus. In these, various fugues, double counterpoints, and other ornaments are used.

MESSE Concertati, masses wherein the parts reciting are intermixed with chorusses.

MESSALA, M. VALERIUS CORVINUS, in *Biography*, an illustrious Roman, of an ancient and noble family, who distinguished himself in youth by his eloquence and patriotism, and joined the republican army under Brutus and Cassius against the triumvirs. He is described in very high terms by Cicero, in a letter to Brutus, as being almost, or altogether unequalled for integrity, constancy, and the affection which he displayed for the commonwealth. Of his eloquence, Quintilian says, it is splendid, fair, and bearing the stamp of his nobility. At the battle of Philippi he had a distinguished command, and with his legion was the first that turned the left wing commanded by Octavianus Cæsar. After the death of the two republican chiefs, he made his peace with the victor, and, according to one of the historians of Rome, there was no circumstance of the victory more pleasing to Cæsar than the preservation of Messala, nor did any man ever give proof of greater attachment and gratitude than Messala towards Cæsar. Yet, to his honour, it is asserted, that he never, and on no occasion, was backward in shewing his regard to the memory of his earlier friends, and his decided preference of their cause. When he recommended Strato to Cæsar, he said, with tears flowing from his eyes, "this, sir, is the man who performed the last kind office for my beloved friend Brutus;" and at another time, when Cæsar reminded him that he had been no less zealous for him at Actium, than *against* him at Philippi, he answered, "I always espoused the most just side of every question." In the year 31 B.C. he was the emperor's colleague in the consulate, and was sent as his legate into Asia a year or two afterwards. In 37 he obtained a triumph over the Aquitanians; after this, he for a short time held the office of prefect, which he resigned, finding it ill adapted to his habits. He was addicted to literary pursuits, and was a patron of literary persons, particularly of Tibullus, who commemorates him in his elegies, and has left an express panegyric upon him. In old age he composed a work "De Familiis Romanis," cited by Pliny. At the age of seventy, about two years prior to his decease, the faculties of his mind underwent a total decay, and his memory so completely failed him, that he forgot his own name. Plutarch.

MESSALIANS. See **EUCHITES**.

MESSALINA, VALERIA, in *Biography*, a daughter of Messala Barbatus, married the emperor Claudius, and disgraced herself by her cruelties and scandalous incontinence. Her husband's palace was not the only seat of her lasciviousness, but she even prostituted herself in the most public manner. Her extravagancies at last irritated Claudius so much, that he was obliged to summon her to answer to all the accusations which were brought against her, upon which she attempted to destroy herself, and when her courage failed, one of the tribunes dispatched her with his sword in the year 48. The satirist, in speaking of her, says,

"Et lassata viris, necdum satiata, recessit."

There was another person of this name called also Statilia, who was descended of a consular family, and married the consul Atticus Vistinus, whom Nero murdered. She received with tokens of tenderness her husband's murderer, and married him. She had married four husbands before she came

to the imperial throne; and after the death of Nero retired to literary pursuits and peaceful occupations. Otho, after this, paid his addresses to her, but before the consummation of marriage he destroyed himself. In his dying moments he wrote her a pathetic and very consolatory letter.

MESSANA, in *Ancient Geography*. See **MESSINA**.

MESSAPIA, a country of Italy, which, though scantily watered, was covered with trees and pastures. Its principal towns were Brundisium, Rudia, Lupia, Hydruntum, Callipolis, and Tarentum. It was also called Iapygia.

MESSAR, in *Geography*, a small island in the Red sea. N. lat. 17° 26'.

MESSARA, a province of the island of Crete, which lies south to that of Candia, and which is the most fertile, and the most agreeable of the island; it has, among others, a very beautiful plain, six leagues in extent, in which are found an abundance of wheat, barley, flax, cotton, and a variety of fruits. It is crossed by a small river called at this day "Malognithi," and formerly known by the name of "Lethe." It passes by the side of the ruins of Gortyna, and empties itself into the sea facing the Paximadi islands. The wheat of Messara yields a great quantity of flour, which makes excellent bread; it is conveyed on the backs of asses to Candia, Retimo, and Canea; while the inhabitants themselves live all the year on a very coarse barley bread. Messara is reckoned the granary of Crete: its wheat is one of the best in Turkey. The Turks are here more numerous than the Greeks.

MESSASAGUES, or **MISSASAGAS**, a tribe of Indians in America, on a river of this name, which discharges itself into the N.W. part of lake Huron. This tribe, a few years ago, numbered 500 warriors, but now 80.

MES-SEELAH, a town of Africa, in the kingdom of Algiers; 80 miles S.S.E. of Dellys.

MESSEGNA, a town of Naples, in Otranto; 21 miles N.W. of Lecce.

MESSENE, MAURA-MATHI, a town of European Turkey, in the Morea, on a river which runs into the gulf of Coron; 30 miles N.W. of Mistra. This was the ancient Messene or Mycene, the capital of Messenia, N. of Æchalia and S. of Ithome. It was founded by Epaminondas, and peopled about the year 369 B.C. It was a large and magnificent town, embellished by the temples of Neptune, Venus, Ceres, Lucina, &c. by a variety of statues, &c. Strabo represents it as one of the strongest places among the ancients, and compares it with Corinth, being defended by a fortress built on mount Ithome, as the latter city was by a double citadel. On the path which led to this citadel was a fountain called Clepsydra, signifying concealed water. It was pretended, that the nymphs which reared Jupiter came to bathe secretly in this fountain, whence it derived its name. N. lat. 37° 15'. E. long. 21°.

MESSENE, a kind of island, formed by the Euphrates on the W. and the Tigris on the E. It had, to the north, the wall of Semiramis, and to the south a canal, which separated it from Babylonia, and the Seleucide territory.

MESSENGERS, in the *English Polity*, are carriers of letters and messages; or, more particularly, certain officers, chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all manner of dispatches, foreign and domestic.

They are always employed with the secretaries warrants to take up persons for high treason, or other offences against the state, which do not so properly fall under the cognizance of the common law; and, perhaps, are not properly to be divulged in the ordinary course of justice. The prisoners they apprehend are usually kept at their own houses, for each

each of whom they are allowed by the government a compensation. Although it is the constant practice to make commitments to messengers, it is said that it shall be intended only in order to the carrying of offenders to gaol. (1 Salk. 347. 4 Hawk. P. C. c. 16. § 9.) An offender may be committed to a messenger, in order to be examined before he is committed to prison; and though such commitment to a messenger is irregular, it is not void. (Skin. 599.) When they are dispatched abroad, they have an allowance for their journey.

MESSENGERS of the Exchequer, are officers attending the exchequer, in the nature of pursuivants; their business is to attend the chancellor and auditor, &c. and to carry their letters, precepts, &c.

MESSENGER of the Press, a person, who, by order of the court, searches printing-houses, booksellers' shops, &c. in order to discover seditious books, &c.

There are also other officers distinguished by this appellation; as the messenger of the lord chancellor, of the privy council, of the great wardrobe, the two messengers of the yeomen of the guards, messenger to the gentlemen pensioners, four messengers to the board of commissioners for India, messenger of the board of longitude, nine messengers of the navy pay-office, four messengers of the victualling office, messenger of the war-office, three messengers of the army pay-office, messengers of the ordnance-office, messengers of the office for auditing the public accounts, messengers of the custom-house, of the stamp-office, of the general post-office, seven messengers to the commissioners of bankruptcy, &c.

MESSENGER, in *Mechanics*, the endless rope employed in the capstan; which see.

MESSENA, in *Ancient Geography*, a country of Greece, which occupied the S. E. part of the Peloponnesus; it was 13 or 14 leagues in its largest dimension, and 10 from S. to N. It was bounded, on the north, by the Elide and Arcadia; on the E. by Laconia, on the S. in great measure by the Messenian gulf, and on the W. by a part of the Ionian sea. This country was mountainous and unfertile: its principal river was the Pamissus, and Messene was its capital. It is said by Pausanias to have derived its name from a princess, called Messene, a native of Argos, daughter of Triopas, and granddaughter of Phorbes. She married Polycaon, the youngest son of Lelex, and persuaded her husband to take possession of a country situated to the W. of Laconia, and inhabited by a savage race. Having done this, he gave to the country the name of his wife, and built in it many towns. When the family of Polycaon became extinct; it passed under the dominion of several successive sovereigns; till at length, after the battle of Leuctra, Epaminondas recalled the descendants of the Messenians, and built Messene.

MESSERAG, in *Geography*, a town of the duchy of Courland; 38 miles E. of Goldingen.

MESSEROF, a town of Poland, in the palatinate of Braclaw; 40 miles N. W. of Braclaw.

MESSERSBURG, a post-town in Franklin county, Pennsylvania; 168 miles W. by S. from Philadelphia.

MESSERSCHMIDIA, in *Botany*, received its name from Linnæus, in honour of Daniel Theophilus Messerschmid, a German botanist who was sent out by the Russian government to explore the natural history of Siberia, prior to the expedition under Pallas. He was born in the year 1685, and died about the age of 30. His researches were never published, and he is only known as an author, by a paper which he left, giving an account of the "*Camelus Bactrianus, binis in dorso tuberibus.*" This was edited by John Amman, and published in the 14th vol. of the *Tran-*

actions of the Petersburg Academy. Linn. Mant. 5. Schieb. 103. Willd. Sp. Pl. v. 1. 789. Mart. Mill. Dict. v. 3. Ait Hort. Kew. ed. 2 v. 1. 323. Juss. Gen. 129. Lamarck. Illustr. t. 95. Gærtn. t. 109.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifolia*, Linn. *Borraginea*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, erect, permanent, deeply cloven into five, somewhat linear segments. Cor. of one petal, funnel-shaped, tube cylindrical, of a rosette texture, longer than the calyx, globose at the base; limb five-cleft, folded, membranous at the sides; throat naked. Stam. Filaments five, minute, in the lower part of the tube; anthers awl-shaped, erect, within the middle of the tube. Pist. Germin. superior, nearly ovate; style cylindrical, very short, permanent, stigma capitate, ovate. Berry dry, corky, of a roundish cylindrical form, abrupt at the summit, which is surrounded with four, obtuse teeth; when ripe it separates into two parts. Seeds two in each division of the berry, oblong, bony, incurved, rounded on the outside, angular within.

Ess. Ch. Corolla funnel-shaped, with a naked throat. Berry corky, divisible into two parts, with two seeds in each.

1. *M. fruticosus*. Linn. Suppl. 132. Syst. Veg. ed. 14. 190.—Stem shrubby. Leaves on stalks. Corolla salver-shaped—A native of the Canary islands, especially in the northern parts of Teneriffe, where it was found by Mr. Francis Masson, who introduced it into Kew gardens in 1779, where it flowers from June to October.—The stem of this shrub is lofty, rugged, rough with hairs, branched; branches panicled at the top. Leaves alternate, on long stalks, lanceolate, entire, veined, hairy. Spikes of flowers compound, directed one way, forked, at the ends of the twigs on the upper part of the stem. Linnæus observes that this species has the corolla of *Tournefortia*, to which the genus is nearly allied, but its fruit is that of a *Messerschmidia*. It is very similar to the following species *M. Arguzia*, differing only in its shrubby stem, stalked leaves, shorter calyx, and smaller, salver-shaped corolla, with a flat limb.

Professor Martyn has quoted a figure of this species as being in the second volume of *L'Heritier's Stirpes Novæ*, on the authority of the editor of the first edition of *Hortus Kewensis*; and we know that this quotation, in the latter work, arose from a communication of L'Heritier to Mr. Dryander. The second volume however of *Stirpes Novæ* never appeared, and therefore Mr. Dryander repented of having quoted it, determining never to refer to an unpublished figure again; accordingly the reference is suppressed in the second edition of *Hortus Kewensis*.

2. *M. Arguzia*. Linn. Mant. 42. Suppl. 132. (Messerschmidia; Hort. Upl. 36. Gmel. Sib. v. 4. 77. Arguzia; Amman. Ruth. 29. Tournefortia sibirica; Linn. Sp. Pl. 202.)—Stem herbaceous. Leaves sessile. Corolla funnel-shaped. A native of dry, gravelly, sunny places in Siberia. Root creeping. Stem erect, three or four inches high. Branches alternate, sterile. Leaves alternate, sessile, ovate-oblong, veined, downy, whitish. Corymbs or tufts of flowers frequently two. Calyx shorter than the tube of the corolla, which is white, larger than in the preceding, with the throat naked and pervious; the limb plaited and its sides membranous.

3. *M. cancellata*. Willd. n. 3. D'Alffo. Synop. n. 162. t. 1. f. 2. (Cerinthe foliis lanceolatis, caulibus ramosis, floribus vix calyceem superantibus, fructibus cancellatis; Querc. Hisp. v. 4. 145. t. 25.)—Leaves sessile, linear, obtuse, hisp. Capsules reticulated.—A native of Spain.—We adopt

this on the authority of Willdenow, without being able to consult his references. "Plant a foot high. Root fibrous, reddish. Stems hairy, branched. Radical-leaves lanceolate, rather obtuse, hispid, those of the stem similar, but narrower. Flowers on stalks, in clusters, of a blue colour."—D'Affo observes that one seed in each division of the berry is abortive.

MESSI, in *Geography*, a town of Asiatic Turkey, in Natolia, built on the site of *Halicarnassus*, which see; 50 miles S.W. of Mogla. N. lat. 37° 46'. E. long. 27° 22'.

MESSIAH, a term signifying *anointed*, or *sacred*; and, in that sense, applied to kings and priests; but, particularly, by way of eminence, to Jesus Christ, the saviour promised by the prophets of the old Jewish law.

The word comes from the Hebrew מָשַׁח, *maschuach*, *anointed*, of the verb מָשַׁח, *maschach*, to anoint; whence

Jesus Christ claims the title on a manifold account; 1, as having been anointed king of kings from all ages; 2, as chief of the prophets; 3, as high priest of the law of grace, or priest for ever after the order of Melchizedech.

The prophecies in the Old Testament, which relate to the coming of the Messiah, are very numerous; some of which may be found in Gen. iii. 15. xlix. 10. Isaiah, vii. 14. c. xi. c. lii. liii. which the Targum of Jonathan interprets of the Messiah. Dan. ix. 25. Micah, iv. 1—5. c. v. 2—4. Haggai, ii. 6, 9. Zechi. iii. 8—10. vi. 12, 13. ix. 9—12. Mal. iii. 1—4. iv. 2—6, &c.

It has been also urged, that there are some remarkable passages in Josephus, Philo, Tacitus, Suetonius, and Celsus, which shew that the expectation of the Messiah, agreeable to the scripture prophecies, prevailed in some degree among the heathen nations; and many have supposed that there is some reference of this kind in the fourth eclogue of Virgil. We shall only add farther, that the best Christian writers lay little stress on the prophecy of Christ cited by Abulpharagius, out of the books of Zerduch or Zoroaster, nor on the pretended prophecy of Confucius, among the Chinese; nor on those of the Sibylline oracles, among the Romans.

The Jews still wait for the coming of the Messiah, being infatuated with the notion of a temporal Messiah, that is to be a mighty conqueror, and to subdue all the world. Most of the modern rabbins, according to Buxtorf, believe that the Messiah is already come, but that he keeps himself concealed, and will not manifest himself because of the sins of the Jews. Some of the Jews, however, in order to reconcile those prophecies that seem to contradict each other, as to the character and condition of the Messiah, have had recourse to the hypothesis of two Messiahs, who are yet to succeed each other; one in a state of humiliation and suffering; the other of glory, splendor, and power. The first, they say, is to proceed from the tribe of Ephraim, who is to fight against Gog, and to be slain by Annillus, Zech. xii. 10. The second is to be of the tribe of Judah, and lineage of David, who is to conquer and kill Annillus, and restore the kingdom of Israel, reigning over it in the highest glory and felicity.

Jesus Christ asserts himself to be the Messiah. In St. John iv. 25. the Samaritan woman says to Jesus, "I know that when the Messiah comes, who is called the Christ, he will tell us all things. Jesus answered her, I that spake to thee am he." There are several impostors, who have endeavoured to pass for Messiahs, as Christ himself predicted. J. Lent, a Dutchman, has written a history of false Messiahs, "De Pseudomesias." The first he mentions was one Barcochab, who appeared under the empire of Adrian. The last was

rabbi Mordecai, who began to be talked of in 1682. A little before him; viz. in 1666, appeared Sabbethai Sebi, who was taken by the Turks, and turned Mahometan.

MESSIEURS, a French title of honour, or civility, lately introduced into our language; being the plural of *monsieur*, and equivalent to the English sirs, or gentlemen.

The French lawyers always begin their pleadings and harangues with *messieurs*; which word is also frequently repeated in the course of their speeches; on which occasion it answers to our English word *gentlemen*.

The French say, *Messieurs du parlement; du conseil; des comptes, &c.*

MESSILLONES, or MUSCLE-Bay, in *Geography*, a bay on the coast of Chili or Peru, in South America; 8 leagues N. by E. of Morrenas bay, and 5 S. by W. of Atacama. It forms part of Atacama bay, and at its entrance, or the anchoring place, ships may ride in 15 fathoms, clean ground, and secured from most winds.

MESSINA, a city and sea-port of Sicily, in the valley of Demona, the see of an archbishop, situated on the E. coast towards the narrow sea, called "The Straits of Messina," formerly called "Zanche," which name it received, according to Thucydides, from the form of its harbour, that resembles a hook. This author supposes that the city was founded by the pirates of Cuma. Other writers trace its origin to a higher antiquity, and date it 530 years before the siege of Troy, and 964 years before Romulus laid the foundation of Rome. They add, that when the inhabitants were molested by the pirates of Cuma, they sought the assistance of the Messenians, a people of Greece, who hastening to their succour, cleared their coasts, entered into an alliance with them, and hence the city was called by the Greeks "Messene," and by the Latins "Messana." Pausanias says, that Anaxilas, tyrant of Rhegium, having formed an alliance with the Messenians of Greece against the Zancleans, with their assistance took possession of the city, which, in compliment to them, he called "Messene." This event is said to have taken place in the year of Rome 94. This city was afterwards seized by the Mamertini, and being made their capital, it became one of the most wealthy and powerful cities of Sicily. The Mamertini transferred it to the Romans, and from them it was taken, in the first Punic war, by the Carthaginians. Under the Romans it enjoyed a long interval of peace, and was spared by the rapacious Verres. In the civil wars it took part with Sextus Pompeius. After the fall of the Roman empire it was for some time in the possession of the Saracens: and, in 1060, was taken by Roger, count of Calabria, who also assumed the name of the count of Sicily. In 1139, Richard I. king of England, made himself master of it in his way to the Holy Land. It was afterwards betrayed to Louis XI., king of France, who was compelled to surrender it. The harbour of this city has been much admired, and the quay is decorated with a range of buildings, nearly uniform in its whole length, and interrupted only by a number of arches, which serve as entrances into the corresponding streets that terminate upon it. At the bottom of the port is the king's palace, the residence of the governor of the city, before whose door the vessels of the royal navy lie at anchor. Near this is a covered walk, which leads to the citadel, which is almost impregnable, and cannot be attacked by sea, on account of the currents and the difficulty of anchorage, nor is it overlooked on the land side, whilst it commands the city and harbour. This was built by Charles XI. after a revolt of the inhabitants. There is a communication by a covered way, and a wide subterranean passage formed under the jettee, between the citadel and two forts;.

forts; one that of the Lantern, which points out the channel in the Calabrian coast, and that of St. Salvador, which defends the entrance of the port. It seems as if nature had designed even the whirlpools of Scylla and Charybdis to serve as guards to this superb port; which is capable of containing all the ships of Europe, and where vessels arrive at the very door of the merchant, finding any required depth of water, and needing not to move an anchor, if it were not for the violence of the Sirocco, the only wind to which it is exposed, and by which the ships are in danger of being driven out to sea. In the middle of the haven are a light-house and lazaretto. Within the city are handsome streets, elegant marble fountains, equestrian and pedestrian statues of bronze, large and handsome churches, vast convents, tolerably well built hotels, a magnificent general hospital, called "La Loggia," another large and rich hospital, and near it a well-regulated as well as spacious Lombard house. The population formerly corresponded with these appearances; but the plague of 1743 and 1744 reduced it from 100,000 to 30,000. In 1780 and 1782 it suffered much from an earthquake. The calamities which this city has suffered have not only diminished its population, but occasioned the decay of many houses and the desertion of their occupiers, as well as the decline of their trade, which, however, is still considerable. In August an annual fair is held, at which great quantities of foreign goods are exposed to sale. The air at Messina is temperate, being continually freshened by the sea, purified by the mountains, agitated by the currents, and moderated by the shade and shelter. So that, as De Non says, it is rendered one of the healthiest and most agreeable habitations of the whole world. Messina claims the prerogative of being styled the capital of the kingdom, though Palermo disputes the precedence with it; 104 miles E. of Palermo. N. lat. 38° 10'. E. long. 15° 40'.

MESSINES, a town of France, in the department of the Lvs, and chief place of a canton, in the district of Ypres. The place contains 3155, and the canton 17,956 inhabitants, on a territory of 167½ kilometres, in 8 communes.

MESSING, a town of Bavaria, in the bishopric of Aichstatt; 14 miles N.N.E. of Aichstatt.

MESSIS, a town of Asiatic Turkey, in Caramania; 15 miles E.S.E. of Adana.

MESSUAGE, **MESSUAGIUM**, in *Law*, a dwelling-house, with some land adjoining, assigned for its use.

By the name of messuage may a garden, shop, mill, cottage, chamber, cellar, or the like, pass.

In Scotland, messuage denotes what we call the *manor-house*, viz. the principal dwelling-house within the barony.

MESSUBY, in *Geography*, a town of Sweden, in Tavastland; 34 miles N.W. of Tavasthus.

MESTA, in *Geography*, a town and cape on the W. coast of the island of Scio. N. lat. 38° 25'. E. long. 30° 54'.

MESTA, a Spanish term, which, in its general acceptation, signifies a mixture of two or more sorts of grain, and is equivalent to the English word "Mellin," denotes, in a more restricted sense, the union of the flocks belonging to several different proprietors into one collective body, which does not strictly attach to any country, but travels backward and forward twice in the year, passing part of it at one place, and part in another. This collection is formed by an association of proprietors, consisting of the nobles, persons in power, members of rich monasteries and ecclesiastical chapters, who feed their flocks on the waste lands, as is done on the commons in England. These flocks they call *Merinos*, or *transhumantes*.

This custom, first introduced by circumstantial necessity, in process of time was converted into a claim, which long possession has now changed into a prescriptive right. It rests at present upon the support of those laws and ordinances which have favoured, protected, and perpetuated the usurpation.

The origin of this custom must be referred to the era in which the great plague ravaged Spain, and destroyed two-thirds of the population. The few persons who survived that destructive scourge took possession of the lands which had been vacated by the death of their former occupiers. These they united with their own for the purpose of forming large properties; but not possessing sufficient means for the cultivation of such extensive domains, they were obliged to convert nearly the whole into pasture, and confine their attention principally to the care and increase of their flocks. Hence has arisen the vast quantity of pasture lands which occupy the greater part of Estramadura, the kingdom of Leon, and other provinces. To this cause, among others, may be attributed the prodigious quantity of uncultivated lands discoverable through the whole kingdom; and hence so many proprietors, who possess extensive tracts of territory, yet have no titles to their estates, and are therefore denominated *Duñes voceros*.

The flocks which, when united, form the Mesta, usually consist of about ten thousand sheep in each. Every flock is conducted by an officer, called a *mayoral*, who superintends the shepherds, and directs the route. It is essential that he should be an active man, well acquainted with the kinds of pasturage, the nature of sheep, and methods of treatment. The mayoral is allowed a horse and one hundred *doublons*, or fifteen hundred livres tournois (thirty pounds eight shillings sterling) *per annum*. Placed under him are fifty shepherds, who are divided into four classes. The wages amount to one hundred and fifty reals, or thirty-seven livres ten sols (one pound eleven shillings and three-pence) *per month*, for the first class; one hundred reals, or twenty-five livres (one pound and eleven-pence) for the second; sixty reals, or fifteen livres (twelve shillings and ten-pence) for the third; and forty reals, or ten livres (eight shillings and four-pence) for the fourth: exclusive of these wages, each is allowed a daily ration of bread, weighing two pounds. They receive individually twelve reals, or three livres (two shillings and six-pence) for travelling expences, when they commence their journey in the month of April or May; and the like sum on their return in October. To each shepherd is granted the privilege also of keeping a few sheep and goats, but the wool and hair belong to the proprietor of the flock; he takes himself the increase, the flesh, and the milk; but he cannot take any part of these away. The number of persons thus employed in the care of the whole of the flocks which compose the Mesta, are about forty-five or fifty thousand. The dogs are also numerous, fifty being the allowance to each flock.

The number of sheep which are thus made to migrate has varied at different periods. It very much decreased during the seventeenth century. It was again increased in the eighteenth. In the sixteenth the enumeration comprised seven millions. At the commencement of the seventeenth, in the reign of Philip III., they were reduced to two millions five hundred thousand. Urtaria states the number in his time, about the end of the same century, at four millions; they amount at present to near five.

The flocks are put in motion the latter end of April, or beginning of May, leaving the plains of Estramadura, Andalusia, the kingdom of Leon, and Old and New Castile, where they usually winter; they repair to the mountains of

the two latter provinces, and those of Biscay, Navarre, and Aragon. The mountainous districts most frequented by these flocks in New Castile are those of Cuenca; and in Old Castile, those of Segovia, Soria, and Buytrago. The sheep, while feeding on the mountains, have occasionally administered to them small quantities of salt. It is laid upon flat stones, to which the flocks are driven, and permitted to eat what quantity they please. During the days the salt is administered, the sheep are not allowed to depasture on a calcareous soil, but are moved to argillaceous lands, where they feed voraciously.

At the end of July the ewes are put to the rams, after separation has been made of those already with lamb. Six or seven rams are considered sufficient for one hundred ewes.

In September the sheep are ochred, their backs and loins being rubbed with red ochre, or ruddle, dissolved in water. This practice is founded upon an ancient custom, the reason of which is not clearly ascertained. Some suppose, that the ochre uniting with the oleaginous matter of the fleece, forms a kind of varnish, which defends the animal from the inclemency of the weather. Others think the ponderosity of this earth prevents the wool growing too thick and long in the staple. But the more eligible opinion is, that the earth absorbs the superabundant perspiration, which would otherwise render the wool both harsh and coarse.

Toward the end of the same month the flocks recommence their march. Descending from the mountains, they travel towards the warmer parts of the country, and again repair to the plains of Leon, Estramadura, and Andalusia. The sheep are generally conducted to the same pastures they had grazed the preceding year, and where most of them had been yeaned: there they are kept during the winter.

Sheep-shearing commences the beginning of May, and it is performed while the sheep are on their summer journey, in large buildings called *Esfquileos*. These, which are placed upon the road, are capable of containing forty, fifty, and some sixty thousand sheep. They are erected in various places; but the principal are in the environs of Segovia, and the most celebrated is that of *Iurviaca*. The shearing is preceded by a pompous preparation, conducted in due form, and the interval is considered a time of feasting and recreation. One hundred and twenty-five men are usually employed for shearing a thousand ewes, and two hundred for a thousand wethers. Each sheep affords four kinds of wool, more or less fine according to the parts of the animal whence it is taken. The ewes produce the finest fleeces, and the wethers the heaviest: three wether fleeces ordinarily weigh on the average twenty-five pounds; but it will take five ewe fleeces to amount to the same weight.

The journey which the flocks make in their peregrinations is regulated by particular laws, and immemorial customs. The sheep pass unmolested over the pastures, belonging to the villages, and the commons which lie in their road, and have a right to feed on them. They are not, however, allowed to pass over cultivated lands; but the proprietors of such lands are obliged to leave for them a path ninety *varas*, or about forty toises (eighty-four yards) in breadth. When they traverse the commonable pastures, they seldom travel more than two leagues, or five and a half miles a day; but when they walk in close order over the cultivated fields, often more than six, or near seventeen miles. The whole of their journey is usually an extent of one hundred and twenty, thirty, or forty leagues, which they perform in thirty or thirty-five days.

The price paid for depasturing the lands, where they winter, is equally regulated by usage, and is very low; but it

is not in the power of the landed proprietors to make the smallest advance. The Mesta has its peculiar laws, which were originally made by the parties interested, the proprietors of flocks, and received the sanction of several sovereigns of Spain, among whom was Charles I., who approved and confirmed them in the year 1544. A particular tribunal also exists, under the title of "*honrado consejo de la Mesta*," or *the honourable council of the Mesta*. This court, in which one of the council at Castile presides, is composed of four judges, denominated "*Alcaldes mayores entregadores*," each having a fiscal or exchequer, and an escheator or *Alguazil mayor*. The cognizance of this court superintends the preservation of the privileges belonging to the Mesta. The judges levy upon the shepherds and their flocks pontage, parage, and other tolls; they settle the disputes and quarrels among the shepherds; direct the route the flocks ought to take in their journeys to and from the mountains; regulate what occurs on their passage; settle what respects their pasturage; in a word, they adjust every concern in which the Mesta can be supposed interested in the slightest degree. The proprietors of flocks, and even the shepherds, possess, to a certain extent, a power of *commitimus*, or commitment, which they very frequently abuse. They have the improper privilege of citing all kinds of persons, of whatever age or condition, before the Mesta, under a supposition, or pretence, that their altercations, or business, have some connection, however distant, with the jurisdiction of its court.

The public opinion throughout Spain is decidedly opposed to the Mesta, against the vexatious circumstances to which it continually gives rise, and the constant obstacles it throws in the way of agricultural improvements. In fact, the grievances arising from its effects are numerous and severe.

1. The number of persons it employs is very great, forty or fifty thousand; which are so many subjects lost to the state, as to the purposes of agriculture and population; and this takes place principally in those provinces where the strength requisite for the cultivation of the soil is most deficient.

2. An immense extent of highly valuable land is converted into pasturage; and produces comparatively nothing. The consequence is, that the inhabitants of such places find no employ, nor means of providing for their wants; they are refused the necessary articles for the support of life, because the lands on which they might be grown do not produce them.

3. The cultivated lands, which lie near the route the flocks take in their journeys to and from the mountains, are subject to continual trespass, which is committed with impunity; for in vain do the owners of those lands appeal against such abuses and solicit indemnity. The damages sustained on these occasions is so much greater, owing to the seasons of the year in which the journeyings of the flocks are made. The first is when the corn is generally far advanced in its growth; and the second when the vines are loaded with grapes.

4. The commonable pastures also, which are in the line of the route, are equally devastated; so that the flocks belonging to places in the vicinity can scarcely find a bare subsistence.

5. The flocks which compose the Mesta are unprofitable for agricultural purposes; for never being folded upon the arable lands, they consequently contribute nothing towards their fertilization.

6. The directors and shepherds are dreaded in every place through which they pass; for they exercise a most insufferable

able despotism, the consequence of the improper privilege they possess of bringing whomsoever they may chuse to insult before the tribunal of the Meffa; whose decisions are almost invariably in favour of its servants.

These grievances have for time immemorial excited the most forcible protestations against them; the general states of the realm have incessantly requested the suppression of the Meffa, and the complaints and addresses of the people have been repeatedly presented at the foot of the throne. For a long series of years all appeals upon the subject were in vain. They at length, however, became so loud and pressing, towards the middle of the eighteenth century, that the government found itself obliged to pay some attention to the subject. A committee was formed to make the requisite inquiry, whether it were more eligible for public utility to continue, or suppress the Meffa? and, provided the committee should determine on the former measure, what modifications might be proper to adopt for its better regulation. The persons interested were very powerful, and they made sure of evading this wise disposition for remedying the evils of the Meffa. The committee, though permanently established, have done nothing these thirty or forty years. Affairs remain in just the same state, and, as it too frequently happens, the interest of a few individuals still obtains the advantage over the public good. Laborde's View of Spain, vol. iv.

MESTERO, in *Geography*, a cape on the N. coast of Egypt; 10 miles N.E. of Rosetta. N. lat. 31° 25'. E. long. 30° 54'.

MESTI, a town of Austrian Poland, in Galicia; 6 miles E.S.E. of Belcz.

MESTRA, a town in the Trevisan; 8 miles N.W. of Venice.

MESTRE BAY, *Little*, a bay on the N.E. part of Newfoundland island, S. of St. Julian, and N. by W. of the islands Gros and Belle.

MESTREZ AT, JOHN, in *Biography*, a celebrated French Protestant minister, was born at Geneva in the year 1592. When he was yet very young he was sent to the academy at Saumur, where he afforded such evidence of his abilities and proficiency, that he was offered a professorship of philosophy when he was only eighteen years of age. He became an eloquent and highly distinguished preacher, and there are said to be no sermons that contain more sublime theology than those which he preached upon the epistle to the Hebrews. He conducted the controversy concerning the authority of the church with forcible reasoning, and completely refuted all the subtilties of father Regourd and cardinal Perron on this subject. He died in 1657, leaving behind him a number of theological works that do honour to his memory: of these the chief are, "A Treatise on the Holy Scriptures, in which is shewn the Certainty and Fulness of Faith, and its Independence on the Authority of the Church;" and "An Exposition on the Epistle to the Hebrews, in a Course of Sermons," making five volumes 8vo. Bayle.

MESTURA, in *Geography*, a town of Africa, in the kingdom of Tunis.

MESUA, in *Botany*, a Linnæan genus, in honour of *Mesue*, the father and son, two celebrated Arabian physicians and botanists, who resided at Damascus, and who flourished in the eighth and ninth centuries. The works of the younger *Mesue*, medical and botanical, were published in folio, with annotations, at Venice, in 1581.—Linn. Gen. 268. Schreb. 471. Willd. Sp. Pl. v. 3. 843. Mart. Mill. Dict. v. 3. Juss. Geol. 258. Lamarek Dict. v. 4. 416.—Class and order, *Menadelphina Polyandria*. Nat. Ord. *Guttifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four, ovate, concave, obtuse, permanent leaves, the two outward, opposite ones smaller. *Cor.* Petals four, abrupt, undolated. *Stam.* Filaments numerous, capillary, the length of the corolla, united at the base into a sort of cup; anthers ovate. *Pysl.* Germen superior, roundish; style cylindrical; stigma thickish, concave. *Peric.* Nut roundish, pointed, marked with four, longitudinal, elevated furrows. *Sed.* solitary, roundish.

Ess. Ch. Calyx simple, of four leaves. Corolla of four petals. Nut slightly four-sided, single-seeded.

1. *M. ferrea*. Linn. Sp. Pl. 734. Fl. Zeylan. 91. (Naghas; Herm. Zeylin. 7. Nagassarium; Rumph. Amboin. v. 7. 3. t. 2. Bellutta Thiampakam, five Castanea rosea indica; Rheed. Malab. v. 3. 63. t. 53.)—A native of the East Indies, and much cultivated, according to Rheede, in Malabar, for the beauty of its flowers, which expand there in July and August. It bears fruit in six years from the nut, and continues to bear during three centuries. The same author subjoins a long account of its medical virtues, and Rumphius says, it is planted in Amboyna, about houses, for the shade it affords, and for the odour of its flowers, which also, when dry, are mixed with other aromatics, such as the white sandal-wood, and used for perfuming ointments.

This tree grows to a large size, having a variegated, thick, hard, smooth, much-branched trunk, like that of a lime-tree. *Bark* smooth, brown, aromatic, of a sharp and bitter taste. *Root* fibrous, red, covered with a smooth, yellow bark, bitter, but sweet-smelling. *Leaves* opposite, on short stalks, smooth, thickish; of a shining green on the upper side; glaucous-blue underneath, like the bloom of grapes. *Flowers* in size and shape like those of the Sweet-briar or Eglantine, but with only four white petals. Their smell partakes both of the rose and violet. *Fruit* smooth and greenish, but reddish and wrinkled when ripe, with a rind like that of the chestnut, and three or four kernels within, the shape, size, substance, and taste of chestnuts.—The specific name is taken from the close texture and hardness of the wood.

MESUA, in *Gardening*, comprises a plant of the exotic shrubby kind, for the hot-house of which the species cultivated is the ferreous Indian mesua (*M. ferrea*.)

Method of Culture.—This plant may be increased by seeds, layers, and cuttings. The seeds should be sown in the spring, in pots of light earth, plunging them in a bark hot-bed in the stove. When the plants have attained some growth, they should be planted in separate pots and be replunged in the bark-bed, where they must be kept.

The layers should be made from the young branches, and should be laid down in the autumn or early spring, being taken off when well rooted, and planted in separate pots, having the same management as the others.

The cuttings should be taken from the young branches, and be planted in the summer in pots of light mould, and plunged in the bark-bed. When they have stricken root, they should be removed into separate pots, and be managed as the others.

Plants of this kind afford variety among other stove plants.

MESUA, in *Geography*, a town of Arabia, in the province of Yemen; 40 miles N. of Chamir.

MESUE, in *Biography*, one of the early physicians among the Arabians, was born at Nisabour, in the province of Khorasan, and flourished in the ninth century. He is said to have died in 846, or, according to other accounts, in 865. His father was an apothecary at Nisabour. Mesue was educated in the profession of physic by Gabriel, the son

son of George Bactishua, and through his favour was appointed physician to the hospital of his native city. Although a Christian of the Nestorian sect, he was in great favour with several successive caliphs, being reputed the ablest scholar and physician of his age. When the caliph Haroun al Raschid appointed his son, Almammon, to the vicerealty of the province of Khorasan, Mesue was nominated his body physician, and was placed by him at the head of a college of learned men, which he instituted there. On his accession to the throne of the caliphs, in the year 813, Almammon brought Mesue to Bagdad, and made him a professor of medicine there, as well as superintendant of the great hospital, which situations he occupied a great number of years. He was also employed, under the auspices of the same caliph, in transferring the science of the Greeks to his own country, by translating their works. Freund is of opinion that Mesue wrote in the Syriac tongue, which prevailed in his native province, long before and after his time; for not only he, but the Bactishuas, are reckoned Syrians by Abulpharagius and Abi Osbaia, though born at Nisabour. He was the author of some works, which are cited by Rhazes and other writers, which appear to have perished: for the works, which are now extant in his name, do not correspond with these citations, nor with the character of them given by Haly Abbas; not to mention, that in these works the writings of Rhazes are quoted, who lived long after his time. Abi Osbaia enumerates thirty-seven books written by Mesue, among which is one upon purging, and another respecting decoctions. Freund's Hist. of Physic, vol. ii.

MESUE, *the Younger*. A writer of this name, or *Mesuech*, who was later than Rhazes, and a Christian of the sect of Jacobites, is mentioned by Leo Africanus. He studied medicine and philosophy at Bagdad, and practised at Cairo, where he died in the year 1015, at the age of 90. He wrote some treatises on potable liquors, and on the composition of medicines: and perhaps to him may be attributed the work entitled, "Joannis Mesue Damasceni de Re Medica, lib. iii." edited by Jac. Sylvius, Paris, 1549, folio, and often reprinted. Eloy Dict. Hist. de la Med. Gen. Biog.

MESURACA, in *Geography*, a town of Naples, in Calabria Citra; 8 miles S.W. of St. Severina.

MESURADA, a sea-port town of Africa, in the country of Tripoli, and residence of a governor: a considerable commerce is carried on at this place by means of the caravans that pass into the interior parts of Africa. This is the chief place of a district anciently called "Cyrenaica" and "Pentapolis," from its five cities; 100 miles E.S.E. of Tripoli. N. lat. 32° 10'. E. long. 15° 10'.

MESURADO, a river of Africa, which runs from the mountains that separate Negroland from Guinea, into the Atlantic, N. lat. 6° 25'. W. long. 10° 35'.

MESURE, Fr.; *Misura*, Ital.; measure, in *Music*. In poetry measure is expressed by *metre*; in music, by *time*. See MEASURE, METRE, and TIME.

MESVRES, in *Geography*, a town of France, in the department of the Sône and Loire, and chief place of a canton, in the district of Autun; 5 miles S. of Autun. The place contains 608, and the canton 6277 inhabitants, on a territory of 302½ kilometres, in 12 communes.

MESYMNIMUM, a name which the ancients gave to a part of their tragedy, or to certain verses in their tragedies.

The mesymnium was a kind of burden, as *Io Pean*; *O Dithyrambe*; *Hymen*, *O Hymenac*; or the like; which, when placed at the end of a strophe, was called *epymnium*; and

when inserted in the middle of a strophe, *mesymnium*. See STROPHE, and CHORUS.

MET, in *Rural Economy*, a term applied to a measure which contains a strike, or four pecks.

META, in *Geography*, a river of South America, which, after receiving several tributary streams, runs into the Orinoko; 30 leagues below the cataracts of Aturas, and 125 leagues from St. Thomas of Guiana. This river, says Depons, seems destined by nature to form vast commercial relations between the whole eastern part of the kingdom of Santa Fé and Spanish Guiana.

METAC, a town of Upper Siam; 130 miles N.W. of Porfelow.

METACAL, an Egyptian weight, used in the weighing of pearls, and consisting either of a carat and a half, or of two carats. Sixteen of these carats make a drachm, each of the carats weighing four grains, and twelve drachms an ounce.

METACARPIUS, in *Anatomy*, the name given by Winslow to the adductor ossis metacarpi digiti minimi; which see.

METACARPUS, one of the divisions of the bones of the hand, placed between the wrist and the fingers. See EXTREMITIES.

METACARPUS, *Fracture of*, in *Surgery*. See FRACTURE.

METACHORESIS, a word used by Galen, to express a recess of a morbid humour from one part of the body to another, a thing very common in many distempers.

METACHRONISM, formed of *μετα* and *χρονος*, *time*, in *Chronology*, an error in computation of time, either on the side of defect or excess.

METACINEMA, from *μετα*, and *κινω*, *to remove*, in *Surgery*, a removal of the pupil of the eye from its natural situation.

METACISM, METACISMUS, in *Grammar*, a defect in the pronunciation of the letter M.

Idore represents the metacism as a final *m*, followed by a vowel, as *bonum aurum*, *Bethlebens erat*, &c.

METACOE, in *Botany*, a name given by the people of Guinea to a plant, of which they are very fond, because of its virtues as a balsamic and vulnerary. Its leaves, being bruised and applied to a fresh wound, cure it. They have also another use for it, twisting the dried leaves into a sort of match for their muskets. Phil. Trans. N° 232.

METACONDYLI is used by some authors for the outermost bones, or joints of the fingers, next the nails.

METADELO, plur. *Metadeli*, in *Commerce*, a corn and liquid measure at Florence. For corn, the moggio contains 24 staja; and the staja 16 metadeli; and the moggio contains about 16 English bushels. Oil is sold by the barile of 32 boccali or metadeli, the whole weighing 88lbs. of Florence, or about 66lbs. avoirdupois.

METAGITNION, *μεταγειτωνων*, in *Chronology*, the second month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our July and beginning of August. The Boeotians called it *Panemus*, and the people of Syracuse, *Carnius*.

It is so called from *Metagitnia*, one of Apollo's festivals kept in it.

METAGONITÆ, in *Ancient Geography*, a people of Africa, who inhabited the environs of the promontory of Metagonium, on the west of Mauritania Tingitana.

METAKOONA, in *Geography*, a town of Hindoostan, in the province of Cattack; 60 miles S. of Cattack.

METALS, in *Chemistry*, a class of simple bodies possessing peculiar properties. The ancients, who valued these bodies

METALS.

bodies most for their physical properties, did not bestow the exclusive name of metal on any body which was not malleable. Other bodies, which possessed similar characters, without being malleable, were called semi-metals. The peculiar brilliancy belonging to the metals is perhaps their most generally distinguishing character. The lustre exhibited by mica has some resemblance to the lustre of metals, but it is very inferior in degree, and is merely confined to the surface. The great specific gravity of most metals has been thought a sufficiently distinguishing character. This property, to a certain extent, was very striking. Till the late discoveries of Mr. (Sir H.) Davy, the lightest of the known metals was of greater specific gravity than the densest body which was not a metal. The bases of potash and soda, however, have all the characters of metals, with the exception of being defective in the property just alluded to, since potassium and sodium are of less specific gravity than water. From these facts, therefore, we are no longer allowed to say that all metals are of greater specific gravity than other bodies.

In the present state of our knowledge there appear to be two classes of elementary matter, namely, oxygen, which constitutes one class, and oxydable bodies, or such bodies as combine with oxygen. Of the latter class, out of 45 varieties, there appear to be only five which are not metallic. The metals, therefore, comprise by far the greatest part of the elementary bodies.

Dr. Thomson has divided the metals into four classes; 1. Malleable. 2. Brittle and easily fused. 3. Brittle, and difficultly fused. 4. Refractory.

I. Malleable.

- | | |
|---------------|-------------|
| 1. Gold. | 8. Mercury. |
| 2. Platinum. | 9. Copper. |
| 3. Silver. | 10. Iron. |
| 4. Palladium. | 11. Lead. |
| 5. Rhodium. | 12. Tin. |
| 6. Iridium. | 13. Nickel. |
| 7. Osmium. | 14. Zinc. |

II. Brittle, and easily fusible.

- | | |
|--------------|---------------|
| 1. Bismuth. | 3. Tellurium. |
| 2. Antimony. | 4. Arsenic. |

III. Brittle, and difficultly fusible.

- | | |
|---------------|----------------|
| 1. Cobalt. | 4. Molybdenum. |
| 2. Manganese. | 5. Uranium. |
| 3. Chromium. | 6. Tungsten. |

IV. Refractory.

- | | |
|---------------|------------|
| 1. Titanium. | 3. Cerium. |
| 2. Columbium. | |

Besides the metals arranged in this table, there are a number of others lately discovered by Mr. Davy, which are the bases of some of the earths, and the two fixed alkalies. If the whole of the earths, as well as the two fixed alkalies, have metallic bases, the number of metals to be added to the above will be 13. Those from potash, soda, barytes, strontian, zinc, and magnesia, have already been obtained, and have been named by Mr. Davy, potassium, sodium, barium, strontium, calcium, and magnesium. The four first of these appear to be malleable metals; the others are not sufficiently known.

Those metals which are not liable to be oxydated by exposure to the air, such as gold, platina, silver, &c. have

been called noble; while those which become tarnished and corroded, were termed base metals. These distinctions have now become obsolete.

The metals have always, and must continue to be of the utmost importance in chemistry, in the arts and manufactures, and in domestic economy. Their malleability and hardness render them highly fitted for making various vessels and utensils, and their lustre and colour are agreeable to the eye. The properties of hardness and tenacity united, such as belong to iron and steel, are of great utility in various kinds of edge-tools, and the elasticity which is constituted by certain degrees of these two properties, could scarcely be furnished by any other substance than steel; hence its great usefulness for making springs.

The ductility of some metals is so great, as to admit of its being drawn into wires much finer than a hair. Gold, although the most laminable of all the metals, or which may be made into the thinnest leaves, does not admit of being drawn into the smallest wire, owing to its want of hardness. Iron, in consequence of possessing greater hardness, with a considerable portion of that property by which the particles of bodies attract each other in all situations equally, is capable of being drawn into finer wire than gold. Indeed pure gold is less ductile than when it contains a certain portion of copper. In treating of some of the physical properties of metals, such as malleability, ductility, hardness, and tenacity, much uncertainty has prevailed, from the want of some of these terms having definite meanings.

That property of a metallic bar or wire, by which it resists the action of a weight in the direction of its length, has been called tenacity, and this is always the measure of its strength. This power in metals, however, is evidently dependent upon two properties, one of which is its hardness, and the other a property for which philosophers have no precise word; perhaps the word flexibility may come the nearest. We mean, however, that property by which its particles can be changed into any situation, without separation. In the drawing of a piece of wire, some of those particles which constitute its thickness, before it passes through the hole of the wire-plate, are, by the process of drawing, brought into the direction of its length. This property in the greatest degree enables a piece of wire, or a thin slip of metal, to be bent backwards and forwards without breaking. A single experiment will satisfy any one of the propriety of these remarks. Take a piece of copper or iron wire, previously well annealed, and it will be found exceedingly flexible, and may be twisted or bent considerably, without breaking. If a weight be hung to it, with a view to break it, it will stretch considerably before it breaks. If a piece of the same wire be drawn through one or two holes, it will be found much stiffer and harder, and of course smaller: it will also be less capable of being bent or twisted without breaking. If, however, a trial be made of its strength, it will require a much greater weight to break it than in the annealed state; although its diameter is diminished. If the hardness be still increased by these means, a maximum of strength would be found under some joint proportion of the hardness, and the property of bending or twisting, which we may for the present call flexibility. It is on this latter property, with a certain degree of hardness, that the malleability and ductility of metals depend. It requires rather less hardness to make a metal to the best advantage into sheets, than to draw it into wire. This evil, however, of the wire breaking from being soft, may be remedied by making less difference in the size of the holes in the wire-plate. By this means the greatest ductility and malleability may exist under the same degrees of hardness and flexibility.

Metals, with regard to their hardness and flexibility, are very different under different circumstances. Some metals, however, are more susceptible of this change than others. Steel may be so soft and flexible as to bear much twisting, and be easily penetrable by the file, which happens when it is newly annealed; while, if it is heated red-hot, and cooled rapidly, it becomes extremely brittle, and is sufficiently hard to cut glass. Lead, on the contrary, under all circumstances, has the same degree of stiffness and hardness. The same is pretty nearly the case with tin.

Some hints were given under the article LIQUIDITY, which may throw some light on this mysterious property of metals. It is there conjectured, that the particles of bodies may be capable of assuming two states, one in which the particles attract each other equally in all directions. Hence whatever motion may take place among them, the same attraction still exists. It is in this state that bodies can be changed in their figure, without destroying their aggregation.

On the other hand, it is supposed that the particles of bodies, under certain circumstances, may possess polarity; and that the strongest attraction, and, consequently, their greatest hardness, may exist, when the particles are so arranged that opposite poles are presented to each other. Any thing, therefore, which facilitates this change to polarity, will increase the hardness of a body. The crystalline form, which is common to some metals, strongly favours this idea; since metals are always harder in this state, than when their *fibrous form*, as it is called, is brought about. Metals seem to acquire the greatest hardness by cooling rapidly, through a great range of temperature. It is in this change, therefore, that the particles acquire the greatest polarity, and by which the body becomes the most brittle and elastic. Indeed it is on the principle of polarity only, that we are enabled to explain the elasticity of bodies. Heat appears to be the most efficacious in destroying the polar property. The body would, however, regain it by rapid cooling; but by slow cooling, it is rendered soft to the greatest degree of which it is capable, and in the same proportion malleable and inelastic.

The hardness of metals, when they have been annealed, may be considerably increased by hammering, rolling, or wire-drawing. This change appears to be brought about merely by condensation. The small degree of polarity left in the particles will exhibit itself in the elasticity, when the particles are brought nearer together. It will be equally evident that the particles will be attracted with more force, and that the hardness will be increased. The hammering does not appear to increase the hardness of a body which has assumed the crystalline form, under which the greatest polar power is supposed to exist, but rather to diminish it. If a piece of steel plate, which has been hardened and tempered, be hammered carefully, the elasticity and hardness become less. Upon heating it, however, till it becomes blue, the elasticity returns. The hammering, in this instance, deranges the poles of the particles, which the slight heat restores to their proper positions.

From what has been observed it will be easy to infer, that no metal can be malleable under its crystalline or polar form. Several of the metals are scarcely susceptible of this form: among these we may enumerate gold, silver, and lead, and, in all probability, mercury. Others are deprived of it, and become malleable by hammering or rolling at a certain temperature. Of these are copper, brass, iron, steel, tin, and zinc. There are other metals, indeed the greatest part of them, which are not capable of any other than the crystalline form, and hence are not malleable. Of these we may mention antimony, bismuth, arsenic, cobalt, and manganese. What strengthens the idea that the crystalline form is the

cause of the want of softness and malleability, is the circumstance of copper and tin being separately very soft and malleable; though an alloy of these two metals is as hard as steel, and does not possess the least malleability. Cast steel and blistered steel are in the crystalline form, till they have been hammered at a certain temperature. In the first state they are hard and brittle; in the latter, they are flexible, and are increased in tenacity.

Brass wire appears to undergo some change in its arrangement, by hanging up in a damp room, or in situations where the fumes of acids prevail. It becomes so brittle as not to admit of bending to a right angle. This appears to arise from an increase in its polar form, for heating it red-hot partly restores its malleability.

The fusibility of metals is a very valuable property, since it not only admits of their being cast into almost any form, but the refuse can be made into its original form, which allows of great economy.

Some metals are better fitted for casting than others. It is observed, that all those metals of which we have spoken as being susceptible of the crystalline form, are the best calculated to take fine impressions. At that point in which the metal passes from the liquid to the solid form, a sudden expansion takes place, by which the volume is increased, and, in consequence, presses more strongly against the sides of the mould. This is particularly the case with brass, cast iron, and copper with tin. In forming alloys the most fitted for casting, a simple method offers itself. Let the specific gravity of the solid be as much as possible less than the liquid. In such bodies it will be found that the solid metals will float upon the liquid.

The property which metals possess of reflecting light, is highly important in the arts, sciences, and in common life. The surfaces of many of the metals, when they are smooth and polished, reflect almost all the light which falls upon them. White metals reflect more light than those which are coloured. The hardest metals are best fitted for reflectors, because they assume the finest polish. It has been thought that this property depended upon the density of these substances. This idea, however, seems incorrect, since sodium and potassium, which are less dense than water, appear to possess the power of reflecting light equal to many other metals. It is the great quantity of light which they reflect to which they owe their lustre. The great facility with which metallic bodies conduct heat is of incalculable utility in the arts, and in the economy of human life. The boiling of most fluids would be almost impracticable in any other vessels than those of metal.

This property has been applied to great advantage in the process of drying various articles. Large tubes of metal, being filled with steam, are kept constantly at nearly 212° . The goods to be dried are wrapped round the outside of the tube.

The metal gives up its heat with such facility, as to dry the substances upon it in a very little time.

Metals are the best conductors of electricity, and hence are highly useful in electrical science, as well as in preserving the lesser conducting substances from the effects of lightning.

The greater number of the metals are acted upon by the air, especially when aided by heat. Metals were thought by the ancients to be compounds of an earth combined with phlogiston. When these bodies were acted upon by the air, they supposed that the phlogiston was separated, leaving behind a calx, or earth. The ancients did not weigh their products, or else they would have found, that although this imaginary substance phlogiston had escaped, yet the residuum was heavier than the original metal. By the greater accuracy

racy of modern experimenters, it has been found that the metal is the simple body, and that, by combining with the oxygen of the atmosphere, the metal is converted into a substance of an earthy appearance, which, in modern chemistry, is called an oxyd of the metal.

The bodies formed by the combination of metals with oxygen, exhibit, as well as the metal, an ample field of utility to man. These bodies, in various forms, are valuable auxiliaries in the healing art. Some of them constitute rich pigments of the utmost importance to the arts. Others are not less valuable to the dyer and the bleacher. Several metallic oxyds are used to great advantage for polishing marble, glass, and metals.

METALS for Specula. See SPECULUM.

METALS, Colours from. As metals have a strong texture in their metalline form, so they preserve their natural colours durable, unless corroded or dissolved by particular menstrua, after which their solutions strike particular durable colours, or afford the strongest stains.

Iron dissolved in stale small beer gives the beautiful yellow and different shades of buff colour, used in printing linens and cottons, &c. When sublimed with sal ammoniac it also affords a yellow; and the common iron-moulds made by ink are owing to the iron dissolved in the copperas of which ink is made.

Copper melted with zinc appears of a gold colour; dissolved in aquafortis, it affords a beautiful green; and in any alkali a beautiful blue. And these solutions may be reduced to dry colours by crystallization or evaporation; and the same metal, precipitated out of aquafortis with common salts, gives the turquoise colour to white glass. Tin, a white or colourless metal, affords a light blue colour, when fluxed with antimony and nitre. The same metal is necessary in striking the scarlet dye with aquafortis and cochineal; and its calx, by strong infusion, turns to a glass of an opal colour.

Lead, corroded by the fumes of vinegar, gives the fine white cerufs; burnt in a strong naked fire, it becomes the strong red-lead, or minium; and melted into a glass with sand, is of the hyacinth colour. Shaw's Lectures, p. 171.

Silver being dissolved in aquafortis, if chalk be put to the solution, turns of a beautiful purple or amethyst colour; and its own solution, though pale as water, durably stains the nails, skin, or hair, brown or black.

Quicksilver, mixed with brimstone, makes a black mass, and this, by sublimation, affords the beautiful red pigment called cinnabar, or vermilion; and the solution of quicksilver being precipitated with common salt, yields a snow-white powder, which also turns black by being mixed with sulphur.

Gold, dissolved in aqua regia, affords a fine yellow liquor, which stains animal substances beautifully purple; and if the solution be sufficiently weakened with water, and mixed with a solution of tin, a fine red or purple powder may be procured, very useful for staining of glass and pastes to a beautiful red.

It appears, from the experiments of sir Isaac Newton, relating to the changes of colour that take place in pellucid colourless substances, that the less refrangible colours are exhibited by the greater thickness of air, water, and glass; and that as the thickness of those substances is diminished, they reflect the more refrangible colours. Hence he infers, that nothing more is requisite for producing all the colours of natural bodies, than the several sizes and densities of their particles. Accordingly he attributes the colours of permanently coloured bodies to the same cause by which they were produced in colourless substances, viz. to the

various thicknesses of their component particles. But no experiments were made on permanently coloured bodies, in order to establish the truth of sir Isaac Newton's opinion, till the ingenious Mr. Delaval directed his attention to this subject. From observing the circumstances above recited, and more largely illustrated under the article COLOURS, it appeared to him, that, if permanently coloured bodies are subject to the same laws as transparent colourless substances are, all such permanently coloured bodies, whenever the size of their particles is diminished, should undergo a change of colour, by ascending from the less refrangible to the more refrangible colours; and that such bodies, when the size of their particles is augmented, should undergo a contrary change, their colour in this case descending from the more refrangible to the less refrangible colours. In order to confirm this conclusion, he made a great variety of experiments with vegetable, animal, and mineral subjects, whereby the size of their particles, upon which their colours depend, might be diminished or increased. The methods which he used, in order to diminish the size of the particles of those bodies which were the subject of inquiry, were by dissolving, attenuating, &c. by means of chemical solvents, heat, putrefaction, dilution, &c. The contrary effects were brought about by such means as are known to condense, incrassate, or unite the particles of bodies into larger masses, as by coagulation, precipitation, evaporation, by diminishing the force of the solvents, &c. The metals afforded him numerous instances in confirmation of the doctrine above explained; for almost every operation, to which they are subject, exhibits a change of colour corresponding to this doctrine. This is particularly the case with regard to the imperfect metals; for every change of their texture is accompanied by a correspondent change of colour. We can only enumerate some of the principal results which Mr. Delaval obtained from a great number of well-conducted experiments. Thus, the green vitriol of iron is changed, in proportion as it is deprived of its solvent part, by exposing it to a strong heat, &c. to yellow, orange, red, and purple; and by a contrary process, viz. by a farther attenuation, by means of the phlogisticated lixivium, in the process of Prussian blue, &c. the colour of the iron ascends from green to blue; so that all the primary colours are produced from the same metal, in proportion as its particles are attenuated or incrassated. It appears, likewise, that when iron is divided into very small parts by means of a large quantity of glass, and by a violent heat, its colour is blue; but in proportion as it is less divided, by the mixture of a smaller quantity of glass, or the application of less heat, its colours are green, yellow, and red. From iron dissolved in its several menstrua, colours are produced in proportion as the solvent power of those menstrua is greater or less. Thus, iron dissolved in its strongest acid solvent, the vitriolic acid, gives green; in its weaker acid solvents, the marine and nitrous acids, yellow and orange; and in its weakest acid solvents, the vegetable acids, red. The colours of the calces of iron precipitated from its solution in the vitriolic and nitrous acid, descend from green to yellow, and from yellow to red; whereas the changes of colour arising from the solution of these calces, proceed in a contrary order, and ascend. Mineral substances are also frequently impregnated with iron, and their colours correspond with the state of the iron contained in them.

In the same manner the colours of the solution of mercury in the nitrous acid vary, in proportion as the solvent is extricated from it, from yellow to orange, and then to red. Thus also, those substances which have the greatest affinity with the acid of the corrosive sublimate produced

by the solution of mercury in the marine acid, disengage from its solution a red precipitate; and those, whose affinity with it is less, produce a yellow one. But these colours are liable to some variation, according to the greater or less quantity of acid in the solution. Mercury dissolved in the vitriolic and in the vegetable acids, exhibits, in proportion as its solvent is taken from it, the same colours which, under similar circumstances, are afforded by that metal dissolved in the other acids. All these mercurial preparations become red, when they are deprived of the principal part of their menstruum; and mercury calcined by heat, without the addition of any acid, acquires the same colour. Its colour, however, is subject to variation, from the action of its solvents; and thus the phosphoric acid changes the red to yellow and white. The same law obtains in the changes of colour to which the mineral manganese is subject; for Mr. Delaval found, that by means of the different degrees of power in the several solvents, these colours were produced in their regular prismatic order, *viz.* yellow, green, blue, purple, and red. The various phenomena of the sympathetic ink of M. Hellot conform to the same law, and are urged by Mr. Delaval as arguments to establish it. Heat and cold, he observes, are not necessary agents in the production or suppression of the colour. But it appears, that the alterations are effected by the moisture of the air, attracted by the saline matter when cold, and expelled from it when heated. When this ink is exposed to a moderate heat, in a white China cup, and when the greater part of the water is evaporated, the saline matter becomes green. This colour arises from a superfluous quantity of the marine acid, which soon flies off, and leaves the remaining part blue, slightly inclining to green. It also forms a hard dry mass, which, in a few minutes after its removal from the fire, grows moist, and assumes a light red colour. These alterations may be often renewed, by alternately heating and cooling the coloured matter; which does not again become green, after the superfluous marine acid is once evaporated. But a drop of spirit of salt, added to the red or blue mass, immediately renders it green. When preparations of cobalt are acted upon merely by heat, the order of the changes of colour effected in them, is such as, in other instances, constantly arises from that means of attenuation. Thus, when the yellow solution of this mineral, in the marine acid, is heated, it assumes a green colour, passing from a less to a more refrangible colour. When this solution is cooled, the yellow is restored.

Mr. Delaval observes, that as the inflammable matter, in the entire metals, acts strongly on the rays of light, it is necessary to calcine or to divide them into extremely minute particles, in order to examine separately the action of the calx, or fixed matter, on the rays of light. In order, therefore, to examine all the metals in the like circumstances, by reducing them into the smallest particles, and depriving them of their phlogiston as much as possible, he exposed each of them, united with a proper quantity of the purest glass, without any additional ingredient, to the greatest degree of fire which they are capable of bearing, without having all colour whatever destroyed. In this state it appears, from a variety of experiments and facts, that they actually do, without any exception, exhibit colour in the order of their densities as follow: gold, red; lead, orange; silver, yellow; copper, green; and iron, blue. He has also shewn that the other preparations of the metals, *viz.* their solutions, precipitates, crystals, &c. do for the most part exhibit the same colour, in the order of their densities, though not so invariably as their glasses; some small variation of colour happening in the more imperfect metals, pro-

bably from a change of density in their different preparations. Thus, gold acquires a red colour, by a minute division of its particles, without any addition. In the process of calcining lead in the furnace, the first of the primary colours which it acquires is yellow; the calx passing from that colour through orange into red. This variety of colours proceeds from the imperfection of the metal; which, probably, during its calcination (as our author supposed), receives a small portion of phlogiston, as well as air; for the effect of such an union must probably be a change of colour from orange to red: as Sir Isaac Newton has shewn, that bodies reflect more strongly in proportion as they possess more phlogiston; and that the less refrangible colours require a greater power to reflect them. The preparations of silver are yellow; the two most imperfect metals, copper and iron, being very easily acted upon by almost all menstrua, the colours of their solutions, &c. *viz.* green and blue, are apt to change into each other's order; the copper in some solvents becoming blue, and the iron green, and in other solvents *vice versa*; which probably depends on the increase or diminution of their densities. The preparations, &c. of mercury have been already examined. The specific gravity of platina being nearly equal to that of gold, it is found, agreeably to the Newtonian doctrine, confirmed by Mr. Delaval, that the precipitates and crystals obtained from solutions of this metal are red; and that a solution of it in aqua regia to perfect saturation is of a dark red, though, when diluted, yellow. Delaval's Experimental Inquiry into the Cause of the Changes of Colours in opaque and coloured Bodies, &c. 1777, passim. Phil. Transf. vol. lv. art. 3, p. 10, &c.

METALS, *Fluxes of.* See FLUX.

METALS, *Granulation of.* See GRANULATION.

METALS in the *Materia Medica*, furnish medicines of considerable importance and utility. Although the operation of the pure metals on the animal system is merely mechanical, yet when they undergo oxydation, or are changed by acids into the state of salts, they acquire a high degree of activity, and become effectual remedies in many disorders, when they are judiciously administered. Mercury and tin have, indeed, been employed in their metallic state. For what purposes and with what effect they have been so used, we state under the articles MERCURY and TIN. But metals are more generally and with greater efficacy previously combined with oxygen, acids, sulphur, &c. This is the case with respect to antimony, arsenic, bismuth, copper, iron, lead, mercury, silver, and zinc. This combination, for medicinal purposes, is effected either by the action of atmospheric air, with an increased degree of temperature; or by desagrations with nitrate of potash; or by the action of water; or by solution in an acid, the acid being subsequently abstracted by an alkali, or by some substance for which it has a greater affinity than it has for the oxyd of the metal. When oxygen is united with a metallic base, or the combination denominated oxydation takes place, in whatever mode it is effected, and oxyds of metals are thus obtained, they are found to lose their lustre, tenacity, inflammability, and other metallic properties, and they are changed into earth-like substances, the weight of which is greater than that of the portion of metal that has been employed. The activity of the oxyds of metals on the animal system depends, with a few exceptions, on the quantity of oxygen with which they are combined. Metals, in consequence of oxydation, become capable of uniting with acids, and forming soluble salts. The "metallic salts," therefore, are oxyds combined with acids, whether the oxyd previously prepared, be dissolved in an acid, or the salt be the product of the direct solution of a metal in an acid. In the latter case, the metal

metal first gains oxygen, either from a part of the acid itself, or from the water, or the air, which it decomposes; and the oxyd, thus formed, is then dissolved by the remainder of the acid. "The properties of the metallic salts are much varied by the previous degree of oxydizement of the metals; and this is a point, the fixing of which in pharmaceutical operations is of the first practical importance; for if in all the indefinite degrees of oxydizement the metallic oxyds combine with acids; the resulting salts must vary in as many shades as exist between the maximum and minimum of oxydizement. In the preparation of the metallic salts, therefore, the same strict attention is requisite in following one established and approved process."—"Many of the metallic salts are altered by exposure to the atmosphere; some effloresce and attract oxygen; some are altered in their properties by moisture; and others are reduced by the action of light; hence, all of them ought to be kept in well-stopped glass bottles; and perhaps these always should be either made of green glass, or otherwise rendered opaque. In compositions which require these salts to be dissolved in water, *distilled or filtered rain-water* should always be employed; and much attention is requisite to avoid combining them with incompatible substances, which may either chemically decompose them, or alter their medicinal properties." (Todd's London Dispensatory, 8vo. 1811.) For the principal metallic preparations used in medicine, see the several metals, *viz.* ANTIMONY, ARSENIC, &c. and also the names of these preparations as they occur in the order of the alphabet. But for a fuller account of them, with the instructions for combining them given in the London, Edinburgh, and Dublin dispensaries, we refer to the comprehensive and useful publication already cited. Part iii.

METAL, *Prince's*. See COPPER, GOLD-coloured Metal, and TOBAC.

This metal derives its name from prince Rupert, whom some supposed to have been the inventor of it, in 1680. But the greatest perfection this metal was ever brought to, was by two Frenchmen, M. La Croix, and M. Le Blanc. Their methods of making the composition, though both beautiful, were very different. M. Le Blanc's was the brightest, and of the most elegant and lively colour; but M. La Croix's was greatly superior to that in ductility and softness, so that it was very easily malleable.

M. La Croix invented a sort of varnish or lacquer for his metal, which added a somewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that while it remained on the metal, it preserved it from rust or decay. This is a very material point in regard to a metal of which copper is the basis, since that is, of all metals, most subject to be injured by the air, or by the contact of liquids of almost any kind. M. Le Blanc's metal is of a deeper, yet equally lively colour, and remarkably bright; and is of such a temper as to be admirably fitted for working. The whole history of these metals is, certainly, that they are composed of zinc and copper in different proportions the one to the other; but it is not easy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microscope, however, shews a manifest difference, which may lead somewhat towards it; for the metal of La Croix is seen to be composed merely of a number of irregular stræ, while the other is discovered to consist of always two regular beds of them, which meet in the centre of the piece; hence it is that this is always brittle, and will not well polish. The fabric of these metals was long kept a secret; but it was always to be discovered by melting it in

a crucible in a strong fire, when it always sent up plain flowers of zinc, and the remaining metal appeared no other than copper altered by calamine; that is, common brass. Mem. Acad. Par. 1732.

METAL, *Bell*, is a composition of copper and tin melted together. See COPPER.

METALS, *Bluing of*. See BLUING of Iron.

METALS, *Painting on*. See PAINTING.

METALS, *Rust of*. See RUST.

METALS, *Line of*. On Gunter's sector are sometimes two lines thus called, and noted with the characters of the seven metals, ☉, ♃, ♄, ♀, ♂, and ♆; their use is, to give the proportions between the several metals as to their magnitudes and weights. See SECTOR.

METALS, *Tincture of*. See TINCTURE.

METAL, *Over*, in Gunnery. When the mouth of a piece of ordnance, in disparting it, lies higher than the breech, it is then said to be "laid over metal."

METAL, *Under*, is when the mouth of a piece of ordnance lies lower than the breech.

METAL, *Right with*. When a piece of ordnance lies truly level, point-blank, or right with the breech, it is said to be "right with its metal."

METALS, *Superficies of*, denotes the surface or outside of a gun.

METAL, in Heraldry. There are two metals used in heraldry, by way of colours, *viz.* gold and silver; in blazon called *or* and *argent*. See COLOUR.

In the common painting of arms, these metals are represented by white and yellow, which are the natural colours of those metals.

In engraving, gold is expressed by dotting the coat, &c. all over; and silver by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour on colour; so that if the field be of one of the metals, the bearing must be of some colour, and *vice versa*; otherwise the arms are false: though this rule admits of some exceptions.

METALEPSIS, in Rhetoric, is a figure in which two or more tropes, and those of a different kind, are contained under one word; so that several gradations, or intervening senses, come between the word that is expressed, and the thing designed by it. Thus, when Sylla says of Julius Cæsar, *In one Cæsar there are many Mariuses*. Suet. in Vit. c. 1. This is a metalepsis. So when Virgil describing that part of the African coast, where Æneas arrived with his ships, says, *A dark wood hung over it*, Æn. lib. i. ver. 665; and in the words of Dido, Æn. lib. iv. ver. 664, the same figure is used. Thus, the Roman phrase of "Fuit," or "Vixit," expresses that a person was dead. "Fuit Ilium et ingens gloria Dardanidum" signifies, by metalepsis, that the glory of Troy is now no more.

METALLIC, or METALLINE, an adjective applied to any thing that bears a relation to metals.

METALLIC Germination, *Mines, Vegetation, and Vitriols*. See the respective substantives.

METALLIC Solutions, in Agriculture, such fluids as contain some sort of metal suspended in them in the state of solution or diffusion. These sorts of liquids were formerly supposed to have a highly noxious or poisonous effect when applied to plants as manures and taken up as food; but some late experiments made by Dr. George Pearson seem to lead to a different conclusion.

This is further confirmed by the remarks of professor Barton of America, who, in a letter to the doctor, states his having been several years engaged in an extensive series of experiments

riments relative to the effects of various stimulant substances, such as camphor, &c. upon vegetables, as well as on the absorption of certain powerful mineral substances into the organical system of vegetables. "In numerous instances, he has subjected the stems and leaves of plants, young and old, large and small, to the influence of the sulphates of iron and copper, and has found that both of these metallic salts are very greedily absorbed by vegetables, inasmuch that he has detected the presence of iron in the vessels of a branch of a mulberry, at the height of five or six feet above the place of immersion in a solution of the sulphate of this metal."

He intends to communicate a full account of his experiments to the public in two memoirs. But suggests, in the mean while, that the sulphate of iron applied to vegetables in the manner he has mentioned, "is only a poison like almost every thing else, from the over dose," as mentioned by the doctor. "In several of his experiments, the branches of vegetables that were placed in vessels containing solutions of the sulphate of iron and copper, lived longer and exhibited more signs of vigour than similar branches that were placed in equal quantities of simple water. It is true, that in many other experiments these metallic salts proved fatal to his plants, but this was when he employed too large a dose. In like manner he has found several years ago that camphor, by greatly stimulating, often kills vegetables; and yet when properly dosed this is a very wholesome stimulant to plants; he had also found that large doses of nitre (which is unquestionably a powerful stimulant both with respect to animals and vegetables) produce an appearance like genuine gangrene in the leaves of vegetables; and yet it is certain that nitre, when it is judiciously dosed, may be made to greatly assist the healthy vegetation of plants.

METALLOID, in *Chemistry*, a name given to those metals which have been obtained from the fixed alkalis, and some of the earths. These bodies are so completely metallic, that they may, with the utmost propriety, be classed with the other metals, and such a distinction will therefore be unnecessary.

The metalloid said to be obtained from ammonia appears to have been given up by chemists. It was said to be produced by applying a globule of mercury at the negative end of a Galvanic battery, in contact with an ammoniacal salt. The mercury became of four or five times its original volume, and in the form of a soft solid. When this substance is exposed to the air, or thrown into water, the mercury assumes its original volume, and ammonia and hydrogen are exhaled. These appearances led Mr. (sir H.) Davy to conceive that the ammonia, like the other alkalis, contained a metallic base; and that during the Galvanic energy, this metallic base had been separated, and had alloyed itself with the mercury. From the great increase of volume, without a perceptible increase of weight, the specific gravity of this supposed base was deemed inconceivably small. Mr. Davy was more warranted in drawing this conclusion from some experiments, in which it appeared that ammonia contained oxygen. This fact, however, has been disproved by the experiments of Dr. Henry, and by those of Berthollet, jun. namely, that ammonia contains oxygen. The light amalgam produced in electrifying an ammoniacal salt with mercury, has been examined by Gay Lussac and Thenard, in their work entitled "*Recherches Physico-Chimiques*," tom. i. p. 52. The chemists consider the amalgam merely a compound of mercury, with hydrogen and ammonia. The phenomena which attend this process are in favour of such an opinion. Oxygen is given out in abundance at the positive wire, while a very little gas is observed at the negative wire, except when the mer-

cury is removed. The writer of this article, seven years ago, discovered that when a wire coated with mercury is on the negative side in pure water, a much less quantity of hydrogen is evolved than what might be expected from the quantity of oxygen at the other wire; and if the battery be not of tolerable strength, no hydrogen at all appears.

In the decomposition of the amalgam, they found that the ammonia was to the hydrogen as 28 to 23.

On the ground that mercury has the property of combining with hydrogen, and from the great levity of the bases of potash and soda, Mr. Murray is of opinion that these substances are compounds of hydrogen with some metallic base, with which we are not as yet acquainted. In addition to this, he observes, that in the decomposition of potash and soda, no hydrogen is given out at the negative wire, although water is present; he therefore concludes that the hydrogen must combine with the metal. It must be remembered, however, that during the decomposition of any metallic oxyd by Galvanism, no hydrogen is given out, although water is present.

The metalloid obtained from barytes has not been noticed under that article, because these discoveries have all been made since that part of this work was published.

Soon after the discovery of potassium and sodium, Mr. Davy subjected barytes to the same decomposing power. He first exposed the moistened earth in contact with mercury to the Galvanic battery. He found that the mercury lost much of its fluidity by being alloyed with a metal. This amalgam, on being exposed to the air, became covered with a crust of barytes. When the same was thrown into water, hydrogen gas was evolved, and barytes formed. This proved the presence of a metallic substance, capable of decomposing water, which was the base of barytes. Mr. Davy next mixed the moistened earth with one-third its weight of red oxyd of mercury, and placed them upon a plate of platina in a small cavity, where was lodged a globule of mercury. These materials being covered with a thin film of naphtha, the plate was connected with the positive side of the battery, the mercury with the negative, the two metals being separated by the earth and the red oxyd of mercury. By the influence of a powerful battery an amalgam was soon formed. This amalgam was then introduced into a bent glass tube, and the mercury distilled off. Although the heat was raised to redness, it was still rather uncertain whether the base was perfectly pure.

Mr. Davy has given the name of barium to this metallic substance. It is a white metal of the colour of silver, different from potassium. It is solid at the common temperature, but becomes liquid at a heat a little short of redness. It is not volatile at a red heat. When exposed to the air it soon absorbs oxygen, becomes tarnished, and ultimately falls down in the state of white powder, having returned to its original state by the absorption of oxygen. When this metal is thrown into water, the latter is decomposed with great rapidity, hydrogen is evolved, and barytes formed. The specific gravity of this metal is greater than that of potassium or sodium, since it sinks in water, and even in sulphuric acid.

Mr. Davy thinks its specific gravity four or five times that of water. Barium appears to be a malleable metal, since it is capable of being flattened at the common temperature.

The proportion of oxygen with which it combines has not been ascertained. If barytes be the first oxyd of barium, and the weight of atom of barytes be 68, the proportion

will be $\frac{68}{7} = \frac{100}{10.3}$, or 10 per cent. of oxygen, nearly.

For

For the rest of the metalloids, see the respective earths and alkalis.

METALLORUM *Crocus, Mater, and Sulphur.* See the respective articles.

METALLURGY, in a general sense, signifies the art of working metals under all circumstances. In its more limited meaning, it is confined to the art of separating metals from their ores. Since, however, these processes are given at full length under the heads of the metals respectively, it will be unnecessary to say more under this article. See **ASSAYING** and **SMEETING**.

METAMORPHISTS, in *Ecclesiastical History*, a sect of heretics in the sixteenth century, whose distinguishing tenet was, that the body of Jesus Christ was, upon his ascension to heaven, changed and metamorphosed into God.

METAMORPHOSIS, *Μεταμορφωσις*, formed of *μετα*, *change*, or removal from one place or state to another, and *μορφη*, *form*, or *figure*, *transformation*, the change of a person or thing into another form.

The ancients held two kinds of metamorphoses; the one real, the other apparent. The metamorphosis of Jupiter into a bull, and of Minerva into an old woman, were only apparent. That of Lycaon into a wolf, and of Arachne into a spider, and the like, they say, were of the real kind.

Most of the ancient metamorphoses include some allegorical meaning, relating either to physics or morality. Ovid's *Metamorphoses* is a collection of histories of such transformations, poetically related. Some authors are of opinion that a great part of the ancient philosophy is couched under them; and Dr. Hooke has made an attempt to unriddle and lay open the hidden meanings of several of them.

METAPARA, in *Geography*, a town of the island of Borneo; 70 miles S.E. of Nagara.

METAPEDIUM, in *Natural History*, a name given by some authors to a kind of stone, called by others *metatarsum*, and supposed to imitate a human foot. It is only a lusus nature in the formation of a common pebble.

METAPHOR, **METAPHORA**, *μεταφορα*, *translation*, or *displacing*, of *μετα*, *trans*, and *φορα*, *I bear*, or *carry*, in *Rhetoric*, a figure of speech, or a species of trope, whereby a word is transferred from its proper signification to another, different from it, by reason of some similitude between them; or whereby the proper denomination of one thing is applied to another: which other thing is more elegantly explained by this tralitious or foreign name, than by that which naturally belongs to it. As, when we say, the light of the understanding; to burn with zeal; to float between hope and despair, &c.

The metaphor is the most common of all the figures of speech; and is that usually meant, when we say a thing is spoken figuratively.

The metaphor is a short simile; or, as Cicero calls it, a similitude reduced to a single word; an image being thereby called from its proper subject to give the resemblance of another. An allegory is no more than a continued metaphor.

Quintilian says, that a metaphor is a short similitude, and differs from it only in this, that the former is compared to the thing we design to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion. But though metaphors are usually taken from a similitude between two things; yet sometimes they are founded in the similitude which two things bear to each other, in some particular respect, by means of which what properly belongs to one of them is transferred to the other: the former of which are

called *simple metaphors*, and the latter *analogous*. Hence the rudder of a ship may be called its reins; for what the reins are to a horse, that the rudder is to a ship, in guiding and directing it. Again, some metaphors are reciprocal in which the similitude holds either way. Thus to steer and govern are used reciprocally, both of a ship and a state; the proper expressions being to steer a ship, and govern a state, and the contrary metaphorical. From this account, therefore, of the nature of a metaphor, it may be defined, the application of a word, by way of similitude, to some other thing than what it properly signifies.

Quintilian distinguishes metaphors into four kinds: the first, when a word is transferred from one animal to another; as when Livy says, that Cato used to *bark* at Scipio; or when our Saviour calls Herod *fox*. To this class belong those forms of expression that occur in the sacred writings, by which the properties and affections of men are ascribed to the deity; as when God is said to hear, see, be angry, and repent, &c. The second, when the word is transferred from one inanimate to another; as *bridle* for *laws*; *floods* of fire, and *clouds* of smoke, denoting large quantities. The third, when inanimates are applied to animates; as the *flower* of youth. Thus, also, Homer calls Ajax the *bulwark* of the Greeks, and Cicero brands ill men with the character of being the *pest* of the state. And the last, when animates are applied to inanimates; as the river *disdain* its bounds. Thus Cicero speaking of Clodius says, the very altars, when they *saw* that monster fall, seemed to *move* themselves, and *assert* their right against him. Virgil, speaking of the impetuous force and rapidity of the river Araxes, says, it *disdain* a bridge. And it is a very usual epithet, which Homer gives to words, to call them *πτερωτα*, or *winged*, to intimate the swiftness of speech. And metaphors of this kind, which give life and action to inanimate things, are esteemed the finest and strongest.

As the metaphor is intended to set things before the eyes, it becomes so much the more perfect, as it shews them the more vividly, by representing them in motion and action. Cicero, speaking of a metaphor, calls it the most florid manner of expression, and brightest ornament of language, that consists in single words. A metaphor should have nothing in it either coarse or shocking, or that may raise it above the simplicity of nature, so as to be forced and harsh; nor should it appear a metaphor to any, but those who view it very closely. A metaphor should never be carried too far; for, in that case, it degenerates into puerility. Metaphors should always be followed in the same kind; they become unnatural, when different images are introduced. In all metaphorical dictions, there should be a kind of suitability to each other; different ideas are always absurd; as in this instance, the church was besieged with a deluge of troubles, where the two images, *siege* and *deluge*, have no relation.

The beauty of a metaphor is very strikingly exhibited in the following passages, extracted from lord Bolingbroke's Remarks on the History of England. Speaking of the behaviour of Charles I. to his last parliament, he says, "About a month after their meeting, he dissolved them; and as soon as he had dissolved them, he repented; but he repented too late of his rashness. Well might he repent; for the vessel was now full, and this last drop made the waters of bitterness flow."—"Here," he adds, "we draw the curtain, and put an end to our remarks." Nothing, as Dr. Blair observes, could be more happily thrown off. The metaphor, we see, is continued through several expressions. The *vessel* is put for the state or temper of the nation, already *full*, that is, provoked to the highest by former oppressions and wrongs;

this

this *last drop* stands for the provocation recently received by the abrupt dissolution of the parliament; and the *overflowing of the waters of bitterness*, beautifully expresses all the effects of resentment let loose by an exasperated people.

There is nothing young writers are more faulty in, than the indiscreet use of metaphors: those who affect the marvellous, are eternally on the metaphorical strain; nor know any bounds or restraint. They, who understand them best, use them with the greatest reserve. Mr. Addison proposes it as a rule for writers, to imagine their metaphors actually painted before them, and to view and examine the justness of their application and assemblage under those circumstances; throwing every thing out of the writing, but what might be retained in the picture. Card. Perron prescribes this general rule for metaphors, that they must always descend from the genus to the species; and never go backwards from the species to the genus: thus, we say figuratively, the *bonds of society*, and not the *human cords*, which tie us together; *bond* being a genus, and *cord* a species.

We shall close this article with a brief recital of the rules laid down by Dr. Blair as proper to be observed in the conduct of metaphors, which will also apply to tropes of every kind. Metaphors should be suited to the nature of the subject of which we treat. They should be neither too many, nor too gay, nor too elevated for it. The excessive or unseasonable employment of metaphors is mere soppery in writing; it gives a boyish air to composition, and, instead of raising a subject, in fact, diminishes its dignity, which should arise from sentiment and thought, not from ornament. This observation, as we have already suggested, demands the particular notice of young writers. A second rule respects the choice of objects, from which metaphors, and also other figures, are to be drawn. Accordingly, we should studiously beware of even using such allusions as raise in the mind disagreeable, mean, vulgar, or dirty ideas. Some approved authors have been incautiously betrayed into this error. Again, care should be taken that the resemblance, which is the foundation of the metaphor, be clear and perspicuous, not far-fetched, nor difficult of discovery. The transgression of this rule produces harsh or forced metaphors, which are always displeasing, because they puzzle the reader, and, instead of illustrating the thought, render it perplexed and intricate. Cowley is often chargeable with this fault. Farther, it must be carefully attended to, in the conduct of metaphors, never to jumble metaphorical and plain language together; never to construct a period so that part of it must be understood metaphorically, part literally, which always produces a most disagreeable confusion. Moreover, two different metaphors should never be made to meet on one object. This is what is called mixed metaphor, and is one of the grossest abuses of this figure; such is Shakspeare's expression, "to take arms against a sea of troubles." This makes a most unnatural medley, and confounds the imagination entirely. If we have occasion to doubt whether metaphors be or be not of the mixed kind, we should try to form a picture upon them, and consider how the parts would agree, and what sort of figure the whole would present, when delineated with a pencil. As metaphors ought never to be mixed, we should also avoid crowding them together on the same object. Finally, metaphors should not be too far pursued. This is called straining a metaphor, and drawing it out into an allegory; by which we shall tire the reader, and render our own discourse obscure. Cowley, lord Shaftsbury, and Dr. Young, transgress in this way. Blair's Lectures, vol. i.

METAPHRAST, METAPHRASTES, a translator, or

person who renders an author in another form, or another language, word for word.

A metaphrase, *μεταφρασις*, usually signifies something more than either a paraphrase, or a translation: according to Baillet, a metaphrast implies a translator, glossator, and interpolator, all at once.

METAPHYSICS, *METAPHYSICA*, *Transnaturalis*, a branch of science, about the nature and idea of which there is some difference among authors.

The word is formed from the preposition *μετα*, *trans*, beyond or above; and *φυσικη*, *nature*, or *φυσικη*, *natural*.

Some define metaphysics, that part of science which considers spirits and immaterial beings; which others choose to distinguish by the name of *pneumatics*, or *pneumatology*.

Others, keeping close to the etymology of the word, explain metaphysics by *trans-natural*, or *preter-natural*, or even *post-natural philosophy*: because it is subsequent in contemplation to the physical, though prior to it in the real order of beings.

Others, with more propriety, conceive metaphysics to be what some others call *ontology*, or *ontology*, *i. e.* the doctrine *de ente*, or of being, *quatenus* being.

In the same view, some philosophers call this science by the name *philosophia*, or *scientia generalis*, as being the foundation, or, as it were, the stem or root from whence all the other parts of philosophy arise, and wherein they all meet; its object being *being* in the abstract, or general, not restrained to this or that species of beings; not to spirit any more than body; so that the doctrines of metaphysics are applicable to all beings whatever.

Philosophers, again, are divided as to the notion of a science *de ente* in general. Some hold it real, precise, and solid enough to be demonstrated; but others judge it too obscure, faint, and confused, to be admitted into philosophy.

Being, abstracted from every sort of species of being, is certainly a very vague term, and does not seem to give scope enough for a science: we do not see how it can affect the mind as an object. Add, that the common metaphysics cannot demonstrate any part of its subject, but assume the whole: there are no principles or axioms, whereon to demonstrate metaphysics which contain the principles of all other sciences.

The first who wrote professedly on the subject of metaphysics is Aristotle. Indeed, he is the first who uses the word: *Μεταφυσικα* is the title of one of his books; but this some of his commentators will have to signify no more than *after the book of physics*. M. du Hamel, taking the preposition *μετα* in the sense of *post*, is even of opinion, that the word was coined by Aristotle's followers: and that it was unknown to Aristotle himself.

Aristotle's metaphysics seem to have been intended for a kind of natural theology. The metaphysics of Aristotle have been lately illustrated by the ingenious Mr. Harris, in his treatise, intitled "Philosophical Arrangements," 8vo. 1775.

Metaphysics, says this ingenious author, are properly conversant about primary and internal causes; and the study of them is metaphysical, because, though prior in itself, it is subsequent in man's contemplation, whose road of science is naturally upward, that is, from effect to cause, from sensible to intelligible.

Accordingly metaphysics have been, not improperly, defined "the science of the principles and causes of all things existing." Aristotle calls this science "the first philosophy," as it is not only superior, but prior in the order of nature, to the whole circle of the other arts and sciences. What is first in nature, however, is not first to man. Nature begins with causes which produce effects; whereas man ascends from

effects to causes. Hence, as "Physica" was the name given by Aristotle to the philosophy of body, some of his interpreters called that of mind "Metaphysics," thus intimating not only that its subject is more sublime and difficult, but that the study of it would be more properly and successfully undertaken "after that of physics." The followers of Aristotle were led to adopt this appellation by their master himself, who to the books in which he pretends to elevate the mind above things corporeal to the contemplation of God and things spiritual, prefixed the Greek words *μετα τα φυσικα*. However significant the name, in reference to the subjects which this science recommends, it has, from misapplication and abuse, as well as from the decline and extinction of the Peripatetic philosophy, sunk into disrepute; and although Malebranche and Mr. Locke have written much more clearly and consistently of metaphysics than any of the ancients; yet more modern writers have comprehended these subjects, which were formerly referred to metaphysics, under the appellation of *Philosophy of the Human Mind*. Under this article we propose to give a general account of it, and to mention the particular subjects which it includes.

METAPHYSICAL, something belonging to metaphysics.

The word is also used to denote something subtle, abstract, and refined. In which sense we say, such a reasoning, such a proof is too metaphysical, &c.

A metaphysical case is an imaginary or chimerical case, which can scarcely ever happen, or not without much difficulty; and which ought not to be laid down as a rule for common occasions.

METAPHYSICAL Certitude, Distinction, Evidence, Form, Perfection, Universality. See the respective substantives.

METAPHYSICAL Sect, in the *History of Learning*, is one of the two great sects into which the philosophical world was divided about the beginning of the 17th century. This sect followed the system of Des Cartes, and considered truth as attainable by abstract reasoning; and from a small number of abstract truths, deduced a long series of propositions, in order to arrive at a precise and accurate knowledge of God and nature, of body and spirit. The metaphysical philosophers, supposing that many things are known by man with the utmost certainty, discovered an undue propensity to form their opinions and doctrines into a regular system. The other sect was the *Mathematical*. (See **CARTESIANS**.) A branch of the Eleatic sect was denominated *Metaphysical*, by way of contradistinction to the *Physical*. See **ELEATIC Sect**.

METAPLASM, **METAPLASMUS**, compounded of *μετα*, and *πλασσω*, *fungo*, in *Grammar*, a transmutation, or change, made in the word, by adding, retrenching, or altering a letter or syllable of it.

METAPLEXIS, in *Botany*, so called by Mr. R. Brown, from *μετα*, together, or between, and *πλεωω*, to plait, or connect, alluding to the alternation of small leaves with the membranous-tipped anthers, composing a sort of wreath in the centre of the flower. Brown in *Wern. Transf.* v. 1. 48—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apo-cynæ*, Juss. *Asclepiadæ*, Brown.

Ess. Ch. Corolla somewhat wheel-shaped. Crown of the stamens of five dwarf-hooded leaves, alternate with the membranous-tipped anthers. Masses of pollen tumid, pendulous, attached laterally. Stigma with an elongated undivided beak. Follicles . . .

A twining smooth shrub, found by sir George Staunton, bart., in the province of Peckelej, in China. The leaves are heart-shaped. Clusters on stalks, inserted between the

footstalks. Lamb of the corolla bearded. No specific name is mentioned.

METAPPOISIS, a word used by many physical writers to express a change of one distemper into another, whether it be by *diadoche*, or *diadexis*, as it is called; when the change is for the better, and the morbid matter removes from a more noble to an ignoble part: or by *metastasis*, when the change is for the worse, and the morbid matter removes from an ignoble to a more noble part.

METASTASIO L'ABATE PIETRO, in *Biography*, the bell lyric poet and writer of operas, or dramas, for music in Italy, during the last century, or perhaps during any age, or in any country. This exquisite poet, second son of Felice Trapassi of Assisi, and Francesca Galassi of Bologna, was born at Rome, January 6th, 1698, in the parish of Santi Lorenzo and Damaso, where he was baptized the 19th of the same month, by cardinal Ottoboni. His father, though descended from a family in Assisi, which had long enjoyed the privileges of free citizens, but which by a gradual decline, was reduced to poverty, not being able to subsist in the place of his birth, hired for a soldier in the regiment of Corsi, and soon after married Francesca Galassi, by whom he had many children besides the poet.

While he was in garrison, to the small pay of a soldier he added something towards the maintenance of his family, by becoming an amanuensis. And at length, having served the usual time, and by extreme industry and economy saved a little money, he entered into partnership with a shop-keeper at Rome, for the sale of goods which belong to what the Romans call *Parte bianca*, consisting of oil, flour, pastry, and other culinary materials.

And having been somewhat prosperous in this kind of merchandize, he placed his two eldest sons, Leopoldo and Pietro, at a grammar-school. The latter discovered an extraordinary quickness and disposition for literature, and a violent passion for poetry, with a power of making verses, extempore, on any given subject, before he was ten years old.

This faculty he was habituated to exercise, after school hours, at his father's shop, where great crowds used to assemble in the street of an evening to hear the young Trapassi sing *all' improvvisa*; who, besides the harmony of his numbers, was gifted with the melody of a fine voice. During one of these tuneful sittings, the learned civilian Gravina, having accidentally passed that way, was struck with the sweetness of the child's voice, and still more with his verses, which he soon found were extempore, and either upon persons who stood near him, or on playful subjects of their suggesting.

Gravina was so astonished and pleased at the precocity of the little bard's talents, that he stopt to carefs and converse with him, offering him money for his performance, which, however, the child modestly declined to accept. This so much increased the civilian's admiration, that he instantly conceived a wish to adopt him, for the pleasure of cultivating a soil which nature had rendered so fertile. that even the spontaneous flowers and fruits it produced were of a superior kind. Without hesitation he therefore applied to his parents, soliciting them to transfer to him the care of their son's education, promising to become not only his preceptor, but father.

As the child was still to remain at Rome, and no cruel preliminary was mentioned, by which his natural parents were prohibited from seeing him, and cherishing reciprocal affection, Felix was too wise, and zealous for the welfare of his son, to refuse the proffered patronage; and the next morning, Pietro was conducted by his father and mother to

the house of Gravina, and wholly consigned to his care and protection.

Our young bard was now, from the legitimate child of a shop-keeper, become the adopted son of a man of letters. And as his learned patron was partial to Greek literature, and wished to implant in the mind of the young Roman a respect and reverence for ancient lore, he translated his name into Greek; calling him *Metastasio*, instead of *Trapassi*; as *Μεταστας*, *Mutatio*, seemed at once to express his former name of *Trapassi*, and his new situation as an adopted child.

And having changed his name, he undertook the more difficult task of changing, or at least enlarging, his mental faculties; and at the same time that he was studying the learned languages, and imbuing his mind with the sciences, he wished to make him an orator rather than a poet, and determined that he should study the law as a profession; that and divinity being the only two roads by which a man of learning could arrive at honours and dignity in Rome. Poets, indeed, were rewarded with barren praise and acclamation, but wealth and affluence were strangers to their doors.

Yet while he was obliged to read the dry books of the law, and was seemingly occupied by other studies, he found time, by stealth, to read the great models of the art of poetry, for which his instinctive passion increased from the difficulty of gratifying it. At the name of Homer and Ariosto, his favourite poets, he was unable to contain himself; and Gravina discovering, in spite of his pupil's determination to conform implicitly to his will, that this exclusive passion for poetry was insuperable, at length permitted him to read those poets which he himself thought not only the best, but the only models of perfection. At the age of fourteen, during the early period of this indulgence, *Metastasio* produced his tragedy of "*Giustino*," conformable to the rigour of all the rules of the ancient Greek dramatic writers, with which his learned preceptor had supplied him.

We have his own opinion of this production, in a letter written to signor Calabigi, in which he says: "I should have wished that none of my early productions, which favour too much of adolescence, might have appeared in the Paris edition, particularly the tragedy of *Giustino*, written at fourteen years of age: when the authority of my illustrious master did not suffer me to move a step from the most religious imitation of the Greeks; and when my inexperience and want of discernment were unable to distinguish gold from lead, even in those mines themselves, of which he then began to display to me the treasures."

After producing this tragedy on the favourite model of his patron and preceptor, the learned civilian seems not only to have tolerated, but encouraged his pupil's adoration of the muses; and at eighteen carried him to Naples, expressly to afford him an opportunity of singing extempore with the most celebrated improvisatori of Italy at that time. *Metastasio*, in a letter to *Algarotti*, written in 1757, gives the following account of this poetical contention: "It is your wish to have specimens of the verses which I made extempore, during my childhood; but how can I possibly gratify this wish? I do not deny but that a natural talent for harmony and the muses was discovered in me, that was thought somewhat uncommon, and more early than usual, that is, at ten or eleven years old; that this phenomenon so dazzled my great master Gravina, that he was partial to it, and cherished me as a soil worthy of his cultivation: and that, so late as the year 1716, he exhibited me to speak verses, God knows how, for the benefit of *Georgio Loren-*

tino, upon all kinds of subjects; at which time I had for competitors the illustrious *Rolli*, *Vagnini*, and the cavalier *Perfetti*, men who were then arrived at full maturity, and veterans in Pindaric battles."

At twenty years of age he had the misfortune to lose his learned preceptor and patron, Gravina, who died in 1718, aged fifty-four. It has been doubted whether this event, which his heart inclined him to regard as the greatest calamity, was not a fortunate circumstance for his fame. *Metastasio*, whose writings evince him to have been all tenderness, gratitude, and disinterested sensibility, bewailed this misfortune with the deepest affliction; and in the elegy, called "*La Strada della Gloria*," written on this occasion, and read at a full assembly of the members of the arcadian academy founded by Gravina, he gave a public testimony of his sorrow and gratitude, expressive of those noble sentiments, which he cherished and practised to the end of his life. Nor did the beneficent will of his master diminish his grief or dry his tears, though, when opened, it was found to have been made in 1717, and that he had appointed him his heir.

By this liberal act, he verified his promise to the parents of *Metastasio*, of treating him as his own child. The advantage to his talents and to the lovers of poetry, which is supposed to have been derived from this early loss of his learned tutor, was the opportunity it afforded his genius to free itself from the trammels of Grecian rules and servile imitation. But though in his dramas he has more pathos, poetry, nature, and facility, than we are now able to find in the ancient Greek tragedians, yet his early study of them certainly elevated his ideas and style, and taught him how to shun the vulgarity and absurdities with which the early popular dramatists of most countries abound. He may be said to write with classic elegance, though he had liberated himself from classic chains.

Gravina's bequest to *Metastasio* consisted of 15,000 Roman crowns, between 3 and 4000 pounds sterling in money, an excellent library, and a great quantity of rich furniture, with three small places of which he had put him in possession before his decease, and a little estate in the kingdom of Naples.

But our young poet, now become a free agent, and a despotic prince over no contemptible fortune, among all his acquirements had not the least idea of prudence and economy. His conversation and verses had too much excellence to want admirers; and his table was too well served to want guests. He now wholly quitted the dry study of the law, and entirely devoted himself and his fortune to the muses and his friends. There was no poetical assembly in which he did not read some new production: as our *Garrick*, in the early part of his life, was found wherever lovers of theatrical amusements were assembled. Stimulated by the applause which every piece universally received, *Metastasio* thought of nothing but how to have it renewed by another composition. The love of praise is an infirmity to which the best minds are perhaps the most subject. During this intoxication, not a thought seems to have been bestowed on his present finances or future fortune. If he reflected at all during these times of dissipation, it was on the number of his friends and admirers, and the certainty of patronage whenever he should want it. What his predecessor *Petrarca* has said of the temple of love, was still more applicable to that of fortune by *Metastasio*.

"Errori, sogni, ed immagini smorte
Eran d'intorno all' arco trionfale,

E false opinioni in fu le porte,
E lubrico sperar in per le scale."

"Errors and dreams and thoughts half form'd abound,
And crowd the baseless fabric all around;
While at the threshold false opinions stand,
And on the steps, vain hope, with magic wand."

His patron's legacy was soon dissipated, not in the support of vice, but munificence and good cheer; so that at the end of two years, finding himself wholly reduced to his two small Roman places, his Neapolitan possessions, and his library, he went to Naples with the firm resolution of seriously resuming the study of the law. Being arrived in that city, 1720, he placed himself under the guidance of an advocate of the name of Paglietti, earnestly entreating his assistance in the study of jurisprudence, and promising, on his own part, to second the instructions which he should receive with all possible diligence and docility. Paglietti was one of the most eminent lawyers, at that time, in the city of Naples; but so rigorous a disciplinarian, and so totally devoted to his profession, that he not only despised but absolutely hated every species of ornamental knowledge or literature. Poetry was therefore ranked by him among the most deadly sins of which an advocate could possibly be guilty.

It is natural, therefore, to suppose that Paglietti, devoid of all taste for the arts of elegance, which help to humanize and polish our savage nature, was rough, sour, and forbidding in his address and manners: he was all law, and of that severe and merciless sort, which knows not how to pardon the smallest imprudence or deviation from worldly wisdom.

Metastasio was not ignorant of his severity and invincible hatred for poetry; but instead of looking upon it as an evil, he was the more eager to place himself under his most rigid discipline, in order to prevent a relapse into poetry, which had hitherto been to him so unprofitable a study. The reception of Metastasio by this Lycurgus, and his first lecture, were perhaps rendered more austere and acrid by the fame of his poetical talents, with which not only Naples but all Italy was already filled; but Metastasio, hearing it with heroic patience, renewed his promise of unwearied application, and kept it so well during his first residence under the advocate's roof, that he began to entertain great hopes of his becoming an excellent lawyer, and treated him with as much sweetness as his bitter nature would allow. He knew that the studies of his young disciple were frequently impeded by the visits of persons of learning and distinction, to whom his poetical abilities were well known, and who remembered him when he was brought to Naples, as an *improvvisatore*, by Gravina. But now their expectations were transferred to his legal abilities, upon which, from his learning and application, they had formed the highest hopes. It is certain that Metastasio, at this time, exercising the greatest tyranny over his natural inclination, refrained entirely, not only from writing verses, but from speaking them extempore, in spite of all solicitation. The first breach of contract with the rugged advocate, and first seduction of the muse during his residence at Naples, was in the beginning of 1721, at the instigation of the countess of Althan, who prevailed on him to write an Epithalamium for the nuptials of her relation, the marquis Pignatelli, with a lady of the Pinelli family: it consists of near one hundred octave stanzas, is full of elegance, and in the highest class of poetry. The drama of "Endymion," the first that he produced expressly for music, is said to have been written on the same occasion.

Metastasio's next infringement of the laws laid down by the advocate Paglietti against the wicked practice of poetry,

was occasioned by an application from the viceroy of Naples himself, that he would write a drama for music, to be performed on the birth-day of the empress Elizabeth, consort of the emperor Charles VI., who was then in possession of that kingdom. It is said that he was with difficulty prevailed upon to enter on this task, and only complied upon a promise that it should be kept a profound secret. Our bard, in perpetual fear of the inexorable lawyer, was obliged to sacrifice his hours of sleep to this contraband commerce with the muses. The piece was entitled "The Gardens of the Hesperides," and is one of the most beautiful of his early productions.

The next drama that was written at the expence of his legal studies, or his moments of rest and recreation, was "Angelica." This was printed at Naples in 1722, and set to music by Porpora for the empress's birth-day. It has been said in some accounts of Metastasio's early productions, that Farinelli's first public performance was in this *serenata*.

The poems which he produced at Naples were the admiration of all persons possessed of a love and taste for poetry, particularly "The Gardens of the Hesperides;" but none felt its beauties so forcibly as the Bulgarella detta Romanina, the greatest female singer and actress of her time; who, having performed the part of Venus in that occasional drama, was so enchanted with the uncommon beauty of the poetry, that she could not rest till she had been introduced to the acquaintance of the author. Indeed, tradition says, that this drama had an effect upon the audience in general, which Naples had never before experienced. The recitative was hardly begun, when the spectators formed a more curious spectacle than the actors themselves: so great was the change in their behaviour and mode of listening that was instantly produced. Violent noise and unbridled clamour used to reign in every part of that theatre, and could never be subdued but with great difficulty, even when some capital singer had a favourite air to perform; and it was no sooner over than the din was renewed with such vehemence, that even the orchestra could not be heard. But now, every one delighted by the new and decorous arrangement of the scenes, original beauty and sweetness of the verse, the force of the sentiments, the texture of the parts, and all the wonders of Metastasio's dramatic poetry, was forced, almost insensibly, into profound silence and attention.

Universal curiosity was excited, and inquiries made, after the author, who, though a poet and fond of praise, is said to have wished to lie concealed. But the Bulgarini, who was not only pleased in common with the lovers of poetry, but impressed with the most lively gratitude to the author of the "Hesperides," for the flattering reception and unbounded applause which this piece had procured her, both as an actress and singer, was impatient to be personally acquainted with him. And having discovered that she knew one of his intimate friends, she prevailed upon him to try to bring the poet to her house. He at first resisted the solicitation; but at length, ceasing to be inexorable, he was induced to make her a visit. The Romanina (as she was generally called from being a native of that city) had no sooner seen him, than she felt an uncommon regard for him. His poetical abilities, elegance of manners, and fine countenance, together with the circumstance of his being her countryman, or rather townsman, all joined to increase her regard; while Metastasio on his part felt equally unable, with all the stoicism he could muster, to resist the desire of improving the acquaintance; and frequently returned to enjoy the pleasure of her conversation.

He had soon reason to believe, from the countenance and

behaviour of Paglietti, that neither his theatrical production, nor the new stage acquaintance which he had made, was unknown to him. The praises he received from the Romanina, and all those to whom the secret had been divulged, and their pressing instances that he would continue to write, awakened his passion for poetry, which he had flattered himself was wholly subdued. He now began to feel, that by the narrow and contracted study of the law, his genius could never expand in his own original ideas, but would be constantly tied down to those of others. His reflections upon the fordidness of sacrificing his whole life to a distasteful business, for the mere hope of acquiring wealth, (as he afterwards confessed to his confidential friends,) joined to the harsh treatment of the old advocate, which became more intolerable in proportion as the assiduity of Metastasio diminished, entirely determined him to quit both him and his profession.

His female friend perceived the conflict and internal war; and in order to stimulate his courage and resolution, she and her husband invited him in the most pressing manner to reside under the same roof, and assured him that they would contribute every thing in their power to render his life as easy and comfortable as possible. He remained several months in a state of uncertainty; but at length determined to accept their offer, to return to poetry, and to enjoy the pleasures of society in full liberty. Yet he did not seem insensible of the apparent indecorum and want of fortitude which he manifested in quitting, with such seeming levity, the pursuit of studies which had been recommended to him by his deceased patron. Nor was he quite at his ease on the side of delicacy, as to appearances; the obligations to the Bulgarini, under which he was loading himself, frequently oppressed his mind. And yet so limited is our power of penetrating into future events, that the measures which he now pursued, far from impeding either his fame or fortune, were the foundations of all his subsequent celebrity. An Italian poet has well described the shortness of mental vision.

“ Sebben sembra talor che torvo e iniquo
Il volto verso noi volga la forte;
Ella seguendo suo costume antico
A inaspettata gioja apre le porte:
E asconde spesso sotto calle obliqua
Della felicità le vie più corte:
Onde non sappia in mezzo ai torti, e ai guai
L'uom che temer, nè che sperar giammai.”

“ Blind to the future, while he sojourns here,
Man knows not what to hope or what to fear;
Amidst misfortune, sorrow, and dismay,
Fate oft, in frowns, points out the shortest way
To fortune, fame, and unexpected joy,
By means which prudence trembles to employ.”

The Bulgarini was engaged to sing in the theatre of Naples, during the carnival of 1724; and being very ambitious of appearing to as much advantage in the next opera as she had done in that for the birth-day of the empress, she pressed the poet to write a drama, in which, as first woman, such a character might fall to her share, as would give her an opportunity of displaying all her powers, both as an actress and singer. It is easy to imagine with what zeal the Abate went to work, in order to gratify her wish. After many heroines had passed in review, Dido was at length chosen, and the drama, entitled “*Didone Abbandonata*,” produced; in which he chose the period of the hero, Æneas, quitting the Carthaginian queen: as it furnished scenes of the greatest force and passion, as well as more expression for his pen, and

more abundant opportunities for the display of the Romanina's abilities, than any other. This was the first perfect musical drama, perhaps, that ever graced the Italian stage. The applause it obtained was equal to that of the “*Orti Esperidi*,” and though the story was so well known, that no effects could be produced by surprise, yet the pleasure of the audience was excessive. It was set by Sarro, and the part of Æneas was performed by Nicolini.

From the great and sudden celebrity of “*Didone*,” which, immediately after its first appearance at Naples, was set by the best composers of the time for the other principal theatres of Italy; the Venetian minister at Rome, where it had been performed to Sarro's music, was instigated to apply to Metastasio to write the opera of “*Siroe*,” which he sent to Venice, where it met with a success equal to that of Dido, to the great emolument of the author, who was magnificently rewarded for the superior excellence of his poetry. This drama was set by Vinci at Venice, and performed and printed in 1726.

It appears from the original *libretti*, or printed books of the words, that the Romanina not only performed the principal female part in Metastasio's four first dramas at Naples, but in “*Didone*” and “*Siroe*,” with Nicolini, at Venice, in which city they were first represented in 1725 and 1726; and, according to Quadrio, (*Storia d'ogni Poesia*,) Metastasio himself was at Venice during these performances. It was during this period that he altered the old opera of “*Siface*,” for the same performers, at the request of Porpora.

In the carnival of 1726, while the dramas of Metastasio received such unbounded applause at Venice, “*Didone*,” as set by Vinci, was received at Rome with acclamation. The famous ex-jesuit Cordara, who was there at that time, in his eulogy of Metastasio, recited at Alexandria in 1782, describes its reception in the following manner:

“ Every scene produced one continued applause. But who can describe the rapture of the pit, when the queen of Carthage, disdainfully rising from the throne, represses the insolent pretensions of the king of Mauritania, with the dignity of an independent princess, by the spirited air, “*Son Regina*,” &c. The noise seemed to shake the theatre to its foundation. I was not there myself, as my habit did not allow me to be present at such spectacles: but I almost heard the rumour in my cell, so full was all Rome with the fame of this production.”

In 1727, the Romanina having fulfilled all her theatrical engagements at Naples and elsewhere, prepared to return to Rome, yet declared at the same time, that she would never see her native city again, unless in the company of her dear friend. He remained for a while irresolute; but, at length, the warm affection he retained for the place of his nativity, in spite of the neglect and disappointment which had driven him thence, heightened perhaps by his regard for the Bulgarini, and fortified by the desire of seeing his father, and the rest of his family, determined him to quit Naples, in company with his benefactress; but not before he had obtained a promise from her, that, in return for the hospitality which he had received under her roof at Naples, she and her family should become his guests at Rome. To this proposition all parties having acceded, he wrote to his agents, to provide a house sufficient for the two families of Trapassi and Bulgarini. And from the time of his arrival in that city, till his departure for Germany, they all lived under the same roof, and constituted one family. The Romanina, as more rich and accustomed to the management of a family, was invested with the superintendance of all household concerns: the rest had nothing to do, but to attend their own pursuits; while

while Metastasio received visits, wrote verses, improved his circumstances, and increased his celebrity.

The first drama which he produced, expressly for Rome, was "Citone in Utica," which was set by Vinci, and performed in that city, 1728; and in 1729, at Venice, to the music of Leo. He chose the subject purposely to please the Romans, supposing that he should gain both applause and gratitude, by displaying the virtue of one of their own heroes. But as it seldom happens that a prophet or a poet (which in ancient times were united in the same person) receives due honour in his own country, particularly at Rome, which is proverbially called the residence of strangers; in spite of the excellence of this drama, which abounds with sublime, as well as tender sentiments and delineations, of the passions of glory, ambition, anger, and love; and in which the conduct was natural, and catastrophe historical; it was instantly attacked by the satirical genius of the Romans, and the performance suspended. The frivolous scenes, and feeble poetry to which they had been long accustomed, had corrupted the taste of the Roman public in general; and, except a few learned men, less invidious than the rest, who, if they knew of no modern Cato, had read, at least, something about the ancient, this piece was at first very coldly received; though afterwards, when their minds and tastes were enlightened and refined by other original and beautiful works of our author, this drama was treated with more justice.

The next opera which our author produced was "Ezio," set by Porpora, in 1728, and "Semiramide Riconosciuta," set by the same composer, 1729; but though both these dramas were received in the most favourable manner, and the praises bestowed upon the poet were unbounded, his fortune was not greatly improved by their success. Poetry has more frequently enriched the bookseller than the author, in every country; but at Rome, it is a drug of less value, even to the bookseller, than elsewhere; and Metastasio's muse, however chaste, was but little better treated for not being meretricious. If Metastasio had been a mere psalmodist, or hymnologist, his monkish rhymes might have obtained him some ecclesiastical preferment; but the poetry which he produced on pagan and secular subjects precluded him from every avenue to the church. He was, however, far from necessitous; and with the assistance of the Romanina, whose purse was always at his service, his fortune and situation were tolerably easy. But the being sometimes obliged to avail himself of the liberality of his generous friend, was a circumstance which humbled and mortified him beyond any other. He could not bear to reflect on being a burthen to her, for whom chiefly he wished to be rich, not only to exempt her from the expences which she incurred on his account, but to manifest his gratitude for the benefits she had already conferred on him.

His amiable friend tried every means in her power to set his mind at ease, concerning his obligations to her: assuring him that he had contributed much more to her professional fame than it had been in her power to do to his fortune; that she was in such circumstances as rendered the small friendly offices, which she had been able to perform, more a pleasure than an inconvenience; and pressed him, in the most urgent manner, to tranquillize his mind on that account, and to believe (which she assured him was the truth) that he was doing her the greatest favour, when he afforded her an opportunity of dividing with him her possessions.

The afflicted poet drew some comfort from these declarations, but it was of short duration. He was perpetually convinced of the ingratitude of his pretended Roman friends,

and the duplicity of his protectors; and having nourished in his soul an ardent passion for general esteem, respect, and admiration, his narrow circumstances threw him into so profound a fit of melancholy, that he became incapable of receiving consolation.

Such was his state of despondency in 1729, when, to his great astonishment, he received a letter from prince Pio of Savoy, inspector of the imperial theatre at Vienna, inviting him to engage in the service of the emperor Charles VI., as the successor of Apollonio Zeno, who, from the year 1718, had filled the place of imperial laureate, whose chief employment had been to furnish dramas for music; and these had been justly thought the bell which the Italian language could bear.

Metastasio was infinitely more surprised and flattered by this unsolicited and splendid offer, from finding that he had been recommended to the emperor's notice by the learned Zeno himself, who, growing in years, wished to retire to Venice, the place of his nativity, and had been applied to by his imperial majesty to recommend a successor.

And yet the offer of this employment to Metastasio, however dazzling, was not long productive of joy without deduction. The quitting Rome, for which he had always a filial fondness, as well as leaving his family, friends, and, perhaps more than all, the Romanina, impressed his mind with a sorrowful alloy to his happiness.

Upon consulting with his family, they instantly conceived such magnificent hopes of his future aggrandizement, as contributed much to their consolation at losing him; and the Romanina was so generous and disinterested, in spite of secret affliction, as to use her utmost eloquence in removing his doubts, and diminishing the causes of his repugnance, at quitting Rome and his friends.

After many consultations and discussions of the several arguments for and against the acceptance of the proposition from Vienna, the answer which he sent, and which has been printed among his letters, contains so many characteristic traits of modesty, propriety, and delicacy, that it deserves to be preserved as a model of conduct under similar circumstances.

The result of meditation, and the advice of his family and friends, was to accept the appointment, and to throw himself at the feet of his imperial master as soon as he could arrange his affairs, and fulfil his engagements to furnish the Roman theatre with two new operas for the ensuing carnival.

His appointment at Vienna was settled at three thousand florins *per annum*, and fifty pounds sterling for the expences of his journey. After completing his two new dramas for Rome, which were "Artaserse" and "Alessandro nell'Indie," and which were both set by Leonardo Vinci, and performed before the poet's departure, he left his native city with a heavy heart, and a most sovereign contempt for the friendship and flattering promises of the great, by whose delusions he had so long entertained hopes of preferment in his native city; whence, at last, he was driven into a kind of splendid banishment, for the rest of his life. These early disappointments, from being extremely credulous, rendered him incurably sceptical, as to all future passages of good fortune; and the effects of hoping too much in early life, and too little after, produced, perhaps, the principal defects in his character.

Upon quitting Rome, Metastasio consigned into the hands of his zealous and affectionate friend, the Romanina, all his effects, interests, and concerns; together with the management of his family affairs: she most willingly submitting to

METASTASIO.

these several tasks, as well as to the care of the produce of the little places, and sums of money, which he left behind him.

Of his reception at Vienna, where he arrived in July, 1730, by prince Pio and his imperial patron, there is among his letters an account written by himself to a friend at Rome, the day after he had been presented. It was to the highest degree flattering. And the emperor, who was of a grave, religious, and moral character, seems to have honoured him not only with his favour but affection, on finding in him principles congenial with his own.

In his correspondence with the Romanina, we have an account of his occupations at Vienna, during the first three years of his residence there; and the reception of his operas of "Adriano in Siria," "Demetrio," "Iffipile," and his oratorio of "Sant' Elena al Calvario."

In 1734 he lost the friend of his head and heart, the Romanina, who died at Rome, and manifested the sincerity of her attachment to the poet, by bequeathing to him all her possessions, after the decease of her husband, to the amount of twenty-five thousand crowns. But Metastasio, always consistent with his usual rectitude and propriety, totally declined accepting of her intended kindness, and transferred the whole bequest to her husband, whose real property, according to our English ideas of jurisprudence, it seems legally to have been. The testamentary laws of Italy may be different from those of our country. Some Italian writers say, that the Romanina left Metastasio *erede di tutto il suo patrimonio*: "heir to all her patrimony." If by patrimony was meant an estate possessed by inheritance, and independently settled upon her at the time of her marriage, her testamentary dispositions are reconcilable to English ideas of law in such cases; though preferring the friend to the husband deviates somewhat from the general custom of our country. That the bequest was legal has never been doubted by Metastasio's biographers, who all speak of his renunciation in the highest terms of panegyric, as uncommonly disinterested, generous, and heroic. And the poet himself, as well as all Italy, regarded it as a noble sacrifice.

Whether Metastasio's connection with the Romanina was purely platonic, or of a less seraphic nature, we shall not attempt to determine. But the husband residing with them both at Naples and Rome, and the friendly manner in which the poet always mentioned him in his letters to the wife, and the openness with which he expressed his affliction in writing to him after her death, would, in England, be thought indications favourable to conjugal felicity. But a chaste actress or opera singer is still a more rare phenomenon in Italy than in Great Britain.

Yet though it is not thought absolutely necessary for the female singers of Italy to be vestals while single, or Lucretias when married, they find it convenient to have a nominal husband, who will fight their battles, contend with the first man, and impresario of an opera; and, occasionally, stand in the gap, as circumstances may require.

But whether the poet's friendship for Bulgarini, the husband, was pure and undisssembled or not, his affliction for the death of his wife seems to have been unfeignedly deep and sincere. The following pathetic letter, written immediately after he had received the news of her decease, and of her testament in his favour, seems a faithful delineation of the state of his mind at this time, and to correspond with that goodness of heart, as well as those tender feelings and lofty ideas of rectitude, which appear in all his other writings, and which have ennobled the general tenor of his life.

"To signor Domenico Bulgarini.

"Oppressed by the afflicting news of the death of our poor Marianna, I know not how to begin this letter. The tidings are intolerable to me on so many accounts, that I can devise no means to diminish the acuteness of my sufferings; and, therefore, I trust you will not accuse me of want of feeling, if I am unable to suggest to you any consolation for your loss, as I have hitherto been utterly unequal to finding any for myself.

"The last disposition of the poor deceased in my favour aggravates the cause of my sorrow, and obliges me to give a public and incontestable proof of the disinterestedness of that friendship, which I professed to her while living, and which I shall preserve for her honoured memory to the last moment of my existence. Knowing, therefore, how much affection, kindness, and zeal, for the welfare of the poor Marianna, you have always manifested, I shall best shew my gratitude to her, by entirely renouncing, in your favour, all claim to her effects; not through pride, God preserve me from such ingratitude! but because it appears to be my duty, as an honest man and a Christian. The advantage which I shall still derive from this inheritance, even after renouncing it, will not be inconsiderable: as the knowing what was intended for me by the generous testatrix will be a lasting proof of her friendship; and the relinquishing it in your favour will be a proof of my disinterestedness with respect to her, and of my equity towards yourself. I am at present, thank God, in no need of such assistance, as I am rewarded beyond my merit; so that I shall not suffer by the sacrifice I make to you. Though I entangle you with no conditions in the renunciation which I enclose, yet I have some requests to make, and counsels to suggest to you.

"My first request is, that the relinquishing this claim may in no wise dissolve our friendship; but that, according to the wish of the poor Marianna, our correspondence may continue as entire as if she were still living; substituting you at all times, and in all places, for her representative.

"My second request is, that you will undertake the trouble of receiving the salaries of my three offices in Rome, and the transacting of my Neapolitan concerns, exactly in the same manner as was done by our incomparable Marianna; for which purpose, I send you proper powers. I write likewise to signor Tenerelli, at Naples, who will treat you in the same manner as signora Marianna herself; remitting to you, from time to time, whatever sums may be due to me from that quarter, continuing to my poor family the usual assignments and provision, if you shall chuse it, jointly with my brother.

"The advice which seems necessary for me to give you is, that you would assist the poor family of signor Francesco Lombardi, by every means in your power; and try by acts of charity to do every thing for them, which, in a similar situation, you would expect from them to you. I have specified in my renunciation some particulars in which you should assist them; but besides my unwillingness to involve you in trouble and difficulty, I am so certain of the goodness of your heart, that I have left all the merit of your benevolence towards them to the liberality of your own determination.

"In all things else, you are at full liberty to act as occasion, and your own prudence, shall suggest.

"At present, my mind is in too great perturbation for me to attempt giving you a plan for the regulation of your conduct. I shall only say, that it appears to me, as if you should dispose of all the effects you can spare, in order to raise a capital, and that you should live in a smaller house.

"I can

METASTASIO.

"I can think of no other testimony to offer you, at present, of my friendship and confidence. Be equally open in your correspondence, and consider my interests as your own, and me as your brother. I am unable now to write a longer letter: when my mind is more tranquil, I shall communicate to you such thoughts as may occur.

"In the mean time, love me, and endeavour to be comforted yourself. Be assured, if it were in my power, that I would try to contribute that to your consolation, which I am unable to receive myself."

In a letter to his brother Leopold, apologizing to him for the renunciation of the Romanina's intended kindness, he says, "I ought not to abuse the partiality of my poor deceased friend, at her husband's expence; and God, I trust, will permit me to prosper by some other means, for my integrity."

To a friend at Rome, on the subject of his affliction, he says, "I am now placed in the world as in a populous desert, and in that kind of desolation in which a man, if he were transported in his sleep to China or Tartary, would find himself in waking, among people of whose language, inclinations, and manners, he was quite ignorant."

If platonic affection can subsist in human nature, we may suppose it possible, perhaps, to have been realized between the poet and such a female friend as the Romanina; who, by what we can gather from Metastasio's letters, seems to have possessed a strong mind and great rectitude of heart.

The solemn manner in which so pious and moral a man as Metastasio says in his letter to a Roman friend, "In the midst of my gloomy imaginations, reason enough is left to tell me who, and what I am; but that is not sufficient to free me from affliction. May God, in whose hands are all events, turn this affliction to my benefit, and teach me by such a manifestation, what a vain hope it is to form systems of happiness, without his assistance." The late Mr. Mason, on reading this passage, regarded it as a proof that there had been nothing criminal between them.—"Such a man as Metastasio, writing to a friend, would have expressed in this place some compunction, at least he would not have invoked the Deity in such a solemn manner."

We have dwelt the longer on this incident in the poet's life, which places him, like Alcides, between virtue and vice, in hopes that a character, so exemplary during every other period of his existence, may, for the honour of humanity, descend spotless to posterity. In all other respects, his private virtues merit equal praise with his poetry, which has so long delighted the most polished and refined inhabitants of Europe.

Among the anecdotes, indeed, that were published after his decease, concerning the private life of our admirable bard, some peculiarities have been related, which seem too serious for ridicule, and from which we should be sorry, for his honour, and for the honour of human nature, not to be able to defend him. What a disgrace to practical virtue and benevolence would it be, to find a writer, whose works breathe the purest principles of virtue and morality, and whose life, during his long residence at Vienna, was unimpeachably innocent, and constant in the exercise of religious duties, to want, not only filial and fraternal affection, but even those common and laudable partialities for his kindred and countrymen, to which the most vulgar minds are naturally prone! It has been said with a degree of levity, perhaps more to enliven a period than from conviction, or a wish to degrade the poet's moral character, that "he refused to hear, and took pains not to know, whether he had, in his latter days, any relation left in the world." But in his correspondence, published by his executor signor Giu-

seppe Martinetz, aulic counsellor, and first keeper of the imperial library, there are letters to his father and brother, so full of filial and fraternal affection, as completely confute such hasty and unjust charges.

The year 1733 seems to have been extremely fertile in the Parnassian domains of our bard. Not only the operas of "L'Olympiade" and "Demofonte," with the oratorio of "Giuseppe Riconosciuto," but his charming canzonet, "La Liberta," were all productions of this year. This celebrated canzonet, "Grazie agl'inganni tuoi," was first set by the poet himself, but soon after by all the great composers of Italy, as a Venetian ballad, a canzonet, a duo, and a cantata, to much more elaborate and fanciful music than that of the poet: yet his own melody, which has been composed more than seventy years, has still its merit; and, compared with airs of the same period and kind, is superior to most of them in elegant simplicity.

In 1734, besides his usual occupations, we find, by his letters, that he was obliged, in the greatest haste, to write an entertainment for music, to be performed by the archduchesses, and to instruct, direct, and assist them. "But in truth," he says, "it is a pleasure which no other can equal, to have such an opportunity of seeing and admiring the excellent qualities of these august princesses. I should not else have believed it possible to meet with such attention, docility, patience, and gratitude. Oh, how many people, of the sixteenth rank, have I known, who were not possessed of the thousandth part of the courtesy of these incomparable personages! They have acted and sung like angels, and it was truly sacrilege, that the whole world was not permitted to admire them; for the festival was extremely private, as none but the Vienna ladies of the highest rank were able to obtain admission, and even these were in masks. As a return for instructing their serene highnesses, I was presented with a gold snuff-box, of about fourscore hungheri (near 40*l.*) in weight; but the workmanship is of much more value."

This little dramatic poem was called "Le Grazie Vendicate," set by Caldara, and performed by the two archduchesses, Maria Teresa, afterwards empress-queen, and her sister Marianne, with another lady of the court.

In the year 1734 he produced, for the emperor's birthday, "La Clemenza di Tito."

It seems as if the character and court of Charles VI. had directed the muse of Metastasio to chuse a virtuous prince for the principal hero of most of the musical dramas that were represented in the imperial theatre. The emperor was a religious prince, and a rigid observer of decorum himself, which consequently kept licentiousness at a distance from his court. And the poet, naturally a friend to virtue and morality, seems to have gratified his own feelings, by conforming to the serious sentiments of his imperial patron.

In 1735 he produced, by command of the empress Elizabeth, a little opera, with three characters only, entitled "Leinesi," for the same two archduchesses and a lady of the court to perform, as an introduction to a Chinese ballet.

The same year he furnished "Il Palladio conservato," and "Il Sogno di Scipione," pieces written for the celebration of the emperor and empress's name-day. These were a kind of birth-day odes, but in a dramatic form, in which the praise was delicately disguised in a fable or allegory.

In 1736, his "Themistocles," set by Caldara, first appeared; but while this was performing, Metastasio had another task assigned him, the difficulties of which he frequently related to his friends, many years after.

To Betinelli, the printer, he writes: "I send you a copy

METASTASIO.

of the opera of 'Achille in Sciro,' which I have been obliged to write in eighteen days and a half, for the nuptials of the archduchess Teresa with the duke of Lorraine. Three months, which I used to allow myself for writing an opera, were never sufficient to finish it to my mind: imagine whether it was possible to satisfy myself with this."

The admirable drama of "Ciro Riconosciuto" was a production of this period.

It seems as if 1737 had been a sabbatical year for our author and his muse; for none of his poetical works bear that date, nor do any of his letters of that period appear in the collection.

In 1738 and 1739 he produced several small occasional pieces, chiefly for the archduchesses to perform; which, though elegantly written, have not been of that general use to the rest of Europe, which fell to the lot of most of his operas on a larger scale, for want of length and more characters.

In 1740, however, his dramatic muse was better employed, and more propitious: for, besides the opera of "Zenobia," and the oratorio of "Ifacco," he wrote "Il Natale di Giove," and the opera of "Attilio Regolo," for the birth-day of the emperor Charles VI.; but that prince dying before it had been represented, it was laid aside, and not performed till 1750, when it was set by Hasse, for the court of Dresden.

The poet laments the death of his patron with great sensibility, in a letter to a friend. Indeed it was a calamity to all Europe, by the general war which immediately ensued.

This prince found in Metastasio a man who encouraged and confirmed his love of virtue, decorum, and propriety; and Metastasio found in his patron a prince susceptible of receiving his recommendations of the moral and social, as well as the heroic virtues. Indeed the poet and the patron seem to have been formed for each other.

Between the death of this emperor, in 1740, and 1745, when prince Charles of Lorraine, consort to the empress-queen, was elected emperor, by the title of Francis I., the court of Vienna had little leisure for being amused by the peaceful arts of poetry and music. We find, among the poet's works, but two complete dramas written during all that time: "Antigono," and "Ipermestra." One of these, "Antigono," was written expressly for the court of Dresden. Both were set by Hasse, who ranked high in the favour of Metastasio, as a great composer and intelligent man.

Our author's poetical productions in 1746 consist only of his two beautiful canzonette, "La Partenza," and "La Palinodia a Nice," thirteen years after he had so piously and elegantly thanked the gods for discovering to him her infidelities, in his "Grazie agl' inganni tuoi."

His correspondence with the celebrated Farinelli began in 1747, to whom 38 of his letters are addressed, in the sixth volume of his correspondence, which seem the most affectionate and confidential in the collection. The poet and musician were nearly of the same age. And having begun their career of fame and fortune together at Naples, in 1723, they, from that circumstance, ever after called each other *Gemello*, or *Twin*, in their correspondence, which lasted to the end of their lives. Many of the poet's letters were addressed to the great singer at Madrid, where, during two successive reigns, he enjoyed the highest favour. See FARINELLI.

The blessings of peace, after the seven years' war, revived at Vienna the innocent pleasures of the lyric theatre; and in 1751 produced Metastasio's beautiful opera of "Il

Re Pastore," which was followed, in 1752, by "l'Eroe Cinese." These were performed in the imperial theatre by persons of the highest distinction, some of whom are said greatly to have surpassed, in many particulars, professed opera singers of the first rank.

In 1756, at the request of his friend Farinelli, and with the permission of his imperial patrons, he furnished the court of Spain with a new opera, entitled "Nitteti," which was brought on the stage there, with the utmost splendour and magnificence, under Farinelli's direction.

The last three operas written by Metastasio, were "Il Trionfo di Clelia," in 1762; "Remolo ed Ersilia," 1765; and "Il Ruggiero," in 1771; which were performed at three several places: the first at Vienna, on the delivery of Isabella of Bourbon, first consort of the emperor Joseph II.; the next at Innebruck, on the marriage of the grand duke of Tuscany with Maria, Infanta of Spain; and the last at Milan, on the nuptials of the archduke Ferdinand with Beatrice, princess of Modena, which terminated the dramatic labours of our admirable lyric bard.

His other poetical compositions, which are very numerous, consist of oratorios, occasional short lyric pieces, hymns, and sacred songs, cantatas, epithalamia, sonnets, canzoni, complimentary verses, &c., all replete with elegance, refined ideas, and every beauty of numbers which the Italian language so copiously can furnish, and melody requires.

Among his prose writings, the extracts from Aristotle's Poetics, and the *Ars Poetica* of Horace, are the principal; and these will long remain indisputable proofs of his learning, good taste, and perfect comprehension of the laws prescribed by these great masters, which he explains with the utmost clearness and practical utility; giving sense to many passages that were thought obscure and unintelligible.

In all his productions, religion, government, sound policy, morals, manners, and even innocent prejudices, are so highly respected, that the most extreme delicacy never finds the least sentiment that can offend or alarm. His doctrines and practice in these particulars so perfectly agreed, that he constantly discountenanced in conversation all tendency to licence, disrespect, and disputation on moral and sacred subjects, though naturally cheerful, and pleasantly metaphorical, in his conversation. This being his invariable practice during his long residence at Vienna, excited as much eagerness in travellers of all ranks to see and converse with him, as the renown which he had justly acquired by his writings.

He was honoured with testimonies of respect and admiration from almost all the sovereigns in Europe, where the Italian language and music were known, which he received with the utmost humility and gratitude.

Such were the delicacy and constancy of his friendly attachments and intercourse, that death could only dissolve them. The princess di Belmonte Pignatelli, the countess d'Althan of the same illustrious family, who knew and patronised him in his early youth; count Canale, baron Hagen, and count Perlas, who spent all their evenings with him at Vienna during their several lives; Farinelli, his correspondent of 50 years duration, count Algarotti, and his brother, the advocate, Leopoldo, to whom 48 of his letters are extant; all these affections were habitual and deeply rooted in his heart.

His whole life appears to have been of that even tenour, which nothing but great accidents or public calamities could disturb. His veneration and gratitude for his patrons, the empress-queen, seem, during the last years of his life, to have been the strongest passions to which he gave admission

METASTASIO.

in his breast. When unfortunate in war, or on account of the sickness or death of any of her family, he was as much agitated as any of her most faithful and best subjects. But when her own life was endangered by disease, his equanimity and philosophy totally left him. Then yielding to the natural sensibility and tenderness of a heart, neither chilled by apathy, nor petrified by stoicism, he became a common man; not too flulborn for affliction, or too proud and obdurate for the impressions of calamity. The sickness of his brother, and death of the countess d'Altham, are likewise illustrations of this occasional sensibility.

His conversation was usually scientific, turning on new discoveries, new books, pleasing events, but rarely on calamity or unpleasant topics. By this means he kept his passions and affections in equilibrio, obtained prosperity in youth, and veneration in old age.

Though his longevity had extended to 84, yet his faculties were so entire, his person so free from any appearance of decrepitude, still possessing a florid countenance, and his accustom'd eloquence, and playful language in conversation, that he was expected to have many years more; but on the 11th of April, 1782, returning from his constant evening visit to count Perlas, he complained of a chilliness, eat very little at supper, and went to bed at his usual hour of 12 o'clock. "The next morning, (says mademoiselle Martinetz in her letter to Farinelli, giving him an account of his friend's decease,) he called for my elder brother, Giuseppe, and consulted him whether he had best rite a d go to church, as he had intended, it being Easter Sunday; but was advised by him to remain in bed, as his pulse was very quick; an hour after the fever increased to such a degree, that it deprived him of speech, and he remained oppressed by a heavy lethargic sleep, which continued during two days, with short intervals, in which he was only able to take the medicines prescribed by Dr. Molinari, his physician. The fever diminished so much on the morning of the fifth day, that he became tranquil, spoke freely, conversed with some of his friends, who visited him, and was able, after dinner, to have the sacrament administered to him. You may imagine, sir, what great consolation this afforded us; but our hopes were of short duration, for at night the fever returned with such violence, that every day he became more lethargic, and baffled all the skill of the most able physicians, who met in consultation; so that on the 12th of April, between 11 and 12 o'clock at night, he finally, without much agony, expired."

Metastasio, lamented by all who knew or had heard of him at Vienna, was interred at the parish church of St. Michael, the 14th of April. The funeral rites were performed with splendour, by his grateful heir, signor Joseph Martinetz, in despite of the poet's injunctions, who had forbidden all kind of pomp. The inheritance of signor Martinetz consisted in a well-furnished habitation, a coach, horses, a great quantity of princely presents, a very ample and select collection of books, with a capital of 130,000 florins; from which, however, were to be deducted, 20,000 for each of the executor's sisters, and 3000 for each of his younger brothers.

The poet's attachment to the Martinetz family was of long standing. In the year 1730, on his arrival at Vienna, the first house in which he took up his residence, was that of signor Nicolò Martinetz, master of the ceremonies to the apostolic nuncio in that city. The eldest son of this gentleman he appointed his heir, jointly with his eldest sister, signora Marianna Martinetz, educated under his eye, and universally admired for her talents and accomplishments, particularly in music, not only as an excellent performer on

the harpsichord, and an exquisite singer, but for her genius and ability in composition, she was an elevè of the great Dr. Hayer, who resided three years under the same roof with Metastasio during her musical studies; and had lessons in singing from the celebrated Porpora, who had many years before been the poet's own music-maister. The productions of mademoiselle Martinetz were communicated to, and approved by the greatest masters of Italy, and her name is inscribed a member of the Philharmonic academy in Bologna and Mantua.

Signor Saverio Martinetz, the most useful of Metastasio's biographers, though he rather gives advice to others, with loose and indigested materials, than a regular life of the poet, says, that "whoever wishes to acquire an exact knowledge of his customs, manners, way of life, opinions of himself and others; of his precision in fulfilling his duties, of the changes in his fortune, his application, and the different degrees of favour with which his several productions were at first received, their chronology, the influence they had on the taste of Italy, and on that of all Europe, with respect to the mel-drama, or lyric stage, can only acquire such information by the perusal of his Letters."

"His Letters (says the abate Crivini, the most accurate and ample of all his biographers, and editor of the Nice edition of his works) will do honour to all Italy, while they discover his most intimate attachments, his most secret thoughts, his favourite opinions, and the history of a man who was all heart and all virtue."

"His genius (says signor Arteaga, *Revol. del Theatro Mus. Ital.*) may be compared to the goddess Chloris of the Greeks, who, in flying through the air, scattered roses wherever she went." The same grace, facility, and elegance of style appear in his prose, as have rendered his poetry so justly celebrated. Till we saw these Letters, we used to think that there was no Italian prose so easy to comprehend and construe, by young students in the language, as the dramas of Metastasio; but we are now convinced, that, in point of facility, the prose of our author is to his own poetry, what the prose of others is to their verse.

What renders these Letters infinitely more natural and satisfactory is, that, like the *Epistolæ Familiæ* of Cicero, they were not written with the least view to publication; as is manifest by the lively complaints which he makes to his correspondents, who, for the gratification of their own vanity, had betrayed his confidence.

Few writers have been fortunate enough to enjoy the favour of the public so completely during their lives as Metastasio. But this felicity is not to be more ascribed, perhaps, to the excellence of his writings, than to his modesty, candour, and determination neither to give nor take offence by censuring the productions of others, or resenting the censures of his own. He seems to have seen, with due horror, the effects of literary war on the combatants.

That celebrity which he enjoyed so indisputably during life, was not diminished by his decease; his works are still in every hand: the philosopher, the courtier, the bigot, the man of the world, austere and gallant females, all equally read them, and all find them equally beautiful. His moral maxims are daily cited, and his productions are become the code of lovers. The setting and singing his verses, have rendered Pergolesi, Vinci, Jomelli, Sacchini, and Farinelli, Caffarelli, Pacchierotti, and Marchesi, as celebrated in all parts of Europe, as Corneille, Racine and Voltaire. Had his dramas been regular tragedies, written for declamation, without music, perhaps we should never have heard of them in England: but music being an universal language throughout Europe, they are certainly obliged to the composer and singer

finger for a great part of their fame, at least out of Italy, notwithstanding the complaints of Metastasio himself, and the admirers of tragedy, who are inimical to music, that they have been injured by composers and performers. Particular operas, and perhaps, at some time or other, all his dramas, may have fallen into the hands of composers without genius, and singers without talents; but upon the whole, excellently written as are Metastasio's dramas, and exquisite as is the Italian language, it must be owned, that music has been the vehicle in which the operas of Metastasio have travelled into foreign countries. Cato, Regulus, Themistocles, Artaxerxes, Olimpiade, and Demofoonte, are allowed to breathe a true tragic spirit, even through the effeminate languor of lengthened tones and long divisions; but it is in the perusal, perhaps, not the vocal performance, that the force and beauty of Metastasio's dramatic scenes have been discovered out of Italy. When an air has been encored, it has not been for the beauty of the poetry, but the composition or performance of that air. It must be allowed, however, without the least deduction, that Metastasio's genius, good taste, and sound judgment, first achieved the difficult task of rendering so wild and incongruous a compound of seemingly heterogeneous ingredients and absurdities, as an *opera*, a rational entertainment.

Even the church has defended the morality of Metastasio's dramas. The ci-devant Jesuit, father Cordaro, in his eulogy of our poet, says, "I well know that he has been accused by some of having brought the passion of love too forward in his dramas, at the risk of seducing and enervating the heart and virtue of the hearers. How shall we defend him from this charge? He would certainly have done better, if he could have confined himself to the love of glory, and of our country, in displaying the virtues of valour, fidelity, and constancy, without meddling with the follies of lovers. But there are certain noble affections, concerning which, the vulgar have but little knowledge, and less taste. On the contrary, every one understands love; and without that seasoning every representation, at present, seems insipid. It is the predominant passion of the times. He was perhaps necessitated to comply with it; but with what precaution and reserve! Has an unchaste word ever escaped him? Or an idea that is not strictly within the limits of the most perfect delicacy? This may be said of his secular dramas taken from profane story; but his sacred dramas are not only exempt from blame with respect to the passion of love, but sufficiently pure in morals and doctrine, to serve as correctives to whatever the most morose critics may object to his productions for the stage."

The chronology and *moral object* of each drama is indicated in the English Memoirs of his Life and Writings, vol. iii. p. 316. &c.

We dare extend this article no farther. Our biographical articles should doubtless, in general, be confined to the battles of heroes, and books of the learned; but Metastasio's private character, meriting as much display as his public productions, we could not in our sketch of his life help stopping on the road to look about us, and admire the beautiful views which a life well spent affords.

METASTASIS, in *Medicine*, μεταστασις, signifies a translation or transition of disease from one part of the body to another, the part first affected recovering its natural functions at the time when the other begins to be diseased.

These transitions of disease have been noticed from the earliest history of the practice of medicine; and the writings of Hippocrates abound with instances of the fact, and with practical precepts, deduced from a careful observation of the

consequences that ensue under the various circumstances of their occurrence. The older writers, who ascribed all diseases to the existence of a morbid matter, which, in whatever part it prevailed, gave rise to peculiar local symptoms, readily explained these instances of metastasis, upon the supposition that the morbid matter was substantially translated from the part first diseased to the seat of the new affection: indeed, this translation of the disease was deemed by them one of the proofs of the existence of a *materies morbi*. But we have already shewn, at some length, that the existence of such a morbid matter, as the efficient cause of diseases, is purely a gratuitous supposition, which more accurate investigation has exploded; and that the fact of the transition of disease by what has been called *metastasis*, although not easily explained upon any hypothesis, is as satisfactorily accounted for on the principle of sympathy, through the medium of the nervous system, which experiment has demonstrated, as upon the notion of an actual transference of morbid matter, which is hypothetically assumed. See *HUMORAL Pathology*.

It is scarcely necessary here to point out examples of the metastasis of diseases, which are universally recognised: such are the severe attacks of disorders in the stomach, when the inflammatory gout suddenly disappears from the extremities; the occurrence of diarrhœa or dysentery, upon the sudden retrocession of the measles, or other extensive eruption on the skin; the appearance of epileptic convulsions upon the cessation of the hæmorrhoidal, or other habitual discharge; the inflammation of the testes in men, or of the mammæ in women, which ensues, when that of the parotid glands in the disease called *mumps*, suddenly disappears; and other cases of a similar nature.

The transition by metastasis, however, is only one of several modes in which diseases are converted into each other. Of these we have already described the varieties in a former article, to which we refer the reader. See *CONVERSION of Diseases*.

METASTASIS, μεταστασις, *Remotio*, in *Rhetoric*, is used for the removing the blame from the person accused to another person, or laying it upon something as a cause. Thus, Adam's excusing himself by blaming Eve, is an example of the former; and the laying the crime of drunkenness upon the wine, is an instance of the latter.

METASTELMA, in *Botany, from μέλα, signifying a change, and στεῖμα, a crown, because the usual crown of the stamens being wanting, its place is supplied by a five-toothed appendage to the mouth of the corolla. Brown in Wern. Transf. v. 1. 52.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocinea*, Juss. *Asclepiadeæ*, Brown.*

Ess. Ch. Corolla bell-shaped; its mouth crowned with five prominent teeth, opposite to the sinuses, running down the tube. Crown of the stamens none. Anthers tipped with a membrane. Masses of pollen compressed, attached by their taper points, pendulous. Stigma pointless. Follicles. . . .

M. parviflorum. (*Cynanchum parviflorum*; Swartz Ind. Occ. 537. Willd. Sp. Pl. v. 1. 1258. *Periploca scandens*, nummulariæ foliis, flore albo; Plum. Ic. 209. t. 215. f. 1.) —Native of wild mountainous thickets in the West Indies, in various islands of which it was gathered by Plumier, Swartz, Masson, and Von Rohr. The stem is somewhat shrubby, twining to a great extent, subdivided, slender, bluntly quadrangular, smooth like every other part of the herbage; its branches thread-shaped, opposite, spreading, and twining. Leaves about an inch long, opposite, distant, stalked, ovate, entire, thin, smooth on both sides, with one rib, and several transverse veins, tipped with a minute,

rigid, awl-shaped point. *Umbels* nearly sessile between the footstalks, of about six or eight small, stalked, greenish-white *flowers*, whose segments are acute, finely downy, thickened at the edges, and reflexed. Mr. Brown complains of the inaccuracy of Dr. Swartz's description of the crown of the flower, and we have also to remark that the umbels are, as the former truly says, between the footstalks, not axillary; and the leaves have a very conspicuous rib, as well as numerous veins. The name was given by Dr. Solander, from whom, as well as Dr. Swartz, we have specimens.

METATARSIIUS, in *Anatomy*, the abductor minimi digiti pedis. See ABDUCTOR.

METATARSUM, in *Natural History*, a name given by authors to a sort of stone supposed to represent a human foot. See METAPEDIUM.

METATARSUS, in *Anatomy*, one of the divisions of the foot. See EXTREMITIES.

METATEPEC, in *Geography*, a town of Mexico, in the province of Guasteca; 50 miles S. of Panuco.

METATHESIS, *Μεταθεσις*, formed of *μετα*, *trans*, and *θεσις*, *position*, *transposition*, a grammatical figure, whereby letters or syllables of a word are transposed, or shifted out of their natural situation; as *Ewandre* for *Ewander*; *I pra* for *prai*.

METATHESIS, a word used by medical writers for a change of place in such humours, or other diseased parts, as cannot be absolutely removed or sent off. Thus a metathesis of a cataract is a depression thereof, so that it no longer shuts out the light.

METATOR, among the Romans, a quarter-master. Out of every legion a tribune, and some centurions, were appointed to go before the army, in order to choose a place for a camp, and assign and mark out quarters to each legion.

METAWAUMKEAG, in *Geography*, a large northerly branch of the river Penobscot, in America.

METCHICOT, a lake of Canada. N. lat. 50° 22'. W. long. 88° 30'.

METCHIGAMIAS, a long narrow lake, or rather dilatation of the northern branch of the river St. Francis, in Louisiana, which falls into the Mississippi from the N.W. about four miles above Kappas Old Fort.

METE, a small island in the Arabian sea, near the coast of Adel. N. lat. 11° 10'. See BABELMANDEB.

METEARA, a town of Hindoostan, in Bahar; 23 miles S.E. of Saferam.

METECAL, or METICAL, in *Commerce*, a weight for gold, silver, and diamonds, in the Levant. At Aleppo it is used for weighing pearls and ambergris, and is 1½ drachm, or 73 English grains. At Damascus, silver is sold by the ounce of 10 pesi, or 6¾ metecalli, weighing 19 dwt. 4 gr. English troy. At Smyrna, gold and silver lace is sold by the metical of 1½ drachm avoirdupois, or 72 grains troy weight, very nearly. See WEIGHTS.

METEGAVEL, in our *Old Writers*, a tribute or rent paid in victuals, which was a thing used in this kingdom, as well with the king's tenants as others, till the reign of king Henry I.

The word is Saxon, *metagavel*; i. e. *cibi gablum, seu vestigal*.

METELAR, in *Geography*, one of the Laccadive islands. N. lat. 12° 18'. E. long. 72° 25'.

METELE, a town of Lithuania, in the palatinate of Troki; 36 miles N. of Grodno.

METELEN, a town of Germany, in the bishopric of Munster; 19 miles N.W. of Munster. N. lat. 52° 14'. E. long. 7° 10'.

VOL. XXIII.

METELIN. See MITYLENE.

METELINOS, a town of the island of Samos; 2 miles N.E. of Cora.

METELLUS, QUINTUS CÆCILIUS, in *Biography*, the son of L. Cæcilius Metellus Calvus, was raised to the consulate, during the Jugurthine war, with M. Junius Silanus, in the year B. C. 109. On calling lots for the consular provinces, that of Numidia fell to Metellus, who made immediate preparations for retrieving the honour of the Roman arms, which had lately fallen into disgrace through the successes of Jugurtha. He was extremely careful in the selection of the officers to serve under him, and chose, among others, of known military talents, the famous Marius, who, for want of interest, had for some time remained unemployed at Rome. Having restored order and discipline in his army, he marched into the centre of Numidia, where he defeated and dispersed the whole force commanded by Jugurtha in person. When the consular year was ended, the command was continued to Metellus as pro-consul, and he pursued the plan of ruining the country of Jugurtha, and cutting off his resources. At length the circumstances of the Numidian obliged him to enter into a treaty with Metellus, by which he delivered up all his elephants, a number of horses and arms, and all the deserters from the Roman army. The latter, to the disgrace of the conqueror, were put to death, with great cruelty. Jugurtha took the first opportunity of appearing again in arms, and the people rose upon a Roman garrison, and massacred the whole, excepting the commander Turpilius. Metellus soon recovered the place, brought Turpilius to a court martial, and caused him to be put to death, on account of which he underwent the keenest remorse: having been influenced in his decision rather by popular clamour than by the strict rules of justice. Marius had been a leading actor in the condemnation of Turpilius, and triumphed in the consequences which it had upon the mind of Metellus, whose character with the people he endeavoured to injure. The third year of his command was going on, and nothing decisive had been effected. Of this his rival, Marius, made a handle, and by his representations to the people was able, not only to procure his own election to the consulate, but to obtain a decree for his superseding Metellus in the conduct of the Numidian war. Metellus deplored his hard fate with tears. He refused to see his rival; delivered up his army by a lieutenant, and immediately embarked for Rome. He was received with great honour by his friends and partizans, who obtained for him the honour of a triumph. Being charged with peculation by a tribune, he would have produced his books in his own justification; but the Roman knights who sat as his judges refused to examine his accounts, declaring that they considered the whole tenor of his life as a sufficient testimonial of his innocence. Having passed with honour through his military career, there remained a trial of his civic virtue and firmness, in which he obtained equal credit. In the year B. C. 100, the most violent measures were carried on by the popular leaders; and the tribune Apuleius Saturninus having prepared an Agrarian law, procured a clause to be previously passed, that the senate would swear to confirm whatever the people should enact. Metellus opposed the proposition; the senate, to a man, joined in a similar opposition. Marius, who had led them to this determination, by pretending to entertain the same sentiments, soon retracted, and took the oath; all the senators, excepting Metellus, followed his example. Metellus persisting in his resolution was condemned to banishment. His friends offered to oppose this act of injustice, but he declared that not a drop of blood should be spilt on his account. He said, "either the state of public affairs will change, and I shall be recalled; or, if they remain

as they are, I shall be better off any where than at Rome." He then passed over to Rhodes, or Smyrna, where he passed his time in the study of philosophy. In the following year, a decree was passed by a great majority for his return: the news was brought to him while he was assisting at some public games, and though he was informed that the packet contained pleasing intelligence, he would not open it till the spectacle, perhaps a religious ceremony, was over. On his return to Rome he was met at the gates by all the persons of distinction in the city, and was accompanied to his house by great crowds of people, and at the next consular election the public esteem for him was shewn by accepting his recommendation of one of his own name and family. After this, we hear no more of this worthy man.

METEMPSYCHL, in *Church History*, heretics, who, in imitation of the Pythagoreans, maintained the transmigration of souls. See **METEMPSYCHOSIS**.

METEMPSYCHOSIS, *Μετεμψυχωση*, formed of *μετα*, *beyond*, and *εμψυχη*, *I animate*, or *enliven*, in the *Ancient Philosophy*, the passage or transmigration of the soul of a man, after death, into the body of some other animal.

Pythagoras and his followers held, that, after death, men's souls passed into other bodies, of this or that kind, according to the manner of life they had led. If they had been vicious, they were imprisoned in the bodies of miserable beasts, there to do penance for several ages; at the expiration whereof, they returned afresh to animate man. But if they had lived virtuously, some happier brute, or even a human creature, was to be their lot.

What led Pythagoras to this opinion was, the persuasion he had, that the soul was not of a perishable nature: whence he concluded, that it must remove into some other body upon its abandoning this. According to Empedocles, human souls, in the course of the transmigration to which they are liable, may inhabit not only different human bodies, but the body of any animal or plant. Lucan treats this doctrine as a kind of officious lie, contrived to mitigate the apprehension of death, by persuading men, that they only changed their lodging; and only ceased to live to begin a new life.

Reuchlin denies this doctrine; and maintains, that the metempsychosis of Pythagoras implied nothing more than a similitude of manners, desires, and studies, formerly existing in some person deceased, and now revived in another alive. Thus, when it was said, that Euphorbus was revived in Pythagoras, no more was meant than that the martial virtue, which had shone in Euphorbus at the time of the Trojan war, was now, in some measure, revived in Pythagoras, by reason of the great respect he bore for the athlete. For those people wondering how a philosopher should be so much taken with men of the sword, he palliated the matter, by saying, that the soul of Euphorbus, *i. e.* his genius, disposition, and inclinations, were revived in him. And this gave occasion to the report, that Euphorbus's soul, who perished in the Trojan war, had transmigrated into Pythagoras.

Ficinus asserts, that what Plato speaks of the migration of a human soul into a brute, is intended allegorically, and is to be understood only of the manners, affections, and habits, degenerated into a beastly nature by vice. Seranus, though he allows some force to this interpretation, yet inclines rather to understand the metempsychosis of a resurrection.

Pythagoras is said to have borrowed the notion of a metempsychosis from the Egyptians (see **EGYPT**); others say, from the ancient Brachmans. It is still retained among the Banians, and other idolaters, of India and China; and makes the principal foundation of their religion. (See **BRACHMANS**, **BANIAN**S, and **GENTO**S). So extremely are they

bigotted to it, that they not only forbear eating any thing that has life, but many of them even refuse to defend themselves from wild beasts. They burn no wood, lest some little animalcule should be in it; and are so very charitable, that they will redeem from the hands of strangers any animals that they find ready to be killed. See **ΠΥΘΑΓΟΡΕΑΝ**S.

METEMPTOSIS, from *μετα*, *post*, and *πειπω*, *cado*, *I fall*, a term in *Chronology*, expressing the solar equation, necessary to prevent the new moon from happening a day too late.

By which it stands contradistinguished from *proemptosis*, which signifies the lunar equation, necessary to prevent the new moon from happening a day too soon.

The new moons running a little backwards, that is, coming a day too soon at the end of three hundred and twelve years and a half; by the *proemptosis*, a day is added every three hundred years, and another every two thousand four hundred years; on the other hand, by the *metemptosis*, a bissextile is suppressed each one hundred and thirty-four years; that is, three times in four hundred years. These alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar easy.

There are three rules for making this addition, or suppression, of the bissextile day, and, by consequence, for changing the index of the epacts. 1. When there is a *metemptosis* without a *proemptosis*, the next following, or lower index, must be taken. 2. When there is a *proemptosis* without a *metemptosis*, the next preceding or superior index is to be taken. 3. When there are both a *metemptosis* and a *proemptosis*, or when there is neither the one nor the other, the same index is preserved. Thus, in 1600, we had D; in 1700, by reason of the *metemptosis*, C was taken; in 1800, there were both a *proemptosis* and a *metemptosis*; so the same index was retained. In 1900, there will be a *metemptosis* again, when B will be taken, which will be preserved in 2000, because there will then be neither the one nor the other. This is as far as we need compute for it: but Clavius has calculated a cycle of 301,800 years; at the end of which period, the same indices return in the same order. See **EPACT**.

METEOR, from *μετεωρος*, *high*, *sublime*, is a general term used to signify the transient, fiery appearances in the heavens; such as are denoted by the more particular names of *shooting stars*, *globes of fire*, *ignes fatui*, *aurora borealis*, &c. The word is used by some writers to signify all the various phenomena of the atmosphere, as *clouds*, *rain*, *hail*; &c. in which case meteors are divided into *fiery* and *watery*; but this last distinction is adopted by few. We shall under this head make a few observations upon the fiery meteors, or those more generally designated by the name meteor, and leave the other to be considered under the article **METEOR**LOGY.

The phenomena called *shooting* or *falling stars* have been seen by every one, as these meteors are visible in greater or less numbers every clear night; they need not therefore be particularly described. These meteors are so very transient, not often exceeding one or two seconds in duration, that they afford no opportunity for observations by which their altitude can be determined with accuracy, and consequently we are in a great measure ignorant of their height. If a few intelligent persons were to agree to make the best observations they could on the altitudes of these meteors some suitable evening, supposing the observers to be stationed at the distance of ten, twenty, or more miles from each other, and to have their watches, &c. duly adjusted, it is very probable that data

METEOR.

might be obtained to ascertain the height of these meteors, within certain limits at least.

Though the general appearance of these meteors is that of stars shooting or falling, yet they occasionally are observed of great magnitude and comparatively of long duration, sometimes almost as large as the moon, and move through a celestial arc of 100°, more or less. As an instance of this kind we may take the great meteor of August 18th, 1783, an account of which was given in the *Philos. Transact.* 1783, by the late Mr. Cavallo, from his own observations, and those of some intelligent friends who happened to be with him, at Windsor. "On the evening of the 18th of August 1783, we were standing upon the N.E. corner of the above-mentioned (Windsor) terrace. The weather was calm, and agreeably warm; the sky was serene, excepting very near the horizon, where a haziness just prevented the appearance of the stars. A narrow, rugged, and oblong cloud stood on the N.W. side of the heavens, reaching from the extremity of the haziness, which rose as high as 18 or 20 degrees, and stretching itself for several degrees towards the east, in a direction nearly parallel to the horizon. It was a little below this cloud, and consequently in the hazy part of the atmosphere, about the N. by W. half W. point of the compass, that this luminous meteor was first perceived. Some flashes of lambent light, much like the aurora borealis, were first observed on the northern part of the heavens, which were soon perceived to proceed from a roundish luminous body, nearly as big in diameter as the semidiameter of the moon, and almost stationary in the above-mentioned point of the heavens. It was then about 25 minutes after nine o'clock in the evening. The ball at first appeared of a faint bluish light, perhaps from being just kindled, or from its appearing through the haziness; but it gradually increased its light, and soon began to move, at first ascending above the horizon in an oblique direction towards the east. Its course in this direction was very short, perhaps of five or six degrees; after which it directed its course towards the east, and, moving in a direction nearly parallel to the horizon, reached as far as the S.E. by E. point, where it finally disappeared. The whole duration of the meteor was half a minute, or rather less; and the altitude of its track seemed to be about 25 degrees above the horizon. A short time after the beginning of its motion, the luminous body passed behind the above-mentioned small cloud, so that during this passage we observed only the light which was cast in the heavens from behind the cloud, without actually seeing the body from which it proceeded for about the sixth or at most the fifth part of its track; but as soon as the meteor emerged from behind the cloud, its light was prodigious. Every object appeared very distinct; the whole face of the country, in that beautiful prospect before the terrace, being instantly illuminated. At this moment the body of the meteor appeared of an oblong form; but it presently acquired a tail, and soon after it parted into several small bodies, each having a tail, or elongation; and all moving in the same direction, at a small distance from each other, and very little behind the principal body, the size of which was gradually reduced after this division. In this form the meteor moved as far as the S.E. by E. point, where the light decreasing rather abruptly, the whole disappeared.

"During the phenomenon no noise was heard by any of our company, excepting one person, who imagined to have heard a crackling noise, something like that which is produced by small wood when burning. But about ten minutes after the disappearance of the meteor, and when we were just going to retire from the terrace, we heard a rumbling noise, as if it were of thunder at a great distance, which in all pro-

bability was the report of the meteor's explosion; and it may be naturally imagined that this explosion happened when the meteor parted into small bodies, viz. at about the middle of its track.

"Now if that noise was really the report of the explosion which happened at the above-mentioned place; the distance, altitude, course, and other particulars relating to this meteor, must be very nearly such as are expressed in the following list; they being calculated with mathematical accuracy upon the preceding particulars, and upon the supposition that sound travels at the rate of 1150 feet per second. But if the noise we heard was not that of the meteor's explosion, then the following results must be considered as quite useless and erroneous.

Distance of the meteor from Windsor castle	}	130 miles
Length of the path it described in the heavens	}	550 miles.
Diameter of the luminous body, when it came out of the clouds	}	1070 yards.
Its height above the surface of the earth	}	56½ miles.

The explosion must have happened perpendicularly over Lincolnshire."

The above account was written the day after the appearance of the meteor; and in his *Natural Philosophy* this author farther observes, "Those accounts which were sent from various parts of this island, as also from the continent, confirmed, as nearly as can be expected, the above-mentioned results respecting its size, velocity, elevation, and explosion over Lincolnshire; but this meteor must have certainly had its origin much farther north than we imagined; and indeed, on account of the intervening cloud, it was impossible for us to perceive it at an earlier part of its course. It is also probable that it must have gone or terminated at a much greater distance than it appeared to us; for as its light diminished until it vanished, we must naturally have lost sight of it sooner than those who stood farther south on the continent. The various accounts seem to establish, that its course commenced beyond the northern extremity of this island, probably somewhere over the northern ocean. It passed a little westward of Perth, and perhaps a little eastward of Edinburgh; it proceeded over the south of Scotland, Northumberland, the bishopric of Durham, Yorkshire, Lincolnshire, over which it seemed to have deviated gradually to the westward, and in the course of that deviation to have suffered the bursting or partition. It then passed over Cambridgeshire, Essex, and the straits of Dover, entering the continent probably not far from Dunkirk, where, as well as at Calais and Ostend, it was thought to be vertical. It was seen at Brussels, Paris, Nuits in Burgundy, and, it is said, even at Rome. Upon the whole, it must have described a track upwards of 1000 miles in about half a minute; an astonishing rate of going, vastly swifter than the motion of sound." Vol. iv. p. 363.

In corroboration of the general accuracy of the above account, the author of this article may add his testimony, having been a witness of the meteor nearly during the whole of its apparition from Kendal in Westmoreland, a place, as it should seem from the above account, situated near to the middle of the meteor's track. The meteor, as seen from thence, rose near the N.W., moved nearly in the direction of the magnetic meridian, and disappeared in the S.E. The apparent velocity was least at first and at last, and greatest during the middle or highest part of the track; but the variation was not more than what would arise from a really uniform

velocity, owing to the optical illusion in such case. The greatest altitude of the meteor seemed to be very nearly 50° , and its duration was about half a minute, more or less; its altitude, when first seen, might be about 15° or 20° , and nearly the same at its disappearance. The sky was quite clear, except a haziness in the S.E. horizon; the twilight was considerable; yet the first attention to the meteor arose from observing the moving shadow of a window frame. No subsequent report was heard; but this might be from the attention being at that time otherwise engaged. From a comparison of observations at different places, its height was estimated to be about 60 miles.

Upon the whole it may be pretty safely concluded, that the height of this meteor was not less than 50, nor more than 60 miles above the earth's surface; and that its motion was nearly in a horizontal direction during the whole of its course.

From the general resemblance of the small meteors or shooting stars to the large globes of fire, except in size and duration, it can scarcely be doubted that they are of the same nature. Whatever hypothesis may be laid down to explain the one, must be expected to apply to the other; and if the results of the recent observations and investigations respecting the stones fallen from the atmosphere are to be credited, these last phenomena are intimately connected with the former.

Dr. Halley conjectured, that a stratum or train of inflammable vapour, gradually raised from the earth, and accumulated in an elevated region, suddenly took fire at one end, and burning like a train of gunpowder, exhibited the meteoric phenomena. (Philos. Trans. vol. 30. N 360.) But this notion appears to have been entirely laid aside, as altogether untenable.

In later times, since the discoveries in electricity, meteors have been very generally ascribed to that agent. There seem, however, insuperable difficulties in explaining their phenomena upon electrical principles. The air, at the height of fifty miles, is probably 30,000 times more rarified than at the earth's surface; in such circumstances, we are almost certain that the electric fluid would either not pass at all, or pass in a very thin, attenuated state, so as to be far from exhibiting that densely luminous appearance which accompanies all the meteors in the form of balls. But admitting that large dense balls of electric fluid could be formed and conveyed through these high regions of the atmosphere, we should still be at a loss for materials to form those ponderable metallic masses which seem occasionally to be precipitated upon the surface of the earth, after the appearance of the meteor.

Professor Clap, late president of Yale college, in New England, in his theory of meteors, supposes them to be "terrestrial comets, revolving about the earth in the same manner as the solar comets revolve about the sun. That moving in very excentric orbits, when in perigee, they pass through the atmosphere, are highly electrified, and consequently become luminous. As they approach their lower apside, their electricity is discharged, the body disappears, and a report is heard. This being admitted, it is not strange that, by the violence of the shock, portions of the meteor should be thrown to the earth, while the main body, not sensibly affected by so small a loss, continues to move on in its orbit, and of course ceases to be luminous." Silliman on Meteoric Stones, American Philos. Trans. vol. 6. p 335.

In the Philos. Transact. 1784, Dr. Blagden has given "An account of some late fiery meteors; with observations." He considers the meteors under the following heads, in all of which he makes various appropriate observations.

1. Their general appearance.
2. Their path.
3. Their shape

- or figure.
4. Their light and colours.
5. Their height.
6. Their noise.
7. Their size.
8. Their duration: and,
9. Their velocity.

In discussing the opinions of philosophers on the subject, he refers to professor Clap's, as follows: "A strong objection to this hypothesis of permanent revolving bodies, is derived from the great number of them there must be to answer all the appearances. Such a regular gradation is observed from these large meteors, which strike all beholders with astonishment, and occur but rarely, down to the minute fires, called shooting stars, which are seen without being regarded in great numbers every clear night, that it seems impossible to draw any line of distinction between them, or deny that they are all of the same nature. But such a crowd of revolving bodies could scarcely fail to announce their existence by some other means than merely a luminous train in the night, as for instance, by meeting or jostling sometimes near the earth, or by falling to the earth in consequence of various accidents; at least one might expect they would be seen in the day-time, either with the naked eye, or telescopes, by some of the numerous observers who are constantly examining the heavens. Another argument of great weight against the hypothesis that fire-balls are terrestrial comets, is taken from the great velocity. A body falling from infinite space towards the earth, would have acquired a velocity of no more than seven miles a second, when it came within 50 miles of the earth's surface; whereas these meteors seem to move at least three times faster. And this objection, if there be no mistake in regard to the velocity of the meteors, as I think there is not, absolutely oversets the whole hypothesis." Page 223.

Dr. Blagden proceeds to explain these meteors on the hypothesis that they are electrical phenomena. His arguments are; 1st. From the great rapidity of their motion, which seems to exceed any other we are acquainted with besides that of electricity. 2dly. From certain electrical phenomena, which sometimes accompany these meteors; and 3dly. From the connection which they have with the aurora borealis, or northern lights. These last are well known to regard the magnetic meridian; and most of the great meteors have been observed to move in a direction nearly coincident with the same meridian. Upon this head he observes; "the tendency towards the magnetic meridian, however, seems to hold good only with regard to the largest sort of fire-balls; the smaller ones move more irregularly, perhaps because they come further within the verge of our atmosphere, and are thereby more exposed to the action of extraneous causes. That the smaller sort of meteors, such as shooting stars, are really lower down in the atmosphere, is rendered very probable by their swifter apparent motion; perhaps it is this very circumstance which occasions them to be smaller, the electric fluid being more divided in more resisting air. But as these masses of electricity, which move where there is scarcely any resistance, so generally affect the direction of the magnetic meridian, the ideas which have been entertained of some analogy between these two obscure powers of nature, seem not altogether without foundation." P. 230.

Dr. Blagden concludes, that there are three regions of the atmosphere, distinguished by electrical phenomena peculiar to each. 1st. The lowest region, in which the phenomena of thunder and lightning occur. 2dly. The middle region, where the fire-balls and shooting stars are observed; and, 3dly. The highest region, where the aurora borealis displays a peculiar kind of electric agency.

Though many of the arguments which Dr. Blagden has advanced in favour of the hypothesis of electricity being the origin of meteors, are of considerable weight, yet the circumstances which have since occurred respecting the falling

METEOR.

of stones from the sky, effectually remove one of his objections to the reception of professor Clap's hypothesis; namely, that of the meteors not "falling to the earth in consequence of various accidents," and at the same time they rise up against the electrical hypothesis; unless indeed another be attached to it, that electricity condenses and fuses the earthy and metallic exhalations in the atmosphere, which are thus precipitated to the earth's surface in greater or less portions. The other great objection to Clap's hypothesis, that of the velocity of fire-balls being greater than is consistent with a body revolving round the earth, however, remains in full force, except it can be shewn that the velocity of meteors has been much overrated. From the law of gravitation it is demonstrable, that the velocity of a body revolving round the earth cannot, even when in perigee, and near the surface of the earth, be less than five, nor more than seven miles *per second*. Hence, then, if the velocity of a meteor exceed seven miles *per second*, it cannot be a body revolving in an orbit round the earth. It does not appear, however, to be satisfactorily ascertained that the velocity of fire-balls exceeds seven miles *per second*. It is not perhaps going beyond probability to say, that no observer saw the great meteor of Aug. 18th, 1783, for more than an extent of 200 miles; as a proof, it may be remarked that the hurrying of the meteor, said to have taken place over Lincolnshire, was not observed at Kendal, though the distance from the nearest point, or that of greatest apparent altitude, was not more than 100 miles. Now if the meteor took 30 seconds to move 200 miles, it gives $6\frac{2}{3}$ miles *per second*; which is within the required limits. And, farther, let those who saw the meteor pass nearly through the zenith, endeavour to estimate the time it seemed to take in passing through an arc of 10° , or let the like observation be made upon a shooting star. Perhaps few, if any, will be found to insist upon the time being so little as one second; at least the writer of this article is not inclined to adopt the affirmative from his own observation. But 10 in one second would correspond only to eight miles of velocity, at the height of 50 miles above the earth's surface. It may therefore perhaps be still deemed problematical, whether the velocity of either the larger or smaller meteors ever exceeds seven miles *per second*; as also whether it ever falls short of five miles *per second*.

Upon the whole, the hypothesis of fire-balls being something of the nature of comets, that is, bodies revolving around the earth in excentric orbits, appears in the present state of the science to be as probable as any other. The light and heat acquired in passing through the perigee might be variously accounted for; but it would be premature to enter into a disquisition on this head, as long as such doubts remain respecting the real velocity of this sort of meteors. See BALLS of Fire and FALLING Stones

Ignis fatuus is the name of a luminous meteor, said to be seen occasionally in the night, hovering over moist ground, and about church-yards. Though it is stated by writers to be a common meteor, we find few authentic accounts of its nature and appearance; and some accounts are evidently mixed with superstitious notions respecting the origin of the meteor, and particularly with regard to its effects in misleading travellers. See *IGNIS fatuus* for more on this head.

One of the most splendid and most surprising of the luminous meteors is the *aurora borealis*, or *northern lights*. An account of this meteor may be seen under the article *AURORA Borealis*; but as some of the latest, and perhaps the most accurate observations on these striking phenomena, have been omitted in that account, it will be proper to introduce them here. The observations are those of Mr. Dalton, published

in his *Meteorological Essays*, 1793. This diligent observer resided in the north of England (at Kendal), during a period when these phenomena were very frequent; namely from 1786 to 1793. The *aurora borealis* has seldom appeared since that period; and it should seem, from the history of this meteor, that it is one in some way subject to periodical apparition.

Mr. Dalton has given the times and appearances of the *aurora borealis*, some of them described minutely, with accompanying observations on the variation of the magnetic needle. It seems the number of the phenomena seen at Kendal and Keswick, was as under:

	Number of <i>Aurora Borealis</i> .

From such a number of observations, and from those previously made by others, to be found in various philosophical works, the author was enabled to generalize the phenomena of the *aurora borealis*. He observes, "the appearances of the *aurora* come under four different descriptions. First, a *horizontal light*, like the morning *aurora*, or break of day. Secondly, fine, slender luminous beams, well defined, and of dense light; these continue $\frac{1}{4}$, $\frac{1}{2}$, or 1 whole minute, sometimes at rest apparently, but oftener with a quick lateral motion. Thirdly, *flashes* pointing upward, or in the same direction as the beams, which they always succeed; these are only momentary, and have no lateral motion, but they are generally repeated many times in a minute; they appear much broader, more diffuse, and of a weaker light than the beams; they grow gradually fainter, till they disappear. These sometimes continue for hours, flashing at intervals. Fourthly, *arches*, nearly in the form of rainbows; these, when complete, go quite across the heavens, from one point of the horizon to the opposite point.

When an *aurora* takes place, those appearances seem to succeed each other in the following order: First, the faint rainbow-like arches; secondly, the beams; and, thirdly, the flashes; as for the northern horizontal light, it will appear in the sequel to consist of an abundance of *flashes* or *beams* blended together, owing to the situation of the observer relative to them. These distinctions, and the terms appropriated for them, must be kept in view, in attending to the following phenomena.

Phenom. 1.—The beams of the *aurora borealis* appear, at all places alike, to be arches of great circles of the sphere, with the eye in the centre, and these arches, if prolonged upwards, would all meet in one point.

Phenom. 2.—The rainbow-like arches all cross the magnetic meridian at right angles: when two or more appear at once, they are concentric, and tend to the magnetic east and west: also, the broad arch of the *horizontal light* tends to the magnetic east and west, and is bisected by the magnetic meridian; and when the *aurora* extends over any part of the hemisphere, whether great or small, the line separating the illuminated part of the hemisphere from the clear part, is half the circumference of a great circle, crossing the magnetic meridian at right angles, and terminating in the magnetic east and west; moreover, the beams apparently perpendicular to the horizon, are only those on the magnetic meridian.

Phenom. 3.—That point in the heavens to which the beams of the *aurora* appear to converge at any place, is the same as

that to which the south pole of the *dipping-needle* points at that place.

Phenom. 4.—The beams appear to rise above each other in succession, so that of any two beams, that which has the higher base has the higher summit also, or its summit nearer the point of concurrence; the angle subtended by the length of each beam is not the same, it being greatest about half way from the horizon to the zenith, and less above and below; also the beams to the south subtend less angles than those to the north, having the same altitude. The greatest angle to the north seems to be about 25° or 30° ; and that to the south 15° or 20° .

Phenom. 5.—Every beam appears broadest at, or near, the base or bottom, and to grow narrower as it ascends, in such sort that the continuation of its bounding lines would meet in the common centre to which the beams tend; yet the summit of the beam is not flat, but pointed; the highest beams seem about 3° broad, and the lowest 1° .

In order to derive the true situation and position of the several objects presented in these phenomena, it was necessary to have recourse to the principles of geometry or perspective. Mr. Dalton premises five propositions. The first is to shew that any line in a plane passing through the eye, appears in the heavens to be an arch of a great circle. The other four propositions relate to the perspective appearance of one or more cylinders, supposed to be arranged upon a horizontal plane at any given elevation above the earth's surface, the cylinders being parallel to each other, and making a given angle with the horizontal plane. The propositions are illustrated by suitable diagrams, and demonstrated in the usual way. By a comparison of the data of these propositions with the above phenomena, the author makes certain inferences respecting the aurora borealis, and draws such conclusions as seem to be warranted by the established methods of reasoning in natural philosophy. These are,

1. The luminous beams of the aurora borealis are cylindrical, and parallel to each other, at least over a moderate extent of country.

2. The cylindrical beams of the aurora borealis are all magnetic, and parallel to the dipping-needle at the places over which they appear.

3. The height of the rainbow-like arches of the aurora, above the earth's surface, is about 150 English miles.

4. The beams of the aurora are similar, and equal in their real dimensions to one another.

5. The distance of the beams of the aurora from the earth's surface is equal to the length of the beams nearly. This distance is subsequently estimated at 75 miles.

6. That appearance which we have called the *horizontal light*, and which is always situate near the horizon, is nothing but the blended lights of a group of beams, or flashes, which makes the appearance of a large luminous zone.

The author next proceeds to develop, at some length, an hypothesis, by which he proposes to explain these wonderful phenomena. It is ingenious, but cannot be considered as satisfactory. Future investigation may derive from it some useful hints. The following is a brief sketch of it.

Mr. Dalton conceives an extremely subtle elastic fluid of a *ferruginous* nature, or at least such as is capable of being acted upon magnetically, to exist in the higher regions of the atmosphere; perhaps without the verge of the common atmosphere. That this elastic fluid is collected into parallel cylindrical beams, and horizontal rings, over the regions of the earth near the magnetic pole, by virtue of the earth's magnetism; and that the beams, &c. are preserved in their due form and position, and distinct from each other by their mutual magnetic action. This fluid is supposed to be an

imperfect conductor of electricity. When the electricity of the upper regions of the atmosphere is disturbed, it is supposed the electric fluid runs along these beams and rings from one part of the atmosphere to another, to restore the equilibrium. The reason why the diffuse flashes succeed the more intense light of the beams, is because the electricity disperses the elementary particles of the beams in some degree, which collect again after the electric circulation ceases. Hence too, he conceives, is the reason of the fluctuations of the magnetical needle below, while the magnetism of the upper regions of the atmosphere is thus affected. The general observations on the disturbance of the needle are stated as under.

1. When the aurora appears to rise only about 5° , 10° , or 15° above the horizon, the disturbance of the needle is very little, and often insensible.

2. When it rises up to the zenith, and passes it there, it never fails to be a considerable disturbance.

3. This disturbance consists in an irregular oscillation of the horizontal needle, sometimes to the eastward, and then to the westward of the mean daily position, in such sort that the greatest excursions on each side are nearly equal, and amount to about half a degree each in this place.

4. When the aurora ceases, or soon after, the needle returns to its former station.

One section on the aurora borealis is destined to the enquiry, How far the moon has an effect in producing this meteor, or whether the phenomenon is influenced by the aerial tides? It appeared that the average number of auroræ observed during the period of spring tides, was to the number observed during the period of neap tides, as 4 to 3. Also, it appeared that spring and autumn (seasons in which the tides are usually highest) are most favourable for the production of this meteor, as may be seen by the following table.

	Number of Auroræ.		Number of Auroræ.
January	18	July	2

Some of the most splendid appearances of the aurora borealis were observed in a troubled and rather tempestuous state of the atmosphere; but it did not appear in general that this meteor affords any decisive prognostic of the weather. See AURORA BOREALIS, FALLING STONES, &c. Also, for other luminous meteors, see RAINBOW, HALO, PARHELIA, ZODIACAL LIGHT, &c.

METEORIC STONES. See FALLING STONES.

METEORISMUS, in *Medicine*, from *μετεωρος*, *sublimis*, has been applied by medical writers to that tumid state of the belly, arising from flatulence, which distends only the upper parts, as the pit of the stomach and the hypochondriac regions. See Sauvages Nosol. Method. clafs x. gen. 16, who has made four species of Meteorismus: also Castelli Lexic. Med. Art. *Meteoros*.

METEOROLOGICAL JOURNAL, is a table recording the daily state of the air, exhibited by the barometer, thermometer, hygrometer, anemometer, and other meteorological instruments. We have many journals of this kind kept at the house of the Royal Society, and by different observers in other places, in the Philosophical Transactions, the Memoirs of the Academy of Sciences, and similar publications.

METEOROLOGY.

METEOROLOGY is a science which treats of the weather, or of the various affections and phenomena of the atmosphere, as winds, clouds, rain, hail, snow, dew, thunder and lightning, and the fiery meteors. The universal importance of this science is acknowledged; and it may be said that for 150 years past, or since the invention of the barometer and the air-pump, almost every distinguished natural philosopher has contributed to its advancement, either by the discussion of hypotheses or by the observation of facts. The difficulty, however, of forming a correct theory of the phenomena of the atmosphere may easily be conceived, when we consider that it is requisite for a person to have a large collection of facts, and an extensive acquaintance with several collateral sciences; for instance, with mechanics, pneumatics, electricity, and chemistry.

The principal instruments of use in meteorology are, the barometer, by which the weight or pressure of the atmosphere over any place is known; the thermometer, which ascertains the temperature of the air; the hydrometer, to denote the moisture or dryness of the air; the pluviometer, or rain-gauge, to measure the depth of rain that falls; the evaporation-gauge, to shew the depth of water evaporated; the wind-dial, to point out the direction of the wind; the anemometer, to measure its force; and the electrometer, to ascertain the kind and intensity of electricity in the air. See these different instruments described under their appropriate heads.

In order to form a proper notion of the phenomena of the atmosphere, as exhibited at any one place, it will be necessary to obtain a correct notion of the atmosphere itself at large. It appears to be a collection or mixture of various elastic fluids in very different proportions, retained on the surface of the earth by their gravitation. The principal part of the weight of the atmosphere arises from the permanently elastic fluids, azotic gas, and oxygenous gas, the quantities of which are as 4 to 1 nearly: about one part in a thousand of the atmosphere is constituted of another permanently elastic fluid, carbonic acid. The rest of the atmosphere consists of aqueous vapour or steam, an elastic fluid subject to partial condensation by a diminution of temperature. The quantity of this elastic fluid is variable at different places and in different seasons; it may perhaps constitute $\frac{1}{70}$ th of the weight of the whole atmosphere, considered as a general average for the earth; but in some places within the torrid zone it may amount to $\frac{1}{30}$ th of the weight of the incumbent atmosphere; and in the polar regions may sometimes be less than $\frac{1}{1000}$ th part of the atmosphere. It is this portion of the atmosphere which more immediately occasions some of the principal phenomena in meteorology, particularly clouds, rain, hail, snow, dew, and thunder and lightning; it has considerable influence on the temperature of the atmosphere; but it has little effect in the production of winds, or on the variation of the barometer.

The atmosphere decreases in density as we ascend in a geometrical progression to equal ascents. As far as experience warrants the conclusion, the several kinds of gas decrease in density in the same ratio: thus, if at three miles in height, the weight of the atmosphere is one-half what it is at the earth's surface; then will the proportions of the several elastic fluids found in a given volume of air, at that place, be the same as what they are in a like volume of air taken at the surface of the earth; all the kinds being diminished one-half nearly in weight and density. This conclusion is not, perhaps, strictly true for every height, nor for any two heights; but experiments have not been made with sufficient accuracy to ascertain the deviation from this law. At six miles elevation the barometer would stand at

$\frac{1}{4}$ the height at the surface, or at $7\frac{1}{2}$ inches; at 9 miles of elevation, $3\frac{1}{4}$ inches; at 12 miles, 1 $\frac{1}{2}$ inch; and at 15 miles, nearly 1 inch. Hence it seems that the greatest part of the atmosphere is at all times within 15 or 20 miles of the surface of the earth; and it is probable that the ordinary phenomena of winds, clouds, rain, &c. are chiefly confined within much narrower limits.

Origin of Winds.—If the atmosphere should be perfectly calm at any one time all over the surface of the earth, it is evident that there must be an equilibrium of pressure, or the weight of air incumbent over every place must be the same, and the real velocity of the air over any place arising from the earth's rotation around its axis, would be the very same as that of the place itself; namely, at the equator the velocity would be about 1000 miles per hour, from W. to E.; and in the lat. of London the velocity would be 620 miles from W. to E.; and at the poles of the earth, the air would have no velocity. If an equilibrium of this kind were once obtained, there appears to be no mechanical reason why it should be disturbed, arising out of the circumstance of the earth's rotation. But if any cause should arise which disposes the air to move from any part of the earth in a northerly or southerly direction, it is also evident that the rotation of the earth would conspire with this cause to modify the direction, and to accelerate the velocity of the current of air so produced. For instance, suppose a body of air in the lat. of London was to receive an impulse or series of impulses, such as to compel it to move 16° southward in a day, with an uniform velocity; this current of air gradually passing through other air of greater velocity eastward, will in part be carried along with the current, and when it arrives at the 10th parallel it will find air disposed to move from W. to E. with a velocity of 750 miles per hour, being the velocity of the place; whereas its own velocity in that direction was only 620 miles. Now if the moving current of air have not acquired the additional velocity of 130 miles per hour from W. to E., it must appear at the place to have a motion from E. to W. with a velocity equal to the difference or deficiency; suppose it has only acquired 105 miles additional velocity eastward, then it will appear to move at the rate of 25 miles per hour westward; and as it moves also 25 miles southward each hour, it is manifest its direction will be truly that of a N.E. wind, and its velocity 35 miles per hour. If the air is impelled northward, instead of southward, then *vice versa*, a S.W. wind is produced. It appears, then, that as soon as any cause operates to impel a portion of the atmosphere either north or south, that instant the rotation of the earth on its axis begins to manifest an effect, which is to accelerate the apparent velocity of the current, and to divert its direction. We are then directed to look for some natural cause or stimulus which may, either occasionally or constantly, operate in impelling the atmosphere in a meridional direction. This cause is found in the unequal temperature of the atmosphere in the different zones of the earth. The torrid zone is always the warmest region of the earth. The temperate zones are colder; but alternately approximate to the temperature of the torrid zone. The frigid zones are colder still, but they also alternately make some approximation to the temperature of the torrid zone. Now it is well known that air is expanded by heat, and hence becomes specifically lighter; the air over the torrid zone being then specifically lighter than the air in the temperate zones, it will have a tendency to ascend, whilst the air in the two temperate zones will press forward to supply the vacancy, and the air in the frigid zones will follow after upon the same principle. Hence it appears that there must always be a draught of air from the polar towards the equatorial regions, greater

METEOROLOGY.

greater or less according to the existing difference of temperature. As, however, an accumulation of air in the torrid zone would thus ensue, and a deficiency in the other zones, means must be found to return the excess of air over the torrid zone into the northern and southern regions. This is effected, without doubt, by the upper regions of the atmosphere in the torrid zone meeting with a less lateral pressure than is adequate to support them. The air rises up, and overflows in some degree, so that currents northward and southward are established, in opposite directions to the two former currents, and superior to them. The two under currents, as has been shewn, will be N.E. and S.E. winds; the two upper currents, by a like method of reasoning, will be S.W. and N.W. winds. The two under currents, or the N.E. and S.E., meeting each other in the torrid zone, their velocities N. and S. are destroyed by their opposition, but their velocity from E. to W. continues, and occasions the regular or trade-winds. But it is not our design in this place to do more than point out the great active principles, which are constantly at work to produce a motion and circulation of the atmosphere; a more particular description and detail will be given under the article WINDS. The principle, however, cannot but be allowed by those who duly consider the effect of the earth's rotation, and the currents of air we ordinarily observe in any room containing a fire.

Origin and Nature of Clouds.—Clouds are constituted of an infinite number of very minute drops of water; they are formed by the condensation of steam or vapour by cold. In order to understand their origin, we must take a view of the atmosphere of steam already mentioned, and consider its rise and properties. Steam, as every one knows, is an elastic fluid arising from the union of water and heat; and it is again condensible into water by cold, so as to lose its elasticity. Steam is formed almost instantaneously from water inclosed in a vacuum; the maximum effect is at once produced, and there is an end of the evaporation, unless the temperature is increased. The same effect is produced when the water is inclosed in the same volume of perfectly dried common air, or any other kind of air perfectly dried, not acting chemically on water. The same quantity of water, in this case as in the former, is converted into vapour, and the same elastic force of steam is produced for the maximum effect; but there is this difference in the two cases, the latter requires a sensible *time*, in order that the maximum effect may be produced. This demonstrates that the presence of air retards evaporation, and that in all probability is, by reason of its pressure on the surface of the water. From all these observations it might be expected that evaporation would go on, and the quantity of steam in the air increase till the maximum effect was produced over all the earth, and then there would be a total cessation. But we find that evaporation is unceasingly going on in almost every place, and even at the very place where rain is descending. This curious fact would appear at first view to be of difficult explanation; but the difficulty is not insurmountable, as will presently be shewn.

It appears that the quantity of steam that can be contained in a vessel, either with or without air, increases nearly in geometrical progression to equal intervals of temperature. Mr. Dalton contends that the increase is *accurately* in geometrical progression, and that the intervals of temperature are not duly measured by the common thermometer; however this may be, there can be no doubt that the former increases more rapidly than the latter. It has been found, that if the maximum of steam in air of 32° be denoted by 2, that of air of 52° will be denoted

by 4, and that of air of 72° by 8. (See Dalton's Chemistry, p. 14.) Hence it is obvious, that if equal portions of air of 32° and 72° , both saturated with vapour, were mixed together, the mean temperature would be 52° , and the quantity of vapour present in the mixture would be 10; whereas, the greatest quantity of vapour that the air of that temperature could contain, is only 8, according to the above statement; whence two parts must be condensed, and would first appear in the shape of a cloud, and be ultimately deposited. Here, then, we perceive the origin of clouds and rain. It has been shewn that an unceasing circulation of air between the equatorial and polar regions takes place; and as both currents of air must be supposed to be near the point of saturation with vapour, there must frequently be a cloud formed by their mixture. The current from the equator is warm and full of vapour, compared with the air of like altitude in the northern and southern regions; and *vice versa* with regard to the air from the north and south towards the equator. This last air is cold, but nearly saturated with vapour for its temperature; and hence will precipitate vapour from warm air. Were the currents of air to and from the equator quite saturated with vapour at their departure, there must be perpetual cloudiness to accompany their progress; but the circulation of air is so quick, and the saturation with vapour is slowly effected by reason of the pressure of the atmosphere, that it rarely happens for the currents to be saturated at their commencement. It is easy to see, then, that this circumstance, with others equally obvious, may modify the effects so far, as that the atmosphere may be either clear or cloudy over any place whilst the general currents are making their ordinary progress. It is owing to the same circumstance (the slowness with which steam circulates itself through the air) that two currents of air may meet in the higher regions of the atmosphere, and a precipitation of vapour may ensue, when the inferior strata of air are not saturated with vapour. This, indeed, is generally the case in showery weather, but never in long continued rain. The more particular details of this theory of rain will be better deferred till the article *Rain* is composed. See RAIN, also CLOUDS, EVAPORATION, &c.

If any doubt should remain as to the correctness of the above views in regard to the formation of clouds and rain, it may be completely removed, if we will take the trouble to examine the phenomena of a drying stove. We may there see the process above described completely copied in miniature. The moment we open the door to enter the stove, the cold air rushes in, and a prodigious cloud is instantly formed, so as to render surrounding objects invisible: soon after the door is shut, the cloud disappears, and the internal air resumes its usual transparency. Here, then, is an instance of a current of cold air rushing into warm, both of them being below the point of saturation with vapour, and yet a great precipitation takes place. Again, if we notice the air which has ascended the air-flues of the stove and is mixing with the atmosphere, we find a copious stream or cloud of condensed vapour spreading itself all around. This is formed by the current of warm air rushing into the cold atmosphere, though both of them are usually below the point of saturation with vapour.

Height of the Clouds.—We shall subjoin the results of a series of observations on the height of the clouds: these are the more valuable, as very few meteorologists have an opportunity of making similar observations. They were made by Mr. Crosswaite, of Keswick, in Cumberland. In mountainous countries the clouds frequently surround the hills, like a girdle, and exhibit a smooth horizontal surface; if

METEOROLOGY.

the height of the hill at the point of intersection be known by previous observation, then the mountain may be made into a scale to measure the altitude of the clouds. The mountain Skiddaw was fixed upon for that purpose, and Mr. Crotthwaite determined its height above Derwent lake to be 1050 yards. This altitude is probably too great, but the error will have no material effect in the present consideration.

“The result of five years’ observations is contained in the

following table. In order to determine what effect the seasons of the year have upon the clouds in this respect, we have kept the observations in the several months distinct. It is to be noted, that the column containing the number of observations when the clouds were above Skiddaw, includes those observations when there were no clouds visible; but Mr. Crotthwaite has noted this last circumstance also in the journal, and it appears that about one observation in thirty, of those in that column, should be deducted on that account.

	Clouds from 0 to 100 Yards high.	From 100 to 200 Yards high.	From 200 to 300 Yards high.	From 300 to 400 Yards high.	From 400 to 500 Yards high.	From 500 to 600 Yards high. “It may be proper to observe, that the supposition of the clouds rising or falling with the barometer, or as the density of the air increases or diminishes, is not at all countenanced by these observations. Also, that in very heavy and continued rains the clouds are mostly below the summit of the mountain; but it frequently rains when they are entirely above it.” Dalton’s Meteorology, p. 40.

By comparing the parts of the above table, it is manifest that clouds are at an average higher in summer than in winter; and by analogy, we may conclude that clouds are higher in the torrid zone than in the temperate zones, and higher in these last than in the frigid zones. From the above observations it would seem, that the large, dense, opaque clouds seldom are found more than one mile elevated in this country; but the thickness of the cloudy stratum is unknown, and may perhaps be several hundred yards. Different strata of clouds are sometimes observed one above another, in summer especially. Small white streaks of cloud are sometimes seen at the elevation of three, four, five miles, or more. In these high regions, any condensation that can take place is probably insufficient to produce a cloud of great density or opacity.

Suspension of Clouds.—It appears to many people wonderful how large and dense clouds, consisting of drops of water, should be so long suspended in the air, as some of them seem to be, without materially descending; especially as water is 800 times the weight of air. This is to be explained on two principles: the one is, that bodies in a state of extreme division are much more resisted in their motion through the air, or any other fluid, than when in large portions. Gravity, or the force of descent, remains the same

whether the body is divided or not; but the surface increases with the division of the body, and the resistance increases with the surface. Hence it is that the extremely small drops, constituting clouds, fall very slowly, till they begin to coalesce or increase in size. The other principle is, that small drops falling into a stratum of air not saturated with vapour, are frequently resolved again into steam; thus, that part of the cloud which actually descends disappears; and it not unfrequently happens that the whole cloud vanishes in this way, being again converted into vapour, and blended with the general mass of the atmosphere.

Rain, Snow, Hail, and Dew.—Whenever two currents of air of different temperatures meet and intermix, each of which is previously near the point of saturation with vapour, or whenever a body of atmospheric air is suddenly cooled (as by the rarefaction occasioned by the stroke of an air-pump, or by opening the cock of a condensing engine), a cloud is formed, and a precipitation often ensues. The precipitation is in the form of rain if the temperature be above 32° Fahr., but in the form of snow if the temperature be below the said degree. Rain or snow is ordinarily observed in all latitudes; but in the torrid zone the latter is confined to the summits of the highest mountains. Hail is an extraordinary form in which the vapour is precipitated; it seems to arise from an inversion of the strata of the atmosphere, by which a cold stratum is placed beneath a warmer one, contrary to the general disposition of the atmosphere. Rain is formed in the upper stratum, and this falling through the under stratum is cooled and frozen, receiving at the same time a considerable accession from the condensation on the surfaces of the frozen drops. Hail-showers occur in all

METEOROLOGY.

seasons of the year, but more rarely in the summer months; they, however, sometimes accompany thunder in those months, and are peculiarly destructive and formidable. Hail seems to be confined principally to the temperate zones: it is probable that in this quarter of the globe hail is seldom observed, except between the parallels of 40° and 60° of latitude. It is more frequent in mountainous places than on plains; in the former hail-showers usually occur on five or six days of the year at an average.

Dew is formed when, instead of cold air mixing with warm, a cold solid or liquid body is presented to (comparatively) warm air. There exists a determinable temperature at all times, which is just capable of supporting the vapour of the atmosphere in an elastic state. (See *HYGROMETRY, on the Dew-point.*) If the temperature of the cold body be below this, then the vapour of the atmosphere is gradually condensed into water on its surface: this is a well-known phenomenon, and presented on various occasions. The dew on the grass and the hoar on walls after the breaking of a frost, are two of the more striking appearances of this kind.

Temperature of the Atmosphere.—This important subject has already been treated upon at large under the heads, *ATMOSPHERE, Temperature of the;* and *HEAT, in Geography,* to which we must therefore refer. There is, however, one remarkable character of the atmosphere, namely, that of the uniform decrease of temperature in ascending, which has never been satisfactorily explained. An ingenious essay on this subject has lately been published, from which we shall here give an extract.

“It is a remarkable fact, and has never, I believe, been satisfactorily accounted for, that the atmosphere in all places and seasons is found to decrease in temperature in proportion as we ascend, and nearly in an arithmetical progression. Sometimes the fact may have been otherwise, namely, that the air was colder at the surface of the earth than above, particularly at the breaking of a frost I have observed it so; but this is evidently the effect of great and extraordinary commotion in the atmosphere, and is at most of a very short duration. What then is the occasion of this diminution of temperature in ascending? Before this question can be solved, it may be proper to consider the defects of the common solution. Air, it is said, is not heated by the direct rays of the sun, which pass through it as a transparent medium, without producing any calorific effect, till they arrive at the surface of the earth. The earth being heated, communicates a portion to the contiguous atmosphere, whilst the superior strata, in proportion as they are more remote, receive less heat, forming a gradation of temperature, similar to what takes place along a bar of iron when one of its ends is heated.

“The first part of the above solution is probably correct: air, it should seem, is singular in regard to heat; it neither receives nor discharges it in a radiant state; if so, the propagation of heat through air must be effected by its conducting power, the same as in water. Now we know that heat applied to the under surface of a column of water is propagated upwards with great celerity, by the actual ascent of the heated particles: it is equally certain, too, that heated air ascends. From these observations it should follow, that the causes assigned above for the gradual change of temperature in a perpendicular column of the atmosphere, would apply directly to a state of temperature the very reverse of the fact; namely, to one in which the higher the ascent, or the more remote from the earth, the higher should be the temperature.

“Whether this reasoning be correct or not, it must, I think, be universally allowed, that the fact has not hitherto

received a satisfactory explanation. I conceive it to be one involving a new principle of heat; by which I mean a principle that no other phenomenon of nature presents us with, and which is not at present recognised as such. I shall endeavour in what follows to make out this position.

“The principle is this:—*The natural equilibrium of heat in an atmosphere, is when each atom of air in the same perpendicular column is possessed of the same quantity of heat; and, consequently, the natural equilibrium of heat in an atmosphere is when the temperature gradually diminishes in ascending.*

“That this is a just consequence cannot be denied, when we consider that air increases in its capacity for heat by rarefaction; when the quantity of heat is given or limited, therefore, the temperature must be regulated by the density.

“It is an established principle, that any body on the surface of the earth unequally heated is observed to tend constantly towards an equality of temperature: the new principle announced above, seems to suggest an exception to this law. But if it be examined, it can scarcely appear in that light. *Equality of heat and equality of temperature,* when applied to the same body in the same state, are found to uniformly to be associated together, that we scarcely think of making any distinction between the two expressions. No one would object to the commonly observed law being expressed in these terms: *When any body is unequally heated, the equilibrium is found to be restored when each particle of the body becomes in possession of the same quantity of heat.* Now the law thus expressed is what I apprehend to be the true general law, which applies to the atmosphere as well as to other bodies. It is an *equality of heat,* and not an *equality of temperature,* that nature tends to restore.

“The atmosphere, indeed, presents a striking peculiarity to us in regard to heat: we see in a perpendicular column of air, a body without any change of form, slowly and gradually changing its capacity for heat from a less to a greater; but all other bodies retain a uniform capacity throughout their substance.

“If it be asked why an equilibrium of heat should turn upon the equality in *quantity* rather than in *temperature*? I answer, that I do not know; but I rest the proof of it upon the fact of the inequality of temperature observed in ascending into the atmosphere. If the natural tendency of the atmosphere was to an equality of temperature, there does not appear to me any reason why the superior regions of the air should not be at least as warm as the inferior.

“The arguments already advanced on behalf of the principle we are endeavouring to establish, are powerfully corroborated by the following facts:—By the observations of Bouguer, Saussure, and Gay Lussac, we find that the temperature of the air at an elevation where its weight is $\frac{1}{2}$, that at the surface is about 50° Fahrenheit less than that at the surface; and from my experiments (*Manch. Memoirs, vol. v. p. 525.*) it appears that air being suddenly rarified from 2 to 1, produces 50° of cold. Whence we may infer, that a measure of air at the earth's surface being taken up to the height above-mentioned, preserving its original temperature, and suffered to expand, would become two measures, and be reduced to the same temperature as the surrounding air; or *vice versa*, if two measures of air at the proposed height were condensed into one measure, their temperature would be raised 50° , and they would become the same in density and temperature, as the like volume of air at the earth's surface. In like manner we may infer, that if a column of air from the earth's surface to the summit of the atmosphere were condensed, and brought into a horizontal position on the earth's surface, it would become

METEOROLOGY.

of the same density and temperature as the air around it, without receiving or parting with any heat whatever.

"Another important argument in favour of the theory here proposed, may be derived from the contemplation of an atmosphere of vapour. Suppose the present aerial atmosphere were to be annihilated, and one of steam or aqueous vapour were substituted in the place; and suppose, further, that the temperature of this atmosphere at the earth's surface were every where 212° , and its weight equal to thirty inches of mercury. Now at the elevation of about six miles the weight would be fifteen inches or one-half of that below, at twelve miles it would be 7.5 inches, or one quarter that at the surface, &c. and the temperature would probably diminish 25° degrees at each of these intervals. It could not diminish more; for we have seen (p. 14.) that a diminution of temperature of 25° reduces the force of vapour one-half; if, therefore, a greater reduction of temperature were to take place, the weight of the incumbent atmosphere would condense a portion of the vapour into water, and the general equilibrium would thus be disturbed perpetually from condensations in the upper regions. But if we suppose, on the other hand, that the diminution of temperature in each of these intervals is less than 25° , then the upper regions would admit of more vapour without condensation; but it must take place at the surface, because vapour at 212° cannot sustain more than the weight of thirty inches of mercury." Dalton's New System of Chemical Philosophy, p. 123.

Thunder and Lightning.—Of all the atmospherical phenomena there are none more awfully sublime than those of thunder and lightning. Respecting the nature and cause of these it would be useless to cite the opinions of ancient philosophers, as all our real knowledge on these subjects is derived from modern discoveries, and particularly those in electricity. Dr. Franklin ascertained the identity of lightning and electricity; since then the attention of philosophers has been directed to the inquiries, how the electric fluid or energy circulates from the earth to the air and back again to the earth; by what means it is raised into the atmosphere, how it becomes redundant, and how it is returned to the earth again. The aqueous vapour, or steam of the atmosphere, appears to be the vehicle. The dry and permanent elastic fluids have probably no more to do than as non-conductors of electricity to obstruct its passage through the atmosphere. When water is evaporated it takes along with it a greater quantity of electricity, as well as heat,

than it had before; that is, the capacity of vapour for electricity is greater than that of water. This fact has been observed by most of those who have, of late years, carefully attended to electrical phenomena. (See *Electricity of the Atmosphere*.) Of course when the steam is condensed into water, there must be a redundancy of electricity as well as of heat; and if the air be a non-conductor (as it undoubtedly is when dry), the drops of water, or the cloud formed, must be electrified positively. This is ascertained to be the fact; indeed it may be seen in the article above referred to, that the electricity of the atmosphere is almost universally positive. If, during a thunder-storm, and on some few other occasions, the atmosphere exhibit signs of negative electricity, it can scarcely be doubted that this is occasioned by the action of some superior cloud, which being positively electrified, makes the other, or the circumambient air, negative by induction, agreeably to the well-known law of electricity. The reason why the atmosphere cannot be negatively electrified is, that in the ordinary course of nature *no evaporation of water insulated by the atmosphere can ever take place*; the evaporation being always originally from the earth's surface. We have observed, indeed, that clouds are sometimes re-dissolved in the air; but then these clouds being insulated must have their excess of electricity about them, and consequently will not rob the atmosphere at large of any electricity that naturally belongs to it.

Conformably to these observations then, we may lay it down as an established maxim, that *the electricity of every cloud at its formation is positive*. It will remain then to be explained how the phenomena of thunder and lightning are to be accounted for on this position. One most obvious question occurs; if the electricity of one cloud find it expedient to force its way to the earth by a violent discharge, why is it not universally the case, and why are not thunder and lightning as frequent as clouds and rain?

Before this question can be satisfactorily answered, we must make ourselves acquainted with the circumstances that usually accompany thunder and lightning. It will be generally allowed, that the frequency of thunder and lightning, in this part of the world at least, is in proportion to the quantity of aqueous vapour in the atmosphere, or, which nearly amounts to the same thing, to the temperature of the air. The following extract from Dalton's *Meteorology*, being the result of five years' observations, will support this assertion. See pages 29 and 46.

	Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Mean temperature each month	37°	39°	39°	45°	51°	56°	57°	58°	53°	46°	41°	35°
Number of days when thunder was heard	1	0	0	3	7	5	12	7	4	2	0	1

In fact, thunder is very rare in winter, perhaps never known in frost, more frequent in spring and autumn; but it is in the months of May, June, July, August, and September, which are the warmest months in the year, that we usually expect, and have to record thunder-storms of any consequence or duration. Of these months, July, which is the middle of the series, is generally the warmest, and from the above statement appears pre-eminent for thunder-storms. It is further remarkable, that when thunder is observed in winter, it is *always during a low barometer, and an unusually warm vapoury state of the atmosphere*; also in summer, whenever the dew-point temperature arrives at a maximum for the season (that is, from 55° to 62° , or upwards), it is reduced for the most part by a thunder-storm and considerable rain. With regard to other climates, it is known that thunder is frequent and violent in low latitudes, and in all places where the extremes of heat and moisture are found;

but we do not often hear of its effects in high latitudes where neither heat nor moisture can be long prevalent. Whenever vapour is precipitated from the atmosphere by the causes we have already assigned, the quantity will be greater in proportion as the absolute quantity of aqueous vapour in the atmosphere is greater: this arises from the increase of vapour being in a geometrical progression to that of temperature in arithmetical progression. Rain, with the dew-point at 60° , will be twice as heavy, all other circumstances the same, as rain with the dew-point at 40° ; because there is twice as much steam in the air in the former case. It has already been observed, that the clouds are higher or more elevated above the surface of the earth in summer than in winter. From combining these observations we may, perhaps, obtain a satisfactory reason for thunder not accompanying every cloud and shower of rain. In winter the clouds are low, less dense, and consequently less

METEOROLOGY.

electric, than in summer; their electricity silently and slowly steals away to the earth's surface. In summer the intensity of the electricity is double, in consequence of its quantity being as the vapour condensed, and it is more removed from the earth, or insulated by its superior altitude; hence its energy may be so far increased as to overcome the resistance of the air. Thus, if an imperfectly rounded ball be presented at a proper distance from the conductor of an electrical machine, it will slowly and silently draw off the electricity; but if the intensity of the electricity be increased sufficiently, nearly the whole will come away in an instant in the shape of a dense spark, with a snapping noise.

There is another circumstance which probably has considerable influence in giving a highly vapourized air its character for favouring thunder. It admits of several strata of clouds arranged one beneath another, which will operate like the series of plates in the Voltaic pile in increasing the intensity of their electric charge. This disposition cannot well occur in winter, as the higher air is too deficient in vapour to spare an adequate quantity for the purpose.

One very remarkable character of thunder has not been duly noticed by philosophers; that is, the long continuance of each single peal. It may, perhaps, be safely asserted, that the duration of a peal of thunder is at an average about twenty seconds; it is certainly longer in many instances. Now, as the flash of lightning is instantaneous, we have no rational method of explaining the continuance of the sound, but by supposing the discharge to extend for a great many miles; if the sound continue half a minute, the discharge cannot be less than through the space of seven miles, but may be twice as much, or more. How, then, is this great length of the discharge to be explained? In order to meet this question, we may remark, that clear air is a bad conductor of electricity, but that clouded air possesses a kind of middle quality, of being neither a good conductor, nor a good non-conductor. We may suppose that the same electric energy which forces a way through 100 yards of clear air, may be capable of forcing a way through 10,000 yards of densely-clouded air. Hence we may account for the long continuance of thunder, by supposing that the electricity of a superior cloudy stratum strikes an inferior stratum at the nearest point, and runs along it for a number of miles. The sound arrives at the ear from the nearest point of the course first, and afterwards successively from the more remote points, and thus occasions the continuance of the sound. This view of the subject is corroborated by the observation, that whenever a clap of thunder is noticed to be remarkably near, or to succeed the flash immediately, by one inhabitant of any large town, it is noticed in like manner by most of the other inhabitants, though situate some miles distant from each other.

Thunder may be heard to the distance of ten or fifteen miles, but seldom further; this is ascertained from a calculation of the velocity of sound during the interval between the flash and the report in a dark night. It is uncertain to what distance lightning may be seen; we sometimes see it in the night when no clouds are visible; in this case it must be at a great distance, perhaps one or two hundred miles, or more. In such cases the flashes are observed to be much more frequent than when the thunder is near; this seems to indicate that in the latter instance we do not perceive all the lightning of the storm.

Causes of the Variation of the Barometer.—One of the most difficult problems in meteorology is to assign the causes for the daily changes in the weight of the atmosphere. Various opinions have been held with regard to these causes, many of which are too futile to merit animadversion. This sub-

ject has already received an ample discussion under the head *BAROMETER, Cause of the Phenomena of*, so that we shall be brief on the present occasion. It may be proper, in the first place, to state the leading facts: namely, that the variation of the barometer is least in the torrid zone, and is greater, as we proceed thence northward or southward; that in the temperate and frigid zones, the variation is always greater in winter than in summer. We shall take for granted that the whole atmosphere of the earth continues the same in quantity, and that the variations of the barometer arise from unequal distribution of the atmosphere, and not from any generation or destruction of elastic fluids. We shall also take for granted that any changes in the aqueous vapour of the atmosphere are insufficient to explain the phenomena, because if the whole quantity of aqueous vapour in the atmosphere were withdrawn from any place on any occasion, it would not depress the barometer one quarter of what is frequently observed in high northern latitudes in winter.

Mr. Kirwan's idea that the atmosphere is higher over the equator than over the poles, owing to the difference of temperature in those two regions, and that the currents occasioned thereby are instrumental in producing the changes of the barometer, is certainly entitled to our consideration. On this principle Mr. Dalton has constructed a table to shew the relative heights of the barometer at given elevations over the equator, the north of England, and the north pole. (*Meteorology*, page 83.) "The mean heat at the earth's surface under the equator is supposed 84° ; the mean heat in these parts for the hottest month of summer at 60° , and for the coldest month of winter at 35° . The mean annual temperature at the north pole being supposed 31° , the mean temperature for the coldest month of winter at that place may perhaps be stated at 2."

Elevation of the Barometer above the Level of the Sea in English Miles.	Height of the mercurial Column of the Barometer in Inches.			
	Above the Equator.	Above the North of England.		Above the North Pole.
		In Summer.	In Winter.	In Winter.
0	30.00	30.00	30.00	30.00
2	20.55	20.10	19.58	18.81
4	13.61	12.96	12.24	11.19
6	8.66	7.98	7.26	6.24
8	5.25	4.65	4.03	3.19
10	3.00	2.52	2.05	1.45
12	1.58	1.24	.93	.56

From this table it should seem, that the weight of air in a vertical column of six miles over the equator is nearly equal to that of a column of five miles over the pole in winter: that is, the heights of the atmosphere at the equator and pole are as 6 to 5 nearly. But the relation between the equator and the north of England in this respect, in summer is as 16 to 15, and in winter as 8 to 7 nearly. Now when the variations in the altitudes are greatest (in winter), the energy or velocity of the great northern and southern currents of air is greatest, as has been shewn above on winds, and therefore the irregularities occasioned by the interference, &c. of these currents must then be also at their greatest. These irregularities are shewn by the barometer. If we were to suppose that, from some extraordinary incidents, the atmosphere over the north of Eng-

land in winter were raised to the same elevation as that over the equator, all other circumstances being the same, the barometer must rise nearly four inches; and it would sink four inches if the atmosphere were depressed as much below the mean. But this supposition is much too extravagant to be admitted, and indeed the facts do not call for any thing near it. The barometer rarely rises or falls more than one and a half inch from the mean in this country; and consequently a slight variation of the mean altitude of the atmosphere is all that is required, and such may well be admitted.

Besides this variation of the mean altitude of the atmosphere, Mr. Dalton thinks there is another cause that acts in combination with it to produce the extraordinary falls of the barometer in winter, (which are observed to go below the mean more than the rises go above it.) He supposes, that during a violent S.W. wind on the occasion of a thaw (at which time the minimum usually takes place), a temporary change in the law of temperature in ascending exists. That the temperature in ascending is then more nearly uniform than at other times; by which means the elasticity in the lateral directions will be equal to any force that may be opposed, whilst the weight of a vertical column will be less than otherwise. See Meteorology, page 109.

For further information on meteorology, see ANEMOMETER, ATMOSPHERE, BAROMETER, CLOUD, DEW, EVAPORATION, FOG, HAIL, HYGROMETRY, LIGHTNING, METEOR, RAIN, SNOW, THERMOMETER, THUNDER, WIND, &c.

METEOROMANCY, a species of divination by meteors principally by lightning and thunder: this method of divination passed from the Tuscans to the Romans, with whom, as Seneca informs us, it was held in high esteem.

METEOROS, *μετεωρος*, from *μετα*, and *αυρα*, to elevate, in *Medicine*, elevated, suspended, sublime, erect, tumid. Thus *μετεωρα αλγυρα*, are expounded by Galen, Com. ad. Aph. 7. lib. vi. sublime pains: those which are above the peritonæum, or affect the superficial and external parts of the body. These pains are opposed to such as are deeply seated, and called *τα μη μετεωρα*, not sublime, but deep, and seated within the peritonæum.

METEOROSCOPE, from *μετεωρος*, high, and *σκοπος*, of *σκοπεωμαι*, I pierce, observe, a name which the ancient mathematicians gave to such instruments as they used for observing and determining the distances, magnitudes, and places of the heavenly bodies; many of which they regarded as meteors.

The name, however, may much more properly be applied to meteorological instruments.

METEPEC, in *Geography*, a town in the province of Mexico.

METERISCH, a town of Moravia, in the circle of Iglau; 17 miles E. of Iglau.

METESSIB, an officer of the eastern nation, who has the care and oversight of all the public weights and measures, and sees that things are made justly according to them.

METEYARD, in *Rural Economy*, a term applied to a flax or beam of a certain length for taking measures.

METEZAU, CLEMENT, in *Biography*, a celebrated French architect, who flourished in the former part of the 17th century, was a native of Dreux, but settled at Paris, became architect to Lewis XIII., and acquired much fame by carrying into execution, with Tiriot, a Parisian mason, the plan suggested by cardinal Richelieu for reducing Rochelle, by means of an immense dyke, in imitation of what Cæsar had done at Durazzo, and Alexander the Great at Tyre.

This scheme was to run a solid wall across a gulf upwards of 740 fathoms, or more than three quarters of a mile broad, into which the sea rolled with great force, and when the wind was high, with an impetuosity which seemed to set at defiance the art of man. Those who had undertaken the business were not to be turned aside by any obstacles: they began, by throwing in huge rocks, to lay a kind of foundation; upon these were placed vast stones, cemented by the mud thrown up by the sea. These were supported by immense beams, driven into the bottom with incredible labour. It was raised so high, that the soldiers were not incommoded by the water, even at spring tides. The platform was nearly 30 feet wide, and 90 feet at the foundation. At each extremity there was a strong fort, in the middle there was an open passage of 150 paces, several vessels being sunk immediately before it, together with high stakes in a double row, and before these 35 vessels linked together, so as to form a kind of floating pallisade. This amazing dyke was completed in somewhat less than six months, and proved the principal means of occasioning the surrender of the city. So honourable were the exertions of M. Metzau in this business, that his portrait was circulated widely through France, to which were attached the following lines,

“ Dicitur Archimedes Terram potuisse movere:
Æquora qui potuit siltare, non minor est.”

METH, METI, or *Mott*, in *Geography*, a small island near the coast of Africa, at the entrance of Babelmandeb, with a town upon it. N. lat. 11° 15'. E. long. 48° 45'.

METHANA, a town of the Morea, near the coast of the gulf of Engia; 56 miles E.S.E. of Napoli di Romania.

METHEGLIN, a drink prepared of honey; one of the most pleasant and general drinks the northern parts of Europe afford; and much used among the ancient inhabitants.

The word is Welsh, *meddyglin*, in which it signifies the same. There are divers ways of making it; one of the best of which follows: put as much new honey, naturally running from the comb, into spring water, as that, when the honey is thoroughly dissolved, an egg will not sink to the bottom, but be just suspended in it; boil this liquor for an hour, or more, till such time as the egg swim above the liquor about the breadth of a groat; when very cool, next morning, it may be barrelled up; adding to each fifteen gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all grossly pounded: a spoonful of yeast may be also added at the bung-hole, to promote the fermentation. When it has done working, it may be closely stopped up; and, after it has stood a month, it should be drawn off into bottles. See MEAD.

METHO, in *Geography*, a small independent country of Africa, S.E. of Fittre.—Also, a town of the Morea; 34 miles E.S.E. of Napoli di Romania.

METHOD, METHODUS, from *μεθοδος*, in *Logic* and *Rhetoric*, the art or rule of disposing things in such a manner, as that they may be easily comprehended; either in order to discover the truth, of which we ourselves are ignorant; or to shew or demonstrate it to others when known, or to fix it in the memory. See DISPOSITION.

Gassendus distributes method, with regard to its object, into three kinds, or branches, *viz.* inventionis, *the method of invention*, or discovering a truth unknown.

Methodus judicii, the method of judging or determining of a truth, or position, proposed.

And

And *methodus demonstrationis*, or method of demonstration; that is, of exhibiting it to another.

Method is distributed by others into two general kinds, *viz.* *natural* and *arbitrary*. *Natural* method is that which observes the order of nature, and proceeds in such a manner, as that the knowledge of things which follow depends in a great measure on the things which go before. *Arbitrary* method leaves the order of nature, and accommodates itself to many purposes: as to treasure up things, and retain them in the memory; to harangue and persuade mankind to any practice in the religious or civil life; or to delight, amuse, or entertain the mind. This kind of method is chiefly pursued in poetry and oratory.

Natural method is again subdivided into two kinds; the one of *resolution*, which is that we generally use in our enquiry after truth. The other of *composition*, by which the truth, once found, is taught or imparted to others.

In the method of *resolution*, called also by geometers the *analytic* method, we proceed from some general known truths to others, which belong to some particular or singular thing.

In the *method of composition*, called also the *synthetic* method, we propose some certain general truths, from which we produce particular truths.

If, in the method of resolution, we lay down any axioms, it is not immediately in the beginning, and all together, but as they are found necessary in the disquisition: on the contrary, in the method of composition, they are proposed all together in the beginning, before there is any absolute need of them.

The two methods differ from each other, as the methods of searching out a genealogy, either by descending from the ancestors to their posterity, or by ascending from the posterity to the ancestors: both of them have this in common, that their progression is from a thing known to another unknown. Those things that are known in each are set in the front, or first place, that by them we may be able to arrive at those which are not known.

Dr. Watts, in his excellent Treatise on Logic, has comprised the general requisites of true method in the pursuit or communication of knowledge, under the following heads. It must be, 1. Safe or secure from error: in order to which great care should be used in laying the foundations of a discourse, or the scheme of our thoughts, on any subject; the primary and fundamental propositions should not only be evident and true, but made familiar to the mind by dwelling on them before we proceed farther; our ground should be made firm in every step; and we should draw up all our propositions and arguments with so much caution, and express our ideas with such a just limitation, as may preclude or anticipate any objections. 2. Plain and easy: for which purpose, we should begin always with those things that are best known and most obvious, and proceed by regular and easy steps to things that are more difficult; nor should we affect excessive haste in learning or teaching any science, nor hurry at once into the midst of it; nor again crowd too many thoughts and reasonings into one sentence or paragraph, beyond the apprehension or capacity of our readers or hearers; we should also avoid too many subdivisions; and acquire in early life a clear and easy way of expressing our conceptions. 3. Distinct: in order to which no needless heterogeneous matter should be introduced; every complicated theme or idea should be divided into its distinct single parts, as far as the nature of the subject, and our present design, require; we should call every idea, proposition, and argument, to its proper class, and keep each part of the subject in its own place; and in

the partition of our discourse into distinct heads, take heed that particulars do not interfere with the general, nor with each other. 4. Full, or without defect: and this is necessary in explaining a subject; in enumerating its parts or properties; in asserting or proving any truth; in illustrating or arguing a point of difficulty; in drawing up a narrative; and in solving any difficulty. 5. Short, or without superfluity: for this purpose, all needless repetitions, tedious prolixity, long parentheses, useless explications, proofs, and refutations, and all scholastic forms, should be carefully avoided. 6. Proper to the subject, the design, and the age and place in which we dwell. 7. Connected: in order to this, we should keep our main design always in view, and preserve an apparent tendency in all the parts of our discourse towards it; the mutual relation and dependence of the several branches of our discourse should be so just and evident, that every part may lead onward to the next; and we should acquaint ourselves with all the proper and decent forms of transition from one part of the discourse to another, and practise them as occasion offers.

The *synthetic* method is only practicable in things whose principles we perfectly know; as in geometry, which is wholly employed in the consideration of abstract modes, of which our mind has clear and adequate ideas. When the inquiry is into substances, as in physics, we cannot make use of the method of *composition*, because their kinds and intimate essences are unknown to us.

This method has not been by any so justly and accurately observed as by the mathematicians, whose principles are perfectly known: its laws, therefore, will be best drawn from their practice; for which, see COMPOSITION.

The supreme law of the philosophical method is, to premise that which is necessary towards the understanding or establishing what follows.

The mathematical and philosophical methods are the same, as may be seen by the practice of the geometers of antiquity, who constantly observe the law here mentioned.

Several authors, as Ramus, Messrs. de Port-Royal, &c. have accused Euclid of want of method. Had these gentlemen attended to the supreme law of all true method, they would have been more cautious in their censures.

METHOD, *Methodus*, is more particularly used, in *Mathematics*, for divers particular processes for solving problems. In this sense we say,

METHOD of *Exhaustions*. See EXHAUSTIONS.

METHOD of *Fluxions*. See FLUXIONS.

METHOD de *Maximis & Minimis*, &c. See MAXIMA, &c.

METHOD of *Tangents*. See TANGENTS.

METHOD *Differential*, &c. See DIFFERENTIAL.

METHOD *Exponential*. See EXPONENTIAL.

METHOD *Poristic*. See PORISTIC.

METHODIC SECT. See METHODISTS, and MEDICINE, *History of*.

METHODISTS, in *Ecclesiastical History*, is a denomination applied to different sects, both Papists and Protestants.

The *Papish* Methodists were those polemical doctors, of whom the most eminent arose in France towards the middle of the seventeenth century, in opposition to the Huguenots or Protestants. The Methodists, from their different manner of treating the controversy with their opponents, may be divided into two classes. The one may comprehend those doctors, whose method of disputing with the Protestants was disingenuous and unreasonable, and who followed the examples of those military chiefs, who shut up their troops in intrenchments and strong holds, in order to cover them from the attacks of the enemy. Of this number were the Jesuit Veron, who required the Protestants to prove the tenets

METHODISTS.

tenets of their church by plain passages of scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihufius, an apostate from the Protestant religion; the two Walenburgs, and others, who confined themselves to the business of answering objections and repelling attacks; and cardinal Richelieu, who restricted the whole controversy to the single article of the divine institution and authority of the church. The Methodists of the second class were of opinion, that the most expedient manner of reducing the Protestants to silence, was not to attack them partially, but to overwhelm them at once, by the weight of some general principle or presumption, some universal argument, which comprehended, or might be applied to all the points contested between the two churches: thus imitating the conduct of those military leaders, who, instead of spending their time and strength in sieges and skirmishes, endeavour to put an end to the war by a general and decisive action. These polemics rested the defence of popery upon prescription; the wicked lives of Protestant princes who had left the church of Rome; the crime of religious schism; the variety of opinions among Protestants, with regard to doctrine and discipline; and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicole, the Jansenist doctor, the famous Bossuet, &c. *Mosh. Eccl. Hist.* vol. v. 8vo.

The *Protestant* Methodists form a very considerable class, principally of the lower people in this country. They sprung up about the year 1729, at Oxford, and were soon divided into two parties, the one under the direction of the two brothers, John and Charles Wesley, and the other under that of Mr. George Whitefield, who joined them in the year 1735. These leaders, and, if we except Mr. William Law, the celebrated mystic, founders of Methodism, were educated at Oxford, and received episcopal ordination; and always professed themselves advocates for the articles and liturgy of the established church: though they commonly practised the dissenting mode of worship. The appellation of Methodists is said to have been derived from the regular distribution of their time, their orderly and composed demeanour, and the supposed purity of their religious principles. Conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impelled to a very considerable degree by a zeal of an enthusiastic and extravagant kind, they became itinerant preachers, and, being excluded from most of our churches, exercised their ministry in private houses, fields, &c. not only in Great Britain and Ireland, but also in America: thus collecting a very considerable number of hearers and proselytes, both amongst the members of the established church and the dissenters. The theological system of Mr. Whitefield and his followers is Calvinistic: that of Mr. Wesley and his disciples, Arminian; and the latter maintain the possibility of attaining sinless perfection in the present state. The subordinate teachers of both these classes of Methodists are generally men of no liberal education, and they pretend to derive their ministerial abilities from special communications of the spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings, which it is impossible to explain, but which, when analysed, seem to be mechanical in their spring and operation, and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or by the aids of learning, but by laying their minds open to the direction and influence of divine illumination: and their conduct has been directed by impulses.

Such is the account given of the followers of Whitefield in *Mosheim's Eccl. Hist.* translated by Dr. Maclaine (vol. vi. p. 36. ed. 1811, 8vo.); but though it may be true in general, as comprehending Methodists of both descriptions, at their first rise and in their early progress, it admits, in the present state of this sect, of many exceptions; and it would be unjust and unandid to charge upon a whole body of Christians, respectable both as to number and character, the errors in sentiment and irregularities in practice, into which the excesses of enthusiasm may have betrayed some of their number. Much as we may disapprove these errors and irregularities, truth requires us to declare from our own knowledge, that those who have passed under the denomination of Methodists have been eminently useful in awakening into consideration the unthinking, and in restraining the profligate, among the lower classes of mankind. We perceive with satisfaction a change of conduct: the idle and dissolute have become diligent and virtuous; religion finds votaries among those who were accustomed to treat it with neglect and contempt; the state of families has been amended, and the community in general, composed of individuals and of domestic associations, has derived benefit from the assiduity and zeal of the Methodists. We look forward with pleasure to a period, when, by the diffusion of knowledge among persons in the inferior stations of life, many of those who are now deemed erroneous enthusiasts will become enlightened, rational, and exemplary Christians. Having rendered this tribute of justice to the Methodists in general, we shall now proceed to give a more particular and detailed account of the two leading classes into which they have been divided.

The opinions of Mr. Whitefield, which we have already stated to have been Calvinistic, as well as his piety, recommended him to the notice of a devout peeress, the countess dowager of Huntingdon, who became his patron, and liberally promoted the erection of meeting-houses for the Calvinistic Methodists; and when her preachers could not obtain episcopal ordination, established a college at Trevecca, in Breconshire, not far from Brecknock, for the education of ministers in the Whitefieldian connection. This seminary, not being endowed, expired with the countess; but a new one was soon after established at Cheshunt, which has furnished the Methodists of this description with useful preachers.

We may here observe, that the proselytes of Whitefield were less numerous than those of Wesley; and that their association was less compact. Their ministers and places of worship were respectively supported by the different congregations, aided for a time by the liberality of the countess above-mentioned and her friends in the higher ranks of life; not, like those of the Wesleyan sect, by a general fund. The former had no annual assembly for the government of the whole body; but the latter had a regular session, under the name of a "Conference," in which the affairs and the circumstances of the confederacy were investigated, funds provided, abuses corrected, and grievances redressed. This meeting was composed of preachers chosen by the assemblies of different "districts" as representatives of the Methodist connection, and of the superintendants of the "circuits," or inferior divisions. It was at first limited to 100 of the senior itinerant preachers; but, in process of time, all the preachers were permitted to assist, if they were so inclined, or had an opportunity of attending. At first, laymen were allowed to preach; but ministers were afterwards ordained for that purpose by the clerical heads of the society. Our readers hardly need to be informed, that Wesley and some of his associates had taken orders in the church of England; and this circumstance increased their ministerial respectability in the general estimation; but it gave them no additional importance

METHODISTS.

importance in the opinion of the peculiar votaries of this connection, who were disposed to listen with profound attention to the effusions of the lowest and most illiterate mechanics. Mr. Wesley, speaking of these unlettered men, affirmed, that they had "help from God for that great work, the saving of souls from death, since he had enabled, and did enable them still, to turn many to righteousness.—Thus hath he destroyed the wisdom of the wise, and brought to nought the understanding of the prudent." Mr. Wesley introduced among his followers "agapæ," or love-meetings. Once in every quarter of a year, after the religious service of the day, a considerable number of persons, of both sexes, "broke bread" with each other. Alms were then collected for the poor members of the society. At these meetings the preachers and others related their respective "experience," and the service was enlivened by hymns, which were sung at certain intervals. These love-feasts were derived from the Moravians, with whom Mr. Wesley at first associated, but whose communion he soon renounced. In order to counteract the misconceptions which some persons might form of the character of the Methodists, Mr. Wesley stated the "distinguishing marks" of his followers. These marks, he said, were to be found, not in "their opinions of any sort," in their words and phrases, or in any desire of being "distinguished by actions, customs, or usages, of an indifferent nature, undetermined by the word of God;" nor did they lay the whole stress of religion upon any single part of it. But they were distinguished by having the love of God shed abroad in their hearts, by being always happy in God, ever resting on him, giving thanks for every thing, praying constantly with earnestness and fervour; by purifying their hearts from the lust of the flesh and of the eye, from envy and malice, from pride and petulance; by doing kind offices to neighbours and strangers, to friends and enemies; and by other fruits of a "living faith." Nothing, he added, was required by St. Paul but the faith here mentioned. By that alone could any one be justified, or accounted righteous before God; and the remission of sins could only be obtained through the merits of Christ, not by the good works or supposed deserts of individuals. Holiness of heart and life would flow from such faith; but good deeds without it would be inoperative and nugatory. No man could produce it in himself, as it was the work of omnipotence. It was the free gift of God to those who were before "ungodly and unholy, and fit only for everlasting destruction." He who received it was born again, yet was not so perfectly regenerate, as to be fully sanctified; for there would still be some struggles between the old and the new man, which would not cease before the Holy Spirit had given to the zealous Christian "a new and clean heart." He would then attain the "acmé" of sanctification, and be qualified for the society of "just men made perfect."

Among these Methodists dissentions existed at the time of the decease of their founder; but an interval of six years elapsed before their difference of sentiment produced an actual separation. The liberties of their church, and the rights of the people, formed the grounds of dispute. On pretence of giving due support to the plan of itinerancy, some leading ministers had endeavoured to obtain an exorbitant degree of power over the community and junior preachers; and they managed the conference in a way which tended to secure this power. Disgusted at these arbitrary proceedings, Mr. Kilham, and other members of the sect, applied to the general assembly for a redress of grievances, and for an admission of the laity to a proper share in the general government of the society. Repeated applications and remonstrances being wholly fruitless, and

Mr. Kilham being expelled from the fraternity by the ruling party, about 5000 discontented members seceded from the connection in the year 1797, and formed independent arrangements on a popular basis. Another body of seceders, assuming the uncouth appellation of "Christian Revivalists," "claimed," says an historian of the Wesleyan sect, "a right to indulge their propensities to prayer and praise, at all times, and on all occasions." See Nightingale's "Portraiture of Methodism," cited in the last edition of Mosheim's Eccl. Hist. by Dr. Coote, vol. vi. p. 308—315. 8vo.

Before we close this article, we shall observe that Methodists of both descriptions are, in general, members of the established church; though they have been erroneously confounded with Protestant dissenters. Mr. Wesley would never allow of a separate communion, and required his followers to frequent the established church, when they had no opportunity of hearing their own preachers, and there to communicate. Of late, indeed, some alteration has taken place in this respect; and parties of the Wesleyans approach more nearly in principles and practice to Protestant dissenters. It is also well known, that the Methodists in Mr. Whitefield's connection, though intermixed with many who call themselves Dissenters, belonged for the most part to the church; and their more general departure from it was occasioned, when, at the request of the pious countess above-mentioned, episcopal ordination was refused to her ministers. Few of them yet understand or adopt the discriminating principles of Dissenters. The ministers, who have been qualified for the exercise of their functions by ordination according to the rites of the church, and who still continue in it, are in popular language called Methodists, or now, more generally, *evangelical* clergy; an appellation appropriating to themselves a distinguishing and peculiar character, which others of their own body are not disposed to allow them, and which, as some of them say, is, with respect to their sentiments and preaching, invidious and degrading. It is our province, in a work of this nature, to state facts and opinions justly and candidly as far as we are able; and we leave contending parties, both *in* and *out* of the church, to settle their differences among themselves.

METHODISTS, in *Medical History*, a title assumed by a sect of physicians at Rome, in order to distinguish themselves from the two opposite sects, the Empirics and Dogmatists, (see EMPIRIC,) with either of which they refused to arrange themselves. The Methodist physicians, as Celsus informs us, generally considered Themison as their founder, who was followed as a leader by Theophilus, and afterwards by Soranus of Alexandria, the last of whom practised at Rome, during the reigns of Trajan and Hadrian. A bold charlatan, Aesclepiades, who settled at Rome about the time of the Mithridatic war, was the first, however, who maintained the principles adopted by this sect. Borrowing the doctrine of atoms laid down by Epicurus, he attempted to account for all diseases upon the obstruction to the circulation of the atoms, occasioned by two opposite states of the system, which he denominated *strictum* and *laxum*, or states of constriction and relaxation. Every disease, which exhibited obvious marks of retention, or appearances of hardness, tumefaction, or external inflammation, was ascribed to the state of constriction; and the opposite phenomena of augmented discharges, softness and diminution of bulk, to the condition of laxity. This doctrine became popular, partly in consequence of the self-confidence of its professors, and the loudness of their declamation against former systems, and partly from the precision and formality of the regimen which they prescribed: and its progress was, perhaps, not
a little

a little aided by the simplicity with which it seemed to explain all the phenomena of disease, and by the indulgence which it sanctioned in the practitioner; inasmuch as it rendered all nice discrimination of symptoms, and particular investigation of local disease, unnecessary. It was enough to ascertain the class in which any disease was to be arranged, and the general treatment would serve for all; the observation both of exciting and of proximate causes was deemed entirely superfluous. "As soon as it was known," says Celsus, "to which of these classes a disease belonged, if the body were bound, it must be opened; if it laboured under a flux, it must be restrained; and if it were of a mixed nature, the most urgent remedy must be first opposed." For they were obliged to admit, in some cases, the insensibility of both *stricture* and *luxum* occurring at the same time, in different organs of the body.

The absurdity of founding the practice of medicine upon these very general principles has been pointed out, with his usual force, by Celsus. He considered the Methodists as even below the Empirics, in the accuracy of their practical views: since the Empirics attended to many circumstances of a disease, while the Methodists only observed the most obvious, and even the most common appearances. Like the farriers, who superintend the diseases of sheep and cattle, but cannot learn from these dumb animals the peculiar symptoms of their complaints, they regard only a few, which are common to all. "Neque adjectum quicquam Empiricorum professioni, sed demum est; quoniam illi multa circumspiciunt, hi tantum facillima, et non plus quam vulgaria. Nam et hi, qui pecoribus ac pimentis medentur, cum propria e jusque ex mutis animalibus nosse non possint, communibus tantummodo insillunt." (Cels. de Medicina. *Præf.*) This intelligent writer then goes on to shew the insufficiency of such general indications in practice. In the state of laxity, for instance, he remarks, "it is one thing to vomit bile, another to vomit blood, and another to reject the food; and there is much difference between a simple purging, and one attended with tormina; *i. e.* between a mere diarrhœa and a dysentery; and likewise between a waiting from profuse sweats, and a mere marasmus. And not one of these complaints is to be cured exactly in the same manner as another."

We have already pointed out the similarity between this doctrine and that of the Brunonian system, which has been the cause of much controversy in our own times; the distinguishing features of which were, the reference of all diseases to two opposite conditions of the constitution, *spbenia* and *asthenia*, or strength and debility, (which might with almost equal propriety have been called *strictum* and *luxum*.) and the consequent exclusion of all particular investigation of the minute distinctions in the phenomena of diseases, which it encouraged. See *MEDICINE, History of*.

The practice of the Methodists was particularly distinguished by their rejection of purgative medicines; by their rigid and formal regimen, especially in the methodical abstinence which they enforced for a certain number of days; and by their copious use of warm ablutions, fomentations, cataplasms, and frictions with oil, together with free bleeding, in diseases ascribed to stricture; and a similar routine with cold drinks, and cold and corrugating applications, in disorders attributed to laxity. An epitome of *methodic* medicine has been handed down by Cælius Aurelianus, who translated the original work of Soranus, which is lost. See his treatise "De Morbis Acutis et Chronicis:"—also Le Clerc Hist. de la Médecine; Walker's Memoirs of Medicine.

METHODIUS, in *Biography*, a Christian bishop and

martyr, who flourished towards the close of the third century; and unless there were two of the same name, who lived about this period, he was bishop of several places, *viz.* of Olympus, in Lycia, of Tyre, and of Patara, &c. He is not mentioned by Eusebius in his Ecclesiastical History, which has been ascribed, yet without probability, to his resentment against him for having written with severity against Origen, of whom, it is known, that Eusebius was a great admirer. There were two opinions concerning the death of this prelate; some say he suffered under Decius, or Valerian, and others contend, that he was one of those who suffered in Dioclesian's persecution. He is highly applauded by Epiphanius, Jerome, and others, by whom he is characterized as a learned and eloquent man, and a zealous defender of the truth. Lardner has given a pretty full account of his works, for which we refer to the third volume of the 8vo edition, 1783. This learned and candid critic says, that in the Remains of Methodius there are many interpretations of texts of scripture, which, in his opinion, do little honour to the author's judgment, and he gives instances in proof of this decision. Dr Lardner likewise observes, that the Remains of Methodius clearly prove, that he admitted into the canon of the holy scriptures the four gospels, the acts of the Apostles, the epistles of St. Paul, and the epistle to the Hebrews as one of them. He also owned as authentic the first epistle of St. Peter, and the first of St. John. His opinion about the rest is not known. He quotes the Revelations as a book of sacred scripture, written by John, whom he probably regarded as the apostle and evangelist. Lardner.

METHODIUS, surnamed the *Confessor*, who flourished about the middle of the ninth century, was born at Syracuse. Having received a good education, he went to Constantinople, where he embraced a religious life, and took up his residence in a monastery at the isle of Chios. He was afterwards ordained priest by the patriarch Nicephorus, and upon the expulsion of that prelate from the see of Constantinople, was sent by him to Rome to implore assistance from pope Paschal in his behalf. Upon his return to Greece, after the death of that patriarch, he signalized himself by his zeal for image-worship, on which account he was committed to prison, and endured many indignities for several years. He recovered his liberty completely in the year 842, and was in a short time preferred to the patriarchate of the church of Constantinople. As soon as he was quietly settled in his see, he introduced the superstition of image-worship into the Greek church. Methodius died in the year 847. He was author of several works, among which was a "Constitution, or Manual for Persons who, after having apostatized, returned again to the Profession of the Christian Faith." Moreri. Mosheim's Eccl. Hist.

METHONICA, in *Botany*, Just. 48. Herm. Lugd. Bat. 688. t. 689, the Malabar name of the Superb Lily. See GLORIOSA.

METHUEN, in *Geography*, a town of America, in Essex county, Massachusetts, on the N. bank of Merrimack river, between Dracut and Haverhill. It contains two parishes and 1253 inhabitants.

METHULLY, a town of Hindoostan, in Guzerat; 15 miles S.W. of Gogo.

METHWOLD, a small market-town in the hundred of Grimshoe and county of Norfolk, England, is situated four miles from Stoke Ferry, and 86 from London. It derived its name from its site, and was anciently written Methelwalde, or Midlewolde, being the wold between Northwolde and Hockwolde. The church, which appears to have been built in the reign of Edward II., is a regular edifice with

a nave, aisles, and chancel. At the west end of the nave is a square tower, embattled; on this is raised another tower of an octangular shape; and from the latter rises a spire. The population of Mettwold in the year 1801, according to the return then made to parliament, was 865, occupying 134 houses. The market, which is kept on Tuesdays, was formerly considerable, but is now almost difused: an annual fair is held on St. George's day. The town has been, from time immemorial, proverbially famous for its extensive rabbit warrens.

In this parish stood Stevesholm or Shisham priory, which was given by William earl of Warren, in the reign of king Stephen, as a cell to the priory of Castle Acre. At the dissolution it was granted to the family of Mundeford, and was afterwards conveyed to that of Seabright. Blomefield's History of Norfolk, vol. ii. Beauties of England, vol. xi. by J. Britton.

METI, a town of Abyssinia, near the coast of the Red sea. N. lat. $13^{\circ} 30'$. E. long. $42^{\circ} 30'$.

METIMCUS, two islands of America, near the coast of Main. N. lat. $43^{\circ} 50'$. W. long. $68^{\circ} 15'$.

METIMIN, a town of Ruffia, near the Pacific ocean. N. lat. $64^{\circ} 55'$. E. long. $180^{\circ} 34'$.

METITCHE, or ΜΕΤΤΙΧΙΑΙ, a plain in the territory of the city of Algiers, which commences about half a mile N.E. of the city and stretches 50 English miles in length, and 20 in breadth, as far as the branch of mount Atlas, at the foot of which lies the town of "Belida." This plain is well cultivated and well watered, and is in this respect superior to the other districts of the kingdom. It is justly reckoned, as Shaw says, the garden of the whole kingdom.

METIUS, ADRIAN, in *Biography*, a celebrated Dutch mathematician, who flourished in the 16th and 17th centuries, was a native of Alkmaer. He pursued his studies at a German university, where he afterwards taught the mathematics with great reputation for several years, and afterwards became professor of those sciences at the university of Franeker. He was author of several books on spherics, astronomy, and arithmetic. He had a brother James, for whom he claimed the honour of having been the first inventor of the telescope; but according to Borelli's account of the discovery of that instrument, it is highly improbable, as it is generally believed, that Zacharias Jansen, a spectacle maker at Middleburg, was the original inventor, (see TELESCOPE,) and that James Metius purchased telescopes of Jansen's children, by which he became acquainted with their construction and principles.

METKERKE, ADOLPHUS VAN, was born at Bruges in 1528, and spent the greatest part of his life in the service of the revolted states of the Low Countries, in the quality of counsellor of state, and envoy to the foreign potentates. In the latter station he was at the court of queen Elizabeth, when he died, in 1591, of grief, it was said, on account of the loss of his son Nicholas, an active commander before Deventer. He was a man of great learning, and was author of the following works; "A Translation, with Notes, of some Pieces of Theocritus, Bion, and Moschus;" "Latin Poems;" "A Treatise in Latin on the true Pronunciation of the Greek Language;" "A Collection of the Proceedings at the Peace concluded at Cologne in 1579." He took a part in other works, particularly in "The Lives of the Cæsars;" "The Medals of Magna Grecia," and "The Fasti Consulares," published by Goltzius.

METO, or METON, a celebrated mathematician of Athens, who flourished 432 B.C., was the son of Pausanias. He observed, in the first year of the 87th Olympiad,

the solstice at Athens, and published his cycle of 19 years by which he endeavoured to adjust the course of the sun and moon, and to make the solar and lunar years begin at the same point of time. This is called the Metonic period, or cycle. It is also called the golden number, from its great use in the calendar. (See CYCLE.) It is known that Meton was living about the year 412 B.C., for when the Athenian fleet was sent to Sicily, he escaped from being embarked on that disastrous expedition by counterfeiting an appearance of idiotism. Moreri.

METOCHE, ΜΕΤΟΧΕ, in the *Ancient Architecture*, a term used by Vitruvius, to signify the space or interval between the dentils. See DENTICLES.

Baldus observes, that, in an ancient MS. copy of that author, the word *metatome* is found for *metoche*. Hence Daviler takes occasion to suspect, that the common text of Vitruvius is corrupted, and concludes, that it should not be *metoche*, but *metatome*, q. d. section.

METOCHITA, THEODORE, in *Biography*, a modern Greek historian, who flourished in the 13th and 14th centuries. He attained to high honours in the Constantinopolitan empire, but in the reign of Andronicus the younger, he was banished and his goods confiscated. He was afterwards recalled, and ended his life in a monastery of his own foundation, in 1332. He was a man of extensive and very deep learning, and was entitled by his contemporaries a living library. He wrote "A Compendium of Roman History, from Julius Cæsar to Constantine," first published with notes and a Latin version by Meursius, in 1618; "A Constantinopolitan History," in one book; "A sacred History;" and "A Paraphrase on Aristotle's Physics."

METONIC CYCLE, in *Chronology*. See CYCLE, and GOLDEN NUMBER.

METONYMY, ΜΕΤΩΝΥΜΙΑ, from μετα, *trans*, and ονομα, *nomen, name*; a rhetorical trope consisting in a transmutation or change of names; or a putting of the effect for the cause, or the subject for the adjunct; and *vice versa*.

The metonymy is the most considerable of all the tropes next to a metaphor, whether we consider its force and elegance, or the frequent use of it both in speaking and writing. It is sometimes also called *transnominatio*, and differs not much from the hypallage.

There are four kinds of metonymies in principal use: the first, called a metonymy of the cause, when the external cause is put for the effect; this cause is either efficient or final. Of the former kind are such metonymies, where we put the inventor for the thing invented; as Bacchus for wine, Ceres for bread. Metonymies of the final cause are such, by which the end in doing a thing is put for the thing done. Such is that of Virgil (Eclog. x. v. 41.), "Phyllis should garlands crop," by which are meant flowers for making garlands. The second metonymy puts the effect for the cause, whether the agent or only the means and instrument: thus Virgil, Æn. vi. v. 844, calls the two Scipios the destruction of Libya, because they were the agents who effected it; and Horace, Carm. i. 1, 2, compliments Mæcenas with the titles of being his guard and honour, that is, his guardian and the author of his honour: and the author is put for his works. The third is, when the subject is put for the adjunct. By subject here, in a large sense of the word, may be understood that, wherein some other thing is contained, or about which it is conversant; as likewise the possessor with respect to the thing he possesses, and the thing signified when put for the sign of it: thus, in the first of these ways, the seat of any faculty or affection is put for the faculty or affection itself; as in the phrases, a man of a clear head or of a warm heart: the place, where any actions are performed, is put for the actions

actions done in it; the country or place of residence for the inhabitants; the time for the persons living in it: in the second way, the object is used for the person, or thing employed about it: as when Cicero, *pro Mil.* cap. 4. says, in time of battle, the laws, *i. e.* the judges, are silent. By the third way, we say to destroy or ruin a man, meaning not his person but his estate. In the last way, statues and pictures are called by the names of the persons whom they represent.

The fourth kind of metonymy is that in which the adjunct is put for the subject, which is done in the same variety of ways as the former. Thus Virgil says, (*Æn.* i. v. 704.) "they lie down upon purple," that is, couches dyed with purple. Also, "Hope deferred maketh the heart sick," where hope is put for the thing hoped for. Titus is thus called by Suetonius "the love and delight of mankind." Thus also, we say of a person, "He has served to many campaigns," meaning so many summers. Moreover, thus a "sceptre" is put for the regal dignity, and the "sword" for the authority of the magistrate.

Vossius adds two other species of metonymy, *viz.* of the antecedent and the consequent, which bear some analogy to the cause and effect, as the one does at least give occasion to the other. By the former, "to hear," when spoken of a superior, sometimes signifies to grant or comply with, and of an inferior to obey: by the latter it is not unusual to say, "I subscribe," or set my hand to such a thing, meaning that we assent or agree to it, &c.

METOPE, or ΜΕΤΟΠΑ, in *Architecture*, the square space or interval between the triglyphs, in the Doric frieze.

The word, in the original Greek, signifies the distance between one aperture or hole and another, or between one triglyph and another; the triglyphs being supposed to be solives or joists that fill the apertures. It is derived from μέτα, *inter, between,* and οπή, *foramen.*

The ancients used to adorn these parts with carved works, or paintings representing the heads of oxen, vessels, basons, and other utensils of the heathen sacrifices.

As there is found some difficulty in disposing the triglyphs and metopes in that just symmetry which the Doric order requires; some architects make it a rule, never to use this order but in temples.

METOPÉ, *Semi*, is a space somewhat less than half a metope, in the corner of a Doric frieze.

Le Clerc observes, that the beauty of metopes consists in their regularity, on appearing to be perfect squares; and yet, when they are equally square, they appear to be less in height than in breadth, on account of the projection of the little bandelet; for which reason they should be made a minute or two more in height than in breadth, in order to make their appearance uniform.

He also observes, that when the triglyphs and metopes follow each other regularly, the columns must only stand one by one; excepting those of the inner angles, which ought always to be accompanied by two others, one on each side; and here it is worth remarking, that these two columns, which accompany that of the angle, are not less necessary on account of the solidity of the building, than of the regularity of the intercolumniations.

METOPIMUM, in *Botany*, a name given by Pliny to the plant which produces the gum ammoniacum. He says that the ancient Greeks called it also by this name, but in that he errs. See AMMONIAC.

METOPOSCOPY, ΜΕΤΩΠΟΣΚΟΠΙΑ, from μέτωπον, *frons, forehead,* and σκοπία, *inspection, or observation,* I view, the art of discovering the temperament, inclinations, and manners

of persons, by inspecting their features, and the lines in their faces, and especially of their forehead.

Metoposcopy is no more than a branch of physiognomy; the latter taking its conjecture from all parts of the body; but both the body and the branch are extremely precarious, not to say vain.

Ciro Spantoni, who has written on the subject of metoposcopy, observes, that there are seven principal lines to be considered in the forehead; each of which has its peculiar planet. The first is the line of Saturn, the second of Jupiter, &c.

METOSIS, in *Surgery*, an amaurosis, or rather a blindness, from excessive short-sightedness, since *amaurosis* implies that the defect of sight is owing to torpor, or insensibility of the retina and optic nerve. See CUTTA *Serena*.

METRAIENNY, or ΜΙΝΙΕΤ ΡΑΙΗΝΙ, in *Geography*, a town of Egypt; 6 miles S. of Gizeli.

METRAMA, a river of Naples, which rises in Calabria Ultra, and runs into the Mediterranean; 4 miles S. of Nicotera. N. lat. 38 30'. E. long. 16 15'.

MÈTRE, or ΜΕΤΡΗ, ΜΕΤΡΩ, in *Poetry*, denotes a system of feet of a just length. Aristides defines metre, a system of feet composed of dissimilar syllables, of a just extent. In which sense metre amounts to much the same with genus carminis, or the sort of verse, and differs from rhythm. See PROSOODY.

It was during the reign of Edward VI. that metrical psalmody, in the same manner as is still practised in our parochial churches, had its beginning, or at least became general in England, by the version of Thomas Sternhold, John Hopkins, and others; which, though it now appears bald, coarse, and despicable, was then equally refined with the poetical taste of the most polite courtiers and polished scholars of the nation. But time, which has added strength and energy to the *prose* translation of the psalms, as well as other parts of scripture, and made them still more venerable, has rendered the *verse* of these translators a disgrace to our literature and religion. See PSALMODY, *Metrical*, CLEMENT MAROT, GOUDIMEL, and CLAUDE LE JEUNE.

METRE, in the *French Measures*, is the ten millionth part of a quadrant of the meridian, which is adopted as the unit of length; and from which, by multiplication and division, all other measures are derived. The length of the quadrant was computed by measuring an arc of the meridian between the parallels of Dunkirk and Barcelona, and found to be 5,130,740 French toises. This number, divided by ten millions, gives 443,296 French lines, the length of the metre, which is equal to 36.9413 French inches, or 39.3702 English inches. See MEASURE and STANDARD.

METRE, or *Meter*, a measure for oil and other liquids in Turkey. The meter weighs eight okes, or 22½ lb. avoirdupois.

METRETES, the name of a measure used among the ancients, containing somewhat more than nine gallons.

METRICAL VERSES, are those consisting of a determinate number of long and short syllables; as those of the Greek and Latin poets.

Capellus observes, that the genius of the Hebrew language is incompatible with metrical poetry.

METRICE, or METRICA, among the *Ancients*, was that part of poetry employed about the quantities of syllables, feet, sorts of metre, or verse, &c.

METRO, in *Geography*, a river which traverses the duchy of Urbino, and runs into the Adriatic, N. lat. 43 50'.

METROCELIDES, from μητηρ, *a mother,* and χηλιδις, *a mole,* in *Surgery*. See NÆVUS *Maternus*.

METROCOMIA, from μητηρ, *mother,* and χωμη, *town,* or *village,* a term in the *Ancient Church History*, signifying a

borough, or village, that had other villages under its jurisdiction.

What a metropolis was among cities, a metrocomia was among country towns. The ancient metrocomia had each its chorepiscopus or rural dean, and here was his see or residence. See METROPOLIS and CHOREPISCOPI.

METROMETER, Fr., a machine to determine the time of a piece of music. It requires a pendulum, which, while a movement is performing, may be lengthened or shortened at the pleasure of the composer, till the oscillations exactly agree with the bar, or any of its accented parts. The length of the pendulum must be specified at the beginning of a piece. Many attempts at such an expedient have been made; but we believe it has never been brought to perfection: if it had in Handel's time, many of his compositions would not be frequently injured by being performed too fast or too slow, to satisfy those who remember his works performed under his own direction.

METRONOMII, Μετρονομοι, among the Athenians, officers that inspected all sorts of measures, except those of corn; there were five of them in the city, and double that number in the Pyræus, in which the greatest mart in Attica was kept.

METROPI, in *Geography*, a town of European Turkey, in the province of Livadia; 28 miles S. of Athens.—Also, a small island in the gulf of Engia; 3 miles W. of Engia.

METROPOLI, a town of the island of Crete or Candia, said to be situated on the site of the ancient *Gortyna*; which see; 22 miles S. of Candia. N. lat. 35° 1'. E. long. 25° 4'.

METROPOLIS, Μετροπολις, from μητηρ, *mother*, and πολις, *city*, the *mother-city*, &c. the capital of a country, or province: or the principal city, and, as it were, mother of all the rest.

METROPOLIS is also applied to archiepiscopal churches, and sometimes to the principal, or mother-church of a city. The Roman empire having been divided into thirteen dioceses, and one hundred and twenty provinces, each diocese and each province had its metropolis, or capital city, where the proconsul, or the vicar of the empire, had his residence.

To this civil division the ecclesiastical was afterwards adapted, and the bishop of the capital city had the direction of affairs, and the pre-eminence over all the bishops of the province. His residence in the metropolis gave him the title of *metropolitan*. See DIOCESE.

The erection of metropolitans is referred to the end of the third century, and was confirmed by the council of Nice. Indeed archbishop Usher, and De Marca, maintain it to be an establishment of the apostles; but in vain: for it is next to certain, that the ecclesiastical government was regulated on the plan of the civil; and that it was hence the name and authority of metropolitans were given to the bishops of the capital cities of the empire, or the provinces that composed it. This is so true, that, in the contest between the bishop of Arles and the bishop of Vienne, each of whom laid claim to the metropolitanship of the province of Vienne, the council of Turin appointed, that whichever of them could prove his city to be the civil metropolis, should enjoy the title and rights of ecclesiastical metropolitan.

Nothing is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear, in the first century, the smallest trace of that association of provincial churches, from which, says Mosheim, councils and metropolitans derive their origin. (See DIOCESE.) The order and decency of those assemblies which were called councils, and introduced towards the close of the second

century, required, says this author, that some one of the provincial bishops met in council, should be invested with a superior degree of power and authority; and hence, he adds, the rights of metropolitans were derived. See PATRIARCHS.

Though the ecclesiastical government, however, was modelled on the political, yet, in Gaul, and some other countries, the distinctions of metropolitan and primate were not observed till very late. As the præfectus Galliarum resided by turns at Trevoux, Vienne, Arles, and Lyons, he communicated the rank and dignity of metropolitan and primate to each of them in their turn; and yet none of the Gallican bishops assumed to themselves the rights, nor even the precedence, of metropolitans. The episcopate levelled them all, and they had no regard but to the privileges of seniority. This equality lasted till the fifth century, when the contest between the bishops of Vienne and Arles was set on foot.

M. Du Pin observes, that in the provinces of Africa, excepting those of which Carthage was the metropolis, the place where the most aged bishop resided became the metropolis: the reason of which, without doubt, was this, that neither the proconsul, nor præfectus, ever fixed their residence any where.

The same author observes, also, that in Asia there were metropolitans merely nominal; that is, which had no suffragan, nor any rights of metropolitans. The bishops of Nice, Chalcedon, and Berytus, had the precedence of the other bishops, and the title of metropolitans, but this, without any other prerogative besides the honour of the appellation; they themselves being subject to their metropolitans.

A metropolitan has the privilege of ordaining his suffragans; and appeals from sentences passed by the suffragans are preferred to the metropolitan. See ARCHBISHOP.

The name metropolis was originally given to those Greek cities, which had established colonies in other places; and to these certain rights or privileges belonged, partly *honorary*, and partly *profitable*. Those of the first kind principally related to religion. *E. g.* The colonies were obliged to send annually to their metropolis deputies for offering sacrifices on their behalf to the gods of the country, and to present to them their first fruits. If the sacred fire should by any accident be extinguished, the colonies could not rekindle it any where but in the prytæneum of their founders. The colonies were under an obligation to provide themselves with priests, particularly those of their tutelar deity from their metropoles. The first places in the public solemnities, their games, &c. belonged to citizens of their respective metropolis. It was also the custom for the colonies to adorn the temples of their ancient country with considerable presents, such as the spoils of enemies, trophies, statues, and other embellishments; and it was also usual for the greater number of the Greek cities to pay a yearly tribute of certain measures of grain to that of Athens. Among the profitable rights we may reckon the following: the citizens of the metropolis had power of forming alliances, contracting marriages, &c., without having their children considered as strangers; they had likewise the power of purchasing land, and other commodities, in the territory of the colonies; the rights of hospitality took place between the metropolis and its colonies; and, moreover, the metropolis had a right of appointing legislators for their colonies, establishing their form of government, and reviving certain practices that had been abolished: they might also send new citizens into their colonies, who might share in common the benefits of the ancient colonists: generals were sometimes obtained from the metropolis, and new establishments required its sanction; but the most important right was that of demanding

warding succour from its colonies in time of war, both of soldiers and of ships, and affording an asylum to the citizens of the besieged metropolis. Besides these general privileges, some metropolises had peculiar claims on their colonies. The metropolis, on the other hand, had certain services which they were required to perform on behalf of their colonies; and if they failed, the colonies were justified in withdrawing from them their respect and obedience. The title of metropolis was less regarded among the Romans; for though they multiplied their colonies, they had but one metropolis, which was Rome; and as this was the first city of an immense empire, they considered the inhabitants of colonies merely as subjects. In general, however, they regarded as metropolises the cities which we call "capitals," and these were places, in which were held the general assemblies of the province, or where existed tribunals of the last resort.

METROPROPTOSIS, from $\mu\epsilon\tau\rho\upsilon\sigma\iota\varsigma$, *the womb*, and $\pi\rho\omicron\upsilon\tau\iota\varsigma$, *to fall down*, in *Surgery*. See **PROLAPSUS Uteri**.

METROSIDEROS, in *Botany*, so named by Dr. Solander, from $\mu\epsilon\tau\rho\upsilon\sigma\iota\varsigma$, *the pith or heart of a tree*, and $\sigma\iota\delta\epsilon\rho\iota\varsigma$, *iron*, alluding to the hardness and colour of the wood.—Sm. Tr. of Linn. Soc. v. 3. 266. Willd. Sp. Pl. v. 2. 952. Mart. Mill. Diét. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 183. Gærtn. t. 34. f. 2. and f. 9. Lamarek Illustr. t. 421. f. 3. (Angophora; Cavan. Ic. v. 4. 21. Leptospermum; Forst. Gen. t. 36. f. a—e and m—t.)—Class and order, *Icosandria Monogynia*. Nat. Ord. *Hepterideae*, Linn. *Myrti*, Juss.

Gen. Ch. Cal. Perianth half superior, with five spreading teeth or segments. Cor. Petals five, roundish, concave, inserted into the rim of the calyx, alternate with its segments; rude, and often rough, at the keel externally. Stam. Filaments numerous, inserted into the calyx in several rows, thread-shaped, much longer than the corolla; anthers small, roundish, two-lobed. Pist. Germen in the bottom of the calyx, roundish; style simple, angular, erect, much shorter than the stamens; stigma quite simple. Peric. Capsule roundish or ovate, coated in the lower part, of three cells, and as many abrupt valves, bursting at the upper part, the partitions from the centre of the valves. Seeds several, imbricated, roundish or oblong, inserted into the central column.

Eff. Ch. Calyx five-cleft, half superior. Petals five. Stamens much longer than the corolla. Stigma simple. Capsule of three cells.

Sir Joseph Banks and Dr. Solander first distinguished this genus from **LEPTOSPERMUM** and **MELALEUCA**; see those articles. To the latter it is most allied in habit, but differs in having distinct and simple stamens. The length of those organs, but more especially the simple, not capitate, stigma, distinguishes it from *Leptospermum*, and the habit is totally different. Most of the species are large handsome shrubs or trees, with long or broad, mostly smooth and entire, leaves, and fine large, white or crimson, flowers, conspicuous for their long and copious stamens. These plants are disposed in two sections, according to the situation of their leaves.

Section 1. *Leaves opposite.*

1. *M. hispida*. Rough *Metrosideros*. Sm. Tr. of L. Soc. v. 3. 267. n. 1. Exot. Bot. v. 1. 81. t. 42. Ait. n. 1. (*M. anomala*; Vent. Malm. t. 5. *M. hisfuta*; Andr. Repof. t. 281. *Angophora cordifolia*; Cavan. Ic. v. 4. 21. t. 338.)—Leaves opposite; heart-shaped and clasping the stem at their base. Young branches, flower-stalks and calyx bristly.—Gathered near Port Jackson, New South Wales, by Dr. J. White. It was raised from seeds in England by Messrs. Lee and Kennedy about the year 1789, and is now not very unfrequent in the more curious greenhouses, flowering in July

and August. The stem is usually four or five feet high, probably much more in New Holland, rigid, branched, round, and leafy. Leaves evergreen, very rigid and coriaceous, harsh and somewhat hispid, nearly sessile, oblong, obtuse, wavy, a little revolute and slightly crenate, with one rib and many cross parallel veins; glaucous beneath: clasping the stem with their dilated heart-shaped base. The younger branches are downy and bristly, terminating in copious, umbellate or cymose, large, white flowers, whose stalks and calyx are clothed with reddish-brown, prominent, bristly hairs, like those of the beautiful *Rose Acacia*, *Robinia hispida*. This is one of the most stately plants, when in perfection, that have been procured from New Holland. Venterat has figured so miserable a specimen, that it could scarcely be recognized.

2. *M. floribunda*. Many-flowered *Metrosideros*. Sm. n. 2. Ait. n. 2.—Leaves opposite, stalked, ovato-lanceolate. Panicle cross-branched. Flower-stalks umbellate.—Native of New South Wales. Sent by Sir J. Banks, about 1788, to Kew, where it blooms in the greenhouse about July and August. A more spreading, slender and smooth shrub than the preceding, with long, lanceolate, or slightly ovate, pointed, entire leaves, resembling those of an *Eucalyptus*. The flowers are copious, white, much smaller than the former, in numerous small umbels, collected into large, lax, cross-branched, occasionally hispid, panicles. Calyx smooth, with sharp prominent teeth.

3. *M. coccata*. Angular-fruited *Metrosideros*. Gærtn. v. 1. 171. t. 34. f. 2. Sm. n. 3. (*Angophora lanceolata*; Cavan. Ic. v. 4. 22. t. 339.)—Leaves opposite, stalked, linear-lanceolate, pointed, oblique. Panicle repeatedly cross-branched. Flower-stalks imperfectly umbellate.—Native of New South Wales. Leaves narrower, longer, more rigid and shining, than the last, as well as more oblique, or falcate. Panicle more irregularly and repeatedly branched, more stout, angular, and invariably smooth, but less decidedly umbellate in its ultimate divisions. Flowers twice as large, yellowish-white, the strong angles of the calyx permanent in the obovate woody fruit.

4. *M. diffusa*. Spreading *Metrosideros*. Sm. n. 4. Willd. n. 4. (*Melaleuca diffusa*; Forst. Prod. 37. *M. lucida*; Linn. Suppl. 342.)—Leaves opposite, ovate, veiny; smooth on both sides. Panicles axillary and terminal, with opposite flower-stalks.—Gathered by Forster in New Zealand, and by Nelson in Otaheite. We are indebted to Sir J. Banks for a fine specimen from the last-named island. The stem is much branched, and by the name we presume it spreads horizontally. Leaves smooth, numerous, on shortish thick stalks, ovate or obovate, one and a half inch long, with a strong mid-rib, and a pair of very slight evanescent marginal ones; the cross veins numerous, fine and reticulated. Flowers in dense, level-topped panicles. Calyx smooth, short, hemispherical, without angles; the teeth broad and blunt. The petals, and long stamens and style, appear to us crimson; the younger Linnæus judged them, by his ill-dried specimen, to be yellow. The valves of the ripe capsule, besprinkled externally with large resinous dots, rise half their length above the calyx, and have not the obtuse or abrupt termination observable in *M. coccata*. Indeed the species before us, with the four or five following, shew many indications of a generical difference from the first three, which perhaps, if they were compared alive, might be more evident.

5. *M. villosa*. Hoary *Metrosideros*. Sm. n. 5. Willd. n. 5. (*Melaleuca villosa*; Linn. Suppl. 342, excluding the synonym. *M. æthiops*; Forst. Prod. 38. *Leptospermum collinum*; Forst. Gen. 36. n. 2.)—Leaves opposite, ovate, veiny; downy beneath. Panicles dense, axillary and terminal.

METROSIDEROS.

minal, opposite, downy. Flowers sessile, crowded.—Gathered in Otaheite by the Forsters, as well as by Mr. Archibald Menzies. The size and habit are like the last, but the fine downy hoariness of the *flower-stalks*, *calyx*, tender *branches*, and backs of the younger *leaves*, characterise the present beautiful species. The back of each little *calyx-tooth* is smooth, though the *petals* are externally hoary. The latter, like the very long *filaments* and *style*, are crimson. The *leaves* are broadish-ovate, or obovate, with a short, blunt, channelled point. Mr. Menzies informs us this was called *Metrosideros spectabilis* by the late Dr. Solander; therefore it must be Gertner's t. 34. f. 9.

6. *M. florida*. Flowery *Metrosideros*. Sm. n. 6. Willd. n. 6. (*Melaleuca florida*; Forst. Prod. 37. *Leptospermum scandens*; Forst. Gen. 36. n. 1. t. 36. f. a — d.)—Leaves opposite, elliptic-oblong or obovate, veiny, smooth. Panicle dense, terminal. Calyx turbinate, smooth.—Native of New Zealand. A fine species, smooth in every part, with long, leafy, round *branches*. *Leaves* blunt, near two inches in length. *Flowers* large and handsome, crimson, in dense obtuse terminal panicles, whose stalks are usually three-flowered. The *calyx* is remarkably elongated, swelling gradually upward, with a wide mouth and short blunt teeth. The *style* is remarkable for its great size, being, like the *filaments*, above an inch long, with a very slightly dilated *stigma*, permanent. We know nothing of the *fruit* but from Forster, who represents the seeds as small and slender, yet he appears not to have seen them ripe.

7. *M. umbellata*. Umbellate *Metrosideros*. Cavan. Ic. v. 4. 20. t. 337.—Leaves opposite, lanceolate, pointed, smooth. Flowers in terminal simple umbels. Calyx turbinate, silky, with naked teeth. Petals oblong.—Gathered in New Zealand by Mr. Menzies, who gave us a specimen by the name of *M. lucida*, of which finding no traces in authors, we adopt that of Cavanilles, who says his specimens were gathered by Lewis Née, near the town at Port Jackson, New South Wales. We have however never heard of it from thence by any other means. The *stem* is said to be eight or ten feet high. The *branches* are erect, repeatedly forked, smooth, leafy, round, or slightly angular. *Leaves* one and a half or two inches long, elliptic-lanceolate, tapering at each end, slightly revolute, on short thick stalks; the under side palest, most opaque, dotted. *Flowers* large, red, in simple very close umbels, the stalks being extremely short and thick. *Calyx* turbinate, much dilated upwards, very silky, except the teeth, which are broad, obtuse, and naked, glandular at the back. *Petals* elliptic-oblong, twice the length of the calyx-teeth. *Stamens* and *style* thrice as long as the petals.

8. *M. glomulifera*. Cluster-flowered *Metrosideros*. Sm. n. 7. Ait. n. 3.—Leaves opposite, ovate, reticulated with veins; downy beneath. Heads of flowers lateral, stalked, downy as well as the bractæas.—Gathered near Port Jackson by the late Mr. David Burton. Mr. Brown sent it in 1805 to Kew garden, where it blossoms in May and June. This species seems arboreferent. The *leaves* are ovate or oblong, greyish, with innumerable small reticulated veins; rather downy beneath. *Flowers* whitish, in globose heads. *Footstalks*, common *flower-stalk*, *calyx*, and *petals*, clothed with fine hoary down. *Stamens* and *style* reddish.

9. *M. angustifolia*. Narrow-leaved *Metrosideros*. Sm. n. 8. Ait. n. 4. (*Myrtus angustifolia*; Linn. Mant. 74, excluding the synonym of Burmann.)—Leaves opposite, linear-lanceolate, naked. Flower-stalks axillary, umbellate. Bractæas lanceolate, smooth, deciduous.—Native of the Cape of Good Hope, from whence it was sent by Mr. Masson to Kew in 1787, but has not yet flowered there. A bushy *shrub*, with

smooth, narrow, lanceolate *leaves*, two inches long, one-third of an inch broad, finely dotted on both sides. *Footstalks* short and thick. *Flowers* numerous, small, white, in opposite, axillary, stalked, compound, downy, corymbose clusters. *Calyx* hemispherical, quite smooth, at length decaying, its ribs only remaining round the nearly globular capsule. It is singular that Thunberg, who sent perfect specimens, with ripe fruit, to Linnæus, should still retain this plant as a *Myrtus* in his *Prodromus*, p. 87.

Section 2. *Leaves alternate.*

10. *M. ciliata*. Fringed *Metrosideros*. Sm. n. 9. (*Melaleuca ciliata*; Forst. Prod. 38. *Leptospermum ciliatum*; Forst. Gen. 36. n. 3. t. 36. f. r — t.)—Leaves scattered, imperfectly opposite, elliptical, obtuse, coriaceous, somewhat fringed at the base. Corymbs terminal, hairy.—Gathered by Forster in the island of New Caledonia, not in New South Wales. A low bushy *shrub*, with numerous, pale, thick and rigid, oval, concave *leaves*, like those of a *Buxus* or *Celastrus*, an inch long, more or less; the young ones fringed at the base. The short thick *footstalks* are also hairy while young. *Flowers* deep red, large and handsome, most like those of our fourth, fifth, and seventh species, a few together at the ends of the branches, on corymbose, slightly hairy stalks. *Calyx* short, broad and depressed, a little hairy, its teeth oblong, fringed. *Petals* obovate, fringed, rather longer than the calyx-teeth. *Stamens* and *style* very long. *Capsule* broad, tumid, dotted with numerous prominent resinous glands, and rising, in three rounded lobes, much above the rim of the calyx. It is greatly to be wished that this species, and such as most resemble it, could be obtained for the gardens of Europe.

11. *M. linearis*. Linear-leaved *Metrosideros*. Sm. n. 10. Ait. n. 5. (*Melaleuca linearis*; Schrad. Sert. Hannov. 19. t. 11.)—Leaves scattered, linear, channelled, acute, roughish, rigid. Flowers lateral, crowded, sessile.—Native of New South Wales. Communicated to the Kew garden by Sir J. Banks, about the year 1788. A stout and rigid *shrub*, or small *tree*, with round smooth *branches*. *Leaves* not unlike those of some kinds of Fir, in their general appearance, being very numerous, scattered, crowded, sessile, three or four inches long, scarcely more than a line broad, single-ribbed, thick-edged, entire, roughish to the touch, dark green, bluntish with a small pungent point. *Flowers* sessile, in considerable numbers round the young branches, for the space of three inches or more, spreading every way, the branch being continued and leafy beyond them. *Calyx* bell-shaped, smooth and even, with broad, triangular, convex, deciduous teeth. *Petals* orbicular, convex, green, often slightly downy. *Stamens* and *style* an inch long; prominent, of a beautiful shining crimson. *Capsules* globose, somewhat depressed, with a very thick smooth coat from the body of the calyx, often crowding each other into an angular shape. Their little convex valves scarcely rise above the even rim of the calyx.

12. *M. lanceolata*. Lanceolate *Metrosideros*. Sm. n. 11. Ait. n. 6. (*M. citrina*; Curt. Mag. t. 260. *M. lophantha*; Venten. Jard. de Cels, t. 69. *M. marginata*; Cavan. Ic. v. 4. 18. t. 332.)—Leaves alternate, lanceolate, pointed, smooth. Flowers lateral, crowded, sessile.—Native of New South Wales. Frequent in greenhouses. This first flowered in the late Marchioness of Rockingham's collection about the year 1790. It differs from the last only in foliage, the *leaves* of the present being truly lanceolate, about two inches in length, and half an inch broad, with a slender marginal rib. They are smooth on both sides, plentifully dotted. *Flowers* exactly like the last. The *calyx* is sometimes downy,

downy, but not so constantly as we originally thought. Every part when bruised is highly aromatic. In the Transactions of the Linn. Soc. v. 9. p. 17, a suspicion is mentioned that this and the foregoing, and even the following, may be merely varieties of one species. We have seen from the seeds of one single capsule of the *lanceolata*, plants produced greatly differing in the breadth of their leaves, inasmuch that we are almost persuaded of the former part of the position; but the following appears too different in other respects, to be confounded with either of those plants. We have determined to keep them all separate, for the present at least, till Mr. Brown, who has seen them wild, shall give his opinion.

13. *M. fuliginea*. Willow-leaved *Metrosideros*. Sm. n. 12. Ait. n. 7. Venten. Jard. de Cels, t. 70.—Leaves alternate, lanceolate, tapering at each end, pointed. Flowers lateral, crowded, sessile, smooth in every part.—Native of New South Wales. Sent to Kew by Sir J. Banks about the year 1788. It flowers in May and June, and differs from *M. lanceolata* in its less rigid leaves, tapering remarkably at each extremity; flowers not above half so large, with yellowish stamens, their petals not even fringed, but quite smooth in every part, as well as the calyx. To these marks the ingenious Ventenat added, that the scales of the buds are externally striated, which is not the case in the *lanceolata*. Finally, the *fuliginea* has no aromatic flavour.

14. *M. viminalis*. Wand-like *Metrosideros*. Gærtn. v. 1. 171. t. 34. f. 4. Willd. n. 13.—Leaves alternate, linear-lanceolate. Flowers lateral, crowded, sessile, downy.—Native of New Holland. Very different from the last, its leaves being more linear, and not tapering towards the extremities. The flowers are downy, and rather smaller. We have seen it in Sir J. Banks's herbarium only.

15. *M. capitata*. Round-headed Purple *Metrosideros*. Sm. n. 13. Willd. n. 14.—Leaves scattered, rough-edged, obovate, with a minute point. Heads of flowers terminal. Calyx and young branches hairy.—Found near Port Jackson, New South Wales, by Dr. J. White. We have not heard of it in any garden. It seems rather a humble, much-branched shrub; the branches often clustered, hairy when young, round and rather slender; clothed with numerous, scattered, obovate, sessile leaves, rough, or finely serrated, at the edges, from a quarter to half an inch long, with a little recurved point; their ribs three or five, not very apparent; both sides finely dotted, the edges sometimes fringed. Flowers numerous, purple, in little, round, compact terminal heads; the calyx clothed with long, soft, hoary hairs. Bractees lanceolate, fringed, deciduous. The leaves are scarcely aromatic, but rather altringent, with a slight flavour like tea.

16. *M. ericifolia*. Heath-leaved *Metrosideros*.—Leaves imbricated, linear, pointed, hairy; channelled above; convex beneath. Heads of flowers terminal. Bractees feathery. Calyx smooth.—This hitherto nondescript species was gathered by Mr. A. Menzies, near King George's sound, on the west coast of New Holland. It has the habit of an *Erica*, *Diosma*, or *Phyllica*. The stem is leafy, erect, with copious, short, leafy, lateral branches. Leaves very numerous, crowded, about a quarter of an inch long, nearly linear, blunt, with a small point, dotted, hairy, dark green, entire; convex beneath; slightly concave, or channelled, above. Heads of flowers terminal, about the size of the last. Bractees lanceolate, covered at the back with long soft hairs, deciduous. Calyx turbinate, dotted, naked. The petals appear to be purplish. The leaves have a slight astringency, with some flavour of turpentine, but by no means powerful. We have not seen the capsule.

We are well aware that the habit of the two last species, is so different from the three which immediately precede them, especially their inflorescence; and all these together are so unlike those described in the former section, that it is highly probable some good generic difference is to be found in their fructification. On this subject, as on many similar ones, we must wait for the information of Mr. Brown, who alone has compared them all in their native country.

METROVITZ, in *Geography*, a town of Dalmatia; 6 miles N. of Narenta.

METSAMAA, a town of Sweden, in the government of Abo; 38 miles N.N.E. of Björneborg.

METSCHOVSK, a town of Russia, in the government of Kaluga; 40 miles W.S.W. of Kaluga. N. lat. 54° 12'. E. long. 34° 50'.

METTESHOP, or METTENSCHOP, in our *Old Writers*, an acknowledgment paid in a certain measure of corn; or a fine or penalty imposed on tenants, for defaults in not doing their customary service in cutting the lord's corn.

METTIIAH, in *Geography*. See METTICHE.

METTINGEN, a town of Germany, in the county of Tecklenburg; 6 miles N. of Tecklenburgh.

METTINICK ISLAND, an island in the Atlantic, near the coast of Main. N. lat. 43° 51'. W. long. 68° 59'.

METTSECOUBE, a small island, or perforated rock, in the Mediterranean, on the coast of Algiers; where, it is said, Raymond Lully, in his mission to Africa, frequently retired to meditate; six miles N. of Boujeiah.

METTYCONDA, a town of Hindoostan, in Mysore; 25 miles N. of Bangalore.

METUALES, or MUTUALES, a people of Asia, dispersed in great numbers all over Syria; so called from Mutual, a celebrated captain, who destroyed the current religion of the Persians, in order to substitute Mahometanism instead of it. The Mutuales are, therefore, schismatic Mahometans. They admit the Koran as a sacred book, and Mahomet as the first of prophets; and they also venerate Jesus Christ, after the manner of the Turks. The Mutuales renounce the succession of Mahomet, except Ali, whom they acknowledge as distinguished among all the disciples of the prophet by his skill in war, and his knowledge in letters. All forms of religion are held by them in the same contempt. Extreme hunger alone can constrain them to eat with Christians.

METULÆ, a town of Sardinia; 18 miles W.N.W. of Villa d'Iglesias.

METUPETTA, a town of Hindoostan, in the Carnatic; 30 miles S.E. of Tanjore.

METWAY HARBOUR, a bay on the S. coast of Nova Scotia. N. lat. 44° 10'. W. long. 64° 30'.

METYS, a word used by many of the ancient writers to express a substance collected by bees, in order to the stopping up cracks and crevices in their hives.

The old authors mention three kinds of substances used by the bees on this occasion, the *metys*, *pissoceros*, and *propolis*. The moderns use only the latter term to express every thing of this kind: the *metys* and *pissoceros* seeming to have been only the same *propolis*, more or less mixed with wax. The substance is a resin, of a middle consistence between the hard and the fluid ones. It is usually of a reddish-brown on the surface, and yellow within, and is collected from several trees, of which the poplar seems to be the principal, and the willow the next.

METZ, plur. *Metzen*, in *Commerce*, a corn measure in Germany. At Augsburg, 8 metzen = a schaf, and the metz = 4 vierlings, 16 viertels, or 64 maessals: 100 metzen = about 81 Winchester bushels. At Vienna, 30 metzen = a muth;

muth; the metz is divided into 4 viertels = 8 achtels = 16 muhlmaffels = 32 fudarmaffels = 128 bechers, and it contains 3100 French cubic inches = 3753 English ditto; hence 4 metzen = 7 Winchester bushels; and a muth = 6½ English quarters nearly. See *Tab. XXI. of MEASURES.*

METZ, in *Geography*, a city of France, chief place of a district, and capital of the department of Moselle, situated at the conflux of the Seille and Moselle, and containing three cantons, corresponding to the three divisions of the city: the first includes 6455, and its canton 147,81 inhabitants, in 24 communes; the second contains 12,355, and its canton 14,958 inhabitants, in 11 communes; and the third part has 13,289, and its canton 15,000 inhabitants, in 4 communes. The whole extent of its territory comprehends 245 kilometres. Metz is divided into the Old and New Town: the former is large, with narrow streets; but the houses, although built in the old style, are handsome. The New Town is also large, but more beautiful than the other. Besides its fortifications, it has three citadels. Its bishop, before the revolution, assumed the title of prince of the Roman empire; he was suffragan to the archbishop of Treves, and his diocese comprehended 613 parishes, and his revenue was 120,000 livres. Exclusively of the cathedral, it contained three chapters, sixteen parish churches, six abbeys, and a college. The Jews, who are numerous in this city, have a synagogue. The country round Metz, called the Meszin, is tolerably fertile, and produces a little wheat. This was anciently a part of the kingdom of Austrasia; and Metz was its capital and the royal residence. When the children of Charles the Great and Louis the Pious divided the dominions of that crown, the kingdom of Lorraine arose out of the ruins of that of Austrasia; and about the termination of the second royal line of France, Metz, Toul, and Verdun, shook off the yoke, and put themselves, as free cities, under the protection of the emperor. In 1552, these cities placed themselves under the protection of the French, till the peace of Westphalia in 1648, when the three bishoprics were absolutely transferred to France; 30 miles S. of Luxemburg. N. lat. 49° 7'. E. long. 6° 15'.

METZERWISE, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville. The place contains 607, and the canton 13,439 inhabitants, on a territory of 295 kilometres, in 45 communes.

METZONA, a town of European Turkey, in Epire; 25 miles E. of Arta.

METZU, GABRIEL, in *Biography*, one of the most ingenious painters of the Flemish school. He was born at Leyden in 1615. It is not exactly known with whom he learned the rudiments of the art, nor does it much concern us to be informed of it, as his style is entirely his own, having great completion in the finishing, with breadth and freedom quite unlike the tedious minute exactness of Gerard Dow, or still more that of Mieris.

Metzu generally painted small pictures of subjects taken from ordinary occurrences happening among the more polished class of his countrymen. A morning visit at a lady's toilette; a conversation or concert among people dressed in the best style of the time in Flanders; a gentleman stopping to drink at an inn, &c.; such are the objects which generally compose his pictures, in the execution of which one is at a loss to know whether most to admire the beauty of arrangement in the forms, the clearness and harmony of the tones, or the extreme delicacy, breadth, and truth in the execution. His works are by no means scarce in this country, and are eagerly bought at high prices.

He was severely afflicted with the stone, the effect of, and which was probably increased by, his unremitting assiduity. Having, at the age of 43, consented to undergo the operation of cutting for extraction, his constitution was found too weak to support the trial, and he did not survive it.

MEVA, or GNIEV, in *Geography*, a town of Prussia, in Pomerelia, on the Vistula; 22 miles S. of Dantzic.

MEVANGFANG, a town of Upper Siam; 115 miles N. of Porfalone.

MEVELEVITES, in *Modern History*, a sort of dervises, or religious, among the Turks, so called from Meveleva, their founder. They affect to be very patient, humble, modest, and charitable; but in reality are very debauched and dishonest.

MEVIUM, a name mentioned by Fallopius and others, as given by some medical writers to the venereal disease.

MEVIUS, DAVID, in *Biography*, a learned jurist, and privy-counsellor to the king of Sweden, was employed in various negociations by Charles XI., and drew up the regulations by which the German provinces, occupied by Sweden, were to be governed. He wrote "Commentaries on the Law of Lubec;" "Counsels or Deliberations;" and "Universal Jurisprudence."

MEULAN, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles. The place contains 2100, and the canton 12,584 inhabitants, on a territory of 130 kilometres, in 20 communes.

MEULEBECHE, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. The place contains 6660, and the canton 12,506 inhabitants, on a territory of 90 kilometres, in four communes.

MEULEN, ANTHONY FRANCIS VANDER, in *Biography*. This painter was born at Brussels in 1634. He was a disciple of Peter Snayers, a battle painter of considerable note, and his early progress gave strong promise of his future eminence.

His ingenious pictures attracted the attention of M. Colbert, the minister of Louis XIV., who induced V. Meulen to leave Brussels, and settle in Paris; and soon afterwards introduced him to the king, who appointed him to attend and paint the scenes of his military campaigns, gave him a pension of 2000 livres, and paid him besides for his performances. He made sketches of almost all the most remarkable events that occurred in these expeditions of Louis; designing upon the spot the encampments, marches, sieges, &c. of the armies; and the huntings of the king; the assembling of the officers, &c.: from these he composed his pictures, which are skilfully arranged, with great bustle, animation, and spirit, and executed with a very agreeable, though not always a natural tone of colour, and with a sweet and delicate pencil. Some of his pictures exhibit uncommon skill and taste in composition. Frequently the scene he had to paint was flat and insipid, such as a marshy country before long extended walls; even these he contrived to render agreeable by his judicious management of the chiaro-scuro, and the pleasing groups which he displayed with his figures, which, though dressed in the stiff uncouth frippery of the French court of that period, are handled with so much delicacy and corresponding taste, that they never fail to please. He was particularly skilful in portraying the actions of the horse, of which he has left behind him a number of excellent studies, drawn with great care from nature. His pictures frequently include a great extent of country, and an immense number of objects. His perfect knowledge of perspective enabled him to manage

manage the objects and distances with the greatest ease and effect, so that the eye accompanies the figures without confusion, and alligns to each its due action and distance. He lived not beyond the age of 56, but left a great number of pictures, most of which are in France, but they are not very unfrequent in this country.

MEUM, in *Botany*, supposed to be the *μῦμος* of Dioscorides, which is so far correct only as they are both of the umbelliferous order; for the plant described by that ancient author, is said to be sometimes two cubits high; our's is scarcely about a foot. See *LIGUSTICUM*, species twelve; for *Oribasius* read *Aethusa*.

MEUN, or MEUNG, JOHN DE, in *Biography*, an old French poet, was born at Meun, on the river Loire, in the year 1280. He was well acquainted with the studies of the age, but poetry was his favourite pursuit, and having a turn for satire and lampoon, he occasionally offended those who were disposed to be friendly towards him. Some court ladies, smarting under his lash, once seized him, with the resolution of taking their revenge, but he escaped the threatened punishment, by desiring the most unequal to inflict the first blow. He died about the year 1364. By his last will, he directed that his body should be interred in the church of the Dominicans at Paris, bequeathing to them, in the way of recompence, a heavy chest, which was not to be opened till after the funeral. The contents proved to be of no value whatever, which so enraged the holy fathers, that they ordered the dead body to be disinterred: this coming to the knowledge of the parliament, an order was issued to insist upon their giving it an honourable burial in their cloister. The principal work of this author was the continuation of the "Roman de la Rose," begun by William de Lorris. De Meun's addition constitutes more than three-fourths of the whole; it is less poetical than the first part, but has more of satire and real manners. An edition of this poem was published by Du Fresnoy, in three vols. 12mo. to which other pieces are added. Moreri.

MEUN, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Orleans; 10 miles S.W. of Orleans. The place contains 4418, and the canton 9525 inhabitants, on a territory of 207½ kilometres, in 8 communes.

MEURJE, a town of Egypt, on the right bank of the Nile; 23 miles S. of Achmim.

MEURS, or MORS, late a principality of Germany, surrounded by the duchies of Juliers, Cleves, and Berg, the archbishopric of Cologne, and the duchy of Gueldres; about eight miles long, and as many broad. It abounds with corn, cattle, and deer. To the E. its limits are formed by the Rhine, and it is watered by several smaller rivers and brooks. This principality is now annexed to France, and included in the department of the Roer.

MEURS, a town of France, in the department of the Roer, and chief place of a canton, in the district of Creeldt; formerly capital of the above-mentioned principality. The town is small but fortified. It has a Calvinistic church and a Latin school. The place contains 2111, and the canton 9144 inhabitants, in 15 communes; 13 miles S.E. of Gueldres. N. lat. 51° 13'. E. long. 6° 30'.

MEURSIUS, JOHN, in *Biography*, was born at Lofden, near the Hague, in the year 1579. He was an early proficient in classical literature, and composed Latin orations and Greek verses with facility before he was thirteen years of age. He received his academical learning at Leyden, and engaged in the education of Barneveldt's sons; whom he afterwards accompanied on their travels. He

spent some time in the study of the law at Orleans, and in 1608 was made doctor of that faculty. He visited several courts of Europe, formed an acquaintance with many learned foreigners, and examined the most celebrated libraries. On his return to Holland he was appointed to the professorship of history at Leyden in 1610, and next of the Greek language; and in the following year the states of Holland nominated him their historiographer. The wretched fate of Barneveldt involved the happiness of his friend and adherent Meursius, and though his attention to the duties of his office had given his enemies no pretext for depriving him of his situation; yet they found means to render his situation to uneasy, that he only waited for an occasion to quit it with honour. This at length arrived, when, in 1625, he received an invitation from Christian IV., king of Denmark, to occupy the professorship of history and politics in his new university of Sora, together with the post of royal historiographer. These offices he readily accepted, and removed to Denmark, where he continued to support his high reputation, and obtained the esteem of his sovereign and the court. He died at Sora in the year 1639, leaving behind him a high character for profound learning, to which his various works bear ample testimony. His chief publications related to the language and antiquities of Greece, viz. "De Populis Atticis;" "Atticarum Lectio, lib. iv.;" "Archontes Athenienses;" "Fortuna Attica;" "Athenæ Atticæ;" "De Fekis Græcorum;" all which have been admitted into the collections of Grævius and Gronovius. The writings of Meursius were published collectively in twelve volumes folio, 1741. Moreri.

This learned laborious critic and antiquary, was the first who published the Greek text of the three books of Aristoxenus upon music, followed by the Greek treatises of Nichomachus and Alypius, with notes by the editor; which Meibomius has censured, as he has those of Gogavivus, Kircher, and all those who preceded him in commenting, translating, or even mentioning any of the seven Greek writers upon music that are come down to us, and which he has translated into Latin, and been seemingly more successful in translating and explaining than any other critic or commentator who has had the courage to undertake so difficult a task.

Meursius's edition of Aristoxenus, Nichomachus, and Alypius, was published at Leyden, 1616, 4to. See Fabricius *Bibl. Græca*.

MEURTE, in *Geography*, a river of France, which rises near St. Diey, in the department of the Vosges, and joins the Moselle, 5 miles below Nancy.

MEURTE, or *Meurthe*, one of the ten departments of the N.E. region of France, formerly Tulois, and the S. part of Lorraine, bounded on the N. by the department of the Moselle, on the E. by that of the Lower Rhine, on the S. by that of the Vosges, and on the W. by that of the Meuse, in 48° 40' N. lat. Its length is 26 French leagues, and breadth 16, and its extent in kilometres is 6430, or 310 square leagues; and the number of its inhabitants is 342,107, or, according to Hassenfrazt, 351,161; it is divided into 5 circles, and 29 cantons, and 718 communes, or, according to Hassenfrazt, 9 circles, and 74 cantons: the five circles are as follow, viz. Toul, including 59,689 inhabitants; Nancy, 88,384; Chateau-Salins, 50,554; Sarrebourg, 56,091; and Luneville, 87,389: its capital is Nancy. The contributions of this department, in the 11th year of the French era, were 2,681,581 fr.; and its expences charged for administration, justice, and public instruction, 348,829 fr. 33 cents. The soil of the plains is fertile in grain, wine, fruits, &c.;

&c.; and that of the hills is covered with wood and pastures. Here are iron mines, quarries of marble and stone, mineral springs, &c.

MEVSAK, a town of Arabia, in the province of Hedsjas; 60 miles N.E. of Vadilkova.

MEUSE, a river of France, which rises at a village called Meuse, in the department of the Upper Marne, and after being joined by various other rivers in its course, it divides into two streams, the upper one towards the N. taking the name of Merwe, which it preserves, as well as that of Meuse, till it joins the German ocean, after passing the islands of Holland and Zealand.

MEUSE, one of the ten departments of the N.E. region of France, composed of Verdunois and Barrois; bounded on the N. by the duchy of Luxemburg, on the E. by the departments of the Moselle and the Meurte, on the S. by those of the Marne and Vosges, and on the W. by those of the Marne and the Ardennes, in N. lat. 49° ; 33 Fr. leagues long, and 16 broad, in territorial extent 6275 kilometres, or 318 square leagues; the number of its inhabitants is 275,898, or, according to Hassenfratz, 268,108; it is divided into 4 circles, 28 cantons, and 591 communes; or, according to Hassenfratz, into 8 circles and 79 cantons; its four circles are Bar-sur-Ornain, containing 74,168 inhabitants; Commercy, 73,103; Montmedy, 59,572; and Verdun, 69,055. Its capital is Bar-sur-Ornain. Its contributions in the eleventh year of the French era were 2,424,922 fr., and its expences amounted to 231,113 fr. 66 cents. This department is diversified with hills and plains, yielding fruits, grain, and pastures. It has mines of iron and other metals.

MEUSE, *Lower*, one of the thirteen departments of the region of France, called the Reunited country, formed of a part of Gueldres, and of the territories of Liege, Maestricht, and Venloo; bounded on the N. by Brabant, on the E. by the department of the Roer, on the S. by that of the Ourthe, and on the W. by that of the Dyle, and that of the Two Nethes, in N. lat. $50^{\circ} 50'$: its territory comprehends $3622\frac{1}{2}$ kilometres, or 190 square leagues, and it contains 232,662 inhabitants; or, according to Hassenfratz, 216,566. It is divided into three circles, 23 cantons, and 310 communes; or, according to Hassenfratz, three circles and 30 cantons: the circles are Maestricht, including 107,410 inhabitants; Hasselt, 60,399; and Ruremond, 64,853. Its capital is Maestricht. Its contributions in the year eleven were 1,600,995 fr., and its expences 205,543 fr. 33 cents. This department is partially fertile, and yields grain, fruits, and good pastures.

MEUTANG, in *Botany*, the name of a flower much esteemed by the Chinese, which, on that account, they call the king of flowers. It is larger than our rose, and imitates its figure, only its leaves are more expanded. As its smell comes short of that of the rose, so in beauty the rose is outdone by it. It has no prickles, and its colour is a mixture of white with purple, but so as to incline most to white; yet sometimes there are found reddish and yellow ones. The tree it grows on is not unlike our alder-tree, and is cultivated throughout that large empire with great care, being covered in the summer time with a shade to defend it from the scorching heat of the sun.

MEW ISLAND, in *Geography*, a small island in the East India sea, near the W. coast of Java; three miles N.E. of Java Head.

Mew *Islands*, a cluster of small islands on the coast of Honduras, S. of Cape Camaron.

Mew *Stone*, a small island, or round elevated rock, in

the Southern India ocean, near the coast of Van Diemen's land. S. lat. $43^{\circ} 46'$. E. long. $146^{\circ} 24'$.—Alfo, a large rock in the English channel, on the S. coast of Devonshire, E. of the entrance into Plymouth sound; four miles S. of Plymouth. N. lat. $50^{\circ} 18'$. W. long. $3^{\circ} 59'$.

MEWAT, a hilly and woody tract of Hindoostan, lying on the S.W. of Delhi, and on the W. of Agra; confining the low country along the western side of the Jumnah river, to a (comparatively) narrow slip, and extending westwards about 130 British miles. Its length from N. to S. is about 90 miles. This tract, although situated in the heart of the empire of Hindoostan, that is, within twenty-five miles of its former capital, Delhi, is inhabited by people, who have ever been characterized as the most savage and brutal, and whose chief employment is robbery and plundering. In 1265, 100,000 of these wretches were put to the sword; and a line of forts was constructed along the foot of their hills. At the present time, says major Rennell, Mewat is so notorious a nursery for thieves and robbers, that parties of "Mewatti" are taken into pay by the chiefs of Upper Hindoostan, for the purpose of distressing the countries which are made the seat of warfare. In Acbar's division, this tract made a part of the soubahs of Delhi and Agra; but most of it was included in the latter. Mewat contains some strong fortresses, on steep or inaccessible hills; among which is Alwar, or Alvar, the citadel of Macherry Rajah. It has very often changed masters, during the contests between its native rajahs (or kanzadeh), and the Jats, the rajah of Joinagur, Nudjuff Cawn, and Madajee Sindia; and between these powers successively. Sindia has made a considerable progress in the reduction of it.

MEWING, a disorder incident to all kinds of birds; being the casting of their feathers.

MEXIA, PEDRO, in *Biography*, chronicler to Charles V. is one of the few Spanish writers whose works have found their way into our language. He wrote a history of the Cæsars, which includes the German emperors, and is one of the translators of Edward Grimeston: he was author also of "Silva de varia Leccion," with the additions of its Italian and French translators in that "Treasury of ancient and modern Times," which is referred to by Grose, and of which the two parts having been published separately, are not easily to be met with together. Mexia was also the author of certain colloquies to the praise of the afs, in imitation of Lucian and Apuleius, and a history of Charles V. which he left unfinished, and which has never been edited. He was born at Seville, and died in or about the year 1552. Gen. Biog.

MEXICANÓ, or A DAYES, a river of Louisiana, which, after pursuing a S.E. course, discharges itself into the gulf of Mexico, at Cabo du Nord, W. by S. of Ascension bay, and E. by N. of Trinity river. On its banks are rich silver mines.

MEXICO, one of the seven territories, or domains, into which the Spanish dominions in North America have been divided, sometimes improperly called *New Spain*; which is bounded on the N.W. by New Mexico, on the E. by the gulf of Mexico, on the S.E. by the isthmus of Darien, and on the S. and W. by the Pacific ocean. And though Mexico, called Old Mexico by way of distinction from New Mexico, is only a province or kingdom of New Spain, applied in its utmost extent, it is not restricted to the ancient kingdom, which extended from near the lake of Chapala in the north, to Chiapa on the river Tabasco, in the south, but includes many extensive provinces to the north. The provinces which the domain of Mexico comprehends,

MEXICO.

are Tabasco, Oaxaca or Guaxaca, Tlascala, Mexico Proper, Zacatula, Mechoacan, Panuco, New Galicia or Xalisco, and Nayarit; see each respectively. Accordingly, the vice-royalty of New Spain comprehended several provinces, which were not subject to the dominion of the Mexicans. The countries of Chualco and Sonora, that stretch along the side of the Vermilion sea, or gulf of California, as well as the immense kingdoms of New Navarre and New Mexico, which bend towards the W. and N., did not acknowledge the sovereignty of Montezuma, or his predecessors. These regions, not inferior in extent to the whole Mexican empire, have been reduced, some of them to a greater, others to a less degree of subjection, to the Spanish yoke. They extended through the most delightful parts of the temperate zone; their soil is, in general, remarkably fertile; and all their productions, whether animal or vegetable, are most perfect in their kind. They have all a communication, either with the Pacific ocean or with the gulf of Mexico, and are watered by rivers which not only enrich them, but may become subservient to commerce. The peninsula of California, on the other side of the Vermilion sea, discovered by Cortes in the year 1536, seems to have been less known to the ancient Mexicans than the provinces which we have just mentioned. On the E. of Mexico, Yucatan and Honduras are comprehended in the government of New Spain, though anciently they can hardly be said to have formed a part of the Mexican empire. Still further E. than Honduras lie the two provinces of Costa Rica and Veragua, which likewise belong to the vice-royalty of New Spain, but both have been so much neglected by the Spaniards, and are of so little value, that they merit no particular attention. Without attempting to ascertain precisely the limits of the ancient Mexican empire, which have been much controverted, we shall give a brief geographical, historical, and statistical account of this empire, aided by the information which we derive from Clavigero, the abbé Raynal, Dr. Robertson, Estalla, &c. The name of "Anahuac," signifying near the water, originally given to the vale of Mexico only, from the circumstance of its principal cities being situated on small islands, and on the borders of two lakes, was afterwards used to denominate the whole territory, now known under the appellation of New Spain. This extensive country was then divided into the kingdoms of Mexico, Acolhuacan, Tlacopan, and Michuacan; into the republics Tlaxcallan or Tlascala, Cholollan, and Huexotzinco, and several other distinct states. Those who wish to know the exact situation of these several countries may consult the tedious detail of Clavigero. The kingdom of Mexico, although the most modern, was much more extensive than all the other kingdoms and republics above-mentioned taken collectively. It extended towards the S.W. and S., as far as the Pacific ocean; towards the S.E. as far as the vicinity of Quauhquemallan; towards the E., exclusive of the districts of the republics, and a small part of the kingdom of Acolhuacan, as far as the gulf of Mexico; towards the N., to the country of the Huastecas; towards the N.W. it bordered on the barbarous Chichémicas, and the dominions of Tlacopan, on the western border of the lake of Tezucuo, and Michuacan, the most westerly kingdom of all, were its boundaries towards the west. The whole of the Mexican kingdom, says Clavigero, was comprehended between the fourteenth and twenty-first degrees of N. lat., and between 271 and 283 degrees of longitude taken from the meridian of the island of Ferro. The finest district of this country, with regard to situation, as well as population, was the vale of Mexico, crowned by beautiful and verdant mountains, whose circumference, measured at their base, exceeded 120 miles. A great part of the vale is

occupied by two lakes, the upper one of sweet water, the lower one brackish, communicating by a canal, and in circumference not less than 90 miles. Besides Mexico, Acolhuacan, and Tlacopan, there were, says Clavigero, 40 eminent cities in this delightful vale, and innumerable villages and hamlets. The principal inland provinces to the N. were the Otomias; to the S.W., the Matlatzincas and the Cuhtatecas; to the S. the Tlahuicas, and the Colhuicas; to the S.E. were the provinces of the Mixtecas, the Zapotecas, and the Chiaponecas. Towards the E. were the provinces of Tepryaca, the Papolocas, and the Totonacas. The maritime provinces of the Mexican gulf were those of Coatzacoalco, and Cuatlachtlan, called by the Spaniards Cotalla. The provinces on the Pacific ocean were those of Coliman, Zacatollan, Tototepec, Tecuantepec, and Xoconochco. The whole country of Anahuac was, generally speaking, well peopled. The land is, in great part, mountainous, covered with thick woods, and watered by large rivers, some of which run into the gulf of Mexico, and others into the Pacific ocean. Here are several lakes which not only embellish the country, but afford convenience to commerce. The climate of the countries of Anahuac varies according to their situation. The maritime countries are hot, and for the most part moist and unhealthy. The high lands, and especially those that are near to elevated mountains covered with snow, are cold. In the other inland countries, the temperature is such, that the inhabitants feel neither the rigour of winter nor the heats of summer. However, the agreeableness of the climate is counterbalanced by thunder-storms, which are frequent in summer, and also by earthquakes. Some of the mountains are volcanic, and occasionally emit fire. The mountains of Anahuac abound in ores of every kind of metal, and a variety of other fossils. Different parts of the country also furnish precious stones; and also several kinds of stone, valuable in architecture, sculpture, and the arts. The vegetable kingdom is no less productive than the mineral. Hernandez, in his "Natural History," describes about 1200 plants, natives of this country; some esteemed for their flowers, some for their fruit, some for their leaves, some for their roots, some for their trunk or wood, and others for their gum, resin, oil, or juice. The country yields, by culture, the cocoa-tree, the plantain, the citron, orange, and lemon: the fruits are numerous and various, but it is needless to recount them all: we shall content ourselves with specifying the cocoa-nuts, vanilla, Chili or great pepper, cotton, and achiote or rocou. The country also produces wheat, barley, rice, peas, beans, lentils, and other leguminous vegetables. Mexico is particularly distinguished by the excellence, variety, and plenty of its timber. Hernandez describes about one hundred species of trees. It also affords various sorts of plants, that yield profitable resins, gums, oils, and juices. The quadrupeds are horses, asses, bulls, sheep, goats, hogs, dogs, and cats, which have all successfully multiplied, though, as some approved writers say, not without degenerating. The ancient quadrupeds common to Mexico and the old continent, are lions, tigers, wild cats, bears, wolves, foxes, stags both common and white, bucks, wild goats, badgers, polecats, weazels, martins, squirrels, rabbits, hares, otters, and rats. There are other quadrupeds common to Mexico and other regions of the new world, which we shall not enumerate. The quadrupeds peculiarly belonging to Anahuac are the cojotl, resembling, in various respects, the adive or chacal; the tlacojotl, about the size of a dog, and the largest quadruped of those who live under the earth; three species of quadrupeds similar to dogs; an animal belonging to the genus of wild cats, called ocochtli; the cajopollin, of the

MEXICO.

size of a common mouse; the tozan, about the bulk of an European mole, but otherwise very different; the ahuitzotl, an amphibious animal; and the hedge-hog, or porcupine of Mexico. As for birds, their number, variety, and many valuable qualities have occasioned some authors to observe, that as Africa is the country for beasts, so Mexico is the country of birds. We cannot be detained in specifying particulars. The reptiles of Mexico may be referred to the four classes of four-footed, and of apodes, or those without feet. In the lake of Chalco there are three very numerous species of frogs, of three very different sizes and colours, and very common at the tables in the capital. The serpents are very various both in size and colour, some poisonous and others harmless. The rivers, lakes, and seas of Anahuac abound with an innumerable variety of fishes. The Mexican insects, flying, terrestrial, and aquatic, are very numerous. Scolopendras, scorpions, spiders, and ants are very common. The cochineal furnishes a very considerable article of culture and of commerce.

As to the persons and manners of the natives we may observe, that they are generally somewhat above the middle size, and well-proportioned in all their limbs: they have good complexions, narrow foreheads, black eyes, firm, regular, white teeth, thick, black, coarse, glossy hair, thin beards, and generally no hair upon their legs, thighs, and arms: their skin is of an olive colour. Few deformed persons are seen; and though they cannot be called beautiful, they do not verge to the other extreme. The young women are many of them fair and beautiful, and modest and engaging in their manners. The constitutions of these people are robust and their health sound. Some of them attain to the age of one hundred years. Although in eating they are moderate, their passion for strong liquors is indulged to excess. The state of civilization among the Mexicans, when they were first known to the Spaniards, which was much superior to that of the Spaniards themselves when they were first known to the Phœnicians, that of the Gauls when first known to the Greeks, or that of the Germans and Britons when first known to the Romans, are spoken of in terms of high commendation by Clavigero. He says, we have known among the Mexicans some good mathematicians, excellent architects, and learned divines. Of their disposition and general conduct he seems disposed to judge very favourably. He concludes with observing, that the character of the Mexicans, like that of every other nation, is a mixture of good and bad: but the bad may be easily corrected by a proper education. The ancient Mexicans, he adds, manifested more fire, and were more sensible to the impressions of honour: they were more intrepid, more nimble, more active, more industrious than those of modern times; but they were, at the same time, more superstitious and cruel. Authors, however, have differed much in their opinion with respect to the talents, cultivation, and character of the ancient Mexicans. Whilst they have been extravagantly extolled by some, they have been unduly depreciated by others. Dr. Robertson has endeavoured to steer a mean course in his description of these people; neither extravagantly commending them with Clavigero, nor sinking them below their proper level with De Paw and others. After their subjection to the Spanish crown, those who first became acquainted with them were not competent judges of their talents and characters. The rapacious adventurers who formed the train of Cortes, their conqueror, were incapable of judging or pronouncing justly concerning either their mental or moral endowments. But before we form any estimate of the degree in which they had cultivated their minds, or made any

attainments in the sciences and arts, we must advert to their origin and the early history of their establishment in Mexico. The persons who first peopled this country, as Clavigero supposes, came from the more northern parts of America, where their ancestors had been settled for many ages. The Toltecas, according to the account given us by Clavigero, are the oldest natives of whom we have any knowledge, and that is very imperfect. It has been an opinion adopted by several writers, among whom we particularize Siguenza, bishop Huet, &c. that the Mexicans, and other nations of Anahuac, were the descendants of Naphtahim, son of Mizraim, and nephew of Ham. These, it is said, having left Egypt not long after the confusion of tongues, travelled towards America. The reasons on which this opinion is grounded, are the conformity of these American nations with the Egyptians in the construction of pyramidal edifices, of the use of hieroglyphics in the mode of computing time, in their dress, and in some of their customs, and also the resemblance of the word "Teul" of the Mexicans to the "Theuth" of the Egyptians. Clavigero has examined the validity of these arguments, and suggested several objections to which they are liable. He seems to be of opinion, that the ancestors of the nations which peopled the country of Anahuac might pass from the northern countries of Europe into the northern parts of America, or rather from the most eastern parts of Asia to the most westerly part of America. This opinion is supported by the general tradition of those nations, which asserts that their ancestors came into Anahuac from the countries of the N. and N.W.; by the remains of many ancient edifices built by these people in their migrations, as well as the common belief of the people in the north; and also, by some ancient paintings of the Toltecas, which represented the migration of their ancestors through Asia and the northern countries of America. This opinion, with regard to the first peopling of America, has derived confirmation from some modern discoveries, which have ascertained the near approach of the most easterly coast of America to the most easterly part of Asia; so that if they were not, in some remote age, contiguous, a passage from the one coast to the other might be easily effected. The quadrupeds and reptiles of the new world, it is said, passed thither by land; and this opinion is founded on the presumption that the two continents were formerly united, which is adopted by Acolta, Grotius, Buffon, and other persons of established reputation. Clavigero conjectures, that there was formerly a great tract of land which united the now most eastern part of Brazil to the most western part of Africa; and that this whole space of land may have been sunk by some violent earthquakes, leaving only some traces of it in the isles of Cape de Verd, Fernando de Norona, Ascension, St. Matthew, and others, as well as many sand banks discovered by different navigators. However this be, the Toltecas being banished, as they tell us, from their own country Huehuetapallan, supposed to be in the kingdom of Tollan, from which they derived their name, and situated to the N.W. of Mexico, they began their journey in the year 1 "Tecpatl," that is 596 of our era. In every place to which they came, they remained no longer than they liked it, or could be accommodated with provisions; if they determined to make a longer stay, they erected houses, and sowed the land with corn, cotton, and other plants, the seeds of which they carried with them for the supply of their wants. In this migrating manner they travelled southward for 104 years, till they arrived at a place which they called "Tollantzinco," about 50 miles E. of the spot, where, some centuries after, was founded the famous city of Mexico. In this country, however, they did

not choose to settle, although the climate was mild and the soil fruitful; but in about twenty years after, they removed about 40 miles to the W. where, along the banks of a river, they founded the city of Tollan, or Tula, after the name of their native country. That city, supposed to be the oldest in Anahuac, and one of the most celebrated in the history of Mexico, was the capital of the Toltecian kingdom, and the court of their kings. This monarchy began, as it is said, in the year 8, "Acatl," that is, 607 of the Christian era, and lasted 384 years. The Toltecas were the most celebrated people of Anahuac for their superior civilization, and skill in the arts; whence it has been common in after ages to distinguish the most remarkable artists in an honourable manner, by the appellation of Toltecas. They always lived in society, collected into cities, under the government of kings and regular laws. They were not very warlike, and less turned to the exercise of arms than to the cultivation of the arts. The nations that have succeeded them have acknowledged themselves indebted to the Toltecas for their knowledge of the culture of grain, cotton, pepper, and other most useful fruits. Besides the arts which are dictated by necessity, they practised those which administer to luxury. They had the art of casting gold and silver, and melting them to whatever form they pleased, and acquired great reputation for the cutting of all kinds of gems; but nothing raised their character so high as their having been the inventors, or at least the reformers of that system for the arrangement of time, which was adopted by all the civilized nations of Anahuac. It is said, that observing in their own country, how the solar year exceeded the civil one by which they reckoned, about six hours, they regulated it by interposing the intercalary day once in four years, which they did more than 100 years before the Christian era. Their religion, indeed, was idolatrous, and they appear, by their history, to have been the inventors of the greatest part of the mythology of the Mexicans. During the four centuries of the monarchy of the Toltecas, they multiplied exceedingly, extending their population every way in numerous and large cities, but their circumstances changed, when in the first year of the reign of Topiltzin, they suffered for want of rain and the productions of the soil, and a great part of the nation died by famine and sickness. Topiltzin died in the second year "Tecpatl," *i. e.* 1052 of the vulgar era, and with him the Toltecian monarchy terminated. The wretched remains of the nation fought new abodes; some removed to Yucatan, some to Guatemala, and some remained in the kingdom of Tula, and dispersed themselves in the vale where Mexico was afterwards founded. After the destruction of the Toltecas, for the space of one century, the land of Anahuac remained solitary and almost entirely depopulated, until the arrival of the Chachemecas. These came originally from the northern countries. Their native country was called, according to their account, "Amquemecan," where, as they say, different monarchs ruled their nation for many years. In the character of these people a certain degree of civilization was blended with many traits of barbarity. They had distinctions between the nobility and commonalty, and the plebeians were accustomed to reverence those whose birth, merit, or favour with the prince raised them above the other ranks. They dwelt together in communities in places composed, as it is probable, of poor huts; but they neither practised agriculture, nor those arts which accompany civil life. They lived on game, and fruits, and roots, which the earth spontaneously produced. Their clothing was the skins of beasts, and their arms, the bow and arrow. Their religion consisted of the simple worship of the sun, to

which pretended divinity they offered herbs and flowers which they found springing in the fields. One of their princes was sent by Xolotl, his father, to survey the country; and at length Xolotl determined to establish himself in Tenayuca, a place six miles distant from the site of Mexico towards the N., and distributed his people among the neighbouring lands. In process of time he became acquainted with several Toltecian families, encouraged inter-marriages and alliances with them, and from them acquired the arts of agriculture, the manner of digging metals, the art of casting them, and also of cutting stones, spinning and weaving cotton, and of other things, which contributed to improve their means of subsistence, their clothing, their habitations, and their manners. Xolotl obtained from time to time an accession of new settlers; among whom were some of distinguished rank and character; and particularly three princes, to two of whom he gave his two daughters in marriage. When this ceremony had taken place, he divided his kingdom into several distinct states, and assigned the possession of them to his sons-in-law, and the other nobles of each nation. The population daily increased, and with it the civilization of the people; but ambition began to produce injurious effects, and Xolotl, who had hitherto governed with mildness, was obliged to recur to the punishment of some rebels with death. Upon the decease of Xolotl, he was succeeded by his son Nopaltzin II.; and upon his death his son, Tlotzin III. ascended the throne; and the succession continued in his family; according to the following list of Chachemecan kings.

Xolotl began to reign in the	12th century.
Nopaltzin - - -	13th
Tlotzin - - -	14th
Quinatzin - - -	14th
Techotlalla - - -	14th
Ixtlilochitl in the year	1406
Nezahualcoyotl - - -	1426
Nezahualpolli - - -	1470
Caematzin - - -	1516
Cuicuitzatzin - - -	1520
Coanacotzin - - -	1520

Such is the succession of Chachemecan kings, till their monarchy terminated. The Otomies are said to have been one of the most numerous nations which settled in the country of Anahuac; they were a rude and barbarous people, and in the time of the Mexican kings they were treated as slaves. Anciently they were renowned for their dexterity in the chase; at present they traffic in coarse cloths for the dress of the other Indians. The Tarascas, who occupied the extensive, rich, and pleasant country of Michuacan, settled many cities and villages; and their kings were rivals of the Mexicans, and had frequent wars with them. These were idolatrous, but less cruel in their worship than the Mexicans. Their language is copious, sweet, and sonorous. Besides other nations, which settled in and near the vale of Mexico, the most renowned and the most signalized in the history of Mexico, were those vulgarly called the Nahuatlacas. They consisted of seven tribes, who settled in Anahuac after the Chachemecas. The Aztecas, or Mexicans, were the last people who settled in Anahuac. Till about the year 1160 of the vulgar era, they lived in Aztlan, a country situated to the N. of the gulf of California. They left their country, as it has been said, at the instigation of a person of great authority among them, to whose opinion they all paid great deference. He was led to this resolution by the fanciful interpretation of the chirping of a bird; but whatever was the motive of the migration of the Aztecas, they left their country at the time above-mentioned. After various delays

MEXICO.

in the course of their peregrination, they at length arrived to the borders of the lake of Tezeuco, and near the site of Mexico. Here they suffered various persecutions and distresses; they engaged in a conflict with some enemies, whom they vanquished, and, returning to the place of their residence, they erected an altar to their tutelary god. When they fixed upon the spot, on which they determined to erect their city, they built a temple to their god, and consecrated it by the effusion of human blood. Around the sanctuary of their god they constructed wretched huts of reeds and rushes, being at that time destitute of other materials; and they called it Mexico, which denomination, being taken from the name of its tutelary god, signifies place of Mexitli, or Huitzilopochtli, as he had both these names. There are other etymologies of this name. (See MEXICO.) The foundation of this city was laid in the year 2, Calli, corresponding with the year 1325 of the vulgar era. Until the year 1352, the Mexican government was aristocratical; the whole nation paying obedience to a certain body, composed of persons the most respectable for their nobility and wisdom; but at this time they imitated the example of their neighbours, and for greater security from their enemies, formed their little state into a monarchy; and the election fell, by common consent, on Acamapitzin, who was one of the most famous and prudent persons then living amongst them. This monarch governed the city, which comprehended at that time the whole of his kingdom, in peace for thirty-seven years. In his time the population increased, buildings of stone were constructed, and those canals, which served as well for the ornament of the city as for the convenience of its inhabitants, were begun. At his death the monarchy, which was elective, was transferred to his son, Huitziluhuitl. After a reign of twenty years, he was succeeded by his brother Chimalpopoca, whose premature death made way for the election of Itzcoatl, brother to the two preceding kings, and natural son of Acamapitzin by a slave. His government was conducted with prudence; he subdued many neighbouring provinces; and he erected two temples, one to the goddess Cihuacoatl, and some time afterwards another to Huitzilopochtli, the chief Mexican divinity. After a prosperous reign of thirteen years, he was succeeded by one of his grandsons, Montezuma, who was elected with general applause, not less on account of his personal virtues, than the important services which he had performed for his country. As soon as he was fixed on the throne, he erected a famous temple in that part of the city which was called Huitznabuac; and in rearing this magnificent structure, he was assisted with materials and workmen by the neighbouring kings, with whom he was in alliance. He then prosecuted the conquests which he had commenced in the time of his predecessor, and added to the Mexican empire several districts and villages. In the tenth year of his reign, corresponding to the year 1446 of the vulgar era, the city of Mexico was much damaged by an inundation from the adjacent lake; and, in order to prevent a similar calamity, he caused to be constructed a large dyke, nine miles in length, and eleven cubits in breadth, composed of two parallel palisades, the space between which was entirely filled up with stone and mud. The inundation was soon followed by a famine, which was owing to a failure of the harvest of maize. When the city had recovered itself from the effects of this calamity, Montezuma renewed his conquests, and, after a distinguished reign of twenty-nine years, the throne was vacated by his death in 1464, and Axayacatl was chosen to succeed him. This king, having obtained a signal victory over the inhabitants of a neighbouring province, in 1468, undertook the building of a temple, which he called

Coatlan. The progress of his conquests was interrupted by his death, in the 13th year of his reign, A. D. 1477. Tizoc, his elder brother and general of the army, was elected for his successor; but his reign was short and undistinguished by any considerable military exploits. In the 5th year of his sovereignty he was poisoned by some of his feudatory subjects, A. D. 1482. During his time, the power and wealth of the crown had arrived to such a height, that he undertook to construct a temple to the tutelary god of the nation, which was to have surpassed in magnificence all the temples of that country; he had prepared a vast quantity of materials for this purpose, and had actually begun the structure, when death interrupted his projects. Ahuitzotl, the brother of the two preceding kings, a general of the army, was chosen to succeed him. The first object to which his attention was directed was the completion of the temple, which had been designed and begun by his predecessor. This work was diligently prosecuted for four years; and on occasion of his consecration he is said to have sacrificed, as some say, 72,344, and, according to others, 64,060 prisoners. This event happened in 1486. In the year 1498, this king projected to supply the lake with water from a fountain at some distance; and in spite of remonstrances from those who dreaded an inundation, he persisted in the execution of his plan. The apprehended event occurred, and the city was deluged with the overflowing water. This deluge was succeeded by a famine. The last years of Ahuitzotl were passed in constant wars; till at length, in the year 1502, after a reign of about twenty years, he died. At the time of his death, the Mexicans were in possession of all which they had at the arrival of the Spaniards. He was celebrated among his countrymen for magnificence and liberality. Having discovered in the vale of Mexico a quarry of stones, called tetzoutli, he embellished the city with so many new and magnificent buildings, that it was already become the first city of the new world. Upon the death of Ahuitzotl, Montezuma was elected as the 9th sovereign of Mexico. Besides the valour which he had displayed in several battles, as general, he was likewise a priest, and much venerated for his gravity, circumspection, and religion. In order to obtain victims to be sacrificed at his coronation, he entered into a war with some neighbouring revolters; and the ceremonies exhibited on this occasion were singularly splendid and magnificent. Notwithstanding a solemn agreement concerted between the nobility and plebeians in a former reign for chusing the offices of state, Montezuma displaced the latter, and required that all the servants of his palace should be persons of rank. These were very numerous, and very servile and obsequious. The women who attended him were also persons of rank, and they lived immured in a kind of seraglio, where their conduct was vigilantly regarded; but of these the king retained those who pleased him, and disposed of the others as a recompence for the service of his vassals. The forms and ceremonies introduced at court were additional indications of the despotism of Montezuma. The grandeur and magnificence of his palaces, houses of pleasure, woods, and gardens, corresponded to every other circumstance that served to display the splendour of his royal dignity. In Mexico, besides the seraglio for his wives, there was lodging for all his ministers and counsellors, and all the officers of his household and court, and accommodation for all foreign lords and kings who arrived hither for business or pleasure. He had two houses in the city appropriated to animals, one for birds that did not live by prey, and another for those of prey, quadrupeds, and reptiles. The care of the birds was committed to 300 men, besides their

MEXICO.

their physicians, who administered remedies to their distempers. For the support of the birds of prey 500 turkies were killed daily; and the wild beasts were fed upon deer, rabbits, hares, &c. and the intestines of human sacrifices. Montezuma also collected for his amusement all irregularly formed men. All his palaces were surrounded with pleasant gardens, in which was every kind of beautiful flower, odoriferous herb, and medicinal plant. It had likewise woods enclosed with walls, and furnished with variety of game, in which he frequently sported. In one of the royal buildings was an armoury, filled with all kinds of offensive and defensive arms: and he employed a number of artificers in manufacturing these, and also artists, such as goldsmiths, mosaic-workmen, sculptors, painters, and others. One whole district consisted solely of dancing-masters, who were trained up to entertain him. His zeal for religion was no less conspicuous than his munificence. He built several temples to his gods, and made frequent sacrifices to them, observing with punctuality the established rites and ceremonies. However, his mind was totally debased, by the vain fear of the auguries and pretended oracles of the false divinities to whom he dedicated temples. He was inexorable in punishing those who resisted his orders, or transgressed the laws of the kingdom; and he often put the integrity of his magistrates to the test by secret presents, and if he found them guilty, he inflicted severe penalties. He was an implacable enemy to idleness, every species of which he restrained or corrected. With many good qualities which he possessed, he blended a disposition to oppress his people by the imposition of heavy burdens, in order to support his own folly and extravagance, which disgusted them; notwithstanding the liberal donations which he bestowed on individuals, and particularly on his generals and ministers.

With the exception of the war against the republic of Tlascala, in which he was unsuccessful, he subdued several provinces, and extended the kingdom, as it is said, to the boundaries of Nicaragua. Montezuma, whose fate was decided after Cortes took possession of Mexico, reigned almost eighteen years, and died in June, 1520. He was succeeded by his brother, Cuiclahuatzin, or Guatimozin, as he is usually called, who ascended the throne in the beginning of July, 1520, and reigned about three months, when he was taken prisoner and strangled by order of Cortes, because he had planned a revolt after having sworn homage to the emperor Charles V., then king of Spain. His successor was Quauhquemotzin, who finished his reign on the 13th of August, 1521, having been made prisoner by the Spaniards just as Mexico was taken. His reign could not have lasted more than nine or ten months.

Although Juan de Grijalva, who was appointed by Velasquez to the command of a small expedition for discovery, consisting of four ships, and 240 volunteers, first landed in the territory of New Spain, on the island of Cozumel, E. of Yucatan, on the 3d of May, 1518, and gave the country this appellation, he returned to Cuba without making any considerable progress towards the reduction of it. Velasquez, however, hastened his preparations for a new expedition, and he appointed Fernando Cortes for the commander of it. Of this expedition, and the successful issue of it, in the capture of Mexico, and the subjugation of the Mexican empire, we have given an ample account under the article CORTES. We shall now avail ourselves of the information collected by Dr. Robertson, relating to the Mexicans and their empire, and at the same time introduce the occasional reflections of Clavigero, Estalla, and other writers. Little dependance can be placed on the accounts given of the policy and order established in the Mexican monarchy by

Cortes and his adherents. The genius and manners of the people must be inferred from incidents, which they occasionally mention, rather than from their own deductions and remarks. The obscurity in which the ignorance of its conquerors involved the annals of Mexico, was augmented by the superstition of those who succeeded them. As the memory of past events was preserved among the Mexicans by figures painted on skins, or cotton cloth, or on the bark of trees, the early missionaries conceiving them to be monuments of idolatry, which ought to be destroyed, in order to facilitate the conversion of the Indians, committed them to the flames by order of Juan de Zummaraga, the first bishop of Mexico. Thus the knowledge of remote events, which such rude monuments might furnish, was almost entirely lost, and no information remained concerning the ancient revolutions and policy of the empire, but such as was derived from tradition, or from some fragments of their historical paintings, that escaped the barbarous researches of Zummaraga. Tradition, it is well known, is a very unsatisfactory source of information with regard to events long since past; and the Mexican paintings, which are supposed to have served as annals of their empire, are few in number, and of ambiguous meaning; and are not worthy of that confidence, which some historians of Mexico, and particularly Clavigero, have reposed in them.

According to the report of the Mexicans themselves, their empire was not of long duration. Their country, as they relate, and as is evident from the details which we have already given, was originally possessed, rather than peopled, by small independent tribes, whose mode of life and manners resembled those of rude savages. However, at a period corresponding to the tenth century in the Christian era, several tribes moved in successive migrations from unknown regions towards the N. and N.W., and settled in different provinces of Anahuac, the ancient name of New Spain. Some of these, more civilized than the original inhabitants, began to form them to the arts of social life. At length, towards the commencement of the 13th century, the Mexicans, a people more polished than any of the former, advanced, as we have already stated, from the border of the Californian gulf, and took possession of the plains adjacent to a great lake near the centre of the country. After residing there about 50 years, they founded a town, since known by the name of Mexico, which afterwards became very considerable. The Mexicans, long after they were established in their new possessions, continued, like other martial tribes in America, unacquainted with regal dominion, and were governed in peace, and conducted in war, by such as were entitled to pre-eminence on account of their wisdom or valour. Among them, as in other states whose power and territories become extensive, the supreme authority at last centered in a single person; and when the Spaniards, under Cortes, invaded the country, Montezuma was the ninth monarch who had swayed the Mexican sceptre, not by hereditary right, but by election. Such is the traditional account given by the Mexicans themselves, of the origin and progress of their empire; and its duration appears to have been short. From the first migration of their parent tribe, they can reckon little more than 300 years: and from the establishment of monarchical government not above 130 years, as some say, or, according to others, 197 years, had elapsed. Allowing it a duration corresponding to the Spanish accounts of its civilization, it is difficult to conceive how, among a people who possessed the art of recording events by pictures; and who considered it as an essential part of their national education, to teach their children to repeat the historical songs which celebrated the exploits of their ancestors,

MEXICO.

cestors, the knowledge of past transactions should be so limited. But adopting their own system with regard to the antiquity of their nation, it is no less difficult to account either for that improved state of society, or for the extensive dominion to which their empire had attained when it was first visited by the Spaniards. The recent origin of the Mexicans seems to be a strong presumption of some exaggeration in the splendid descriptions which have been given of their government and manners. In the history of the Mexicans some facts occur, says Dr. Robertson, that suggest an idea of considerable progress in civilization in the Mexican empire, and others which seem to indicate that it had advanced but little beyond the savage tribes around it. Our historian of America has stated these facts. The right of private property was perfectly understood, and established in its full extent. Real and moveable possessions, property in land and in goods, were accurately distinguished; and both might be transferred from one person to another by sale or barter; or both might descend by inheritance. Every person, who could be denominated a freeman, had property in land; which was held by various tenures. Some possessed it in full right, and it descended to their heirs; the title of others was attached to the office or dignity which they retained. These two modes of occupying land were deemed noble, and belonged to citizens of the highest class. But the tenure by which the great body of the people held was of a very different kind. In every district a certain quantity of land was measured out, in proportion to the number of families. This was cultivated by the joint labours of the whole; its produce was deposited in a common warehouse, and divided among them according to their respective exigencies. The members of the "Calpulle," or associations, could not alienate their share of the common estate; it was an indivisible permanent property, destined for the support of their families. Whilst the territory of the state was thus distributed, every man had an interest in its welfare, and the happiness of the individual was connected with the public security.

Another circumstance that deserves to be mentioned was the magnitude and number of their cities. In a rude state of society, men have no very operative inducements to crowd together. From choice, and also from necessity, they live dispersed. But when the Spaniards entered New Spain, they were astonished to find the natives assembled in towns which resembled in their extent those of Europe. Zempoalla, though a town of the second or third size, excited their admiration, and they compared it to cities of the greatest note in their own country. But when they afterwards became acquainted with Tlascala, Cholula, Tacuba, Tezeuco, and Mexico itself, their astonishment increased, and they were led to entertain ideas of their magnitude and populousness bordering on what is incredible. Cortes and his companions, little accustomed to estimate and compute the number of people in such cities, and strongly tempted to magnify, in order to exalt the merit of their own discoveries and conquests, might have been betrayed into error, and might have raised their descriptions considerably above the truth. Dr. Robertson therefore conceives, that abatements ought to be made in their calculations of the number of inhabitants in the Mexican cities, so that the standard of their population should be fixed much lower than they have done; nevertheless our author acknowledges that they are cities of such consequence as are not to be found but among people who have made some considerable progress in the arts of social life.

Another circumstance that ought to be regarded is the separation of professions, which is a symptom of improvement. The savage can form his bow, point his arrow,

rear his hut, and hollow his canoe, without the assistance of any person more skilful than himself: but in proportion as refinement spreads, the distinction of professions increases, and they branch out into more numerous and minute subdivisions. Among the Mexicans, this separation of the arts had taken place to a very considerable degree. The functions of the mason, the weaver, the goldsmith, the painter, and of several other crafts, were carried on by different persons.

The distinction of ranks established in the Mexican empire is another circumstance that merits attention. The great body of the people was in a most humiliating state. Some, denominated "Mayeques," were attached, as it were, to the soil, and conveyed with the lands on which they were settled; others felt the utmost rigour of domestic servitude; and they were held in such low estimation, that a person who killed one of these slaves was not subjected to any punishment. Even those considered as freemen were treated by their haughty lords as beings of an inferior species. The nobles, possessed of ample territories, were divided into various classes, to which peculiar titles of honour belonged. Some of these titles descended with the lands from father to son in perpetual succession. Others were annexed to particular offices, or conferred, during life, as marks of personal distinction. The monarch, exalted above all, enjoyed extensive power, and supreme dignity. The respect attached to these different ranks corresponded to their gradation of dignity; and this respect, due from inferiors to superiors, was so established, that it incorporated with the language, and influenced its genius and idiom. The Mexican tongue abounded in terms of reverence and courtesy. It is only in societies, which time and the institution of regular government have moulded into form, that we find such an orderly arrangement of men into different ranks, and such nice attention paid to their various rights.

The political constitution of the Mexicans is an object deserving of consideration; more especially as it has been misunderstood and misrepresented by the Spaniards. The aspiring ambition of Montezuma introduced innovations upon the Mexican policy; and introduced a pure despotism. He disregarded the ancient laws, violated the privileges held most sacred, and reduced his subjects of every order to the condition of slaves. The chiefs or nobles of the first rank wished to shake off the yoke which he had imposed, and in hopes of recovering their rights, many of them courted the protection of Cortes, and joined a foreign power against their domestic oppressor. We must therefore look back beyond the reign of Montezuma in order to discover the form and genius of Mexican policy. The body of citizens, called nobility, formed the most respectable order in the state. They were of various ranks, and considerable with regard to number. Of this order there were 30 in the Mexican empire, each of whom had in his territories about 100,000 people; and subordinate to these, there were about 3000 nobles of a lower class. The territories belonging to the chiefs of Tezeuco and Tacuba were hardly inferior in extent to those of the Mexican monarch. Each of these possessed complete territorial jurisdiction, and levied taxes from their own vassals. But all followed the standard of Mexico in war, serving with a number of men in proportion to their domain, and most of them paid tribute to its monarch as their superior lord.

Traces of feudal policy, in its most rigid form, are discernible in the Mexican constitution, exhibiting its distinguishing characteristics, a nobility possessing almost independent authority, a people depressed into the lowest state of subjection, and a king entrusted with the executive power

MEXICO:

of the state. But the jurisdiction of its crown was very limited, and all real and effective authority was retained by the Mexican nobles in their own hands. Without their consent the king could undertake no measure of importance. At first they elected the king, and afterwards the choice was committed to six electors, of whom the chiefs of Tezcuco and Tacuba were two. Their choice was guided by a view to the activity and valour of their prince more than to the order of birth; so that collaterals of mature age or distinguished merit were often preferred to those who were nearer the throne in direct descent. Thus the Mexicans secured a succession of able and warlike princes, who raised their empire in a short period to that extraordinary height of power, which it had attained when Cortes landed in New Spain. The monarchs, restrained at first, gradually advanced in power and in the splendour of their government, a striking instance of which was presented to the view of the Spaniards in Montezuma's court; but it was not merely in a parade of royalty that the Mexican monarchs exhibited their power; they manifested it more beneficially in the order and regularity with which they conducted the internal administration and police of their dominions. Their attention in providing for the support of government was no less sagacious than the actual administration of it. Taxes were laid upon land, upon the acquisition of industry, and upon commodities of every kind exposed to sale in the public markets; these taxes were equally laid, and, as the use of money was unknown, they were paid in kind. The internal police of the Mexican empire extended to the appointment of couriers for conveying intelligence, to the structure and government of the capital, to its accommodation with water by means of aqueducts, and to a variety of other circumstances respecting the convenience and comfort of its inhabitants. The attention that was manifested in regulations of this kind was such as polished nations have been late in acquiring and exercising.

The progress of the Mexicans in various arts is alleged as a farther decisive proof of their superior refinement; but on this subject some Spanish authors have been charged with exaggeration. The Mexican paintings which some have extravagantly extolled are represented by others as uncouth delineations of common objects, or very coarse images of the human and other forms, devoid of grace and propriety. In the armoury of the royal palace of Madrid, are shewn suits of armour, which are called Montezuma's; they are composed of thin lacquered copper-plates. Dr. Robertson says, that, in the opinion of intelligent judges, these are evidently eastern. Clavigero, with great ardour, and not without some rudeness of attack on the learned historian, maintains that these are really Mexican; because we are certain, from the testimony of all the writers of Mexico, that those nations used such plates of copper in war, and that they covered their breasts, their arms and thighs with them, to defend themselves from arrows; whereas we do not know that such were ever in use among the inhabitants of the Philippine isles, to which Dr. R. refers them, or among any other people who had commerce with them. The Mexicans, says Clavigero, could boast of many inventions worthy of immortalizing their name, such as, besides those of casting metals and mosaic works of feathers and shells, the art of making paper, those of dyeing with indelible colours, spinning and weaving the finest hair of the rabbits and hares, making razors of a stone called "itztli," which they manufactured with such expedition, that in an hour an artist could finish more than 100, making beautiful looking-glasses of this stone set with gold, the cutting and polishing of gems, breeding of the cochineal, and making use of its colour, preparing of cement for the pavements of their houses, &c. &c. Their potters

were famous; and their carpenters wrought several kinds of wood with instruments made of copper. They had also various manufactures of cloth, using cotton for wool, feathers for silk, with the hair of the rabbit and hare, for lint and hemp, ixotl, or mountain palm, &c.

In the wooden prints or copper-plates of their paintings, that have been published by various authors, every figure of men, quadruped, or birds, as well as every representation of inanimate nature, is extremely rude and awkward. But though the Mexican paintings may be ranked low, as works of art, they may be regarded in a higher point of view, when considered as the records of their country, as historical monuments of its policy and transactions; and they become interesting objects of attention. Of their picture writing, some singular specimens have been preserved. The most valuable of these have been published by Purchas in 66 plates, and divided into three parts. The first contains the history of the Mexican empire under its ten monarchs. The second is a tribute-roll, representing what each conquered town paid into the royal treasury. The third is a code of their institutions, domestic, political, and military. Another specimen of Mexican painting has been published in 32 plates by the archbishop of Toledo. The style of painting is the same in all; they represent *things* not *words*; exhibiting images to the eye, not ideas to the understanding; and they may, therefore, be considered as the earliest and most imperfect essay of men in their progress towards discovering the art of writing. The plates already mentioned indicate some approach to the plain and simple hieroglyphic, where some principal part or circumstance in the subject is made to stand for the whole; and the Mexicans seem also to have advanced farther towards the use of the more figurative and fanciful hieroglyphics. In order to describe a monarch, who had enlarged his dominions by force of arms, they painted a target ornamented with darts, and placed it between him and those towns which he subdued. For the notation of numbers the Mexican painters had invented artificial marks, or "signs of convention;" by means of which they computed the years of the reigns of their kings, as well as the amount of tribute to be paid into the royal treasury. The figure of a circle represented unit, and in small numbers the computation was made by repeating it. Larger numbers were expressed by a peculiar mark, and they had such as denoted all integral numbers, from 20 to 80,000. Though they had proceeded far, they had a long course farther to pursue from the delineation of real objects to the simplicity and ease of alphabetical writing.

Their mode of computing time may be considered as a more decisive evidence of their progress in improvement. They divided their year into 18 months, each consisting of 20 days, amounting in all to 360. But as they observed that the course of the sun was not completed in that time, they added five days to the year. These were termed "supernumerary" or "waste" days; and as they did not belong to any month, no work was done, nor sacred rite performed on them, but they were devoted wholly to festivity and pastime. It appears, says Clavigero, from the chronology of the Mexicans, that they not only counted 365 days to the year, but that they also knew the excess of about six hours in the solar above the civil year, and remedied the difference between them by means of 13 intercalary days, which they added to their century of 52 years. The names of their 18 months were taken both from the employments and festivals which occurred in them, and also from the accidents of the season which attended them. The Mexicans, in order to represent a month, painted a circle or wheel, divided into 20 figures, signifying 20 days. To represent a year they

MEXICO.

painted another, which they divided into 18 figures of the 18 months, and frequently painted within the wheel the image of the moon. The century was represented by a wheel divided into 52 figures, or rather by four figures which were 13 times designed. They used to paint a serpent twisted about the wheel, which pointed out, by four twists of its body, the four principal winds, and the beginnings of the four periods of 13 years. See figures of these wheels in Clavigero's Hist. of Mexico.

Such are the principal facts that indicate the progress of the Mexicans towards civilization. On the other hand, there are several circumstances which serve to shew that their character, and many of their institutions did not differ greatly from those of the other inhabitants of America. Their wars, like those of the rude tribes around them, were continual and ferocious; and even in their civil institutions we discover traces of that barbarous disposition which their system of war inspired. Their funeral rites were not less sanguinary than those of the most savage tribes; so that upon the death of any distinguished personage, especially the emperor, a number of his attendants were chosen to accompany him into the other world; and these unfortunate victims were put to death without mercy, and buried in the same tomb. Their agriculture was in a very imperfect state, so that they were often constrained to live on the spontaneous productions of the earth. The difficulty of rearing a numerous family, induced the Mexican women to keep the children at the breast for several years, during which time they did not cohabit with their husbands. Clavigero, however, asserts, that the Mexicans not only cultivated most diligently all the lands of their empire, but by wonderful exertions of industry, created to themselves new territory for cultivation, by forming those floating fields and gardens on the water, which have been highly celebrated by Spaniards, and other foreigners, and are still the admiration of all who sail upon their lakes. They had not only, says this writer, all the plants which were necessary for food, for clothing, and medicine, but likewise the flowers and other vegetables which contributed solely to luxury and pleasure, were plentifully cultivated by them. Cortes, in a letter to Charles V., dated Oct. 1520, says, "the multitude of inhabitants in these countries is so great, that there is not a foot of land left uncultivated."

Although the Mexican empire was extensive, the Spanish historians have enlarged it far beyond its true boundaries, and they have represented the dominion of Montezuma as stretching over all the provinces of New Spain, from the N. to the southern ocean. But we have already stated that many of the countries said to have been included in the empire of the Mexicans did not belong to it. The Otomies were an uncivilized people, occupying a mountainous country. The Chechemecas, who occupied the provinces N. and W. of Mexico, were a mere nation of hunters. None of these recognized the Mexican monarch as their superior. Tlascalala, at the distance of 21 leagues from the capital of the empire, was an independent and hostile republic. Cholula, though still nearer, had been subjected but a short time before the arrival of the Spaniards. Tepeaca, distant 30 leagues from Mexico, was a separate state, governed by its own laws. Mechoacan, the frontier of which extended within 40 leagues of Mexico, was a powerful kingdom, remarkable for its implacable enmity to the Mexican name. Thus limited in its extent, its various provinces had no considerable mutual intercourse. They had no roads for facilitating the communications of one district with another; inasmuch that when the Spaniards first attempted to penetrate the country, they were under a necessity of opening their way through forests and

marshes. As a farther proof of the imperfection of their commercial intercourse, it has been alleged that they had no money, or universal standard by which they might estimate the value of commodities. Their trade was carried on by barter, and this affords an evidence of the infant state of their police. If by money be understood a sign representing the value of all merchandize, as Montesquieu defines it, it is certain, says Clavigero, that the Mexicans, and all other nations of Anahuac, except the barbarous Chechemecas and Otomies, employed money in their commerce. The cacao had its fixed value, and was reckoned by numbers; but to save the trouble of counting it, when the merchandize was of great value, and worth many thousands of the nuts, they knew that every bag of a certain size contained three xiquipilli, or 24,000 nuts. There were several species of cacao, some of which were used in their diet and beverages, but others were in constant circulation as money, and used in no other way than in commerce. In the capital itself of Mexico, where from 18 to 20,000 crowns (pesos fuertes) are annually coined in gold and silver, the poor people still make use of the cacao to purchase small articles in the market.

It has been further argued, that their cities, though extensive and populous, seemed to have been better adapted for the habitations of men just emerging from barbarity, than the residence of a polished people. The structure of the houses, even in Mexico, was for the most part mean; nor does the fabric of their temples and other public edifices appear to have been such as entitled them to the high praises bestowed upon them by many Spanish authors. Their edifices in general appear to have been meanly built with turf and stone, and thatched with reeds; nor have we any satisfactory evidence, notwithstanding the assertion and pretended evidence of Clavigero, that they used lime. The great temple of Mexico was a square mound of earth, 90 feet wide, partly faced with stone, with a quadrangle of 30 feet at the base, on which was a shrine of the deity, probably of wood. The stairs were made of large stones, and consisted of 114 steps, each a foot high; and at the eastern extremity were raised two towers to the height of 56 feet. Cortes affirms, that within the enclosure of the wall which encompassed the temple, a town of 500 houses might have stood. Although their architecture, says Clavigero, is not to be compared with that of the Europeans, it was certainly greatly superior to that of most of the people of Asia or Africa. Who would form a comparison between the houses, palaces, temples, bastions, aqueducts, and roads of the ancient Mexicans, and the miserable huts of the Tartars, Siberians, Arabs, and other wretched nations which live between the Cape de Verd, and the Cape of Good Hope; or the buildings of Ethiopia, of a great part of India, and the Asiatic and African isles, except those of Japan? The houses of the emperor and those of the principal nobility, it has been said, exhibited some elegance of design, and a commodious arrangement of the apartments into which they were distributed. But on the other hand it is observed, that no remains of them are visible, nor are there any ruins, which can justly be considered as monuments of their ancient magnificence. Eitalla, cited by Pinkerton, observes, that those great palaces, gardens, and temples, those immense and populous cities subject to Mexico, and whose kings were tributary to Montezuma; that high and vast wall which divided the Mexican empire from the republic of Tlascalala, and the other wonders related by historians, should at least have left some few ruins in testimony of their existence, even granting that the Spaniards entertained the extravagant wish of destroying all, in order that they might

MEXICO.

be obliged to construct, with great labour and expence, other edifices far inferior.

The chief remaining antiquities of the Mexicans appear to be earthen ware, in which the Indians of Guadalupe and Mechoacan excel to this day; as the Tarascan of the Peribanez, in that of japanning, the black colour lasting as long as the wood itself, while the figures equal those of the Chinese artists, and the gilding in gold and silver is of great lustre and permanency. Dr. Robertson concludes upon the whole, that though the state of society in Mexico was considerably advanced beyond that of savage tribes, yet with respect to many particulars, the Spanish accounts of their progress in civilization and refinement appear to be highly embellished. At the same time it is allowed, that the accounts given by the Spanish writers of the Mexican power, policy, and law ought not to be rejected, or censured, as the fictions of men who wished to deceive, or who delighted in the marvellous.

With regard to religion, the Mexicans have probably been represented as more barbarous than they really were. Their religious tenets, and the rites of their worship, have been described as wild and cruel in an extreme degree. Religion, among the Mexicans, was formed into a regular system, with its complete train of priests, temples, victims, and festivals. From the genius of the Mexican religion we may form a just conclusion with respect to its influence upon the character of the people. The aspect of superstition in Mexico was gloomy and atrocious. The divinities were clothed with terror, and delighted in vengeance. The figures of serpents, tygers, and other destructive animals, decorated their temples. Fear was the only principle that inspired their votaries. Fasts, mortifications, and penance, all rigid, and many of them excruciating to an extreme degree, were the means employed to appease the wrath of their gods, and the Mexicans never approached their altars without sprinkling them with blood drawn from their own bodies. But of all offerings, human sacrifices were deemed the most acceptable. As their religious belief was blended with the implacable spirit of vengeance, and added new force to it, every captive taken in war was brought to the temple, devoted as a victim to the deity, and sacrificed with rites no less solemn than cruel. The heart and head were the portion of the gods; while the body was resigned to the captor, who, with his friends, feasted upon it. Under the impression, thus produced, the spirit of the Mexicans was unfeeling, and the genius of their religion counterbalancing the influence of policy and arts, their manners, instead of being softened, became more fierce. Although the Mexicans had some confused idea of a supreme, independent being, to whom fear and adoration were due, they represented him under no external form, because they believed him to be invisible, and they named him by the common appellation of God, in their language denominated "Teotl;" and they applied to him certain epithets expressive of grandeur and power. They called him "Ipalnemoani," *i. e.* he by whom we live, and "Tloque Nahuaque," *i. e.* he who has all in himself. But their principal worship seems to have been directed to an evil spirit, the enemy of all mankind, called "Tlaccatecolotl," or, rational Owl, and they said that he often appears to men for the purpose of terrifying them or doing them an injury. They considered the human soul as immortal, allowing immortality also to the souls of brutes. They believed in a kind of transmigration, and thought that the souls of soldiers who died in battle or in captivity among their enemies, and those of women who died in labour, went to the house of the sun, to lead a life of delight; but they supposed that after four years of this glorious life, they animated birds of beautiful feathers and

of sweet song, with liberty to rise again to heaven, or to descend upon the earth. The souls of inferior persons were supposed to pass into weazels, beetles, and such other meaner animals. The souls of those that were drowned, or struck by lightning, of those who died by dropsy or other diseases, went, along with the souls of children, to a cool and delightful place, the residence of "Tlalocan," where they enjoyed the most delicious repasts. The abode of those who suffered any other kind of death was the "Mictlan," or hell, which they conceived to be a place of utter darkness. The Mexicans are said to have had a clear tradition, somewhat corrupted by fable, of the creation of the world, of the universal deluge, of the confusion of tongues, and of the dispersion of the people; and these events were actually represented in their pictures.

Among all the deities worshipped by the Mexicans, which were very numerous, there were 13 principal or greater gods, in honour of whom they consecrated that number. The greatest god, after the invisible god or supreme being, was "Tezeatlipoca," the god of providence, the god of the world, the creator of heaven and earth, and the maker of all things. He was always young, so that no length of years diminished his power, and to him it belonged to confer benefits on the just, and to punish the wicked with diseases and other afflictions. Among their greater gods were also the sun and moon, the god of the air, "Tlaloc," the god of water, to whom they ascribed the fertility of the earth and the protection of their temporal goods; to him they consecrated a temple, and in honour of him celebrated festivals every year; the god of fire, who was greatly revered in the Mexican empire; "Centeotl," or goddess of the earth and of corn, who had five temples in Mexico and three annual festivals; the god of hell, and his female companion, much honoured by the Mexicans; the god of night, to whom they recommended their children, that they might sleep; and "Mexitli," the god of war, most honoured by the Mexicans and regarded as their chief protector. There were other gods of commerce, fishing, hunting, &c. They had also 260 gods, to whom they consecrated as many days. The number of images by which the gods were represented and worshipped in the temples, the houses, the streets, and the woods, were almost infinite. These images were generally made of clay, and certain kinds of wood and stone; but sometimes of gold and other metals, and some of gems. The most extraordinary idol of the Mexicans was that of "Huitzilopochtli," which was formed of certain seeds pasted together by human blood. The divinity of these false gods was acknowledged by prayers, kneeling, and prostrations, with vows, fasts, sacrifices, and various rites. In their prayers they turned their faces towards the east, and their sanctuaries were constructed with their doors to the west. Annexed to the great temple, which we have already mentioned, were various other buildings; and the temples in the whole city of Mexico have been reckoned to amount to 2000, and that of the towns to 360. Each temple had its own lands and possessions, appropriated to its support. The number of the priests corresponded with that of the gods and temples; among these there were several orders and degrees, the chief of whom were two high priests, who were consulted in all affairs of moment, to whom it belonged to anoint the king after his election, and to open the breasts and take out the hearts of the human victims, at the most solemn sacrifices. The high priests of Mexico were distinguished by a tuft of cotton, hanging from their breasts, and at the principal feasts they were dressed in splendid habits, on which were represented the insignia of the god whose feast they celebrated. All the offices of religion were

MEXICO.

divided among the priests; four times a day they offered incense to the idols. The dress of the Mexican priests consisted of a black cotton mantle, which they wore in form of a veil over their heads. They never shaved themselves, so that the hair of many of them reached to their legs, and it was twisted with thick cotton cords, and bedaubed with ink. The austerities and voluntary wounds of the priests, their filthy and poisonous ointments, and their other abominable rites, as they are related by Clavigero, form a system of religion, if we may thus profane the name of religion, the most execrable that ever appeared, no less dishonourable to God than pernicious to man; and it unquestionably does not warrant our entertaining any very exalted notions of their refinement and civilization. The human victims sacrificed at the consecration of two temples were 12,210!

This system is, as Pinkerton very justly observes, so totally unlike any that was ever practised in any part of Asia, that it affords a kind of presumption, either that the people were indigenal, or proceeded from Africa, in which alone (as among the Giagas) such cruelties may be traced. The Asiatic religions seem to be universally mild, and even gay, as natural in the worship of a being who is benevolence itself; while in Africa the preponderance of the evil spirit seems to have been acknowledged by many nations. It should be recollected, however, that the Manichean system was not restricted to Africa; and that the devil, or wicked demon, has had his votaries and worshippers in Asia, as well as Africa; and that the emigrants from thence might have brought the worst part of their system of worship along with them. We merely suggest, that this circumstance affords no convincing evidence with regard to the original peopling of this part of the world, or the remote origin of their ancestors. We must allow, that the Spaniards never sacrificed more victims than the Mexicans themselves devoted; and "the clamours of pretended philosophy will often be found in opposition to the real cause of humanity, which it aspires to defend. Could a change of manners have been effected without the use of the sword, it would have been highly desirable; but the design might have been fruitless as a sermon to a tiger or a rattlesnake. The cruelties of the Spaniards must, by candour, be partly imputed to the profusion of torture and human blood, which every where met their eyes in this unhappy country; as such scenes change the very nature of man, and inflame him like the carnage of a battle." Pinkerton. It should be recollected, however, that the Spaniards had known a religion, and ought to have imbibed its spirit, which was most justly characterised by its divine founder, as "peace on earth and good will towards men."

The Mexicans performed various superstitious rites upon the birth of children, at their marriages, and at their funerals. The child was bathed, and then the diviners were consulted as to its future fortune. He was then named; the name of boys being taken from the sign of the day on which they were born, or from some circumstances attending the birth. Men had often the names of animals, and women those of flowers. The surname was acquired from their future actions. The religious ceremony of bathing was followed by a feast, when drinking was often indulged to excess. Superstition had a great share in the Mexican marriages; but nothing occurred that was inconsistent with decency or honour. Marriage between persons in the first degree of consanguinity was forbidden, unless it was between cousins. The parents were the persons who settled all marriages, and none were ever executed without their consent. The male was thought fit to form the marriage contract at the age of 20 to 22, and the female from 16 to 18 years; and before the union

was concluded, the diviners were consulted, who decided on the happiness or infelicity of the proposed match. If their sentence was unpropitious, the young female was abandoned, and another sought. If the sentence was favourable, the young woman was demanded of her parents by certain women, who were held in respect and esteem. These women went at midnight to the house of the parents with a present, and demanded the damsel in a humble and respectful style. After a few days, these women repeated their visit, stating the rank and fortune of the youth, and gaining information what was her fortune. The parents then founded the inclinations of their daughter; and in due time a decisive answer was returned. On the day appointed for the nuptials, the parents, after exhorting their daughter to a suitable conduct, led her, with a numerous company and music, to the house of her father-in-law; if noble, she was carried on a litter. The bridegroom, and her parents, received her at the gates of the house, with four torches borne by four women. At meeting, the bride and bridegroom offered incense to each other; and the bride was led by him to the hall or chamber prepared for the nuptials. They were then seated on a mat, and a priest tied a point of the gown of the bride to the mantle of the bridegroom, and in this ceremony the matrimonial contract chiefly consisted. They then offered copal to their gods, and exchanged presents with each other. This ceremony was followed with a repast, at which the bride and bridegroom gave some food to each other, and to their guests; and after the exhilaration occasioned by drinking, a dance took place; and the married pair remained in the chamber, and continued there four days; which were passed in prayer and fasting, being dressed in new habits, and adorned with certain ensigns of the gods of their nation. The marriage bed was adjusted by the priest, and the consummation of the marriage did not take place till the fourth night. On the ensuing morning they bathed and put on new dresses, and those who had been invited adorned their heads with white, and their hands and feet with red feathers. The ceremony was concluded with making presents of dresses to the guests; and on that day the mats, canes, &c. were carried to the temple. In the Mexican empire, polygamy was allowed.

The funeral rites were more superstitious than any others, and certain persons of advanced years were appointed for the conducting of them. Having clothed the body of the deceased in a habit appropriate to his former profession or business, they gave him a jug of water, and pieces of paper with instructions, adapted to his journey into the other world. They also killed a domestic quadruped, which was to be his companion. This they buried or burned together with the body of his master. The ashes were collected and deposited in a pot, together with a valuable gem: the earthen pot was deposited in a ditch, and at the interval of fourscore days, they made oblations of bread and wine over it. At the death of kings, lords, or persons of high rank, other ceremonies were practised, for the detail of which we must refer to Clavigero; merely observing, that the bodies of the deceased were generally burned, and that the ashes of kings and lords were usually deposited in the towers of the temples.

To the education of their youth, the Mexicans paid particular attention; they are habituated from their earliest age to industry, virtue, and the forms of religion; truth was inculcated by express precepts, and the violation of it severely punished, and reverence for their parents and aged persons was sedulously inculcated. Besides their domestic education, children were sent to public schools, situated near the temples, and there they were instructed for three years in religion and good customs. Adultery among the Mexi-

Can was always punished with death, nor was any divorce allowed without the permission of the judges. Those who were guilty of incest or unnatural crimes were hanged; and incontinence was severely punished; but for simple fornication no punishment was prescribed. The penalty annexed to theft in slighter cases was mere restitution, but in concerns of greater value, slavery. A person who robbed in the market place was there banished to death. Hanging was the punishment of tutors and guardians who did not give a good account of the estates of their pupils, and also of those who squandered away their patrimony in vice. Drunkenness in youth was a capital crime, and in advanced years it was punished with severity; and in case of a nobleman, it incurred forfeiture of office and rank, and entailed infamy. The prisoners of war were generally sacrificed to their gods; and slaves were allowed to possess their property, nor was slavery entailed upon their descendants. Necessitous parents might procure relief by the sale of their children, and any freeman might sell himself for the same purpose.

The highest military dignity among the Mexicans, was that of a general of the army; and in order to encourage a military spirit, they rewarded the services of warriors with one of the three orders, called by names which denoted princes, eagles, and tigers. When they went to war, different persons from the king to those of inferior rank were distinguished by peculiar badges. The defensive arms were shields of different forms; breast-plates of cotton, arrow-proof, and other armour for the defence of other parts of their bodies; the officers and nobles had a beautiful plume of feathers on their heads; but the common soldiers were entirely naked, except a girdle round the middle. The offensive arms of the Mexicans, were arrows, slings, clubs, spears, pikes, swords and darts. They had also standards and musical instruments proper for war. Previously to a declaration of war, the alleged cause of it was submitted to the judgment of the supreme council, and before it commenced, the enemy was apprized of it. The king, or the general, gave the signal for action by the beat of a drum; and the first onset was furious; but their great aim was not to kill, but to make prisoners for sacrifices when the battle was terminated. The victors celebrated their conquest with great rejoicings, and rewarded the officers and soldiers who had taken prisoners. Before any siege was begun, the citizens removed their children, women, and sick persons to a place of security in the mountains. For the defence of their cities, they used various kinds of fortification, such as walls and ramparts, breast-works, palisades, ditches, and entrenchments; but the most singular fortifications of Mexico in particular were its temples, and especially the greater temple, which resembled a citadel. The Mexicans, though fond of war, are said to have addicted themselves to the arts of peace, and particularly to the cultivation of the earth. Although they had no ploughs nor oxen, nor any other animals proper to be employed in agriculture, they supplied the want of them by labour and industry. In the operations of the field, the men were assisted by the women; the former being employed in occupations that required the greatest exertion, and the latter in the lighter and more easy employments. In their farm-yards they had threshing floors and granaries; and of the latter some were so large as to contain 5 or 6000, or sometimes more, fanegas of maize. The Mexicans were also well skilled in the cultivation of gardens, both for use and for pleasure. They were likewise attentive to the preservation of their woods, which served for fuel, for building, and for the diversion of their king, in the pursuit of game. They also paid particular attention to the breeding of animals. Fishing, hunting,

agriculture, and the arts, furnished the Mexicans with several branches of commerce. Merchandizes were sold in their fairs and markets by number and measure; but they are said not to have used weights. Their markets were subject to various regulations for the prevention of frauds, and for securing to the king his revenue. For the convenience of merchants, Clavigero says, that they had public roads, bridges for crossing their rivers, and houses of accommodation in the mountains and uninhabited places. Their sailing vessels were guided merely by oars, and were of various sizes; and many of them were made of a single trunk of a tree. Some ancient historians, probably inclined to exaggerate, say, that the number of those which continually traversed the Mexican lake exceeded 50,000. They had also for the convenience of navigating their lake and rivers, platforms or floats of solid canes, which were tied firmly on large, hard, and empty gourds. The maritime commerce of the Mexicans was very inconsiderable. The commerce of the Mexicans, it is said, was little embarrassed or impeded by the variety of languages which were spoken in those countries; for the Mexican tongue was the most prevalent, and was every where understood. This language, says Clavigero, is entirely destitute of the consonants B, D, F, G, R, and S, and abounds with L, X, T, Z, Tl, and Tz; but although the letter L is so familiar to this language, there is not a single word that begins with this consonant; nor is there a word of an acute termination, except some vocatives. Almost all the words have the penult syllable long. Its aspirates are moderate and soft, and no occasion occurs for making the least nasal sound in pronunciation. This language, notwithstanding its want of the above-mentioned consonants, is said to be very copious, tolerably polished, and remarkably expressive. The Mexican language, like the Hebrew and French, wants the superlative term, and like the Hebrew, and some other living languages of Europe, the comparative term, which are supplied by certain particles equivalent to those which are used in other such languages. It abounds in diminutives and augmentatives; and also in verbal and abstract terms; for there is hardly a verb from which there are not many verbals formed, and scarcely a substantive or adjective from which there are not some abstracts formed. It is not less copious in verbs than in nouns; as from every single verb others are derived of different significations. The Mexicans, like the Greeks, have the advantage of making compounds of two, three, or four simple words. The arts of poetry and oratory were much exercised by the Mexicans. Dramatic, as well as Lyric, poetry was held in high estimation among these people, and they had theatres in which these kinds of compositions were rehearsed. Their music was more imperfect than their poetry; and it is said, that they had no stringed instruments. But imperfect as was their music, their dances, to which they were much addicted from their youth, were eminently graceful. Their dances, which were of various kinds, were almost always accompanied with singing, which, like their dances, was always adjusted by pulsatile instruments. The amusements of the Mexicans were not confined to the theatre and dancing; they had various games, not only for public occasions, but for the relaxation and diversion of private individuals. The Mexican paintings have been already mentioned; and they were very numerous, and applied to various purposes. Their colours were brilliant, though their designs were coarse and uncouth. We shall here add to what has been already said, that the Mexicans were skilled in sculpture; and the usual materials of their statues were stone and wood. They also valued themselves on the works which they executed by

MEXICO.

the casting of metals, and on those Mosaic works which were made of the molt delicate and beautiful feathers of birds. The state of medicine among the Mexicans, Clavigero has described much in detail; as he has also their surgery and their baths. Their food and drink consisted of preparations of maize, cacao, chia, and the French bean. Of animal food they partook more sparingly. They had different sorts of wine made of the magnai or Mexican aloe, the palm, and maize. Their dress was simple, consisting of a girdle about the loins, a square mantle, and a piece of square cloth with which the women wrapped themselves from their waists down to the middle of the leg. Besides this they had a little under vest, or waistcoat, without sleeves. Persons of superior station added to their dress a variety of ornaments. Besides feathers and jewels, with which they adorned their clothes, they wore ear-rings, pendants at under lip, and many at their noses, necklaces, bracelets, and rings like collars round their legs. The ear-rings and pendants of the poor were shells, pieces of crystal, amber, or some other shining little stone; but the rich wore pearls, emeralds, amethysts, and other gems set in gold. Their household furniture was mean and coarse. Their beds consisted of two coarse mats of rushes, to which the rich added fine palm mats and shirts of cotton: and the lords, linen woven with feathers. The pillow of the poor was a stone or piece of wood; that of the rich was probably of cotton. Their drinking vessels were made of a fruit similar to gourds. They made no use of candlesticks, or wax, or tallow candles, or of oil to give light. They kindled fire by the friction of two pieces of wood; and generally made use of the achiote, or rocou of the French. It is added, that they also struck fire from flint. After dinner, the lords used to compose themselves to sleep with the smoke of tobacco; the leaves of which they put with the gum of liquid amber, or some other warm odorous herbs, into a little pipe of wood, or reed, or other more valuable substance; they then received the smoke by sucking the pipe and stopping the nostrils with the fingers, so that it might pass more easily to the lungs. The deficiency of soap they supplied by a fruit and a root. As to the population of the whole Mexican empire, Estalla says that it could not have surpassed three or four millions, even including the people of Tlascala, and other towns, not subject to Montezuma.

Having given an extended account of ancient Mexico, we shall now close the article with a brief description of Mexico in its more modern state. The viceroyalty of Mexico may be regarded as the chief in Spanish America, and is extended over a territory equal to an European empire. But there are several inferior governors, named by the Spanish sovereign. A considerable part of his power consists in the patronage of all the churches. His salary was formerly 40,000 ducats, afterwards 60,000, and lastly 84,000, exclusively of the disposal of lucrative offices, monopolies, connivances, presents, &c. which sometimes rise to an enormous amount. His court is formed on the regal model, with horse and foot guards, a grand household, and numerous attendants. In their vice-royalty there are three grand tribunals, called Royal Audiences, viz. that at Guatemala, that of Mexico, and that of Guadalajara. There are a few several inferior tribunals. The population of all the Spanish provinces in North America has been estimated at little more than seven millions; of whom the natives, called Indians, are supposed to amount to four millions; and the Spaniards and inhabitants of mixed races, are computed at three millions, of which the Spaniards may constitute one-third. It is probable, however, that the whole population of Spanish North America does not exceed six millions. They have suffered much from the small-pox, and

a disease called the black vomit, which occasionally ravages like a pestilence. And besides, the number of priests, monks, and nuns is injurious to population. Estalla observes, that though he has not been able to acquire exact information concerning the population of New Spain, yet by the most intelligent computations, there are in the Intendency of Mexico 1,200,000 souls, including 140,000 for the city: and by the proportion between this province and the others, as well as by the best founded calculations, it may be supposed there are in all the kingdom, three millions and a half of inhabitants. The troops in New Spain are estimated at 43,191, including 5982 regulars, 31,523 militia, &c. and 5686 for garrisons, &c.; so that it may well be doubted whether the whole grand vice-royalty of New Spain could send into the field 15,000 effective men. The revenue which Mexico yields to the Spanish crown has been shewn by Dr. Robertson to amount to above a million sterling, but it is subject to great expences. Dr. Robertson shews, from Campomaner, that the whole produce of the American mines is 7,425,000*l.* of which the king's fifth, if regularly paid, would be 1,485,000*l.*; and it is probable that the mines of New Spain or Mexico, prior to the opulent discoveries in the N.W. provinces, did not yield above one-half of the whole amount. From Estalla we learn, that a very great augmentation has taken place in all the branches of the royal treasury in this vice-royalty; so that the sums paid into the royal treasury have been tripled, and amount annually to 19 millions of dollars, and even more. Allowing the expences of administration, salaries, &c. to amount to 4,800,000 dollars, there will be an overplus of 14,200,000 dollars; that is, more than 1,800,000*l.* sterling. These revenues increase according to the progress of agriculture, the mines, commerce, industry, and population. There are some branches of the revenue which are considerable in their amount; such are the tributes, the products of the coinage, of quicksilver, gunpowder, cards, duties on goods sold, the drink called "pulque," bulls of indulgence, tobacco, lotteries, letters, all which are under the management of the minister of state. Other branches are administered in the royal coffers by their respective superintendants; such as the duties on gold, silver-plate, the assays, tythes, ninth, various ecclesiastical concessions, titles of Castille, vendible offices, compositions and confirmations of land, cock-fighting, snow and ice, stamps, fines, &c. the product of the mines, copper, lead, tin, alum, and others. From this statement there will appear to result a clear sum of 7,800,000 pesos, or about 1,170,000*l.* sterling; and if the peso fuerte be used, one-third must be added.

The ecclesiastical revenue is also very considerable. The archbishopric of Mexico is extremely opulent; and yet deemed inferior to the bishopric of Puebla de los Angeles. The ecclesiastical courts are numerous; and the holy tribunal of the faith, or the Inquisition, is very vigilant and severe. The chapter of the cathedral comprehends 26 ecclesiastics. While the revenue of the archbishop is computed at 100,000 dollars, the dean has more than 10,000; the canons from 7 to 9000, the lesser canons from 2 to 4000; some curacies are worth many thousand ducats; and one in the archbishopric of Mexico is valued at 14,000 ducats a year; while many of the curates, in their career of ambition, become prebendaries and bishops. There are two archbishoprics, those of Mexico and Guatemala, with eight bishoprics, Puebla de los Angeles, Oaxaca, Durango, Mechoacan, Antequera, Guadalajara, Yucatan, and Chiapa. The curacies are computed at 235.

The chief city of New Spain is *Mexico*, which see; and there are many other flourishing cities in this wide empire.

MEXICO.

The most interesting in a commercial view are the two chief ports, Acapulco on the Pacific ocean, and Vera Cruz on the Atlantic: to these we may add, Puebla de los Angeles, Cordova, Xalapa, Queretaro, Guadalupe, and Guatemala, &c. &c. which see respectively.

The manufactures of New Spain are not of any great importance. Coarse cottons form the universal dress of the Indians. There are many tanneries; but the leather is far from being equal to the Spanish; and the same observation is applicable to the glass and earthen ware, though the materials be excellent. The commerce of New Spain is extensive and important, and has recently undergone material improvements; so that since the year 1778, when greater freedom began to be introduced, the commerce has greatly increased. Two advantages have arisen from the liberty of commerce; industrious individuals and the general mass of the people have been enriched; while the great capitals of the former monopolists returned to support agriculture and the mines. The number of shops has been greatly augmented. The imports also have been increased, so that at Vera Cruz alone they amounted, in 1792, to 14,23,000,889 dollars. See *VERA CRUZ*.

The climate of this country is singularly diversified, between the tropical seasons and rains, and the temperature of the southern and even middle countries of Europe. The maritime districts of Mexico are hot and unhealthy, so as to occasion much perspiration even in January; the inland mountains, on the other hand, present snow and ice in the dog-days. In other inland provinces, however, the climate is mild and benign, with some snow of short duration in winter; but no artificial warmth is necessary, and animals sleep all the year under the open sky. From April to September there are plentiful rains, generally after noon; hail-storms are not unknown: thunder is frequent; and earthquakes and volcanoes occasionally occur. The climate of the capital, in lat. $19^{\circ} 25'$, differs much from that of the parts of Asia and Africa under the same parallel; which difference seems to arise chiefly from the superior height of the ground. Humboldt found, that the vale of Mexico is about 6960 feet above the level of the sea, and that even the inland plains are generally as high as mount Vesuvius, or about 3600 feet. This superior elevation tempers the climate with a greater degree of cold. Upon the whole, the climate cannot be regarded as unhealthy, as the aborigines sometimes attain a great age; and the appearances of decay are not perceived till a late period of life. But though they are exempted from paying tribute after the age of sixty, yet they can rarely count the years of their existence, and they cannot always be traced in the parish registers. It appears from such facts, that the prejudices of some philosophers against the climate and productions of America are unfounded. If there be any where a marked difference in every respect, of climate, men, animals, and vegetables, it is in Africa, a most ancient part of the ancient world, that it must be sought. (See on this subject *Clavigero, ubi supra*.) The face of this interesting country is diversified by grand ridges of mountains, numerous volcanoes, some of which are covered with perpetual snow, cataracts worthy of the pencil of Rosa, delicious vales, fertile plains, picturesque lakes and rivers, romantic cities and villages, an union of the trees and vegetables of Europe and America. The soil is often a deep clay, surprisingly fertile and requiring no manure except irrigation. The progress of agriculture in this country may be partly inferred from the state of the tithes, which, in the archbishopric of Mexico, for ten years, from 1769 to 1779, amounted to 4,132,630 pesos; while, for the ten years from 1779 to 1789, they advanced to 7,830,879 pesos. A similar difference appears

in the bishoprics of Puebla, Oaxaca, Guadalupe, and Durango, which, with Valladolid, comprehend the whole vice-royalty of Mexico; Guatemala being considered as a distinct kingdom. The product of cotton might be increased: of indigo there are annually exported 1500 arrobas, and 8000 quintals of pimento: the cultivation of sugar is increased: tobacco has become an important branch: vineyards afford a favourable prospect; and the annual exports of cochineal are computed by Estalla at 23,600 arrobas; but by another computation, the quantity of cochineal exported to Spain is 460,000 pounds, colling in New Spain about 12s. per pound, and yielding at Cadiz about 13 or 14s. The people employed in this culture are estimated at between 25 and 30,000. It has been observed, by the author often cited in this article, that the produce of many articles has been tripled within these few years, such as indigo, cotton, pimento of Talasco, and, above all, the precious cochineal; while tillage, and the rearing of herds and flocks, have been far more universally diffused.

The principal rivers of this country are Rio Bravo, the Medina, Magdalena, or river of Guadalupe, that of Flores, the Ariguitas, Chicowanshi, Mexicano, Colorado, Gila, Hiaqui, Nafus, Barneja or Esquitlan, Panuco, Zacatula, Yopez, Alvarado, Grijalva, Balleze, Yare, St. Juan, and Chagre. The chief chain of mountains in Spanish North America is Topia or Sierra Madre, to which we may add the grand ridge of Tamalipa, the great chain of Apanaca, Canatagna, and Urraca. The composition of the mountains of New Spain is not accurately ascertained, but it is supposed by Humboldt and Pinkerton to be mostly of argillaceous schistus, which is a substance generally prolific of metals. The volcanoes in New Spain have been reckoned 21 from that of Soconusco in the north to that of Varu in the south. These are all on the south-western coast, and after a considerable interval they again emerge towards the eastern coast, in the vicinity of Mexico. The volcano of Orizava is considered as the most majestic in the viceroyalty. The richest silver mines of New Spain were formerly supposed to be those of Zacatecas, about 200 miles N.W. of Mexico; but at present the grand mines are at Guanajuato, between $21^{\circ} 30'$ and $22^{\circ} 30'$ N. lat. and 103° and 105° W. long., extending from N. to S. 75 miles, from E. to W. 85 miles. Humboldt estimates the population of the administration at 5,173,300, and of the capital, in N. lat. 21° W. long. 103° , about 41,000, See *GUANAJUATO*.

During 11 years from 1766 to 1778, Mr. Pinkerton states, that there were coined at Mexico 203,882,948 pesos, seven reals; but, during another 11 years, from 1779 to 1791, there were coined 252,042,419 pesos, and half a real; the difference being more than 48,000,000. Before the freedom of commerce, the coinage never exceeded 20,000,000 of pesos; and in 1792, 1793, it annually surpassed 24,000,000. In the viceroyalty are found many other metals besides gold and silver. Not far from the capital are mines of tin; this metal is also found in New Mexico. Clavigero says, that the Mexicans used thin pieces of tin and bits of copper for money. Copper is obtained from the rich mines of Guanajuato and also in mines W. of Pasquaro, the capital of Mechocan. Lead is among the products of New Leon. New Spain also furnishes amber and asphalt, and a few diamonds; the mountains also produce jasper, marble, alabaster, magnet, steatite, jade and talc. The "Tetzontli," red and porous, was used in building, being perhaps, as Pinkerton suggests, a kind of tufa; and the "Itzli," mentioned in a preceding part of this article, as used for mirrors and razors, is called "pietra del Galinazzo" in South America, and is the obsidian or volcanic glass of modern mineralogy. In this country

MEXICO.

try have been found, among the fossils, the bones of elephants; bones of this kind were found in digging the foundations of the convent of Guadalupe near Mexico; and they have been found in other places. They are the same with those of the mammoth of Siberia and North America, and belonged to an animal now extinct. Pinkerton's Geography, vol. iii.

MEXICO *Proper*, a district or territory of the domain or viceroyalty of Mexico, forming part of the ancient Mexican empire, already amply described in the preceding article.

MEXICO, signifying according to Clavigero the place of *Mexitli*, or Huitzilopochtli, *i. e.* the Mars of the Mexicans, on account of the sanctuary there erected to him, the chief city not only of Mexico or New Spain, but of old Spanish America. It is situated, in a beautiful vale, on fenny ground near the banks of the lake of Tezenco, and crossed by numerous canals, the houses being all founded on piles. Hence it would seem that the waters of the lake have diminished, so as to leave a fenny morass on the west; and it is not improbable that this might happen after the inundation of 1629, when a wide canal was led through a mountain to drain the lake. The seat of the modern Mexico is the same with that of the ancient city; the viceroy residing on the spot of Montezuma's palace, in a large mansion built by Cortes, and still rented at 4000 ducats from the marquises de Valle, his descendants. The ancient city is said to have been situated upon a small island in the forementioned lake; and N. of its junction with that of Chalco, and on the W. side of the lake of Tezcuco, accessible on the W. side by three large causeways of earth and stone, but on the E. side there was no communication otherwise than with canoes or boats. The circumference of the city, exclusive of the suburbs, measured more than 10 miles, and the number of houses was at least 60,000. The city was divided into four quarters, and each quarter into several districts, bearing Indian canoes. The four quarters were divided by four broad roads, which led from the four gates of the area of the greater temple. To the four parts into which the city was divided from the first foundation A.D. 1325, the city of Tlatlalolco was added as a fifth, situated towards the N.W. having been united after the conquest of king Axajacatl to Tenochtitlan, and both together formed Mexico. Around the city there were many dykes and reservoirs for collecting water, and within it many canals, so that there was hardly a district that could not be approached by boats. Among the various buildings of the city, besides temples and magnificent royal palaces, there were other palaces in which the feudatory lords resided when they attended the business of the court. All the houses, it is said, those of the poor excepted, had balconies and parapets, and some of them battlements and towers, much smaller than those of the temples; and serving for the defence of the inhabitants in their streets and houses as well as their temples. Besides the large and famous square of Tlateloco, where the principal market was held, there were other smaller markets distributed through the city, where ordinary provisions were sold; and in different places there were fountains and fish-ponds, particularly near the temples, and many gardens, some of which were laid out on the natural level of the earth, and others raised on high terraces. Of the modern city, Chappe d'Au-terroche, cited by Pinkerton, gives the following account. The streets are wide and straight, but very dirty; and the houses, resembling those of Spain, are tolerably built. The chief edifice is the viceroy's palace, which stands near the cathedral in a central square, and it is rather solid than elegant. Behind the palace is the mint, in which more than 200 workmen are employed, as the owners of the mines here

exchange their bullion for coin. The other chief buildings are the churches, chapels, and convents, which are very numerous and richly ornamented. The outside of the cathedral is unfinished, as they doubt the foundations; but the rail round the high altar is of solid silver, and there is a silver lamp so capacious that three men may go into it to clean it; and it is also enriched with lions' heads, and other ornaments, in pure gold. The images of the Virgin, and other saints, are either solid silver, or covered with gold and precious stones. Besides the great central square, there are two others, each of which has a fountain in the middle. To the N. of the town, near the suburbs, is the public walk, or "Alameda." A rivulet runs round it, and forms a pretty large square, with a basin and jet d'eau in the middle. Eight walks, each of which has two rows of trees, terminate at this basin like a star. There are also some other promenades; although the country about Mexico is swampy ground, and full of canals. Facing the "Alameda" is the "Quemadero," where they burn the Jews, and the unhappy victims of the Inquisition. It is an inclosure between four walls, and filled with ovens, into which are thrown, over the walls, the wretches that are condemned to be burnt alive; condemned, as the author says, by judges professing a religion whose first precept is charity. The Spanish inhabitants are commonly clothed in silk, their hats being adorned with belts of gold and roses of diamonds; for even the slaves have bracelets and necklaces of gold, silver, pearls, and gems. The ladies are of distinguished gallantry.

Mexico, though inland, is a place of immense commerce between Vera Cruz on the E., and Acapulco on the S.; and the shops display a profusion of gold, silver, and jewels. In magnificent regularity it yields to few cities on the ancient continent. Gage says, that, in his time, A.D. 1640, there were supposed to be 15,000 coaches, some of them adorned with gold and gems; the people being so rich, that it was imagined one-half of the families kept carriages. From the work of Eitalla, published in 1799, and quoted by Pinkerton, we derive some further information concerning this famous city.

The lake, it is said, has retired a Spanish league from the city, which circumstance is supposed to render the air less salubrious. The winter frost is gentle, and is thought severe when the ice exceeds the thickness of paper. The summer heats are tempered by the regular showers which fall in the evenings. Water-spouts often occur, but they always fall in the lake; however, they have sometimes ruined mining stations. The yearly cold at Mexico, though just within the tropic of Cancer, appears by observations on the thermometer to exceed the heat. The rainy season extends from the middle of May to the middle of September.

The plain of Mexico is, as we have already said, surrounded with mountains, covered with cedars, rare shrubs, and medicinal plants, and containing minerals and precious stones. On these mountains are romantic cottages and farms, watered by clear rivulets. In the middle of this delicious plain are the lakes Tezcuco and Chalco. The city has received no augmentation since the year 1712. The streets are well opened, running in right lines from E. to W. and from N. to S. Great improvements have lately taken place by the cleanliness and good police of the place: the city is lighted, and the streets paved, and sewers and water-courses have been opened, so that Mexico has become the largest, most beautiful, and most sumptuous of the whole Spanish monarchy. The cathedral is a magnificent edifice, the work of 94 years; it has two images of the Virgin, one of gold, which weighs 6984 castellanos, the castellano being the 50th part of a mark, and a mark being $\frac{2}{3}$ ds of a pound or eight

eight ounces. For 14 parishes, there are more than 100 other churches, most of which are neat and richly decorated. The religious houses are very numerous, and the nunneries amount to 25. Among the numerous courts and offices of justice, established in this city, are the royal audience and chancery of New Spain; the court for strangers, and those who die intestate; the royal tribunal of regillers; the royal coffer; the royal mint; the tribunal of the inquisition; the house of the missions of California; the mount of piety, erected by the charity of the count de Regla, who gave no less than 315,000 pesos; the royal tribunal of mines; that of the descendants of Cortes; the illustrious chapter, justice and government of the noble and imperial city itself, to which the ancient arms were confirmed by Charles V., being a castle with three towers, an eagle on a tree with a snake in its beak, at the foot of the tree is the lake; the whole surmounted with an imperial crown, and supported by two lions. Philip V. granted to Mexico, in 1728, all the privileges and distinctions of a grandee of Spain; and Charles III., in 1773, indulged the chapter, or magistrates, with the use of uniforms laced with gold, declaring their precedence over all tribunals and bodies, except the royal audience and tribunal of accounts. The patroness of the city is St. Mary of Guadalupe, solemnly chosen in 1737, and whose worship has extended over all Spanish America. The general character of the natives, who have a considerable disposition for the arts and boast of their eminent painters, is that of a liberal, courteous, affable, and charitable people. The city has thirteen hospitals, and other charitable establishments. The viceroy is commander in chief, and president of the economical and political government. He resides in the royal palace. He is also president of the tribunal of accounts, which inspects all those of the royal revenue. The city council consists of a corregidor or mayor, twelve regidores, or aldermen, and other officers. The common alcalds judge criminal and civil cases in the first instance subject to an appeal to the royal audience.

The city of Mexico is amply supplied with grain, fruit, and vegetables, from the environs, which are very fertile; those on the east side of the lake of Tezcuco excepted, where vegetation is impeded by the saline exhalations of the lake. The more populous parts of the city extend from north to south four English miles, and from east to west three English miles. The city is surrounded merely by a trench or ditch, without walls or other defence. There are six principal gates; and by the gate of Guadalupe all the pulque enters, which, being the general drink of the inhabitants, yields a revenue of about a million of dollars to the king. The streets are well paved. The manufactory of cigars, employing more than 5000 persons, is a modern and magnificent edifice. The consumption of cigars is very great; for all the Mexican ladies smoke tobacco; and they take their paper cigars from a case of gold or silver, hanging by a chain or ribbon, while on the other side they wear little pincers of the same metal. As soon as one cigar is exhausted, another is lighted: they smoke even at the theatre, and only cease to smoke when they eat or sleep. The tribunal of "La Acordada" was one of the most terrible in the viceroyalty; the judge, who is called captain of the holy brotherhood, being also inspector of prohibited liquors: but Charles III. ordered that the viceroy, with two or three judges, should revise the sentences. The judge of the "Acordada" has from eight to ten thousand men, dispersed through the viceroyalty, under the names of lieutenants, corporals, &c. This holy brotherhood maintains, by its

vigilant police, the public tranquillity of the city and viceroyalty, performing their rounds day and night, and speedily punishing every excess. Capital criminals are hanged in a field, called "Exido de Concha," from the name of a captain of this brotherhood; and the tribunal has become more useful, since the viceroy has obtained the privilege of reviewing sentences of death. The market for trifling and second-hand commodities is a square of shops, and the theatre is small but handsome.

Mexico is supplied with water by two aqueducts. The most splendid festivals of the Mexicans are the procession of Corpus Christi, and the entrance of a new viceroy. There are other festivals, such as the anniversary of the conquest, and the publication of the bulls of indulgence.

Although the climate of Mexico is in general salubrious, yet there are some prevalent, and even epidemic diseases. The ravages of the small-pox, however, are likely to be restrained by the Jennerian antidote, which is not unknown even in Mexico; and the black vomit, or yellow fever, is scarcely known in this city. Agues are frequent; pulmonary consumptions, apoplexies and epileptic diseases, spotted fevers and pleurisies, are not uncommon: but the most universal disease of men and women is that called "flado," or the wind, which presents singular and almost incredible symptoms; the patients appearing as if they were demoniac or frantic, sometimes excessively hot and cold by very sudden changes, laughing and weeping, and agitated by convulsions, as if they were possessed. This disease seems to proceed from the hot and unhealthy regimen, and from the abuse of tobacco, destructive alike of the nerves and stomach.

Some individual artizans are very rich, but of late property is more generally diffused: there are, however, many entailed estates, founded by the conquerors, from ten to sixty thousand dollars a-year; but the chief that remain are the products of commerce and of the mines. Within the last twenty or thirty years, the number of houses that sell "pulque" is greatly increased: they are open, by regulation of the police, only from ten in the morning till four in the afternoon, and during this interval they occasion quarrels, and sometimes murders. Estalla computes the population of Mexico at 140,000 souls; but it is probably more considerable. As there is no money of bullion at Mexico, the shop-keepers issue tokens of copper, iron, or wood, which pass in the neighbourhood; and even grains of cacao pass as small coin. The city has several useful regulations for guarding against fires, and any consequent tumults. The water-pipes have been enlarged, and ten public fountains have been constructed, with cocks instead of cisterns, which are found more convenient. The price of bread is regulated every four months, according to the price of grain. The foot-paths are guarded with little pillars; the pavement is kept in good repair, and there is a covered sewer in the middle of the streets, and the city is well lighted by large lamps of the reflecting kind. Watchmen clean and supply the lamps, and guard the houses and passengers; and the municipal troops perform their nightly rounds. In this celebrated capital great quantities of rum are distilled from the refuse of the numerous sugar-mills.

The university of Mexico, founded in 1551, is styled royal and pontifical; and the cloister is composed of two hundred and fifty-one doctors, of all faculties. It is governed by a rector, annually elected by the lesser cloister, composed of the former rector and eight counsellors, chosen by lot from the doctors and bachelors. The office of chancellor is annexed to the dignity of schoolmaster of the me-

tropolis; his office being to preside at conferring some degrees, while on other occasions he holds the second rank. The professors of this university are named by a junta, consisting of the archbishop, the regent of the royal audience, the dean of the cathedral, the oldest inquisitor, the rector of the university, the master of the metropolitan schools, the professor of the first class of theology, and the dean of the faculty. The public library of the university was founded about forty years ago, and is well furnished with old books of divinity, but is miserably deficient in new editions of the classics, or new works of science and philosophy. This library is open to the public at certain hours, except on Sundays and holidays. The college of St. Mary-of-all-Saints is the only one of the first rank in the Spanish American possessions: it has a public library. The seminary was founded by an archbishop of Mexico in 1682; and at present it has thirteen professors. The students amount to four hundred, and a new building was erected in 1750. The Jesuits had formerly five colleges, two of which only remain: they are directed by the viceroy, or a junta, of which he is president. The buildings are magnificent; the chapel and grand hall being the most beautiful in the viceroyalty. The college of St. John of Lateran is the most ancient of any in New Spain, having been founded in the reign of Charles V., for the instruction of those descended from Spanish and Indian parents. It has been improved in 1764, and again in 1789. The college of St. Jago is without the walls of Mexico, in a house of the Franciscans; but it is now merely a boarding-school for children. Other religious orders have also public schools. A college of mines has lately been erected, in which young persons are not only instructed in that science, but in other important parts of education. The royal academy of the three noble arts is a valuable institution: it is provided with good professors in architecture, painting, sculpture, and engraving; and there is also a professor of mathematics. There are also particular houses in Mexico where Latin grammar is taught by preceptors approved by the government and university.

The environs of Mexico are richly cultivated with flax, hemp, cotton, tobacco, indigo, sugar, and magneys; and furnish the city with ample supplies of meat, poultry, vegetables, and fruits. The most celebrated sanctuary in the vicinity of the city is that of our lady of Guadalupe, which has a college, a church, &c. Another sanctuary, or house of pilgrimage, is that of our lady de los Remedios, erected on the spot whither Cortes retired when he was repulsed from Mexico. Without the barrier of Santiago is the sanctuary of our lady of the Angels, formerly the residence of a hermit. At the distance of five leagues from Mexico is the desert of the Carmelites, in an enclosure about a league in circuit; the retreat of the most austere monks there being in solitary cells. The aqueduct of Chapultepec adorns the immediate environs; and on the hill so called was a palace of Montezuma. Traspansa is another place of resort, where are several good houses; and many settle there, as the air is esteemed very healthy. On the side of San Lazaro, about half a league from Mexico, is the rock of the baths, which are warm, but the quality is not ascertained. N. lat. 19° 54'. W. long. 99° 51'. Pinkerton's Geog. vol. iii.

MEXICO, *New*, a large territory of the Spanish dominions in North America, sometimes called a kingdom, but properly a single province, lying eastward of California, and divided by the gulf from that peninsula. Northwards it is bounded by high mountains and an unknown country, on the east by Louisiana, on the west by the Californian lake and Rio Coiorado, and on the south by some of the pro-

vinces of New Spain, or Mexico proper. This province was discovered by a missionary in 1581, but scarcely subdued till 1644; nor were many missions established till after the year 1660; and the capital, Santa Fé, was founded in 1682. It is a fertile and delightful province, producing maize, wheat, and excellent fruits. The mines are said to be all of tin; and the animals and plants are of singular variety. In the map of Alzate, the northern limit is marked at 38°, and the southern at 30° 30'; the medial breadth, on both sides of the Rio Bravo, being only 2°, or 120 geographical miles. Pinkerton.

MEXICO, a town of America, in Oneida county, New York, at midway between Oneida lake and Oswego, 20 miles from each. The township is extensive, comprehending a number of houses.

MEXICO, *Gulf of*, a large bay or gulf of the Atlantic, extending north to south, from the coast of Florida to the coast of Tabasco and Yucatan, about 600 miles, and east to west, from Cuba to the coast of Mexico, about 700. This gulf lies in a favourable climate, and presents at its entrance the grand archipelago of North American islands, called the West Indies. See *Gulf Stream*.

MEXIMIEUX, a town of France, in the department of the Ain, and chief place of a canton, in the district of Trevoux; 17 miles N.E. of Lyons. The place contains 1691, and the canton 8372 inhabitants, on a territory of 230 kilometres, in 14 communes.

MEYAPONTE, a river of Brasil, which runs into the Parana.

MEYENBERG, a town of Switzerland, in the Free Bailiwicks, once an independent lordship; 10 miles N. of Lucerne.

MEYENBURG, a town of Brandenburg, in the mark of Prenzitz; 60 miles N.N.W. of Berlin. N. lat. 53° 18'. E. long. 12° 15'.

MEYENFELD, a town of the Grisons, and principal place of a jurisdiction. It is said to have been the first place in which the reformation was encouraged. This town was a kind of staple for goods that passed to and from Germany and Italy; 52 miles E. of Lucerne. N. lat. 46° 57'. E. long. 9° 38'.

MEYER, JAMES, in *Biography*, an historian, was born in Flanders in the year 1491. He studied in the university of Paris, and entered into holy orders. For several years he taught school at Ypres and Bruges, and in the latter city had a benefice, in the church of St. Donatian. He died at Blankenberg, in the year 1552. He was on terms of intimacy with Erasmus, and other learned men; and wrote several works, of which the principal are, 1. "Flandricarum Rerum Decus," being an account of the origin, antiquity, nobility, and genealogy, of the counts of Flanders; and, 2. "Annales Rerum Flandricarum," which begin with the year 445, and come down to 1477. They are written in a pure and easy style, and have been reprinted in the collection of Belgic historians. Moreri.

MEYERA, in *Botany*, a genus of Schreber's, named, we presume, in honour of Dr. Frederic Albert Anthony Meyer, a physician at Göttingen who died in 1795, and who was the author of various tracts on Natural History. Willdenow has not adopted the genus, nor do we find any notice of it under *Sclerocarpus*, although its author says they are nearly allied, but belonging to different orders of the class *Syngenesia*. It must however be recollected that these orders are not always permanently distinct in nature. *Meyera* rests solely on the authority of Schreber, not having been taken up by any other author, so that we can only translate

translate his own generic character. If its habitat had been published, possibly a more clear and satisfactory reference might have been made of the plant in question. Schreb. 570.—Class and order, *Syngenesia Polygamia Superflua*. Nat. Ord. *Discoides*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyc* of four, large, broad, heart-shaped, concave, veined leaves, spreading at the top, rather acute, shorter than the disk, the two inner ones opposite. *Cor.* compound, tubular, convex; florets in the disk numerous, perfect, funnel-shaped, five-cleft, somewhat erect; those of the radius several, ligulate, lanceolate, entire. *Stam.* (in the perfect florets) Filaments five, capillary; anthers cylindrical, tubular, five-toothed. *Pist.* (in the same) Germen oblong; style thread-shaped, longer than the filament; stigmas two, revolute. In the female ones the style is longer than the florets. *Peric.* none, except the permanent calyx. *Seed* in both kinds of florets solitary, oblong, transversely compressed, crescent-shaped, striated, scaly; down none. *Recept.* convex, small; scales cartilaginous, imbricated, triangular, incurved, furrowed at the back, downy towards the top externally, oblique at the extremity, each enveloping a single seed, the outer ones a little broader.

MEYNIAC, in *Geography*, a town of France, in the department of the Correze, and chief place of a canton, in the district of Ussel. The place contains 2978, and the canton 7726 inhabitants, on a territory of 322½ kilometres, in 11 communes.

MEYNTHAL, or VAL DE MAGGIA. See MAGGIA.

MEYO, in *Commerce*, a measure for corn, salt, and other dry commodities, in Portugal; it contains 15 fanegas; each fanega being = 4 alquieres = 8 meyo = 16 quartos = 32 outavas = 64 mequias. The alquiere is = 675 French = 817 English cubic inches; so that 21 alquieres = 1 English quarter, nearly, or, more exactly, 50 alquieres = 4 alquieres of Oporto are reckoned equal to 5 alquieres of Lisbon, and 2 alquieres of Oporto, or 2½ of Lisbon, are computed to be equal to an English bushel.

MEYRINGEN, in *Geography*, a large and neat village of Switzerland, the capital burgh of Hasliand, a district in the canton of Berne, which enjoys peculiar privileges. The people are governed by their own magistrates, and only take oaths of fidelity to the sovereign council. The authority, which the bailiffs in the other cantons enjoy, is possessed in a great measure by the landamman, who resides at Meyringen. The place is situated near the Aar, in a romantic vale, surrounded by meadows of a luxuriant verdure, and sprinkled with cottages, which are occasionally separated by huge stones and deep channels, the vestiges of storms and floods; 28 miles S.E. of Thun.

MEYRUEIS, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Florac; 22 miles S. of Mende. The place contains 2890, and the canton 5235 inhabitants, on a territory of 345 kilometres, in seven communes. N. lat. 44° 11'. E. long. 3° 31'.

MEYSSAC, a town of France, in the department of the Correze, and chief place of a canton, in the district of Brives. The place contains 2072, and the canton 10,466 inhabitants, on a territory of 160 kilometres, in 14 communes.

MEYWAR. See OUDIFOUR.

MEYZIEU, a town of France, in the department of the Isere, and chief place of a canton, in the district of Vienne. The place contains 1045, and the canton 9547 in-

habitants, on a territory of 212½ kilometres, in 16 communes.

MEZA, a river of Russia, in the government of Pottok, which runs into the Dwina; 16 miles N.E. of Veliz. MEZAIR. See MESAIR.

MEZALANA, in *Geography*, a town of Italy, in the department of the Mincio; four miles S. of Mantua.

MEZANA, a town of Liomone, in the island of Corsica, and chief place of a canton, in the district of Ajaccio: the canton contains 1751 inhabitants.—Also, a town of Italy; five miles S. of Padua.

MEZANA, *La*, a town of Naples, in Basilicata; 17 miles S.W. of Turfi.

MEZANINE, or MEZZASINE, a term used by some architects, to signify an attic, or little story, contrived occasionally over the first story, for the conveniency of a wardrobe, or the like.

The word is borrowed from the Italians, who call *mezzanini* those little windows, less in height than breadth, which serve to illuminate an attic, or entresole.

MEZDA, in *Geography*, a town of Africa; 60 miles S. of Tripoli.

MEZDAGA, a town of Fez, in the province of Chau, at the foot of mount Atlas.

MEZE, a town of France, in the department of the Herault, and chief place of a canton, in the district of Montpellier; 15 miles S.W. of Montpellier. The place contains 2800, and the canton 8729 inhabitants, on a territory of 135 kilometres, in seven communes. N. lat. 43° 25'. E. long. 3° 42'.

MEZELIEMEINA, a town of Africa, in Tunis, on the lake Bizerta; 28 miles N. of Tunis.

MEZEMNA, a sea-port of Algiers, in the kingdom of Fez, on the coast of the Mediterranean; 80 miles E. of Tetuan. N. lat. 35° 22'. W. long. 4° 5'.

MEZEN, a sea-port town of Russia, in the government of Archangel, near the White sea, at the mouth of a river of the same name; 128 miles N.N.E. of Archangel. N. lat. 66° 30'. E. long. 43° 34'. The river rises in the government of Archangel, N. lat. 64° 15'. E. long. 49° 14', and runs in a S.W. direction to the town of Poshanskoi, when, changing its course, it runs N. westerly to N. lat. 66° 30'. E. long. 48° 34', where it flows into the Frozen ocean.

MEZEN, a mountain of France, which gives name to a district, in the department of the Ardèche; 27 miles W. of Valence.

MEZERAI, FRANCIS EUDES DE, in *Biography*, a celebrated French historian, was born in 1610, at Ry, in Lower Normandy. After studying at Caen he came to Paris, and obtained the post of an officer of the artillery, in which capacity, he served two campaigns. He then quitted the army, and retired to the college of St. Barbe, where he applied with great ardour to study, having projected a history of France, of which, under the patronage of cardinal Richelieu, he published the first volume, folio, in the year 1643. The two others appeared in 1646 and 1651. On account of this, the court recompensed his labours by a pension of 4000 livres, with the title of historiographer. This success engaged him to compose an abridgment of it under the title of "Abregé Chronologique de l'Histoire de France," in three vols. 4to.; it was reprinted in Holland, in 6 vols. 12mo. In this work he published an account of the origin of all the public imposts, with some very free reflections, which gave so much offence to the minister Colbert, that he remonstrated with the author, who pro-

mised to make the requisite corrections in the second edition. This he performed, but, at the same time, informed the readers that he was compelled to do so; and his corrections, moreover, were only palliations, he was therefore punished by withdrawing half his pension. On his making a complaint, the other half was also suppressed, upon which he declared, that he would not continue his history. On the death of Conrart, in 1675, he was elected to the vacant place of perpetual secretary to the French academy; in this situation he prepared a sketch of the projected dictionary of the academy. Mezerai died in 1683. Besides the works already mentioned, he wrote "Traité de l'Origine des François;" "L'Histoire des Turcs, depuis 1612 jusq' en 1649." A translation of John of Salisbury, "De Nugis Curialium," and of Grotius, "De veritate Relig. Christi." Mezerai was a man of great singularities in his temper and habits. He was fond of low company, and so squalid in his dress, that he was once taken up by the police for a beggar. He never wrote but by candle-light, even in the day-time, and in the midst of the summer, and he had always a bottle on the table. He affected to be a sceptic in his religion, but in his last illness his early impressions recurred, and he entreated his friends to forget his impieties, and to recollect "that Mezerai dying was more to be believed than Mezerai in health." Moreri.

MEZEREON, in *Botany*, seems by Bauhin's *Pinax* 462, and Lobel's *Adversaria* 157, to be a word of Arabian origin. In the book last mentioned it is said to belong properly to the *Cneorum iricoccum* of Linnæus, which however is not known to grow in Arabia, but in Spain and the south of France. The name is now transferred to the *Daphne Mezereon*, or *Laureola Mezereon Germanica* of the older writers, and is become the familiar English appellation of that charming shrub. See CNEORUM and DAPHNE.

MEZIDON, in *Geography*, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Lisieux; 11 miles W.S.W. of Lisieux. The place contains 528, and the canton 9089 inhabitants, on a territory of 160 kilometres, in 34 communes.

MEZIERES, a town of France, and principal place of a district, in the department of the Ardennes, situated on an island formed by the Meuse, over which it has two bridges, with a citadel; two miles S. of Charleville. The place contains 7400, and the canton 11,567 inhabitants, on a territory of 137½ kilometres, in 12 communes. N. lat. 49° 46'. E. long. 4° 47'.—Also, a town of France, in the department of the Indre, and chief place of a canton, in the district of Le Blanc. The place contains 1338, and the canton 7084 inhabitants, on a territory of 390 kilometres, in nine communes.—Also, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Bellac. The place contains 1313, and the canton 9107 inhabitants, on a territory of 307½ kilometres, in eight communes.

MEZIN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Nerac; six miles S.S.W. of Nerac. The place contains 2860, and the canton 10,136 inhabitants, on a territory of 280 kilometres, in 16 communes. N. lat. 44 3'. E. long. 0° 20'.

MEZIRIAC, CLAUDE-GASPARD BACHET, in *Biography*, was born in 1581, of a noble family at Bourg-en-Bresse. He entered among the Jesuits, and at the age of twenty was professor of rhetoric at their house in Milan. A bad state of health induced him to quit the society, and he passed much

of his time at Paris and Rome in literary pursuits. His reputation was so great, that he was mentioned as a fit person to be preceptor to Lewis XIII., but the dread of such an office induced him to quit Paris and retire to his native place. He died in 1638, leaving behind him many works that bore witness to his great erudition. He wrote verses in French, Latin, and Italian, and was a profound Greek scholar, an excellent grammarian and critic, a philosopher, theologian, and mathematician. His principal works are as follow: "Problemes plaisans et delectables que se font par les Nombres;" "Diophanti Alexandrini Arithmeticonum Lib. vi. et de Numeris multangulis Lib. i." translated from the Greek with commentaries: "La Vie d'Esopé:" "Epistolæ et Poemata varia."

MEZOUR, in *Geography*, a town of Asia, in Candahar; 63 miles N.E. of Candahar.

MEZTITLAN, a town of Mexico; 25 miles N. of Mexico.

MEZUZOTH, in the *Jewish Customs*, certain pieces of parchment, which the Jews fix to the door-posts of their houses, taking that literally which Moses commands them, saying, "Thou shalt never forget the laws of thy God, but thou shalt write them upon the posts of thy house, and on thy gates." This expression means nothing else, but that thou shalt always remember them, whether thou comest into thy house, or goest out. But the Hebrew doctors imagined, that the law-giver meant something more than this. They pretended that, to avoid making themselves ridiculous, by writing the commandments of God without their doors, or rather to avoid exposing themselves to the profanation of the wicked, they ought, at least, to write them on a parchment, and to enclose it in something. Therefore they wrote these words upon a square piece of parchment, prepared on purpose with a particular ink, and a square kind of character. (Deut. vi. 4, 5, 6, 7, 8, 9.) "Hear O Israel the Lord our God is one Lord, &c." Then they left a little space, and afterwards went on, (Deut. xi. 13.) "And it shall come to pass, if thou shalt hearken diligently to my commandments, &c.," as far as, "Thou shalt write them upon the door-posts of thy house, &c." After this they rolled up the parchment, and put it into a case of reeds, or other matter; they wrote on the end of the case the word "Shadai," which is one of the names of God; and they put it at the doors of their houses, chambers, and all places most frequented; they fixed it to the knockers of the door, on the right side; and as often as they entered in, or went out, they touched it in this place with the end of their finger, which they afterwards kissed out of devotion. The Hebrew word *mezuzza* properly signifies the door-posts of a house; but it is also given to this roll of parchment now mentioned. Leo of Modena may be here consulted.

MEZZA PAUSA, in the *Italian Music*, half a pause, intimates that the part wherein it is found must be still the time of a semibreve in common time. See PAUSE.

MEZZA Tirata. See TIRATA.

MEZZAROLA, in *Commerce*, a liquid measure of Genoa, containing for wine two barrili, or 100 pinte, and reckoned at 18 rubbi, or 45lbs. peso sottile; the mezzarola is = about 39 English gallons.

MEZZEREB, in *Geography*, an island in the Red sea. N. lat. 27° 43'.

MEZZO, an Italian adjective, which means half; as *mezzo sorte*, *mezzo piano*, *mezza voce*, which imply nearly the same thing, i. e. a middle degree of piano, or soft. *Mezzo soprano*, a pitch of voice between the *soprano* or treble, and counter-tenor. See CLEFS, and COMPASS of Voices.

MEZZO-

MEZZO-TINTO.

MEZZO-TINTO, in *Sculpture*, a particular manner of engraving figures on copper.

Mezzo-tinto is said to have been first invented by prince Rupert, about the year 1649; and Mr. Evelyn, in his *History of Chalcography*, gives us a head, performed by that prince, in his way; though Mr. Le Blon is said to have introduced it into practice with the greatest success.

The prince laid his grounds on the plate with a channelled roller; but one Sherwin, about the same time, laid his ground with a half-round file, which was pressed down with a heavy piece of lead. Both these grounding tools have been laid aside for many years; and a hand-tool, resembling a shoemaker's cutting-board-knife, with a fine crenelling on the edge, was introduced by one Edial, a smith by trade, who afterwards became a mezzo-tinto painter.

It is very different from the common way of engraving. To perform it, they rake, hatch, or punch the surface of the plate all over with a knife, or instrument made for the purpose, first one way, then the other, across, &c., till the face of the plate be thus entirely furrowed with lines or furrows, close and as it were contiguous to each other; so that if an impression was thus taken from it, it would be one uniform blot, or smut.

This done, the design is drawn, or marked on the same face; after which, they proceed with burnishers, scrapers, &c. to expunge or take out the dents or furrows, in all the parts where the lights of the piece are to be; and that more or less, as the lights are to be stronger or fainter: leaving those parts black, which are to represent the shadows, or deepnings of the draught.

As it is much easier to scrape or burnish away parts of a dark ground, corresponding with the outline of any design sketched upon it, than to form shades upon a light ground, by an infinite number of hatches, strokes, and points, which must all terminate with exactness on the outline, as well as differ in their force and manner, the method of scraping, as it is called in mezzo-tinto, consequently becomes much more easy and expeditious, than any other method of engraving. The instruments used in this kind of engravings are cradles, scrapers, and burnishers.

In this engraving, the plate must be prepared and polished in the same manner as for other engraving (see *COPPER-PLATES*); and afterwards divided equally by lines, parallel to each other, and traced out with very soft chalk. The distance of these lines should be about one-third of the length of the face of the cradle which is to be used, and these lines should be marked with capital letters, or strokes of the chalk. The cradle is then to be placed exactly betwixt the two first lines, and passed forwards in the same direction; being kept as steady as possible, and pressed upon with a moderate force. The same operation must be repeated with respect to all the other lines; till the instrument has thus passed over the whole surface of the plate. Other lines must be drawn then from the extremities of the other two sides, in the same manner; which intersecting the first at right angles, will with them form squares; and the same operation must be repeated with the cradle, as in the case of the first. New lines must then be drawn diagonally, and the cradle passed betwixt them as before; and when the first diagonal operation is performed, the lines must be crossed at right angles as the former, and the cradles passed betwixt them in the same manner. The plate having undergone the action of the cradle, according to the disposition of the first order of lines, a second set must be formed, having the same distances from each other as the first. But they must be so placed as to divide those already made into spaces one-third less than

the whole extent; *i. e.* every one after the first on each side will take in one-third of that before it, *e. g.* beginning at A, of which the first third must be left out; the third of B will consequently be taken in; and so of the rest. These lines of the second order must be marked with small letters, or lesser strokes, to distinguish them from the first; and the same treatment of the plate must be pursued, with respect to them, as was practised from the others. When this second operation is finished, a third order of lines must be made, the first of which, *e. g.* in A, must omit two-thirds of it, and consequently take in two-thirds of B, &c. By these means the original spaces will be exactly divided into equal thirds; and the cradle must be again employed betwixt these lines as before. When the whole of this operation is finished, it is called *one turn*; but in order to produce a very dark and uniform ground, the plate must undergo the repetition of all these several operations, for above twenty times; beginning to pass the cradle again betwixt the first lines, and proceeding in the same manner through all the rest. When the plate is prepared with a proper ground, the sketch must be calked on it, by rubbing the paper on the backside with chalk. It is also proper to overtrace it afterwards with black-lead or Indian ink. The scraping is then performed, by parting or cutting away the grain of the ground in various degrees; so that none of it is left in the original state, except in the touches of the strongest shade. The general manner of proceeding is the same as drawing with white upon black paper. The masses of light are first begun with; and those parts, which go off into light in their upper part, but are brown below: the reflections are then entered upon; after which the plate is blackened with a printer's blacking-ball made of felt, in order to discover the effect; and then the work is proceeded with; observing always to begin every part in the places where the strongest lights are to be.

But the present mode of this engraving is rendered still more expeditious and easy to the artist, not only in laying the ground, but in scraping the plate. Instead of using the cradle or grounding tool three times, it is now found to produce a better grain by only repeating it twice, or *double ways*, as it is called by artists. In laying the ground, the copper is ruled as formerly, and instead of taking up a third of the way already executed, it now only takes up one-half, by which means the grain of the ground, or texture, is more dotty, and has a more solid look, and consequently is less liable to the appearance of cuts or lines, which was too much the character of the former process. Fifteen ways in this manner worked close, will be sufficient to fill the ground, and give it a velvet-like tint. The former mode of making an outline from the painting, is now found to be wholly unnecessary, and the most ready and masterly method is to square the painting in any number of given squares, and the same number on the plate, agreeable to the size of it, and with a black-lead pencil draw backwards the picture (which with a little practice becomes familiar) on the ground, and the scraping is then performed by the original method. The art of mezzo-tinto engraving was considered formerly as only adapted to broad subjects, and where high minute finishing was required, it was thought vain to attempt it; but the great advances made in that art since the time of prince Rupert, have convinced every amateur to the contrary, and the successful works of Eadom, especially his masterly flower-pieces, are admirable specimens of its power, as also the ever grateful productions of Hodges, Dixon, and many rising artists of the present time. In engraving portraits, it is decidedly most appropriate for resembling both the touch and effect. This is the most usual way of performing this operation.

The art of scraping mezzo-tintos has been applied to the printing with a variety of colours, in order to produce the resemblance of paintings. The inventor of the method of doing this was J. C. Le Blon, a native of Francfort, and pupil of Carlo Marata, between the years 1720 and 1730. It was established by the inventor on this principle, that there are three primitive colours, of which all the rest may be composed, by mixing them in various proportions: that any two of these colours being mixed together, preserve their original power, and only produce a third colour, such as their compound must necessarily give; but if transparent colours be mixed, and three primitive kinds compounded together, they destroy each other, and produce black, or a tendency to it, in proportion to the equality or inequality of the mixture; and that, if, therefore, these three colours be laid, either separately, or upon each other, by three plates, engraved correspondently, on these principles, to the colouring of the design, the whole variety of teints necessary may be produced. The requisites, therefore, to the execution of any design in this method of printing, are as follow. 1. To settle a plan of the colouring to be imitated; shewing where the presence of each of the three simple colours is necessary, either in its pure state, or combined with some other, to produce the effect required; and to reduce this plan to a painted sketch of each, in which not only the proper outlines, but the degree of strength should be expressed. 2. To engrave three plates according to this plan, which may print each of the colours exactly, in the places where, and proportion in which, they are wanted. 3. To find three transparent substances, proper for printing with these three primitive colours. The manner in which Mr. Le Blon prepared the plates was as follows: the three plates of copper were first well fitted with respect to size and figure to each other, and grounded in the same manner as those designed for mezzo-tinto prints; and the exact place and boundary of each of the three primitive colours, conformably to the design, were sketched out on three papers, answering in dimensions to the plate. These sketches were then calked on the plates; and all the parts of each plate, that were not to convey the colour, to which it was appropriated, to the print, were entirely scraped away, as in forming the light of mezzo-tinto prints. The parts that were to convey the colour were then worked upon; and where the most light or diluted teints of the colour were to be, the grain in the ground was proportionably taken off; but where the full colour was required, it was left entire. In this regard was had, not only to the effects of the colour in its simple state, but to its combined operation, either in producing orange-colour, green, or purple, by its admixture with one alone; and likewise to its forming brown grey, and shade of different degree; by its co-operation with both the others. But though the greatest part of the engraving was performed in the mezzo-tinto manner, yet the graver was employed occasionally for strengthening the shades; and for correcting the outline, where it required great accuracy and steadiness. It was found necessary sometimes to have two separate plates for printing the same colour, in order to produce a stronger effect: but the second plate, which was used to print upon the first, was intended only to glaze and soften the colours in particular parts that might require it. With respect to the black and brown teints, which could not be so conveniently produced in a due degree, by the mixture of the colours, umber and black were likewise used.

With respect to the order in which the plates are to be applied, it may be proper to observe, that the colour which is least apparent in the picture should be laid on first; that which is betwixt the most and least apparent, next; and that which predominates, last; except where there may be occa-

sion for two plates, for the same colour, as was before mentioned; or where there is any required for adding browns and shades.

Mr. Le Blon applied this art to portraits, and shewed, by the specimens he produced, the possibility of its being brought, by farther improvements, to afford imitations of painting, which might have some value. It is nevertheless much better adapted to the simpler subjects, where there are fewer intermixtures of colours; and where the accuracy of the reflections, and demi-teints are not so essentially necessary to the truth of the design, from the greater latitude of form, and disposition of the colour, as in plants, anatomical figures, and some subjects of architecture. But perhaps plates engraved, or rather finished, with the tool, particularly with respect to the outline, would be better accommodated in some of these cases, than those prepared only by scraping.

Mr. Cochin remarks, at the end of an account he has given of Mr. Le Blon's manner, that though this ingenious artist confined this method principally to the use of three colours; yet should this invention be again taken up and cultivated, there would be more probability of success in using a greater variety: and that several different kinds might be printed by one plate; provided they were laid on in their respectively proper places, by printing balls, which should be used for that colour only. His hint might, however, be very greatly improved, by the further assistance of pencils, accommodated to the plates, for laying on the colours in the proper parts. — Handmaid to the Arts, vol. ii. p. 182, &c. Encyclopedie, Art. GRAVEUR en Couleurs, &c.

For the method of taking off mezzo-tinto prints in glass, see BACK-painting.

MEZZOVO, in *Geography*, a ridge of mountains in European Turkey, which divides Thessaly from Albania.

MGLIN, a town of Russia, in the government of Novgorod Sieverskoi, on the Iput. N. lat. $53^{\circ} 12'$. E. long. $32^{\circ} 34'$.

MHARAS, a mountain of Arabia, in the province of Yemen; 16 miles W. of Kataba.

MI, a river of China, which rises in the province of Chantong, and runs into the Chinese sea, N. lat. $37^{\circ} 12'$. E. long. $129^{\circ} 14'$.

MI, in *Musick*, the third found in the ascending scale of Guido's hexachords. See SOLMISATION, and HEXACHORD.

MIA, in *Geography*, a town of Japan, in the island of Niphon; 85 miles E. of Meaco.

MIACO. See MEACO.

MIADWZNA, a town of Poland, in the palatinate of Kiev; 36 miles S.S.E. of Bialacerkiev.

MIALNANAEN, a mountain of Scotland, in the county of Perth; 10 miles E.N.E. of George's Town.

MIAM, in *Commerce*, a weight for gold at Malacca, 320 mians being = 20 buncalls = a catty = 29oz. 17dwt. 16gr. English troy; and a money of account at Siam, 16 miams being = 4 ticals = a tale, and 20 tales = a catty; and as 10 mians are accounted = 1 Chinese tale, 5 tales of Siam = 8 Chinese tales.

MIAMAJA, in *Geography*, a town of Japan, on the N. coast of Niphon. N. lat. $41^{\circ} 10'$. E. long. 141° .

MIAMI, or MAWNEE, *Great*, a river of America, in the state of Ohio, forming the western boundary of the state, and dividing it from Indiana territory. It enters the Ohio, 333 miles below Marietta, according to the winding of the river. At its mouth it is 300 yards wide; but at the Pickawee towns, above 70 miles higher, it is not above 30 yards wide, though it is passable for loaded boats 50 miles higher. Its stream is rapid, without cataracts. This river has several boatable branches, one of which extends towards the Sandusky, with

an intermediate portage of six or eight miles, and another opens a communication with Au Glaze by a short portage. The channel of the river is stony; hence it is sometimes called *Affreniet*, or *Rocky river*. Its waters are very clear and transparent. One of the principal branches of the Miami river is called "Mad river," or "Pickawee fork." This is a pleasant stream, and passes through an agreeable level country of the greatest fertility.

MIAMI, *Little*, discharges itself, after a south-western course, into the Ohio, about 300 miles below Marietta. It is 70 miles in length, and at its mouth 70 miles wide. Its depth of water does not allow the passage of loaded boats. On its borders the land is good, and its banks are so high that it is seldom overflowed.

MIAMI of the *Lake*, sometimes called "Omec" and "Mannick," is a considerable stream, navigable with canoes to the portages which lead to the head of the Wabash, and through Au Glaze, one of its branches towards the head of Lorome's creek, a head water of the Great Miami. Its portage is three miles. This river falls into lake Erie, at the S.W. corner of the lake. On this river there is a village called Miami, near Miami fort.

MIAMIS, an Indian nation, which inhabit the vicinity of the Miami river, and the southern side of lake Michigan. These people can raise about 300 warriors. In consequence of lands ceded to the United States by the treaty of Greenville, Aug. 3d, 1795, government paid them a sum in hand, and engaged to pay them annually, for ever, to the value of 1000 dollars in goods.

MIANA, a town of Persia, in the province of Adirbeizan, where M. Thevenot the traveller died on his return from Ispahan; 45 miles S. of Ardebil. N lat. 37 12'. E. long. 47 22'.—Also, a town of Italy, in the Bellunese; 24 miles W.N.W. of Belluno.

MIAO-TSE' MOUNTAINEERS, a general name under which are comprehended several tribes, who differ from one another only by some particular customs. This half-barbarous people are dispersed throughout the Chinese provinces of Se-tchuen, Koei-teheou, Hou-quang, Quang-li, and on the frontiers of the province of Quang-tong. They often come down from their mountains, and make incursions into the flat, open country, although the Chinese, in order to restrain them, have built castles and fortresses in several places, in which numerous garrisons are maintained. The Miao-tse are under the government of princes, who have no less authority over their subjects than those of the "Lo-los" have over theirs; they maintain household officers and a regular militia; they have under them several petty feudatory lords, who, although sovereigns, are obliged to levy troops for them whenever they receive orders. The usual arms of the Miao-tse are bows and half-pikes. Their horses are much esteemed by the Chinese, on account of the agility with which they climb the mountains. The Miao-tse, who inhabit the province of Koei-teheou towards Liping-fou, have houses built of brick, containing only one story; in the lower part of which they keep their horses, oxen, cows, sheep, and hogs, which render their habitations very filthy and disgusting; and therefore the Tartar princes prefer lodging in the wretched barracks of the soldiers than in these houses. These Miao-tse are collected in villages, and live in great harmony with one another. They cultivate the earth, make cloth, and manufacture a kind of carpets, which serve to cover them during the night. Their cloth is only a coarse sort of muslin of little value; but their carpets are good, and well woven. The timber of their forests is purchased by the Chinese, and floated down the river that traverses their country; and the price consists of a certain num-

ber of cows, oxen, and buffaloes. The skins of these animals are used by the Miao-tse for breast plates, which they cover with thin lamina of steel or copper. The ordinary dress of these Miao-tse consists of a pair of drawers, and a kind of jacket which laps over their breast. Those of the Miao-tse tribe, who are dispersed in that part of Hou-quang which is nearest to the provinces of Quang-tong and Quang-si, are equally independent, though they seem to acknowledge the jurisdiction of the Chinese mandarins. They climb their rocks and run among their mountains barefooted, with great speed. The head-dress of their women is singular, as they place transversely upon their heads a board about a foot long, and five or six inches broad, over which they spread their hair, fixing it to the wood by means of wax. The greater part of the Miao-tse is composed of independent people; but some of them are subject to the Chinese government. Such are those who live towards the middle, and southern part of the province of Koei-teheou, and who are under two distinct governments. Some of these are subject to the mandarins of the province, and form a part of the Chinese people, whose customs they have adopted. The rest are subject to hereditary mandarins, who are considered as naturalized, although Chinese by extraction. These petty princes judge, in the first instance, the causes of their vassals, and have a right of punishing them, but not capitally. The Chinese entertain a sovereign contempt for the whole Miao-tse nation. Their account of them is very unfavourable; but the missionaries assure us, that they found them an active, laborious, and obliging people, and remarkably honest and punctual in restoring the baggage, and other effects which they had entrusted to their care. These mountaineers, on their part, no less detest the Chinese, whom they consider as harsh and severe masters, who, unable to subdue them, and reduce them to a state of slavery, keep them blocked up in their country, and cut off from all communication with their neighbours. In the year 1776 these mountaineers were driven into their inmost retreats, and totally subdued by Akoui, a Chinese general. Grosier's China, vol. i.

MIASMA (from *μαζια*, the most direct interpretation of which is to *daub*) may be applied to any kind of impurity. Among medical writers, however, to whom the word is now chiefly confined, it relates principally to impurities in the air, and is sometimes used indiscriminately with *Contagion* or *Infection*; which see. Under the former article we felt disposed to adopt Dr. Wilson's distinction between contagion and infection, *viz.* that the first should express a morbid poison, the application of which may excite disease, and the latter the condition of the subject after the morbid poison has induced such an effect.

This definition has the advantage of being consistent with the etymology of the two words, particularly of the latter, the allusion of which is to dyeing or staining: for as a colouring substance may come into contact with another, under such circumstances as to leave no stain, so a subject may be sometimes exposed to a contagion without being infected.

The variety of effects induced by different impurities of the air, renders it absolutely necessary to discriminate them with as much accuracy as possible. We shall, therefore, confine the term *miasma* to its original meaning, as used by Hippocrates, and, as all the rest have appropriate terms, we shall defer them to the articles in their order, namely, **MORBID Poisons, PLAGUE, QUARANTINE, and TYPHUS.**

The father of physic remarks, that there are three great causes of disease, food, drink, and air. The latter, he continues, is by far the most important, because we eat and drink only, at certain times, and can even subsist for a few days without

without either, but are perpetually breathing, and cannot exist without air but for a few seconds. His dissertation on this subject relates principally to the temperature of the atmosphere, the aspect of places, according to the neighbouring mountains and seas, the various seasons of the year, climates, and manners of the inhabitants. Consequently but little information can be derived from him, concerning those most deleterious properties in some particular districts, which never could be visited but through the enterprising spirit of modern navigators. As this subject is now become particularly interesting, not only on account of our commercial connections, but from the importance of preserving the lives of our army and fleet, we shall not scruple to dwell upon it with some minuteness.

Though miasmata may be of different kinds, yet as they are only known by their effects on the human body, and the sources from which they are derived, we cannot venture to offer any other distinction. This distinction will be principally in degree, for, as Dr. Cullen remarks, the source seems to be universally from marshes, or moist ground acted on by heat. The properties of marshy soils in England is pretty generally understood, and their effects on the human body. We shall, therefore, only in general remark, that the ague induced by them is for the most part milder in spring than in autumn, and that for some time before and after the solstices, these places may be visited even by strangers with impunity. That all new comers are more certainly, and for the most part with more violence, affected than the constant residents; and that, from causes hitherto unknown, the disease is more general, more severe, and more fatal in some years than in others.

All these, however, like other pathological facts, must be admitted with certain limitations. The vernal agues, though so generally mild as to be formerly considered wholesome visitations to the constitution at that season, are sometimes severe; and the autumnal have in some seasons been found mild. There are constitutions which can never be injured to this kind of air, but are constantly and severely affected on each returning autumn; and there are new comers who remain with impunity till a severe season affects them, and probably many of the natives. At these times the season has been known to be protracted from the vernal almost to the autumnal period, and not to cease till winter has set in.

In England the intermittent fever is no longer an object of terror, since the introduction of the bark, and the safe use of some most powerful remedies; but most of all in proportion as the sources of the miasma have been diminished by the draining and improved cultivation of the soil. In Sydenham's time ague was among the epidemics of the metropolis, and the bills of mortality of those days shew how frequently it proved fatal. When London is now visited by ague, it is for the most part only sporadic, and in many instances, where it is least suspected, will be found to have been contracted by a residence in the country; for we shall presently have occasion to shew that miasma, received into the constitution, shews its effects at very uncertain, and sometimes very distant periods. There are, however, seasons when ague attacks those who have never left the town, probably by the air wafted from the marshes, in which cases the miasma is so diluted as to affect those only who are particularly susceptible. The years 1765, 1766, as well as 1782, are particularly marked as ague years in London, and even in 1808, the disease very often shewed itself. During each of these seasons a long prevalence of easterly winds was remarked. This, however, is too common an event during the summer and autumn to be considered a sufficient cause

of itself. The truth is, the season was particularly sickly to the inhabitants of the low lands on the eastern side of the metropolis: and so powerful was the effect of the miasma at its source, that instead of the usual mild and regular intermittent, remittent and even continued fevers were very frequent and very fatal.

In the Netherlands the dreadful effects of this miasma have been too recently experienced to require, at this time, any considerable commentary. One might suppose such events would never be entirely forgotten, were it not that so many records are preserved, which appear to have been overlooked before the last unfortunate expedition to Walcheren. Not to mention the account given by sir John Pringle, whose medical character and long practice in the army have rendered him an oracle in these enquiries, we shall transcribe part of Dr. Wind's observations, who with his father had practised at Middleburgh for nearly 30 years.

"Towards the end of August, or beginning of September," says he, "is a continual burning fever, attended with a vomiting of bile, which is called the gall-sickness.—Foreigners in indigent circumstances, who are garrisoned in the adjacent places, are apt, after these fevers, to become dropical, and many die." Dr. Lind, to whom we are indebted for the above extracts, further remarks, "the Scotch regiment in the Dutch service at Sluys has been known to bury their whole number in three years." Lind on Climates.

The insalubrity of the lower parts of Hungary, and still more of the Campania of Rome, are too well known to require our particular notice. We cannot, however, omit the history preserved by Lancisius, physician to pope Clement XI. "Thirty Romans of distinction of both sexes, having made an excursion upon a party of pleasure towards the mouth of the Tyber, the wind suddenly shifted and blew from the south over the putrid marshes, when twenty-nine were seized with tertian fever, only one escaping."

Though Africa has something terrific in its sound, yet it seems probable, that the northern coast, and for a considerable way inward, if we except the Lower Egypt, is as healthy as any part of the world. But the southern coasts, and particularly as we advance inward along the rivers, are so destructive to European constitutions, that probably neither our love of novelty, nor enterprising temper, will ever be sufficient to overcome these difficulties, so as to form a permanent settlement. In all these places the first rains are found so certainly deleterious, even to the natives, that they endeavour at these times to confine themselves to their houses, and to shut out as much as possible the external air. After a time, though the rain continues, the miasma is less pestilential, but soon after its cessation, as the surface of the ground becomes drier from its exposure to an almost vertical sun, the exhalations are pregnant with the exciting causes of all the tropical diseases.

In the countries leading from Africa to Asia, particularly Bassora, and other parts about Arabia, the English find the climate healthy, excepting at certain well-marked seasons.

Of the four presidencies in the East Indies, that of Bencoolen, in the island of Sumatra, is found the most unhealthy. Bengal, however, at certain seasons, is scarcely less fatal to the British, and often even to the Asiatic inhabitants. In the year 1762, it was well ascertained that 30,000 blacks and 800 Europeans died of the fevers of that country during the sickly season. Bombay has been rendered more healthy since an embankment, by which the overflowing of the sea has been prevented; and Madras has generally been considered a station not unfavourable to British constitutions.

Of all the unhealthy spots in Asia, Batavia is pretty generally allowed to be the worst. The fatal mistake, too common among Europeans, of attempting to assimilate the customs of a new country to their own, is said very much to have increased the infalubrity of that settlement. It seems hardly consistent with common understanding, that the Dutch, after the experience of so many years, should still persevere in preserving their dykes, to lessen the expence of carriage at the charge of human life. Yet such we are assured is the case. Among the many instances of mortality, for which that colony is so well known, we shall mention only two. In the year 1763, the *Falmouth*, a ship of 50 guns, was at Batavia for about six months, during which time she buried 75 of her crew, and 100 soldiers of the 79th, who had embarked on board her; every soul on board having been seized with fever, excepting only the captain. In the year 1764, the *Panther*, during a very short stay, buried 25 of her men, among whom was the commander, captain Matthewson. Nor was the sickness confined to the ship's company. The whole city exhibited no other scene but disease and death. Streets crowded with funerals, bells tolling from morning till night, and horses jaded with dragging hearses to the burial places.

Though we have remarked above the great probability that the nature of this miasma is every where the same, as its sources are evidently similar, yet it is right to observe that its effects on the human body are somewhat diversified in different quarters of the globe. Throughout the whole of Hindoustan, and northward, as far as the British have formed any settlements, the liver seems to be principally affected, and the principal danger to arise from the too high action of its vessels, and even the entire disorganization of that important viscus.

On the southern coast of Africa, and along the margins of its extensive rivers, the liver is the organ principally affected, and rarely, if ever, recovers its due functions, where the injury has been considerable. The liver suffers in the tropical regions of the West, though not with the same uniformity. In the southern parts of the N. western hemisphere, and in all the West India islands, the liver is often affected, but in many instances of the most violent fevers in this part of the world, it may be doubted whether the stomach is not primarily affected, and the liver only sympathetically, the black vomit being now pretty generally admitted to be derived from the stomach, and the yellow colour of the skin not making an essential character of the fever known by that name. It is not improbable that the Zealand disease, though distinguished by the name of the gall-sickness, may only affect the liver in common with the other viscera. It is certain that the brain suffers much in this disease, and not uncommonly those who escape with life remain for months, and sometimes years, with impaired memory and even degraded intellect.

In England, the enlargement of the spleen is the most common effect; the consequences of which are very rarely considerable, if the disease is not suffered to remain long without relief.

The most important consideration, and the most to our present purpose, is the means of preventing the existence of miasma, or, where that cannot be done, of avoiding its effects. The first, it is evident, can only be accomplished by draining the low grounds. This may always be attained where the surface is above the level of the sea, or still easier, if above the level of a neighbouring river. What has been done in this way in our island is hardly credible. The attempts to drain the Pontine marshes are not less honourable to

human industry; and if we can believe the present accounts, it would appear that such attempts are now persevered in with more steadiness than ever. The vast embankments made by cardinal Richelieu on the coast of Rochelle, in the bay of Biscay, are well known, and must for ever live in the writings of Voltaire. When, as is often the case, a town has been constructed on a hill by the banks of a river, if the population, after spreading along the side of the river, should gradually extend itself over the back of the hill, at right angles with the river or the sea-coast, there will always be danger of water stagnating in the valley behind. The force of the miasma from this cause will be greatly increased by the illuvis from the cottages which usually are the first erections at these extremities. To this London at one time owed, if not its agues, at least its vernal and autumnal fevers, as described by Sydenham. The great fire proved the means of forming a proper level as far as that formidable, though fortunate event extended; but it was not till within these last thirty years, that the northern part of the city, or rather its suburbs, has been drained by a sewer, which, if ever London should share the fate of Carthage, will immortalize the well-directed industry and enterprize of its inhabitants. This sewer, which is cylindrical, not less than six feet in diameter, and in some parts more than twenty feet below the surface, was carried through some of the narrowest streets, considerably below the foundations of the houses; to protect which, such a quantity of timber and planks was buried as would form almost an impassable grove if it were all to appear above ground. The sudden growth of the cities in North America has produced the most fatal effects in proportion as the heat of the solstitial and autumnal sun is greater, and as the increase of their towns has outrun most others in every part of the world. This is now so well understood, that the more prudent inhabitants of the large towns are attending much more to securing themselves from yellow fever by draining, than by the enforcement of quarantines.

In our own country it is incredible to what extent the spirit of draining has extended; besides those large undertakings which can only be brought about by the union of whole counties. Sometimes assisted, or at least empowered, by parliamentary authority, every enterprising farmer, whose lands are of any extent, has his *underground drain* wherever it is necessary, and can be accomplished.

We are not, however, to consider all the danger as removed when an old morass is drained: for even if such land is secured from being overflowed under the most unfavourable seasons, which is rarely the case, yet whenever it is first converted from pasture to arable, fevers are in some places excited much more formidable than the common intermittent. This leads us to the second consideration, that of avoiding the effects of miasma where the cause cannot be entirely removed.

The first part of the inquiry here must be, whether the disease is infectious? If we reason from cause to effect, we should conceive that a disease derived from exhalations from the earth could only be excited by a similar cause, and, consequently, that a sick person removed from the source could convey no contagion to others. But we should recollect that he may arrive with his clothes so impregnated with the effluvia of such miasma, as to be dangerous to those who first receive him, as we find persons often carry with them the smell of their particular occupation or habits. To determine, therefore, that a disease is contagious, it will be necessary to prove that others have been infected who have been exposed to the sick only, and neither to the feet of the

miasma itself, nor to such substances as may contain what is called the fomes.

At the source of the disease we shall find the greatest difficulty in determining the question; for where one general cause affects several, it will often be difficult to say whether an attendant on the sick has taken the disease from them, or from the same common cause that has affected the whole neighbourhood. This difficulty we shall see is much increased when we come to the article *TYPHUS*. At present, we shall only make two general remarks:

First, that wherever a number of persons are collected, if sickness of any kind prevails among them, a kind of infectious air is generated, which is the source of typhus fever.

Secondly; that during the prevalence of any epidemic, those who are affected with any other disease are generally the earliest seized with the epidemic, their reduced state of health rendering them less able to resist the force of the miasma; and as two diseases cannot occupy the same constitution at the same time, the consequence must often be, that their former complaint gives way to the reigning disease.

It may seem remarkable that this chain of events should be more accurately attended to by the ancient historians than by modern physicians; but the terms in which they explain themselves may shew the cause of this difference. Thucydides makes no mention of contagion till the advanced period of the plague in Athens; and Livy expressly says, that at first the men became sick from the badness of the season, and the unhealthiness of the place, and that afterwards the attendance on the sick rendered disease more common. By this evidently marking, that the accumulation of the sick had induced the hospital, in addition to the endemic, fever. See *CONTAGION*.

We have been obliged to anticipate this part of a succeeding article, because it involves a question of the highest importance, in avoiding the *effects* of miasmata where the *cause* cannot be entirely removed. If the disease induced by such a cause had a contagious property similar to small-pox and measles (see Dr. Cleghorn on the Diseases of Minorca), the probability is, that it would not cease till it has invaded all who are exposed to it; and that should any leave the country with the disease, or its fomes, the consequences would be equally general in every place to which the sick should be carried. In this case the only remedy would be to confine the sick and healthy to the spot, and not suffer them to escape till the disease has entirely ceased; after which there should be an universal ablution and purification before any general intercourse should take place. But if the disease is known to arise only from the season and the nature of the country; if from experience it should be ascertained that with a change of season the disease will cease; if it is further found by experience that no infection can be traced till the number and accumulation of the sick has produced a hospital or camp fever; if all this can be ascertained, surely the first step should be to encourage all the inhabitants instantly to quit so fatal a spot, and not to return to it till a change of season has produced a change in the properties of the atmosphere. It is much to be regretted that this discrimination has been so little attended to in the late controversies concerning the yellow fever in the West Indies, as well as the epidemics, which have visited Gibraltar and the various cities in the south of Spain. In America the question seems to be unfolding itself; and, as we before remarked, the terror of contagion is gradually giving way to a more rational precaution.

Where a country has been drained, after the ploughing of which the exhalations are found deleterious, no remedy remains but to confine this branch of husbandry to the solstices, afterwards leaving the broken ground to the effects of air and rain. This caution should be extended to the opening of new land wherever the surface is formed of an accumulation of autumnal leaves impeding the current of rain, and annually putrifying for a considerable number of years.

When vessels are cruising, or moored in the neighbourhood of swamps or thick woods, particularly in tropical regions and at dangerous seasons, the sailors should never be allowed to sleep on deck, and as few as possible should remain there after sun-set. If it is necessary to wood or water, every endeavour should be used to employ for this purpose the aborigines of the place, or negroes, whose constitutions are seldom affected by such miasmata, and when they are, the effect rarely exceeds that of the common tertian, which readily gives way to the usual remedies. If it is absolutely necessary to send the crew on shore, they should always return before sun-set and sleep on board.

When, as is often the case, it is found necessary to conduct a siege on one of these unwholesome spots, the first consideration should be to commence the operations at the least dangerous season. At this time the greatest attention should be paid to raising batteries as high as possible, consistently with the safety of the besieged, the miasma being always found to be most powerful the nearer to the soil. At the same time the level of the ground should be examined, to see how far it will admit of draining without turning up too much of the surface. When the sickly season arrives, as few men as the service will permit should be left on the ground during night, who, on the succeeding morning, and for several days after, should be carefully examined by the medical officer, that the first approaches of disease may be instantly met. Such men as are found best to withstand the effects of the miasma should be oftenest on duty. Above all, the hospitals should be prepared before they are wanted, and in a situation as remote as possible from the source of disease. Where the situation of the place will admit, it would be best to use floating hospitals, or hospital-ships, which in fair weather might make frequent cruises with their port-holes and scuteheons open, and with as many of the men on deck as can be moved thither. The attendants should be selected among the convalescents.

By attention to these rules, many expeditions might be much more successful, and much less wasteful of human life: many lands might be cultivated by those who would enjoy the benefit of their bold and enterprising undertaking, and many lives rendered comfortable which at this time are dragged on with misery and resigned without regret. See *EPIDEMIC; FEVER, Causes of; HEALTH, &c.*

MIATA, in *Geography*, one of the Society islands in the S. Pacific ocean. S. lat. 7° 52'. W. long. 148° 6'.

MIA-TAU, a cluster of small islands in the Chinese sea, near the coast of Chang-tong; extending from six to 36 miles N. of Tong-tcheou.

MIATHIR, a town of Morocco, in the province of Duquella, near a mountain of the same name.

MIAU-SHEHR, a town of Persia, in the province of Ghilan; 50 miles N.W. of Reshd.

MICA, *Glimmer*, Wern.; *Mica*, Haüy.

The usual colour of this mineral is grey, which occurs yellowish, greenish, smoke, and ash-grey; the yellowish-grey passes into yellowish and greenish-white, and into silvery, and also into wax-yellow, brassy and gold-yellow, reddish, pinchbeck,

pinchbeck, and blackish-brown; the greenish-grey passes into mountain and asparagus-green, also into leek-green and blackish-green; the ash-grey is found of various shades, and passes into perfect black. Sometimes several colours occur together in the same piece. Upon the whole the colour is found considerably to vary, according to the different degrees of transparency of the specimen. The black variety appears brown, when placed between the eye and the light. The colour of the powder is always greyish-white.

Mica is found principally disseminated and in thin layers alternating with other fossils, such as quartz and feldspar, in gneiss, &c; but it also frequently occurs in mats and crystallized.

Its primitive form is the short, straight, rhomboidal prism of 120 and 60°. Integrant molecule the same.

The principal crystallizations are; 1. The short straight four-sided prism with rhomboidal planes; being the primitive form (*Mica primitif*, Haüy, pl. 60, fig. 205.) These prisms are generally so low, that they may be considered as four-sided tables. They are easily and distinctly divided in a direction parallel to the bases; the cleavage in the other direction is generally indistinct.

2. The regular six-sided prism, generally very low, so as to appear tabular. (*Mica prismatique*, Haüy, ib. fig. 207.)

3. The lengthened rectangular table (*Mica binaire*, Haüy, ib. fig. 208.)

4. The low regular six-sided prism with truncated terminal edges. (*Mica annulaire*, Haüy, ib. 206.)

The crystals are sometimes large, but generally middle-sized and small; they are sometimes found separate, but oftener grown together; they are now and then seen fascicularly aggregated and in roses. The lateral planes of the crystals are smooth and splendid; the terminal planes shining. Internally specular splendid; lustre sometimes resinous, sometimes pearly, often semi-metallic and metallic; in the uncrystallized mica, the lustre of the planes of fracture is generally less intense.

Fracture partly straight, oftener curved, or undulatingly foliated. The foliated fracture sometimes passes into the broad and narrow radiated, which is partly parallel, partly fascicularly or stellularly diverging. The fractural surface, particularly that of the broad radiated variety, is sometimes marked with feather-like streaks. Fragments tabular. The massive shews coarse, large and small-grained distinct concretions; the radiated is composed of cuneiform columnar concretions.

The common massive varieties of mica are opaque, or only translucent on the edges; the detached folia are mostly translucent and even transparent. Some crystallized varieties are perfectly transparent in all directions. The separation of the folia from each other, though not observable to the eye, is generally the cause of the loss of transparency.

It is semi-hard, approaching to soft; easily divisible in the direction of the folia, and may be easily cut with a knife; it feels smooth, not unctuous, and is elastic flexible. Specific gravity 2.654—2.634, Haüy; 2.726, Karst; 2.767, Kirw.; 2.866, Reufs; 2.934, Blumenb.

Before the blowpipe, the dark coloured varieties (according to Wiedenmann) take a pinchbeck or brass-yellow hue, but they are nearly as difficultly fusible into enamel as the colourless varieties. The enamel of black coloured mica affects the magnetic needle.

The analyses which we possess of this substance vary considerably, at least with respect to the relative quantity of the constituent parts of the several varieties.

This very common but remarkable fossil, forms a principal ingredient of some of those rocks which belong to the primitive slate formation of Werner, particularly granite, gneiss, and mica slate: it is also found in primitive limestone, and in-grau-wacke. Nor is it wanting in the trapp-formation, as in sienite, porphyry, greenstone, basalt, wacke; though in the last mentioned rocks it is probably derived from primitive rocks by disintegration. In some cases it is known to form entire beds, like those at Zinnwald. It rarely occurs in veins, such as those belonging to the tin-lone formation in Bohemia and Saxony.

The localities of mica being those of the widely extended primitive rocks above-mentioned, need not to be particularised. The mica in large plates, called Muscovy glass, from the use to which it is applied, occurs in granite in several parts of Siberia, and on the shores of the Caspian, at Uda, on the borders of the Upper Tunguska, the lake Jenesej, Baikal, in Georgia, &c.

By far the greatest part of the large foliated mica is employed in the Russian empire, especially in Siberia, where it is generally used instead of glass for windows. The poorer classes employ the small plates, which they sew together. It is said to have been a substitute for glass in the windows of Russian men of war, as being less liable to be broken by the concussion of the air during the discharge of heavy artillery; but to this use mica is no longer applied. We find that in the year 1781, upwards of 200 pud of this variety of mica were exported from Peterburg to Lubeck, and 2721 pud to Great Britain. Beckmann, who makes mention of this exportation, is at a loss to guess the use in which these 116,800 pounds of Muscovy glass may have been employed.

According to Ellis's account, the same kind of mica occurs in large plates in Hudfon's bay; and Kalm found it in Pennsylvania, in leaves of half a yard in diameter, and of equal transparency with the Siberian variety. Indeed the Swedes, who from 1630 to 1655 had colonies in New Jersey and Pennsylvania, employed it, as the Russians do, instead of glass in the windows.

The tenuity of the laminæ of the large foliated varieties is such, that, according to Haüy's calculation, a piece $\frac{1}{4}$ ths of a line in thickness, may be divided into 23,255 separate laminæ. This property, and the facility with which it is cut, render the Muscovy glass peculiarly proper for inclosing minute objects to be viewed by the microscope.

MICA-slate, *Glimmer-schiefer*, Werner; *Micaceous schist*, Kirwan; *Schiste micacé*, Broch.

This primitive rock is essentially composed of mica and quartz, disposed in layers, which are more distinct than those of gneiss, into which it is frequently seen to form a transition. The colour of the mica, which generally forms the

predominant part, is usually of a grey colour, mixed with greenish; the quartz is almost always white.

This rock, which is of great importance to the miner, as being particularly rich in ores, contains also frequently other minerals, particularly common and noble garnets, which may even be considered as forming an essential component part of mica slate; shorl, both the common and tourmaline (such as that of Dunkeld and Blair-in-Athol in Scotland), kyanite (which has been found in the varieties from Mainland, one of the Shetland islands, and near Banchoory in Aberdeenshire), rutile (that of Salzburg, Hungary, &c.), feldspar, but only in single grains.

Besides the common mica slate, which is straight, and rather thick flaty, the Wernerian geognostians distinguish three other varieties, *viz.* the undulated mica slate, which has not been found to include other substances; the talcky mica slate, which is straight flaty, composed of green mica, and traversed by thick layers of quartz; and lastly, the fine flaty variety, which forms a transition into clay slate, which rests on it; it is generally of a greyish-yellow colour, and almost entirely unmixed with quartz.

As mica slate passes on one side into clay slate, (the next rock in succession,) in the same manner it forms a very distinct transition into gneiss, on which it rests; the outgoings of its strata being lower than those of the latter, and higher than those of the clay slate, which usually cover them. It surrounds the older rocks in mantle-shaped stratification.

The mica slate mountains, which are generally much less craggy and bold than those of gneiss, contain far more foreign beds than both granite and gneiss mountains; the most remarkable beds observed in them are those of granular limestone, of hornblende slate, hornblende rock, and actinote; as likewise galena, copper and iron pyrites, magnetic iron-stone, and other ores. The greatest part of the metaliferous mines of Sweden and Norway, and several of those of Hungary and Saxony, are situated in this rock.

Mica slate constitutes considerable mountains in most parts of Europe, and also, according to Humboldt, in South America. In Scotland, it occurs abundantly in the valley between Dunkeld and Blair-in-Athol, on the mountain of Schehallion, in the island of Arran, the island of Jura and Isla, &c. Jameson.

It is often employed for constructing or lining furnaces, whence it has been called *Gestellstein*, or *Saxum fornacum*; names which are, however, given to several other fossil rocks applied to the same purpose.

MICABA, in *Geography*, a town of Japan, in the island of Nippon; 100 miles N.N.E. of Meaco.

MICAH, in *Scripture History*, the seventh in order of the twelve minor prophets. He is called the "Morasthite," or of "Morefa," a village near the city of Eleutheropolis, in the south of Judah. He was nearly contemporary with Isaiah, and has some expressions in common with him: compare Isaiah, ii. 12. with Micah, iv. 1; and Isaiah, xii. 15. with Micah, iv. 13. St. Jerom says, that Micah was buried at Morasthi, and Sozomen says, that his tomb was discovered to Zebennus, bishop of Eleutheropolis, in the reign of Theodosius the Great. Some have confounded Micah with Micajah, son of Imlah, who was of Ephraim, and who prophesied in the time of king Ahab. Micah prophesied under Jotham, Ahaz, and Hezekiah for about 56 years, from the beginning of the reign of Jotham, or 754 B.C., to the last year of Hezekiah 698 B.C. His prophecy contains seven chapters; in which the first foretells the calamities of Samaria; afterwards he prophesies against Judah, and having exclaimed against the iniquities of Samaria, he foretells the

captivity of the 10 tribes, and their return. After a pathetic invective against the princes of the house of Jacob, and the judges of the house of Israel, he speaks of the birth and reign of the Messiah. The two last chapters contain an invective against the iniquities of Samaria; after which he predicts the fall of Babylon, the re-establishment of Israel, their happiness, &c. in such lofty terms, as chiefly agree with the state of the Christian church. The style of Micah is for the most part close, forcible, pointed, and concise; sometimes approaching the obscurity of Hosea; in many parts animated and sublime, and in general truly poetical.

MICARELLE, in *Mineralogy*. See PINITE.

MICE, in *Gardening*, a sort of vermin which are highly destructive to several sorts of garden crops, such as peas, beans, &c. in the early spring, and lettuces, melons, and cucumbers in frames in the winter season. When discovered they should of course be immediately destroyed, either by traps or some other means. See VERMIN.

The author of "Phytologia" has suggested, that "the destruction of grain after it is sown by field-mice, which mine their way very quickly under newly ploughed lands near the surface, is supposed by Mr. Wagstaff, in the papers of the Bath Society, to be effected in some seasons to a very great extent. And that the tussocks of wheat, seen to arise in many fields, are owing to the granaries of these diminutive animals, which he has found to contain nearly a hatful of corn, which grows into a tuft, if the owner becomes accidentally destroyed. It is also further asserted, that they feed much on the young plants, as they arise from the seed, and multiply at that time very fast. He detects their habitations by small mounds of earth being thrown up, on or near the apertures of their dwellings, or of the passages which lead to their nests or granaries; and by following the course of these passages, he found and destroyed the parents and the progeny." He likewise "recommends the taking up and dividing the tussocks of wheat, thus sown in the autumn by the field-mice, and transplanting them in the spring; and also to thin other parts of a young crop, as they appear too thickly sown, which he esteems an advantageous practice."

And it is found, that "acorns when sown, as well as garden beans, and peas, are liable to be dug up or devoured by these voracious little animals, which may be destroyed by traps baited with cheese; or best of all, by the encouragement of the breed of owls, so active in the pursuit of nocturnal vermin, and thence so useful to the gardener and farmer, who still permit their servants and children to destroy both their eggs and callow young."

These little plunderers may be readily destroyed by the use of the poisonous substance, usually known by the title of *nux vomica*, which should be finely rasped down, and mixed with some sort of meal or other similar material, of which they are fond.

MICELLA, in *Geography*, one of the smaller Molucca islands.

MICHAEL I., in *Biography*, surnamed *Rhangabe*, emperor of the East, was son of Theophylact, governor of the isles, and married Procopia, daughter of the emperor Nicephorus I., by whom he was raised to the office of great master of the palace. He was present at the battle against the Bulgarians, in which Nicephorus was slain A.D. 811. Stauracius, the son of the emperor, had received a severe wound in the battle, and was, besides, universally hated. The empire was therefore offered to Michael, who at first hesitated to accept it, but finding that Stauracius designed to put out his eyes, he obliged him to retire to a convent,

where

where he soon after died. Michael was possessed of private virtues, but wanted vigour to control the spirit of his wife, who excited the indignation of the soldiers, by appearing at the head of the army, and it was generally acknowledged that he was deficient in the military talent requisite at such a crisis. He marched against the Bulgarians, ventured upon an engagement, in which he was defeated, and returned with disgrace to Constantinople, leaving a discontented army under the command of dissipated generals. By their intrigues the soldiery proceeded to the deposition of Michael, and offered the imperial crown to Leo the Armenian. The senate, the clergy, and the people of the capital still adhered to Michael, but he declared that not a drop of blood should be shed on his account, and resigning the ensigns of sovereignty retired with his family to a monastery, having filled the throne less than two years. He was permitted to live in peace, and in a religious retreat, during thirty-two years, which he survived his abdication. Gibbon. Univer. Hist.

MICHAEL II., surnamed the *Stammerer*, a native of Phrygia, was educated among the Jews and heretical Christians, and during the early period of his life, he adopted opinions that probably rendered him obnoxious among those who styled themselves of the orthodox faith. When he attained to years of discretion he was appointed an officer under Nicephorus, and was a principal instrument in raising to the throne Leo the Armenian. During the reign of this emperor he was employed in high offices, but having incurred the suspicion of conspiring against his sovereign, he was arrested and brought to trial. At that period, conviction and accusation followed each other of course, and Michael was condemned to the cruel death of being burnt in the furnace of the private baths. The execution of this sentence, which had been fixed for Christmas-day, was suspended through devout scruples of the empress, and in the mean time Michael informed his friends of his danger, and threatened them with detection, unless they effected his deliverance. The hope of self-preservation excited them to exertion, and in consequence of it, Leo was dethroned and murdered, but Michael with fetters on his legs was seated on the imperial throne in December 820. One of his first acts was to reverse the late sovereign's decrees, by recalling a number of bishops and other ecclesiastics who had been banished, for refusing to comply with the late emperor's edict against the worship of images. Notwithstanding this conduct, Michael himself was by no means friendly to this kind of worship, and tolerated it only without the precincts of the capital. He is therefore reckoned among the enemies of the Catholic church, and the calamities of his reign have been imputed to his heresy. A revolt in the Asiatic provinces was the commencement of a civil war, which nearly subverted the throne. One Thomas, at the head of a vast army of barbarians, over-ran Lesser Asia and Syria, defeated the troops sent against him, and laid siege to Constantinople. At length, however, he was unsuccessful in his efforts against the established power, and falling into the emperor's hand, he was put to a cruel death. During these internal commotions, the Saracens landed in Crete, and formed a settlement in that island, from which Michael in vain attempted to expel them. During the sixth year of his reign he married, from a convent, Euphrosyne, the daughter of Constantine VI., which has been imputed to him as a most irreligious act; it succeeded likewise as an example to one of his officers, Euphemius, to gratify a licentious passion, by forcibly taking a nun from her convent in Sicily, which was the cause of the loss of that island. Euphemius, in order to avoid punishment, fled to the Saracens in Africa,

and returning with a large body of troops of that nation, endeavoured to gain possession of Syracuse. He lost his life in the attempt; but the Saracens, thus introduced into Sicily, by degrees made themselves masters of it, as well as of the neighbouring provinces of Italy. Michael, after an unfortunate reign of nearly nine years, died in 829, and was succeeded by his son Theophilus.

MICHAEL III., grandson of the preceding, was born in 836, and succeeded his father Theophilus in 842, when he was only six years of age. He had been educated in habits of piety and virtue by his mother Theodora, but as he grew up, he abandoned all the early impressions of his childish years, became famous for the dissolute course of his life, and deservedly obtained a place among the most unworthy emperors. He did not assume the reins of government till he was in his twentieth year, when Theodora and her daughters were obliged to quit the court and enter a monastery, where she soon died of a broken heart. Michael seemed to rejoice in the event; while his virtuous mother was alive, her conduct was probably some restraint to his passions, but as soon as death had levelled her with the dust, her worthless son was anxious to surpass even a Nero in his profligacy and buffoonery. In imitation of that prince, whose name and memory are devoted to infamy, he pursued the sports of the circus, and took into his favour and confidence those who were deemed the most skilful charioteers. He was perpetually guilty of excess in wine, and, in the hours of his brutal intoxication, issued the most sanguinary commands, which his servants, more humane than their master, frequently ventured to disobey. It was one of his amusements to profane with mock solemnities the most sacred ordinances of religion. Amidst these follies he undertook an expedition to the Euphrates against the Saracens, who put him and his army to flight. He was long under the influence of Bardas, whom he raised to the dignity of Cæsar, and by whose advice the patriarch Ignatius was deposed and imprisoned, and the learned Photius placed in his chair. In 866, Michael was induced by Bardas to undertake an expedition into Crete, to oppose the ravages of the Saracens, who from that island had made a descent into Thrace. This advice proved fatal to the favourite and minister, for having excited the jealousy of the emperor, he ordered him to be stabbed in the tent of audience. This cruel and treacherous deed excited the indignation of the soldiers, and Michael returned privately to Constantinople, where he soon after raised Basil the Macedonian, who had been the instrument in the assassination of Bardas, to a partnership with him in the throne, and devolved upon him all the business of the state. Basil, who it is said, had just ideas of the imperial character and duties, endeavoured by remonstrances to reclaim Michael from his abandoned course of conduct. But his habits were too deeply rooted to admit of a change, and it was determined to ruin the monitor. Basil was fortunately apprized of his danger, and resolved to strike the first blow, and with the aid of accomplices murdered him while asleep, and in a state of intoxication, in the year 867, in the thirty-first year of his age. Univer. Hist. Gibbon.

MICHAEL IV., a native of Paphlagonia, of obscure birth, was brought up to the trade of a money-changer, but being introduced at the court of Romanus III., his personal beauty caught the eye of the licentious empress Zoe, who made him her chamberlain, and exacted from him attentions inconsistent with the homage which he owed to his sovereign. At length the empress, advancing from one degree of guilt to another, poisoned her husband, celebrated her nuptials with Michael, and raised him to a partnership in the throne.

This event was accomplished in the year 1034. The empress was disappointed in the expectations which her passions had excited, as well on account of the ill state of health which her husband fell into, as on account of the torture which he experienced from a consciousness of the crimes in which he had participated. All authority soon devolved into the hands of his brother John, an eunuch, who had originally introduced him to court, and who quickly reduced Zoe to a state of insignificance, surrounded with spies, and made a prisoner in her own palace. Michael began now to endeavour to atone for his guilt by liberality to the poor, and by the endowment of churches and hospitals. A revolt of the Bulgarians roused him to exertion; he headed his army, and though in his first expedition he was obliged to retreat with disgrace, in a second encounter he was more successful, and returned in triumph to Constantinople. Warned with the approach of death, he retired to a monastery, which he had himself founded, and in which he died, in the year 1041: having first nominated as a successor his sister's son,

MICHAEL V., furnamed *Calaphates*, from his father's occupation of a caulker of ships. He was proclaimed emperor immediately on the death of his uncle, but his reign was of very short duration. His first sovereign decrees were the banishment of his uncle John, the eunuch, and the confinement of Zoe to a monastery. The people, who generally take part with the oppressed, revolted at these acts of tyranny, recalled Zoe and her sister Theodora, and proclaimed them joint sovereigns. Michael was now glad to take refuge in a monastery, and assumed the religious habit, hoping to escape farther injury, but at the instance of Theodora he was deprived of his sight, an usual though horrible punishment at that period, and, with all his relations and adherents, was sent into banishment, having occupied the throne only four months. Gibbon. Univer. Hist.

MICHAEL VI., furnamed *Stratioticus*, was appointed by the empress Theodora as her successor on the throne, which he ascended in the year 1056. He was already advanced in years, and enjoyed a reputation for military talents, but was wholly unacquainted with the art of government, its nature and principles. He gave himself up to the dominion of his eunuchs, who made an ill use of their influence, so that a conspiracy was excited, and Isaac Comnenus was elevated to the imperial dignity. The new emperor assembled an army in the eastern provinces, with which he proceeded towards the capital. In the neighbourhood of Nice he was met by the forces of Michael, and an engagement ensued, in which the latter were completely overthrown. Michael now saw that he had in vain exacted an oath from the citizens of Constantinople never to acknowledge Comnenus for emperor. At the approach of the conqueror, a decree was unanimously passed, investing him with the imperial title and authority, and a deputation of bishops was sent to Michael, commanding him formally to renounce the sovereignty. "What," said the fallen prince, "will you give me in exchange for the empire?" "The kingdom of heaven," they replied. He submitted and retired to a monastery, after a reign of about a year. Gibbon. Univer. Hist.

MICHAEL VII., furnamed *Parapinaces*, the son of Constantine XI., was proclaimed emperor in the year 1071, on the defeat and capture, by the Turks, of Romanus Diogenes. He had been well educated, and had studied philosophy and rhetoric, but was unfit for the cares of the empire, which devolved upon his uncle. He was charged with diminishing the measure of corn for his own emolument, during a scarcity, which fixed upon him his reproachful surname. An invasion of the Turks, and a revolt among his own people,

forced him to resign his crown, and retire to a monastery, after a reign of six years and a half. He died at Ephesus, having been consecrated bishop of that see. Univer. Hist.

MICHAEL VIII., of the noble family of Palæologi, was brought up to the military service, and obtained popularity and distinction by the graces of his person and manners. In his youth he was commander of the French mercenaries in the employ of the empire. During the reign of John Vataces he was accused of ambitious designs, but cleared himself so well of the charge, that he was not only honourably acquitted, but made governor of Nice. In the year 1255, new charges were brought against him, and he privately withdrew to the Turkish sultan of Iconium, by whom he was honourably received, and placed at the head of a body of Greeks in Turkish pay, with whom he distinguished himself against the Tartars. After this he was recalled by the emperor Theodore, and at his death, in 1259, he recommended him as the guardian and protector of his son John, who was then a minor. He now assumed the title of grand-duke, and the office of regent of the empire was delegated to him. His ambition began to display itself, and he employed every art to give splendour to his administration, and impress the people with the idea of his fitness for the throne. The news of a victory over the despot of Epirus was the signal for the people in Michael's interest to salute him with the title of emperor, and it was agreed that he and the young prince John should wear the purple conjointly. The patriarch, with great reluctance, was induced to place the imperial crown upon the head of Michael alone, while John walked in his train, distinguished only by a diadem of very inferior worth. This was in 1260, and in the following year Michael received the welcome intelligence of the recovery of Constantinople, to which city he and his court removed from Nice. He shewed that he was capable of acting on the most liberal principles: he restored the city to its ancient splendour, and encouraged the continued residence of the Genoese, Venetian, and Pisan merchants; but having attained to a good share of popularity, he felt himself sufficiently strong to commence a new era by reigning sole emperor. To remove his competitor from the chance of opposing his projects, he caused his sight to be destroyed. For this infamous act of barbarity, the patriarch Arsenius pronounced a sentence of excommunication against him, which he refused to recal, unless he would exhibit signs of repentance by abdicating his throne. The emperor, trusting to his own strength, deposed and banished the patriarch, but he had attached to his cause so large a party among the clergy, that a schism in the Greek church was the consequence, which continued a number of years. Michael, as a warrior and politician, was successful in many of his projects; he recovered several of the finest islands in the Archipelago, as well as part of the Morea, from the Franks; but on the other hand, the despot of Epirus, and the king of Bulgaria, made incursions into Thrace, and laid waste the country with fire and sword. These and many other troubles induced him to seek the favour of the Roman see, by proposing an union between the Greek and Latin churches, with an acknowledgment of the supremacy of Rome. This was effected at the general council of Lyons, under pope Gregory X., in 1274, an act which extremely disgraced his own subjects, and he was obliged to institute a violent persecution against the schismatic Greeks, in order to preserve the semblance of an union. This so irritated his own family, and the inhabitants of Constantinople, that he was eventually excommunicated by pope Martin IV., for the share which it was known he had in the massacre of the French in Sicily, known by

by the name of the Sicilian vespers. He died in 1283, at the age of 58, and in the 24th year of his reign. His son Andronicus, whom he had associated with himself in the empire, instantly dissolved the union of the churches, and refused his father Christian burial. Gibbon. Univer. Hist.

MICHAEL, FRONDOVITCH, czar of Russia, was son of Theodore Nikiliz Romanof, an archbishop of Rostock. After the dethronement of the czar Zulkri, in 1610, a party of Russian nobles offered the crown to Ladislaus, prince of Poland, and a Polish garrison had been admitted into Moscow, which was the occasion of much bloodshed. It was after some time expelled by a more numerous party of Russians, who elected Michael, the subject of this article, then a youth of seventeen, as new czar. He was distinguished by his descent from a daughter of Ivan Vasilevitch, and rendered dear to the nation by the virtues of his father. At the time of the election he was in a monastery with his mother, while his father was a prisoner in Poland; and when the proposal was made to raise him to the throne, the unhappy fate of some of the late czars filled his mother with such apprehensions, that she did every thing in her power to get him excused the intended honour. The senate, however, persisted in their choice, and Michael was solemnly elected in 1613. He was immediately involved in a war with the generals of Gustavus Adolphus, king of Sweden, which was concluded in 1617, and in the following year a truce was made with the Poles, who had supported, by force of arms, the prior election of their prince Ladislaus, and had actually ravaged the country as far as Moscow. In 1625, the young czar married Eudocia, the daughter of a poor gentleman of no fortune, but of great beauty and accomplishments. The interval of peace he employed in promoting the internal prosperity of Russia, and formed a commercial connection with the states of the United Provinces. War was renewed with Poland in 1632, but was terminated in about two years, and from this period the czar preserved his country in a state of tranquillity, respected by neighbouring sovereigns for his equity and good faith, and greatly beloved by his subjects, on account of the mildness and beneficence of his government. He died in 1645, in the thirty-third year of his reign, leaving his crown to his son Alexis. Coxe's Travels.

MICHAEL CERULARIUS, patriarch of Constantinople, was raised to that dignity in the year 1043. He was a person of vast ambition, and a determined enemy to the church of Rome and the papal claims, and in 1053 he revived the famous contest between the Greek and Latin churches, which had been suspended for a considerable time. He pleaded in his justification a sacred regard to truth and the interests of religion, but the true and genuine causes were the arrogance and ambition of the Grecian patriarch and Roman pontiff. Among the measures to which they mutually had recourse, in order to sap the foundations of each other's authority and influence with the people, were accusations of holding corrupt doctrines. Cerularius struck the first blow, by a letter written in his own name, and in the name of Leo, bishop of Acrida, in which he publicly accused the Latins of various errors. To this letter pope Leo IX. wrote a very imperious reply; assembled a council at Rome, and excommunicated the Greek churches. Bitter and very violent measures succeeded on both sides till the year 1057, when a struggle took place between Stratoticus and Isaac Comnenus for the imperial crown: the patriarch embraced the interests of the latter, and was a chief instrument in raising him to that dignity. In the following year, the emperor being compelled by the exhausted state of the public treasury to impose heavy taxes upon the people, drew from

the monasteries a part of their great wealth, with which they had been enriched by his predecessors. This the patriarch resented, and threatened to pull him from the throne to which he had raised him, unless he restored what he had taken from the religious houses. The emperor, without hesitation, arrested, deposed, and banished the patriarch, and in a state of exile he soon died. Some of this patriarch's letters remain, and are referred to by Cave, Dupin, and Mosheim.

MICHAEL, *St.*, in *Geography*, a town of Italy, in the duchy of Mantua, on the Tartaro; 20 miles E. of Mantua.—Also, a town of Italy; 12 miles S.W. of Mantua.—Also, a small island in the English channel, off East Looe, in Cornwall. N. lat. 50° 18'. W. long. 4° 32'.—Also, a town of the duchy of Holstein; 6 miles S. of Meldorp.—Also, a town of England, in the county of Cornwall, which, though a small place without a market, sends two members to parliament; 8 miles N.E. of Truro, and 249 W.S.W. of London. N. lat. 52° 22'. W. long. 4° 52'.—Also, a town of Canada, in the river St. Lawrence; 15 miles N.E. of Quebec.—Also, a river of Maryland, which runs into the Chesapeake, N. lat. 38° 50'. W. long. 76° 22'.—Also, a town of Sweden, in the province of Savolax; 10 miles N.N.E. of Chrilliana.—Also, a town of America, in the state of Maryland, and county of Talbot; 21 miles S.E. of Annapolis.—Also, a town on the S. peninsula of St. Domingo island, called "Fond des Nagra;" 10 leagues N.E. of St. Louis.—Also, an island in the Atlantic, called "San Miguel," the largest of the Azores, discovered by Gonfalo Velho Cabral in the year 1444. It is about sixty miles in circumference, and has several towns and villages, which carry on a great trade in corn, wine, and cattle, though none of its harbours are good or safe. Its chief towns are Punta del Gada, and Villa Franca. The former is rendered important by its commerce, by its strong castle, in which the Portuguese keep a garrison, and by its being the residence of the primate of the Azores. The number of inhabitants in this island is variously estimated, from 25,000 to 50,000. The town of Punta del Gada is situated in N. lat. 37° 47'. W. long. 25° 42'.

MICHAEL, *St.*, in *Lungau*, a town of the archbishopric of Salzburg; 14 miles S.S.E. of Radstadt.

MICHAEL'S *Bay, St.*, a bay on the W. coast of the island of Curaçoa.—Also, a bay of Nova Scotia, on the W. coast of the bay of Fundy.—Also, a bay on the E. coast of Labrador. N. lat. 52° 55'. W. long. 55° 40'.

MICHAEL'S *Point, St.*, a cape on the N.W. coast of Prince's island, in the Atlantic. N. lat. 1° 55'. E. long. 7° 1'.

MICHAEL, *St. Gulf of*, a bay on the coast of South America, in the S.E. part of the gulf of Panama, formed by the mouths of the rivers Congo, Santa Maria, and some others. In it are several islands, which shelter good ridings for ships, and the gulf is sufficiently capacious for a large fleet. The sides are surrounded with mangroves, growing in wet and swampy land.

MICHAEL, *Order of St.*, in *Heraldry*, was instituted by Lewis XI., king of France, in the year 1469, but declined under the reigns of Charles IX. and Henry III. In the year 1661, Lewis XIV. regulated this order, and lessened the number of knights; thus restoring its reputation, so that it rose into high esteem in France. The mantle of the order was of white damask, bordered all round with embroidery in gold and colours, representing the collar of the order, and lined with ermine; the chaperon was of crimson velvet, embroidered like the mantle, under which the knights wear a short coat of crimson velvet. The badge of the or-

der is a medallion of gold, representing St. Michael trampling on a dragon, enamelled in proper colours, and worn pendent to a collar, composed of escallop-shells, and chains of gold interwoven like knots. The knights usually wear this badge pendent to a broad black watered ribbon.

MICHAEL, *Order of the Wing of St.*, an order in Portugal, instituted in 1172 by Alphonso, king of Portugal, in commemoration of a signal victory which he gained over Albarac, king of Seville, in consequence, as he imagined, of his having ardently invoked the aid of St. Michael the archangel. The habit of the order was of white silk, on the left breast of which was embroidered a wing purple, within a circle of rays gold. The badge was a cross fleury, fitchy gules, cantoned in base with two fleurs-de-lis; over the cross, on an escroll, this motto, "QUIS UT DEUS."

MICHAELIS, JOHN DAVID, in *Biography*, a celebrated biblical critic, and professor of divinity and the Oriental languages, was born at Halle, in Lower Saxony, in the year 1717. He received a private education, but the Greek language made no part of it till within half a year of its completion, a circumstance which he never ceased to regret. In 1729 he was sent to the public school of the orphan-house, and at the same time he occasionally attended his father's lectures on the Hebrew language. Here he received lessons in divinity from Baumgärtner, but the chief benefit which he received from that professor was in the philosophical course. During the latter part of his time at school, he acquired a great facility in speaking Latin, and in thinking systematically, from the practice of disputation, in which one of the masters frequently exercised him. By his Latin master he was taught to write Latin verses, but as he advanced in life he renounced that study, considering it to be a pedantic mis-employment of time. In the year 1733, Michaelis entered into the university of his native place, in order to qualify himself either for the clerical profession, or for the chair of oriental literature, in which his father hoped to see him one day his successor. Here he applied himself with all diligence to the study of mathematics, metaphysics, theology, and the oriental languages. He also prepared himself for pulpit services, and preached with great approbation at Halle and other places. In the year 1739 he took a degree in philosophy, and about the same time he was the subject of a temporary melancholy, which threatened to prove a serious injury to his health, and which was owing to religious impressions, originating in certain misconceptions of some of the scriptural precepts, to which he affixed literal interpretations. Upon his recovery, he was appointed assistant lecturer under his father, having shewn how well qualified he was for that situation, by publishing a small treatise, "De Antiquitate Punctionum Vocalium." In 1741 he left his own country with a view of visiting England, and passing through Holland, became acquainted with the celebrated Schultens, from whom he received many marks of the most friendly attention. Upon his arrival in England, he engaged to officiate for the German chaplain to the court, who was at that time in an infirm state of health, and continued to preach at the palace-chapel nearly a year and a half. During this period he visited the university of Oxford, greatly increased his knowledge of the oriental languages, and formed an intimacy with some of the first literary characters of that age, particularly with Dr. Lowth, afterwards bishop of London, on some of whose lectures "De Sacra Poesi Hebræorum" he attended. Upon the return of Michaelis to Halle, he resumed his labours in the professional chair, as assistant to his father, and delivered lectures on the historical books of the Old Testament, the Syriac and Chaldee languages, and also upon natural history, and the Roman classics; by the exercise of his ta-

lents on these subjects he maintained and increased the fame which he had already acquired, but without having the prospect of any immediate good establishment. He therefore resolved to quit Halle, and in 1745 he went to Gottingen, in the capacity of private tutor. In the following year he was made professor extraordinary of philosophy in the university of Gottingen, and, in 1750, professor in ordinary in the same faculty. In 1751 he was appointed secretary to the newly instituted Royal Society of Gottingen, of which he afterwards became director, and about the same time was made aulic counsellor by the court of Hanover. During the year 1750, he gained the prize in the Royal Academy of Berlin, by a memoir "On the Influence of Opinions on Language, and Language on Opinions." While the seven-years' war lasted, in which the university of Gottingen was particularly distinguished, Michaelis met with but little interruption in his studies, being exempted, in common with the other professors, from military employment; and when the new regulations introduced by the French in the year 1760, deprived them of that privilege, by the command of marshal Broglio, it was particularly extended to M. Michaelis. For this mark of his favour he was indebted to the good offices of his friend Thierry, who was in great esteem with the minister. Soon after this, he obtained from Paris, by means of the marquis de Lottange, the manuscript of Abulfeda's Geography, from which he afterwards edited his account of the Egyptians. From this time that nobleman was Michaelis's firm friend, and had no little share in procuring him the honour of being chosen correspondent of the "Academy of Inscriptions at Paris," in 1764, and of being elected one of the eight foreign members of that institution. In the year 1760, the professor gave great offence to those of the clergy who styled themselves orthodox, by publishing his "Compendium of dogmatic Theology," consisting of doctrinal lectures which he had delivered by special licence from the government. Shortly after this, Michaelis shewed his zeal for the interests of science and literature, by the part which he took in the project of sending a mission of learned men into Egypt and Arabia, for the purpose of obtaining such information concerning the actual state of those countries, as might serve to throw light on geography, natural history, philology, and biblical learning. He first conceived the idea of such a mission, which he communicated by letter to the privy counsellor Bernstorff, who laid it before his sovereign Frederic V. king of Denmark. That sovereign was so well satisfied of the benefits which might result from the undertaking, that he determined to support the expense of it, and he even committed to Michaelis the management of the design, together with the nomination of proper travellers, and the care of drawing up their instructions. Upon the death of Gefner in 1761, Michaelis succeeded in the office of librarian to the Royal Society, which he held about a year, and was then nominated to the place of director, with the salary for life of the post, which he then resigned. Two years afterwards he was invited by the king of Prussia to remove to Berlin, but his attachment to Gottingen led him to decline the advantages which were held out to him as resulting from the change. In 1766 he was visited at Gottingen by sir John Pringle, whom he had known in England, and Dr. Franklin. With the first he afterwards corresponded on the subject of the leprosy, spoken of in the books of Moses, and on that of Daniel's prophecy of the seventy weeks. The latter subject was discussed in the letters which passed between them during the year 1771, and was particularly examined by the professor. This correspondence was printed by sir John Pringle in 1773, under the title of "Joan. Dav. Michaelis de Epistolæ, &c. LXX. Hæbdomalibus

domalibus Danielis, ad D. Joan Pringle, Baronettum: primo privatim mittit, nunc vero utriusque Consensu publicè edita." In the year 1770, some differences having arisen between Michaelis and his colleagues in the Royal Society, he resigned his directorship. In 1775 his well-established reputation had so far removed the prejudices which had formerly been conceived against him in Sweden, that the count Höpkin, who some years before had prohibited the use of his writings at Upsal, now prevailed upon the king to confer upon him the order of the Polar star. He was accordingly decorated with the ensigns of that order, on which occasion he chose as a motto to his arms "libera veritas." In 1782 his health began to decline, which he never completely recovered; in 1786 he was raised to the rank of privy counsellor of justice by the court of Hanover; in the following year the Academy of Inscriptions at Paris elected him a foreign member of that body; and in 1788 he received his last literary honour by being elected a member of the Royal Society of London. He continued his exertions almost to the very close of life, and a few weeks before his death, he shewed a friend several sheets, in MS., of annotations which he had lately written on the New Testament. He died on the 22d of August, 1791, in the seventy-fifth year of his age. He was a man of very extensive and profound erudition, as well as of extraordinary talents, which were not less brilliant than fold, as is evident from the honours which were paid to his merits, and the testimony of his acquaintance and contemporaries. His application and industry were unwearied, and his perseverance in such pursuits as he conceived would prove useful to the world, terminated only with the declension of his powers. His writings are distinguished not only by various and solid learning, but by a profusion of ideas, extent of knowledge, brilliancy of expression, and a frequent vein of pleasantry. In the latter part of his life he was regarded not only as a literary character, but as a man of business, and was employed in affairs of considerable importance by the courts of England, Denmark, and Prussia. His works, as an author, were exceedingly numerous, of which a very long list is given in the General Biography. Of those with which the English scholar has been brought acquainted, the most important is the "Introduction to the New Testament," translated into English from the first edition, and published in 1761, in a quarto volume. In 1788, the fourth edition was published in two volumes quarto. The object of this work, which is purely critical and historical, is to explain the Greek testament, with the same impartiality, and the same unbiassed love of truth, with which a critic in profane literature would examine the writings of Homer, Virgil, &c. The first volume contains an examination of the authenticity, inspiration, and language of the New Testament. The second volume contains a particular introduction to each individual book of the New Testament. An English translation of it has been published by the Rev. Herbert Marsh, in six volumes, royal octavo. Gent. Magazine, March 1792. See also the prefaces by Mr. Marsh.

MICHAELIS, JOHN-HENRY, a learned German divine and orientalist, the son of a citizen of Elrich, was born at Kettenburg, in the county of Hohenstein, in the year 1668. He was intended for trade, but discovering a stronger inclination for study than business, he was allowed to follow the bias of his mind, and obtained admission into the school of St. Martin in the city of Brunswick. Here he was appointed to instruct some of the younger scholars, in which employment he acquitted himself greatly to the satisfaction of the rector of the school. After this he was entered of the university of Leipzig, where he went through courses of philosophy and divinity, and also studied the oriental languages and rabbinical

Hebrew. In 1694 he quitted Leipzig for the university of Halle, where he taught the Greek, Hebrew, and Chaldee with great reputation. Here he published, with the assistance of professor Francke, a work entitled "Conamina brevioris Manuductionis ad Doctrinam de Accentibus Hebræorum Prolatæ." In 1696 he published another piece, entitled "Epiertia philologica de reverendi Michaelis Beckii, Ulmenis, Disquisitionibus philologicis, cum responsionibus ad Examen XIV. Dictor. Gen." He was now thoroughly conversant, not only with the Greek, Hebrew, and Chaldee, but likewise with the Syriac, Samaritan, Arabic, and rabbinical Hebrew, and having formed an acquaintance with Job Ludolf, he accompanied him to Frankfort, for the purpose of learning the Ethiopic language under his instructions. In 1699, he succeeded Francke in the Greek professorship at Halle, and in 1707 was made keeper of the university library. He was afterwards nominated professor of divinity in ordinary, and admitted to the degree of D.D. In 1732 he was made senior of the faculty of divinity, and inspector of the theological seminary. He died in 1738, at about the age of seventy. He was author of many works besides those already mentioned, the titles of which are enumerated in Mœri.

MICHAELMAS, the feast of St. Michael the archangel, held on the 29th of September.

MICHAELMAS *Island*, in *Geography*, a small island at the entrance of king George III.'s Sound, on the S.W. coast of New Holland; 4 miles N.N.E. of Bald Head.

MICHAILA, *St.*, a town of Russia, in the government of Revel; 36 miles S. of Revel.

MICHAILOV, a town of Russia, in the government of Riazan; 24 miles S.S.W. of Riazan. N. lat. 54° 20'. E. long. 38° 38'.

MICHALOWKA, a town of Poland, in Volhynia; 52 miles N. of Zytomiers.

MICHAUT, PIERRE, in *Biography*, secretary to the count de Charolois, son of the duke of Burgundy, in 1466, was author of the poem, entitled "Doctrinal de la Cour, ou Danse des Aveugle;" Instructions for the Court, or Blind-man's-buff. From a beautiful copy of this satirical poem, finely illuminated, M. Laborde has given representations of all the musical instruments used in France during the 15th century in the hands of the performers. *Essai sur la Mus.*

MICHAUXIA, in *Botany*, named by M. L'Heritier, in one of his monographs, in honour of his friend Andrew Michaux, botanist to the late king of France, Louis XVI., and well known by his botanical expeditions to Syria (where he gathered this plant), Persia, North America, and New Holland. The *Flora Boreali-Americana*, often quoted by us, the fruit of his six years' labours in America, was published by his son. We have already offered some remarks on the name of the present genus. (See MEDIUM.) As to its botanical stability, none who consider the variety of shapes in the corollas of reputed *Campanula*, can feel quite sure on the subject; but the author of this genus had contemplated the question with singular attention, and with all his wonted sagacity. He declares *Michauxia* to differ from *Campanula*, as *Chlora* from *Gentiana*, the number of the parts being as eight to five, and the corolla that of a *Phyteuma*, but in eight divisions. It is at least a good artificial genus, and now generally adopted, except that Justieu adheres to one of its ancient names. (See MINDIUM.) L'Herit. Monogr. 3. Schreb. 840. Willd. Sp. Pl. v. 2. 342. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 353. Lamarck Dict. v. 4. 134. Illustr. t. 295. (Mindiium; Juss. 164.)—Clafs

and order, *Ochlandria Monozynia*. Nat. Ord. *Campanaceæ*, Linn. Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in sixteen lanceolate unequal segments, every other one reversed. *Cor.* of one petal, wheel-shaped, much larger than the calyx, in eight very deep, widely spreading, linear-lanceolate, equal segments, revolute at their points. Nectary of eight valves, bearing the stamens. *Stam.* Filaments eight, awl-shaped, permanent; anthers vertical, linear, very long, pressed close to the style. *Pist.* Germen inferior, turbinate; style columnar, permanent; stigma in eight awl-shaped, revolute segments. *Peric.* Capsule turbinate, abrupt, of eight angular cells, without valves, opening by pores at the base. *Seeds* very numerous, oblong, small, affixed to the proper receptacle of each cell, which unites with the central column.

Eff. Ch. Calyx in sixteen deep segments, alternately reflexed. Corolla in eight deep segments. Nectary of eight valves, bearing the stamens. Capsule of eight cells, opening by pores at the base. Seeds numerous.

Obf. It must be allowed that the number of cells in the fruit being equal to that of the parts of the flower, is very different from *Campanula* and *Phyteuma*, and also that there is no botanical analogy between eight and five or three; so that as far as number can be allowed to guide us, no genus can be better defined.

1. *M. campanuloides*. Rough-leaved Michauxia. L'Herit. Monogr. t. 1, 2. Curt. Mag. t. 219. (*Medus*; Diosc. book 4. chap. 18. *Medium* Dioscoridis, or *Mindium* Rhazis; Rauwolf. It. 284. f. 284. Dalech. Hist. append. 33. Bauh. Hist. v. 2. 805. *Campanula peregrina maxima, laciniatis foliis*; Morif. sect. 5. t. 3. f. 31.)—Gathered by Rauwolf in Syria, near Tripoli; and by Michaux, above 200 years afterwards, in the same country. Labillardiere is also said to have found it on mount Lebanon. It was raised from seed at Paris; and was communicated to Kew garden by L'Heritier in 1787, but being a greenhouse biennial plant, and rarely ripening seeds in England, is now not to be met with. The root is spindle-shaped, whitish, milky, like the rest of the plant. Stem from two to six feet high, erect, round, leafy, rough, more or less branched, many-flowered. Leaves scattered, lanceolate, acute, jagged, very rough, wrinkled, dark green, sessile, clasping the stem; the lower ones stalked; the radical ones heart-shaped, soon disappearing. Flowers ranged along the sides, and solitary at the ends of the branches, sessile, drooping, two inches in diameter, very handsome and singular, not unaptly compared by Curtis to some distant resemblance of a Passion-flower. Corolla white, with a tinge of purple at the outside. Stamens and style green, the upper half of the latter loaded with pollen, lodged by the anthers among the hairs which invest it, before they retire and curl themselves together.

L'Heritier's two plates, of this plant and its fructification, are the finest possible, scarcely wanting the assistance of colour to give a complete idea of the objects, and even vieing, in that respect, with the prints of the Houghton Van Huysum. The rude cuts of Rauwolf, Dalechamp, and Bauhin are expressive enough. Morison's engraving, copied and perverted as usual, from them, is very bad. Curtis's plate is necessarily a fragment, but faithful. Tournefort and Linnæus were unaccountably deceived concerning this fine plant. The former confounded it with his own *Campanula foliis profunde incis, fructu duro*; Tourn. Cor. 3, which is *C. lyrata*; Lamarck Dict. v. 1. 588. Hence Lamarck was led into the same error, which he corrected in his v. 4. 134, as above quoted; and hence Mr. Salisbury, in his Prodrômus 127, calls our *Michauxia, Campanula lyrefolia*, citing Lamarck by mistake, and asserting that its fruit is "exactly that of

a *Campanula*." Linnæus confounded our plant with *C. laciniata*, Sp. Pl. 237, figured in Tournefort's Voyage, v. 1. t. 99, than which few things, at all akin, can be more distinct. He also, by the specific name of *Medium*, applied to another kind of *Campanula*, very common in gardens, seemed to consider that as the *μυδιον* of Dioscorides, which we apprehend to be no less a mistake. Dr. Sibthorp suspected *C. laciniata* might be the true *μυδιον*, being probably unacquainted with the *Michauxia*. The latter surely answers best to the original description, such as it is; of which we here subjoin a translation. "Medium grows in shady stony situations. Its leaves are like succory (*σικυ*). Stem three cubits high. Flowers purple, large, and circular. Fruit (or seed) small, like that of *Cnicus*. Root a span long, as thick as a walking-stick." The colour of the flowers probably varies, from different shades of purple, to white.

MICHAUXIA, in *Gardening*, comprehends a plant of the herbaceous flowering, exotic kind, of which the species cultivated is the rough-leaved michauxia (*M. campanuloides*.)

Method of Culture.—It may be raised from seed procured from its native situation, and sown in the early spring season in pots, and plunged in a hot-bed, or simply on a moderate hot-bed. When the plants have attained a little growth, they should be removed into separate pots, and be replunged in the hot-bed. This must afterwards be managed as tender green-house plants.

Plants of this fertile variety in collections of this nature.

MICHAU, in *Geography*, a town of Prussia, in Pomerania; 22 miles W.N.W. of Dantzic.

MICHEL, ST., a small island in the gulf of Venice, near Venice, where the Protestants, who trade thither, have purchased ground on which to build a church.—Also, a town of Italy, in the Veronese; 14 miles N.W. of Verona.—Also, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of St. Jean de Maurienne; 7 miles S.S.E. of St. Jean. The place contains 1450, and the canton 6244 inhabitants, on a territory of 342½ kilometres, in 8 communes.

MICHEL di Capa, St., a town of Peru, in the jurisdiction of Arica, on the borders of a large forest of pimento, which is said to produce annually 300,000lbs. weight of that spice.

MICHEL-Gemote, in *History*. See PARLIAMENT.

MICHEL-Synoth. See PARLIAMENT.

MICHEL LAU, in *Geography*, a town of Prussia, in the territory of Culm; 36 miles E. of Culm.—Also, a town of Silesia, in the principality of Brieg; 8 miles S.S.E. of Brieg. N. lat. 50° 46'. E. long. 17° 35'.

MICHEL BACH, a town of Germany, in the county of Schwarzenburg; 20 miles W. of Anspach.

MICHEL ROMANO, in *Biography*, a disciple of Soriano, and a famous canonist, who flourished at the latter end of the 16th century, and beginning of the next; author of a very curious and scarce work, published at Venice, 1615, entitled "Musica vaga et artificiosa continente motetti con obblighi, e canoni diversi, tanto per quelli che vorranno professare d'intendere diversi studii della Musica," folio; or, Artful and curious Music, as well for those who receive delight from the performance of it, as for others who make music their peculiar study. Hist. vol. iii. p. 519.

MICHEL, JAMES-BARTHOLOMEW, an able mathematician, was born of an ancient family at Geneva, in 1692. He entered into the French military service, and became a captain. In 1738, he retired to his native country, where he applied chiefly to mathematical and philosophical studies. He constructed a number of charts, invented a new thermometer,

monometer, and composed several memoirs, printed at Basle. These are on meteorology and the temperature of the globe; light; the comet of 1680; the universal deluge; &c. He surveyed the Glaciers of Switzerland, of which he took several views, which have been engraved. In the troubles which agitated his country he was a sharer, and was imprisoned a long time by order of the government of Bern. He died in 1766.

MICHELÌ, PETER ANTHONA, an Italian botanist of great celebrity, particularly in what is now called the cryptogamic department, was born at Florence, December 11, 1679. His parents were indigent, and took but little care of his education. He is said, nevertheless, to have been destined to the occupation of a bookseller, but an insatiable thirst after natural knowledge over-ruled all other objects. Content in the humblest poverty, he resigned himself to his favourite pursuit, trusting to that, even for his means of livelihood. Nor was he disappointed. His good character, and distinguished ardour, soon procured him the notice and favour of the marquis Cosmo da Calligione, in whose family a taste for Botany has been almost hereditary, and for whom Micheli in his early youth made a collection of Umbelliferous plants, which even then proved his accuracy and discernment. This gentleman introduced him to the celebrated count LAWRENCE MAGALOTTI, (see that article,) by whom he was presented to his sovereign, the grand duke Cosmo III. The *Institutiones Rei Herbariæ* of Tournefort had just appeared at Paris; and the first pledge of the grand duke's favour, was a present of that book, which to Micheli, who had hitherto found the want of some systematic guide, was a most important and welcome acquisition. He speedily adopted the tone of his leader, with respect to generic distinctions and definitions, and improved upon him in a more frequent adaptation of original specific ones.

In the autumn of 1706, the care of the public garden at Florence, founded by Cosmo I., was confided to Micheli, he being appointed botanist to the grand duke. He was commissioned to travel, not only in Italy, but in various distant countries, to collect plants, and to establish a correspondence, for the benefit of his trust. By the co-operation of his friends Franchi and Gualtieri, the garden was enriched from the then more flourishing one at Pisa; and a Botanical Society was instituted at Florence in 1717, which greatly promoted the interests of the science. In the summer of that year, the great William Sherard, returning from Smyrna to England, visited Florence in his way, and formed a friendship with Micheli, that continued till his own decease in 1728. A frequent correspondence, and interchange of specimens, took place between them, as amply appears by the collections preserved at Oxford, and by the writings of Micheli.

The subject of our memoir continued his scientific studies, as well as his bodily exertions in frequent journies. The fruit of the former was the publication of his great work, entitled *Nova Plantarum Genera*, a folio of 234 pages and 108 plates, in 1729. The result of his journies proved but too soon disastrous. He spent near three months, from the 4th of September to the 30th of November 1736, in an excursion to the north of Italy, visiting the famous mount Baldus, and the Venetian isles; but he caught a pleurisy, from the consequences of which he never recovered, dying at Florence, January 2, 1737, new style, in the 58th year of his age. He was buried in the church of Santa Croce, amongst the ashes of some of the greatest men of his country, and of the civilized world, where a neat marble tablet was erected to his memory by his associates. The simple and elegant inscription was probably composed by his

learned friend Antony Cocchi, to whom he always confided the revision of his Latin works, before publication, and who delivered an Italian oration in his praise, in the council chamber of the Old Palace, August 7, 1737, which was soon after published. The epitaph is as follows.

PETRUS ANTONIUS MICHELIVS
vixit annos LVII dies XXII in tenui re
beatus omnis historiæ naturalis
peritissimus magnorum etrutic
ducum herbarius inventis et scriptis
ubique notus ac propter sapientiam
suavitatem pudorem optimis
quibusque ætatis suæ egregie carus
obiit IV nonas Januarias MDCCXXXVII
amici vere conlato titulum posuere.

It does not appear that Micheli was ever married. He is described by his contemporaries as a man of the most pleasing, modest, and liberal manners, no less ready to communicate, than eager to acquire, knowledge. His bodily constitution was good; his health uninterrupted; till his last illness, which was of so decided a nature, that he placidly yielded to his fate, not only with the Catholic ceremonies, but with the feelings of a Christian. His friend Cocchi informs us, that "he was endued with a clear and concise natural eloquence; and although the poverty of his parents deprived him of the advantages of a learned education, he had, by his own application, acquired, with wonderful felicity, a knowledge of Latin."—"The writings of the most eminent botanists were so familiar to him, that he had learned to express his ideas in Latin, by no means amiss, he having a very quick perception as to any barbarous expressions."

We are anxious to collect every particular of the life and character of the author of such a book as the *Nova Plantarum Genera*; a work much more extensive in its compass than the *Historia Muscorum* of Dillenius, superior in physiological merit, as well as in technical style of definition, though deficient in historical and critical disquisition, as well as in description. It is to be lamented that Micheli fell so much into the dry catalogue style of Tournefort, though he has greatly improved upon his model; because they have neither of them attained any thing like the technical synoptical terseness and precision of subsequent times. The great merit of Micheli consists in his accurate scientific illustration of some of the most difficult tribes of plants, which Tournefort had left unattempted. The order of the *Calamariæ*, and particularly the difficult genus *Carex*, first assumed an intelligible form under his hands. The seeds of the latter, and their coverings, were first resorted to, with the happiest effect, for specific discrimination. (See CAREX.) A vast number of species of the hitherto neglected genus *Lichen* were ascertained and well delineated. It is with great injustice that Dillenius, whose figures of the crustaceous and imbricated Lichens are the meanest part of his work, charges Micheli with erring on the side of luxuriance in his representations. He had indeed more favourable subjects of investigation, owing to the climate in which he lived; for in Italy the plants in question are found vastly more luxuriant and prolific than in the north of Europe; and we can aver that the figures and descriptions of Micheli are as faithful as those of Dillenius himself; they cannot be more so. (See DILLENIVS.) The parts of the flowers of Mosses, properly so called, were first displayed in the work of Micheli, though he did not understand their real uses. (See MUSCI.) He was equally successful in the collateral families, now termed *Hepatica*, founding the genera of *Blasita*, *Marfiltea*, *Jungermannia*.

nia, *Spharocarpus*, *Anthoceros*, *Targionia*, &c. In the natural order of *Fungi*, till then almost totally neglected, he displayed great accuracy and originality, and gave the first synoptical distribution of those difficult vegetables, by which his followers have profited. Many genera of the more perfect or phænogamic plants are also illustrated or founded in this work of Micheli; but neither their distinctions nor their nomenclature is, in general, so good as the former. In specific distinction, he was too prone to raise varieties to the importance of species, of which his numerous kinds of *Trifolium* are instances.

Our author had extended his studies to the Submarine plants, or Sea-weeds, and had numerous plates engraved, for publication in a second volume, had his life been prolonged. Of these plates a set of impressions, procured by the late lord Bute, was bought at his lordship's sale, by the Rt. Hon. sir Joseph Banks, and is, through his liberality, accessible to all. Another set, now in the Linnæan library, was given to its present possessor by Dr. Targioni Tozzetti of Florence, whose father purchased all Micheli's remains, among which are valuable manuscripts of various kinds; especially the descriptions of these plates. There are likewise some rude drawings of *Orchidææ*, the work we believe of Micheli himself. His pencil however was not sufficiently excellent to enable him to be in general his own draughtsman; still less could he, like Dillenius, engrave the plates he published. In studying the above-mentioned marine productions, it is not wonderful, nor reprehensible, that he then confounded corals and corallines with plants, and made a genus out of the present *Sertularia*, which he called *Dillenia*.

Micheli had prepared an alphabetical catalogue of the plants in the garden, of which he had the superintendance. This was published in 1748, in folio, with seven botanical plates, besides a plan of the garden, under the title of *Catalogus Plantarum Horti Cæsarei Florentini*; for the race of the Medici, and the golden age of Florence, had now passed away. Their imperial successors, however, patronized science, and the volume in question is dedicated to the emperor Francis I., by its editor John Targioni Tozzetti, who has prefixed an excellent historical preface of his own; as well as a more oratorical Italian discourse, upon natural history, by the before-mentioned Antony Cocchi.

The studies of Micheli were extended to fossils, and petrifications, of both which numerous specimens remain in his museum: but he published nothing respecting them. An account of three of his botanical tours in Italy is said, by Haller, to be extant, in the sixth volume of Travels published by Targioni Tozzetti; but of this publication we have seen only the first volume. We ought also to mention his first publication in 1723, an octavo pamphlet on *Orobanche*, in Italian, chiefly with a view to its extirpation, as a noxious weed. This is said to be best accomplished by eradicating the beans or other plants, on which the *Orobanche* may be perceived to have fixed itself, in the month of April; by which procedure, being an annual herb, its propagation is cut off. Works of Micheli. Smith's Tour on the Continent. Cocchi Elogio di P. A. Micheli. Halber Bibl. Bot. S.

MICHELIA, in *Botany*, so denominated by Linnæus, in memory of the great Florentine botanist Micheli. (See the last article.) Linn. Gen. 278. Schreb. 374. Willd. Sp. Pl. v. 2. 1260. Mart. Mill. Ord. *Coadunate*, Linn. *Magnolia*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, coriaceous, splitting longitudinally, falling off as the flower expands. Cor. Petals numerous, lanceolate, in several rows; the outer ones largest. Stam. Filaments numerous, short, linear, inserted into the common receptacle of the pistils below the germens; anthers terminal, linear, of two cells, bursting longitudinally at the inner side, surmounted by a bluntish point. Pist. Germens numerous, imbricated in an oblong spike; styles none; stigmas reflexed, obtuse. Peric. Berries equal in number to the germens, coriaceous, globose, of one cell, disposed in a large cluster. Seeds from four to eight, angular on one side, convex on the other.

Ess. Ch. Calyx of one leaf, coriaceous, immediately deciduous. Petals numerous, in several rows. Berries numerous, with several seeds.

1. *M. Champaca*. Sweet Yellow Michelia, or Champawk. Linn. Sp. Pl. 756. (Champacam; Rheede Hort. Mal. v. 1. 31. t. 19. Sampacca; Rumph. Amboyn. v. 2. 199. t. 67. Champe; Baul. Pin. 470.)—Leaves lanceolate, somewhat ovate. Calyx externally silky.—Native of Malabar, in sandy places, flowering twice in the year, but not bearing fruit till it is very old. Rheede. Commonly cultivated throughout India, especially in the Malay countries, but never found wild. Rumphius. Cultivated at Orford, Lancashire, by John Blackburne, esq. in 1779. Hort. Kew. This tree is celebrated for the exquisite perfume of its flowers, of which most Europeans, who have been in India, speak with rapture, though some find it too powerful. The natives adorn their heads with these flowers, both for the sake of the perfume, and for the elegant contrast of their rich orange colour, with their own black hair. The tree is of a moderate size; the bark of its root red, bitter, and very acrid, according to Rheede. Branches round, alternate, smooth, leafy, chiefly at their extremities. Leaves alternate, flaked, a span long, ovato-lanceolate, entire, taper-pointed; a little tapering at the base; somewhat silky when young, but finally smooth, or nearly so; rather glaucous beneath; furnished with a midrib, and many transverse, oblique, parallel veins, connected by innumerable fine reticulations. Footstalks an inch long, minutely hairy, channelled above. Stipulas none. Flowers not unlike a double narcissus, axillary, solitary, on simple, short, very thick stalks. Petals elliptic-lanceolate, the colour of the yolk of an egg, the outermost about an inch and a half long. Calyx ovate, scarcely an inch long, finely silky, splitting down one side, and separating from the base, before the flower can expand. Fruit resembling a large bunch of grapes, of a pale yellowish-white when ripe, very acrid to the taste, and unpleasant to the smell, according to Rheede. The seeds are from four to eight, angular from mutual pressure, the size of small peas.

Such is the real *M. Champaca*, of which we have obtained fine specimens from Madras, and have consequently been enabled to correct the description of the calyx, which authors have greatly misunderstood. Rheede and Rumphius misled Linnæus to suppose there was none; for he originally described this plant from books only. Afterwards procuring, by the name of *Tsiampacca lalac*, a specimen of our *Magnolia pumila*, (see *MAGNOLIA*, n. 7, where it will appear how much such exotic names are liable to corruption,) he mistook this for *Michelia Champaca*, and thence altered the character of the genus, in his *Mantissa* 40, attributing to it a calyx of three oblong petal-like leaves. How Lamarck discovered and figured a short permanent three-leaved calyx we know not. Linnæus had in his herbarium the real *Champaca*, inscribed *Tsiampacca eoengang*, as far as we can decypher the scrawl, which he marked *M. Tsiampacca*.

Tsiampacca. Our Indian botanical friends assure us this is only the same name spelt differently, and therefore some contend for the excellence of only one species of *Michelia*. We shall endeavour to establish a second.

2. *M. sylvestris*. Wild Whitish Michelia. (*M. Tsiampacca*; Linn. Mant. 78. *M. eunymoides*; Burm. Ind. 124. *Simpacca sylvestris*; Rumph. Amb. v. 2. 202. t. 68.)—Leaves elliptical. Calyx nearly smooth.—Linnaeus received this from India by the name of *Tsiampacca poeti*, or White Champawk, which agrees with the name and synonym in Rumphius. It differs from the former in the broad elliptical shape, and perfect smoothness of its leaves. The calyx also is smooth, having merely a very slight silkiness at the tip; the rest being finely granulated. Our specimens shew nothing further, but they agree with all the above synonyms perfectly, except that Burmann has a very erroneous quotation of Sloane, and moreover says the Javanese call this species *Tsiampacca connexa*, which Linnaeus, we know not on what authority, applied to the former. We could not retain Burmann's specific name, because it seems suggested by Sloane's synonym, and is totally irrelative to our plant. *Tsiampacca* and *Champaca* are, as we have said, synonymous and ambiguous. We therefore adopt a name from the manuscripts of Linnaeus, which it is pity he altered. Rumphius describes the *M. sylvestris* as a more tall and upright tree than the *Champaca*, with larger and broader leaves, the breadth of four fingers (exactly as we have them); and he very accurately remarks that they have fewer ribs, or transverse veins. Flowers exactly like the former, except that their petals are broader, whitish, or straw-coloured, with but a slight degree of odour. When cultivated however they acquire a stronger and more delightful smell, though not equal to the *Champaca*. The fruit is much the same, though the seeds, which vary from two to seven in number, are scarcely so red. It is very possible that this may, after all, be only the wild state of the *Champaca*, but we have now furnished sufficient materials to prevent any future mistake of either, and we trust the generic character is sufficiently established. Gærtner obtained from Thunberg, as the fruit of *M. Tsiampacca*, what looks most like a *Magnolia*, and we cannot but think, the more it is compared with Rumphius, whose figures, we must always recollect, are diminished, the more it will prove different from his.

If Andrews's tab. 229, *Magnolia fuscata*, (see *MAGNOLIA* n. 8,) be compared with our description of the calyx of *Michelia*, they will be found to agree. The petals however are those of a *Magnolia*, and we must still remain in doubt for want of the fruit of this elegant shrub. It is curious that Linnaeus had a specimen of this *Magnolia*, which he very incautiously marked *Michelia Tsiampacca*. On dissecting a flower, he found the calyx of three leaves. Whether this be correct or not, though we have three coloured figures of this plant in our periodical publications, none of them enables us to form even a conjecture, except Andrews, and this but incidentally. We have some suspicion that Loureiro's *Liriodendron Figo* may possibly be the same with *Magnolia fuscata*, but unfortunately his slight mention of the fruit affords no certain information as to its genus. The calyx however, being of one leaf, agrees. He says his plant is called at Macao *Fula Figo*. Has this any connection with the *Fulle*, Bauh. Pin. 470?

This fine tribe of plants is so little understood by botanists, and so many errors have attended the history of the *Michelia*, which the Linnaean herbarium alone could explain or remove, that we have been more particular than usual, and still the subject is far from being exhausted. S.

MICHELIA, in *Gardening*, comprehends a plant of the tree or shrub kind, of which the species commonly grown is the *champaca*, or Indian *Michelia*, (*M. champaca*.)

Method of Culture.—This is a plant which may be increased by seeds, layers, and cuttings, being managed in the same manner as the more tender green-house plants afterwards.

They afford variety in collections of stove plants.

MICHELPACH, in *Geography*, a town of Austria; 12 miles S.E. of St. Polten.

MICHELSDORF, a town of Bohemia, in the circle of Chrudim; 9 miles N.E. of Leutmschl.

MICHICOU, a river of America, in the state of Vermont, which runs into lake Champlain. N. lat. 44° 55'. W. long. 72° 56'.

MICHIGAN, the largest lake in the territory of the United States, lies between 41 8', and 45 40' N. lat. and between 84° and 87° W. long. Its length is estimated at 260 miles from N. to S., and its circumference at 945 miles; and, according to Mr. Hutchins, it contains 10,368,000 acres. It is navigable for ships of any burden. It communicates with lake Huron at the N.E. part through the straight of Michillmackinac, which is six miles broad, with a fort of its name on an island at its mouth. In this lake are several kinds of fish, and particularly excellent trout, weighing from twenty to sixty pounds. On the N.W. parts of this lake the waters pass through a narrow strait, and branch out into two bays; that to the northward is called Noquet's bay, and the other to the southward Puans, or Green bay, which forms with the lake an extended peninsula, called cape Townsend, or Vermilion point. About thirty miles S. of Bay de Puans, is lake Winnebago, which communicates with it, and a very short portage interrupts the communication south-westward from Winnebago lake through Fox river, then through Onisconm, into the river Mississippi. Chicago river, at the S.W. extremity of lake Michigan, furnishes a communication, interrupted by a still shorter portage, with Illinois river. Lake Michigan receives many small rivers from the W. and E., some of which are 150 and even 250 yards broad at their mouths.

MICHILLIMAKKINAK, called by the Canadians "La Gros Isle," the name of an island, fort, and village, on the S.W. side of the straits of the same name. The island on which the village and fort stand is very barren, but, as the grand rendezvous of the Indian traders, a considerable traffic is carried on; and its situation will probably render it a place of commercial importance. It is within the line of the United States, and contains 251 inhabitants: distant about 200 miles N.N.W. from Detroit. N. lat. 45° 48' 34". W. long. 84° 30'.

MICHILLIMAKKINAK, *Little*, a river on the N.W. territory of America, which enters the S.E. side of Illinois river, by a mouth fifty yards wide, at which there are between thirty and forty small islands. It runs a N.W. course, and is navigable about ninety miles. On its banks is plenty of good timber, viz. red and white cedar, pine, maple, walnut, &c.; and here are also coal-mines.

MICHIPICOTEN, a river which runs into lake Superior, on the N.E. side of the lake. At its mouth it forms a bay of its own name; and on the W. part of the bay is a large island, so called, close to the land. On the E. side of the mouth of the above river, in N. lat. 47° 56', is Michipicoten House, belonging to the Hudson's Bay company.

MICHISCOU, the Indian and present name of the most northerly river in Vermont. It is navigable seven miles from its mouth.

MICHISCOU Tongue, a long point of land which extends southerly

foutherly into lake Champlain from the N.E. corner of Vermont, on the W. side of the bay of this name, and forms the township of Allburg.

MICHO, the name of a cove or bay of Canada, on the S. coast of the river St. Lawrence; 218 miles below Quebec. N. lat. $49^{\circ} 5'$. W. long. $66^{\circ} 30'$.

MICHOWITZ, a town of Bohemia, in the circle of Kaurzim; 12 miles W.S.W. of Kaurzim.

MICKELSO, a small island in the Baltic, E. of Aland. N. lat. $60^{\circ} 12'$. E. long. $20^{\circ} 5'$.—Alfo, a small island on the E. side of the gulf of Bothnia. N. lat. $63^{\circ} 27'$. E. long. $21^{\circ} 19'$.

MICKERY, a small island in the Frith of Forth; 8 miles N.W. of Leith. N. lat. $56^{\circ} 2'$. W. long. $3^{\circ} 17'$.

MICKLE, WILLIAM JULIUS, in *Biography*, was born, in 1734, at Langholm, in Dumfriesshire, Scotland, of which place his father was minister. After a preparatory education under his father, he was sent to the High-school at Edinburgh, where he was continued till he was sixteen years of age, when he went into the counting-house of a relation to be initiated in the art of brewing. He remained in this business a few years; but a taste for reading and poetry rendered him unfit for the necessary routine of trade. In 1763, he quitted Edinburgh for London, with a view of soliciting employment in the sea service, to which he felt a strong inclination. He took in his pocket a poem, entitled "Providence," which he contrived to get introduced to lord Lyttleton, at that period a patron of the muses, but with respect to our author it produced nothing but a complimentary correspondence. Several projects for a settlement at home and abroad, in a commercial or official situation, having failed, he at length accepted the humble situation of corrector to the Clarendon press at Oxford. In 1767, he published his poem, entitled "The Concubine," the title of which, after it had gone through three editions, was changed to "Sir Martyn," as the first title had occasioned some misconception of its nature. It was written in the style and manner of Spenser, and displays much poetical imagery, with a considerable facility of versification. Its object is to expose the evils and disgraces resulting from illicit love, terminating in concubinage. His name now became known to the public, and a way was prepared for the reception of his most considerable performance, which was the translation of the "Lusiad" of Camoens. He had, at first, doubts of the probable success of such a work, and published, as a specimen, the first book; and being encouraged by his friends and the public, he resigned his office at the Clarendon press, and took lodgings at a farm-house, in order that he might devote his whole attention to the task. His translation was finished in 1775, and published under the title of "The Lusiad, or the Discovery of India," with an introduction, containing an account of the Portuguese conquests in that country, the life of Camoens, a dissertation on the Lusiad, &c. &c. This work obtained for him a high rank among the English poets, and it is said by an able critic, that, "as far as splendour of diction and melody of versification can go to establish a poetical character, the name of Mickle has not many superiors." No metrical translator ever took greater liberties with his original than Mickle; and it is certain that his poem, and that of Camoens, have little more in common than the plan and outline. Their difference consists not only in the language, but in many circumstances and incidents of the piece. Thus Mickle has painted a storm and a naval action in three hundred lines, of which there is not the smallest vestige in the original. His suppressions are as frequent as his interpolations, of which the reader should be apprized, if he go

to compare the Portuguese poem with its English translation. His purpose was to give a poem that might live in the English language, which he has attained. Previously to the publication of the Lusiad, he had written a tragedy, entitled the "Siege of Marseilles," which being offered to Garrick, was refused as unfit for the stage. The same sentence was passed upon it by Mr. Harris and Sheridan, and he submitted, after a time, to their decision with decent fortitude. In 1779, he went out as secretary to governor Johnstone, who had been appointed to the command of the Romney man of war. He was left at Lisbon as joint-agent for prizes. Here, on account of the honour that he had done to the chief poet of the country, he received many very many flattering marks of attention, and was admitted into the Royal Academy of Lisbon at its first opening. While at the Portuguese capital, he wrote his poem of "Almada-hill, an Epistle from Lisbon," which by no means supported the reputation which he had acquired by the Lusiad. In his foreign mission he had acquired some property, and on his return he settled at Wheatley, near Oxford, where he died in 1789, leaving behind him a character for strict integrity and honour, intermixed, perhaps, with some foibles and imperfections.

MICKLE ROOE, in *Geography*, one of the smaller Shetland islands. N. lat. $60^{\circ} 30'$. W. long. $1^{\circ} 49'$.

MICKLEHAM, a village and parish situated in the hundred of Cophthorn, and county of Surrey, England. The houses are placed in a vale between Leatherhead and Dorking, and the valley is watered by the river Mole, and claims the attention of the topographer on account of the peculiar and picturesque nature of its scenery, and the many handsome seats included within its jurisdiction. On the west of the village rises a gentle hill, adorned by the handsome mansion of Norbury-park, the property of William Locke, esq. and on the east is Mickleham Down, a very fine sheep-pasture, belonging to sir Lucas Pepys, bart. Part of this Down is covered with plantations, which were begun by the late sir Cecil Bishop, about the year 1763, which serve both to shelter and ornament the seat of the proprietor, situated immediately beneath them. A part of the Roman road, called Stanes-street, can be distinctly traced not far from the house. At some distance further, to the south-east, is an eminence called Boxhill, from the vast quantity of box trees growing on its summit and side. This hill ascends abruptly from the Mole, and commands, from its summit, a very grand and extensive prospect. What is remarkable, there is a well on the top of it, the water of which stands at only fifteen feet from the surface, whereas, on another hill opposite, it is necessary to raise the water 430 feet. The Mole, which in its passage through this parish forms a very serpentine current, sinks entirely into the ground at different places, which commonly are denominated the Swallows.

The church of Mickleham is a very ancient building, and is rather remarkable in its architecture. It is built of stone, and consists of a nave, with a chancel at the east end of it, a small chapel on the north side, and a south aisle, separated from the nave by round pillars supporting semi-circular arches. The east window is adorned with handsome tracery works, and on each side of the chancel are two windows, with lancet-shaped tops within a round-headed arch, which rests upon round pillars, and is ornamented with a single row of square billet-work. At the west end rises a low square tower, strengthened by double angular buttresses, and surmounted by a pyramidal spire. The font is of solid stone, the basin having been hollowed out from it. Here are several monuments, but none of them peculiarly interesting. The living is a rectory.

According

According to the parliamentary returns of 1801, the number of inhabitants in the whole parish amounted to 389 persons, of whom 186 were males, and 203 females. The grounds of Norbury park are finely wooded, and diversified with lofty eminences. The house has long been noted for its pictures and works of art; one room is covered with paintings, by Barrett, and is much admired for its style and execution. It represents the mountain and lake scenery of Westmoreland. See Gilpin's *Western Counties*, and Manning's *History of Surrey*, edited by William Bray, esq. F. S. A. fol. vol. ii. 1809.

MICKMACKS, American Indians, who inhabit the country between the Shapody mountains and the gulf of St. Laurence, in Nova Scotia, opposite to St. John's island. These people are said to convey their sentiments by hieroglyphics, marked on the rind of the birch, and on paper, which the Romish missionaries perfectly understand. Many of them reside at the heads of the rivers in King's and Hants counties.

MICCONTRAFA, in *Counterpoint*, was long regarded as a solecism in harmony. The natural diatonic scale consisting of tone, tone, and semitone, as C D *ef*, or *ut, re, mi, fa*; G A B *c*, or *sol, la, mi, fa*; if the 4th *fa*, in the key of C, or C in the key of G, was made sharp, it would be called *tritonus*, or a dissonant series of four whole tones; which, before the ear was accustomed to crude intervals, in the infancy of counterpoint, was so offensive, that it used to be said, *Mi contra fa est diabolus*. Alluding to this in king Lear, act i. sc. 7. there is a passage which has much embarrassed the commentators: "O, these eclipses portend these divisions! *Fa, sol, la, mi*." Shakspeare, however, shews by the context, that he was well acquainted with the nature of the musical intervals contained in the *tritonus*, or sharp 4th, which, consisting of three tones without the intervention of a semitone, is extremely difficult to sing, and disagreeable to uncultivated ears when sung, if *mi* or *fa* terminate the passage.

The false 5th is only an inversion of the sharp 4th, as B F or F B, which were held in equal horror by our fore-fathers; though at present the chief beauties of melody and harmony are derived from these intervals.

MICOTSI, MOSES, in *Biography*, a learned Spanish Jew, who flourished in the 14th century, is chiefly known as author of a work, entitled "Sepher Miseroth Gadol," or "The Great Book of Precepts," which is explanatory of the commandments of the Jewish law, and which was printed at Venice in 1545. It is much applauded by father Simon, who says it is highly deserving of diligent perusal, on account of the great learning and judgment with which the author has treated the subject. Moreri.

MICOYA BAY, in *Geography*, a bay situated on the S.W. coast of Mexico, on the Pacific ocean. N. lat. 10° 18'.

MICRANTHEMUM, in *Botany*, from *μικρον*, small, and *ανθος*, a flower. Michaux Boreal-Amér. v. 1. 10. (Globifera; Gmel. Syst. Nat. Linn. v. 2. 32.)—Class and order, *Diandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Lyfimachieæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in four deep, somewhat spatulate segments; the two uppermost rather the smallest. *Cor.* scarcely longer than the calyx, of one petal, nearly bell-shaped; tube very short, smooth within; limb in four deep unequal segments, obsolete two-lipped, its upper segment smallest. *Stam.* Filaments two, incurved towards each other, with an appendage at the base; anthers of two roundish lobes. *Pist.* Germen superior, almost globular; style short, rather declined; stigma capitate, depressed,

oblique. *Peric.* Capsule nearly globular, clothed with the permanent calyx, of one cell and two valves. *Seeds* numerous, ovate, finely striated, sessile upon the central depressed receptacle.

Ess. Ch. Corolla unequally four-cleft. Stamens with an appendage at their base. Capsule of one cell and two valves. Seeds numerous. Calyx inferior, in four deep spatulate permanent segments.

1. *M. orbiculatum*. Michaux, t. 2. (Anonymus umbrosa; Walt. Carolin. 63. Globifera umbrosa; Gincl. n. 1.)—Native of damp shady places, in the woods of Carolina and Georgia, flowering in August. *Michaux.* Roots fibrous, annual? *Stems* prostrate, branched, a span long, thread-shaped, leafy, smooth like every other part of the herb. *Leaves* opposite, sessile, nearly orbicular, entire, one-fourth of an inch long, with one rib, and several nearly longitudinal veins. *Flowers* axillary, alternate, solitary, on short capillary simple stalks, not half the length of the leaves, white, the size of a small pin's head.

MICRANTHIUS, (from the same derivation as *Micranthemum*.) Wendl. Obs. 39. (see *PHYALOSTIS*); Willd. Sp. Pl. v. 3. 342.

MICRELIIUS, JOHN, in *Biography*, a very learned German Lutheran divine, was born at Catlin, in Pomerania, in the year 1597. He pursued his theological course at Stettin, and became distinguished for his industry and talents. He took his degrees, in succession, with much applause. In 1653, he made a voyage to Sweden, and received many tokens of respect, and testimonies of liberality, from queen Christina. He died in 1658, leaving behind him several works of great learning and research. Among these may be mentioned "Lexicon Philologicum;" "Lexicon Philosophicum;" "Syntagma Historiæ Mundi;" "Syntagma Hill. Ecclesiæ;" some school books, as "Arithmetica, usus Globorum, &c.;" and a vast number of "Theses," "Orations," &c.

MICROCARPÆA, in *Botany*, so named by Mr. Brown, from *μικρον*, small, and *καρπος*, fruit, the capsules of his original species being no larger than a pin's head, and the numerous seeds consequently extremely minute. Brown Prod. Nov. Holl. v. 1. 435.—Class and order, *Diandria Monogynia*. Nat. Ord. *Personateæ*, Linn. *Scrophulariææ*, Juss.

Ess. Ch. Calyx inferior, tubular, five-sided, five-cleft. Corolla two-lipped. Barren Stamens none. Capsule of two valves and two cells, with a contrary, and at length loose, partition.

1. *M. muscosa*. Br. (*Limosella diandra*; Linn. Mant. 252. Willd. Sp. Pl. v. 3. 342. *Pæderota minima*; Koenig in Retz. Obs. fasc. 5. 10. Willd. Sp. Pl. v. 1. 77.)—Leaves linear-spatulate, about as long as the flower-stalks.—Gathered by the late Dr. I. G. Koenig, in sandy, occasionally inundated, places, at the Cape of Good Hope, as well as at Madras; and by Mr. Brown in the tropical part of New Holland. This diminutive plant grows in dense patches. When examined separately, it will be found very like the European *Limosella aquatica*, though but one-fourth its size; nor can we wonder at Linnæus for having referred it, though diandrous, to the same genus; especially since Krocker has found the *aquatica* to be sometimes diandrous; see Willdenow. Mr. Brown however, finding the corolla irregular and two-lipped, and the capsule of two cells, thought himself justified in establishing the present as a distinct genus; to which we cannot but assent; though it must be observed that the real *limosella* betrays some irregularity of corolla in the incurvation of its two upper segments.—*M. muscosa* has a considerable likeness to *Montia fontana*. The whole herb is smooth. Roots fibrous, pale, probably annual. Stem creeping,

creeping, branched. *Leaves* opposite, erect, stalked, spatulate, narrow, entire; not an inch long, including their footstalks. *Flower-stalks* axillary, solitary, quadrangular at least when dry, scarcely overtopping the leaves. *Braçteas* none. *Flowers* solitary, erect; their limb pale purplish. Segments of the *calyx* broad, short, and blunt.

2. *M. cochlearifolia*. (*Pæderota cochlearifolia*; Koenig MSS. *Hedyotis maritima*; Linn. Suppl. 119. Willd. Sp. Pl. v. 1. 566.)—Leaves obovate, concave. *Flowers* nearly sessile.—Gathered by Koenig, and by his pupil Rottler, in the East Indies; we believe on the coast of Coromandel. This has the habit of the first species, but is of a much larger proportion. *Root* of long simple fibres, apparently annual. *Stems* numerous, prostrate, variously branched and divaricated, four or five inches long, slender, smooth, leafy. *Leaves* opposite, on short stalks, obovate, obtuse, entire, smooth, somewhat fleshy, rather concave, about half an inch in length, with some smaller axillary ones. *Flowers* axillary, opposite, solitary, on very short thick stalks. *Capfule* nearly globose, the size of coriander seed, pale brown, thin and brittle.

Mr. Brown points out the very near affinity of this plant to the former, from which he says it differs, in having a capsule without valves. This is indeed so far correct, that the capsule usually breaks casually at the sides; but traces of two distinct valves, each with a narrow partition from its centre, may readily be perceived, and these sometimes separate regularly at the top, in the usual way, even to the base, as we find by examining various specimens. This difficulty therefore being removed, we are glad to find a proper place for the plant in question, whose disagreement with *HEDYOTIS* we have already pointed out; see the conclusion of that article. Dr. Koenig having made it, like the former, a *Pæderota*, proves its having but two stamens, he being so rigid a Linnæan, that he usually considered the characters of the artificial classes as absolute, the orders having been, in his day, little observed.

MICROCHLOA, from *μικρος*, *small*, and *χλωρ*, *a grass*. Brown Prod. Nov. Holl. v. 1. 208.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Eff. Ch. Spike unilateral, without joints. *Calyx* single-flowered, of two nearly equal, acute, membranous valves. *Corolla* included, inverted, of two beardless hairy valves. *Stigmas* feathery.

1. *M. setacea*. Br. (*Rottboellia setacea*; Roxb. Coromand. v. 2. 17. t. 132. *Nardus indica*; Linn. Suppl. 105. Willd. Sp. Pl. v. 1. 315.)—Native of old walls, on the coast of Coromandel, and of the tropical region of New Holland. A diminutive annual grass, with a fibrous *root*, and several erect *stems*, from two to six inches high, smooth, round, and leafy. *Leaves* short, keeled, channelled, with a sheathing base. *Spikes* terminal, long, simple, very slender, a little incurved, composed of a single rank of imbricated purplish *flowers*, all directed one way. *Stamens* yellow, two or three. *Styles* purple.

MICROCORYS, from *μικρος*, *small*, and *κορυς*, *a helmet*, alluding to the shortness of the upper lip of the flower. Brown Prod. Nov. Holl. v. 1. 502.—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Eff. Ch. *Calyx* semi-five-cleft. *Corolla* ringent; its concave upper lip very short; middle segment of the lower lip broadest. Two upper stamens included, the fertile lobe of their anthers smooth, the empty one bearded; two lower with deeply cloven abortive anthers.

A genus of *scrubs*, found by Mr. R. Brown in the south part

of New Holland. All the species have entire *leaves*, three in a whorl. *Flowers* axillary, solitary, either white or purple, each with two *bracteas*.

1. *M. virgata*.—Leaves linear, obtuse, smooth like the calyx. *Braçteas* deciduous. *Stem* erect, with thread-shaped branches.

2. *M. barbata*.—Leaves linear, obtuse, smooth. *Calyx* and corolla externally hairy. *Braçteas* deciduous. *Stem* diffuse.

3. *M. purpurea*.—Leaves oval-oblong, recurved at the margin; minutely downy on both sides; dotted beneath. Young branches silky. *Calyx* hoary. *Braçteas* brittle-shaped, permanent.

MICROCOS, so called by John Burmann, Thefaur. Zeyl. 159, who appears to have had in his contemplation the smallness of the berry, or drupa, and therefore the word is to be derived from *μικρος*, *small*, and *κοκκος*, *a berry*, abbreviated for the sake of harmony. Linn. Gen. 267. Schreb. 356. Willd. Sp. Pl. v. 2. 1168. Gærtner. t. 57.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Columnifera*, Linn. *Tiliaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, bluntish, spreading, deciduous leaves. *Cor.* Petals five, linear, equal, emarginate, rather spreading, various in size. *Nectary* none. *Stam.* Filaments numerous, capillary, the length of the calyx, inserted into the base of the germen; anthers roundish. *Pist.* Germen roundish, supported by a short five-sided column, at whose top the stamens are inserted; style cylindrical, shorter than the stamens; stigma bluntish. *Peric.* Drupa roundish. *Seed.* Nut turbinate, clothed with long capillary fibres connected with the pulp, of three close cells, filled with solitary kernels.

Eff. Ch. *Calyx* of five leaves. *Petals* five, without any separate nectaries. *Drupa* stalked, with a hairy nut of three cells.

Linnæus, after having adopted this genus from Burmann, reduced it in his *Systema Vegetabilium* to *Grewia*, from which Gærtner, who is followed by Schreber and Willdenow, again separated it. He seems to have fallen into an error in saying, v. 1. 274, that the seeds of *Grewia* have no albumen; but there are sufficient distinctions besides. (See *Grewia*.) Besides the characters in the fructification, we may add, on the score of habit, that the inflorescence of *Microcos* is paniced and terminal, that of *Grewia* axillary, and either simple or somewhat umbellate. We are enabled to strengthen the genus with two new species, in addition to the original one.

1. *M. paniculata*. Smooth *Microcos*. Linn. Sp. Pl. 735. (*M. foliis alternis oblongis acuminatis*; Burm. Zeyl. 159. t. 74. *Grewia Microcos*; Linn. Syst. Nat. ed. 12. v. 2. 602. Juss. Ann. du Mus. v. 4. 89. Ait. Hort. Kew. ed. 2. v. 3. 301. Schageri-Cottam; Rheede Hort. Malab. v. 1. 105. t. 56.)—Leaves ovate, nearly smooth.—Native of various parts of the East Indies, in a sandy soil. A *shrub* about a man's height, with alternate, round, leafy *branches*, which are a little downy when young only. *Leaves* alternate, on short roughish stalks, ovate, pointed, more or less oblique, from three to five inches long, and two broad, slightly and unequally serrated, green on both sides, furnished from the base with three ribs, but the lateral ones vanish about the middle, and are replaced by many large veins from the mid-rib, connected by an infinity of minute reticulations; both sides are a little rough to the touch, but naked, except a bristly roughness on the ribs. *Panicle* terminal, doubly or triply compound, the branches clothed with a scurfy, somewhat flattened, pubescence. *Flowers* reddish, two or three together, in a common *involucrum* of about

about seven oblong downy deciduous leaves, resembling those of the penstemon, which is less downy within. *Petals* not longer than the germens, obtuse, recurved, downy at the outside.

2. *M. tomentosa*. Downy-leaved Microcos.—Leaves elliptical, very downy beneath.—A specimen of this is preserved in the herbarium of the younger Linneus, marked *Grewia*, but without any indication of its native country. The *branch* is round, clothed with dense rusty down, as are the *footstalks*, *flower-stalks*, and backs of the *leaves*, the latter part being very soft. The *leaves* are the size of the former, but elliptical and blunt, with a short point, and obsoletely serrated chiefly towards the extremity. Their upper surface feels soft, from scarcely visible downiness. The *panicle* is much like the foregoing, but the leaves of the *involucrum* are linear, narrow, and more distant; others resembling them, but three-cleft, being scattered about the lower part of the *panicle*, so that they ought rather to be called *bracteas*.

3. *M. scabra*. Rough-leaved Microcos.—Leaves oblong, heart-shaped at the base, rough at the back.—Sent from Amboyna, by the late Mr. Christopher Smith. A larger species than either of the former; its *branches*, *stalks*, and backs of the *leaves* rough and harsh to the touch. The *leaves* are a foot long or more, four or five inches broad, pointed, obliquely heart-shaped at the base, with five radiating hispid ribs, and innumerable transverse, parallel, reticulated veins; the margin is slightly uneven; the upper surface rather shining and smooth, except the ribs; the under opaque, and minutely hispid, with starry, finally deciduous, hairs. *Panicle* ample, spreading, repeatedly branched, terminal, but attended by axillary branches, likewise doubly compound, from some of the upper leaves. *Involucral* leaves, embracing two or three flowers, dilated, membranous, downy, often palmate; the *bracteas* which resemble them, under each branch of the *panicle*, more decidedly palmate. *Flowers* the size of the two former, but much more abundant. *Petals* lanceolate, tapering at the base, as long as the calyx, hairy at their backs.

We have seen nothing of the fruit of these two last species, but their inflorescence, with the peculiar involucreal leaves or bracteas, being so unlike in all, and the structure of the flowers, as far as we can investigate it, agreeing equally well, it is presumed there can be little uncertainty about their genus, if *Microcos* be allowed that rank at all. S.

MICROCOSM, *Μικροκοσμος*; formed from *μικρος*, little, and *κοσμος*, world, a Greek term, literally signifying little world; chiefly understood of man, who is so called by way of eminence, as being an epitome of all that is wonderful in the great world, or macrocosm.

MICROCOSMETER, a name given by Dolæus to an imaginary being, which he supposes to reside in the brain, and direct all the actions.

MICROCOUSTICS, the same with microphones.

MICROGRAPHIA, MICROGRAPHY, compounded of *μικρος*, small, and *γραφειν*, description, a description of the parts and portions of objects that are too small to be viewed without the assistance of a microscope.

MICROLÆNA, in Botany, seems to be formed of *μικρος*, small, and *λανος*, wool, alluding to the little bearded stalk of the flower, within the calyx. Brown Prod. Nov. Holl. v. 1. 210.—Class and order, *Tetrandria Digynia*. Nat. Ord. *Gramina*.

Ess. Ch. Calyx single-flowered, of two minute valves. Corolla supported by a bearded stalk, longer than the calyx, double, each of two valves, smooth; those of the outer-

most nearly equal, each with a terminal awn. Nectary of two opposite scales, alternate with the valves of the corolla. Stigmas sessile, feathery.

1. *M. stipoides*. Br. (*Ehrharta stipoides*; Labill. Nov. Holl. v. 1. 91. t. 118.)—Gathered by M. Labillardiere in Van Diemen's land, and by Mr. Brown at Port Jackson.—A smooth grass, about a foot and a half high. *Stem* round, slender, simple, leafy. *Leaves* spreading, short, flat, taper-pointed, with very long sheaths, and a jagged stipula. *Panicle* a span long, capillary, drooping, simply branched. The bearded stalk on which the flower stands within the calyx, and the long awned glumes, give this grass the aspect of an *Andropogon*, or *Stipa*. The French author describes and figures six *stamens*, and therefore referred the plant to *Ehrharta*, with which it has no other character in common, nor scarcely any agreement in aspect. Mr. Brown, after repeated examinations, declares it to be certainly tetrandrous. The *stigmas* are two, sessile and feathery. *Seed* elliptic-oblong, slightly compressed, enclosed in the permanent husks of the corolla. The *nectary* is extremely minute.

MICROLEUCONYMPHÆA, one of Boerhaave's sesquipedalian names, such as he distributed plentifully among the Proteaceous family, and which is equivalent to Small-white-water-lily. He applied it to the plant now more happily termed *Hydrocharis*; see that article.

MICROLOGUS, *Μικρολογος*, from *μικρος*, parvus, and *λογος*, ratio, sermo, that which gives reasons for obscure and minute things, a minute enquiry into latent things: the title given by Guido d'Arezzo to his treatise on music, in which his system is unfolded.

The most curious part of the micrologus is the chapter "De Diaphonia, et Organi jura;" as it shews the state of music at the time it was written, and gives such specimens of the first rude attempts at harmony as may be safely pronounced authentic. See GUIDO, HEXACHORD, and COUNTERPOINT.

MICROLOMA, in Botany, from *μικρος*, small, and *λωμα*, a fringe, the five tufts of hairs, alternate with the scales, in the middle of the flower, having altogether that appearance. Brown Tr. of the Wernerian Society, v. 1. 53. (*Ceropegia*; Lamarck Illustr. t. 179.)—Class and order, *Pentandria Digynia*: Nat. Ord. *Contorta*, Linn. *Apocinea*, Juss. *Asclepiadeæ*, Brown.

Ess. Ch. Corolla pitcher-shaped, with an inflated angular tube, much longer than the limb, naked at the mouth. Scales five, inserted into the tube under each sinus, alternate with as many tufts of hair. Stamens without a crown. Anthers arrow-shaped, tipped with a membrane; masses of pollen compressed, attached by the apex, pendulous. Stigma with a small point. Follicles

A genus of twining slender shrubs, with opposite leaves, and umbels inserted between the footstalks. It is formed of the two Linnæan Cape species of *Ceropegia*, which Mr. Brown observes are widely different from the original species of that genus. See CEROPEGIA, (by mistake CEROPEGIUM).

1. *M. sagittatum*. (*Ceropegia sagittata*; Linn. Mant. 215. Lamarck fig. 1. *Cynanchum radice glandulosa, foliis angustis sinuatis, floribus urceolatis miniatis*; Burm. Afr. 36. t. 15.)—Leaves arrow-shaped, downy. Limb of the corolla rather acute.—Native of the Cape of Good Hope. Root of several oblong fleshy knobs. Stems two or three, slender, twining, somewhat branched. Leaves on shortish stalks, linear-oblong, revolute, dilated and arrow-shaped at the base. Flowers in small hairy lateral umbels, scarlet, with a sharp hairy calyx. The angles of the corolla also are downy.

2. *M. lineare*. (*Ceropegia tenuifolia*; Linn. Mant. 215. Syll. Veg. ed 14. 255. Lamarck fig. 2. *Periploca tenuifolia*; Linn. Sp. Pl. 310, β . *Cynanchum linearibus foliis acutis, floribus urceolatis rubris*; Burm. Afr. 37. t. 16. f. 1.)—Leaves linear, smooth. Limb of the corolla very blunt.—Native of the Cape of Good Hope. The root is tuberous. Habit very like the foregoing, but the leaves are more narrow, strictly linear throughout, and smooth. Flowers red, differing from the former in the very oblique and obtuse form of the segments of their limb.

Mr. Brown appears to have, by mistake, copied the Linnæan specific name *tenuiflora* instead of *tenuifolia*, which last need not have been changed, though the appellation he has chosen we confess to be more particularly expressive.

MICROMETER, an astronomical machine, which, by means of a very fine screw, serves to measure extremely small distances in the heavens; as the apparent diameters of the planets, to a great degree of accuracy.

The word comes from the Greek μικρός, *parvus*, and μέτρον, *mensura*: because a small length, e. g. an inch, is hereby divided into vast numbers of parts, e. g. in some 2800, and in others more.

This instrument is so contrived as to move a fine wire parallel to itself, in the plane of the picture of an object, formed in the focus of a telescope, and with great exactness to measure its perpendicular distance from a fixed wire in the same plane; and thus are measured small angles, subtended by remote objects at the naked eye. *E. G.* Let a planet be viewed through a telescope; and when the parallel wires are opened to such a distance as to appear exactly to touch two opposite points in the circumference of the planet, it is evident, that the perpendicular distance between the wires is then equal to the diameter of the picture of the planet, formed in the focus of the object-glasses. Let this distance, whose measure is given by the mechanism of the micrometer, hereafter described, be represented by the line *pq*, *Plate X. Optics, fig. 5*; then, since the measure of the focal distance *qL* may be also known, the ratio of *qL* to *qp*, that is, of the radius to the tangent of the angle *qLp*, will give the angle itself by a table of sines and tangents; and this angle is equal to the opposite angle *PLQ*, which the real diameter of the planet subtends at *L*, or at the naked eye. There is some controversy about the invention of the micrometer. Messrs. Auzout and Picard have the credit of it in common fame, as being the first who published it, in the year 1666; but Mr. Townley, in the Philosophical Transactions, claims it for one of our own countrymen, Mr. Gascoigne. He relates, that from some scattered papers and letters of this gentleman, he had learnt, that, before our civil wars, he had invented a micrometer, of as much effect as that since made by M. Auzout, and had made use of it for some years, not only in taking the diameters of the planets, and distances upon land, but in determining other matters of nice importance in the heavens; as the moon's distance, &c.

Mr. Gascoigne's instrument fell into the hands of Mr. Townley, who says, that by the help of it he could make above forty thousand divisions in a foot. This instrument being shewn to Dr. Hooke, he gave a drawing and description of it, and proposed several improvements in it, which may be seen in the Philosophical Transactions, Abr. vol. i. p. 217. Mr. Gascoigne divided the image of an object, in the focus of the object-glasses, by the approach of two pieces of metal, ground to a very fine edge, in the place of which Dr. Hooke would substitute two fine hairs stretched parallel to one another. Two other methods of Dr. Hooke, different from this, are described in his Posthumous Works,

p. 497, &c. An account of several curious observations which Mr. Gascoigne made by the help of his micrometer, particularly in the mensuration of the diameter of the moon and other planets, may be seen in the Phil. Transf. vol. xlvi. p. 190, where Dr. Bevis refers to an original letter of Mr. Gascoigne, to Mr. Oughtred, written in 1640—1, for an account given by the author of his own invention, &c.

Mons. de la Hire, in a discourse on the era of the inventions of the micrometer, pendulum clock, and telescope, read before the Royal Academy of Sciences in 1717, makes M. Huygens the inventor of the micrometer. That author, he observes, in his Observations on Saturn's Ring, &c. published in 1659, gives a method of finding the diameters of the planets by means of a telescope; viz. by putting an object, which he calls *virgula*, of a proper bigness to take in the distance to be measured, in the focus of the convex object-glasses: in this case, says he, the smallest object will be seen very distinctly in that place of the glass. By such means, he adds, he measured the diameters of the planets, as he there delivers them.

This micrometer, M. De la Hire observes, is so very little different from that published by the marquis de Malvasia, in his Ephemerides, three years after, that they ought to be esteemed the same: and the micrometer of the marquis differed yet less from that published four years after his by Auzout and Picard. Hence, M. De la Hire concludes, that it is to M. Huygens the world is indebted for the invention of the micrometer; without taking any notice of the claim of our countryman Mr. Gascoigne, which, however, is prior by many years to any of them.

M. De la Hire says, that there is no method more simple or commodious for observing the digits of an eclipse, than a net in the focus of the telescope. These, he says, were generally made of silken threads, and for this particular purpose six concentric circles had also been made use of, drawn upon oiled paper; but he advises to draw the circles on very thin pieces of glass, with the point of a diamond. He also gives several particular directions to assist persons in using them. In another memoir he shews a method of making use of the same net for all eclipses, by using a telescope with two object-glasses, and placing them at different distances from one another. *Ac. Par. 1701, and 1717.*

MICROMETER, *Construction and Use of the*. Wolsius describes a micrometer of a very easy and simple structure, first contrived by Kirchius, thus:

In the focus of a telescope fit a brass or iron ring *AB* (*Plate X. Optics, fig. 6.*) with female screws diametrically opposite to each other; into these insert male screws *CE* and *FB*, of such length as that they may be turned in the tube, so as to touch each other: and with this instrument very small spaces in the heavens may be accurately measured.

For when any objects, viewed through a tube, appear contiguous to the screws, if these be turned till they just touch two opposite points, whose distance is to be measured, it will be evident how many threads of the screw they are apart. To determine how many seconds answer to each thread, applying the tube towards the heavens, turn the screws till they touch two points, whose distance is already accurately known; and observe the number of threads corresponding to that interval; thus, by the rule of three, a table may be made of the seconds corresponding to the several threads; by means of which, without greater labour, the distances of any points may be determined.

The structure of another micrometer, with the manner of fitting it to the telescope, and applying it, is as follows: *ABCg* (*fig. 7.*) is a rectangular brass frame, the side *AB* being about three inches long, and the side *BC*, as likewise the

MICROMETER.

the opposite side *A g*, about six inches; and each of the three sides about eight tenths of an inch deep: the two opposite sides of this frame are screwed to the circular plate, to be mentioned hereafter.

The screw *P*, which has exactly forty threads in an inch, being turned round, moves the plate *G D E F*, along two grooves made near the tops of the opposite sides of the frame; and the screw *Q*, having the same number of threads in an inch as *P*, moves the plate *R N M Y* along two grooves, made near the bottom of the said frame, in the same direction as the former plate moves, but with only half the velocity of that other; these screws are turned both at once, and the plates are moved along the same way, by means of a handle turning the endless screw *S*, whose threads fall in between the teeth of the pinions on the screws *P* and *Q*. And note, that two half revolutions of the endless screw *S* carry the screw *P* exactly once round.

The screw *P* turns the hand *a*, fastened to it, over a hundred equal divisions, made round the limb of a circular plate, to which the above named two opposite sides of the frame are screwed at right angles; the teeth of the pinion on the screw *P*, whose number is 5, take into the teeth of a wheel on the backside of the circular plate, whose number is 25. Again, on the axis of this wheel is a pinion of two, which takes into the teeth of another wheel, moving about the centre of the circular plate, on the outside of it, and having fifty teeth; this last wheel moves the lesser hand *b* once round the above mentioned circular plate in the $\frac{1}{25}$ th part of the time the hand *a* is moving round: for because the number of teeth in the pinion of the screw *P* is 5, and the number of teeth of the wheel this pinion moves, is 20; therefore the screw *P* moves four times round in the time that wheel is moving once round. Further, since there is a pinion of two which takes into the teeth of a wheel, whose number is 50; therefore this wheel with 50 teeth will move once round in the time that the wheel of 20 teeth moves 25 times round; and, consequently, the screw *P*, or hand *a*, must move a hundred times round in the same time as the wheel of 50 teeth, or the hand *b*, has moved once round.

Hence it follows, that if the circular plate *W*, which is fastened at right angles to the other circular plate, be divided into two hundred equal parts, the index *x*, to which the handle is fastened, will move five of those parts in the same time in which the hand *a* moves one of the hundred divisions round the limb of the other circular plate. Thus by means of an index *x*, and plate *W*, every fifth part of each of the divisions round the other plate may be known.

Further, since each of the screws *P* and *Q* have exactly forty threads in an inch; therefore the upper plate *G D E F* will move one inch while the hand *a* moves forty times round; the four-thousandth part of an inch while the hand moves over one of the divisions round the limb; and the twenty-thousandth part of an inch while the index *x* moves one part of the two hundred round the limb of the circular plate *W*: and the under plate *R N M Y* will move half an inch, the two-thousandth part of an inch, and the ten-thousandth part of an inch, the same way, in the said respective times.

Hence, if the under plate, having a large round hole in it, be fixed to a telescope, so that the frame is moveable, together with the whole instrument, except the said lower plate; and the straight smooth edge *H I*, of the fixed plate *A B I H*; as likewise the straight smooth edge *D E*, of the moveable plate *G D E F*, be perceivable through the round hole in the under plate, in the focus of the object-glass; then when the handle of the micrometer is turned, the edge *H I*, of the narrow plate *A B I H*, fixed to the frame, and *D E*, of the moveable plate, will appear through

the telescope equally to approach to, or recede from, each other.

By these edges we shall be able to measure the apparent diameters of the sun, moon, &c. the manner of doing which I take as follows:

Suppose, in looking at the moon through the telescope, you have turned the handle till the two edges *D E* and *H I* are opened, so as just to touch or clasp the moon's edges; and that there were twenty-one revolutions of the hand *a* to complete that opening: first say, at the focal length of the object-glass, which suppose ten feet, is to radius, so is one inch to the tangent of an angle subtended by one inch in the focus of the object-glass; which will be found twenty-eight minutes thirty seconds; again, because there are exactly forty threads of the screws in one inch; say, if forty revolutions of the hand *a* give an angle of $28' 30''$, what angle will twenty-one revolutions give? The answer will be, fifteen minutes eight seconds; and such was the moon's apparent diameter. And so may the apparent diameters of any other objects be taken. It must be here observed, that the divisions on the top of the plate *G D E F* are diagonal divisions of the revolutions of the screws, with diagonal divisions of inches against them; thus, as the said plate slides along, these diagonals are cut by divisions made on the edge of the narrow plate *K L*, fixed to the opposite side of the frame by means of two screws. These diagonal divisions serve for a register to count the revolutions of the screws, and to shew how many there are in an inch, or the parts of an inch.

Dr Derham tells us, that his micrometer is not, as usually, to be put into a tube, but to measure the spectra of the sun on paper (of any radius), or to measure any part of them. By this means, he can easily, and very exactly, with the help of a fine thread, take the declination of a solar spot at any time of the day; and, by his half-seconds watch, measure the distance of the spot from the sun's eastern and western limb.

A micrometer of a better sort is made in this manner: in the middle of an oblong plate of brass, (*A B*, Plate X. *Optics*, fig. 8.) there is cut an oblong hole, *abcdefj*, (to be placed in the focus of a telescope,) having a fine wire, *bc*, extended lengthways over the middle of it, at right angles, to two slender brass bars or sights *gh*, *ik*, lying cross the hole; of which *gh* is fixed to the plate *A B* by screws at *g* and *h*, but *ik* is moved parallel to *gh* by twirling a round knob *C* fixed upon one end of a long iron screw *D E*, which turns upon a tapering point at its end *D*, while its other end turns round in a hole at *E* in the centre of an index plate *E F*, fixed at right angles to the main plate *A B*. The long screw *D E* works through two hollow screws in two cubical blocks of brass, fixed behind the plate *lm*, bent square to the plate *no*, that slides upon the main plate *A B*, either backward or forward, and carries a perpendicular arm *op* extended over the hole *bc*; while *p*, the extremity of the arm *op*, slides under a brass ledge *qr*, screwed to the main plate *A B*, along the side of the hole. One side, *st*, of the moveable sight-plate *ikst*, lies over the arm *op*, being fixed to it by the flat-headed screws at *s* and *t*, the holes in the plate *st* being oblong or larger than the shanks of the screws, to give liberty for placing the edge *ik* coincident with *gh*, when carried up to it by turning the screw *D E* by the knob *C*; the part *ik*, which projects over the arm *op*, being hammered down to lie flat upon the main plate *A B*. The edge *ik*, after this adjustment, will always move parallel to the edge *gh*; its inclination to the screw *D E* being every where the same, provided the screw be straight, and the interval of the concave screws behind *lm* be sufficiently great and their motion steady. For this purpose about a quarter-

MICROMETER.

round of a third concave screw presses upon the long screw DE at v , the block of it being fixed to the middle of a springing plate wvx ; whose extremities lying behind the blocks at l, m , not so near as to touch them, are pressed towards them with screws at w and x ; which occasions the block at v to spring upon the screw DE, and to hold it tight to the opposite side of the concave screws at l, m . To prevent any motion lengthways in the screw DE, its tapering point D turns in a hollow point at the end of an opposite screw y , which working through a fixed block at z , holds up the shoulder of the long screw DE, against the back of the index-plate, where its neck is inserted.

The two indexes upon the plate EF shew the number of revolutions and parts of a revolution of the screw DE, answering to the interval of the sights gb, ik . In the outward plate there is a circular slit $\alpha\beta\gamma$, which discovers part of the divisions upon the circumference of an inner plate, turned about a centre by two wheels and pinions within: so that for every revolution of the screw, an index EF, which shews the parts of it, one division upon the plate $\alpha\beta\gamma$, passes by a fixed point at β ; which shews the number of revolutions answering to the intervals of the sights gb, ik .

This micrometer received a very great improvement by an ingenious contrivance of the reverend Dr. James Bradley, professor of astronomy at Oxford, for turning it in its own plane about the intersection δ of the fixed sight gb , and of the transverse wire $b\delta e$, without stirring the telescope: which is thus executed. Upon the backside of the main-plate turned upwards, and here represented by the parallelogram GHIK, (*fig. 9.*) there is laid such another plate LMNO, of the same breadth and thickness but somewhat shorter; in the middle of which there is an oblong hole, answering to the other in the lower plate, but somewhat larger; being terminated at its sides by the straight lines $\epsilon\zeta, \eta\theta$, and at its ends by the concave arches $\theta\epsilon, \zeta\eta$, whose common centre is the point δ above-mentioned. The concave arch $\epsilon\theta$ slides round this centre against a concentric convex arch of an annular plate $\lambda\mu\nu$; somewhat longer than the concave arch, of the same thickness as the upper parallelogram, and strongly screwed to the under one, round that end of the hole which is nearest to the centre δ ; and at the same time the other concave arch $\zeta\eta$ slides also against another concentric convex arch $o\pi$, of another annular plate just as thick as the upper parallelogram, and strongly screwed to the under one. This convex arch $o\pi$ is shorter than the contiguous concave one $\zeta\eta$, to give room for the circular motion of the plates; which are held together by two annular plates similar to $\lambda\mu\nu$ and $o\pi$, but somewhat broader, to cover the coincident arches when laid over them, and screwed down to the respective annular plates underneath. The circular motion upon these arches about their centre δ , is gradually given to the upper parallelogram by an endless screw at ϵ , having an axis $\sigma\tau$ laid cross the end of the under parallelogram, and turning upon a point at one end, and in a collar at the other, both fixed to the under plate; while the spiral thread ϵ moves the teeth of a brass arch fixed at v , to the end of the upper parallelogram.

To hold the micrometer in the tube of a telescope, along each side of the upper parallelogram there is fixed a long brass plate about an inch broad; having its opposite sides bent contrary ways, so as to form two opposite ledges, about one-eighth of an inch broad, at right angles to the intermediate part of the plate, as represented in the figure. One of the ledges of each plate is placed inwards along the sides of the upper parallelogram, and is firmly fixed to it by several screws. The figure $\phi\chi\psi$ represents one of the equal and opposite holes cut in the sides of a square tube, through which the

micrometer is put; the notches $\phi\chi$ being made to receive the ledges of the side-plates, to keep the plate of the micrometer perpendicular to the tube at a just distance from the object-glasses. Which distance being once determined by trials, as above explained, must be kept invariable in all observations, by stops or pins, if the tube consists of two or more joints that draw in and out.

The Measures of the Micrometer.

	Inches.
The length of the plate A B	8.0
Its breadth M N	3.6
Its thickness	0.2
Length of the hole $b\epsilon$	3.5
Its breadth $g b = \delta e$	2.2
Breadth of the hole in the other plate at $\zeta\eta$	2.6
Length of the screw D E	5.5
Its thickness	0.3
The line A b	1.6
The interval $l m = w x$	3.0
Length of the side cheeks	4.5
Their breadth	0.8
Their ledges	0.2
Diameter of the index-plate	3.1
Its thickness (being double with two wheels within)	0.3
The greatest opening of the sights $g b, i k = \delta e$	2.2
Threads of the screw in an inch, 40	
The inch is divided by the index-plates into 40 times 40, or 1600 equal parts. Instead of the brass sights $g b, i k$, two others, with parallel wires a , may be screwed on at pleasure.	

When the sight-plates are made to coincide, the two indexes of the revolutions and their parts must be set to the beginning of the numerations upon the index-plates. Then as the sights are opened, it is evident from the make of a screw, that the numbers of revolutions will be as the intervals of the sights, and consequently as the angles subtended by them at the centre of the object-glasses; the intervals being insensibly different from the arches that measure these small angles. Therefore when any one angle corresponding to a given number of revolutions, is determined by experiment, an angle corresponding to any other number of revolutions may be found by the rule of three. And thus may tables be made to shew by inspection the number of minutes and seconds in an angle answering to any given number of revolutions and parts.

To determine some one angle, the larger the better, because the same error in the determination will be proportionably smaller in a given angle deduced from it; fix the telescope upon any known star in the equator, or very near it, and open the sights to their utmost limit and note the number of revolutions of the screw. Then by a pendulum-clock observe the interval of time in the star's transit over the given interval of the sights, and having turned it into minutes and seconds of an arch, they are the measure of the angle required. But if the star be remote from the equator, the number of minutes and seconds thus found, must be diminished in the ratio of the radius of the sine of the star's distance from the pole. To this micrometer Dr. Bradley applied an ingenious contrivance, by which it is adapted for taking the difference of right ascension and declination of such objects as are at a greater distance than the telescope will take in at once, but which pass through the aperture of it at different times. Let ABC (*fig. 10.*) represent a flat ring of brass, fixed in the focus of the telescope; and abc a smaller

MICROMETER.

smaller concentric ring lodged in a circular groove turned within the larger, and kept in the groove by three small plates of brass fixed to the outward ring, and extended over the edge of the inner one. Upon the inner ring is fixed a concentric arch of a wheel *de*, having teeth cut in its convexity, which are driven round by the threads of an endless screw, whose axis *DEF* turns in a collar at *E*, and upon a point at *F*, both fixed to the outward ring. The hairs *gb*, *ik*, cross at right angles in *f*, the centre of the rings; and when the telescope is so fixed that the image of the star falls upon *f*, let it move along any line *fg*, and by turning the screw *DEF*, and by consequence the hair *fk*, about the fixed point *f* till it touches the star at *g*, it will then coincide with the tract of the star's motion; and then all other stars will move parallel to it as was required. To find the difference of declination of two stars, he observes the times of their appulses to the edges of two slender brass bars *gio*, *gkp*, fixed to the inner ring, and equally inclined to its diameter *gb* in such angles that the perpendiculars *fi*, *fk*, on each side of *fg*, shall be severally equal to half *fg*; and consequently that the whole base *ik*, of the equicrural triangle *igk*, shall be equal to its perpendicular height *fg*; and by consequence that the difference of any two bases *ifk*, *lmn*, shall be equal to *fm*, the difference of their heights; so that the difference of the times of the transits of two stars over these bases, may give the difference of their declinations. Smith's Optics, art. 876, &c.

M. Cassini first made use of four cross hairs or threads, intersecting one another at half right angles, for determining the difference of right ascensions and declinations of objects near the same parallel: but the micrometer, according to its latter improvements, will answer this purpose with greater exactness. Dr. Maskelyne has published directions for the use of it, extracted from Dr. Bradley's papers, in the Philos. Transf. vol. lxii. art. 6. p. 46, &c.

A considerable improvement with regard to the micrometer, was communicated to the Royal Society, in 1743, by Mr. Servington Savery, an account of which, extracted from the minutes by Mr. Short, was published in the Phil. Transf. for 1753, vol. xlviii. art. 26. The first hint of such a micrometer was suggested by M. Roemer, in 1675; and M. Bouguer proposed a similar construction to that of Mr. Savery, in 1748, for which see HELIOMETER. The late Mr. Dollond made a farther improvement in this kind of micrometer, an account of which was given to the Royal Society by Mr. Short, and published in the Phil. Transf. vol. xlviii. art. 27. Instead of two object glasses, he used only one, which (after having been truly ground and well centered) he neatly cut into two semi-circles, and fitted each semi-circle in a metal frame, so that their diameters sliding in one another, by means of a screw, may have their centres so brought together as to appear like one glass, and so form one image; or by their centres receding, may form two images of the same object: it being a property of such glasses, for any segment to exhibit a perfect image of an object, although not so bright as the whole glass would give it. If proper scales are fitted to this instrument, shewing how far the centres recede, relative to the focal length of the glass, they will also shew how far the two parts of the same object are asunder, relative to its distance from the object glass; and consequently give the angle under which the distance of the parts of that object are seen. This divided object-glass micrometer, which was applied by the late Mr. Dollond to the object end of a reflecting telescope, has been with equal advantage adapted by his son to the end of an achromatic telescope, is so easy of use, and affords so large a scale, that it is generally looked upon by astronomers as the most conve-

ment and exact instrument for measuring small distances in the heavens. However, the common micrometer is peculiarly adapted for measuring differences of right ascension, and declination of celestial objects, but less convenient and exact for measuring their absolute distances; whereas the object-glass micrometer is peculiarly fitted for measuring distances, but has been generally supposed improper for measuring differences of right ascension and declination. But Dr. Maskelyne has found that the latter may be applied with very little trouble, and small additional expence to this other purpose as well as the former; and he has furnished the directions necessary to be followed when it is used in this manner. The addition requisite for this purpose is a cell, containing two wires, intersecting each other at right angles, placed in the focus of the eye-glass of the telescope, and moveable round about, by the turning of a button. For the description of this apparatus, together with the method of applying and using it, we shall refer to Dr. Maskelyne's paper on the subject, in the Phil. Transf. vol. lxi. part ii. art. 49. p. 536.

After all, the use of the object-glass micrometer is attended with difficulties, arising from the alterations in the focus of the eye, which are apt to cause it to give different measures of the same angle at different times. In order to obviate these difficulties, Dr. Maskelyne, in 1776, contrived a prismatic micrometer, or a micrometer consisting of two achromatic prisms, or wedges, applied between the object-glass and eye-glass of an achromatic telescope, by moving of which wedges nearer to, or farther from, the object-glass, the two images of an object produced by them appeared to approach to or recede from each other, so that the focal length of the object-glass becomes a scale for measuring the angular distance of the two images. The rationale and use of this micrometer are explained in the Phil. Transf. vol. lxxvii. part ii. art. 36. p. 799, &c. A similar invention by the abbé Rochon, and improved by the abbé Boscovich, was also communicated to the Royal Society, and published in the same volume of the Transactions, art. 35. p. 789, &c.

Mr. Ramsden, an ingenious optician, has described two new micrometers, which he has contrived with a view of remedying the defects of the object-glass micrometer. One of these is a catoptric micrometer, which, beside the advantage it derives from the principle of reflection, of not being disturbed by the heterogeneity of light, avoids every defect of other micrometers, and can have no aberration, nor any defect arising from the imperfection of materials, or of execution; as the extreme simplicity of its construction requires no additional mirrors or glasses to those required for the telescope; and the separation of the image being effected by the inclination of the two specula, and not depending on the focus of any lens or mirror, any alteration in the eye of an observer cannot affect the angle measured. It has peculiar to itself the advantages of an adjustment, to make the images coincide in a direction perpendicular to that of their motion; and also of measuring the diameter of a planet on both sides of the zero, which will appear no inconsiderable advantage to observers, who know how much easier it is to ascertain the contact of the external edges of two images than their perfect coincidence. A (fig. 11.) represents the small speculum of a reflecting telescope of Cassegrain's construction, to which this micrometer is adapted, divided into two equal parts; one of which is fixed on the end of the arm *B*; the other end of the arm is fixed on a steel axis *X*, which crosses the end of the telescope *C*. The other half of the mirror *A* is fixed on the arm *D*, which arm at the other end terminates in a socket *y*, that turns on the axis *X*; both arms are prevented from bending by the braces, *a, a*. *G* represents a double screw, having one part, *e*, cut into double

MICROMETER.

double the number of threads in an inch to that of the part g ; the part e having a hundred threads in one inch, and the part g fifty only. The screw, e , works in a nut F , in the side of the telescope, while the part g turns in a nut H , which is attached to the arm B ; the ends of the arms B and D , to which the mirrors are fixed, are separated from each other by the point of the double screw pressing against the flud b , fixed to the arm D , and turning in the nut H on the arm B . The two arms, B and D , are pressed against the direction of the double screw, $e g$, by a spiral spring within the part n ; by which means all shake or play in the nut H , on which the measure depends, is entirely prevented.

From the difference of the threads on the screw at e and g , it is evident that the progressive motion of the screw through the nut will be half the distance of the separation of the two halves of the mirror, and consequently the half mirrors will be moved equally in contrary directions from the axis of the telescope C .

The wheel V , fixed on the end of the double screw, has its circumference divided into 100 equal parts, and numbered at every fifth division with 5, 10, &c. to 100; and the index, I , shews the motion of the screw with the wheel round its axis, while the number of revolutions of the screw is shewn by the divisions on the same index. The steel screw, R , may be turned by the key S , and serves to incline the small mirror at right angles to the direction of its motion.

The other micrometer, invented and described by Mr. Ramsden, is suited to the principle of refraction. This micrometer is applied to the erect eye-tube of a refracting telescope, and is placed in the conjugate focus of the first eye-glass; in which position, as the image is considerably magnified before it comes to the micrometer, any imperfection in its glass will be magnified only by the remaining eye-glasses, which in any telescope seldom exceeds five or six times; and besides, the size of the micrometer glass will not be the $\frac{1}{100}$ th part of the area which would be required, if it were placed at the object-glass; and yet the same extent of scale is preserved, and the images are uniformly bright in every part of the field of the telescope. This micrometer is represented in *Plate XI. Optics, fig. 1.* A is a convex or concave lens divided into two equal parts by a plane across its centre; one of these semi-lenses is fixed in a frame B , and the other in the frame E , which two frames slide on a plate H , and are pressed against it by thin plates, a, a : the frames, B and E , are moved in contrary directions by turning the button D ; L is a scale of equal parts on the frame B ; it is numbered from each end towards the middle with 10, 20, &c. There are two verniers on the frame E , one at M , and the other at N , for the conveniency of measuring the diameter of a planet, &c. on both sides of the zero. The first division on both these verniers coincides at the same time with the two zeros on the scale L ; and, if the frame is moved towards the right, the relative motion of the two frames is shewn on the scale L by the vernier M ; but if the frame B be moved towards the left, the relative motion is shewn by the vernier N .

This micrometer has a motion round the axis of vision, for the conveniency of measuring the diameter of a planet, &c. in any direction, by turning an endless screw F , and the inclination of the diameter measured with the horizon is shewn on the circle, g , by a vernier on the plate V . The telescope may be adjusted to distinct vision by means of an adjusting screw, which moves the whole eye-tube with the micrometer nearer or farther from the object-glass, as telescopes are generally made; or the same effect may be pro-

duced in a better manner, without moving the micrometer, by sliding the part of the eye-tube m on the part n , by help of a screw or pinion. The micrometer is made to take off occasionally from the eye-tube, that the telescope may be used without it. *Phil. Transf. vol. lxxix. part ii. art. 27.*

Dr. Herschel has applied a lamp micrometer to Sir Isaac Newton's reflecting telescope. (*See Phil. Transf. vol. lxxii. p. 165, &c. and vol. lxxiii. p. 5, &c.*) Two moveable lamps, the light of which comes through two small holes, are placed at a convenient distance from the telescope, in the direction at which you look at the image. These points of light are looked at by the left eye, and brought, e, g , to the opposite sides of a planet looked at by the right eye; and by measuring their distance from each other, and from the eye, the angle under which the magnified diameter appears will be known, which, divided by the magnifying power of the telescope, gives the apparent diameter required. The construction of this micrometer is as follows: $ABCGFE$ (*Plate XI. Optics, fig. 5.*) is a stand nine feet high, upon which a semi-circular board, $q b o g p$, is moveable upwards or downwards, in the manner of some fire-screens, as occasion may require, and is held in its situation by a peg, p , put into any one of the holes of the upright piece AB . This board is a segment of a circle of fourteen inches radius, and is about three inches broader than a semi-circle, to give room for the handles, rD, eP , to work. The use of this board is to carry an arm L , thirty inches long, which is made to move upon a pivot at the centre of the circle, by means of a string, which passes in a groove upon the edge of the semi-circle $p g o b q$; the string is fastened to a hook at o , (not expressed in the figure, being at the back of the arm L), and passing along the groove from $o b$ to q , is turned over a pulley at q , and goes down to a small barrel e , within the plane of the circular board, where a double-jointed handle, eP , commands its motion. By this contrivance we see the arm, L , may be lifted up to any altitude from the horizontal position to the perpendicular, or be suffered to descend by its own weight below the horizontal to the reverse perpendicular situation. The weight of the handle, P , is sufficient to keep the arm in any given position; but if the motion should be too easy, a friction spring applied to the barrel will moderate it at pleasure.

In front of the arm, L , a small slider, about three inches long, is moveable in a rabbet from the end L towards the centre backwards and forwards. A string is fastened to the left side of the little slider, and goes towards L , where it passes round a pulley at m , and returns under the arm from m, n , towards the centre, where it is led in a groove on the edge of the arm, which is of a circular form, upwards to a barrel (raised above the plane of the circular board) at r , to which the handle, rD , is fastened. A second string is fastened to the slider, at the right side, and goes towards the centre, where it passes over a pulley n , and the weight, w , which is suspended by the end of this string, returns the slider towards the centre, when a contrary turn of the handle permits it to act.

a and b are two small lamps, two inches high, one inch and a half in breadth, by one inch and a quarter in depth. The sides, back, and top, are made so as to permit no light to be seen, and the front consists of a thin brass sliding door. The flame in the lamp, a , is placed three-tenths of an inch from the left side, three-tenths from the front, and half an inch from the bottom. In the lamp b , it is placed at the same height and distance, measuring from the right side. The wick of the flame consists only of a single very thin lamp-cotton thread; for the smallest flame being sufficient; it is easier to keep it burning in so confined a place. In the

MICROMETER.

top of each lamp must be a little slit, lengthways, and also a small opening in one side near the upper part, to permit air enough to circulate to feed the flame. To prevent every reflection of light, the side opening of the lamp *a* should be to the right, and that of the lamp *b* to the left. In the sliding door of each lamp is made a small hole, with the point of a very fine needle, just opposite the place where the wicks are burning; so that when the sliders are shut down, and every thing dark, nothing shall be seen but two fine lucid points of the size of two stars of the third or fourth magnitude. The lamp, *a*, is placed so that its lucid point may be in the centre of the circular board, where it remains fixed. The lamp, *b*, is hung to the little slider, which moves in the rabbet of the arm, so that its lucid point, in a horizontal position of the arm, may be on a level with the lucid point in the centre. The moveable lamp is suspended upon a piece of brass, fastened to the slider by a pin exactly behind the flame upon which it moves as a pivot. The lamp is balanced at the bottom by a leaden weight, so as always to remain upright, when the arm is either lifted above, or depressed below, the horizontal position. The double-jointed handles, *rD*, *cP*, consist of light deal rods, ten feet long, and the lowest of them may have divisions, marked upon it near the end *P*, expressing exactly the distance from the central lucid point in feet, inches, and tenths.

From this construction we see, that a person at a distance of ten feet may govern the two lucid points, so as to bring them into any required position south or north preceding or following, from 0 to 90°, by using the handle *P*, and also to any distance from six-tenths of an inch to five or six and twenty inches, by means of the handle *D*. If any reflection or appearance of light should be left from the top or sides of the lamps, a temporary screen, consisting of a long piece of paste-board, or a wire-frame covered with black cloth, of the length of the whole arm, and of any required breadth, with a slit of half an inch broad in the middle, may be affixed to the arm by four bent wires, projecting an inch or two before the lamps, situated so that the moveable lucid point may pass along the opening left for that purpose.

Fig. 6. represents part of the arm *L*, half the real size; *S*, the slider; *m*, the pulley, over which the cord, *xy z*, is returned towards the centre; *v*, the other cord going to the pulley, *n*, of *fig. 5*; *R*, the brass piece moveable upon the pin *c*, to keep the lamp upright. At *R* is a wire rivetted to the brass piece, upon which is held the lamp by a nut and screw. *Figs. 7, and 8,* represent the lamps, *a, b*, with the sliding doors open, to shew the situation of the wicks. *W* is the leaden weight, with a hole, *d*, in it, through which the wire *R*, of *fig. 6*, is to be passed, when the lamp is to be fastened to the slider *S*. *Fig. 9.* represents the lamp *a*, with the sliding door shut; *l*, the lucid point; and *ik*, the openings at the top, and *s* at the sides, for the admission of air.

Every ingenious artist will soon perceive that the motions of this micrometer are capable of great improvement, by the application of wheels and pinions, and other well known mechanical resources; but, as the principal object is only to be able to adjust the two lucid points to the required position and distance, and to keep them there for a few minutes, while the observer goes to measure their distance, it will not be necessary to say more upon the subject.

Mr. Smeaton's equatorial micrometer, together with its use in an observation of a transit of Mercury, is described and exhibited in the *Phil. Trans.* vol. lxxvii. art. 33. We have the description of a micrometer for taking the angle of position, with drawings for illustrating its construction, as

it was executed by Messrs. Nairne and Blunt, in a paper by Dr. Herschel, *Phil. Trans.* vol. lxxi. p. 500, and a further account of its use and the mode of improving it by Dr. Herschel, *Phil. Trans.* vol. lxxxv. p. 46. Mr. Troughton's micrometer is applied to the eye-piece of a telescope for measuring exceedingly small angles, as the diameter of the heavenly bodies, &c. *Fig. 2.* is an orthography of this instrument projecting endways; *fig. 3.* is a section of the box containing the wires; and *fig. 4.* a section lengthways: the same letters, as far as they can, are used in all the figures. *Figs. 2 and 4.* A is an eye-tube containing a convex lens at each end; this slides in another tube, *dd*, so as to adjust the glass to distinct vision of the wire; the tube, *dd*, is screwed into another, *bb*, which is much larger, through this a thin long box, *DDD*, containing the wire slides. The micrometer is screwed to the telescope by a male screw, *cc*, (*fig. 4.*) in the same piece with which is a circular plate, *ff*, cut all round with fine teeth; this plate fits against the flat bottom of the box, *b*, and turns round concentrically with it by means of a ring, *k*, fitting into a conical hole in the centre of the plate, *ff*, and screwed to the box; a small endless screw, *h*, (*fig. 2.*) turning in two brass collars screwed to the box, *b*, works in the teeth cut round the plate, *f*, and by that means when the milled head on the arbor of the endless screw is turned, it turns the eye-tube and box, *DD*, round, to bring it to any convenient position for measuring the angles required; the box containing the wires is shewn open in *fig. 3*, it containing two frames, *bbb* and *lll*, one sliding within another, which moves in the box, without lateral shake, yet fitted so as to slide easily backwards and forwards in the box, by the screws *m* and *n*, in the same manner as the microscope in the upper part of the same plate; *o* and *p* are springs to counteract the screws and make the motion pleasant. A wire is stretched across the frame, *bb*, at right angles to its sides, and another of the same size is fixed across the slider, *lll*, exactly parallel to the former; a small quantity of the under side of the latter is cut away, and its wire is fixed in another plane to the wire of *bbb*, so that the wires can pass each other without touching, but as near as possible; when they are placed by their screws over each other, and viewed through the eye-tube, they appear but as one wire: the divided circle, *a*, on the nuts of screws are then slipped round, without the screw, to bring the first division on them to the index *l*; the instrument is now adjusted for observing any angle, it is screwed to the telescope, and by the endless screw, *n*, (*fig. 2.*) the micrometer is turned round so as to bring a fixed wire *x*, which is perpendicular to the others, to cover the two objects; the two wires are then separated by turning either of the nuts, *F*, until the wires include the angle to be measured: the whole box (*fig. 3.*) of the micrometer slides through the tube, in the direction of its length, to follow any moving object. When the observation is completed it is read off by a scale of notches in the box, (*fig. 3.*) determining the number of revolutions the screw has made, and the divisions pointed out on the circles, *a*; by the indexes, *l, l*, the number of aliquot parts is denoted; the circular plate, *ff*, is divided into degrees, as shewn in *fig. 2*, and it is by this that the angle line measured makes with the horizon is registered.

The circles are divided in one hundred parts, and have no determinate value in angular measurement, but their value is determined experimentally by observing through the telescope, it is applied to the diameter of the sun, or any other body whose angular measure has been previously and accurately determined by some other divided instrument,

MICROMETER.

and from this the angle given by each observation is calculated.

Mr. Cavallo has contrived a micrometer of very simple and easy construction. It consists of a small semi-transparent scale or slip of mother-of-pearl, about the 20th part of an inch broad, and of the thickness of common writing paper. It is divided into a number of equal parts by means of parallel lines, every fifth and tenth of which divisions is a little longer than the rest.

This micrometer, or divided scale, is situated within the tube at the focus of the eye-lens of the telescope, where the image of the object is formed, and with its divided edge passing through the centre of the field of view; though this is not absolutely necessary. It is immaterial whether the telescope be a refractor or a reflector, provided the eye-lens be convex, and not concave, as in the Galilean telescope.

The simplest way of fixing it, is to stick it upon the diaphragm, which generally stands within the tube, at the focal distance of the eye-lens.

By looking through the telescope, the image of the object and the micrometer will appear to coincide: hence the observer may easily see how many divisions of the latter measure the length or breadth of the former; and knowing the value of the divisions of the micrometer, he may easily determine the angle which is subtended by the object.

There are several methods of ascertaining the value of the divisions of a micrometer in a given telescope. The following is one of the easiest.

Direct the telescope to the sun, and observe how many divisions of the micrometer measure its diameter exactly; then take out of the Nautical Almanack the diameter of the sun for the day in which the observation is made; divide it by the above-mentioned number of divisions, and the quotient is the value of one division of the micrometer. Thus, suppose that $26\frac{1}{2}$ divisions of the micrometer measure the diameter of the sun, and the Nautical Almanack gives for the measure of the angle, which is subtended by the same diameter, $31' 22''$, or (by reducing it all into seconds) $1882''$. Divide $1882''$ by 26.5 , and the quotient, neglecting a small remainder, is $71''$, or $1' 11''$; which is the value of one division of the micrometer; the double of which is the value of two divisions; the treble is the value of three divisions; and so forth.

This mother-of-pearl micrometer may be applied to a microscope; and it will thus serve to measure the linear dimensions of the object; and the value of its divisions are ascertained by placing an object of a known dimension before the microscope, and by observing how many divisions of the micrometer measure its magnified image; for instance, place a piece of paper, which is exactly one-tenth of an inch long, before the microscope, and if you find that 50 divisions of the micrometer measure its magnified image, you may conclude that each division is equal to, or rather denotes an extension of the 500th part of an inch in the object; for if 50 divisions measure one-tenth, 500 divisions must measure the whole inch; &c. Cavallo's Philosophy, vol. iii. Phil. Transf. vol. lxxxii. art. 19.

The micrometer has not only been applied to telescopes, and employed for astronomical purposes; but there have been various contrivances for adapting it to microscopical observations. M. Leeuwenhoek's method of estimating the size of small objects was by comparing them with grains of sand, of which a hundred in a line took up an inch. These grains he laid upon the same plate with his objects, and viewed them at the same time. Dr. Jurin's method was similar to this; for he found the diameter of a piece of fine

silver wire, by wrapping it as close as he could about a pin, and observing how many rings made an inch; and he used this wire in the same manner as Leeuwenhoek used his sand. Dr. Hooke used to look upon the magnified object with one eye, while, at the same time, he viewed other objects, placed at the same distance, with the other eye. In this manner he was able, by the help of a ruler, divided into inches and small parts, and laid on the pedestal of the microscope, to cast, as it were, the magnified appearance of the object upon the ruler, and thus exactly to measure the diameter which it appeared to have through the glass; which being compared with the diameter as it appeared to the naked eye, easily shewed the degree in which it was magnified. A little practice, says Mr. Baker, will render this method exceedingly easy and pleasant.

Mr. Martin, in his Optics, recommends such a micrometer for a microscope as had been applied to telescopes; for he advises to draw a number of parallel lines on a piece of glass with the fine point of a diamond, at the distance of $\frac{1}{40}$ th of an inch from one another, and to place it in the focus of the eye-glass. By this method, Dr. Smith contrived to take the exact draught of objects viewed by a double microscope; for he advises to get a lattice, made with small silver wires or squares, drawn upon a plain glass by the strokes of a diamond, and to put it into the place of the image formed by the object-glass. Then by transferring the parts of the object, seen in the squares of the glass or lattice, upon similar corresponding squares drawn on paper, the picture may be exactly taken. Mr. Martin also introduced into compound microscopes another micrometer consisting of a screw. See both these methods described in his Optics, p. 277.

The most minute and accurate division of any scale which the editor has ever seen, was performed by Mr. Coventry of Southwark. The micrometers of his construction are parallel lines drawn on glass, ivory, or metal, from the 10th to the 10,000th of an inch. These may be applied to microscopes, for measuring the size of minute objects, and the magnifying power of the glasses; and to telescopes, for measuring the size and distance of objects, and the magnifying power of the instrument. For measuring the size of an object in a single microscope, lay it on a micrometer, whose lines are seen magnified in the same proportion with it, and give at one view the real size of the object. For measuring the magnifying power of the compound microscope, the best and most ready method is the following. On the stage in the focus of the object-glass, lay a micrometer, consisting of an inch divided into one hundred equal parts; count how many divisions of the micrometer are taken into the field of view; then lay a two-foot rule parallel to the micrometer: fix one eye on the edge of the field of light, and the other eye on the end of the rule, which move, till the edge of the field of light and the end of the rule correspond; then the distance from the end of the rule to the middle of the stage will be the half of the diameter of the field: *e. gr.* if the distance be ten inches, the whole of the diameter will be twenty, and the number of the divisions of the micrometer contained in the diameter of the field, is the magnifying power of the microscope. Thus, suppose the number of divisions seen in the micrometer to be $\frac{5}{100}$ ths, and that the diameter of the field measures with the rule twenty inches; the $\frac{5}{100}$ th of 20 inches is 40, which is the diameter of the field; $40 \times 40 = 1600$ the superficies, and $1600 \times 40 = 64000$, the magnified cube of the object: in like manner each object-glass or magnifier must be proved, and a table kept of their several magnifying powers. For measuring the height and distance of objects by a micrometer

in the telescope, see TELESCOPE. Mr. Adams has applied a micrometer, which instantly shews the magnifying power of any telescope.

MICROPHONES, instruments contrived to magnify small sounds, as microscopes do small objects.

MICROPUS, in Botany, derived from *μικρο*, small, and *πούς*, a foot; possibly from an allocation of ideas with *Leontopodium*, Lion's-foot, as this genus is nearly assimilated in habit to the *Filago Leontopodium* of Linnæus. It was even supposed by Dr. Sibthorp to be the real *Asplenium* of Dioscorides; (see *LEONTORIUM*).—Linn. Gen. 451. Schreb. 588. Willd. Sp. Pl. v. 3, 2388. Mart. Mill. Diet. v. 3. Ait. Hort. Ord. *Composita Nucamentaceæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common calyx* double; the outer of five, slender, small, obsolete leaves, at the base of the inner, which is very large, and composed of five, loose, distinct, helmet-shaped, compressed leaves, conniving longitudinally at the margin. *Cor.* compound, with ten perfect florets in the disk, and five female ones in the radius; the former of one petal, with five teeth, erect; the latter without any petal. *Stam.* (in the perfect florets) Filaments five, bristle-shaped, very short; anthers cylindrical, tubular, as long as the florets. *Pistl.* (in the same florets) Germen obsolete; style thread-shaped, longer than the filament; stigma obsolete: (in the female ones) Germen obovate, compressed, concealed within each scale of the common inner calyx; style from the inner side of the germen, bristle-shaped, turned towards the perfect florets, the length of the calyx; stigma cloven, slender, pointed. *Peric.* none, except the common inner calyx enlarged and hardened. *Seeds* (in the perfect flowers) none: (in the female ones) solitary, obovate, inclosed each in its appropriate leaflet of the inner calyx. *Recept.* furnished with acute, small scales, which separate the seeds of the females, but not the florets of the disk.

Ess. Ch. Receptacle fealy. Down none. Calyx double. Radius without a corolla. Female florets inclosed by the scales of the common inner calyx.

1. *M. supinus*. Linn. Sp. Pl. 1313. Cavan. Ic. v. 22. t. 35.—Stems prostrate. Leaves opposite, obovate-wedge-shaped.—A native of Portugal, Spain, Italy, and the Levant, flowering from May to September. Introduced into Chelsea garden in 1759, by Mr. Philip Miller.—*Root* annual, somewhat tapering, small, fibrous. *Stems* trailing, numerous, three or four inches long, covered with a sort of silvery nap, as indeed is the whole plant. *Leaves* in pairs, generally opposite, or nearly so, connate, plaited, three-nerved. *Flowers* axillary, sessile, from the base to the top of the stem, minute, in small tufts, white and very downy. *Seeds* ovate, brown.

2. *M. erectus*. Linn. Sp. Pl. 1313. Læf. It. Hisp. 166. t. 1. f. 5.—Stems upright. Leaves alternate, lanceolate.—A native of the East, as well as of France, Italy, and Switzerland.—*Root* annual, fibrous. *Stems* erect, branched, extremely downy. *Leaves* alternate, narrower and more woolly than in the last, as is the whole plant, even the flowers which are sessile, in axillary tufts.

MICROSCOPE, *Μικροσκοπεῖον*, formed of *μικρος*, small, and *σκοπεῖον*, I consider; an optical instrument, by means of which very minute objects are represented exceedingly large, and viewed very distinctly, according to the laws of refraction or reflection.

Microscopes are properly distinguished into simple, or single; and compound, or double.

Microscopes, *Single*, are those which consist of a single lens, or a single spherule.

Microscopes, *Compound*, consist of two or more lenses duly combined. As optics have been improved, other varieties have been contrived, in the sort of microscope; hence we have *resting* microscope, *water* microscope, &c. Each of these two kinds has its peculiar advantage: for a single glass shews the object nearer at hand, and rather more distinct; and a combination of glasses presents a larger field, or, in other words, exhibits more of an object equally magnified, at the view. As each of these has its advantages, each of them has had its advocates, at least in practice. M. Leeuwenhoek never used any but single microscope; and, on the contrary, Dr. Hooke made all his observations with double ones.

When, and by whom, microscopes were first invented, is not certainly known. Huygens tells us, that one Drebell, a Dutchman, had the first microscope, in the year 1621, and that he was reputed the first inventor of it: though F. Fontana, a Neapolitan, in 1646, claims the invention to himself, but dates it from the year 1618. As a telescope inverted is a microscope, the discovery might easily enough have arisen from thence.

Nothing more is certain concerning microscopes, than that they were first used in Germany about the year 1621. According to Borellus, they were invented by Zacharius Jansen, in conjunction with his son, who presented the first microscope they had constructed to prince Maurice, and Albert, archduke of Austria. William Borell, who gives this account in a letter to his brother Peter, says, that when he was ambassador in England, in 1619, Cornelius Drebell shewed him a microscope, which he said was the same that the archduke had given him, and had been made by Jansen himself. Borellus de vero Telescopii inventore, p. 35. See LENS.

MICROSCOPES, *Foundation and Theory of Single*. If an object AB (Plate XII. Optics, fig. 1.) be placed in the focus of a small convex lens, or a simple microscope DE, and the eye be applied close to the other side of the microscope, the object will be seen distinct, in an erect situation, and magnified in the ratio of the distance of the focus to the distance at which objects are to be placed to be seen distinctly by the naked eye.

For the object A B being placed in the focus of the convex lens DE, the rays issuing from the several points of it, after refraction, will be parallel to each other: consequently, the eye will see it distinctly, by virtue of what is proved under the word TELESCOPE.

Further, since one of the rays A F, proceeding from the point A, after refraction, becomes parallel to the incident ray; and therefore, setting aside the thickness of the lens, is found directly against it; and the same holds true of all the other rays carried to the eye; the rays A F and B F, to which the rest coming from A and B are parallel, will enter the eye in the same manner as if they entered without passing through the lens; and will therefore appear erect, as if the lens were away.

Lastly, it is manifest, that the object A B will be seen under the same angle as if viewed by the naked eye: but since it appears very distinct, whereas to the naked eye, at the same distance, it would appear extremely confused; it is the same thing as if the object should seem removed to the distance F H, at which it is viewed with equal distinctness, and under the same angle: the diameter of the object A B, therefore, will be to the apparent diameter I K, as F C to F H, i. e. as the distance of the focus of the lens to the distance at which an object is to be placed, in order to view it distinctly. Since, therefore, the interposition of the glass

MICROSCOPE.

has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye.

Huygens, in *Dioptrics*, prop. lix. p. 222, takes it for granted, that an object, seen with the naked eye, is then in its utmost distinctness when seen at the distance of eight digits, or tenths of a foot; which agrees pretty nearly with the observations of others; who make the nearest limit of distinct vision to be eight inches. So that if the glass be a small round globule, whose focal distance is $\frac{1}{20}$ th of an inch, this globule will magnify as 8 to $\frac{1}{20}$ th, or as 160 to 1.

The distance of distinct vision varies in different individuals. Some have stated it at six inches; others at seven; but it has been generally supposed to be eight inches. The medium of seven inches has been adopted by several optical writers. But whatever it be, if this least distance be divided by the focal distance of the glass, the quotient will shew how much the glass magnifies the diameter of the object.

MICROSCOPES, Laws of Single. 1. Simple microscopes magnify the diameter of the object *AB* in the ratio of the distance of the focus *FC* to an interval of eight digits: *v. gr.* if the semi-diameter of a lens, equally convex on both sides, be half a digit, and consequently its focal distance the same; $AB : IK :: \frac{1}{2} : 8 :: 1 : 16$; that is, the diameter of the object will be increased in a sedecuple proportion, or as sixteen to one. 2. Since the distance *FH* is constant, *viz.* eight digits; by how much the distance of the focus *FC* is smaller, so much the smaller ratio will it have to *FH*; consequently the diameter of the object will be so much the more magnified. 3. Since, in plano-convex lenses, the distance of the focus is equal to the diameter; and, in lenses equally convex on both sides, to the semi-diameter: simple microscopes will enlarge the diameter so much the more, as they are segments of smaller spheres. 4. If the diameter of the convexities of a plano-convex lens, and a lens convex on both sides, be the same, *viz.* = 1: the distance of the focus of the first will be 1, of the second $\frac{1}{2}$: consequently, the semi-diameter of the object *AB* will be to the apparent one, in the first case, as 1 to 8; in the latter, as $\frac{1}{2}$ to 8; *i. e.* as 1 to 16. A lens, therefore, convex on both sides, magnifies twice as much as a plano-convex lens.

As the whole depends on the just and steady situation of objects with regard to the lens, various methods have been contrived to that end; whence we have several different kinds of single microscopes. The most simple is as follows:

1. *AB* (*fig. 2.*) is a little tube, to one of whose bases, *BC*, is fitted a plain glass, to which an object, *viz.* a gnat, wing of an insect, down, or the like, is applied; to the other base, *AD*, at a proper distance from the object, is applied a lens convex on both sides, whose semi-diameter is about half an inch; the plain glass is turned to the sun, or the light of a candle, and the object is seen magnified; and, if the tube be made to draw out, lenses of different spheres may be used.

Again, a lens, convex on both sides, is inclosed in a cell *AC* (*fig. 3.*), and by a screw *H* is there fastened: through the pedestal *CD* passes a long screw, by means of which, and the female screw *I*, a style or needle, fixed perpendicular to its extreme, is kept firm at any distance from the lens: in *E* is a little tube, on which, and on the point *G*, the various objects are to be disposed: thus there may be lenses of various spheres applied.

2. But the microscope which is found to answer the end

best, is Mr. Wilson's pocket microscope, which has nine different magnifying glasses, eight of which may be used with two different instruments, for better applying them to various objects. One of these instruments is represented at *AABB* (*fig. 4.*) and is made of ivory, brass, or silver; it has three thin brass plates at *E*, and a spiral spring of steel wire *H* within it; to one of the thin plates of brass is fixed a piece of leather, wood, or ivory *F*, with a small furrow, *G*, both in the leather and brass to which it is fixed: in one end of this instrument there is a long screw *D*, with a convex glass placed in the end of it at *C*: in the other end, *AA*, of the instrument there is a hollow screw, in which any of the magnifying glasses, *M*, are screwed when they are to be made use of. The nine different magnifying glasses are all set in ivory, eight of which are set in the manner expressed at *M*. The greatest magnifier is marked upon the ivory, in which it is set, with $N^{\circ} 1$, the next $N^{\circ} 2$, and so on to $N^{\circ} 8$; the ninth glass is not marked, but is set in the manner of a little barrel box of ivory, as at *b, fig. 5.* *R* is a flat piece of ivory, of which there are eight belonging to this set of microscopes (though any one who has a mind to keep a register of objects may have as many of them as he pleases); in each of them there are four holes *f, f, f*, in which four or more objects are placed between two thin glasses, or talcs, when they are to be used with the greater magnifiers.

The use of this instrument *AABB* is this. Having taken the handle *W* from the instrument in *fig. 5.* and screwed it upon the button *S*, take one of your flat pieces of ivory, *R*, or sliders (if you please to call them so), and slide it betwixt the two thin plates of brass at *E*, through the body of the microscope, so that the object you intend to look upon be ju't in the middle; remarking that you put that side of the plate *R*, where the brass rings are, farthest from the end *AA*; then you are to screw into the hollow screw in the end *AA* of the body of your microscope *M*, the 3d, 4th, 5th, 6th, or 7th magnifying glass; which being done, put the end *AA* close to your eye, and while you are looking through your magnifying glass upon the object, you are to screw in or out the long screw *D*, which moving round upon the leather *F*, held tight to it by the spiral wire *H*, will bring your object to the true distance; which you will know by seeing it clearly and distinctly: but since in the greater magnifiers you can see but a small part of the object, *viz.* the legs or claws of a flea; while you are looking upon any part of the object, if you take hold of the end of the plate or slider *R*, on which the object lies, and move it gently, you may see the whole object successively, or any part of the object you please; and if that part of the object you design to look upon be out of the true distance, remember your end screw, *D*, can always bring it in, by screwing it one way or the other. A simpler and more convenient method of mounting single microscopes is to fix the several magnifying lenses in a flat circular piece of brass, which can be moved round a point as a centre, by the action of an endless screw upon the toothed circumference of the circular plate.

After this manner may be seen all transparent objects, dusts, liquids, crystals of salts, small insects, such as fleas, mites, &c. If they be insects that will creep away, or such objects as one intends to keep, they may be placed between the two register glasses *f, f*. For by taking out (with the point of a pen-knife or small piers) the ring that keeps in the glasses *f, f*, where the object lies, they will fall out of themselves; so that you may lay the object between the two hollow sides of them, and put the ring in as it was before: but if the objects be dusts or liquids, a small drop of the liquid, or

MICROSCOPE.

a little of the dust laid on the outside of the glass *ff*, and applied as before, will be seen very easily.

As to the first, second, and third magnifying glasses, being marked with a + upon the ivory in which they are set, they are only to be used with those plates or sliders that are also marked with a +, in which the objects are placed between two thin tales; because the thickness of the glasses in the other plates or sliders, hinders the object from approaching to the true distance from these greater magnifiers. But the manner of using them is the same with the first: only remember to be careful when you put in or pull out the plate or slider R, on which the object lies, or move it from one object to another, not to let it rub your magnifying glass; which is done by unscrewing a little the end screw D, when you put in or pull out your plate, or move it from one object to another.

For seeing the circulation of the blood at the extremities of the arteries and veins, in the transparent parts of fishes' tails, &c. there are two short glass tubes, the one bigger and the other lesser, in which the fish is to be put; when these tubes are to be used, you are to unscrew the end screw D in the body of the microscope, until the glass tube can be received easily into that little cavity G of the brass plate fastened to the leather F, under the other two thin plates of brass at E. When the tail of your fish lies flat to the glass tube, set it opposite to your magnifying-glass, and by screwing in or out your end screw D, as is said before, you may easily bring it to the true distance, and see the blood circulate with great pleasure.

If you would see the blood circulate in a frog's foot, choose such a frog as will just go into your tube; then with a little slick expand the hinder foot of the frog, and apply it close to the side of the tube, observing that no part of the frog hinders the light from coming on its foot; and when you have it at the just distance, by means of the screw D, as above said, you will see the rapid motion of the blood in its vessels, which are very numerous, in the transparent thin membrane that is between the frog's toes. For this object the fourth and fifth magnifiers will do very well; but you may see the circulation in the tails of water-newts with the sixth and seventh glasses, because the globules of the blood of those newts are as big again as the globules of the blood of frogs or small fish, as has been taken notice of in N^o 280 of the Philosophical Transactions, p. 1184.

The circulation cannot so well be seen by the first, second, and third magnifiers, because the thickness of the glass tube in which the fish lies, hinders the approach of the object to the focus of the magnifying glass.

The other instrument (*fig. 5.*) is made of brass or prince's metal, with joints P, P, P, to turn easily any way, and with a small pair of tongs G G, which open at the points K, by pressing together the two heads of the pins I, I. for taking up of objects. At the other end of these tongs G G, is screwed on a round piece of black wood H, with a piece of ivory let into it, for placing opaque objects on, according to their difference of colour. Upon the end L there is a screw, upon which the glass *b* set in the barrel-box may be screwed. When the other glasses are to be used, there is a ring R of brass to be screwed on the end L, into which ring all the other glasses, M, (*fig. 4.*) may be screwed. So when any object is taken up in the points of the tongs K, or laid upon the other end H, it may very easily (as one who sees the instrument will perceive) be applied to the true focal distance of any of the glasses M, by the help of the joints P, P, P, and by means of the screw C, with the nut D, which being regulated by a spring N, will bring the object to the exact distance for distinct vision.

The glass placed in the manner of a barrel-box at *b*, is only to be used with the brass instrument (or in your hand) being the least magnifier for greater objects, such as fleas and common insects, &c. remembering to put the hole at *b* next to your eye.

In the viewing of objects, one ought to be careful not to hinder the light from falling on them, by the hat, peruke, or any other thing, especially in looking at opaque objects; for nothing can be seen with the best of glasses, unless the object be at a due distance, with a sufficient light. The best lights for the plates or sliders, where the object lies between the two glasses, is a clear sky-light, or where the sun shines on any white thing, or the reflexion of the light from a looking-glass. The light of a candle is likewise good for the viewing of very small objects, though it be a little uneasy to those who are not practised in microscopes to find it out. The only use of the convex lens at C (*fig. 4.*) is to collect the light into a narrower compass where it falls upon the object, after it has passed through a moderate hole in the leather F.

For the convenience of those who would draw, or make any sketches or designs of microscopical objects, they may also have a pedestal to fix the two instruments above described, and make them stationary to any convenient light. This pedestal may be placed on a table, and after the object and light are fixed, as many persons as please may view the object without any trouble or difficulty in finding the light. (Phil. Trans. abr. vol. iv. p. 199, &c.) Mr. Baker in his treatise "Of Microscopes," (vol. i.) has described an invention for fixing the pocket microscope of Wilson, and giving light to it by a speculum. For this purpose a scroll of brass is fixed upright and steady on a round pedestal of wood. A brass screw is made to pass through a hole in the upper limb of the scroll into the side of the microscope, so as to screw it fast to the scroll. On the pedestal is fixed an arch, in which a concave speculum, set in a box of brass, is suspended by means of two small screws, that fasten to its opposite sides. As the arch turns on the pin by which it is fixed to the pedestal, and the speculum turns within the arch, it may, by this twofold motion, be easily adjusted in such a manner as to reflect the light of the sky, the sun, or a candle, directly upwards, through the microscope that is fixed perpendicularly over it; and by so doing, may answer almost all the purposes of the large double reflecting microscope. The body of the microscope may also be fixed horizontally, and objects may be viewed from that position, by any light you choose; which is an advantage that does not belong to the reflecting microscope. It may be also rendered further useful, by means of a slip of glass, one end of which being thrust between the plates where the sliders go, and the other extending to some distance, such objects may be placed upon it as cannot be applied on the sliders; and then, having a limb of brass that may fasten to the body of the microscope, and extend over the projecting glass a hollow ring on which to screw the magnifiers, all sorts of subjects may be examined with great convenience, if a hole be made in the pedestal to place the speculum exactly underneath, and thereby throw up the rays of light. What has been said hitherto, is to be understood of *lenticular* microscopes; as for *spherical* ones, their doctrine will be understood from what follows.

If an object A B (*fig. 6.*) be placed in the focus of a glass spherule F, and the eye be behind it, *v. gr.* in the focus G; the object will be seen distinct, in an erect situation, and magnified, as to its diameter, in a ratio of $\frac{3}{4}$ ths of the diameter E I, to the distance at which objects are to be placed to be seen distinctly with the naked eye.

MICROSCOPE.

The first part of the proposition is proved in the same manner of spheres, as of lenses. As, then, a good eye sees an object distinctly at the distance of eight digits, a glass spherule will enlarge the diameter of an object in a ratio of $\frac{3}{4}$ ths of the diameter to eight digits. Suppose, then, the diameter of the spherule E $\frac{1}{100}$ th of a digit, CE will be $= \frac{1}{20}$, and $FE = \frac{1}{40}$; and therefore $FC = \frac{1}{20} + \frac{1}{40} = \frac{3}{40}$. Consequently, the true diameter of an object to its apparent one is in the ratio of $\frac{3}{40}$ to 8; *i. e.* as 3 to 320, or as 1 to 106 nearly.

Now a lens, convex on both sides, increases the diameter in a ratio of the femidiameter to the space of eight digits; wherefore $\frac{1}{2}$ having a less ratio to eight than $\frac{3}{4}$ ths, if a lens and a sphere have the same diameter, the former will magnify more than the latter; and, pretty much after the same manner, it may be shewn, that a sphere, of a less diameter, magnifies more than another of a large one.

As for the methods of casting little glass spherules for microscopes, they are various. The first person who improved single microscopes by using small globules of glass, made by melting them in the flame of a candle, was Hartsoeker, who thus discovered the animalcula in femine masculino, and laid the foundation of a new system of generation. Wolfius describes the following method of making globules of this kind; a small piece of very fine glass, sticking to the wet point of a steel needle, is to be applied to the extreme blueish part of the flame of a lamp, or, which is better, to the flame of spirit of wine, to prevent its being blackened: being there melted and run into a little round drop, it is to be removed from the flame, upon which it instantly ceases to be fluid; folding, then, a thin plate of brass, and making very small smooth perforations, so as not to leave any roughness on the surfaces; and, farther, smooth them over, to prevent any glaring, fit the spherule between the plates against the apertures, and put the whole in a frame, with objects convenient for observation.

Mr. Adams gives another method, thus: take a piece of fine window-glass, and raise it, with a diamond, into as many lengths as you think needful, not exceeding an eighth of an inch in breadth; then holding one of those lengths between the fore-finger and the thumb of each hand, over a very fine flame, till the glass begins to soften, draw it out till it be as fine as a hair, and break; then, applying each of the ends into the purest part of the flame, you have two spheres presently, which you may make larger, or less, at pleasure: if they stay long in the flame, they will have spots; so they must be drawn out immediately after they are turned round. As to the stem, break it off as near the ball as possible; and, lodging the remainder of the stem between the plates, by drilling the hole exactly round, all the protuberances are buried between the plates; and the microscope performs to admiration.

Mr. Butterfield, in the *Phil. Transf.* N^o 141, recommends, for making glass globules clear and without specks, the flame of a lamp, made with rectified spirit of wine, and instead of a cotton wick, fine silver-wire, doubled like a skain of thread; then having beaten some fine glass to powder, and washed it clean, he directs to take a little of it upon the sharp point of a silver needle, wetted with spittle, and to hold it in the flame, turning it about till it melts, and becomes quite round. When many globules are thus formed, he rubs them with soft leather; and having several small pieces of thin brass plates, twice as long as they are broad, he doubles them up into the form of a square, and pushes a fine hole through the middle of them, and having rubbed off the bur about the holes with a whetstone, and blackened the inside of the plates with the smoke of a candle, he places

a globule between the two holes, and tacks the plates together with two or three rivets.

Dr. Hooke used to take a very clear piece of glass, and to draw it out into long threads in a lamp; then he held these threads in the flame, till they ran into round globules hanging to the end of the threads. Then having fixed the globules with sealing-wax to the end of a stick, so that the threads stood upwards, he ground off the ends of the threads upon a whetstone, and polished them upon a smooth metal plate with a little putty. Mr. Stephen Gray tells us, (*Phil. Transf.* N^o 221. 223.) that for want of a spirit lamp, he laid a small particle of glass, about the size of the intended globule, upon the end of a piece of charcoal; and by means of a blast-pipe, with the flame of a candle, he soon melted it into a globule. He thus made them indifferently clear, and the smallest very round; but the larger by resting upon the coal were a little flattened, and became rough on that side. He therefore ground and polished them upon a brass plate, till he reduced them to hemispheres. But he found that the small round globules not only magnified more, but shewed objects more distinct than the hemispheres.

By these methods may spheres be made much smaller than any lens; so that the best single microscopes, or those which magnify the most, are made of them. For suppose the diameter of a spherule to be $\frac{1}{10}$ of a digit, the distance of its focus will be $\frac{1}{4}$; and therefore its real diameter to its apparent one, as $\frac{1}{10}$ to $\frac{1}{4}$; that is, as $\frac{3}{10}$ to 8, or as 3 to 512; or, lastly, as 1 to 170. The surface of an object, therefore, will be increased by it in the proportion of 1 to 28900, and its bulk in a ratio of 1 to 4913000.

Mr. Leeuwenhök and M. Muschenbroek have succeeded very well in spherical microscopes; and the apparatus of the latter is much commended; but we forbear any descriptions of them; it being easy for any one who considers the structure of those consisting of lenses, to conceive how those of spheres may be contrived.

Mr. Leeuwenhök's microscopes were all single ones; each of them consisting of a small double convex glass set in a socket, between two silver plates, riveted together, and pierced with a small hole; and the object was placed on the point of a needle, so contrived, as to be placed at any distance from the lens. If the objects were solid, he fastened them with glue; and if they were fluid, or, on other accounts, required to be spread on glass, he placed them on a small piece of Muscovy talc, or glass blown very thin, which he afterwards glued to his needle. He had however a different apparatus for viewing the circulation of the blood, which he could fix to the same microscopes. Those which he bequeathed to the Royal Society were contained in a small Indian cabinet, in the drawers of which were thirteen little boxes or cases, in each of which were two microscopes, neatly fitted up in silver; and both the glass and the apparatus were made with his own hands. The greatest magnifier among these enlarged the diameter of an object about 160 times. *Phil. Transf. Abr.* vol. vi. p. 129, &c. *Id.* vol. viii. p. 121, &c.

Several writers, says Mr. Baker (*ubi infra*) have represented the glasses used by Mr. Leeuwenhök in his microscopes, to be little globules or spheres of glass; but he assures us, from an inspection of his cabinet, that every one of the 26 microscopes contained in it, was a double convex lens, and not a sphere or globule.

The smallest globules, and consequently the greatest magnifiers for microscopes that have yet been executed, were made by F. Di Torre of Naples, who, in 1765, sent four of them to the Royal Society. The largest of them was only

MICROSCOPE.

only two Paris points in diameter, and is said to magnify the diameter of an object 640 times; the second was the size of one Paris point; magnifying the diameter 1280 times, and the third no more than one-half of a Paris point, or the 144th part of an inch in diameter, and was said to magnify the diameter of an object 256 times, and consequently the square of such a diameter 6553,600 times. But since the focus of a glass globule is at the distance of one-fourth of its diameter, and, therefore, that of the third globule of Di Torre, above mentioned, only the 576th part of an inch distant from the object, it must be with the utmost difficulty that globules so minute as these can be employed to any purpose; and Mr. Baker, to whose examination they were referred, considers them as matters of curiosity rather than of real use. (Phil. Trans. vol. lv. p. 246. vol. lvi. p. 67, &c.) For an account of observations made with these globules on the blood, see BLOOD.

Experience, says Mr. Baker, in his treatise "Of Microscopes," has taught us, that those globules which were at first highly extolled and much sought after, admit so little light, can shew only such an exceeding minute part of any object, are so difficult to be used, and strain the eyes so much, that their power of magnifying, for want of due distinctness, is rather apt to produce error than to discover truth, and therefore now they are very rarely employed.

In order to state clearly and distinctly the method of determining the magnifying powers of glasses employed in single microscopes, we shall observe, that if the focus of a convex lens (*e. g.*) be at one inch, and the natural sight at eight inches, which is the common standard, an object may be seen through that lens at one inch distant from the eye; and will appear, in its diameter, eight times larger than to the naked eye. But as the object is magnified every way equally, in length as well as breadth, we must square this diameter, to know really how much it appears enlarged; and we shall then find, that its superficies is indeed magnified sixty-four times.

Again: suppose a convex lens whose focus is at one-tenth of an inch distant from its centre: in eight inches there are eighty such tenths of an inch; and therefore an object may be seen through this lens eighty times nearer than it can distinctly be by the naked eye. It will consequently appear eighty times longer, and eighty times broader, than it does to common sight; and a eighty multiplied by eighty makes six thousand and four hundred, to many times it really appears magnified.

To go one step farther: if a convex glass be so small, that its focus is no more than one-twentieth of an inch distant; we shall find that eight inches, the common distance of sight, contain an hundred and sixty of these twentieth parts; and, in consequence, the length and breadth of an object, when seen through such lens, will each be magnified an hundred and sixty times; which multiplied by an hundred and sixty, to give the square, will amount to twenty-five thousand six hundred; and so many times, it is plain, the superficies of the object must appear larger than it does to the naked eye at the distance of eight inches.

Therefore, in a single microscope, to learn the magnifying power of any glass, no more is necessary than to bring it to its true focus; the exact place of which will be known, by an object's appearing perfectly distinct and sharp when placed there. Then, with a pair of small compasses, measure, as nearly as you can, the distance from the centre of the glass to the object you were viewing, and afterwards applying the compasses to any ruler with a diagonal scale of the parts of an inch marked on it, you will easily find how many parts of an inch the said distance is. When that is known, compute how many times those parts of an inch are contained in eight inches, the common standard of sight, and that will give you the number of times the diameter is magnified: squaring the diameter will give you the superficies; and if it be an object whose depth or whole contents you would learn, multiplying the superficies by the diameter will shew the cube or bulk.

A TABLE of the Magnifying Powers of Convex Glasses, employed in Single Microscopes, according to the Distance of their Focus: Calculated by the Scale of an Inch divided into an Hundred Parts: Shewing how many Times the Diameter, the Superficies, and the Cube of an Object is magnified, when viewed through such Glasses, to an Eye whose natural Sight is at Eight Inches, or Eight Hundred of the Hundredth Parts of an Inch.

		Magnifies the Diameter.	Magnifies the Superficies.	Magnifies the Cube of an Object.

MICROSCOPE.

N.B. The greatest magnifier in Mr. Leeuwenhoek's Cabinet of Microscopes, presented to the Royal Society, has its focus, as nearly as can well be measured, at $\frac{1}{2}$ th of an inch distance from its centre, and consequently magnifies the diameter of an object 160 times, and the superficies 25,600. But the greatest magnifier in Mr. Wilson's single microscopes, as they are now made, has usually its focus at no farther distance than about the fiftieth part of an inch; whereby it has the power of enlarging the diameter of an object 400, and its superficies 160,000 times.

The following Table is calculated on the supposition that the nearest distance at which we can see distinctly is seven inches; and shews the magnifying power of small convex lenses or single microscopes, not exceeding an inch in focal length.

Focal Distance of the Lens or Microscope.	Number of Times that the Diameter of an Object is magnified.	Number of Times that the Surface of an Object is magnified.	Number of Times that the Cube of an Object is magnified.	
100ths of an Inch.	Times. Dec. of a Time.	Times.	Times.

Ferguson's Mechanics by Brewster, vol. ii. p 449.

MICROSCOPE, Water. Mr. S. Gray, and, after him, Wolfius, and others, have contrived water microscopes, consisting of spherules, or lenses of water, instead of glass, fitted up somewhat after the manner of those above mentioned (as spheres of water may be likewise used instead of glass in any of the common microscopes.) But since the distance of the focus of a lens or sphere of water is greater than that of one of glass (the spheres whereof they are segments being the same), water microscopes magnify less, and are therefore less esteemed than those of glass. The same Mr. Gray first observed, that a small drop or hemispherule of water, held to the eye by candlelight or moonlight, without any other apparatus, magnified the animalcula contained in it vastly more than any other microscope. The reason is, that the rays, coming from the interior surface of the first hemi-

sphere, are reflected so as to fall under the same angle on the surface of the hind hemisphere, to which the eye is applied, as if they came from the focus of the spherule; whence they are propagated to the eye in the same manner as if the objects were placed without the spherule in its focus. Phil. Trans. N^o 221. 223. Smith's Optics, vol. ii. p. 334. &c.

Hollow glass spheres, of the diameter of about half a digit, filled with spirit of wine, are frequently used for microscopes: but they do not magnify near so much.

Dr. Brewster, in the Appendix to his edition of Ferguson's Mechanics, &c., describes a microscope totally different from that of Mr. Gray, though founded upon the same general principle. Instead of water, he makes use of very pure and viscid turpentine, which he takes up by the point of a piece of wood, and drops successively upon a thin and well polished glass: different quantities being thus taken up and dropped in a similar manner form four or more plano-convex lenses of turpentine varnish, which may be made of any focal length, by taking up a greater or less quantity of the fluid. The lower surface of the glass having been first smoked with a candle, the black pigment below the lenses is then to be removed, so that no light may pass by their circumference. The piece of glass is then to be perforated, and surrounded with a toothed wheel, which can be moved round the hole as a centre by an endless screw. The apparatus is then placed in a circular case, and this case fixed to an horizontal arm by means of a brass pin, which passes through its upper and under surfaces, and through the hole already mentioned, which does not embrace the pin very tightly, in order that the toothed wheel may revolve with facility. On the upper surface of the circular case is an aperture directly above the line described by the centres of the fluid lenses, when moving round the central hole; and in this aperture is inserted a small cap, with a little hole at its top, to which the eye is applied. A moveable stage carries the slider, on which microscopic objects are laid, and is brought nearer or removed from the lenses by a vertical screw. The objects on the slider are illuminated by a plain mirror, which has both a vertical and horizontal motion for this purpose. When the microscope is thus constructed, the object to be viewed is placed upon the slider, and the endless screw is turned till one of the lenses be directly under the aperture; and the slider is thus raised or depressed by the vertical screw, till the object be brought into the focus of the lens. In this manner, by turning the endless screw, and bringing all the lenses, one after another, directly below the aperture, the object may be successively examined with a variety of magnifying powers. These fluid lenses have been employed as the object-glasses of compound microscopes.

The *single aquatic microscope* of Mr. Ellis has the advantage of being simple in its construction, portable, and very commodious for the purposes of practical botanists, the observers of animalcula, &c. K (fig. 7.) represents the box containing the whole apparatus: it is generally made of fish-skin; and on the top there is a female screw, for receiving the screw that is at the bottom of the pillar A: this is a pillar of brass, and is screwed on the top of the box. D is a brass pin which fits into the pillar; on the top of this pin is a hollow socket to receive the arm which carries the magnifiers; the pin is to be moved up and down, in order to adjust the lenses to their focal or proper distance from the object. [N. B. In the representations of this microscope, the pin D is delineated as passing through a socket at one side of the pillar A; whereas it is usual at present to make it pass down a hole bored through the middle of the pillar.] E, the bar which carries the magnifying lens; it fits into the socket

MICROSCOPE.

socket X, which is at the top of the pin or pillar D. This arm may be moved backwards and forwards in the socket X, and sideways by the pin D; so that the magnifier, which is screwed into the ring at the end E of this bar, may be easily made to traverse over any part of the object that lies on the stage or plate B. F F is a polished silver speculum, with a magnifying lens placed at the centre thereof, which is perforated for this purpose. The silver speculum screws into the arm E, as at F. G, another speculum, with its lens, which is of a different magnifying power from the former. H, the semicircle which supports the mirror I; the pin R, affixed to the semicircle H, passes through the hole which is towards the bottom of the pillar A. B, the stage, or the plane, on which the objects are to be placed; it fits into the small dove-tailed arm which is at the upper end of the pillar D A. A plane dove-tail glass, with a small piece of black silk stuck on it, is used to lie in a circular groove made in the stage B. A hollow watch glass is to be laid occasionally on the stage instead of the plane glass. L, a pair of nippers. These are fixed to the stage by the pin at bottom; the steel wire of these nippers slides backwards and forwards in the socket, and this socket is moveable upwards and downwards by means of the joint, so that the position of the object may be varied at pleasure. The object may be fixed in the nippers, stuck on the point, or affixed, by a little gum-water, &c. to the ivory cylinder N, which occasionally screws to the point of the nippers.

To use this microscope: take all the parts of the apparatus out of the box; then begin by screwing the pillar A to the cover of it; pass the pin R of the semicircle which carries the mirror through the hole that is near the bottom of the pillar A; push the stage into the dove-tail at B, slide the pin into the pillar (see the N.B. above); then pass the bar E through the socket which is at the top of the pin D, and screw one of the magnifying lenses into the ring at F. The microscope is now ready for use: and though the enumeration of the articles may lead the reader to imagine the instrument to be of a complex nature, we can safely affirm that he will find it otherwise. The instrument has this peculiar advantage, that it is difficult to put any of the pieces in a place which is appropriated to another. Let the object be now placed either on the glasses of the stage, or in the nippers L, and in such manner that it may be as nearly as possible over the centre of the stage: bring the speculum F over the part you mean to observe; then throw as much light on the speculum as you can, by means of the mirror I, and the double motion of which it is capable; the light received on the speculum is reflected by it on the object. The distance of the lens F from the object is regulated by moving the pin D up and down, until a distinct view of it is obtained. The best rule is, to place the lens beyond its focal distance from the object, and then gradually to slide it down till the object appears sharp and well defined. The adjustment of the lenses to their focus, and the distribution of the light on the object, are what require the greatest attention: on the first the distinctness of the vision depends; the pleasure arising from a clear view of the parts under observation is due to the modification of the light. No precise rule can be given for attaining accurately these points; it is from practice alone that ready habits of obtaining these necessary properties can be acquired, and with the assistance of this no difficulty will be found.

Mr. B. Martin has also contrived a microscope for similar purposes with those to which that of Mr. Ellis is adapted. A B (fig. 8.) represents a small arm supporting two or more magnifiers, one fixed to the upper part as at B, the other to the lower part of the arm at C; these may be used

separately or combined together. The arm A B is supported by the square pillar I K, the lower end of which fits into the socket E of the foot F G; the stage D L is made to slide up and down the square pillar; H, a concave mirror for reflecting light on the object.—To use this microscope, place the object on the stage, reflect the light on it from the concave mirror, and regulate it to the focus, by moving the stage nearer to or farther from the lens at B. The ivory sliders pass through the stage; other objects may be fixed in the nippers M, N, and then brought under the eye-glasses; or they may be laid on one of the glasses which fit the stage. The apparatus to this instrument consists of three ivory sliders; a pair of nippers; a pair of forceps; a flat glass and a concave ditto, both fitted to the stage.

The two last microscopes are frequently fitted up with a toothed rack and pinion, for the more ready adjustment of the glasses to their proper focus.

Dr. Withering, in his "Botanical Arrangements," describes a portable botanic microscope. It consists of three brass plates, A, B, C. (fig. 9.) which are parallel to each other; the wires D and E are rivetted into the upper and lower plates, which are by this means united to each other; the middle plate or stage is moveable on the aforesaid wires by two little sockets which are fixed to it. The two upper plates each contain a magnifying lens, but of different powers; one of these confines and keeps in their places the fine point F, the forceps G, and the small knife H.—To use this instrument, unscrew the upper lens, and take out the point, the knife, and the forceps; then screw the lens on again, place the object on the stage, and then move it up or down till you have gained a distinct view of the object, as one lens is made of a shorter focus than the other; and spare lenses of a still deeper focus may be had if required. This little microscope is the most portable of any. Its principal merit is its simplicity.

Mr. B. Martin has contrived to mount several lenses in one frame, which are convenient for various purposes, and are carried in the pocket. He calls this apparatus a "Hand Megaloscope," from its use in viewing the larger sort of small objects expeditiously. The case with its three frames and lenses, is represented in fig. 10. The lenses are commonly of 1, 1½ and 2 inches focus; they are contrived so as to turn over each other, and that into the case. The three lenses singly afford three magnifying powers; and by combining two and two, we obtain three more; *d* with *c* making one, *d* with *f* another, and *c* with *f* a third; and all three combined together make another; so that by this simple apparatus we have seven different magnifying powers. When the three lenses are combined, it is better to turn them in, and look through them by the small apertures in the sides of the case. The eye in this case is not incommoded by external light; the aberration of the superfluous rays through the glasses is precluded; and the eye coincides more exactly with the common axes of the lenses.

M. Lyonet has invented a curious and useful microscope, for the purpose of minute dissections and microscopic preparations. A B (fig. 11.) is the anatomical table, which is supported by a pillar N O; this is screwed on the foot CD. The table A B is prevented from turning round by means of two steady pins. In this table or board there is a hole G, which is exactly over the centre of the mirror E F, that is to reflect the light on the object; the hole G is designed to receive a flat or concave glass, on which the objects for examination are to be placed.

R X Z is an arm formed of several balls and sockets, by which means it may be moved in every possible situation; it is fixed to the board by means of the screw H. The last

MICROSCOPE.

arm I Z has a female screw, into which a magnifier may be screwed as at Z. By means of the screw H, a small motion may be occasionally given to the arm I Z, for adjusting the lens with accuracy to its focal distance from the object.

Another chain of balls is sometimes used, carrying a lens to throw light upon the object; the mirror is likewise so mounted, as to be taken from its place at K, and fitted on a clamp, by which it may be fixed to any part of the table A B.

To use the Dissecting Table.—Let the operator sit with his left side near a light window; the instrument being placed on a firm table, the side D H towards the stomach, the observations should be made with the left eye. In dissecting, the two elbows are to be supported by the table on which the instrument rests, the hands resting against the board A B; and in order to give it greater stability (as a small shake, though imperceptible to the naked eye, is very visible in the microscope), the dissecting instruments are to be held one in each hand, between the thumb and two fore-fingers.

MICROSCOPES, Theory of Compound, or Double. Suppose an object-glass E D, (*Plate XII. Optics, fig. 1.*) the segment of a very small sphere, and the object A B placed without the focus F.

Suppose an eye-glass G H, convex on both sides, and the segment of a sphere greater (though not too great) than that of D E; and let it be so disposed behind the object, as that if C F : C L :: C L : C K; the focus of the eye-glass may be in K.

Lastly, suppose L K : L M :: L M : L I.

If, then, O be the place in which an object is seen distinct with the naked eye; the eye, in this case, being placed in I, will see the object A B distinctly, in an inverted situation, and magnified in a compound ratio of M K to L K, and L C to C O; as is proved from the laws of dioptrics; *i. e.* the image itself is larger than the object, and we are able to view it distinctly at a less distance. *E. G.* If the image be twenty times larger than the object, and by the help of the eye-glass we are able to view it five times nearer than we could have done with the naked eye, it will, on both these accounts, be magnified 5 times 20, or 100 times.

MICROSCOPES, Laws of Double 1. The more an object is magnified by the microscope, the less is its *field*, *i. e.* the less of it is taken in at one view.

2. To the same eye-glass may be successively applied object-glasses of various spheres, so as that both the entire objects, but less magnified, and their several parts, much more magnified, may be viewed through the same microscope. In which case, on account of the different distances of the image, the tube L K, in which the lenses are fitted, should be made to draw out. For the proportion of the object-glass to the eye-glass, some commend the subduple ratio, and some the subsextile. De Chales will have the semidiameter of the convexity of the object-glass to be $\frac{1}{3}$ of a digit, or, at most, $\frac{1}{2}$; in the eye-glass an entire digit, or even $1\frac{1}{2}$. Chrubin makes the semidiameter of the object-glass $\frac{1}{4}$, $\frac{1}{3}$, or $\frac{1}{2}$ of a digit; the semidiameter of the eye-glass $1\frac{1}{3}$, or $1\frac{1}{2}$ of a digit.

3. Since it is proved that the distance of the image L K from the object-glass D E will be greater, if another lens, concave on both sides, be placed before its focus; it follows, that the object will be magnified the more, if such a lens be here placed between the object-glass D E, and the eye-glass G H. Such a microscope is much commended by Conradi, who used an object-lens, convex on both sides, whose semidiameter was two digits, its aperture equal to a mustard-feed; a lens, concave on both sides, 12, or at most

16 digits; and an eye-glass, convex on both sides, of six digits.

4. Since the image is projected to the greater distance, the nearer another lens, of a segment of a larger sphere, is brought to the object-glass; a microscope may be composed of three lenses which will magnify prodigiously.

5. From these considerations it follows, that the object will be magnified the more, as the eye-glass is the segment of a smaller sphere; but the field of vision will be the greater, as the same is a segment of a larger sphere. If, then, two eye-glasses, the one a segment of a larger, the other of a smaller sphere, be so combined, as that the object appearing very near through them, *i. e.* not farther distant than the focus of the first, be yet distinct; the object, at the same time, will be exceedingly magnified, and the field of vision much greater than if only one lens was used; and the object will be still more magnified, and the field enlarged, if both the object and eye-glass be double. But in regard an object appears dim, when viewed through so many glasses, part of the rays being reflected in passing through each, the multiplying of lenses is not advisable; and the best, among compound microscopes, are those which consist of one object-glass and two eye-glasses. These eye-glasses are placed sometimes close together, and sometimes an inch asunder; by which means, although the object appears less magnified, yet the visible area is much enlarged by the interposition of a second eye-glass, and thus a much pleasanter view is obtained. This additional lens is called the amplifying glass, and is generally about $1\frac{1}{2}$ inch in diameter, and $2\frac{1}{2}$ inches in focal length.

Dr. Hooke tells us, in the preface to his Micrography, that in most of his observations he used a microscope of this kind, with a middle eye-glass of a considerable diameter, when he wanted to see much of the object at one view, and took it out when he would examine the small parts of an object more accurately; for the fewer refractions there are, the more light and clear the object appears.

For a microscope of three lenses, De Chales commends an object glass of $\frac{1}{3}$ or $\frac{1}{4}$ of a digit; and the first eye-glass he makes 2 or $2\frac{1}{2}$ digits; the distance between the object-glass and eye-glass about twenty lines. Conradi had an excellent microscope, the object-glass of which was half a digit, and the two eye-glasses (which were placed very near) four digits; but it answered best, when, in lieu of the object-glass, he used two glasses, convex on both sides, their sphere about a digit and a half, or at most two, and their convexities touching each other within the space of half a line. Eustachius de Divinis, instead of an object-glass convex on both sides, used two plano-convex lenses, whose convexities touched; Grindelius did the same, only that the convexities did not quite touch. Zahnus made a binocular microscope, in which both eyes were used.

It is observed that compound microscopes sometimes exhibit a fallacious appearance, by representing convex objects concave, and *vice versa*. See Phil. Trans. N 476. p. 387.

The magnifying power of a microscope with more than two lenses, must be computed from the effect of all the lenses (see LENS); or it may be ascertained experimentally in the following manner. Place part of a divided ruler before the microscope, so that, looking through the instrument, you may see one of its divisions magnified; then open the other eye also, and looking with it at the ruler out of the microscope, you will perceive the image of the magnified division as it were projected upon the ruler; and you may easily see how many divisions of the unmagnified ruler measure, or are equal to, the single magnified division, and that number is the magnifying power of that microscope. Thus, if the

MICROSCOPE.

ruler be divided after the common way into inches and tenths, and if you find that one magnified tenth is equal to three inches, you may conclude that the microscope magnifies 30 times.

MICROSCOPE. Structure or Mechanism of a Double. The industry and address of our countryman, Mr. Marshall, here deserve to be remembered; the construction of the original double microscope being of his contrivance. In this the eye-glass is at *W* (*Plat. XIII. fig. 1.*) the object-glass at *C*, the middle glass at *A* 1: *B* is the cover or lid, to keep out the dust from the eye-glass *W*; *X* is the place of the eye, *W* a screw where the eye-glass lies; *A* 1 a screw where the middle glass lies; *A* 2 the drawer, where the outermost tube *A* 1 *A* 2 is disjoined from the inner one, of the same length; *Z* the frame or basis on which the microscope stands firm; *T* a small drawer in the frame or basis, with a ledge or till in it, having six partitions to hold so many several object-glasses, one magnifying more than another, and fixed in brass cells ready to screw on at *C*, and marked 1, 2, 3, 4, 5, 6; these partitions are also marked 1, 2, 3, 4, 5, 6; the other part of the drawer serves to hold the object-plate; a pair of small nippers, to take up, or handle any object conveniently; another object-plate, having one side white and the other black, to fix your objects upon, as black upon white, and white objects on black. *L M* is a brass ball and socket, on which the whole body of the microscope is moveable, so as to lie in any position for the light. *L K*, a square brass pillar, on which the microscope is moveable up and down, by means of the collar *E*, into which the axis *D* (holding the microscope) is continued. *G*, another brass collar sliding up and down on the pillar *L K*, having a small screw *H*, by which it is, as occasion serves, fixed fast to the said pillar, at any height. *I*, a large brass nut, in whose centre is a female screw, fitted to the male screw *F*, which is fixed in the collar *E*; by the turning of which nut *I* (the collar *G* being first fixed to the pillar by the screw *H*) the microscope is raised up or down on the pillar, and made to come nearer or go farther from the object *P c*; and, which is also a very great advantage, the axis of the microscope is always kept perpendicular to that point of the object, over which it was first placed; so that here is not the inconvenience which occurs in other glasses of often losing the sight of the object, by screwing the glass *C* higher or lower. *P Q* is a glass object-plate fixed in a brass frame, whose arm *NN* is fixed to the pillar by means of the nut *O*. The arm *NN* hath in it a slit, by which it is easily put on, or taken off the pillar, and by which it may be fixed upon it at any distance. *P*, a small fish lying on the glass-plate, that the circulation of the blood may be seen in the end of the tail-fin. *R*, a convex glass, by whose help a bright spot of light is brought from a candle at *S*, standing on the ground, while the microscope stands on the edge of a table or stool, which spot of light, *c*, serves to render the circulation more conspicuous. *V*, a leaden coffin to be put on the fish, to hinder it from springing away, and moving his tail out of the light. 1, 2, 3, 4, 5, 6, are marked on the pillar *L K*, to shew the respective distances of the object-glasses from the object you look upon according as the object-glasses you make use of magnify more or less. Thus, for instance, if you use the object-glass 5 or 6 (either of which will shew the circulation of the blood) you must fix the upper edge of the collar *E*, at the mark 5 or 6 on the pillar. And then the microscope will be very near its exact distance from the object; so that by a small turn or two of the nut *I* one way or the other, to be found by trial, you may soon fit it exactly to your own eye.

By this microscope liquors also may be very commodiously examined; for if you place a small drop of any liquor on the

glass-plate, just in the middle of the spot of light *c*, the parts of it will become very visible, and its animalcula, if it have any, will be discovered. And thus may the cells in vinegar, the small creatures in black-pepper water, or in water where wheat, barley, &c. has been infused, the cells and other small living creatures in puddle-water, be as plainly seen as by almost any other microscope.

In the microscope, in which the objects are illuminated by reflection, made by Mr. Culpeper and Mr. Scarlet, as an improvement of Mr. Marshall's, the inner tube, *ab*, (*fig. 2.*) which slides in the outer, *cd*, holds all the glasses. The eye-glass is at *aa*, the broad middle glass at *bb*, and the object-glass, being set in a button at *c*, is screwed upon the end of a narrower tube *fg*; which being fixed in the base of the inner tube, passes freely through a hole in the base of the outer. The buttons that contain several object-glasses are marked 1, 2, 3, &c. and the convexity of the inner tube is also marked with dotted circles, numbered 1, 2, 3, &c. in order to bring that circle to coincide with the mouth *cc* of the outer tube, whose number is the same as that of the object-glass then made use of. But if the object does not yet appear quite distinct, the pinion *R* must be turned, which, by a rack on the tube of the microscope, brings it nearer to the object placed below it. Of these glasses the greater magnifiers are known by their having smaller apertures.

The base *dd* of the outer tube is supported by three brass pillars, fixed into a wooden pedestal *b*; and a little below the object-glass *f*, a circular plate *ik* is fixed like a stage between the pillars, having a circular hole in the centre to receive glasses, &c. to place objects upon. Three small brass circles *mn*, with holes through the middle of them, are to be placed over the hole in the middle of the stage; and then the ivory sliders with objects may be put between the two uppermost of these circles, which are pressed together by a spiral spring wire lodged between the two undermost; the two outermost being held together by two small pillars passing through two holes in the circumference of the middle circle. For viewing the circulation of the blood, the button *p*, on the under side of the frame of a broad plane glass *qr*, being put through a slit made in the stage, a small brass bolt *s*, under the stage, must be shoved inwards, till a smaller slit in it embraces the neck of the said button; and then the fish being laid upon this glass, and covered with the leaden coffin *V*, (*fig. 1.*) its tail may be brought exactly under the object-glass by turning the glass *p q* about the button, or by shoving it inwards or outwards along the slit in the stage. The circular object-plate *v x* has a like button in its centre, to be put into the same slit as before; and then the different objects, placed between two talcs in the holes made round the circumference of the plate, may be viewed successively by turning the plate about its centre.

All these transparent objects are illuminated extremely well in this microscope, either by candle-light or sky-light reflected upwards from a concave looking-glass *y z*, placed in a frame from the centre *b* of the pedestal. While you are viewing the object through the microscope, turn this concave upon its horizontal poles *y z*, and you will soon find out that position of it in which it reflects the most light through the hole in the stage upon the object; and this happens when it reflects the rays very obliquely. Opaque objects, when laid upon a black ebony or a white ivory plate, put into the hole upon the stage, may be illuminated by candle-light transmitted through a double convex lens *αβ*; the stem of the frame *αε*, in which it turns, being put into the hole in the stage. The candle must be placed in a line drawn from the object through the middle of this lens, at such a distance from it as

MICROSCOPE.

shall cause the spot of light upon the object-plate to be the narrowest. By day-light this lens gives little or no advantage to the direct sky-light.

Mr. Adams, in his "Essays," has described an improvement of this kind of microscope, which is as follows: A B (*Plate XIV. fig. 1.*) represents the body of the microscope, containing a double eye-glass and a body-glass: it is here shewn as screwed to the arm C D, from whence it may be occasionally removed, either for the convenience of packing, or when the instrument is to be used as a single microscope.

The eye-glasses and the body-glasses are contained in a tube which fits into the exterior tube A B; by pulling out a little this tube when the microscope is in use, the magnifying power of each lens is increased.

The body A B of the microscope is supported by the arm C D; this arm is fixed to the main pillar C F, which is screwed firmly to the mahogany pedestal G H; there is sometimes a drawer to this pedestal, which holds the apparatus.

N I S, the plate or stage which carries the slider-holder K L: this stage is moved up or down the pillar C F, by turning the milled nut M; this nut is fixed to a pinion, that works in a toothed rack cut on one side of the pillar. By means of this pinion, the stage may be gradually raised or depressed, and the object adjusted to the focus of the different lenses.

K L is a slider-holder, which fits into a hole that is in the middle stage N I S; it is used to confine and guide either the motion of the sliders which contain the objects, or the glass tubes that are designed to confine small fishes for viewing the circulation of the blood. The sliders are to be passed between the two upper plates, the tubes through the bent plates.

L is a brass tube, to the lower part of which is fixed the condensing lens for concentrating the light reflected up from the mirror O; it fits into the under part of the slider-holder K L, and may be set at different distances from the object, according to its distance from the mirror or the candle.

O is the frame which holds the two reflecting mirrors, one of which is plane, the other concave. These mirrors may be moved in various directions, in order to reflect the light properly, by means of the pivots on which they move, in the semicircle Q S R, and the motion of the semicircle itself on the pin S: the concave mirror generally answers best in the day-time; the plane mirror combines better with the condensing lens, and a lamp or candle. At D there is a socket for receiving the pin of the arm Q (*fig. 2.*) to which the concave speculum R, for reflecting light on opaque objects, is screwed. At S is a hole and slit for receiving either the nippers *abc* (*fig. 7.*), or the fish-pan (*fig. 8.*); when these are used, the slider-holder must be removed. A hole is made in the opposite side of the stage to receive the pin *g* of the convex lens S, *fig. 3.*

To use this microscope: Take it out of the box. Screw the body into the round end of the upper part of the arm C D. Place the brass sliders, which contain the magnifiers, into the dove-tailed slit which is on the under side of the aforesaid arm, as seen at E, and slide it forwards until the magnifier you mean to use is under the centre of the body: opposite to each magnifier in this slit there is a notch, and in the dove-tailed part of the arm C D there is a spring, which falls into the above-mentioned notch, and thus makes each magnifier coincide with the centre of the body. Pass the ivory slider you intend to use between the upper plates of the slider-holder K L, and then reflect as strong a light as you can on the object by means of one of the mirrors; after this, adjust the object to the focus of the magnifier and your eye, by turning the milled screw M, the motion of which raises and depresses the stage N I S. The degree of light necessary for each object, and the accuracy required in the adjustment

of the lenses to their proper focal distance from the object, will be easily attained by a little practice.

When *opaque* objects are to be examined, remove the slider-holder, and place the object on a flat glass, or fix it in the nippers (*fig. 7.*); the pin *c* of these fits into the hole on the stage; screw the concave speculum R into the arm Q (*fig. 2.*) and then pass the pin of this arm through the socket D, (*fig. 1.*) the light is now to be reflected from the concave mirror to the silver speculum, and from this down on the object. No exact rule can be given for reflecting the light on the object; we must therefore refer the reader to the mother of all aptness, practice. The speculum must be moved lower or higher, to suit the focus of the different magnifiers and the nature of the object.

The foregoing directions apply equally to the using of this instrument as a *single* microscope; with this difference only, that the body A B is then removed, and the eye is applied to the upper surface of the arm C D, exactly over the magnifiers.

This microscope is sometimes made with the following *alterations*, which are supposed to render it still more convenient and useful. The arm C D that carries the body and magnifiers is made both to turn on a pin, and to slide backwards and forwards in a socket at C; so that, instead of moving the objects below on the stage, and disturbing them, the magnifiers are more conveniently brought over any part of the objects as desired. The condensing glass is made larger, and slides upon the square bar C F quite distinct from the stage, like the mirrors below; and it is thereby made useful for any other objects that may be applied on glasses fitted to the stage, as well as those put into the slider-holder K. It is thereby not confined to this stage alone, as in the preceding. When the body A B is taken away, the arm C D may be slipped away from its bar, with the magnifiers, and the forceps, wire, and joint, applied to it as at *fig. 7.*; and it thereby serves the purpose of a small hand angle or opaque microscope, for any object occasionally applied to this wire. The magnifiers in the slider E are mounted in a wheel case, which perhaps prevents its being in the way so much as the long slider E before described. This contrivance is represented in *fig. 5.* and separated in *fig. 4.*

Mr. Martin's new universal compound microscope, which combines the uses and advantages of the single, compound, opaque, and aquatic microscopes, as now constructed by the opticians of London, is represented in *fig. 5.* A, B, D, is the body of the microscope; which consists of four parts, *viz.* A B the eye-piece, or that containing the eye-glasses, and is screwed into the top of a moveable or sliding tube which contains the body-glass screwed into its lower part. D is the exterior tube or case, in which the other slides up and down in an easy and steady manner. This motion of the interior tube is useful to increase or decrease the magnifying power of the body-glass when thought necessary, as before-mentioned. E is a pipe or snout screwed on to the body of the microscope D, and at its lower part, over the several magnifying lenses hereafter described. F G H I is the square stem of the microscope, upon which the stage R moves in an horizontal position, upward or downward, by means of the fine rack-work of teeth and pinion. K L is a strong solid joint and pillar, by which the position of the instrument is readily altered from a vertical one to an oblique or to a perfectly horizontal one, as may be required: it is thus well adapted to the ease of the observer either sitting or standing; and as it is very often convenient to view objects by direct unreflected light, when the square stem F I is placed in an horizontal position for this purpose, the mirror T is then to be taken off in order to prevent the obstruction of

MICROSCOPE.

the rays. N O P, the tripod or foot by which the whole body of the microscope is steadily supported; these three arms fold up under each other at N, when packed into the case. W is a brass frame, that contains the condensing lens, and acts in conjunction with the large concave and plane mirrors below at T; the reflected rays from which, either of the common light or of that of a candle or lamp, it agreeably modifies, and makes steady in the field of view.

The particulars of the apparatus to this microscope are as follow: Q (see also *fig. 4.*) is a circular brass box, containing six magnifiers or object lenses, numbered 1, 2, 3, 4, 5, 6; the digits of which appear severally through a small round hole *y*, (*fig. 4.*) in the upper plate of it. To the upper side is fixed a small circle of brass *z*, by which it is connected with, and screwed into, the round end of the arm *abcd*; which is a long piece of brass, and moves through either by teeth or pinion, or not, as may be desired, in *ef*; which is a socket on the upper part of the pillar, and admits, with a motion both easy and steady, the brass arm. R is a fixed stage, upon which the objects to be viewed are to be placed: it is firmly fastened to the square pillar, which is moved by the rack-work. In the middle is a large circular hole, for receiving concave glasses, with fluids, &c. it has also a sliding spring-frame to fasten down slips of glass or other things: at *q t x* are three small sockets or holes, intended to receive several parts of the apparatus. S is the refractor, or illuminating lens, for converging the sun's rays upon opaque objects laid upon the stage R. On it may be fixed, as in *fig. 3.* to move in a semi-circle, fixing its long shank *g*, in a spring socket *h*, in the arm *t*; this arm moving every way by a stout pin *k* in the socket *t* of the stage. In this manner it is easily adjusted to any position of the sun, candle, &c.—T, the reflecting-glass frame, containing a concave and plane speculum, which is moved upon the square pillar by the hand. The use of it is to illuminate all transparent objects that are applied to the stage above.

Besides the apparatus represented, there is an auxiliary moveable stage; which by means of a pin is placed in the hole *t* of the stage R, and can be moved in an horizontal direction over the whole field of the stage. In this stage, there are three circular holes with shouldered bottoms; a large one in the middle, and on each side a small one, for the reception of the three following necessary articles: a watch-glass to be placed in the large hole, to hold fluids containing animalcules, &c.; a circular piece of ivory, one side of which is black, the other white, to support opaque objects of different contrived colours; and circular plane and concave glasses, for extemporaneous transparent objects.—The same use is made of the two small holes as of the large one, only in a lesser degree, to receive small concave glasses, plates, &c.

L (*fig. 6.*) is the silvered speculum, called a *Lieberkhun*, which makes the single opaque microscope, by being screwed to the slider *abc* (*fig. 5.*) in room of the box of lenses Q, and the body A E above it. The chief use of this is to view very small objects strongly illuminated near the compounded focus of the mirror T (*fig. 5.*) In *fig. 7.* are the forceps or pliers, for holding such kind of objects, and by which they can be applied very readily to the focus of the lens in the Lieberkhun. They have a motion all ways by means of the spring socket *a*, the joint *b*, and the shank *c*: they are placed with the pin *c* in the socket *t* of the fixed stage R (*fig. 5.*) and *7* is a small piece of ivory, to be placed upon the pointed end of the pliers: it is black upon one side, and white upon the other, to receive opaque objects.

R (*fig. 2.*) is a Lieberkhun of a larger size than that first mentioned, with a hole in its centre: this is screwed into

the hole Q of a brass ring, fastened to a long wire *d*; which moves up and down in the spring socket *x* of the stage R, (*fig. 5.*) in which it also moves sideways; and thus, with the body A E above, forms an *aquatic compound microscope* for showing all sorts of objects in water and other fluids placed under it in a watch-glass on the stage.

Sometimes a cone is used, with a proper aperture to exclude superfluous light, that would disturb a critical observation of a curious object; it is screwed to the under side of the fixed stage R.

There is what is usually called a *bug-box*, consisting of a concave glass with a plane one screwed over it; by means of which a bug, louse, flea, &c. may be secured and viewed alive. It is to be placed on the stage R.

Fig. 8. is the fish-pan. In the long concave body *a b*, a fish may be so confined by the ribband *c*, that the transparent tail may be in part over the slit or hole at *d*. In this state, it is placed on the stage R, with the pin *d* in the hole *t* of the stage, and moves freely and horizontally for viewing the circulation of the blood, &c.

A slider-holder may be placed on the stage R: it receives the sliders and tubes when filled with transparent objects, to be viewed either by the compound or single microscope.

Fig. 9. represents the ivory slider, to hold the objects between the tales as usual.

Fig. 10. is a useful auxiliary slider framed in brass. In this slider small concave glasses are cemented; and a slip of plane glass slides over them; by which any small living object, as mites, &c. may be confined without injury, and deliberately viewed.

The instrument has a set of glass tubes, three in number, one within another; they are useful for small tadpoles, water-nets, eels, &c. when the circulation of the blood is to be viewed. There is a small hole at one end of each tube, that serves to admit the air; for when they are filled with water, the other end is stopped with a cork.

A small ivory box, containing spare tales and wires, to supply the sliders with occasionally.

X, (*fig. 6.*) is a brass cell or button, containing a very small lens, properly set between two small plates of brass, that it may be brought very near to the object when viewed with it as a single microscope. This magnifier is screwed into the same hole as the wheel of six magnifiers Q are in *fig. 5.*

There is a lens, adapted to view and examine objects, by magnifying them sufficiently, so as to be able to apply them to the microscope for inspection: on this account it is called the *explorator*.

The preceding are the chief articles of the apparatus; which, on account of their being somewhat different from what is applied to other microscopes, we have been thus particular in describing. In using the microscope, and while viewing objects by either the single or compound instrument, the focal distances of the magnifiers are made perfectly exact by turning of the pinion at the nut *w*, in one way or the other, very gently in the teeth of the rack-work at the front of the bar F I.

It is necessary that the centres of the object lenses or magnifiers, the stage, and the mirrors at bottom, should all be in a right line in the axis of the microscope, when opaque objects are to be viewed, that are placed upon the ivory plate *7*, or the forceps, and all other such sorts of objects which are placed in the centre of the stage R, or the slider-holder: but when aquatic or living objects, which require a great space to move in, are to be viewed, then the horizontal motion at *ef* (*fig. 5.*) is made use of, and the view may be extended laterally over the whole of the diameter of the object or field of view; and by putting the arm *a b c* forward

MICROSCOPE.

or backward in its socket *ef*, the view is extended in the contrary direction equally well; and in this manner the whole of the objects may be viewed without the least disturbance.

As the brass arm *abc* may be brought to the height of three or four inches above the stage R; so, by means of the rack-work motion of the stage, a lens of a greater focal distance than the greatest in the wheel Q may be occasionally applied in place of the wheel, and thereby the larger kind of objects be viewed; the instrument becoming, in this case, what is called a *megascopæ*. Two sizes of these lenses, furnished with Lieberkhuns, are shewn at L M, *fig. 6*.

In viewing moving living objects, or even fixed ones, when nice motions are requisite, a rack-work and pinion is often applied to the arm *abc*: the arm is cut out with teeth; and the pinion, as shewn at Y, is applied to work it. This acts but in one direction; and, in order to produce an equally necessary motion perpendicular to this, rack-work and pinion is applied tangent-wise to the stage, which is then jointed.

To fit microscopes, as well as telescopes, to short-sighted eyes, the object-glass and the eye-glass must be placed a little nearer together, so that the rays of each pencil may not emerge parallel, but may fall diverging upon the eye.

MICROSCOPE, *Reflecting*, is properly that which magnifies by reflection, as the above-mentioned ones do by refraction.

The structure of such a microscope may be conceived thus: near the focus of a concave speculum, AB (*Plate XIII. fig. 3*.) place a minute object C, that its image may be formed larger than itself in D; to the speculum join a lens, convex on both sides, EF, so as the image D may be in its focus.

The eye will here see the image inverted, but distinct, and enlarged; consequently, the object will be larger than if viewed through the lens alone.

The inventor of this microscope is the great sir I. Newton; but the objects appear dim in it.

Any telescope is converted into a microscope, by removing the object-glass to a greater distance from the eye-glass. And since the distance of the image is various, according to the distance of the object from the focus; and it is magnified the more, as its distance from the object-glass is greater; the same telescope may be successively converted into microscopes, which magnify the object in different degrees.

The construction of this microscope is more particularly explained in *fig. 4*, in which, instead of the lens *def*, there is placed a small speculum *def*; so that the object *acb* being placed above it, at a little greater distance from the focus *g*, has its image ACB, formed by reflection, as in the other case it was by refraction, through the lens *df*. Now if we suppose the focal distance of the object speculum *def*, and lens *def* the same, the effect of the microscope in other respects will be the same also.

For the distance of the object *ab* above the speculum, will be equal to the distance of the object *ab* below the lens, in order that the image may be formed at the same distance *ce*. The position of the object will be inverted; for all the rays flowing from the point *a*, will be reflected by the speculum to the point A, in the same manner as if they came by refraction through the lens from the point *a*. Thus the part *b* in the object will be reflected to the focus B in the image, which, therefore, is inverted. The power of magnifying will also be the same in this and in the reflecting telescope of a similar construction. For since the image AB and the object *ab* are seen under equal angles from the vertex *e* of the speculum, the triangles *acb*, and A*CB* will be similar, and therefore $AB : ab :: Ce : ce$; but in the other it is $AB : a b :: Ce : ce$. But the latter ratio of these analogies is the same in both, and consequently the first is so too. This microscope is not so easy to manage as the common sort. For vision by reflection,

as it is much more perfect, so it is far more difficult than that by refraction. Nor is this microscope so useful for any but very small or transparent objects. For the object, being between the speculum and image, would, if it were large and opaque, prevent a due reflection.

In Dr. Smith's reflecting microscope there are two reflecting mirrors, one concave and the other convex, and the image is viewed by a lens. To explain it, let AD (*fig. 5*.) be a large concave speculum, and *ada* a small convex one, each perforated in the middle with the holes BC, *bc*. Both these are segments of the same sphere, or ground on tools of an equal radius, *viz.* of two inches, that so the focal distance of each speculum may be just one inch.

These two speculums are placed at the distance of about $1\frac{1}{2}$ inch from each other, that so an object OPQ, being placed a little below the smaller speculum, might be between the focus F and centre E of the larger speculum. Things thus circumstanced, the rays PA, PD, which flow from the point P in the object, on the speculum AD, will be reflected towards a focus *p*; where an image *opq* would be formed, if the rays were not intercepted by the convex speculum *ad*; and the point *p* being nearer than its focus *f*, the rays A*a*, D*d*, which tend or converge towards it, will be reflected to a focus P, where the last image, OPQ, will be formed, to be viewed through the eye-glass G, by the eye at I.

This microscope, though far from being executed in the best manner, performed, Dr. Smith says, nearly as well as the very best refracting microscopes; so that he did not doubt, but that it would have excelled them, if it had been executed properly. Dr. Smith's own account of this instrument may be seen in his Optics, Remarks, p. 94.

MICROSCOPE, *Solar*, called also the *camera obscura* microscope, was invented by Mr. Lieberkuhn in 1738 or 1739, and is composed of a tube, a looking-glass, a convex lens, and a Wilson's microscope. The tube *e* (*fig. 6*.) is brass near two inches in diameter, fixed in a circular collar of mahogany, with a groove on its periphery on the outside, denoted by 2, 3, and connected by a cat-gut to the pulley 4 on the upper part; which turning round at pleasure, by the pin 5 within, in a square frame, may be adjusted easily to a hole in the shutter of a window, by the screws 1, 1, in such a manner that no light can pass into the room, but through the aforesaid tube *e*. Fastened to the frame by hinges, on the side that goes without the window, is a looking-glass G, which, by means of a jointed brass-wire, 6, 7, and the screw H 8, coming through the frame, may be moved either vertically or horizontally, to throw the sun's rays through the brass tube into the darkened room. The end of the brass tube without the shutter has a convex lens, 5, to collect the rays, thrown on it by the glass G, and bring them to a focus in the other part, where D is a tube sliding in and out, to adjust the object to a due distance from the focus; and to the end G of another tube F, is screwed one of Wilson's simple pocket microscopes, containing the object to be magnified in a slider; and by the tube F, sliding on the small end E of the other tube D, it is brought to a true focal distance.

The solar microscope has been introduced into the small and portable, as well as the large camera obscura; and if the image be received upon a piece of half-ground glass, shaded from the light of the sun, it will be sufficiently visible. M. Lieberkuhn made considerable improvements in his solar microscope, particularly in adapting it to the view of opaque objects; and M. Æpinus, Nov. Com. Petrop. vol. ix. p. 326, has contrived, by throwing the light upon the fore-side of any object, before it is transmitted through

MICROSCOPE.

the object lens, to represent with equal advantage all kinds of objects by it. In this improvement, the body of the common solar microscope is retained, and only an addition made of two brass plates, CA and BA (*fig. 7.*) joined by a hinge, and kept at a proper distance by a screw. A section of these plates, and of all the necessary parts of the instrument, may be seen in *fig. 8.*, where *c, a.* represent rays of the sun converging from the illuminating lens, and falling upon the mirror *db*, which is fixed to the nearer of the brass plates. From this they are thrown upon the object at *ef*, and thence are transmitted through the object lens at K, and a perforation in the farther plate, upon a screen, as usual. The use of the screw *n* is to vary the distance of the two plates, and thereby to adjust the mirror to the object with the greatest exactness. A very considerable improvement may be made in the solar microscope, by substituting Ramsden's achromatic eye-piece instead of the convex object-lens. For M. Euler's method of introducing vision by reflected light into this microscope, see *MAGIC lantern.*

An improved solar microscope, as used with the improved single microscope, with teeth and pinions, is exhibited in *Plate XV. figs. 1, 2, and 3.* The former figure represents the whole form of the single microscope; the parts of which are as follows: ABCD the external tube; GHIK the internal moveable one; QM part of another tube within the last, at one end of which is fixed a plate of brass hollowed in the middle, for receiving the glass tubes: there is also a moveable flat plate, between which, and the fixed end of the second tube, the ivory sliders are to be placed. L, a part of the microscope, containing a wire spiral spring, keeping the tube QM with its plates firm against the fixed part I K of the second tube.

E F is the small rack-work of teeth and pinions, by which the tube I G is moved gradually to or from the end A B, for adjusting the objects exactly to the focus of different lengths. NO is a brass slider, with six magnifiers; any one of which may easily be placed before the object. It is known when either of the glasses is in the centre of the eye-hole, by a small spring falling into a notch in the side of the slider, made against each of the glasses. Those parts of the apparatus before described, viz. iron-sliders, with holder, glass tubes, forceps, Lieberkhuns, buttons, &c. &c. are made use of to this microscope. GH is a brass cell, which holds an illuminating glass for converging the sun's beams, or the light of a candle strongly upon the objects. The aperture of the glass is made greater or less, by two circular pieces of brass, with holes of different sizes, that are screwed separately over the said lens. But at times, objects appear best, when the microscope is held up to the common light only, without this glass. It is also taken away when the microscope is applied to the apparatus now to be described.

Fig. 2. represents the apparatus, with the single microscope screwed to it, which constitutes the solar microscope. A B is the inner moveable tube, to which the single microscope is screwed. CD is the external tube, containing a condensing convex glass at the end D, and is screwed into the plate E F, which is cut with teeth at its circumference, and moved by the pinion I, that is fixed with the plate G H. This plate is screwed fast against the window-shutter, or board fitted to a convenient window of a darkened room, when the instrument is used. KL is a long frame, fixed to the circular plate E F; containing a looking-glass or mirror for reflecting the solar rays through the lens in the body of the tube D. O is a brass milled head, fastened to a worm or endless screw; which on the outside turns a

small wheel, by which the reflecting mirror M is moved upwards or downwards.

In using this microscope, the square frame GH is first to be screwed to the window-shutter, and the room well darkened: which is best done by cutting a round hole of the size of the moveable plate E F, that carries the reflector, in the window-shutter or board; and by means of two brass nuts *a, a.* let into the shutter to receive the screws P, P, when placed through the holes in the square frame GH, at the two holes Q, Q; which will firmly fasten the microscope to the shutter, and is easily taken away by only unscrewing the screws P, P.

A white paper screen, or white cloth to receive the images, is to be placed several feet distant from the window: which will make the representations the larger in proportion to the distance. The usual distances are from six to 16 feet.

The frame KL, with its mirror M, is to be moved by turning the pinion I, one way or the other, till the beams of the sun's light come through the hole into the room: then, by turning of the worm at O, the mirror must be raised or depressed, till the rays become perfectly horizontal, and go straight across the room to the screen. The tube CD, with its lens at D, is now to be screwed into the hole of the circular plate E F: by this glass the rays will be converged to a focus; and from thence proceed diverging to the screen, and there make a large circle of light. The single microscope, (*fig. 1.*) is to be screwed on to the end A B (*fig. 2.*) of the inner tube; and the slider NO, with either of the lenses marked 1, 2, 3, 4, 5, or 6, in the centre of the hole at the end A B. This will occasion a circle of light upon the screen much larger than before. The slider or glass tube, with the objects to be viewed, is to be placed between the plates at I K against the small magnifier, and moved at pleasure. By shifting the tube A B in or out, you may place the object in such a part of the condensed rays as shall be sufficient to illuminate it, and not scorch or burn it; which will generally require the glass to be about one inch distant from the focus. It now remains only to adjust the object, or to bring it so near to the magnifier that its image formed upon the screen shall be the most distinct or perfect: and it is effected by gently turning the pinion F, (*fig. 1.*) a small matter one way or the other. If the object be rather large in size, the least magnifiers are generally used, and *vice versa*.

N^o 1. is the greatest magnifier, and N^o 6. the least, in the brass slider NO. But, if desired, single lenses of greater magnifying powers are made: and they are applied, by being screwed to the end A B, (*fig. 1.*) and the brass slider NO is then taken away.

The same object may be variously magnified, by the lenses severally applied to it; and the degree of magnifying power is easily known by this rule: *As the distance of the object is to that of its image from the magnifier; so is the length or breadth of the object to that of the image.*

Instead of the brass sliders with the lenses N, O; there is sometimes screwed a lens of a large size, and longer focal distance: the instrument is then converted into a *megascroscope*; and is adapted for viewing the larger kind of objects contained in larger sliders, such as is represented at R (*fig. 3.*) And, in the same manner, small objects of entertainment, painted upon glass like the sliders of a magic lantern; are much magnified, and represented upon the same screen.

The *lucernal* microscope of Mr. Adams, as mounted to view opaque objects, is represented in *fig. 4.* ABCD is a large mahogany pyramidal box, which forms the body of the microscope; it is supported firmly on the brass pillar

MICROSCOPE.

F, G, by means of the socket H and the curved piece I K.

L M N is a guide for the eye, in order to direct it in the axis of the lenses; it consists of two brass tubes, one sliding within the other, and a vertical flat piece, at the top of which is the hole for the eye. The outer tube is seen at M N, the vertical piece is represented at L M. The inner tube may be pulled out or pushed in, to adjust it to the focus of the glasses. The vertical piece may be raised or depressed, that the hole, through which the object is to be viewed, may coincide with the centre of the field of view; it is fixed by a milled screw at M, which could not be shewn in this figure.

At N is a dove-tailed piece of brass, made to receive the dove-tail at the end of the tubes M, N, by which it is affixed to the wooden box A B C D E. The tubes M, N, may be removed from this box occasionally, for the convenience of packing it up in a less compass.

O P, a small tube which carries the magnifiers.

O, one of the magnifiers; it is screwed into the end of a tube, which slides within the tube P; the tube P may be unscrewed occasionally from the wooden body.

Q R S T V X, a long square bar, which passes through the sockets Y, Z, and carries the stage or frame that holds the objects; this bar may be moved backward or forward, in order to adjust it to the focus by means of the pinion which is at *a*.

b, a handle furnished with an universal joint, for more conveniently turning the pinion. When the handle is removed, the nut (*fig. 5.*) may be used in its stead.

d, a brass bar, to support the curved piece K I, and keep the body A B firm and steady.

f g h i, the stage for opaque objects: it fits upon the bar Q R S T by means of the socket *h i*, and is brought nearer to or removed farther from the magnifying lens by turning the pinion *a*: the objects are placed in the front side of the stage (which cannot be seen in this figure) between four small brass plates: the edges of two of these are seen at *k l*. The two upper pieces of brass are moveable; they are fixed to a plate, which is acted on by a spiral spring, that presses them down, and confines the slider with the objects: this plate, and the two upper pieces of brass, are lifted up by the small nut *m*.

At the lower part of the stage, there is a semicircular lump of glass *n*, which is designed to receive the light from the lamp (*fig. 29.*), and to collect and throw it on the concave mirror *o*, whence it is to be reflected on the object.

The upper part *f g r s* (*fig. 4.*) of the opaque stage taken out, that the stage for transparent objects may be inserted in its place.

Fig. 6. represents the stage for transparent objects; the two legs 5 and 6 fit into the top of the under part *r s h i* of the stage for opaque objects; 7 is the part which confines or holds the sliders, and through which they are to be moved; 9 and 10 a brass tube, which contains the lenses for condensing the light, and throwing it upon the object: there is a second tube within that, marked 9 and 10, which may be placed at different distances from the object by the pin 11.

When this stage is used as a single microscope, without any reference to the lucernal, the magnifiers, or object lenses, are to be screwed into the hole 12, and to be adjusted to a proper focus by the nut 13.

N. B. At the end A B (*fig. 4.*) of the wooden body there is a slider, which is represented as partly drawn out at A; when quite taken out, three grooves will be perceived; one of which contains a board that forms the end

of the box; the next contains a frame with a greyed glass; and the third, or that farthest from the end A B, two large convex lenses.

In the use of this microscope for examining opaque objects, take out the wooden slider A (*fig. 4.*), then lift out the cover and the grey glass from their respective grooves under the slider A.

Put the end N of the guide for the eye L M N into its place, so that it may stand in the position which is represented in this figure.

Place the socket, which is at the bottom of the opaque stage, on the bar Q X T, so that the concave mirror *o* may be next the end D E of the wooden body.

Screw the tubes P, O, into the end D E. The magnifier you intend to use is to be screwed on the end O of these tubes.

The handle G *b*, or the milled nut (*fig. 5.*), must be placed on the square end of the pinion *a*.

Place the lamp lighted before the glass lump *n*, and the object you intend to examine between the spring-plates of the stage; and the instrument is ready for use.

In all microscopes there are two circumstances, which must be particularly attended to: first, the modification of the light, or the proper quantity to illuminate the object; secondly, the adjustment of the instrument to the focus of the glasses and eye of the observer. In the use of the lucernal microscope there is a third circumstance, which is, the regulation of the guide for the eye.

1. To throw the light upon the object. The flame of the lamp is to be placed rather below the centre of the glass lump *n*, and as near it as possible; the concave mirror *o* must be so inclined and turned as to receive the light from the glass lump, and reflect it thence upon the object: the best situation of the concave mirror and the flame of the lamp depends on a combination of circumstances, which a little practice will discover.

2. To regulate the guide for the eye, or to place the centre of the eye-piece L so that it may coincide with the focal point of the lenses and the axis of vision: Lengthen and shorten the tubes M, N, by drawing out or pushing in the inner tube, and raising or depressing the eye-piece M L, till you find the large lens (which is placed at the end A B of the wooden body) filled by an uniform field of light, without any prismatic colours round the edge; for till this piece is properly fixed, the circle of light will be very small, and only occupy a part of the lens: the eye must be kept at the centre of the eye-piece L, during the whole of the operation; which may be rendered somewhat easier to the observer, on the first use of the instrument, if he hold a piece of white paper parallel to the large lens, removing it from or bringing it nearer to them till he find the place, where a lucid circle, which he will perceive on the paper, is brightest and most distinct; then he is to fix the centre of the eye-piece to coincide with that spot; after which a very small adjustment will set it perfectly right.

3. To adjust the lenses to their focal distance. This is effected by turning the pinion *a*, the eye being at the same time at the eye-piece L. The grey glass is often placed before the large lenses, while regulating the guide for the eye, and adjusting for the focal distance.

If the observer in the process of his examination of an object, advance rapidly from a shallow to a deep magnifier, he will save himself some labour by pulling out the internal tube at O.

The upper part *f g r s* of the stage is to be raised or lowered occasionally, in order to make the centre of the object coincide with the centre of the lens at O.

MICROSCOPE.

To delineate objects, the grey glass must be placed before the large lenses; the picture of the object will be formed on this glass, and the outline may be accurately taken by going over the picture with a pencil.

The opaque part may be used in the day-time without a lamp, provided the large lenses at A B are screened from the light.

To use the Lucernal Microscope in the Examination of transparent Objects.—The instrument is to remain as before: the upper part *fgs* of the opaque stage must be removed, and the stage for transparent objects, represented at *fig. 6*, put in its place; the end *g 10* to be next the lamp.

Place the greyed glass in its groove at the end A B, and the objects in the slider-holder at the front of the stage; then transmit as strong a light as you are able on the object, which you will easily do by raising or lowering the lamp.

The object will be beautifully depicted on the grey glass: it must be regulated to the focus of the magnifier, by turning the pinion *a*.

The object may be viewed either with or without the guide for the eye. A single observer will see an object to the greatest advantage by using this guide, which is to be adjusted, as we have described above. If two or three wish to examine the object at the same time, the guide for the eye must be laid aside.

Take the large lens out of the groove, and receive the image on the grey glass; in this case, the guide for the eye is of no use: if the grey glass be taken away, the image of the object may be received on a paper screen.

Take out the grey glass, replace the large lenses, and use the guide for the eye; attend to the foregoing directions, and adjust the object to its proper focus. You will then see the object in a blaze of light almost too great for the eye, a circumstance that will be found very useful in the examination of particular objects. The edges of the object in this mode will be somewhat coloured: but as it is only used in this full light for occasional purposes, it has been thought better to leave this small imperfection, than, by remedying it, to sacrifice greater advantages; the more so, as this fault is easily corrected, and a new and interesting view of the object is obtained, by turning the instrument out of the direct rays of light, and permitting them to pass through only in an oblique direction, by which the upper surface is in some degree illuminated, and the object is seen partly as opaque, partly as transparent. It has been already observed, that the transparent objects might be placed between the slider-holders of the stage for opaque objects, and then be examined as if opaque.

Some transparent objects appear to the greatest advantage when the lens at *g 10* is taken away; as, by giving too great a quantity of light, it renders the edges less sharp.

The variety of views which may be taken of every object, by means of the improved lucernal microscope, will be found to be of great use to an accurate observer: it will give him an opportunity of correcting or confirming his discoveries, and investigating those parts in one mode which are invisible in another.

To throw the Image of transparent Objects on a Screen, as in the Solar Microscope.—It has been long a microscopical desideratum, to have an instrument by which the image of transparent objects might be thrown on a screen, as in the common solar microscope: and this not only because the sun is so uncertain in this climate, and the use of the solar microscope requires confinement in the finest part of the day, when time seldom hangs heavy on the mind; but as it also affords an increase of pleasure, by displaying its wonders to several

persons at the same instant, without the least fatigue to the eye. This purpose is now effectually answered, by affixing the transparent stage of the lucernal to a lantern, with one of Argand's lamps.—The lamp is placed within the lantern, and the end *g 10* of the transparent stage is screwed into a female screw, which is rivetted in the sliding part of the front of the lantern; the magnifying lenses are to be screwed into the hole represented at *12*, and they are adjusted by turning the milled nut. The quantity of light is to be regulated by raising and lowering the sliding plate or the lamp.

Apparatus which usually accompanies the improved Lucernal Microscope.—The stage for opaque objects, with its semicircular lump of glass, and concave mirror. The stage for transparent objects, which fits on the upper part of the foregoing stage. The sliding tube, to which the magnifiers are to be affixed: one end of these is to be screwed on the end D of the wooden body; the magnifier in use is to be screwed to the other end of the inner tube. There are eight magnifying lenses, so constructed, that they may be combined together, and thus produce a very great variety of magnifying powers. A fish-pan, such as is represented at *Plate XIV. fig. 8*. A steel wire, with a pair of nippers at one end, and a small cylinder of ivory at the other. (*Plate XIV. fig. 7.*) A slider of brass, containing a flat glass slider, and a brass slider, into which are fitted some small concave glasses. A pair of forceps. Six large, and six small ivory sliders, with transparent objects. Fourteen wooden sliders, with four opaque objects in each slider; and two spare sliders. Some capillary tubes for viewing small animalcula. One of the improved Argand lamps, which are the most suitable for microscopic purposes, either with this or any other instrument, on account of the clearness, intensity, and steadiness of the light. A description of its structure will be found under the article LAMP.

The Microscope for opaque objects was also invented by M. Lieberkuhn about the same time with the former, and remedies the inconvenience of having the dark side of an object next the eye; for by means of a concave speculum of silver, highly polished, in whose centre a magnifying lens is placed, the object is so strongly illuminated, that it may be examined with ease. A convenient apparatus of this kind, with four different speculums and magnifiers of different powers, was brought to perfection by Mr. Cuff. *Phil. Trans. N^o 458. § 9.*

The several parts of this instrument, made either of brass or silver, are as follows:

Through the first side A (*Plate XV. fig. 7.*) passes a fine screw B, the other end of which is fastened to the moveable side C.—D is a nut adapted to the said screw, by the turning of which the two sides A, C, are gradually brought together.—E is a spring of steel, that separates the said two sides when the nut is unscrewed.—F, a piece of brass turning round in a socket, whence proceeds a small spring tube moving upon a rivet, through which tube there runs a steel wire, one end of which terminates in a sharp point G, and the other hath a pair of plyers, H, fastened to it.—The point and plyers are to thrust into or take up and hold any insect or object: and either of them may be turned upwards, as suits your purpose best.—I, a ring of brass with a female screw within it, mounted on an upright piece of the same metal, which turns round on a rivet, that it may be set at a due distance when the least magnifiers are employed.—This ring receives the screws of all the magnifiers.—K, a concave speculum of silver, polished as bright as possible, in the centre of which a double convex lens is placed, with a proper aperture to look through it. On the back of this speculum a male screw,

screw, L, is made fit to the brass ring I to screw into the said ring at pleasure.

There are four of these concave specula, of different depths, adapted to four glasses of different magnifying powers, to be used as objects to be examined may require. The greatest magnifiers are known by having the least apertures. M, a round object-plate, one side white and the other black, intended to render objects the more visible, by placing them, if black upon the white, and if white on the black side. A steel spring N turns down on each side to make any object fast; and issuing from the object-plate is a hollow pipe, to screw it on the needle's point G.—O, a small box of brass, with a glass on each side, contrived to confine any living object, in order to examine it: this also has a pipe to screw upon the end of the needle G.—P, a turned handle of wood, to screw into the instrument when it is made use of.—A pair of brass plyers accompanies this instrument to take up any object, or manage it with convenience: and a soft hair brush, to clean the glasses or specula, or apply a drop of any liquid to the insides of the box O, in order to view the animalcules.—Also, a small ivory box for insid-glasses, to be placed, when wanted, in the small brass box O.

When you would view any object, screw the speculum, with the magnifier you think best to use, into the brass ring I. Place your object either on the needle G, in the plyers H, on the object-plate M, or in the brass hollow box O, as may be most convenient, according to the nature and condition of it: then holding up your instrument by the handle P, look again! the light, through the magnifying lens, and by means of the nut, D, together with the motion of the needle, by managing its lower end the object may be turned about, raised, or depressed, brought nearer the glass, or put farther from it, till you hit the true focal distance, and the light be seen reflected from the speculum strongly upon the object: by which means it will be shewn in a manner surprisingly distinct and clear. And for this purpose the light of the sky, or of a candle, will answer to your satisfaction.

This microscope is principally intended for opaque objects, but transparent ones may also be viewed by it: observing only, that when such come under examination, it will not always be proper to throw on them the light reflected from the speculum: for the light transmitted through them, meeting the reflected light, may, together, produce too great a glare. A little practice will teach how to regulate both these lights to good advantage. For an account of microscopes attached to astronomical instruments, and designed for assisting the observer to read off minute divisions; see CIRCLE.

MICROSCOPIC OBJECTS. All things too minute to be viewed distinctly by the naked eye, are proper objects for the microscope. Dr. Hooke has distinguished them to be exceeding small bodies, exceeding small pores, or exceeding small motions.

Exceeding small bodies must either be the parts of larger bodies, or things, the whole of which is exceedingly minute, such as small seeds, insects, salts, sands, &c.

Exceeding small pores are the interstices between the solid parts of bodies, as in stones, minerals, shells, &c. or the mouths of minute vessels in vegetables, or the pores in the skin, bones, and other parts of animals.

Exceeding small motions are the movements of the several parts or members of minute animals, or the motion of the fluids, contained in either animal or vegetable bodies. Under one or other of these three heads, almost every thing about us affords us matter of observation, and may conduce both to our amusement and instruction.

An examination of these objects, however, so as to discover truth, requires a great deal of attention, care, and patience, with some skill and dexterity, to be acquired chiefly by practice, in the preparing, managing, and applying them to the microscope.

Whatever object offers itself as the subject of our examination, the size, contexture, and nature of it, are first to be considered, in order to apply it to such glasses, and in such a manner as may shew it best. The first step should always be to view the whole together, with such a magnifier as can take it in all at once, and after this the several parts of it may the more fitly be examined, whether remaining on the object, or separated from it. The smaller the parts are which are to be examined, the more powerful should be the magnifiers employed; the transparency or opacity of the object must also be considered, and the glasses employed accordingly suited to it; for a transparent object will bear a much greater magnifier than one which is opaque, since the nearness that a glass must be placed at, unavoidably darkens an object if in its own nature opaque, and renders it very difficult to be seen, unless by the help of the apparatus contrived for that purpose, which has a silver speculum. Most objects, however, become transparent by being divided into extremely thin parts.

The nature of the object also, whether it be alive or dead, a solid or a fluid, an animal, a vegetable, or a mineral substance, must likewise be considered, and all the circumstances of it attended to, that we may apply it in the most advantageous manner. If it be a living object, care must be taken not to squeeze or injure it, that we may see it in its natural state and full perfection. If it be a fluid, and that too thick, it must be diluted with water; and if too thin, we should let some of its watery parts evaporate. Some substances are fittest for observation when dry, others when moistened; some when fresh, and others after they have been kept some time.

Light is the next thing to be taken care of; for on this the truth of all our observations depends; and a very little observation will shew how very different objects appear in one degree of it to what they do in another: so that every new object should be viewed in all degrees of light, from the greatest glare of brightness to perfect obscurity, and that in all positions to each degree, till we hit upon the certain form and figure of it. In many objects it is very difficult to distinguish between a prominence and a depression, a black shadow, and a black stain, and in colour between a bright reflection and whiteness. The eye of a fly, in one kind of light, appears like a lattice drilled full of holes; in the sunshine like a solid substance, covered with golden nails; in one position like a surface covered with pyramids, in another with cones, and in others with still different shapes.

The degree of light must always be suited to the object; if that be dark, it must be seen in a full and strong light, but if transparent, the light should be proportionably weak: for which reason there is a contrivance both in the single and double microscope to cut off abundance of the rays, when such transparent objects are to be examined by the largest magnifiers. The light of a candle for many objects; and especially for such as are very bright and transparent, and very minute, is preferable to day-light; for others a serene day-light is best; but sun-shine is the worst light of all, for it is reflected from objects with so much glare, and exhibits such gaudy colours, that nothing can be determined from it with any certainty. This, however, is not to be extended to the solar, or camera obscura microscope; for in that nothing but sun-shine can do, and the brighter that is, the better; but in that way we do not see the object itself on
which

which the sun-shine is cast, but only the image or shadow of it exhibited on a screen; and therefore no confusion can arise from the glaring reflection of the sun's rays from the object to the eye, which is the case in other microscopes. But then in that solar way we must rest contented with viewing the true form and shape of an object, without expecting to find its natural colour; since no shadow can possibly wear the colour of the body it represents.

Moll objects require also some management, in order to bring them properly before the glasses. If they are flat and transparent, and such as will not be injured by pressure, the best way is to enclose them in sliders between two Muscovy tales or singlass. In this way the feathers of butterflies, the scales of fishes, and the *varioæ* of flowers, may be very conveniently preserved, as also the parts of insects, the whole bodies of minute ones, and a great number of other things. These are to be kept in sliders, each containing three, four, or more holes, and these must not be filled promiscuously; but all the things preserved in one slider should be such as require one and the same magnifying power to view them, that there may not be a necessity of changing the glasses for every object; and the sliders should be marked with the number of the magnifier it is proper to be viewed with. In placing the objects in the sliders, it is always proper to have a small magnifier, of about an inch focus, in your hand, to examine and adjust them by, before they are fixed down with the rings.

Small living objects, such as lice, fleas, bugs, mites, minute spiders, &c. may be placed between these tales without injuring them, if care be taken to lay on the brass rings without pressing them down, and they will remain alive many weeks in this manner; but if they are too large to be treated thus, they should be either preserved between two concave glasses, or else viewed immediately, by holding them in the pincers, or sticking them on the point at the other end of that instrument.

If fluids come under examination, to discover the animalcules in them, a small drop is to be taken with a hair-pencil; or on the nib of a clean pen, and placed on a plate of glass; and if they are too numerous to be thus seen distinctly, some water warmed, by holding it in the mouth, must be added to the drop, and they will then separate, and be seen distinctly. This is particularly necessary in viewing the animalcules in the *semen masculinum* of all creatures; which, though extremely minute, are always so numerous, that without this caution their true form can seldom be seen. But if we are to see the salts in a fluid, the contrary method must be observed, and the plate of glass must be held gently over the fire, till part of the liquor is evaporated.

The dissection of minute animals, as lice, fleas, &c. requires patience and care; but it may be done very accurately by means of a needle and a fine lancet, placing the creature in a drop of water, for then the parts will readily unfold themselves, and the stomach, guts, &c. be very distinctly seen.

These seem the best ways of preserving transparent objects; but the opaque ones, such as seeds, woods, &c. require a very different treatment, and are best preserved and viewed in the following manner.

Cut cards into small slips about half an inch long, and a tenth of an inch broad; wet these half way of their length in gum-water, and with that fasten on several pieces of the object, and as the spots of cards are of different colours, such should be chosen for every object as are the most different from its own colours. These are very convenient for viewing by the microscope made for opaque objects with the sil-

vered speculum; but they are proper for any microscope that can view opaque bodies.

A small box should be contrived for these slips, with little shallow holes for the reception of each; and this is conveniently done, by cutting pieces of paste-board, such as the covers of books are made of, to the size of the box, so that they will just go into it, and then cutting holes through them with a small chisel, of the shape of the slips of card, these paste-boards having then a paper pasted over their bottom, are cells very proper for the reception of these slips, which may be taken out by means of a pair of pincers, and will always be ready for use.

Great caution is to be used in forming a judgment on what is seen by the microscope, if the objects are extended or contracted by force or dryness.

Nothing can be determined about them, without making the proper allowances; and different lights and positions will often shew the same object as very different from itself. There is no advantage in any greater magnifier than such as is capable of shewing the object in view distinctly; and the less the glass magnifies, the more pleasantly the object is always seen.

The colours of objects are very little to be depended on, as seen by the microscope; for their several component particles being by this means removed to great distances from one another, may give reflections very different from what they would, if seen by the naked eye.

The motions of living creatures also, or of the fluids contained in their bodies, are by no means to be hastily judged of, from what we see by the microscope, without due consideration; for as the moving body, and the space in which it moves, are magnified, the motion must be so too; and therefore that rapidity with which the blood seems to pass through the vessels of small animals must be judged of accordingly. Suppose, for instance, that a horse and a mouse move their limbs exactly at the same time, if the horse runs a mile while the mouse runs fifty yards; though the number of steps are the same in both, the motion of the horse must notwithstanding be allowed the swiftest; and the motion of a mite, as viewed by the naked eye, or through the microscope, is perhaps not less different. Baker's Microscope, p. 52. 62. Adams on the Microscope. See ANIMALCULES and *Plates of Microscopic Objects*.

MICROSTEMMA, in Botany, from μικρός, *small*, and στεμμα, *a crown*, alluding to the sort of coronet which accompanies the anthers.—Brown Tr. of the Wern. Soc. v. 1. 25. Prodr. Nov. Holl. v. 1. 459.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asteraceæ*, Brown.

Ess. Ch. Corolla wheel-shaped, five-cleft. Crown of the stamens of one leaf, fleshy, with five lobes, alternate with the anthers, which are without any membranous point. Masses of pollen attached laterally by the middle, lying over the stigma, which is pointless. Follicles slender, smooth. Seeds comose.

1. *M. tuberosum*. Br.—Native of New Holland, within the tropic. A smooth upright perennial herbaceous plant, with a tuberous root. Stem simple in the lower part, and furnished with minute leaves; branched above. Leaves opposite, linear. Umbels lateral and terminal, nearly sessile. Corolla blackish-purple, bearded at the inside.

MICROTEA, named by Professor Swartz, from μικροτή, *smallness*, on account of the parts of fructification being extremely minute, compared with others of its natural order.—Swartz Prod. 53. Ind. Occ. 542. Schreb. 797. Willd. Sp. Pl. v. 1. 1309. Mart. Mill. Dict. v. 3. Lamarck

Illustr. t. 182. Class and order, *Pentandria Digynia*. Nat. Ord. *Holeraceae*, Linn. *Atriplices*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five, oblong, permanent leaves. *Cor.* none. *Stam.* Filaments five, thread-shaped, the length of the calyx, inserted into the receptacle; anthers rather globose. *Pist.* Germen superior, roundish, echinated; styles two, very short, divaricated; stigmas simple. *Peric.* a dry, leathery, slender drupa, beset with prickles. *Seed*, a roundish, smooth nut, with a single kernel.

Ess. Ch. Calyx of five leaves, spreading. Corolla none. Drupa dry and prickly. Seed roundish, covered with a leathery, echinated bark.

1. *M. debilis*. Willd. n. 1. Swartz Ind. Occ. t. 12.—(Schollera; Rohr A&S. Soc. Hafn. v. 2. p. 1. 210.)—A native of several of the West India islands.—The whole plant is smooth, and about a foot in height. *Stem* herbaceous, branched, diffuse, nearly erect, striated. *Branches* irregular, diverging, weak, spreading. *Leaves* alternate, on stalks, ovato-lanceolate, pointed, entire, nerved, veinless, rather succulent, and of a dark green colour. *Flower-stalks* terminal or lateral, opposite to the leaves, each bearing two, slender, rather close. *Clusters* of numerous, nearly upright flowers, mostly directed one way, on separate, short stalks, very minute, greenish-white. *Bractees* lanceolate, pellucid. *Drupa* the size of mustard-seed, with very minute, prickly-edged cells all over the surface. *Nut* black and shining; or it may be considered as a seed covered with a leathery, prickly, or muricated bark.

Mr. Van Rohr, in the Copenhagen Transactions, named this plant which was communicated to him by Jacquin, *Schollera*, in honour of the author of *Flora Barbienfis*.

MICROTIS, so named by Mr. Brown, from μικρός, small, and ως, ωτος, an ear, alluding to a pair of minute ear-like appendages to the anther. Brown Prodr. Nov. Holl. v. 1. 320.—Class and order, *Gynandria Monandria*. Nat. Ord. *Orchidæ*.

Gen. Ch. *Cal.* Perianth three-leaved, ringent; its two side-leaves sessile, nearly opposite to the lip. *Cor.* Petals two, much like the calyx, ascending. Nectary a lip proceeding from the lower part of the style, oblong, obtuse, spreading, callous at the base. *Stam.* Anther an hemispherical, moveable, terminal lid, of two cells, attached to the posterior edge of the top of the style, permanent, accompanied by a membranous auricle at each side; masses of pollen two in each cell, powdery, affixed by their base to the stigma. *Pist.* Germen inferior, obovate, erect, furrowed; style erect, funnel-shaped; stigma in front. *Peric.* Capsule of one cell. *Seeds* numerous, minute.

Ess. Ch. Calyx ringent, its side-leaves nearly opposite to the lip. Petals ascending. Lip without a spur, obtuse, callous at the base. Anther a lid, terminating the style behind. Pollen powdery.

Five species of this new genus were found by Mr. Brown in New Holland, chiefly in the colder parts, and a sixth is our *Epipactis unifolia*. (See EPIPACTIS.) The bulbs are undivided and naked. *Herbage* smooth. *Leaf* solitary, cylindrical, fistulous, embracing the stem with its long sheathing base. *Spike* of many small, greenish or white, flowers, the lip of some of which is undivided, in others two-lobed. The leaves of the calyx, as well as the petals, are more or less linear, the former frequently revolute. The lip differs greatly in form in the different species, and its margin is in some even and naked, in others wavy, warty, or tuberculated. The appearance of the whole is observed by Mr.

Brown to be very different from *Epipactis*, and most like another genus of his own, named *Praefophyllum*.

MICTUS CRUENTUS. See BLOODY URINE.

MID, or MIDDLE, in *Philosophy* and *Mathematics*. See MEAN and MEDIUM.

MIDA, in *Natural History*, the name of a worm or maggot, of which is produced the purple fly, found on bean-flowers, and thence called the bean-fly.

MIDAD ALHENDI, in the *Materia Medica of the Arabians*, a name given to the common indigo blue.

The express meaning of the words is India ink; but this is an erroneous name, founded on Pliny's misunderstanding the words of Dioscorides.

MIDAS, in *Fabulous History* and *Mythology*, was, according to Pausanias, the son of Gordius and Cybele, and reigned in the Greater Phrygia, as we learn from Strabo. According to the former of the two authors, he built the city of Ancyra, and that of Pessinus, upon mount Agdistis, famed for the tomb of Atys; but the latter merely says, that he and Gordius his father fixed their residence near the river Sangar, in cities, which in his time were mean villages: as he was rich, and a great economist, it was fabled that he turned into gold whatever he touched. It is suggested that this fable took its rise from his having been the first who discovered gold in the Pactolus. From his infancy it was foreseen, that he would be very rich and very frugal, because the ants, approaching his cradle, had put grains of corn into his mouth. However, his talent for accumulation did not extend to the acquirement of taste and knowledge in the fine arts; and, perhaps, his dulness and inattention to these, provoked some musical poet to invent the fable of his decision in favour of Pan against Apollo.

Pan, who thought he excelled in playing the flute, offered to prove that it was an instrument superior to the lyre of Apollo. The challenge was accepted, and Midas, who was appointed the umpire in this contest, deciding in favour of Pan, was rewarded by Apollo, according to the poets, with the ears of an ass, for his stupidity.

The scholiast upon Aristophanes, for explaining the fiction of the asses' ears, which Apollo had presented to Midas, says that it was designed to intimate that he had a very fine ear, like that animal, or because he kept spies through all his dominions, or because he commonly dwelt in a place named ωσα ωτες, the asses' ears. The fable reports, that his power of converting whatever he touched into gold was given him by Bacchus; but the present foon became injurious to him; for it is said, that whilst he was waiting for his dinner, the water in which he washed his hands, and also the bread, wine, and meat that were served up to him, were converted into gold, when he was ready to starve amidst all his riches: but applying to Bacchus, with a request that he would revoke the grant, Bacchus ordered him to wash his hands in the Pactolus, by which act he transferred the virtue which he possessed to the river, which, from that time, rolled a golden sand. This fable is thus explained. Midas, frugal to avarice, reigned over a very rich country, and made considerable sums by the sale of his corn, wine, and cattle. His avarice afterwards changed its object, and having learned that the Pactolus furnished gold dust, he abandoned the care of the country, and employed his subjects in gathering the gold of that river, which brought him a new and ample supply. On account of his attention to religion among the Lydians, he was reckoned, according to Justin, a second Numa.

MIDAS'S Ear-shell, in *Conchology*. See TRUMPET-FISH.

MIDDATOOR, in *Geography*, a town of Hindoostan, in Golconda; 15 miles S.E. of Canoul.

MIDDEL-

MIDDELBURG, a sea port town of Holland, in the state of Zealand, situated in the centre of Walcheren, of which it is the capital. The town-house is a magnificent building, and the fortifications are strong and regular, with eight gates, and twelve bastions for defending the walls and ramparts, besides large and deep ditches filled with water; and such also is its situation, that the inhabitants may lay the country under water whenever they please. The number of inhabitants has been estimated at about 26,000. N. lat. $51^{\circ} 34'$. E. long. $3^{\circ} 29'$.

MIDDING, in *Agriculture*, a provincial term applied to a dunghill.

MIDDLE BANK, in *Geography*, one of the fishing banks of Newfoundland; S.E. of Cape Breton. N. lat. 45° . See **FISHERY**.

MIDDLE Cape, lies to the south-west of cape Anthony, in Staten Land, on the strait Le Maire, and the most westerly point of that island; at the extremity of South America.

MIDDLE Island, a small island in the straits of Salayer, near the south coast of Celebes. S. lat. $5^{\circ} 40'$. E. long. $120^{\circ} 52'$.—Also, a small island in the East Indian sea, near the south-west coast of Boulton. S. lat. $5^{\circ} 38'$. E. long. $123^{\circ} 50'$.—Also, an island in the straits of Sunda, in the Indian sea. N. lat. $5^{\circ} 57'$. E. long. $104^{\circ} 53'$.—Also, a small island in Upper Canada, east of the Bals islands, and north of Ship island and Cunningham's island, in lake Erie.

MIDDLE Islands, a cluster of small islands in lake Huron. N. lat. $45^{\circ} 1'$. W. long. $83^{\circ} 33'$.—Also, a cluster of small islands in the Pacific ocean, near the coast of Mexico. N. lat. $9^{\circ} 30'$.

MIDDLE Island Creek, a river of Virginia, which runs into the Ohio, N. lat. $39^{\circ} 16'$. W. long. $81^{\circ} 22'$.

MIDDLE Lake, a lake of Canada; 300 miles N. of Quebec. N. lat. $51^{\circ} 44'$. W. long. $69^{\circ} 35'$.

MIDDLE Latitude, in *Navigation*, is half the sum of two given latitudes.

MIDDLE Latitude sailing, is used for a method of working the several cases in sailing, nearly agreeing with Mercator's way, but without the help of meridional parts. See **SAILING**.

MIDDLE Point, in *Geography*, a cape on the east coast of Labrador. N. lat. 59° . W. long. 63° .

MIDDLE Region. See **REGION**.

MIDDLE Sister, in *Geography*, a small island at the west end of lake Erie, in Upper Canada, situated between the East and West Sister.

MIDDLE States, one of the grand divisions of the United States of America, comprehending New York, New Jersey, Pennsylvania, Delaware, Ohio, and Indiana.

MIDDLE Tint, in *Painting*. See **HALF-TEINT**.

MIDDLE Voice, in the *Greek Language*, holds an intermediate rank between the Active and the Passive, being supposed to have a middle signification between them. Its tenses are formed partly on the model of the Active, and partly on that of the Passive tenses. The tenses peculiar to the middle voice are the two futures, the two aorists, the perfect, and the pluperfect. The two futures and the two aorists borrow the terminations of the Passive, while the two perfect tenses borrow those of the Active voice. For the manner in which these tenses are formed, we refer to the valuable Grammar of the Greek Tongue, on a new and improved plan, by Mr. John Jones. This excellent grammarian also observes, that as the middle voice derives its origin and explanation from the Passive, it is frequently used, like a Passive verb, in a sense purely active, and has after it an accusative noun; and this usage abounds in all writers of

prose as well as poetry. It is further observed, than when an accusative noun is not annexed, the personal pronoun, combined with the verb in the oblique case, is the object of the verb. Hence it is that the middle verb expresses a reciprocal or reflex sense. Our author infers from this statement, that the middle verb is in the strictest sense an Active verb; but whether or not it conveys a reflex signification, depends on the circumstance whether an accusative noun be annexed or not. The presence of a noun in the accusative, causes, as it were, the combined pronoun to disappear, and the verb becomes purely active; while its absence gives room for the objective pronoun to display itself, which consequently assigns to the verb the character of "reflex." Although the middle verb contains an objective pronoun in itself, yet it is sometimes distinctly annexed, in order to render the meaning more emphatic or prominent. Sometimes a noun equivalent to the reflex pronoun is annexed to a middle verb. For the illustration of these remarks by apposite examples, we refer to the author himself, *ubi supra*.

MIDDLE Wale, in a *Ship*, two or three thick strakes wrought fore and aft, between the lower and middle decks, in three-deck ships.

MIDDLEBOROUGH, in *Geography*, the Namasket of the ancient Indians, a post-town in Plymouth county, Massachusetts, incorporated in 1660, and containing 4458 inhabitants; 40 miles S. by E. of Bolton. This town is remarkable for a large range of ponds, which produce several sorts of fish, and large quantities of iron ore.

MIDDLEBOURG KEY, a small islet, separated from St. Martin's in the West Indies, on the north-east.

MIDDLEBROOK, a post-town of America, in Augusta county, Virginia; 186 miles from Washington.

MIDDLEBURG, a post-town of America, in Lowden county, Virginia; 47 miles from Washington.—Also, a post-town of Nelson county, Kentucky; 603 miles from Washington.

MIDDLEBURG, a town of Flanders, which derived its name from an abbey called "Middleburg," to which it belonged. In this town the free exercise of the Roman Catholic religion is allowed; 7 miles N.E. of Bruges. N. lat. $51^{\circ} 16'$. E. long. $3^{\circ} 15'$.

MIDDLEBURG. See **EA-00-WEE**.

MIDDLEBURG, New, a town of Dutch Guiana, at the extremity of the colony.

MIDDLEBURG, a small island near the west coast of New Guinea. S. lat. $0^{\circ} 18'$. E. long. $132^{\circ} 32'$.—Also, a small island in the gulf of Manar, near the west coast of Ceylon; 18 miles N. of Manar.

MIDDLEBURY, a post-town of America, in Vermont, capital of Addison county. Here are a brewery on a large scale, three grist mills, four saw mills, a forge, a gun and card manufactory, gaol, court-house, college, and about 400 dwelling-houses. The township lies on the east side of Otter creek, and contains 1263 inhabitants; 511 miles N.E. of Washington.

MIDDLEFAHRT, a town of Denmark, on the west coast of the island of Funen, in the Little Belt, which is here scarcely one mile wide, and called "Middlefahrt sound." Here is a ferry to Snogboy in Jutland; 34 miles W. of Odensee. N. lat. $55^{\circ} 32'$. E. long. $9^{\circ} 39'$.

MIDDLEFIELD, a township of America, in Hampshire county, Massachusetts; 30 miles N.W. of Springfield; incorporated in 1783, and containing 817 inhabitants.—Also, a thriving town in Trumbul county, state of Ohio; 15 miles N. of Warren.

MIDDLEHAM, a small market-town and parish in the

wapentake of Hang-West, in the North Riding of the county of York, England, is situated on the southern bank of the river Ure, 10 miles from Richmond, 44 from York, and 220 from London. Leland says, "The town is set on a hille side. The greates hill above hit more then a mile of hit is cawllid Penhil, and is countid the hiest hille of Riche-montshire. Middleham castle joynith harde to the town side, and is the fairest castel of Riche-montshire next Bolton, and the castel hathe a parke by hit caullid Sonstene, and another cawllid Westparke, and the third cawllid Gauncleffe, half a mile of. Westparke and Gauncleffe be well woddid. There is at the est ende of Middleham a little hospital, with a chapel of Jesus." The parish church is a handsome structure. In the year 1476, Richard duke of Gloucester (afterwards king Richard III.) obtained a licence from his brother, Edward IV., to make it collegiate, with provision for a dean, six chaplains, four clerks, and six choristers; but the establishment was never completed. The minister of the parish hath yet the title of dean of Middleham, and enjoys several privileges; but there probably never were any chaplains, clerks, or choristers. The castle, now in ruins, was the birth-place of king Richard III.; and in it Edward IV. was confined, after having been taken prisoner in his camp by Nevill, earl of Warwick. Middleham contained, according to the return in the year 1801, under the population act, 154 houses, and 728 inhabitants, of whom a considerable number are employed in the woollen manufacture. A weekly market is held on Monday, and here are three annual fairs.

MIDDLE-HORNED, in *Agriculture*, a term applied to a useful breed of neat cattle. This breed, which are often employed in team labour, is distinguished by different characteristic marks in the different varieties; which, in the Devonshire sort, is by a high red colour without white spots, by a light dun ring round the eye, by the muzzle having the same colour, by being fine in the bone and clean in the neck, by the medium length of the horns, and their being turned upwards, by being thin-faced, fine in the chops, wide in the hips, with a tolerable barrel, rather flat on the sides, by the tail being small and set on high, by being thin-skinned and silky in handling, and by the property of fattening at an early age, or arriving quickly at maturity. They are admirably fitted for the purpose of draught in hardiness, quick movement, and the form of the shoulder.

The principal varieties of this breed are the Devonshire, the Suffex, and the Herefordshire; all of which are highly useful sorts, and differ in some slight particulars from each other, as is seen under the head *Cattle*, where a full description of each kind is given. See **CATTLE**.

MIDDLESEX, *Earl of*, in *Biography*. This nobleman is often mentioned in opera annals, from the year 1741, when Handel retired from the Haymarket theatre as manager, or *impresario*; his lordship having taken upon himself that perilous and troublesome office, persevered in his love of dramatic music, and of rule, to his great loss, till 1748. See *OPERA History in England*.

MIDDLESEX, in *Geography*, an inland county of England, is bounded on the north by Hertfordshire, on the south by the river Thames, which divides it from Surrey, on the west by the river Colne, which separates it from Buckinghamshire, and on the east by the river Lea, which divides it from Essex. Its shape is extremely irregular, but, on the whole, approaches to that of the quadrangle. The greatest extent of the shire, from east to west, measures about 20 miles; and its greatest breadth, from north to south, about 17 miles. The superficial area of the whole county is

estimated by Mr. Middleton, in his *Agricultural Survey*, at 280 square miles, or 179,200 acres. Some other writers, however, state its contents at 218,000 acres. According to the parliamentary returns of 1801, it contained 118,083 houses, inhabited by 818,129 persons, viz. 373,655 males, and 444,474 females, of whom 162,260 were stated to be employed in different branches of trade and manufactures, and in agriculture.

This county, before the Roman invasion, formed part of the territories of the Trinobantes, or Trinovantes, a tribe of Britons, who are supposed to have derived their name from the peculiar nature of the country they occupied; being a broad valley on the banks of a wide spreading river. This tribe possessed two considerable cities, or fortified places; of which the eminence between the Thames and Moorfields, nearly the centre of modern London, was the seat of one; the other, and most important at that early period, was Camalodunum, now Colchester in Essex. Being torn by internal dissensions, the Trinobantes were the first who found themselves compelled to submit to the Roman arms. After the complete subjugation of the island, their territories, and consequently Middlesex, were included in the division called Flavia Cæsariensis; and Londinum or Augusta, now London, became a principal Roman station, though, from some cause unknown, it never was dignified with the name of a colony. See an interesting account of the Roman station and antiquities of London, by J. Moser, esq., in *European Magazine* for September 1812.

After the retreat of those illustrious conquerors, and the establishment of the Saxon heptarchy, this county appears for some time to have constituted a kingdom of itself; for which, however, its kings were obliged to do homage to those of Kent or Mercia. It was ultimately incorporated with the kingdom of the East Saxons, and remained in that condition till the dissolution of their monarchy, by the subjugation of the several kingdoms of the heptarchy to one monarch. Subsequent to this event, the history of London is intimately connected with the history of Middlesex. See *Turner's History of the Anglo-Saxons*, 2 vols. 4to.

The surface of this county, though mostly flat, presents a variety of hills, near its union with Hertfordshire, many of which rise almost imperceptibly to their summits, and are, on that account, admirably adapted for the purposes of agriculture; being sufficiently sloping to secure a proper drainage, and, at the same time, free from abrupt elevations. This inequality of surface, moreover, contributes in no small degree to health, ornament, and beauty; though only a few spots can be considered as eminently picturesque. The ground, for the most part, ascends from the banks of the Thames towards the north; and, within four miles of London, appears a range of gentle eminences, which shelters the metropolis from the northern blasts, and agreeably breaks the uniformity of the horizon. Of these heights the chief are Hampstead, Highgate, and Muswell Hill; all of which afford many pleasing and extensive prospects. So likewise does Harrow Hill, which, from rising in a sort of isolated manner, forms a prominent object for many miles around. This eminence approaches a higher and more extensive ridge, stretching north-eastward in interrupted swells from Pinner, Stanmore, Eltham, Totteridge, and Barnet, to the forest scenery of Enfield Chase. The average elevation of these hills is about 400 feet above the stream of the Thames. Such land as lies contiguous to that river, and to the Colne and Lea, is in general perfectly level, and exhibits a state of the highest cultivation.

The mineralogy of this county affords fewer objects of interest than perhaps any other in England. According to

MIDDLESEX.

Mr. Middleton, the disposition of the strata is, "first, cultivated surface; secondly, siliceous gravel, from five to ten feet in thickness; thirdly, a strong leaden coloured earth, generally called clay, varying from one to three hundred feet in thickness; fourthly, marine sediment, sometimes cockle shells, but principally oysters, agglutinated together, and hardened into a sort of stony stratum, three, four, or five feet deep; fifthly, loose sand and gravel, from which the water is found to rise in such quantity, as to preclude the possibility of digging further. No metallic strata have yet been discovered in any part of the county; and appearances indicate, that if there really are any such, they lie at too great a depth to be made subject to the operations of the miner." A thin stratum of fullers' earth, however, was found, in 1802, about a mile from Paddington, on the Edgeware road; and in 1798, a quantity of loose coal, twelve inches in thickness, was discovered at Chelsea, nearly fifty feet from the surface. Fossil shells, principally bivalves, together with other marine exuviae, have occurred in different parts.

The soils in Middlesex are various, but loam and clay, or sand and gravel, more or less intermixed with loamy clay, are the most prevalent. The latter sort of surface predominates on the summits of most of the hills. Hampstead Hill consists chiefly of yellow iron-stained sand, with some loam and rounded flints placed on a pure white sand, many feet in depth. A loamy sand is the prevailing soil in that district of the county which forms its south-westernmost angle, and lies between the river Thames, and the road stretching from Hounslow to Colnbrook. From Tottenham to Enfield Wash the superstratum is of a similar description, and rests upon the same under strata. Westward from Hanwell and Hounslow, the loam existing in much greater quantity than the sand, agriculturists distinguish the soil here by the appellation of a sandy loam. The same soil is found in the parishes of Twickenham, Isleworth, Ealing, Chiswick, Kennington, Fulham, Brompton, and Chelsea, as likewise in the south division of the parish of Harefield. All the land from Ruisslip and Ickenham on the west, to Gneeford, Apperton, and Harrow on the east, and between Pinner on the north, and Northcote on the south, is composed of strong loam; the land about Mims is of the same kind, and the level between Islington, Hampstead, and Hornsey, is a strong but very unproductive loam. The loamy clay predominates on the north side of a hill between Uxbridge Common and Harefield, to the north-west of Ruisslip, and between the river Brent and Hampstead on the Hendon road. From Nightingale Hall by Colney Hatch to Whetstone, the soil is a loamy clay mixed with pebbles of flint, and also from Potters'-Bar for about two miles towards South Mims. The north side of Highwood Hill has a thin layer of loamy clay on a subsoil of yellow clay, every where abounding with rounded flints. In the Isle of Dogs, and in all the lands on the flat borders of the rivers Lea and Colne, together with some spots immediately adjacent to the Brent and the Thames, the soil is of that peculiarly rich kind which is formed by the collection of the various substances that may be washed down by the rivers from the high grounds, villages, towns, and cities. The moors extending from Rickmansworth to Staines consist chiefly of peat on a subsoil of siliceous gravel, which in various parts shews itself at the surface. Some peat has likewise been found in the Isle of Dogs.

Middlesex, from its situation with regard to London, presents more variety in its agriculture than any county in Great Britain. To give the reader, therefore, a proper idea of this subject, it will be necessary to enter at greater length

into detail than might otherwise be requisite. In general, however, it may be premised that the eastern division of the county, with the exception of the gardens in the vicinity of the metropolis, are appropriated to meadow, pasture, and potatoe-grounds; and that the western division, excepting Hounslow Heath, Sunbury, and Ruisslip commons, and some other spots, consists chiefly of arable lands.

The greater part of the upland, meadow, and pasture-grounds in this county has, no doubt, been at one time under cultivation, as they still exhibit unequivocal marks of the plough. These grounds are kept in the highest state of order, and are plentifully furnished with manure, so that they afford the most luxuriant crops. The manner and period of applying the manure are studied by the farmers with great attention. They observe, says Mr. Middleton, the state of the atmosphere, and should it indicate rain after the hay is removed from the ground, they put the dung of neat cattle upon it. Should the barometer, however, not promise rain in considerable quantities, the decomposed manure is allowed to remain on the dunghills till the end of September, at which time it is put on while the ground is dry enough to bear the loaded carts without injury. Meadow land in the occupation of cow-keepers is usually mown two or three times during summer, the great number of cows kept by them enabling them to dress it every year. As their chief object is to obtain their hay of a soft grassy nature, they cut it young, conceiving it to be better provender for milk cows in that state than after the feeding stems have risen.

The pasturage or grass-lands lie principally, if not entirely, on the banks of the several rivers with which this county is supplied. Those adjoining to the river Lea contain about 2000 acres, of which upwards of 1200 are inclosed, and the remainder divided by land-marks among a great number of proprietors. The several tracts of grass-lands on the banks of the Colne include about 2500 acres, and such of them as are inclosed are extremely fertile. By far the greater proportion of them, however, are Lammas Meads; and one of the necessary consequences of this condition is, that the ditches are so much neglected as to be grown up. The richest grass-land in the whole county is that of the Isle of Dogs, which, since the formation of the East India Docks, has been reduced from 1000 to less than 500 acres.

Before concluding the subject of meadow and grass-lands, it may not be improper to notice shortly the method of hay-making practised in this county, the decided superiority of the farmers in that art being acknowledged by all who have any pretensions to agricultural skill. Here it is reduced to a regular system, unknown in other parts of the kingdom. When the grass is about to be mown, the farmer engages a certain number of persons for that work, according to the extent of his lands. At the same time he provides five haymakers to each mower, who are paid by the day. On the first day all the grass mown before nine o'clock is tedded, in which operation great care is taken to shake it out well, and strew it evenly over the ground. After this, it is turned once or twice with similar care; and in the course of the afternoon is raked into what are called single wind rows, and towards the evening is put into grass cocks. On the second day the business commences by tedding all the grass mown on the first day after nine o'clock, and all that has been mown this day before nine o'clock. Next the grass cocks are well shaken out into separate plats, called saddles, of five or six yards diameter. The saddles are next turned, and after that is done, the grass tedded in the morning is turned once or twice in the same manner as described for the first day. After dinner the saddles

are.

MIDDLESEX.

are formed into double wind rows; the grafs is next raked into fingle wind rows; then the double wind rows are put into baltard cocks; and laftly, the fingle wind rows are put into grafs cocks. On the third day the grafs mown and not fpread on the fecond day, and alfo that mown in the early part of this day, is firft tedded in the morning, and the grafs cocks are fpread into ftaddles, as before, and the baltard cocks into ftaddles of lefs extent. Thefe leffer ftaddles, though laft fpread, are firft turned, then thofe that were in the grafs cocks, and laftly, the grafs, once or twice; after which, the people go to dinner. Should the weather prove fine, the hay which was in baltard cocks the preceding night, will, this afternoon, be in a proper ftate to be carried, but not fo if the weather has been cloudy and cool. In the latter cafe, the firft operation after dinner is to rake the grafs cocks of the laft night into double wind rows, and the grafs which was this morning fpread from the fwaths into fingle wind rows. Afterwards, the baltard cocks of the laft night are made up into full fized cocks, and care taken to rake the hay up clean, and alfo to put the rakings upon the top of each cock. Next, the double wind rows are put into baltard cocks, and the fingle wind rows into grafs cocks, as on the preceding days. On the fourth day the great cocks are ufually carried before dinner. The other operations of the day are conducted in the fame routine as on thofe already defcribed, and fo on daily till the harvelt is finifhed.

The fruit gardens of Middlefex, folety intended for the fupply of the public market, are fuppofed to occupy about 3000 acres. They extend, principally, on each fide of the high road, from Kenfington through the parifhes of Hammerfmith, Brentworth, Illeworth, and Twickenham. Thefe gardens, on an average, furnifh conftant employment to about ten perfons *per* acre, men, women, and children; but during the fruit feafon, this number is increafed from thirty-five to forty. The annual produce of the labour of thefe individuals collectively is eftimated at 300,000*l.*, about three-fourths of the whole fupply of London. In thefe gardens it is ufual to have two crops, one called an *upper*, and the other an *under* crop. The former confifts of the larger fpecies of fruits, and the latter of the fmaller, fuch as rafpberries, goofeberrys, currants, and others which are known to fuffer little injury by exclusion from the influence of the fun. Some gardens are inclofed by very high walls, againft which grow a vaft variety of wall fruits; and artificial banks are alfo frequently formed, by means of which the gardeners are enabled to raife certain crops many weeks earlier than they could otherwife effect.

The nurfery gardens lie moftly in the neighbourhoods of Chelfea, Brompton, Kenfington, Hackney, Dalton, Bow, and Mile-End, and are computed to comprife upwards of 1500 acres. In thefe gardens are to be found almoft every variety of fruit trees, ornamental fhubs, and rare plants, known in any quarter of the world. Indeed, fo celebrated are the nurfery-men of Middlefex for the cultivation of exotics, that, in times of peace, a great exportation of thefe articles takes place to France, Spain, Portugal, Italy, Ruffia, and other countries.

The extent of ground fituated in Middlefex appropriated to kitchen gardens for the fupply of the London markets, is eftimated at nearly 3000 acres, or about one-fourth of the whole lands fo employed in the neighbourhood of the metropolis. About a tenth part of thefe gardens is entirely prepared by the fpade, and the remainder partly by the fpade, and partly by the plough. The average produce of thefe gardens, which are kept in a ftate of high fertility by an abundant fupply of manure, is fuppofed to amount to

200*l.* *per* acre annually, the profit upon which may be about 120*l.* Willows for the ufe of the bafket-makers are much cultivated in the iflands and on the banks of the Thames, particularly in the vicinity of Brentford, Twickenham, and Sunbury. The profits arifing from this fpecies of cultivation are faid to be immense, but they are carefully concealed from public scrutiny.

Farms in this county, from the manifold divifion of its landed property, are ufually of fmall extent. The rents vary extremely, according to local and other circumftances, being in fome places averaged fo low as ten fhillings, and in others at above twelve pounds. They are, without exception, paid in money, with the addition, in fome few inftances, of fupplying the landlord's family in town with fresh butter at 8*d.* or 9*d.* *per* pound, of 16 ounces to the pound, and with cream at 6*d.* *per* pint. Tithes, from which only a very few farms are free, are chiefly taken in kind, though in fome cafes an annual compofition is preferred. The wages of labourers in husbandry here in winter vary from ten to twelve fhillings *per* week, and in fummer from twelve to fifteen. Thofe employed only in hay-time and harvelt have from fifteen to eighteen fhillings, with beer occasionally, and fometimes a dinner. A great part of the agricultural bufinefs, however, is done by the piece, the prices varying according to the feafon. Farm-houfes, built within the laft hundred years, are moftly conftituted of brick, and well adapted for the accommodation of a refpectable family. The offices erected within the fame period are likewise laid out upon a good plan. If of older date, however, than the 18th century, both houfes and offices are of wood, lathed and plaifttered, with the roofs thatched; and from the many repairs, additions, and alterations they have undergone, have the appearance of being built by piece-meal, to fuit the immediate wants of the farmers, who may properly be divided into various claffes or defcriptions of perfons. Thofe who rent land in the immediate neighbourhood of the metropolis are chiefly cow-keepers, gardeners, and nurfery-men. The lands lying immediately behind their's are occupied by the villas of wealthy citizens and others; and thefe are fucceeded by farmers, who may be again divided, firft, into perfons with whom farming is but a fecondary occupation; and, fecondly, fuch as, having acquired an eafy fortune by other purfuits, retire to farming, with the idea of uniting profit and amufement in their agricultural labours. The third clafs is lefs numerous than either of the former, and confifts likewise of perfons who have abandoned fome former purfuit entirely, and directed their attention excluifively to farming as a profefion: this clafs forms the moft intelligent and moft accurate of husbandmen. The fourth and laft clafs is equal in number nearly to all the other claffes conjoined, and is compofed of perfons who have been originally bred to farming, and have continued to employ themfelves in the fame occupation.

The arable lands in Middlefex are chiefly fpread out in common fields, not above one-fourth of the whole being inclofed. This department of husbandry is much lefs underftood than thofe divifions of it already noticed. Ploughing is, for the moft part, conducted upon an injurious and expenfive plan. The ploughs, as well as the carts, are much too clumsy, requiring an unneceffary number of cattle to drag them. Fallowing is feldom praftifed, becaufe the farmers regard the introduction of green crops, at certain intervals in the rotation of crops, as rendering this mode of recruiting the ground altogether unneceffary; and it muft be confeffed, the idea derives fome confirmation from experience, for in the parifh of Helton, where the belt wheat in the county is grown, that praftice is wholly excluded. The

MIDDLESEX.

corn chiefly raised here is wheat and barley, rye and oats being cultivated only in very small quantities. The whole extent of land cropped with wheat in Middlesex is about 10,000 acres, and new grain recently threshed is mostly preferred for seed. About 4000 acres are laid down in barley; 3000 acres are appropriated to beans; and nearly the same amount to peas. The remainder of the arable lands is occupied by a variety of other green crops, as turnips, cabbages, white and red clover, ray-grass, (usually cut green,) and tares for the food of cattle; together with turnips, potatoes, carrots, parsnips, &c. for the use of man. Liquorice and hops are likewise among the saleable commodities cultivated in a few fields in the vicinity of London.

The number of live stock kept in this county is smaller, even in proportion to its extent, than in any other in England, with the exception of the cows appropriated for the supply of London with milk. These cows, which are of a large size, are commonly distinguished by the appellation of the Holdernefs breed, from a district of that name in Yorkshire; but they have long since ceased to be confined to that particular kind. The total number kept in Middlesex, for the purpose above-mentioned, is stated by Mr. Foot, in his Agricultural Report, at 7200. The mode of treating these cattle is as follows. During the night they are confined to their stalls, and about three o'clock in the morning each is provided with half a bushel of grains. From four to half past six they are milked by the retail dealers, and as soon as that operation is finished, each cow receives a bushel of turnips, and not long afterwards a small portion of soft meadow hay. These several feedings are commonly finished by eight o'clock in the morning, when the cattle are turned into the cow-yard. At twelve, they are again confined to their stalls, and are served with the same quantity of grains which they had in the morning. The milking recommences about half past one, after which follows again the turnips and hay. This mode of feeding continues from the month of September to May. During the other months they are fed with grains, cabbages, tares, and second cut grass, except when the weather is peculiarly fine, and then they are turned out to graze; but even in this case they still receive a portion of grains. One bull is the usual proportion to a flock of thirty cows. The net profit of the cow-keeper, upon every cow, is estimated at 6*l.* annually. Calves are generally disposed of at one, two, or three days old. Many, however, are likewise suckled for eight or ten weeks, when they become fat, and are thought to furnish the best veal.

The Middlesex sheep are not of any particular breed, the farmers either directly or indirectly purchasing their stock from almost every county in England. Such ewes, however, as are kept for the supply of the London markets with house-lambs, are all of the Dorsetshire breed. This last branch of farming is, perhaps, the most profitable of any in the county. Early-lambing ewes, of which those of a large size with white noses are preferred, are sought for with great diligence, the prices varying from forty to fifty shillings. Early grass-lambs are likewise an object of importance with the farmers of Middlesex; and for supplying these, the Dorset ewes are chiefly selected, but the South-down breed is occasionally preferred. The feed both of the ewes and lambs is principally turnips and second crop hay. The lambs are usually sold fat in the months of April, May, and June, at from thirty shillings to two guineas each.

The number of horses kept in this county amounts to between thirty and forty thousand, but very few of them are bred in it. Such as are employed in agricultural opera-

tions, as well as those used by the brewers, distillers, and carmen of London, are mostly bred in Leicestershire and the adjoining counties. The coach and saddle-horses are principally brought from Yorkshire. No horses can surpass the draught horses of the brewers, coal-masters, &c. in strength and figure. Hogs are kept in considerable numbers, but chiefly by the malt-distillers, for whom they are purchased lean at a large market held on Finchley Common, to which there are vast numbers brought from Shropshire and other distant counties. The fattened hogs are bought for the hog-butcheries about London; and the bacon cured here is reckoned very little inferior to that of Wiltshire and Yorkshire. A great supply of poultry is reared in Middlesex, chiefly, however, for home consumption. Many pigeons and rabbits are also bred, particularly in the neighbourhood of London, by the poor people and journey-men tradesmen. The only regular warren in the county is that on Uxbridge Common; so that a great proportion of the rabbits sold by the poulterers in London are of the house-breed.

Middlesex, considering the proximity of every part of it to the British metropolis, cannot boast of such good roads as might be expected. For, notwithstanding the immense sums raised to keep them in repair and proper condition, it is a fact, that even the great roads which branch off immediately from the city, as from a centre, are frequently suffered to remain in the most neglected state, especially during the winter months. This arises, in a great measure, from the inappropriate means employed in cleaning them, and from the inadequacy of the materials employed in their construction and repair, to sustain the continued pressure of the immense loads which are constantly drawn along them. It must be confessed, however, that many improvements in this respect have been made within these few years, and that even as they are, they would be accounted excellent in every other part of Europe, except in the neighbourhood of London. The parish highways, as they are denominated, are usually kept in excellent order; but the same remark cannot be applied without considerable limitation to the streets of London, which, in the carriage-ways, are usually paved with Scotch granite. The canals which intersect Middlesex are the Grand Junction canal, and the Paddington canal. The former, striking off from the Thames at Old Brentford, passes the grounds at Sion Hill and Osterley, and running through a rich corn district near Hanwell, Norwood, Harlington, West-Drayton, Cowley, Uxbridge, and Harefield, leaves this county near Rickmanworth. This canal, which is navigable for vessels of sixty or seventy tons burthen, has fourteen locks to Harefield Moor, where the level is 114 feet two inches above that of the river Thames. From its numerous cuts, side branches, and collateral streams, it is, beyond doubt, the most important inland navigation in the kingdom, as it affords a direct water communication to all the various manufacturing towns of Warwickshire, Staffordshire, Lancashire, Derbyshire, and several other counties. The general breadth of this canal is thirty feet, but at the bridges it is contracted to fifteen. The Paddington canal branches off from it near Cranford, and is continued on a level from thence to the dock at Paddington, the sides of which are occupied with yards and warehouses, for the reception and security of merchandise. The advantages derived to the metropolis and the country at large from this canal, are likewise various and important. A third canal, called the Regent's Canal, stretching from the Thames, west of London, to join that river near Limehouse, has been lately projected, and is now carrying into execution. Though there are no streams of any consequence which take their rise in this county, several considerable

derable ones water it in different directions. Of these, the most important, not only in Middlesex, but in England, is the Thames, which serves as the boundary between this county and Surrey, as already mentioned. See THAMES.

The other principal rivers of Middlesex are the Colne, the Brent, and the Lea; all of which discharge their waters into the Thames. The Lea, which joins it at Bow Creek, is navigable as high as Ware and Hertford. All of these waters are covered at different points with mills, and other machinery, employed in the various departments of manufactures and the arts. Besides these streams there are several others, which, though of trivial size, have some claims to attention. Fleet Brook, which is now enclosed from the view in its passage through London, was formerly navigable for barges. It takes its rise among the high grounds at Hampstead Heath and Caen Wood, from whence it proceeds by Kentish Town, Pancras, Bagnigge Wells, Mount Pleasant, and Saffron-hill, crossing Chick-lane, and running under Fleet-market and Bridge-street, where it enters the Thames. The New River is an artificial stream, formed by the collected waters of several small springs issuing from the vicinity of Chad-well, in Hertfordshire. (See NEW RIVER.) Several mineral springs rise in the immediate vicinity of London; and some of them were formerly of much repute, though they are now but seldom used. The Spa fields, north of London, derive their name from the number of chalybeate springs that rise within them, of which that at Islington Spa, called also New Tunbridge Wells, is the principal. At Bagnigge Wells are springs both chalybeate and cathartic. The other springs of note are St. Chad's Wells, near the bottom of Gray's-inn-lane road, Kilburn Wells, Acton Wells, and several more situated at Hampstead, and in the parishes of St. Pancras and Shadwell.

Middlesex, as containing London, is the principal seat of commerce and manufactures in Great Britain. While its traders visit the most distant parts of the known world, its artificers at home produce almost every variety of articles which any district in the country can furnish. The chief portion of these, as may be presumed, is manufactured in London and its suburbs: but many important manufactories are likewise spread over the county; most of them, however, the property of individuals established in the town.

The maintenance of the poor in this county is too important a branch of its civil economy to be passed over unnoticed, even in a general account like the present. According to the returns made to parliament on this subject, in the year 1804, the number of persons maintained in work-houses, from the 20th of April 1802 to the 12th of April 1803, was 15,186; and the number of those relieved out of work-houses, 47,987. The total annual expence, incurred in supporting the former, was 224,048*l.* 2*s.* 1½*d.*; and the expence of relieving the latter, 121,901*l.* 12*s.* 3*d.*; making in all, the sum of 364,034*l.* 14*s.* 10½*d.*, or 5*l.* 15*s.* 3*d.* for each parishioner. Besides these, however, there were 32,506 persons, not parishioners, who had received occasional relief, to the amount of 3250*l.* 12*s.*: so that the whole sum expended for the benefit of the poor, during that year, was 367,284*l.* 12*s.* 10½*d.* The amount of the rates, for the same period, was 490,144*l.* 1*s.* 7½*d.*; an average of 10*s.* 10½*d.* per head on the whole resident population, then computed, as has been seen, at 818,129 persons. Eight persons in the hundred, according to this calculation, were relieved by the poor's rate. Independent of these parochial burthens, there were then 1132 friendly societies, of which 54 were stated to be female societies, and 750 to have been enrolled at the quarter-sessions, pursuant to the acts passed in the 33d and 35th years of his present majesty. The

total number of persons belonging to these societies is stated at 72,741, (of whom 3754 were females,) being nine in a hundred of the resident population.

The Romans seem to have had only two stations in this county: Londinum or Augusta, now London; and Sullonica or Brockley hills, near Elstree, on the borders of Hertfordshire. Roman remains, however, have been discovered at many other places. The Roman roads appear to have concentrated in London, and to have branched off from that city in different directions, as from a common centre. The Watling-street, running from Dover, is presumed to have entered Southwark at the point now called Dowgate, and, keeping along the present Watling-street, to have quitted the city at Aldersgate. After this, its precise direction cannot be easily determined; but it probably turned westward at the end of Old-street, and continuing along Wilderneys-row and Clerkenwell, crossed the Fleet Brook, and ascended the hill at Portpool-lane; thence pursuing a north-westerly direction, it fell into the tract which now forms the high road to St. Alban's, and approaching the station of Sullonica, passed on through Elstree to Verulamium. The Ikenild-street, taking an easterly direction up Old-street, and over Bethnal Green, went on by Old Ford to Camaldunum or Colchester. The Ermin-street led northwards through Islington, Stoke Newington, and Hornsey, to Enfield: then turning off near that town, it passed Clay-hill, and entered Hertfordshire. A fourth Roman road led into Surrey and Berkshire, by the towns of Brentford, Hounslow, and Staines, along the course of the present turnpike; and there seems every reason to believe that a fifth took the direction of Essex, through Whitechapel and Stratford-le-Bow. Several camps of British and Roman construction are dispersed throughout the county, but none of them are peculiarly interesting: and in general it may be remarked, that, except in London and Westminster, there are few remains of antiquity in Middlesex, which have any claims to the particular notice of the antiquary.

Middlesex is divided into six hundreds, exclusive of the cities and liberties of London and Westminster, and the Tower Hamlets. The total number of parishes, places, precincts, and extra-parochial places, in the whole county, as returned under the population act, was 234. All of these, with the exception of the city and liberties of Westminster, which are governed by the dean and chapter of Westminster, are included in the diocese of London. It contains nine market-towns, distinct from the metropolis, namely, Barnet, Southall, Finchley, Uxbridge, Brentford, Hounslow, Edgware, Staines, and Enfield. Uxbridge market is principally for corn; and at Hounslow there is always a very considerable show of fat cattle, for the supply of the London butchers. Beauties of England and Wales, vol. x. by E. W. Brayley. Camden's Britannia, by Gough, fol. vol. ii. Stukeley's Itinerary, fol. Agricultural Survey of Middlesex, by Middleton, 8vo.

MIDDLESEX, a county of America, in Massachusetts, bounded north by the state of New Hampshire, east by Essex county, south by Suffolk, and west by Worcester county. It is nearly of a square form; its greatest length being 52, and its greatest breadth 42 miles. It has 42 townships, containing 46,928 inhabitants, and was made a county in the year 1643. It is watered by five principal rivers, viz. Merrimack, Charles, Concord, Nashua, and Mystick, besides some smaller streams. The chief towns are Charlestown, Cambridge, and Concord. The southern and northern sides of the county are hilly, but none of the hills exceed 100 feet in height; and they are either covered

with wood, or cultivated to the summit. The air is generally serene, and the temperature mild. The soil in some parts is rich black loam, but in others it is light and sandy. It produces the timber, grain, and fruit, which are common throughout the state, either by natural growth or cultivation.—Also, a maritime county of Connecticut, bounded north by Hartford county, south by Long Island Sound, east by New London county, and west by New Haven. It is divided into six townships, containing 13,873 inhabitants, of whom 72 are slaves. The chief town is Middletown.—Also, a county of New Jersey, bounded north by Essex, north-west and west by Somerset, south-west by Burlington, south-east by Monmouth, east by Raritan bay, and part of Staten island. It contains 17,890 inhabitants. From the mouth of Raritan river to Brunswick, the land on both sides is generally good, both for pasture and tillage, and produces considerable quantities of every kind of grain, and of hay. The chief town is New Brunswick.—Also, a county of Virginia, on the south side of Rappahannock river, on Chesapeake bay, about 35 miles long, and 7 broad, containing 1687 free inhabitants, and 2516 slaves. The chief town is Urbanna.

MIDDLESEX, one of the three counties into which the island of Jamaica is divided; the two others being Cornwall and Surry. This county is composed of eight parishes, one town, viz. St. Jago-de-la-Vega, or Spanish Town, the capital of the island, and thirteen villages.

MIDDLESEX, *Bill of, in Law.* See BILL.

MIDDLETON, Sir HUGH, in *Biography*, a public-spirited man, was the sixth son of Richard Middleton, esq. governor of Denbigh castle, in the reigns of Edward VI., Mary, and Elizabeth. The subject of this memoir settled in London, as a goldsmith; but in early life he had engaged in mining speculations in his own country, and worked a copper-mine in Cardiganshire, which brought him in a considerable income. During the reigns of Elizabeth and James I., the citizens of London obtained a power to bring a new supply of water to the city, from certain streams or springs in Middlesex or Hertfordshire. Various attempts were made; but they were all abandoned, on account of the difficulty and expences attached to so vast a concern. At length the city made over to Mr. Middleton, and his heirs, all the powers and rights conferred by an act of parliament; and he began the business in the year 1608. Two springs, one rising near Ware, and the other at Amwell, in Hertfordshire, were united for the supply of an artificial river, which was conducted to the metropolis. The expences of the undertaking were so great, that they exhausted the fortune of the projector, who, having in vain applied to the corporation of London for assistance, procured it from the king, to whom a half-share of the concern was made over, in consideration of his taking an equal share in the expences. This great work was completed in 1613; and on Michaelmas day, the water was let into the reservoir of Islington with great solemnity. Mr. Middleton was rewarded with the honour of knighthood; but his profits were so small, that he was under the necessity of engaging in the business of a surveyor, or what is now denominated a civil engineer, and in that capacity rendered essential services to his country, by various schemes of mining, draining, &c. In 1622 he was created a baronet, and he died in the year 1631; since which, the value of the shares in this New River, as it is still called, have advanced so much as to create large fortunes to the heirs of the original holders. A hundred pounds share, some years since, sold as high as fifteen thousand pounds. Of late, however, there have been several acts of parliament passed in favour of other

projects, which will be noticed under the article *Water-Works*, and which have reduced the value of the New River shares full one half. It is the fashion now to decry the company as extravagant in their charges for supplies of water; but it should be remembered, that the shares of this corporation, like those of other commercial companies, are perpetually changing their masters; and it is probable that the majority of share-holders, when their value was even at the highest, had paid their full price, so as to gain only a moderate interest upon their purchase money. *Biog. Brit.*

MIDDLETON, WILLIAM, a Welsh poet, was born at Gwernnog in Denbighshire, and died about 1600. He served in the armies of queen Elizabeth, and afterwards commanded a ship of war; and when at sea, turned the book of Psalms into Welsh verse. This work was finished in the West Indies, in 1595. He was also the author of a Grammar, and Art of Poetry, published in 1598.

MIDDLETON, CONYERS, a celebrated divine of the church of England, was born in the year 1683 at Richmond, in Yorkshire, where his father was minister. At the grammar-school of that town he was educated, and from a very early period he gave fair promise of future excellence. At the age of seventeen he was sent to Trinity-college, Cambridge; and in 1702 was chosen a scholar upon the foundation, and took his degree of B.A. In a short time afterwards he entered into deacon's orders, and officiated as curate to one of the senior fellows of his college, at Trumpington, a village near Cambridge. In 1706 he was elected fellow of his college, and in the following year he proceeded M.A. Soon after his election to the fellowship, he took an active part in the measures which were concerting in opposition to Dr. Bentley's imperious conduct, as master of the college; and he united in a petition to the bishop of Ely, which charged the doctor with many misdemeanors. For his zeal in this business he was considered by the doctor as his most determined and dangerous enemy. While this discussion was carrying on, Mr. Middleton married a lady of large fortune, and was obliged to vacate his fellowship; but he still resided at Cambridge, till he was inducted to a living in the Isle of Ely. To this he removed, but finding the situation unhealthy, he left it in about a year, and returned to Cambridge, where he was when George I. paid a visit to the university. On this occasion he got his name inserted, with those of several others, in the royal mandate for the degree of doctor of divinity, which he accordingly received from the hands of Dr. Bentley, the regius professor. Dr. Middleton on this occasion resisted the fees, for the ceremony called creation, which led to a controversy, that run out to a considerable extent, and which was carried on with great bitterness. The addition made to the public library at Cambridge, by a present from the king of bishop More's books, which had been purchased at the expence of six thousand pounds, induced the university to pass a decree for erecting a new senate-house, that a suitable place might be provided for the reception of his majesty's donation. This decree was accompanied with a vote for a new office in the university, viz. that of principal librarian, which was conferred upon Dr. Middleton. Such a promotion was no more than what was justly due to his literary merit. To shew how well qualified he was for that appointment, he published, in 1723, a little piece, entitled "*Bibliothecæ Cantabrigiensis ordinandæ Methodus quædam; quam Domino Procancelario Senatuique considerandam et perficiendam, Officii et Pietatis ergo proponit.*" Soon after the doctor had completed the arrangement in the new library, his health requiring a change of climate, he applied for leave of absence from the university; and having obtained a

MIDDLETON.

Special grace for that purpose, though not without difficulty, he set out for the continent, in company with lord Coleraine, a nobleman of considerable learning, who, upon their arrival at Paris, introduced him to the celebrated Montfaucon. Here Dr. Middleton separated from his lordship, and travelled by the direct route for Rome, where he arrived early in the year 1724. After residing in this city about twelve months, Dr. Middleton returned through France to England, and arrived at Cambridge in the latter end of the year 1725. Almost immediately after his return he published a tract, entitled "De Medicorum apud Romanos veteres degentium Conditione Dissertatio; qua contra Viros celeberrimos Jac. Sponium, et Ric. Meadium M.D.D. servilem atque ignobilem eam fuisse ostenditur." Dr. Mead had just before this published an oration, in which he had defended the dignity of the medical profession, and endeavoured to vindicate it from the reproach of its having been held in such low estimation by the ancient Romans, as to be left in the hands of slaves and the meanest of the people. In defence of the opinion of the learned physician, a work was published under the title of "Ad Viri Reverendi Con. Middletoni, S.T.P. de Medicorum apud Veteres Romanos degentium Conditione, &c. Dissertationem Responsio." This was published without any author's name, but it was soon found to be the production of professor Ward, who had been engaged by Dr. Mead to write it; and at his expense it was printed and published. Dr. Middleton replied in a very spirited defence both of his character and argument, entitled "Dissertationis de Medicorum Romæ, &c. Defensio." With this the doctor finished his part of the debate; and through the whole progress of it, he did not fail on every occasion to express a proper regard for Dr. Mead's real merit: and this literary altercation did not prevent them from living afterwards upon very good terms with each other. While our author was at Rome, he had the advantage of beholding popery in the full pomp and display of its pageantry, which he compared rather to the solemn acts of idolatry of old Rome, than to any thing recommended by the plain and simple precepts of Christianity. He examined it very accurately; and with the view of tracing the similarity, he made notes and observations while he was in Italy; and, after his return home, kept up an epistolary correspondence with his friends and acquaintance there. From these materials he drew up, and published in 1729, "A Letter from Rome, shewing an exact Conformity between Popery and Paganism; or, the Religion of the present Romans derived from that of their heathen Ancestors." This performance was exceedingly well received by the public, and went through several editions in a very short space of time. While, however, the author was entitling himself to the thanks of the Protestant world, by exposing the corruptions and impostures of the Romish church, there were some, even of the church of England, who took grievous offence at the book, pretending that he had attacked the Popish miracles with a gaiety that seemed to condemn all miracles, and particularly those of our Saviour, by invalidating the force of certain rules which had been established by some divines as the criterion of true miracles. Our author next made an attack upon Dr. Waterland's, "Vindication of the Scriptures, &c." which had been written in reply to Tindal's famous book, entitled "Christianity as old as the Creation." This drew upon Dr. Middleton the charge of infidelity, and he narrowly and with much difficulty escaped academical censure. During the contest in which he had involved himself on this subject, he was appointed to the new professorship of physiology at Cambridge, which had been founded in pursuance of the

will of Dr. Woodward. He delivered, in the year 1731, a Latin inaugural oration, at his entrance upon the office, that did credit to the appointment of Dr. Woodward's executors. The duties of this post Dr. Middleton discharged with fidelity and reputation, till the year 1734, when he resigned it. In the following year he published "A Dissertation concerning the Origin of Printing in England, shewing that it was introduced and practised by William Caxton, at Westminster, &c." About this time the doctor was introduced to the celebrated lord Harvey, by whose advice and encouragement he undertook to write "The History of the Life of M. Tullius Cicero." This great work, which was well adapted to his taste, and for which he was perfectly qualified, employed so much of his time and attention, that it was not ready for publication till the year 1741, when it appeared in two volumes, 4to. It was published by subscription, and the profits enabled him to purchase a small estate in the neighbourhood of Cambridge, at which he usually spent the summer season.

While Dr. Middleton was employed on the life of Cicero, a vacancy occurred in the mastership of the Charter-house; and he was mentioned for it by sir Robert Walpole, and came to London with the hope of obtaining it; but was disappointed in his expectations, and returned to the composition of his favourite work. In the progress of this work, he engaged with Mr. Tunstall in a controversy respecting the authenticity of Cicero's letters to Brutus, and of those of Brutus to Cicero. He also, about the same period, published "Germana quædam Antiquitatis eruditæ Monumenta, quibus Romanorum veterum Ritus varii tam facti, tam profani, tum Græcorum atque Ægyptiorum nonnulli illustrantur. Romæ olim maxima ex Parte collecta, ac Dissertationibus jam singulis instructa." This work, which consisted of the figures of those curious remains of antiquity that he had purchased at Rome, and other places, with a dissertation on each, was followed, in 1747, by "A Treatise on the Roman Senate, in two Parts," which terminated Dr. Middleton's labours in profane literature; and he now proceeded to the publication of a treatise, which laid the foundation of another fierce controversy with his clerical brethren. It was published in 1747, and was "An introductory Discourse on the miraculous Powers supposed to have subsisted in the Christian Church from the earliest Ages, &c." To this numerous answers were written, which, however, did not prevent him from proceeding with his plan; and in 1749 he produced the larger work, to which the former was, as it assumed to be, only an introduction. This was entitled "A free Inquiry into the miraculous Powers, &c." The main object of the *Inquiry* is to shew, that there is no sufficient reason to believe that any miraculous powers did ever actually subsist in any age of the church, after the times of the apostles. The publication of this piece raised up against him a host of adversaries, who charged him with the most pernicious designs. He had, however, the satisfaction of knowing that the truth of his argument was generally admitted by almost all enlightened and disinterested readers. The author set about preparing an "Answer to all the Objections made against the free Inquiry;" which, however, he did not live to publish. A few months after his death, the greater part of what he had written was given to the world, under the title of "A Vindication of the free Inquiry, &c." In the spring of 1750 he published "An Examination of the Lord Bishop of London's Discourses concerning the Use and Intent of Prophecy." The design of the bishop's discourses was to shew, that there is a manifest connection between the prophecies of every age, from the beginning of the

the world to the commencement of the gospel of Jesus Christ; which chain of prophecies, delivered at different times, and reaching through several thousand years, is yet manifestly subservient to one and the same administration of Providence. Dr. Middleton denied the principle, and laboured to refute the theory of the prelate; maintaining that the authority of the gospel, as far as it is grounded on prophecy, rests on those single and independent predictions, which are delivered occasionally in the law and the prophets, and not on any fanciful scheme of prophecy deduced from Adam and the antediluvian world. Within a few months of the publication of the last-mentioned work, our author's constitution began to give way; and on the 28th of July 1750, he departed this life. His character has been drawn with great accuracy, by the writer of his article in the *General Biography*, from which we shall extract a few sentences. "That Dr. Middleton was a very learned and ingenious divine, will not be disputed by any one. That he was an ardent lover of truth, as well as steady and disinterested in the pursuit of it, may be fairly concluded from the circumstances of his life above related, the sacrifices which he must have made by adopting and avowing sentiments that at once cut off all his hope of preferment, and the firmness with which he encountered the utmost rage and malice of fierce bigots and hypocritical zealots. That he was a sincere believer in the Christian religion, his own express and repeated declarations sufficiently prove, as well as his concise and admirable exposure of one of its most artful and malignant enemies, in his "Letter to Dr. Waterland," and his devoting many of his learned inquiries to its service. His faith he acknowledges was not of that kind which can easily digest incredibilities, but only a principle grounded on the perception of truth, and claiming no other merit than that of being a slave to his reason, to whose dictates it paid an absolute and unreserved submission. Confined within these just limits, however, it produced the noblest fruits, in a life spent in habits of temperance, study, and the search after truth; and which, in other respects, likewise, was as exemplary and agreeable to the rules of the gospel, as that of the most zealous of all his orthodox opponents." There were found among his papers, after his death, materials for a life of Demosthenes, correspondent to that of Cicero. In 1752, his "Miscellaneous Works" were published in four volumes, 4to. of which a second edition was published in five volumes, 8vo.

MIDDLETON, in *Geography*, an interior township, in Essex county, Massachusetts, incorporated in 1728, and containing 598 inhabitants; 20 miles N. of Boston.—Also, a city, post-town, and port of entry of Middlesex county, pleasantly situated on the western bank of Connecticut river. Its public buildings are a Congregational church, an Episcopal church, a court-house, and naval office. It contains about 500 houses, and carries on a considerable trade.

MIDDLETON, a post-town of the county of Cork, Ireland, which was a borough before the union, and which, from its proximity to Cork harbour, has some business, chiefly carried on at the village of Ballinacurra, about a mile distant. Here are an endowed school, a barrack, two bolting mills, and a brewery. The parish, from a union made several years ago, is one of the most valuable in Ireland, being above 3000*l.* per annum. Middleton is 121 miles S.W. from Dublin, and 12 miles E. of Cork, on the road to Youghel.

MIDDLETON, a market-town and parish in the hundred of Salford, and county palatine of Lancaster, England, was first constituted a town in the year 1791, since which time it has been gradually increasing in extent and popula-

tion. The market is held on Friday every week, in a very commodious market-place, laid out by lord Suffield, who is lord of the manor. The government of the police here is confided to two constables, who are chosen annually at the court-leet. In the church, a venerable pile of building, are several monuments of the Atheton family, who for many centuries were resident in this parish. The side aisles of this edifice are embattled; and in the windows appear some stained glass of shields, and other devices. A carved screen of seven compartments divides the chancel from the choir. It is ornamented with a great profusion of armorial bearings of the Athetons, Radcliffes, Grosvenors, and Stanleys. The living is a rectory. Here is a free grammar school, which was founded by Dr. Alexander Nowel, dean of St. Paul's, and principal of Brasen-nose college, in 1572. This is now a most respectable establishment, and frequently contains between 150 and 200 scholars. Dean Nowel was educated at this place. See *Chariton's interesting Life of Nowel*, 8vo. 1809.

The chief support of this town is derived from its cotton manufacture; but there are likewise a considerable twill manufactory, and some bleaching works. The population here, in 1801, according to the parliamentary returns of that year, amounted to 3265 persons. *Beauties of England and Wales*, vol. ix. by J. Britton.

MIDDLETOWN, a township of America, in Strafford county, New Hampshire; about 40 miles N. by W. of Portsmouth.—Also, a township of Rutland county, Vermont; 39 miles N. of Bennington.—Also, a township in Delaware county, New York; 40 miles W. of Catskill.—Also, a township in Newport county, Rhode island, containing 931 inhabitants. In the town, situated on the island which gives name to the state, about two miles from Newport, is a large cavity in the rocks, called "Purgatory."—Also, a town of about 60 or 70 houses in Berkeley county, Virginia, near the North mountain: it has two churches, one for Presbyterians, and one for Baptists.—Also, a small post-town in Newcastle county, Delaware, on Apaquinimy creek; 21 miles S.S.W. of Wilmington.—Also, a township in Monmouth county, New Jersey, which contains two places of worship, one for Baptists, and one for the Dutch Reformed church, and 3226 inhabitants. The salt-works are in North river, which divides this town from Shrewsbury. Here is an academy of 40 or 50 students. The light-house on the point of Sandy-beach is in this township. The high lands of Navesink, which are on the sea-coast near Sandy-beach, are 600 feet above the level of the water, and are the lands first discovered by mariners in this part of the coast.—Also, a flourishing post-town in Dauphin county, Pennsylvania, on the north-west side of Swatara creek, which discharges itself into the Susquehannah, two miles below: it contains a German church, and more than 100 houses, and carries on a brisk trade with the farmers in the vicinity. It is estimated that 200,000 bushels of wheat are brought down the river annually to the landing-place, two miles from the town; 92 miles W. by N. from Philadelphia. N. lat. 40° 12'. W. long. 76 44'. There are also two other townships of the same name in this state; one in Delaware county, and the other in that of Cumberland.—Also, a post-town in Frederick county, Maryland; nearly 8 miles W.N.W. of Frederickstown.—Also, a town in Dorchester county, Maryland; 8½ miles N.W. of Cambridge.

MIDDLEWICH, a considerable market-town in the hundred of Northwich, and county of Chester, England, is situated at the conflux of the rivers Croco and Dane, about 6 miles from Northwich, 22 from Chester, and 167 from London. Its name was derived from its central situation

between the Wiches, or Salt Towns, of which there are three in the county; and its origin has been supposed to be as remote as the time of the Romans; the road to it from Northwich being mentioned by Camden, as raised with gravel to such a height as to be readily known for a work of that people. The church is a spacious structure, and includes two chapels. On the south side is a college, founded by Thomas Savage, archbishop of York. The government of the town is vested in a bailiff and burgesses, annually chosen. Under the population act of 1800, the number of houses was returned as 268, occupied by 1190 persons. Considerable employment is derived to the inhabitants from the manufacture of salt, which has been carried on in this town from a very early period; very valuable brine springs being found in the town and its vicinity. A cotton manufactory has been recently established here. A grammar school was founded at Middlewich about the end of the 17th century: the school-house was given by Ralph Lowndes. Markets are held on Tuesdays and Fridays, and two fairs annually. The parish of Middlewich is very extensive, and comprises 15 townships. One of these, Kinderton, has been decided by Mr. Whitaker to be the Condate of the Romans. Lysons's *Magna Britannia*, vol. ii. *Beauties of England and Wales*, vol. ii.

MIDDLING-TEETH, in the *Manege*, are the four teeth of a horse that come out at three years and a half, in the room of other four foal-teeth, seated between the nippers and the corner-teeth; from which situation they derive the title of *middling*. There is one of them above, and one below, on each side of the jaws. See TEETH.

MIDERFELS, in *Geography*, a town and castle of Bavaria; 12 miles N.E. of Straubin.

MID-FEATHER, in the English *Salt-works*, the name given to a sort of partition placed in the middle of the furnace, over which the pan is set for boiling the sea-water or brine into salt.

This partition divides the body of the furnace into two chambers. See SALT.

MID-HEAVEN, *Medium cali*, in *Astronomy*, is that point of the ecliptic which culminates, or is in the meridian. See CULMINATION.

MIDHURST, in *Geography*, a market-town in the hundred of Eastbourne and county of Sussex, England, is pleasantly situated on an eminence, surrounded by several small hills, and watered by the river Arun. The petty sessions for the hundred, and a weekly market on Thursdays, are held here. In the town is a free grammar school. The church is in the patronage of lord Montague. According to the parliamentary returns of 1801, this town contained a population of 1073 persons, of whom thirty-one only were engaged in agriculture, and 194 in different departments of trade.

Adjoining to the town is a plot of ground, called the *borough* of Midhurst, which has the privilege of sending two members to parliament; though, like the borough of Old Sarum, not a single house stands within its limits. The situation of the burghage tenures, however, is distinctly marked by large stones set up for that purpose. This place possesses its privileges as a borough by prescription, having been the site of a town of considerable importance previous to the Norman conquest. The governing officers here are a steward and bailiff, who are chosen annually at the court leet of the manor, and exercise jurisdiction over the town.

Gale and Stukeley regard Midhurst as the Miba of Ravenna, from a tortuous etymology of its name; but Camden considers the opinion of these antiquaries on this subject as

wholly devoid of probability, all the MSS. being against them.

In a park, at a short distance from the town, stand the ruins of Cowdray house, which was formerly the seat of the ancient family of Montague. This noble edifice was destroyed by fire in 1793, when most of the furniture and valuable paintings which it contained were consumed. It was an immense building, of a quadrangular form, with a court in the centre, which was ornamented with a fine reservoir of water. An account of this house, with views of it, were published in the *Vetusta Monumenta*, by the Society of Antiquaries; but it is to be regretted that the history of the town has never been laid before the public. Our chief authority for this article is Hay's *History of Chichester*, 8vo. 1804, which is very unsatisfactory.

MIDIAH, a town of European Turkey, in Romania, on the Black sea; 69 miles E. of Adrianople.

MIDIAN, *Land of*, or *Midianitis*, in *Ancient Geography*, a country inhabited by the Midianites, who were the descendants of Abraham by Keturah, and who were seated on the N. of the Amalekites; having the Dead sea on the W., the Ishmaelites on the E., and the Moabites and Reubenites on the S.; the river Arnon parting them from this last tribe. Their country was hot, sandy, and in many parts of it quite desert; yet it abounded with cattle, particularly with camels, which were useful beasts of burden for their caravans, with which they traded into Egypt in the time of the patriarch Jacob. The land of Midian was divided into a kind of pentarchy, or five kingdoms, in the time of the Exodus; so that the Israelites, in the war which they waged with the Midianites, are said to have slain its five kings, whose capitals are supposed to have been situated near the Dead sea. They had also a famous metropolis, called after the name of their progenitor, often mentioned in the prophetic books of scripture, as well as by other authors; particularly by Josephus, who places a town of that appellation near the Red sea, not far from the spot where Ptolemy places that of Madiana. (See MADIAN.) Besides these towns, there were in this country Dibon-Gad, a large town on the river Arnon, and Almon-Diblathaim, not far from it, Beeroth, so called from its many wells, and some others, placed by geographers within the Midianitish territories. As to the city of Midian, it is probable that they rebuilt it, after the havoc committed upon them by the Israelites, because Eusebius and St. Jerom, who place it on the river Arnon, eastward of the Dead sea, and south of Ar, or Arcopolis, inform us, that in their time some remains of it were visible.

MIDIANITES, in *Ancient History*, derived their origin and name from Midian, the fourth son of Abraham by Keturah. He, as well as the rest of his brethren, having received a portion from their father, were sent into the East country, that they might be at a proper distance from Isaac. The Midianites, in early times, were confounded with the Ishmaelites (see that article); and many ages afterwards they are mentioned in conjunction with the Nabatæans and Kadarenes, the posterity of Nabioth and Kadar, the sons of Ishmael. We also find them so incorporated with the Moabites, that Moses seems to have regarded them as almost one nation. Their religion was the same, and they acted in the strictest concert together against him and the Israelites. They were likewise united by ties of blood with these nations, as on the one side they were descended from Abraham, and on the other from Lot; and, moreover, as they happened to live in the northern and southern parts of their country, they joined either the Moabites or the Ishmaelites. The Midianites were a very numerous race, and

and may be distinguished into two classes, viz. shepherds and merchants. The shepherds moved here and there in tents, and drove their cattle before them; even when they went to war. The merchants also travelled from place to place in companies or caravans, as the merchants of those parts do at this day, and left the care of their cattle to the women. The former had probably no fixed habitations, except some strong holds near their borders; the merchants also had few or none but inns or stations, in places convenient for their trade. These, by exchanging their gold and jewels with their brethren for their cattle, enriched the shepherds with precious ornaments. Their manners respectively differed according to their mode of life; but they are in general represented as being very sumptuous in their apparel. (See *Judg.* viii. 26.) From the book of *Job* (ch. xix. 23, 24.) we learn, that the use of writing was known at an early period in those parts among the descendants of Abraham; and the Midianites being of the number, we may reasonably suppose, could not have been unacquainted with it. They must also have had some knowledge of arithmetic, and also of ship-building; so that we may extend the circle of their sciences beyond writing and arithmetic, and allow them a competent skill in geography, geometry, and astronomy. The Midianites varied in religion as much as in their manner of life. In the north of Midian they appear in the days of Moses to have been addicted to all the abominations of the Moabites; but in the south we find that they were attached to a rational and sublime system, long after their brethren had sunk into the grossest corruption. The government of the Midianites is represented rather as aristocratical than monarchical. Their chiefs, however, are styled kings. The most ancient account of this nation that occurs, after what we have already stated, is that of their war with Hadad the Horite, when Midian was smitten by him in the field of Moab. The next is that of their purchasing Joseph from his brethren for twenty pieces of silver, and carrying him away with them into Egypt. See the article *JOSEPH*.

Many years after this event there lived in Midian, near the Red sea, a priest or prince of the southern Midianites, called Jethro; whose daughters were molested by some shepherds, and prevented from procuring water for their father's flocks. On this occasion Moses, who in his flight from Pharaoh had arrived in Midian, interposed on behalf of these females, and caused the shepherds to retire. In consequence of this seasonable act of kindness, Moses was invited to the house of Jethro, who gave him one of his daughters in marriage, and kept his son-in-law with him forty years. (See the article *MOSES*.) When Moses overcame Sihon the Amorite, the Midianites were at enmity with Israel; at least those who bordered upon the Moabites; and they seem about this time to have been very active in seducing the Israelites from the worship of God to idolatry. The Jewish lawgiver, however, made preparation for invading their country, and they fortified their castles and combined all their strength in order to resist the enemy. Their efforts were unavailing; as they were defeated with great slaughter, and all their cities and castles were laid in ashes, and their country plundered and desolated. About 150 years after this slaughter of the Midianites, two kings, named Zebah and Zalmunna, appeared as their conductors in a war against the Israelites; and they were joined by the Amalekites and Arabians. The destruction occasioned by these combined forces continued for seven years; and the Israelites were compelled by the ravages of the plains and by want of sustenance, to retire to the mountains, and shelter themselves in caves and fortresses. Gideon, however, exerted himself

for the rescue of his country; and his efforts were so successful, that the Midianites never afterwards presumed to contend with Israel. They were, however, a powerful nation many ages after this event, as well as famous for their industry, riches, and the magnificence of their tents; but in the first century of the Christian era their name sunk into disuse, and was swallowed up by that of the more powerful people of Arabia. Between 3 and 400 years ago there was a ruined city, which bore the ancient name, in the neighbourhood of which they pretend to shew the place where Moses watered his father-in-law's cattle. Abulfeda calls it Medyan, and Moses's father-in-law, Shoaib; and the place is still one of the stations in the pilgrimage from Egypt to Mecca, under the name of Shoaib's cave. *Anc. Un. Hist.* vol. ii.

MIDNAPOUR, in *Geography*, a river of Hindoostan, situated partly in Bengal, and partly in Orissa; bounded N. by Burdwan and Pachete, E. by Bissunpour and Hoogly, S. by Mohurbunge, and W. by Allahabad, about 110 miles long, and from 30 to 40 broad. The capital of the same name is a town of Bengal; 60 miles W. of Calcutta. N. lat. 22° 28'. E. long. 87° 27'.

MIDNIGUNGE, a town of Hindoostan, in Oude; 25 miles N. of Allahabad.

MIDNOI. See *COPPER Island*.

MIDNYPOUR, a town of Hindoostan; 35 miles N.E. of Benares.

MIDONNO, a town of Japan, in the island of Nippon; 85 miles N.N.W. of Jedo.

MIDRIFF, in *Anatomy*. See *DIAPHRAGM*.

MIDSAMA, in *Geography*, a town of Japan, in Nippon; 12 miles N.E. of Tomu.

MIDSHIP, is a term of distinction, applied by shipwrights to several pieces of timber which lie in the broadest part of the vessel, called the *midships*, although it is not in the middle of her length with regard to the breadth; it is a supposed line from the stem to the stern-post.

MIDSHIP-Beam, is the beam upon which the extreme breadth of the ship is formed, and which is situated in the midship frame, nearly in the middle of her length, serving as a standard from whence the dimensions and proportion of the mast and yards are to be taken. See *BEAM*.

MIDSHIP-Frame, is a name given to that timber, or combination of pieces, formed into one timber, which determines the extreme breadth of the ship, as well as the figure and dimension of all the inferior timbers.

MIDSHIP-Men, are officers on board a ship of war, whose station, when they are on duty, is, some on the quarter-deck, others on the poop, &c.

Their business is, to mind the braces, to look out, and to give about the word of command from the captain, and other superior officers. They all assist, on occasion, both in sailing the ship, and in stowing and rummaging the hold; and in performing the necessary business of the vessel, either aboard or ashore. The number of midship-men, like that of all other officers, is always in proportion to the size of the ship to which they belong. Thus a first-rate man of war has twenty-four, and the inferior rates a suitable number in proportion. No person can be appointed a lieutenant, without having previously served two years in the royal navy in this capacity, or in that of mate, besides having been at least four years in actual service at sea, either in merchant ships, or in the royal navy.

MIDSUMMER-DAY, is the festival of St. John the Baptist, held on the 24th of June. See *QUARTER-Day*.

MIDWAY, in *Geography*, a town, or rather a village, of America, in Liberty county, Georgia, 10 miles N.W. of Sunbury.

Sunbury. Its inhabitants are descendants of emigrants from Dorchester, near Boston, who migrated in 1700.—Also, a township of Rutland county, Vermont; E. of and adjoining Rutland.

MIDWIFE, a woman employed in assisting women in child-birth. Johnson supposes it to be derived from a Saxon word, meaning mead, or reward. As the practice of midwifery was entirely confined to women, until very lately, we have no term by which to denominate a male practitioner, but the barbarous compounded one, man-midwife. Had a more significant term been found for the women, we might have used it as we have the word author, from which we have made authoress, a female writer; though we think Johnson neither admits that word, nor the word man-midwife into his dictionary. The Romans, entertaining, perhaps, a more favourable opinion of the capacities of women, have the word *auxilium*, a female writer, from *auxilium*, which seems to justify us in the use of the word authoress. The French, more fortunate, call a midwife an *accoucheuse*, from the verb *accoucher*, to put to bed, and the male practitioners, *accoucheurs*; a term which we have now pretty generally adopted.

MIDWIFERY is the art of delivering women of their young. It must be nearly coeval, as a practice, with the creation. At first it was very simple, and consisted solely in the knowledge of the method of dividing the navel-string. Animals usually bite it asunder with their teeth. Women, probably, first made use of the sharp edge of a stone, or of a shell, for the purpose, which is the mode still practised in barbarous countries. As difficulties would occasionally occur, either in the exclusion of the fœtus, or of the placenta, or after birth, some female friend, or relative, would be called upon to give assistance. If the placenta happened to be detained beyond the usual time, which is one of the most ordinary accidents in labours, the assistant would naturally attempt to draw it away by the funis, which she would find hanging from the pudenda. If a leg or arm of the fœtus presented, instead of the head, she would, doubtless, take hold of the presenting part, and endeavour by that means to draw the child from its confinement. In these attempts, if it should be one of the lower limbs that presented, her exertions would generally be crowned with success; but as the obstacle making assistance necessary, supposes a relative disproportion between the birth and the passage through which it is to pass, the child would usually be dead born. On the other hand, if an arm presented, the same success would attend the exertions of the midwife in a few cases only; as in premature birth, or where the child happened to be remarkably small. It would more commonly happen, that all attempts to bring the child in that posture would fail; but the uterus persisting to exert itself, or, in other words, the labour-pains continuing, they would sometimes thrust down the feet, or the breech of the child, the head and shoulders gradually receding, and rising upwards, and it would at length be forced into the world in that position. In these cases, though the child would be dead, the woman would frequently recover. It would more often happen, that this evolution would not take place, and that the woman, exhausted by long continued and fruitless exertions, bruised and injured by the pressure of the fœtus, and tormented by the distention of her bladder, no access being allowed to the urine, would fall a sacrifice to the pressure of so many accumulated evils.

Some of the earliest means made use of in tedious and difficult labours, appear to have been, anointing the pudenda with oils, and putting the woman into warm baths, as we find it recommended by Hippocrates, Avicenna, and other

ancient writers; by these means they hoped to relax the parts, and render them more easy of distention, and thence to procure a freer passage for the fœtus. This continued to be the practice for many ages.

From examining the little that has been written by the ancients on the subject, it is evident they had no knowledge of that species of obstacle to the birth of the child, which is occasioned by the mal-conformation of the bones of the pelvis of the woman. They attributed the whole of the difficulty to a rigidity of the muscles, or of the ligaments connecting the bones of the pelvis together, which they hoped by these means to loosen.

Hieronymus Mercurialis, who flourished about the middle of the sixteenth century, tells us, it was not unusual to put women on a course of bathing and anointing several weeks before they attained to the period of parturition. Speaking of what is to be done, prior to the labour, he says, "Utatur balneis aquæ dulcis, in quibus herbæ laxantes et emollientes coquantur. Inungatur etiam eodem tempore, dorsum, et pectus, similiter loca muliebria iis linimentis, quæ possunt emollire, et lenire." (De Morb. Mul. lib. ii.) Another custom which was probably only practised among the common people, was placing the parturient woman in an erect posture, that they might profit by the weight of the fœtus, and shaking them strongly; thinking, probably, that the child would drop down, as fruit falls from the tree.

"Alii," Moschioni says, (Harm. Gynæc. p. 11.) "ad scalas ligabant, et sic pendere jubebant; alii infinitum deambulare et salire cogebant; alii scalas ascendere; alii autem, manibus sub axillis missis, a terra subleabant, et diutius exagitant." Hippocrates had long before, and probably with the same view, recommended in cases where the head of the child presented, but on account of the straightness of the passage was detained above the brim of the pelvis, to anoint the parts, and to put the woman into a bath of warm water. These methods failing, the head of the child was to be opened with a scalpel, and then to be extracted with a strong iron pincers, or hooks. "Caput gladiolo dissectum. Instrumento quod constringat comminuto, et officula per ossium volsella extrahito, aut unco attractorio ad clavicularum uti firmiter adhzreat immisso, non confestim, sed paulatim remittendo, et rursus adurgendo, extrahito." (Hip. Oper. Om. Fælio. p. 618.) Celsus recommends a similar practice, (lib. vii. cap. 29. De Medicina.) Avicenna mentions a kind of fillet that was used in these cases. (See the article **FILLET**.) This contrivance, although it had a few favourers, was never in general use; the more common method in tedious and difficult births was to diminish the bulk of the child, or of the part nearest to the external surface, with scalpels, or other cutting instruments, and then to draw it away with iron hooks, pincers, or forceps, armed with teeth. Those who wish to see the forms of these instruments, or a more particular account of the methods of applying or using them, may consult Albucaasis's *Methodus Medendi*, lib. ii. and Ruett, *De Conceptione et Gen. Hominis*, in which many of them are particularly delineated and described.

As cases of such difficulty as to render the use of instruments necessary are rare, not occurring oftener than once in five or six hundred labours, and as the practice of midwifery was for many ages, indeed so late as to the end of the sixteenth century, almost exclusively in the hands of women, it is not to be wondered at, that little improvement was made in the method of assisting women in the only cases that would come under the care of the surgeon, until a very late period. Hippocrates having learned that in ordinary births the child presented with its head to the orifice of the womb, thought that in all cases, when it offered in a different posture,

posture, it ought to be pushed back, in order to bring down the head. Thus he attempted to do even when the breech or the feet came first. If an olive he lays, comes into the neck of a bottle across, and you attempt to bring it through in that posture, you will either crush the olive, or break the glass; but as it is of little consequence which of the ends of the olive comes first, he should have seen, that it is nearly equally immaterial which end of the child comes first. This, however, does not seem to have occurred to him, and as his name was of great authority in every thing relating to medicine, his rules continued to be followed until the middle of the sixteenth century. Ambrose Parey, who flourished about that time, first recommended turning the child and bringing it by the feet in all cross presentations. This may be considered as the first material improvement that had been made in the practice of midwifery. The rule was further explained and extended by his pupil Guillemeau, and afterwards by Mauriceau, Le Motte, Peu, Puzos, and other French writers, and it has long since been adopted by the practitioners in the art in every part of Europe, not only in cross-births, but in all cases of flooding, in whatever posture the child may present, also when the funis umbilicaris comes down before the head of the child, and by some surgeons, as we shall see by and by, in cases where the forceps or lever are now ordinarily used.

A few years before Ambrose Parey's book appeared, Eucharius Rhodion, a physician of Frankfort, published the first popular work that we are acquainted with on the subject. As it was intended for the instruction of the midwives, it was printed at first in the German language. In 1532, it was translated into Latin, under the title of "De partu hominis," and in a few years after, into French, English, and other modern languages. The practical rules recommended by him, are such as he had learned from Hippocrates, Avicenna, and other ancient writers. In cross presentations, the midwife was to endeavour to bring down the head; when this could not be effected, if the breech, or feet, were next the uterine orifice, the child was to be allowed to come into the world in that posture, taking, however, especial care, he says, that the hands should be brought down, and placed one on each side of the body of the child, a rule which could not possibly be followed, and which shews that the writer had never practised the art. The same censure may be passed upon almost every regulation, that had been hitherto promulgated on the subject. Nearly all of them tending rather to mislead, than to inform the practitioner, and to increase rather than diminish the pain, difficulty, and danger of the labour.

We have two translations of Rhodion's book into our language. The first by Richard Jones, who dedicated it to Katherine, queen to king Henry VIII. It was printed in the year 1540, and is decorated or illustrated with some indifferent engravings on copper, which, however, are esteemed, as being the first specimens of the kind executed in this country. In 1545, Thomas Raynold, physician, published a second translation. This has passed through several editions, under the title of "The Birth of Mankind," and was nearly the only manual used by the midwives until the year 1672, when Dr. Hugh Chamberlen gave a translation of Mauriceau's "Treatise on the Art of Midwifery," in which the first dawning of a rational practice of the art appears. In the preface to the translation, Dr. Chamberlen announces an invention, "known only," he says, "to his father, brothers, and himself, with which they were enabled to terminate the most difficult labours, without injuring either the mothers or the children." Though he gives no intimation by which it could be discovered what were the means used

for the purpose, yet it was in time found out to be the forceps. The merit of the invention consisted in making the blades of the instrument separable, and capable of being locked, or united together, after being introduced into the vagina, and placed one on each side of the head of the child. (See the article FORCEPS, in *Midwifery*.) A most invaluable discovery, and which has deservedly immortalized the inventor. (See CHAMBERLEN, HUGH.) But he at first very much overrated their power, imagining that they were applicable in all cases, where the head of the child was "enclavée," or fixed in the pelvis, not having met with a case, we may suppose, where the bones forming that cavity were considerably distorted. Accordingly he undertook to deliver a woman whose pelvis was so contracted and narrow, as to render it impossible that the head of a full grown fœtus should pass through it undiminished. The operation, or trial, which was performed at Paris, where he went with the view of selling his secret, failed. Mortified at the check he received, he left the country, and went to Amsterdam, where he is said to have sold the secret to Roonhuysen, a surgeon in great practice in that city, who has the credit of having invented the lever which bears his name. See that article.

About the same time Deventer, an eminent surgeon of a town in Holland of that name, acquired considerable fame by his practice in the obstetric art. As the form, as well as the manner of using the forceps and lever were kept secret by the proprietors of those inventions, or only disclosed to persons who would pay a large sum of money for them, Deventer declaimed violently against the use of instruments, affirming he could terminate the most difficult labours with his hand alone. He contended that the greatest obstacle to the birth of the child arose from the oblique position of the uterus, its fundus falling too much forward, or to one side of the abdomen of the mother. The head of the child was therefore forced by the pains, either against the sacrum, or against one of the sides of the pelvis, instead of being directed into the centre of that cavity. In all cases of difficulty, if the head of the child was not forced down so low as to render it impracticable, he passed his hand into the uterus, turned the child, and delivered it by its feet. When that could not be done, he introduced his left hand into the back part of the vagina, and gradually pushed back the bones of the coccyx, so as to give space sufficient for the head of the child to pass. In cases where the pelvis was distorted, he must necessarily have failed in his attempt, for the same reason that Chamberlen failed with his forceps, but as such cases would only occur once in five or six hundred labours, that small number of exceptions would give little check to his fame, which was continued to his name for many years after his death. This doctrine and practice, which have long since been exploded, were patronized in this country by Mowbray, sir Richard Manningham, and Eaton, who were all averse to the use of instruments.

The construction and use of the forceps being at length made public by Mr. Butter in the third volume of the *Medical Essays* in 1732, and more fully by Chapman in 1734, and that of the lever by M. Preville, in his translation of Smellie's *Midwifery* into French, published at Paris, in 1754, the teachers of the art were careful in instructing their pupils in the method of employing those instruments, which have entirely superseded the rude practice of Deventer. The *perforator* and *scrotchet* (see those articles) came into use about this time, and continue to be employed in the few cases that require such assistance, in the place of the scalpel, and the forceps with teeth.

Practitioners in the art being now possessed of such powerful

erful assistants, it was to be feared they might be induced to have recourse to them for the purpose of accelerating the labour, in cases where there were only such obstacles as in a moderate space of time would be overcome by the pains. Cautions against this fascinating practice are found in all the late treatises on the art. Smellie, who had a larger share of practice, and who instructed a greater number of pupils than any other professor in his time, is frequent in his admonitions against using art, other than in aid of nature, where she is absolutely and decidedly incompetent to the completion of the labour. How seldom also this happens, he is careful to inform them. He very much simplified the form of the forceps, and that they might not be used before the head of the child had descended sufficiently low in the pelvis, he considerably reduced them in length; he also contrived a method of locking them, much more convenient than had been before used. Before he retired from the practice, in which he introduced several valuable improvements, he published, in 1752, "A Treatise on the Theory and Practice of Midwifery," which contained the substance of every thing that was useful, that had been printed on the subject, as well as the result of his own extensive practice. This was followed by a set of plates, in large folio, correctly drawn and well engraved, illustrating his practice. Soon after he published two volumes of cases, arranged in classes, referring to his treatise, and shewing the efficacy of the rules he had there inculcated.

While Smellie was making large strides toward improving every part of the practice of midwifery, and bringing it to perfection, Levret, and various other writers on the continent, were exerting themselves in a similar manner, and with perhaps equal felicity. In the mean while, hospitals and other institutions were formed, for the reception of parturient women. As the management and care of these were under the immediate direction of the physicians and surgeons, and the opportunity which for so many ages had been wanting, of acquiring an exact knowledge of the process of a natural labour, and of the obstacles that occasionally obstructed its progress and completion, was now obtained. To this also, the change that had been taking place, within something more than a century, in the opinions and manners of the public had contributed. Several physicians and surgeons had, in the course of that time, applied themselves to the practice of midwifery. Hence we find, Mauriceau, Deventer, Ruysch, Roonhuysen, our countryman Dr. Chamberlen, and others, enjoying a considerable portion of practice in the art.

The custom of employing men in the place of women, originated among the ladies of the highest rank in France, and gradually descended to the middling and lower classes of the people. The advantages derived from the change, both in the manner of conducting the labour, and in the management of the woman and child after the labour, became so obvious, that the practice has by degrees spread over all Europe. That the poor who could not, and a few who from prejudice still refused to employ men, might reap the benefit of the improvements that have been made in the practice of the art, no women are now allowed to engage in the business, who have not been previously instructed by some public teacher, and who do not obtain from him certificates of their qualifications. The consequence of these arrangements has been, that every part of the art has been investigated with the greatest care, and such has been the zeal of the professors, or persons engaged in the practice, that the works on the subject of midwifery, which have been published within less than a century, are sufficiently numerous to form of themselves no inconsiderable library. Thus this art, which was

so late in being cultivated, has already attained a degree of perfection, that puts it on an equality, at least, with any other branch of medicine. Of this great mass of publications, many of them excellent, it may be sufficient to mention, among foreign productions, Puzo's "Traité des Accouchemens," Baudelocque's "Art des Accouches," Crant's "De Re Instrumentaria," and the "Opuscula" of Roederer, and of Plenck, which embrace the whole circle of the art. Among our own writers, White "On the Management of Pregnant and Lying-in Women," and Rigby "On Uterine Hemorrhage," have each in their way given directions that are calculated to abide the test of time. "Observations on human and comparative Parturition," published in 1794, may be added, as containing a number of curious and useful facts not generally known or attended to. The late Dr. William Hunter's splendid plates of the human gravid uterus, and not more splendid than correct, places before our eyes the fœtus at different periods of its existence, shews the posture in which it lies in the uterus, and the manner in which it is connected with that viscus; and lastly, Dr. Denman's "Introduction to the Practice of Midwifery," which has already passed through several editions. For comprehensiveness and exactness, it holds the same rank now that Smellie's Treatise did at the time when it was published, embracing and explaining, in a luminous and judicious manner, every thing, we believe, that is known on the subject.

MIEDNIKI, in *Geography*. See MEDNIKI.

MIEDZIAL, a town of Lithuania, in the palatinate of Wilna; 52 miles S. of Breslaw.

MIEDZINECZE, a town of Poland, in the palatinate of Brzesk; 25 miles W. of Brzesk.

MIEDZIRZECZKA, a town of Poland, in the palatinate of Volhynia; 52 miles N.N.W. of Zytomiers.

MIEDZYRZECZ, a town of Lithuania, in the palatinate of Novogrodek; 44 miles W.S.W. of Novogrodek.

MIEDZYRZYCZ, a town of Russian Poland, in the palatinate of Kiev; 32 miles W.S.W. of Czyrkafy.

MIEGIA, in *Botany*, appears to have been named by Schreber in honour of two Swiss anatomists and botanists, who flourished in the beginning and middle of the last century. Most probably they were father and son, but we are not sufficiently acquainted with their history positively to assert this. John Rodolph Mieg published his inaugural Dissertation on *Chamæmelum leucanthemum* at Basil, in 1721, which was reprinted two years afterwards. Achilles Mieg published a work in 1751, at the same place, which he calls *Specimen observationum anatomicarum atque botanicarum*, and in this are described some rare grasses, as well as the genus *Montia*. Schreb. 786. Willd. Sp. Pl. v. 1. 311. Mart. Mill. Dict. v. 3. (Remirea; Aubl. Guian. 44. Juss. 34. Lamarck Illustr. t. 37.)—Class and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume single-flowered, of two, ovate, concave, ribbed valves; the upper shorter and obtuse; the lower somewhat longer and rather acute. *Cor.* of two, swelling, ribbed valves; the outer ovate, obtuse, within the lower calyx-valve, and longer than it; the inner oblong, compressed at the top, rather acute, with folded margins, longer than the outer, within the upper calyx-valve. Nectary of one leaf, ovate, gibbous at the back, slightly compressed, acute, smooth, thick, corky, thinner at the tip and margins, shorter than the corolla, opposite to its inner valve, enclosing the germen. *Stam.* Filaments three, capillary, longer than the corolla; anthers oblong, acute. (Aubl.) *Pist.* Germen oblong, nearly triangular, within the nectary; style simple, capillary, longer than the corolla; stigmas two, capillary. *Peric.* none. *Seed* solitary, oblong, triangular, approaching

approaching to globose, wrapped up in the nectary, and enclosed by the permanent calyx and corolla.

Ell. Ch. Calyx of two opposite valves, single-flowered. Corolla of two valves. Nectary of our leaf, enveloping the germens.

Obl. The above generic character was made by Schreber, from the parts of fructification as they were found by him in a dried specimen. The nectary he observes is remarkable. Aublet's character of *Remirea* is very different from that of Schreber's *Miccia*.

1. *M. mariima*. Willd. n. 1. (*Remirea maritima*; Aubl. Guian. t. 16.)—A native of the sea shores of Cayenne and Guiana, flowering and bearing seed at various times of the year.—Root perennial, creeping, long, branched, knobbed, solid. Stems about six inches high, branched at their summits, leafy and scaly below. Leaves oblong, narrow, rigid, striated, acute, rough at the margin, sheathing at the base. Flowers crowded together into a nearly sessile, terminal, short and thick panicle. The roots, when bruised or mallicked, afford a grateful, aromatic smell, shewing an affinity to the genus *Cyperus*, from which indeed this plant seems to differ chiefly in its solitary florets, and corky nectary.

MJEIBOW, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 58 miles W.S.W. of Novogrodek.

MIEKOW, a town of Austrian Poland, in the palatinate of Cracow; said to have been built after the model of Jerusalem by Gripfius Jaxa, after his return from a pilgrimage to that city; 12 miles N. of Cracow.

MIEL, JAN, in *Biography*, a painter, known in Italy by the name of Giovanni della Vite, probably because he chose to disregard the grand style of art in which at first he practised with Andrea Sacchi, and paint common nature and living objects.

He was born in Flanders in 1599, and first learnt to paint under Gerard Segers; but he soon left him, and went to Italy, where he studied the antique and the works of the best masters with great success, and was employed to paint pictures as large as the life for several of the churches in Rome. He had the honour to study in the academy of Andrea Sacchi, then in great repute, and was invited by him to assist in a large picture he was then engaged upon; but they soon disagreed, and Miel left his master in disgust, piqued with a satiric expression of Sacchi concerning his talent for painting *bambocciate*, or scenes of merriment, drolls, &c. his imagination principally leading to such subjects.

In consequence, he set himself afresh and with increased diligence to study the grand style, and rival Sacchi; but after a time gave it up almost altogether, and painted those subjects for which nature appears to have designed him, with a portion of talent nearly equal to Bamboccio himself. His success was fully equal to his skill, and he filled the cabinets of the nobility of Rome, Florence, and other places, with his ingenious performances.

The lustre of his fame induced Charles Emanuel, duke of Savoy, to invite him to Turin, where he arrived in 1659, and was received by his highness with great respect, and engaged to paint for him several pictures relative to the chase, in which he introduced an immense number of small figures of persons of all ranks, horses, dogs, different species of game, &c. all which he finished so much to the satisfaction of the duke, that he honoured Miel with knighthood, and besides paying him handsomely for his pictures, presented him with a cross ornamented with diamonds of great value.

He remained at Turin six years, during which time he painted a great number of pictures, and at the end of it died of a slow fever, or rather consumption, brought on, Baldi-

nucci assert, by his uneasiness at not obtaining his patron's permission to revisit Rome.

MIELAN, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; 6 miles S.S.W. of Mirande. The place contains 1403, and the canton 10,121 inhabitants, on a territory of 27 $\frac{1}{4}$ kilometres, in 29 communes. N. lat. 43° 25' E. long. 0° 23'.

MIELEC, a town of Poland, in the palatinate of Sandomirz; 56 miles S.W. of Sandomirz.

MIELNICK, a town of Poland, in the palatinate of Bielsk; 44 miles S.W. of Bielsk.

MIEN, a town of China, of the second rank, in Setchuen; 56 miles W. of Pao-king. N. lat. 51° 28'. E. long. 104° 29'.

MIEN-TAM-KEOU-TOUKA, a town of Chinese Tartary. N. lat. 41° 1'. E. long. 119° 43'.

MIEN-YANG, a town of China, of the second rank, in Hou-quanz. N. lat. 30° 12'. E. long. 112° 49'.

MIER-CHAS-KUN, a town of Persia, in the province of Farfistan, containing about 400 houses and several bazars, the ruins of Persepolis; 40 miles N. of Schiras.

MIERIS, FRANCIS, in *Biography*, a most admirable painter of the Flemish school, who was born at Leyden in 1635. He acquired the principles of the art under Gerard Dow, who honoured him with the title of prince of his disciples, and this praise he justly merited, for he more nearly approached the purity and delicacy of Dow than any other man has ever done; indeed, in some respects he became viceroy over that king of high and minute finishing, being more agreeable in his designs, and having more correctness in drawing.

He painted portraits with great delicacy, but his general subjects were conversations, persons performing on musical instruments, doctors with their patients, and such like: these he treated with great ingenuity in composition and execution; painting his draperies with so much minuteness, that all the peculiarities of their different textures are visible. Silk, velvet, stuff, carpets, &c. all were not only marked with their general characteristic appearances, but the threads of their texture were made as visible as in nature, and rendered completely deceptive. It is this attention to minutia, united to breadth and truth, which give so much value to his works; which are very rare, and very costly of course. His own valuation of his time was a ducat an hour: and for one picture of a lady fainting, with a physician attending her, and applying remedies, he was paid at that ratio, so large a sum as fifteen hundred florins. The grand duke of Tuscany is said to have offered 3000 for it, but was refused. One of the most beautiful of the works of Francis Mieris, in this country, where they are not very common, is in the possession of Mr. P. H. Hope, and is known by the appellation of the "Shrimp Man." He died in 1681, and is called by connoisseurs the Old Mieris, to distinguish him from his son,

MIERIS, WILLIAM, who of course is called the Young. He was born at the same place as his father, and learned from him the art of painting, till he arrived at the age of 19; when, his father dying, he was left to follow the dictates of his own mind, which happily led him to study nature, and in that study he made a considerable progress towards obtaining an equal reputation with his father.

At first he painted the same subjects as his father, but afterwards, ambitious of a nobler fame, he attempted higher subjects, but not being prepared with proper studies, he did not succeed so happily as his adventurous spirit deserved. He sometimes painted landscapes and animals, and also modelled his figures with very considerable skill. Probably

this division of his time and studies operated to prevent his arriving at the same degree of excellence in minute finishing as his father: certain it is, that his works will not bear the comparison, being poor and thin, and wrought by a less full, and more timid pencil. He died in 1747, aged 85, and left a son, Francis Mieris, born at Leyden in 1689, who not having the talent of originality, employed himself in copying the works of his father and grandfather; and it is most likely, that nine out of ten of the works distributed at sales under the name of Mieris, are the second-hand productions of this, the younger Francis.

MIES, or MUZA, in *Geography*, a town of Bohemia, in the circle of Pilsen; 14 miles W. of Pilsen. N. lat. 49° 43'. E. long. 13° 6'.

MIETOU, a town of Sweden, in the government of Abo; 14 miles N.W. of Abo.

MIEZA, a town of Spain, in the province of Leon; 42 miles W. of Salamanca.

MIFFLIN, a county of Pennsylvania, in America, surrounded by Lycoming, Franklin, Cumberland, Northumberland, Dauphin, and Huntingdon counties; containing 1851 square miles, 1,184,960 acres, and divided into eight townships. The mountains of this county abound with iron ore, and several forges have been erected for working it. It is well watered by the Juniatta and other streams; it has several mineral springs, and abundance of lime-stone. This county and Center contain 13,609 people. The chief town is Lewistown.—Also, a small town in the above county, on the E. side of the Juniatta; 12 miles E. of Lewistown.—Also, a fort on a small island, at the mouth of Schuylkill river; about six miles S. of Philadelphia.

MIFFLINBURG, a post-town of Northumberland county, Pennsylvania; 218 miles from Washington.

MIGLERE, LA, a town of Italy, in the department of the Po, on the Stura; 24 miles N.N.W. of Turin.

MIGLIAJO, in *Commerce*, a weight and measure by which oil is sold at Venice: the weight = 40 miri, each being 25lb.: the measure = 1210lb., or 40 miri, each = 30 $\frac{1}{2}$ lb.: so that such a miri corresponds to about 4 $\frac{1}{4}$ English gallons.

MIGLIANICA, in *Geography*, a town of Naples, in Abruzzo Citra; 7 miles E. of Civita di Chieti.

MIGLIANO, a town of Naples, in Principato Ultra; 15 miles N.N.E. of Conza.—Also, a town of Italy, in the department of the Lower Po; 15 miles E. of Ferrara.

MIGLIAVACCA, GIOVANNI AMEROSIO, in *Biography*, counsellor of legation, and opera poet to the elector of Saxony, king of Poland, author of an opera intitled "Solimano," and of many cantatas performed at Vienna and Dresden. This poet endeavoured to imitate the elegant and natural style of the amiable Metastasio.

MIGLIONICO, in *Geography*, a town of Naples, in Basilicata; 9 miles S.W. of Matera.

MIGNANO, a town of Naples, in Lavora; 11 miles N. of Sezza.

MIGNARD, PETER, in *Biography*, an historical and portrait painter, born at Troyes, in Champagne, in 1610. He was the disciple of Vouet, but quitted his school at an early period of his life, and went to Rome, anxious to see and study the works of Raphael, Michael Angelo, and the Caracci. He there lived with Du Fresnoy, and they studied together the noble works of art which that city presented to them; they also travelled together to Florence and Venice, that they might leave no source of improvement unsought which the extraordinary talents of their great predecessors had prepared and left for their study and imitation.

The residence of Mignard at Rome, which he prolonged

for 22 years, and the style he acquired of composition and drawing by the imitation of the Roman masters, together, obtained for him the appellation of the Roman; but to judge candidly, one would imagine that the former was the principal cause of that denomination; for his style of design favours too much of the flutter of the French school, instead of the chaste simplicity of Raphael and the best of the Romans.

Mignard enjoyed a full share of favour and fortune during his life. He painted portraits of the popes Urban VIII. and Alexander VII., together with those of many of the nobility of Rome.

Louis XIV., hearing of his fame and abilities, sent for him to Paris, and is said to have sat to him for his portrait ten times. Almost all the illustrious nobles of the French court followed the example of their sovereign, and were painted by Mignard. His style of execution in these portraits is wrought up with all the false taste and pompous parade which distinguished that vicious period of the French nation; when parade passed current for true splendour; what was only specious or subtle, was received as useful and learned; and bombast assumed the station due only to true dignified simplicity. His pictures are all flutter; every thing seems in motion; even when the scene is laid in a close room, the draperies are flying about as in a high wind. The actions of his figures are in assumed airs, like pompous, and not unfrequently bad actors, and the colouring of his pictures, though fresh and vigorous, is not true, but teinted, and reminds the observer of the palette. With these defective points in his character as an artist, Mignard is not unworthy of regard. His drawing is correct: his arrangement of parts is ingenious: and his invention fertile. He contrived to make his pictures ornamental, and is the best portrait painter of the French school.

His patron, Louis, ennobled him; and, after Le Brun's death, appointed him his principal painter, and the director of the manufactories of Seve and the Gobelins. He lived to the age of 85, dying in 1695. He had an elder brother, whose name was Nicholas, a skilful painter, but who never rose to equality with him.

MIGNATRICE, LA, *Ital.*, a miniature painteress in 1770, the late Mrs. Corri, whose family name was Bicchelli, then a young and beautiful woman, a professed miniature painteress, and a brilliant and very pleasing singer at the Academie, or private concert of the nobility and gentry at Rome, where no females are allowed to appear on the stage, was best known by the title of La Mignatrice. After her marriage with her singing-master, Corri, she came with him to Edinburgh in 1772, to sing at the concerts in that city, where he was engaged to direct the concerts, and give instructions in music. They remained at Edinburgh till about the year 1787, when they removed to London, where Mrs. Corri, mother of the accomplished Mad. Duffec, died in 1802, much lamented by her family, friends, and all who had heard her sing in the early part of her life.

MIGNONETTE, in *Botany*. See RESEDA.

MIGNOT, STEPHEN, in *Biography*, a learned French ecclesiastic, a native of Paris, was born in the year 1698. He was brought up to the church, and was admitted to the degree of doctor by the faculty of the Sorbonne, and rendered himself eminent for his acquaintance with the sacred scriptures, the fathers, ecclesiastical history, and canon law. When upwards of sixty years of age, he was elected a member of the Royal Academy of Inscriptions and Belles Lettres. He died in the year 1771, leaving behind him numerous works, of which the following seem most worthy of notice: *viz.* "A Treatise on Commercial Loans," in four volumes; "The Rights of the State and of the Prince, with Reference to the Estates of the Clergy," in six volumes;

"The

"The History of the Contest between Henry II., and St. Thomas of Canterbury;" "The Reception of the Council of Trent, in Catholic Countries;" "A Paraphrase on the New Testament," in four volumes; "A Memoir relating to the Liberties of the Gallican Church."

MIGRATION, or TRANSMIGRATION, the passage or removal of any thing out of one state or place into another; particularly of colonies of people, birds, &c. into other countries.

The migration of the souls of men into other animals after death, is the great doctrine of the Pythagoreans, called the *metempsychosis*.

The migration of birds, as the swallow, quail, stork, crane, field-fare, woodcock, nightingale, and other birds of passage, is a very curious article in natural history, and furnishes a notable instance of the powerful instinct impressed by the Creator. Dr. Derham observes two things remarkable in this subject; the first, that these untaught, unthinking creatures, should know the proper times for their passage, when to come, and when to go; as also, that some should come when others go? No doubt, the temperature of the air, as to cold and heat, and their natural propensity to breed their young, are the great incentives to those creatures to change their habitation. But why should they at all change their habitations? and why is not some certain place to be found, in all the terraqueous globe, affording them convenient food and habitation all the year round?

The second, that they should know what way to steer their course, and whither to go. What instinct is it that moves a poor foolish bird to venture over vast tracts of land and sea? If it be said, that, by their high ascents up into the air, they can see across the seas; yet what should teach or persuade them, that another land is more proper for the purpose than this? that Britain, for instance, should afford them better accommodation than Egypt? than the Canaries? than Spain? or any other of the intermediate countries? *Physico-Theol.* p. 349.

Lud. de Beaufort remarks, that birds, in their migration, observe a wonderful order and polity: they fly in troops, and steer their course through vast unknown regions, without the compass. (*Cosmol. Divin.*) It is to be added, that the birds of passage are all peculiarly accommodated, by the structure of their parts, for long flights.

Naturalists are divided as to the places whither birds of passage retire when they leave us. Mr. Willughby thinks the swallows fly into Egypt and Ethiopia.

Olaus Magnus says, they lurk in holes, or under water; which is confirmed by Etmuller, who assures us, that he saw a bushel of them taken out of a frozen fish-pond, all hanging together, head to head, feet to feet, &c. in one cluster. (*Disert.* ii. c. 10.) Olaus adds, that this is a common thing in the northern countries; and that such a cluster being carried accidentally by some boys into a stove, the swallows, after thawing, began to fly about, but weakly, and only for a little time.

A farther confirmation of this account was given by Dr. Colas, a person very curious in such things, to the Royal Society. Speaking of the way of fishing in the northern parts, by breaking holes, and drawing their nets under the ice, he related, that he saw sixteen swallows so drawn out of the lake of Samrodt, and about thirty out of the king's great pond at Rosincilen; and that at Schlebitten, near a house of the earl of Dohna, he saw two swallows just come out of the waters that could scarcely stand, being very wet and weak, with their wings hanging on the ground. He added, that he had often observed the

swallows to be weak, for some days after their first appearance.

Some of our own countrymen have given credit to the submersion of swallows; and Klein patronises this doctrine in his *Hist. Av.* 205, 206. But they assign no reason, why these birds are capable of enduring so long a submersion without being suffocated, or without decaying in an element so unnatural to them; when we know that the otter, the cormorant, and the grebe soon perish if caught under ice, or entangled in nets; and it is well known, that these animals will continue much longer under water than any others to whom nature hath denied that particular structure of heart, necessary for a long residence beneath that element. Mr. John Hunter, having dissected many swallows, found nothing in them different from other birds as to the organs of respiration; whereas all those animals which he had dissected, of the class that sleep during winter, such as lizards, frogs, &c. had a very different conformation in those organs. He farther adds his opinion, that these animals breathe in their torpid state; and, as far as his experience reaches, he knows they do; and he, therefore, esteems it a very wild opinion, that terrestrial animals can remain any long time under water without drowning.

There is another more probable opinion, with respect to the disappearance of swallows, which has high antiquity to support it. Aristotle and Pliny assert, that these birds do not remove very far from their summer habitation, but winter in the hollows of rocks, and during that time lose their feathers. We have had many instances of some species of swallows having been discovered in a torpid state, on the cliffs of the Rhine, in old dry walls and sand-hills in Scotland, in the chalky cliffs of Suffex, in hollow trees, and lead mines, &c. These several places are supposed to be the lurking habitations of later hatches, or of those young birds that are incapable of distant migrations; where they generally continue insensible and rigid, though, like flies, they may sometimes be re-animated by an unseasonable hot day in the midst of winter. From these facts, it is reasonable to conclude, that, though one part of the swallow tribe migrates, others may have their winter-quarters nearer home. If it should be asked, why swallows alone are found in a torpid state, and not the many other species of soft-billed birds, which likewise disappear about the same time? the following reason, says Mr. Pennant, may be assigned. No birds are so much on the wing as swallows; none fly with so much rapidity and swiftness; none are obliged to such sudden and various evolutions in their flight; none are at such pains to take their prey; and none exert their voice more incessantly; whence they suffer a great expence of strength and spirits, and acquire such a texture of blood, as other animals do not experience; and become thus disposed to a more lasting repose than other birds. But notwithstanding this concession, it is most probable that swallows in general, as well as other birds, migrate from colder into warmer climates, in search of proper food, a sure asylum from man during the time of courtship, incubation, and nutrition, and a temperature of air suiting their constitutions.

The generality of birds that remain the winter with us have strong bills, or are enabled to feed on what they can find at that season; those which leave us have usually very slender bills, and their food is the insects of the fly kind; which disappearing towards the approach of winter, compel them to seek them in regions where they may be found; and the length of the wings of the generality of these birds, enables them to prey flying, if there be food for

MIGRATION.

them in their way, and to continue a long time on the wing without rest.

The various conjectures about the places to which they retire, are owing to want of ocular testimony; but if we consider the vast tracts of land yet unknown to us, we cannot doubt but there may be many places for them, in which we can have had no opportunities of finding them. But the most probable conjecture seems, that the places to which they retire lie probably in the same latitude in the southern hemisphere, as the places from whence they depart; where, the seasons reverting, they may enjoy the like agreeable temperature of the air. And, if these places are supposed to be divided from them by too large seas, why may not some other parts of the southern hemisphere, which are less distant, serve their turn?

This, certainly, seems much more reasonable than that they should remain on our side of the northern tropic, within a few degrees of which, at the winter solstice, it is so cold as frequently to produce snow; which, by dispersing such insects as birds that feed upon the wing subsist on, must make them perish, were they not to remove to those warmer climates where they may still find food. The swallows, as they cannot subsist so long in cold seasons as some other birds of passage, which feed, after the disappearance of flies in the air, on what insects they find in their recesses, visit us later, and depart from us sooner, than the rest. The nightingales, and some other birds, which leave us for the winter, are seen, sometimes, a month after the swallows; and from the whole it seems natural to infer, that the swallows pass the tropic of Cancer, though it is not yet known to what place they at length retire.

The manner of the birds of passage journeying to their southern abode may vary, according to the different structure of their bodies, and their power of supporting themselves in the air. Those birds with short wings, such as the redstart, blackcap, &c. though they are incapable of such long flights as the swallow, or of flying with so much celerity, yet may pass to less distant places, and by slower movements. Swallows and cuckoos may perform their passage in a very short time; but there is for them no necessity for speed, since every day's passage affords them an increase of warmth, and a continuance of food.

Providence, which has guided the defenceless animals in many other instances to the safest methods of performing their necessary works, may have instructed many of these birds which have shorter passages to make, or places to stop at by the way, to fly only in the night, that they may be secure from the birds of prey; and Mr. Catesby gives a proof that some species do so, from his own observation; for, lying on the deck of a sloop on the north side of Cuba, himself and the whole company heard successively, for three nights, flights of rice birds, which are easily distinguished from all other birds by their notes, and which were passing over their heads northerly; which is their direct way from Cuba, and the southern continent of America, from whence they get to Carolina, annually, about the time that rice begins to ripen, and from whence they return southward again, when it is gathered, and they are become fat.

That this is the case also with some species of swallows, has been proved beyond contradiction by M. Adanson, *Hist. de Senegal*, p. 67. We often observe them collected in innumerable flocks on churches, on rocks, and on trees, previous to their departure hence; and Mr. Collinson proves their return here, perhaps, in equal numbers, by two curious relations of undoubted credit; the one communicated to him

by Mr. Wright, master of a ship, and the other by the late sir Charles Wager; who both described to the same purpose what happened to each of them in their voyages. "Returning home," says sir Charles, "in the spring of the year, as I came into soundings in our channel, a great flock of swallows came and settled upon my rigging: every rope was covered; they hung on one another like a swarm of bees; the decks and carving were filled with them. They seemed almost famished and spent, and were only feathers and bones; but being recruited with a night's rest, took their flight in the morning." This apparent fatigue proves that they must have had a long journey, considering the amazing swiftness of these birds; so that in all probability they had crossed the Atlantic ocean, and were returning from the shores of Senegal, or other parts of Africa.

The short-winged birds are supposed little qualified for long flights, particularly the quail, which is a bird never seen long together on the wing, or making any long flights; its not doing this frequently is, however, no proof that it is not able to do it; nor does the structure of its body at all bespeak its inability; and Bellonius affirms, that he saw them in great flights passing over, and repassing, the Mediterranean sea, at the very seasons when they leave us, and they return again. The same instinct that directs these birds to depart to distant countries, doubtless also directs them to the shortest way, and sends them to the narrowest cuts, not the wider seas, to cross.

Among the birds of passage, we have some also which come to us in the autumn, at the time when the summer birds are leaving us; and go from us again in the spring at the times when these return: these, however, are only four kinds; the field-fare, the redwing, the woodcock, and the snipe; and of these the two last often continue with us through the summer, and breed; so that the two first seem the only kinds that certainly leave us at the approach of spring, retiring to more northern parts of the continent, where they live the summer, and breed; and, at the return of winter, are driven southerly from those frigid climes, in search of food, which there the ice and snow must deprive them of. There are many others also, particularly of the duck, or wading kind, that breed and make their summer abode in the desolate fenny parts of our island; and when the severity of our winters deprives them of their food, necessity forces them to retire towards the sea in numerous flights; where they find water unfrozen, and where they remain till the return of summer; but those cannot properly be called birds of passage.

It seems pretty evident from the whole, that the summer birds of passage leave us only in search of a more warm climate, and a greater plenty of food; both which advantages they procure to themselves by their alternate change of climate; but the migration of the winter birds of passage is not so easily accounted for, since there is no such apparent necessity for their leaving us, either on the score of food or climate. The place of the summer retirement of these birds is Sweden, and some other countries in that latitude; but as they would find those places too cold and destitute of provision, were they to hasten immediately to them on their departure from us, they journey along gradually, and prolong their passage through the more moderate countries of Germany and Poland; by which means they do not arrive at their northern habitations, where they are to pass their summer, and where they breed, till the severity of the cold is so far abated as to render it pleasing to them, and there is proper food for them; and when they revisit us the

following winter, their journey is performed in the same leisurely manner.

Sweden and the other countries whence they come to us, seem the proper home of these birds; since there they were bred; and the journey they take to us being only for a warmer climate, and plenty of food, it is no wonder that, when these benefits are to be expected again in their native place, they return to it.

The principal food of these birds, while with us, is the fruit of the white thorn, or haws, which hang on our hedges in winter in prodigious plenty; but where they breed, and seem to live most at ease, as in Sweden, &c. there are no haws, nor, indeed, in many of the countries through which they journey in their way; so that it is evident they change their food in their passage. And upon the whole it appears, that Providence has created birds, &c. with constitutions and inclinations adapted to their different degrees of heat and cold; which, to them, are most agreeable, and to which they will travel from places which to other animals might seem more agreeable: by this means no part of the globe is without its inhabitants. Phil. Trans. vol. xlv. p. 435, &c. vol. li. p. 459, &c. Pennant's British Zoology, vol. i. p. 406, &c. vol. ii. p. 709, &c.

MIGREEVO, in *Geography*, a town of Russia, in the government of Novgorod; 36 miles S. of Tcherepovetz.

MIGU, a town of Arabia, in the province of Oman; 140 miles S.W. of Julfar.

MIGUEL-ESTEVEAN, a town of Spain, in New Castile; 40 miles S. of Huete.

MIGUEL-Turria, a town of Spain, in New Castile; 4 miles S.E. of Ciudad Real.

MIGUEL, *St.*, a town of Mexico, in the province of Guatimala; 50 miles E. of Cuzcatlan.—Also, a town of S. America, in the kingdom of Grenada; 85 miles E. of Santa Fé de Bogota.—Also, a town of Spain, in the province of Seville, between the rivers Guadiana and Odier, near the coast of the Atlantic.—Also, a town of S. America, in Popayan; 90 miles E.S.E. of Païto.—Also, a town of Paraguay; 360 miles E. of Assumption.—Also, a town of Mexico, in the province of Nicaragua, on the N.W. coast of Amapalla bay; 100 miles S.E. of Leon. N. lat. 13° 35'. W. long. 88° 56'.—Also, a town of Mexico, in the province of Mechoacan; 80 miles N. of Mechoacan. N. lat. 21° 20'. W. long. 102° 26'.—Also, a town of S. America, in the province of Chiquitos.—Also, a town of S. America, in the province of Quito; 50 miles S.W. of Quito.—Also, a town of S. America, in the audience of Quito; 15 miles N.W. of St. Josef de Huales.—Also, a mission of Spanish monks in New Albion, near the coast of the Pacific ocean. N. lat. 31° 58'. E. long. 243° 42'.—Also, a small island in the N. Pacific ocean, called also "St. Bernardo," the most westerly of the range which forms the western boundary of the canal of St. Barbara. N. lat. 34°. E. long. 240° 3'.—Also, a river of Brasil, which runs into the Atlantic, S. lat. 10° 8'.—Also, a town of Brasil, in the government of St. Paul; 15 miles E. of St. Paul.—Also, a town of Congo, and capital of the province of Ovando; 150 miles S.S.E. of St. Salvador. S. lat. 7° 45'.—Also, a town of Mexico, in the province of Culiacan, on the Ciguatlan; 30 miles S.E. of Culiacan. N. lat. 24° 6'. W. long. 107° 52'.—Also, a town of New Mexico, in the province of Cinaloa; 70 miles W.N.W. of Cinaloa.—Also, a town of New Mexico; 60 miles S. of Santa Fé.

MIGUEL, *St.* See MADEIRA.

MIGUEL Archangel, *St.*, an island in the Pacific ocean, discovered by Quiros in the year 1606.

MIGUEL d'Ibarra, *St.*, a town of South America, and capital of a jurisdiction of the same name, in the audience of Quito, containing about 10,000 inhabitants. The houses are built of stone, and tiled. The suburbs are inhabited by Indians, in mean cottages. The parish church is a large, elegant, and well-ornamented building. Here are convents of Franciscans, Dominicans, and Fathers of Mercy, a college, and a nunnery of the order of the Conception; 45 miles N.N.E. of Quito. N. lat. 0° 25'. W. long. 77° 40'.—Also, a jurisdiction of S. America, in the government of New Grenada, and audience of Quito. The temperature of the air is different in all the villages of this jurisdiction, but generally warm, on account of their low situations. Most of the farms have plantations of sugar-canes, and mills for extracting the juice, of which they make large quantities of white sugar. Some farms are planted with fruits, common in a hot climate, and in others they only cultivate cotton, which is obtained in the greatest perfection. In those farms that are situated in a less hot part of this jurisdiction are sown maize, wheat, and barley. Here are also large multitudes of goats, but not many sheep. The Indians weave a considerable quantity of cloth and cotton. This jurisdiction has several mines of salt, which supply the countries that lie to the north of it. Near a village, called Mira, there is a great number of wild asses.

MIGUEL de Piura, *St.* See PIURA.

MIGUEL de Ribera, *St.*, a town of Peru, in the diocese of Arequipa; 62 miles W.S.W. of Arequipa.

MIGUEL de Tucuman, *St.*, a town of S. America, in the province of Tucuman; the see of a bishop, containing several monasteries. Its situation is elevated and agreeable, and in its vicinity are fertile fields, and several silver mines: some mules are bred; but the chief traffic is in a kind of cars, or covered waggons, which pass to Buenos Ayres and Jujuy, and which the inhabitants are enabled to build by their abundance of wood; 200 miles E. of Copiapo. S. lat. 27° 25'. W. long. 66° 30'.

MIGUEL Bay, *St.*, a bay on the E. coast of the island of Luçon. N. lat. 14° 12'. E. long. 123° 40'.

MIHALY, a town of Hungary; 10 miles N. of Zutmar.

MIHAU, a small island in the English Channel, near the coast of France; 15 miles W. from the island of Bas. N. lat. 48° 47'. W. long. 3° 30'.

MIHEL, a district of the archduchy of Austria, between the Danube and Bohemia.

MIHIEL, *St.*, a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy, situated on the Meuse, in a valley surrounded with mountains. It has six gates and three fauxbourgs. The place contains 5022, and the canton 14,010 inhabitants, on a territory of 255 kilometres, in 28 communes. N. lat. 48° 54'. E. long. 5° 37'.

MIHIRA, a name, in the Sanscrit, for the sun. See SURYA.

MIHLACK, in *Geography*, a town of Austria; 18 miles S.W. of Freystadt.

MIJARISIMA, one of the small Japanese islands. N. lat. 34° 10'. E. long. 139° 45'.

MIJAS, a town of Spain, in the province of Grenada; 10 miles N.E. of Marbella.

MIJASKA, a river of Russia, which runs into the Iser, in the government of Tobolsk.

MIJAVARA, a town of Japan, in the island of Nippon; 12 miles S. of Awasi.—Also, a town of Japan, in the island of Ximo; 28 miles S.E. of Ikua.

MIJO, a town of Peru, in the diocese of La Plata; 70 miles E.S.E. of Lipas.

MIIT DEMSIS, a town of Egypt, on the east branch of the Nile; 35 miles N. of Cairo.

MIIT Gera, a town of Egypt, on the east branch of the Nile; 12 miles S. of Mansfara.

MIIT Harun, a town of Egypt, on the east branch of the Nile; 2 miles N.W. of Miit Demsis.

MIIT el Koli, a town of Egypt, on the east branch of the Nile; 10 miles N.N.E. of Mansfara.

MIIT Laffi, a town of Egypt, on the east branch of the Nile, opposite to Miit Demsis.

MIIT Nafer, a town of Egypt, on the east branch of the Nile; 3 miles S. of Semennud.

MIIT Kamer, or Miit Ghamer, called by Savary *Mit Khamr*, a town of Egypt, on the east branch of the Nile; 24 miles N. of Cairo. This town, though small, is populous and commercial. The market places are narrow, and badly lighted; the streets are crooked and dirty. Here is a mosque, with a square tower, which seems to have served as a church for the Christians, before the Arabian conquest. Through all Egypt there is not a similar minaret; all being round, narrow, and lofty.

MIKALIDI, or MAARLICH, a town of Asiatic Turkey, in the province of Natolia, situated on a river, the ancient Rhyndus, which runs into the sea of Marmora. It has a port about two miles from the town, whence they send silk, wool, grain, and fruit to Smyrna, Constantinople, &c.; 35 miles W. of Bursa. N. lat. 40° 10'. E. long. 28° 22'.

MIKANIA, in *Botany*, a genus separated by Willdenow from the *CACALIA* and *EUPATORIUM* of Linnæus; see those articles; and named by him in honour of professor Joseph Mikan of Prague, of whose botanical performances we find nothing mentioned, except a mere catalogue of plants, an epitome of the 13th edition of the Linnæan *Systema Vegetabilium*, with some new species of Jacquin superadded, published at Prague in 1776; an octavo of 403 pages.—Willd. Sp. Pl. v. 3. 1742.—Clafs and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* oblong, simple, of from four to six erect, equal, oblong, channelled, unarmed, permanent scales. *Cor.* compound, uniform, discoid; florets mostly equal in number to the scales of the calyx, all uniform, perfect, fertile, monopetalous, funnel-shaped, with a regular, four or five-cleft, spreading border. *Stam.* Filaments five, capillary, short; anthers united into a cylindrical tube. *Pist.* Germen minute; style thread-shaped, mostly rather longer than the corolla, deeply divided; stigmas slender, spreading. *Peric.* none, except the permanent, somewhat expanded calyx. *Seeds* solitary to each floret, oblong, angular; down sessile, simple, longer than the calyx. *Receptacle* small, naked.

Eff. Ch. Receptacle naked. Calyx of from four to six equal leaves, containing as many florets. Seed-down simple, sessile.

Section 1. *Stem climbing.*

1. *M. Houstonis*. Willd. n. 1. (*Eupatorium Houstonis*; Linn. Sp. Pl. 1172. Swartz. Obf. 300.)—Stem twining. Leaves ovate, entire. Flowers spiked.—Native of bushy places at Vera Cruz. *Houston*. In Jamaica, but rare. Swartz. The stem is twining, shrubby, round, smooth, with widely spreading branches. Leaves opposite, stalked, ovate, pointed, entire, ribbed, shining. Spikes opposite, spreading almost horizontally, many-flowered. Flowers minute, white, inodorous. Calyx of four scales. Florets four.

2. *M. hastata*. Willd. n. 2. (*Eupatorium hastatum*; Linn. Sp. Pl. 1172. Swartz. Obf. 299. Kleinia? scandens; Browne Jam. 316. t. 34. f. 3.)—Stem twining.

Leaves hastate, somewhat heart-shaped, acute, slightly toothed, smooth. Flowers spiked.—Native of thickets on the hills of Jamaica. Stem shrubby, climbing, round, striated, purplish, slightly downy. Leaves opposite, hastate, acutely pointed at each lobe, from one to near three inches long, three-ribbed, smooth, except a slight downiness on the ribs or veins; heart-shaped at the base; obscurely toothed or serrated at the margin. Footstalks about as long as the leaves, sometimes much shorter, slender. Spikes axillary and terminal, about the ends of the branches, downy, bracteate, near two inches long, obscurely whorled. Flowers usually four in a whorl, white, smelling like *Cacalia suaveolens*. The whole plant has a bitter taste. Sw.

3. *M. scandens*. Willd. n. 3. (*Eupatorium scandens*; Linn. Sp. Pl. 1171. Jacq. Ic. Rar. v. 1. t. 169. *Conyza scandens*, folani folio anguloso; Plum. Ic. 86. t. 99?)—Stem twining. Leaves heart-shaped, taper-pointed, wavy and toothed; lobes spreading. Flowers corymbose.—Native of Virginia, in a watery soil. This was introduced into the English gardens about 100 years ago, and is a hardy perennial, flowering in August and September, but of no remarkable beauty. The stem is rather herbaceous than shrubby, climbing, smooth, or downy. Leaves on long stalks, one and a half inch long, roughish, veiny, three-ribbed at the base. Flowers white, in axillary, stalked, leafy, more or less compound corymbs. Seed-down tawny; not white, as mentioned by Willdenow. Florets four.

4. *M. volubilis*. Willd. n. 4. (*Eupatorium volubile*; Vahl. Symb. v. 3. 93. *E. cordatum*; Burm. Ind. 176. t. 58. f. 2.)—Stem twining. Leaves heart-shaped, crenate, acute, lobes rounded, approximated. Corymbs panicked.—Native of the East Indies. The stem in our's is very nearly smooth, much less downy than in the last. Willdenow mentions the reverse. Leaves much larger, exactly heart-shaped, acute, nearly smooth, bluntly crenate; occasionally entire, as figured by Burmann. Corymbs compound, on long stalks. Seed-down bluish-coloured, or purplish.

5. *M. denticulata*. Willd. n. 5. (*Eupatorium denticulatum*; Vahl. Symb. v. 3. 93.)—"Stem climbing, angular. Leaves heart-shaped, bluntish, finely toothed, rough. Flowers corymbose."—Native of Surinam. "Branches with five prominent angles. Leaves two inches long, stalked; paler and slightly downy beneath; sometimes entire. Florets and calyx-scales four. Seed-down purplish." Of this we have seen neither specimen nor figure.

6. *M. tomentosa*. Willd. n. 6. (*Eupatorium tomentosum*; Lamarck Dict. v. 4. 410.)—Stem twining. Leaves alternate, heart-shaped, finely toothed, somewhat angulated, cottony beneath; the upper ones ovate. Spikes panicked.—Native of the Isle de Bourbon. One of Commerlon's specimens was given by Thouin to Linnæus. It is said to have the scent of lilac. The stem is very long, slender, twining, round, cottony when young. Leaves alternate, stalked; smooth, or slightly cottony, above; clothed with snow-white dense pubescence, like a white poplar, beneath. Spikes of flowers numerous, alternate, composing axillary leafy panicles. Calyx smooth. Seed-down white.

7. *M. amara*. Willd. n. 7. (*Eupatorium amarum*; Vahl. Symb. v. 3. 93. *E. parviflorum*; Aubl. Guian. v. 2. 797. t. 315.)—Stem twining, roughish. Leaves ovate, entire; rough beneath. Flowers corymbose. Bractæas spatulate, at the base of the smooth calyx.—Native of the banks of rivers in Guiana, flowering in August. Communicated by E. Rudge, Esq. The stems are ten feet long, branched, twining, round, rough with short, dense, rigid pubescence. Leaves opposite, stalked, three inches long; nearly smooth above; rough and harsh beneath. Flowers in

in corymbose, leafy, axillary panicles, three together sessile at the end of each partial stalk, with two or three short, spatulate, stalked, leafy bractlets. Florets and calyx-scales four. When wounded, the stem and branches discharge a yellowish, viscid, aromatic fluid.

8. *M. latifolia*.—Stem twining, smooth. Leaves ovate, taper-pointed, nearly entire, smooth. Flowers corymbose. Bractlets lanceolate, at the base of the roughish calyx.—Native of the island of St. Lucia. Very near the last, but differing in the above characters. The leaves are dark green above, and very smooth; pale, scarcely roughish to the touch, beneath. Inflorescence as in *M. amara*, but the bractlets are much smaller, sessile, lanceolate or elliptical, minutely roughish. Calyx also roughish. Florets, and rufous down of the seed, half as long again as the calyx; whereas in the last species they are much shorter, and concealed within it.

9. *M. chenopodiifolia*. Willd. n. 8.—“Stem twining. Leaves ovate, somewhat triangular, pointed, wavy, five-ribbed, smooth. Flowers corymbose.”—Native of Sierra Leone. Stem with smooth striated branches, apparently climbing. Leaves opposite, stalked, triangular-ovate, slightly hastate, smooth on both sides. Corymbis dense, stalked, terminal. Calyx smooth, of four scales, with as many florets. Down reddish. Willd.

10. *M. auriculata*. Willd. n. 9. (*Eupatorium auriculatum*; Lamarck Dict. v. 2. 411. *E. scandens*; Thunb. Prodr. 142?)—Stem twining, angular, smooth. Leaves alternate, triangular, somewhat hastate, toothed, smooth. Stipulas rounded. Flowers corymbose.—Gathered by Sonnerat at the Cape of Good Hope; and Willdenow well conjectures that it is probably the *E. scandens* of Thunberg, with whose short definition it seems to agree. The stem has many angles, and is much branched, twining and zigzag. Leaves small, with a pair of clasping stipulas at the base of their stalk, and sometimes a pair of similar auricles. Calyx of five or six scales, with as many florets. Lamarck.

11. *M. stipulacea*. Willd. n. 10. (*Eupatorium stipulaceum*; Vahl. Symb. v. 3. 94.)—Stem twining, round, smooth. Leaves opposite, hastate, acute, somewhat toothed, smooth. Stipulas oblong. Flowers corymbose.—Gathered by Commerçon in Brazil. Stem twining, slender, finely striated. Leaves stalked, much like those of some hastate *Chenopodium*; rather glaucous, and obscurely downy, beneath. Stipulas recurved, small, oblong, acute. Flowers in many axillary, opposite, stalked, often compound corymbs. Calyx roughish at the base, membranous upward, of four scales, with as many florets. Down purplish, rough, projecting, with the florets, much beyond the calyx.

12. *M. rubiginosa*. (*Cacalia cordifolia* varietas, foliis integris; Linn. Suppl. 352.)—Stem twining, downy. Leaves opposite, heart-shaped, pointed, wavy, finely downy. Panicles axillary, cymose. Bractlets spatulate. Native of South America? Of this we have seen but an imperfect specimen in the Linnæan herbarium, on which there is no mark to indicate its native country. By its resemblance to many of the foregoing species only, can we judge of its being a climber; for we have but an inch and a half of the stem, with a pair of opposite stalked leaves, each two inches long, with an axillary stalked corymbose panicle, accompanied by a pair of small leaves, to each. Every part is clothed with extremely short, dense, soft, rusty, velvet-like pubescence. The surface of the leaves, on both sides, sparkles with excessively minute golden resinous dots. Flowers not very numerous. Bractlets as long as the calyx, spatulate or obovate, obtuse, with or without a small point,

and tapering at their base. Scales of the calyx very much like them in shape and size, and both are equally downy externally. Seed-down reddish, scarcely extending beyond the calyx. This is certainly very distinct from the following, with which the younger Linnæus, who found the specimen here described in his father's herbarium, marked *Eupatorium*, confounded it.

13. *M. cordifolia*. Willd. n. 11. (*Cacalia cordifolia*; Linn. Suppl. 351.)—Stem twining? angular, roughish. Leaves opposite, heart-shaped, pointed, toothed, rough. Panicles axillary? cymose, leafy. Bractlets ovate, pointed, shorter than the calyx.—Gathered by Mutis in New Spain, South America. By its near agreement with the last species, we judge this also to be a climbing plant. The Linnæan specimen consists of only a large compound corymbose branch of flowers, accompanied by small opposite leaves, as usual in this section of the genus, but whether it may have been axillary or terminal, we cannot determine. With it are two separate leaves, not unlike those of a *Helianthus*, each three inches long, of a very broad heart-shaped figure, oblique or unequal, minutely but distantly toothed, with a short taper point. They are rough on both sides, with minute harsh pale bristles, their ribs, which are three in the middle, and two at each side, clothed with rusty down. Footstalks two inches long, or more, rusty. Panicle many-flowered, with roughish angular stalks. Bractlets scattered, stalked, gradually smaller upwards, ovate, pointed, entire, bristly at the edges; those which are close to the flowers elliptic, shorter than the calyx. Scales of the calyx four, elliptic-lanceolate, acute, ribbed, concave; the two outermost roughish, especially upward; the innermost only being smooth as described in the *Supplementum*. Seed-down reddish, rough, longer than the calyx, as are also the florets.

14. *M. laurifolia*. Willd. n. 12. (*Cacalia laurifolia*; Linn. Suppl. 351.)—Stem twining? Leaves opposite, elliptic-ovate, triple-ribbed, very smooth and shining. Panicles dense, terminal, downy.—Native of Mexico. Mutis. This has all the appearance of a climbing shrub, though Willdenow could have no reason, from the Linnæan description, to suspect it. The branches are much twisted, forked, round, smooth, leafy at their extremities. Leaves one and a half or two inches long, near an inch wide, almost elliptical, obtuse, entire, slightly revolute, rigid, smooth; varnished as it were on the upper side; thickly dotted beneath; their lateral ribs springing from the middle one at a good distance from the base, besides a pair at the very bottom. Panicle three inches long, dense obtuse, with hairy corymbose stalks. Bractlets small, oblong. Scales of the calyx four, linear, hairy, (by no means smooth as in the *Suppl.*), rather dilated and feathery at the tips. Seeds furrowed, angular, rough, nearly as long as the calyx. Florets and down much longer. Styles greatly protruding, with long, narrow, purplish stigmas.

Section 2. *Stem erect*.

15. *M. meliffolia*. Willd. n. 13. (*Eupatorium meliffolium*; Lamarck. Dict. v. 2. 411.)—Stem erect. Leaves opposite, ovate, crenate, sessile, downy beneath. Flowers corymbose, terminal.—Gathered by Dombey in Peru. Stem about two feet high, round, slightly downy, panicked above. Leaves sessile, and even somewhat embracing the stem, oval, coarsely crenate, green, about two inches or more in length, and one inch and a half wide. Flowers purplish. Calyx of five straight scales. Florets five. Down rough.

16. *M. saturifolia*. Willd. n. 14. (*Eupatorium saturifolium*; Lamarck. Dict. v. 2. 411.)—Stem erect, branched. Leaves opposite or scattered, linear, obtuse, entire,

entire, downy. Flowers corymbose.—Gathered by Commerfon at Monte Video. The *stem* feems fcarcely shrubby, round, alternately branched, downy, leafy. *Leaves* mostly fattered, the lower ones only being often oppofite, feffile, linear, or linear-lanceolate, obtufe, nearly or quite entire, tapering at the bafe, thickly dotted, minutely hairy; paler beneath. *Flowers* large, purple, a few together in tufts on terminal, corymbose, downy ftalks. *Calyx* downy, but half the length of the florets and rough brownifh *feed-down*. *Corolla* five-cleft, flightly hairy.

Commerfon gathered at the fame place a fender variety, with much fmaller *leaves*, and only one or two *flowers* at the top of a few of the branches. We agree with him that, though very different in appearance, the fpecimen difplays no diftinctive fpecific character. Indeed we have an intermediate variety, which leaves the matter without any uncertainty. We make no apology for correcting the barbarous conftruction of the fpecific names of this and the foregoing. S.

MIKELSBURG, in *Geography*, a fortified town of Tranfylvania, with a depôt of arms for the principality; 6 miles S.E. of Hermanftadt.

MIKLOS, ST., a town of Tranfylvania; 12 miles N.N.W. of Medies.

MIKLOSVAR, a town of Tranfylvania, on the river Alaut; 16 miles N. of Cronftadt.

MIKOLAIOW, a town of Auftrian Poland, in Galicia; 28 miles S.S.W. of Lemberg.—Alfo, a town of Poland, in Volhynia; 24 miles W. of Lucko.

MIKULINOZE, a town of Poland, in Podolia; 56 miles N.N.W. of Kaminiac.

MILA, a town of Thibet; 222 miles S.W. of Latac.—Alfo, a town of Tunis; 30 miles S. of Conftantina.

MILAGRO, a town of Spain, in the province of Aragon, at the confluence of the Arga and Aragon; 5 miles E. of Calahorra.

MILAN, *Duchy of*, a country of Italy, bounded on the north by the Grifons, on the east by the Venetian ftates, on the fouth by the ftates of Piedmont and Parma, and on the weft by Piedmont and Savoy. Its greateft breadth from north to fouth is upwards of 100 miles, and its greateft length from east to weft 108 miles. This fertile duchy is faid to contain, on 2432 fquare miles, a population of 1,116,850 perfons; and it has formerly produced to the king of Spain a revenue of above two millions of dollars. According to Mr. Young's ftatement, the foil is chiefly ftrong loam, or loamy fand; and the climate has a fingular circumftance belonging to it, that the northern mountainous tracts are mild and warm, but the plains are cold. Orange and lemon trees flourish in the open air, on the weftern fides of the lake of Como, though bounded by the high Alps, which to the north are covered with perpetual fnow; while, in the plain of Lombardy, even to the Apennines, thefe trees require fhelter. The Boromean ifles alfo, in the Lago Maggiore, are covered with thefe delicate trees. The lands in this duchy are mostly enclosed; but its agriculture can never prosper, while the prefent fyftem continues, which is that of the landlord's paying taxes and repairs, and the tenant's providing cattle, implements, and feed, and then their dividing the produce between them. For the irrigation of the country, they have canals, fubfifting as early as the 11th century, fome of which are more than 30 miles long, and nearly 52 feet wide. The arable lands produce the ufual kinds of grain and fruits, and the paftures are excellent, affording means for breeding cattle in abundance, and for making cheefe that has been every where held in eftimation. The wine is good, and the mulberry trees, for

the culture of filk, are numerous. Its fheep are but few and bad. Its mines have not been much explored: however, there are fome of copper and lead above the lake of Como, and the mountains; and the Boromean ifles prefent frefh-coloured granite, and lapis ollaris is plentiful near Como. In this duchy are manufactures of wool and filk, though its filk is not equal to that of Piedmont; and it has numerous workmen in gold, filver, embroidery, and fteel, as well as in crystal, agate, aventurine, and other ftones. The trade of the Milanefe is confiderable; but its imports generally exceed its exports. Its ftuffs are moftly confumed at home; its filks, ftockings, gloves, and handkerchiefs, are exported.

After the fall of the kingdom of Lombardy, Milan became fubject to the emperors of the Weft. After the contefts between the emperors and the popes, it loft its form of a republic, and became fubject to the archbifhop: in 1277, Otto Vifconti, the archbifhop, was declared lord of Milan. His family long poffeffed this rich principality. After two or three changes it was feized, in 1535, by Charles V., as a fief of the empire, and he gave it to his fon Philip; whofe fucceffors, as kings of Spain, retained the Milanefe till the year 1706, when it became an appanage of Auflria, though a confiderable part of it had been transferred to the houfe of Sardinia. Its revenues have been lately eftimated at about 300,000*l*. When the Cifalpine republic was formed, the Milanefe was divided into four departments, *viz* Olona, Verbano, Lario, and Delle Montagna. Milan was appointed the capital of the whole republic; and the fame eftablifhment ftill refpects the kingdom of Italy.

MILAN, a city, and capital of the lately eftablifhed kingdom of Italy, and, before the revolution in France, the capital of the duchy above defcribed. Including its gardens, it is faid to be ten miles in circumference, and it is chiefly defended by a wall and rampart, together with a citadel having fix bafions at fome diftance, fo that it has been reputed a ftrong place. It has fome ftraight and broad ftreets, among many that are narrow and crooked; but its paper windows, or thofe of glafs and paper intermixed, give it a mean appearance. It has 12 gates, 230 churches, 90 convents, 100 religious fraternities, 120 fchools, and about 120,000 inhabitants. It is the fee of an archbifhop, and its nobles are numerous. Its cathedral is a large but irregular building, conftructed of marble, and ornamented with marble ftatues: its treafury, among other valuable articles, contains an invaluable coffin of rock-crystal, in which are deposited the remains of St. Charles Boromeo, cardinal and archbifhop of Milan. The chief church for antiquities is that of St. Ambrofe; and the Ambrofian college, in the centre of the town, was founded by Frederic Boromeo, and has fixteen profefors, who communicate their inftructions gratis. The fine library which he began was finifhed by cardinal Gelbert Boromeo, and is faid to contain more than 40,000 printed volumes, and fome thoufands of MSS. In this college are alfo an academy of painting, and a mufem. The feminary for fciences, where ftudents are both taught and maintained, and the college of the nobles, are ftately buildings, but inferior to the Helvetian college, founded for a number of Swifs. Here is alfo a mathematical academy. The great hofpital is a fine building, and liberally endowed by duke Francis Sforza IV.; and its income is faid to be between 90 and 100,000 rix-dollars. This hofpital, which has feveral others dependent upon it, admits not only fick perfons, but alfo foundlings and lunatics. The large lazaretto is only ufed in time of contagion. Among the civil buildings is the old and fpacious regency-houfe, and the new and ftately town-houfe, where is an equeftrian ftatue of Philip II.

This city was founded by the Gauls about 584 years B.C.; but has undergone many sieges, and particularly that by the emperor Frederic I. in 1162, who, after a siege of seven months, destroyed the gates, ramparts, and edifices, leaving only a few churches, and sowed salt on the ruins. However, it recovered from these disasters; and it still maintains many manufacturers and artisans; and by means of several rivers and canals, carries on a considerable trade. In 1800 it was taken by Bonaparte; and when the Cisalpine republic was established, it became the capital of the department of Olona and of the whole republic, and it maintains the same rank in the kingdom of Italy; 132 miles W. of Venice, 65 N. of Genoa. N. lat. 45° 26'. E. long. 9° 11'.

MILAPOUR, a town of Hindoostan, in Mysore; 22 miles E. of Colar.

MILASA, or MARMARA, a town of Asiatic Turkey, in Naxos; anciently called Mylassa. In this place are the remains of three temples, and of a column, called Meander's pillar; 16 miles S.W. of Mogla. N. lat. 37°. E. long. 27° 50'.

MILATIA, a town of Poland, in Volhynia; 44 miles S.W. of Lucko.

MILAVARAM, a town of Hindoostan, in the circle of Condapilly; 14 miles N. of Condapilly.

MILAY, a town of Bohemia, in the circle of Leitmeritz; 16 miles S. of Leitmeritz.

MILAZZO, CAPE, a cape of Spain, on the W. coast of Galicia. N. lat. 38° 20'. E. long. 15° 23'.

MILBANK'S SOUND, an inlet in the North Pacific ocean, between Point Day and Cape Swaine.

MILBORNE-PORT, a borough-town and parish in the hundred of Honethorne, and county of Somerset, England. The former stands on one of the branches of the river Parret, at the distance of ten miles from Ilchester, and two from Sherborne, in Dorsetshire. This place is of great antiquity, having been a borough of considerable importance prior to the Conquest; after which event it lost much of its consequence, though it retained all its former privileges till the reign of Edward III., by whom it was deprived of the right of sending members to parliament. In the reign of Charles I., however, that franchise was restored; and it now returns two representatives, who are chosen by the inhabitants paying scot and lot. The government of this town is vested in the owners of nine bailiwicks, who are lords thereof, assisted by two deputy bailiffs, two constables, and several other inferior officers. Besides these there is likewise an association within the borough, consisting of nine persons, two stewards, and seven assistants, who are privileged to hold property in their corporate capacity, for the benefit of the poor.

The buildings of Milborne-Port are chiefly disposed in four streets, the principal one of which, called High Street, is of considerable width, but extremely irregular. In this street stands the guild-hall, an ancient edifice, having a door-case partly of Saxon and partly of Norman architecture. The old market-house is now converted into warehouses, and there is no regular market now held. The church, an ancient structure, built in the form of a cross, is surmounted by a very massive quadrangular tower, supported by two pointed and two semi-circular arches. In the north aisle are several handsome monuments, in honour of the Medlycot family. On opening a plot of ground near the church-yard, for the purpose of building, sixty bodies of men and women were discovered, arranged in regular rows, which, from the want of coffins, are supposed to have been buried at the time of the great plague.

Besides the borough, the parish of Milborne-Port contains two considerable villages, called Kingsburg-Regis and

Milborne-Wyke. The former has land-tax and parochial assessments peculiar to itself; and there is held here an annual court-baron, wherein the lords' rents are paid, presentments made, and a constable, tything-man, and hayward appointed. The lands in this vicinity are mostly arable, and in a high state of cultivation and fertility.

According to the parliamentary returns of 1801, the total population of this parish amounted to 953 persons, 440 males and 513 females; of which number 577 were engaged in different branches of trade, and 200 in agriculture. Col-linson's History and Antiquities of Somersetshire, vol. ii. 3 vols. 4to. Maton's Western Counties, vol. ii. 8vo.

MILBOURN, LUKE, in *Biography*, an English divine, was the son of Mr. Luke Milbourn, a nonconformist minister, who was ejected from the living of Wroxhall, in Warwickshire, in 1662, and died at Newington in 1667. His son received a good education, became master of arts, and obtained the rectory of St. Ethelburg in London. He published sermons and theological tracts, 2 vols. 8vo.; a poetical version of the Psalms; and several poems, for which Pope gives him a place in the *Dunciad*. He died in 1720.

MILICE, in *Geography*, a town of Poland, in Volhynia; 34 miles N.N.W. of Lucko.

MILDEN. See *MOUDON*.

MILDENHALL, a market-town and parish in the hundred of Lackford, and county of Suffolk, England, is situated on the river Lark, at the distance of 12 miles from Bury, and 70 from London. The parish is of great extent, from the dispersed arrangement of its streets, which in fact form a series of little villages. That part of the town called the Borough, or High-town Mildenhall, is its principal division, and contains both the church and the manor-house. The former is a very large and handsome structure, and has a rich roof of carved work, and a lofty tower, and contains a variety of monuments in honour of the family of the Norths. This church is supposed to be of very ancient foundation, and is much admired for its architecture. The manor-house, likewise an old edifice, but greatly altered and repaired of late years, constitutes the family residence of sir Thomas Charles Bunbury, bart., who was one of the representatives for the county in the last parliament. The ancient mansion of the Norths here has a gallery in front, extending the whole length of the house. This town was much injured by a fire, which broke out on the 17th of May 1507, and in a few hours consumed 37 dwelling houses, besides barns, stables, and other appurtenances.

Mildenhall is the chief town of the hundred, and, according to the parliamentary returns of 1801, contained a population of 2283 persons, 1095 males and 1188 females; of which number 390 were returned as engaged in agriculture, and 147 in different branches of trade and manufactures. The petty sessions are held here, as well as a weekly market on Friday. This town has furnished London with two lord mayors, Henry Barton and William Gregory; the former of whom held that honourable office in 1428, and the latter in 1451.

The vicinity of Mildenhall presents to the view a flat, open country, wholly devoid of any interesting features, except a few family-seats, the chief of which are Ickworth, Rushbrook, and Culford. Ickworth is distinguished for its noble park, which is no less than ten miles in circumference. Kirby's Suffolk Traveller, 8vo. 1764. Carlisle's Topographical Dictionary.

MILDEW, in *Agriculture*, a disease frequently destructive to corn, pulse, and other crops.

MILDEW.

M. Duhamel states, that "it attacks the blades and stems of corn, which it covers with a powder of the colour of rust of iron, when at the height of their vegetation. This substance does not adhere strongly to the blades; for he has seen the hair of white spaniels full of this powder, after they have run through a field attacked with this disease. It is likewise known, that if the infected wheat is washed by a plentiful rain, the rust disappears almost entirely, and the grain suffers little from it. The French give it the name of rust, from the colour of the powder, and it seems to be the same distemper, which the Roman writers term *rubigo*. He adds, that the cause of this distemper is usually said to be dry gloomy weather, happening while the corn is at the height of its vegetation; and in effect, he has many times observed, that when a hot sun has succeeded such dry hazy weather, corn was rusted within a few days afterwards. It is not common in clear, dry, hot years: but when the spring is wet, the finest fields of wheat run great hazard of being destroyed by it, which generally appears upon the breaking out of the sun in the morning, after close and sultry weather, during which there has not been any dew. The rusty powder then gathers upon the blades in such quantities as to cover the earth around. M. de Chateauxvieux cut off the mildewed blades, and found the trial answer: the same plants produced new blades, and throve much better than those on which this operation had not been performed, but this cannot be done, except when the corn is very young. It is very fatal; as the finest wheat is suddenly brought almost to nothing, when it is entirely attacked with it.

"If it attacks the plants while they are young, and before their stems begin to rise, the mischief is sometimes not very great, provided there comes on a season favourable to their farther growth. In this case they are only weakened, as if they had been fed or mowed. They shoot out anew, and produce ears; though their straw is shorter, and those ears are smaller than they would otherwise have been. But if both blades and stalks are mildewed at the same time, the further growth of the plant is stopt and the grain gets scarcely any more nourishment; so that the crop is exceedingly diminished."

It was observed that, "in the autumns of 1753 and 1754, when the corn was rusted, the second crop of hay was so likewise. The grass turned from a fine green to the ugly rusty colour of the corn: it was covered with the same kind of powder, and its quantity diminished sensibly every day; and as the whole of a field of corn is not usually affected at the same time, so this distemper extended only to some parts of the meadow."

"The cause of this distemper is undoubtedly the same in corn and in grass; but its effect is not exactly similar. It may destroy annual plants, such as corn, entirely; but in perennials, like grass, it destroys only the leaves or blades. May not the preservation of these last be owing to the taking off those leaves or blades, when they are cut for hay? But this is only conjecture; for it is confessed, that he has not yet made any observation on this head.

It may be noticed that these causes are far from being satisfactory; but it is a difficult enquiry, and one which has lately, especially by botanical writers, been considered in a very different point of view. The facts that have been lately presented to the public on this subject, shew that it is not much influenced by soil, situation, or the nature of the climate. The answers that have been given to different enquiries on this matter, may probably lead to some useful conclusions. On this subject Mr. Chatterton states, in the 44th volume of the *Annals of Agriculture*, that "1. From what he has seen, and heard from others, it appears that all soils in

his neighbourhood, Yorkshire, have had mildewed crops upon them; but as far as he can judge, the heavy clays, which had a good fallow, have escaped the best." But it is afterwards observed, that though "this was the case in some parishes about him, yet, for the most part, in the East Riding they suffered more severely than any others, upon whatever soil: the reason seems to be, that in general they were more luxuriant, and laid some time before they were ripe. And he also understands that crops on all soils (where thrown down) were the most affected with the disease, if it may be so called; from which it should seem not to arise from any previous cause, such as the season of sowing, the difference of seed or manure, &c., but from some uncommon bad state of the atmosphere not long before harvest, which most affected the straw that rested in an horizontal position. He has further learned from a person, who says he cut a field of wheat, which was affected with the mildew, while in a green state (but not before the grain had arrived at a good degree of solidity), and that it is much better corn than others which were suffered to stand till ripe. On the sea side, there appeared just before reaping time, but little (in comparison) damaged in the vicinity of the beach; yet two or three miles from the sea, it seemed as bad as in other places at a greater distance; and he has known, when all the gardens have been ruined by frosts in the spring, at a distance from the sea, while those upon the edge of the cliff have not suffered at all."

And it is afterwards observed, 2. That "both early and late sown crops have suffered; but which have suffered most is hard to ascertain.

3. "That it is not easy to say, what situations have been most affected with mildew; it may be said all are nearly the same: he has observed upon the wolds in Yorkshire a great deal that would not pay for thrashing; so bad was it, that hens would prefer shelling oats for their broods, rather than pick up the wheat that lay about them; and in the low lands at the foot of the wolds, both on strong and light soils, much of the straw appeared black in many fields.

4. "It is supposed, that both thick and thin sown crops have been equally affected.

5. "He imagines, from what he has heard, that old or new seed had no effect.

6. "That this subject seems to be enveloped in mystery, as several persons in this neighbourhood have had two fields of wheat adjoining each other—situations and soils alike—management similar in every respect, only not all sown at the same time—yet both may be said to have been sown in good season: the one field entirely escaped the mildew, the other so much damaged, that it was not worth thrashing. Something might here be advanced on earlier or later sowing; but, perhaps, not any thing that could in the least guide the farmer in his future management, as seasons are so various.

7. "That the crops of both kinds of land have suffered severely, and in some places both have escaped; without a general survey, it is hard to decide.

8. "But he has not heard of any difference in crops arising from difference of manure; he has not, however, inquired much into this matter.

9. "He has not heard of the different kinds of seed being different in regard to mildew."

And the results of the inquiries of another writer in the same work are, that in Lincolnshire the soils most liable to it, are 1. "In general light, loamy, and rich ones. 2. Late sown crops. 3. That there is very little difference in situations, but if any, high ones have the advantage. 4. That the quantity of seed has little or no advantage; but drilling the

the seed has, on account of the greater and uniform depth. 5. That he never knew any difference between old and new seed, with regard to the mildew in wheat. 6. That he attributes the sole cause of the mildew in wheat to mild winters, and to the inflammation of oxygen gas at the eye of harvest. 7. That fallow crops on strong clay soils have been least affected. 8. That all kinds of manures dispose wheat to mildew in such seasons; lime in some degree prevents it. 9. That he has no knowledge of the barberry having any effect at all upon wheat. 10. That no kind of wheat that he knows of, is exempted wholly from the mildew. 11. That early cutting from early sowing, has the greatest advantage, but not before the milk in the grain is completely coagulated."

It is also stated, 1. "That in Staffordshire Dr. Lewis made some observations on the disease, and means of preventing it.

2. "That he does not think it of consequence to the question, at what time of the season wheat is sown, because the period of the approach of the mildew cannot be even conjectured, as it has ever been variable. In this neighbourhood it so happened, that the wheat which was sown in September and November 1803, suffered in general more from the mildew, than that of October.

3. "That high and consequently ventilated situations are doubtless more likely to receive a remedy to the disease, than low and sheltered ones; but he believes they were all equally affected.

4. "That it has not appeared, that any particular mode of sowing has been a preservative to the crop. That drilled corn, rather than broad-cast, is more easily cured, must be granted, if the drill be wide enough to admit of a person to set his foot between the rows, because with a long pole, which, by means of straps, might be suspended from his shoulders across his breast to a proper height, he might brush off the greater part of the dew, as he walked up and down, to the extent of three yards on each hand: and indeed, in a field of broad-cast, the same means might economically be pursued, as it would surely answer to destroy a part of the diseased grain, which if left to itself would be good for but little, to save the remainder. Those crops which were strong and thick, suffered, in general, considerably more than those which were thinner. 5. That it does not appear to him, that either new or old seed is of consequence to the question. 6. That the cause exists in the atmosphere, as he has already said. He has no doubt, and he thinks, we may fairly conclude its being of that kind, which is termed phlogisticated; that particularly in the summer it is so loaded with the putrid effluvia of animal and vegetable substances, as to be incapable of attaining the height necessary to undergo the chemical process of purification by the action of the vitriolic, nitric, and muriatic particles with which the air of the higher regions is charged; and that, therefore, it descends in that undepurated and unwholesome fluid which we term mildew. It has frequently been observed, that in those seasons, which have been preceded by a severe winter, the air is more pure than when the winter has been mild; but whether the mildew has been more prevalent after a hard or temperate winter, has not yet made a part of his observation. Late frosts and fogs are generally reckoned inimical to vegetation, though he never heard it suggested, that they are in any degree connected with the succeeding mildew. That crops on fallows and those on layers have shared an equal fate. 8. Nor has there been any difference in consequence of different kinds of manure. 9. That the barberry tree is of such rare

growth in this parish, that if it had any effect upon wheat, it could not but have been ascertained long since, beyond controversy; but, when once an idea has gone abroad, every instance in favour is deemed a proof, while the many in contradiction are never advanced. He hesitates not to pronounce, that it has *no effect* on wheat. Mr. Barker of Congreve had last year, within 50 yards of his barberry tree, one of the best crops of wheat in this neighbourhood; while Mr. Keeling, his next neighbour, at 200 yards distance from the same tree, and near no other, had a crop as bad as Mr. Barker's was the contrary. He knows not of five barberry trees in this parish, but there were more than 50 times as many bad crops; which proportion he dare venture to say, will be found to bear throughout England. How then can it be concluded, that the tree is so peculiarly pernicious in this instance? Since writing the above, he has received an account of Mr. Makerell, who lives in the parish of Brewood, having had a fine piece of wheat, not in the least affected by the mildew, though immediately in the vicinity of a hedge almost entirely composed of barberry bushes. 10. He has never either seen or heard of any exception in favour of wheat of the bearded kind, nor indeed of any other; nor yet that any one sort suffered particularly. 11. That as the mildew totally prevents those ears, which it affects, from coming to any perfection, it does not strike him, that the period of its being reaped can be of any consequence, and if not it must be best to let it stand till the straw has received its full benefit."

And the statements of Mr. Lumbert on this subject are, "1. That no soil is peculiar to the mildew. 2. That late sown crops have generally suffered most; but there have been instances of the reverse. 3. That low and sheltered situations have suffered most; but this has been, perhaps, attributable to the wheat growing more luxuriantly, from its situation, than the stamina of the land could support when it was arriving at maturity: to this may be added a want of ventilation. 4. That a huge crop may be considered a cause of mildew; for an unkind season, or want of stamina in the land, may check the vegetable mucilage before the corn is completely filled, and thereby produce a predisposition to mildew. 5. That no difference is observed in new and old seed, where the situations have been similar. 6. That the first cause of mildew is a predisposition in the wheat. This predisposition is created by a decrease of mucilage in the straw, which allows the watery particles to insinuate themselves, and still further check the circulation of the juices in the stem that are necessary to the perfection of the grain, and had before become languid from the unkindness of the season, or the feebleness of the soil. When the watery particles have insinuated themselves, the straw becomes discoloured, and he has no doubt but a complete putrefaction would immediately succeed it, if it were not prevented by a circulation of air. At all times during its growth, barley and oat straw appears to have sufficient mucilage in itself to resist the effects of the watery particles; but when it is cut it becomes like the stubble in the fields, and cannot much longer resist it. 7. That fallows and layers have been equally liable. 8. He has observed, that an over luxuriant growth in the spring is favourable to the mildew, and has noticed that that luxuriance may be produced by particular manure, such as green vetches ploughed in, &c. which seem to cause a considerable fermentation in the soil, and produce a rapid vegetation for a short time. 9. That early cutting and laying down is most clearly beneficial; and if the wheat is severely affected, it is almost impossible to cut it too soon."

And farther, the facts collected by professor Balsamo in

MILDEW.

Sicily, and detailed in the same work, lead to the same conclusions. For he states it as "evident that the mildew was common to the grain of all Sicily, without exception of kind, of soil, exposition, or other circumstances. It attacked, in different degrees, the barley, oats, and the plants of meadows; almost all plants, whether spontaneous or cultivated: and this consideration proves to him that the opinion which attributes the distemper to fogs and dews, is erroneous; nor is it at all probable, that any meteor should, at one time, be the cause, in places which, from the vicinity of mountains, rivers, and a multitude of other circumstances, had a very different climate from each other; and from the observations registered at the Royal Observatory, it appears, that, as every one knows, the fogs were rather heavier and more frequent in April and May 1803, when no mildew ensued, than in the same months in 1804, when the great mischief followed. And many cases have occurred to him of spots peculiarly given to fogs, and from which the countrymen argued a ruinous mildew, yet bright and clear crops were produced, while spots more free from fogs have been attacked." The same reasoning may "be applied to dews; these are more frequent and copious in the vicinity of rivers and stagnant waters, than in other places; and it is true, that in many of these last, and in more than one of the first, the grain better resisted the mildew. Brucato is a humid district, washed by rivers, and chequered by marshes, which render the air insalubrious; yet it produced this year of mildew a reasonable crop of grain. And he observed at Margana, that the wheat upon a farm situated on the banks of a river, and very humid, with a bad air, was generally better than in the neighbouring country of Vicari, notably more dry from its situation. Grain that is thin upon the ground, is more subject to mildew than that which from thickness retains much more of the dew." It is stated that the "Abbé Rozier, in his voluminous Dictionary, says, that the mildew is caused by the drops of water formed by fogs and dews when dissipated by a hot sun; but in Sicily, the sun in April, and much more in May and June, is always active; and our fogs in May are proverbial." And "in travelling in the beginning of summer, through the country, it is visible, that the mildew, in its various degrees, is connected with the soil, and the divers methods of cultivation; but the variety of effects is mysterious and inexplicable, on the supposition that the cause is external to the plant."

After some remarks on the nature of the disease, Mr. Marshall says, that a certain prevention of it would be a discovery worth millions to the country. "Until this be made, let the grower of wheat, not only endeavour to sow early; but let him look narrowly to his crop, during the critical time of the filling of the grain; and whenever he may perceive it to be smitten with the disease, let him lose no time in cutting it: suffering it to lie on the stubble, until the straw be firm and crisp enough to be set in sheaves, without adhering in the binding places: allowing it to remain in the field, until the grain shall have received the nutriment which the straw may be able to impart. Where wheat has been grown on 'lammas land,' and the ground obliged to be cleared by the first of August, crops have been known to be cut, 'as green as grass,' and to be carried off and spread upon grass land to dry. Yet the grain has been found to mature; and always to afford a fine skinned beautiful sample. Rye-grass that is cut, even while in blossom, is well known to mature its seeds, with the sap that is lodged in the stems. Hence there is nothing to fear, from cutting wheat or corn, before the straw be ripe." The opinion of Mr. Young is likewise the same; he therefore

advises the farmer to be very attentive to his wheat crops in July, as "they are every where liable to this fatal distemper, which admits but of one cure or check, and that is, reaping it as soon as it is struck. The capital managers in Suffolk, know well, that every hour the wheat stands after the mildew appears, is mischievous to the crop. It should be cut, though quite green, as it is found that the grain fills after it is cut, and ripens in a manner that those would not conceive who had not tried the experiment, which he has done many times; reaping so early, that the labourers pronounced he should have nothing but hens'-meat. They were always mistaken, for the sample proved good, while others, who left it longer, suffered severely. The fact is now pretty generally admitted."

It is further stated by the first of these writers, "that the operation of this disease is carried on by the fungus tribe, evidently appears, from the ingenious and persevering labours of botanists," as lately shewn by sir Joseph Banks. (See BLIGHT.) "But fungi, it is equally evident, are an effect, not the cause of the disease. They are the vermin of the more perfect vegetables; and fallen on them, whether in a dead, or in a diseased state; but seldom while they are in full health and vigour. Their minute and volatile seeds may be said to be every where present, ready to produce their kind wherever they may find a genial matrix. Such, at least, appears to be the nature of the fungus, or fungi, of wheat; for it may be liable to the attack of more than one species. In a dry warm summer, which is well known to be favourable to the health, vigour, and productiveness of the wheat crop, the seeds of fungi are harmless, so long as the fine weather continues. On the contrary, in a cold wet season, which gives languor and weakness to the wheat plants, few crops escape, entirely, their destructive effects. A standing crop not unfrequently escapes, while plots that are lodged in the same field, especially in pits and hollow places, become liable to their attack. And, by the facts above stated, we plainly see, that even strong healthy crops may, in a few days, or perhaps in a few hours, be rendered liable to be assailed; not progressively, as by an infectious disease; but at once, as by a *blast* or *blight*. In the state of the atmosphere we are to look for the cause of the disease, in a *standing crop*: and nothing is so likely to bring on the fatal predisposition of the plants as a succession of cold rains, while the grain is forming. The coolness necessarily gives a check to the rich saccharine juices which are then rising towards the ear; and the moisture may, at the same time, assist the seeds of the fungi to germinate and take root. Thus reason and facts concur, in pointing out the cause, and the operation of the disease. There appear to be two reasons why corn which happens to be struck with this disease, in a dry warm summer, is exposed to excessive injury; as facts pretty evidently shew that it is. The habits of the plants render them more susceptible of injury, their rich juices more liable to be checked; and the seeds of fungi, it is probable, are more widely, if not more plentifully, distributed, by such a state of the air; than they are by a cool moist atmosphere. The natural event is too well known: and it is the business of art to endeavour to prevent it."

Consequently "if by cutting down the crop, as soon as it is found to be diseased, the operation can be stopped, as experience, in different instances, has shewn it may, the remedy is easy. It may be asked, in what manner the remedy is thus effected. But to the practical farmer, the fact is all that is required. To him, it is equally indifferent, to know the operation of the remedy, as the operation of the disease. Those who have profited by the remedy here

recom-

recommended, believe, that it 'kills the mildew.' And if it shall appear that the fungus of wheat requires a free supply of air to keep it alive, or in a state of health and vigour, the effect of cutting down the crop will be explained. It will perhaps be found, by experience, that the closer it is allowed to lie upon the ground, and the longer it is bound up in sheaves (provided the natural ascent of the sap to the ear be not interrupted), the more effectual and complete will be the remedy. Further, on the evidence of attentive observation, if wheat, which has been attacked by this disease, be suffered to remain in the field, with the ears exposed, until it may have received the ameliorating influence of dews, or moderate rain (to soften, relax, and assuage the natural rise of the sap), the more productive it will probably become. And it may be still further added, that grain which is cut while under-ripe, is less liable to be injured in the field by moist weather, than that which has stood until it be fully or over-ripe." And a "probable mean of prevention is that of inducing early ripeness (for reasons above offered): either by sowing early; or by forcing manures; or by selecting and establishing early varieties, of wheat most especially; as early varieties of pease, and other esculent plants, are raised by gardeners: a work which only requires ordinary attention; and which, it is hoped, will, without delay, be set about and encouraged by every attentive grower of wheat, and every promoter of rural improvements, in the united kingdom." The method of raising and improving varieties of which will be afterwards noticed. See WHEAT.

MILDEW, in *Gardening* is a vegetable disease, very hurtful to different kinds of trees and plants. It is supposed to proceed from different causes: some consider it as a kind of thick clammy moisture, which falls on, or rather transpires from, the leaves and blossoms of plants, which, by stopping up the pores, prevents perspiration, and hinders their growth. But the author of "The Philosophy of Gardening" suspects it to be a plant of the fungus kind, which grows without light or change of air, and with its roots penetrates the vessels of the vegetables to which it adheres, which are probably previously diseased, and thus deprives them of their due nourishment. But what is commonly denominated mildew, is an insect which is frequently found in vast numbers feeding upon the effused moisture. In a treatise upon this disease by M. Segar, it is conceived to be of a very sharp corrosive nature, and by its acrimony to hinder the circulation of the nutritious sap, in consequence of which the leaves begin to fade, and the blossoms and fruit to be greatly injured.

It is conceived by the first mentioned author, that the best method of removing it is by admitting more light and air, by proper thinning or pruning, so as to restore the natural vigour of the plants.

It is noticed by Mr. Forsyth, that, "contrary to the common opinion, trees are more liable to mildew on south and west walls, than on an east wall;" and that he has frequently removed such trees from a south or west wall, to a north or east wall, where they have frequently recovered.

It is advised, that "whenever danger is apprehended, to wash or sprinkle the trees well with urine and lime-water mixed; and when the young and tender shoots are much infected, to wash them well with a woollen cloth dipped in the following mixture, so as to clear them of all the glutinous matter, that their respiration and perspiration may not be obstructed.

"Take of tobacco one pound, sulphur two pounds, unslaked lime one peck, and about a pound of elder-buds; pour on them ten gallons of boiling water; cover it close,

and let it stand till cold; then add as much cold water as will fill a hogthead. It should stand two or three days to settle, when the scum may be taken off, and it is fit for use.

And "there is a sweet saccharine substance found on the leaves of certain trees, which is generally but erroneously supposed to fall from heaven like dew. It is known by the title of *honey dew*. There are supposed to be two kinds of it, one of which," Mr. Forsyth thinks, "transpires from the leaves of the trees where it is found; and the other is the excrement of a small insect called a vine-freeter, a species of the aphid. Bees and ants are very fond of both these kinds of honey-dew." As this exudation, "by its viscous quality, closes up the pores, and stops the perspiration of trees, it must of course be very hurtful to them."

This is a vegetable disease, which should, in his opinion, be treated in the same manner as the mildew, by washing at the same times.

The nature of mildew is more fully explained in speaking of it as relating to agriculture. See the preceding article.

MILDMAY, Sir WALTER, in *Biography*, the founder of Emanuel college, Cambridge, was surveyor of the court of augmentations in the reign of Henry VII., and privy counsellor, chancellor, and under treasurer of the exchequer in that of Elizabeth. He is celebrated for his uncommon merits in his private and public character. Sir Walter died in 1589.

MILDORFF, in *Geography*, a town of Austria; ten miles W. of Crems.

MILE, FRANCESCO, in *Biography*, born at Antwerp in 1644, was a very ingenious landscape painter, who made the heroic style of Nicolo Poussin his model, and succeeded to a very considerable degree in competition with him. In tones of colour he frequently surpasses him, and more nearly approaches Titian. He fails in the conception of scenery, and the composition of his forms.

He was poisoned, by some envious person, at the early age of 36. Had he been spared for a longer period, we may reasonably expect he would have completely rivalled his great predecessor.

MILE, in *Geography*, a long measure, whereby the English, Italians, and some other nations, use to express the distance between places. See MEASURE.

In which sense mile is used to the same purpose with league, used by the French and other nations.

The mile is of different extent in different countries. The geographical or Italian mile contains a thousand geometrical paces, mille passus, whence the term mile is derived.

The English mile consists of eight furlongs, each furlong of forty poles, and each pole of sixteen feet and a half; so that it is equal to one thousand seven hundred and sixty yards, or five thousand two hundred and eighty feet.

The mile employed by the Romans in Great Britain, and restored by Henry VII., was our present English mile. A degree of the meridian in England, N. lat. 52, according to the late measurement of colonel Mudge, is 121,640 yards, or 69,114 miles. A geographical or sea-mile is the 60th part of such a degree, i. e. 2027 $\frac{1}{2}$ yards; and three sea-miles make a league. A degree of the meridian in N. lat. 45, as measured in France in 1796, is 57008 toises = 121512 yards = 69.092 English miles.

Casimir has made a curious reduction of the miles, or leagues, of the several countries in Europe into Roman feet, which are equal to the Rhinland feet generally used throughout the north.

The

	Fect.		Fect.
The mile of Italy	50,000	The mile of Germany, the largest	25,000
of England	5,454	of France	15,750
of Scotland	6,000	of Spain	21,270
of Sweden	30,000	of Burgundy	18,000
of Muscovy	3,750	of Flanders	20,000
of Lithuania	18,500	of Holland	24,000
of Poland	19,850	of Perfia, called also parafanga	18,750
of Germany, the small	20,000	of Egypt	25,000
the middle	22,500		

The following TABLE shews the Length of Miles, Leagues, &c. Ancient and Modern, in English Yards.

Ancient Roman mile	1610.348
Olympic stadium = $\frac{1}{8}$ th of an ancient Roman mile	201.2935
Stadium = $\frac{1}{10}$ th of an ancient Roman mile	161.0348
Stadium = 1100th part of a degree	111.2
Jewish risin, of which $7\frac{1}{2}$ = an ancient Roman mile	214.713
Gallic leuca = $1\frac{1}{2}$ ancient Roman mile	2415.522
German raft, or common league in France = 2 Gallic leuca	4831.044
Perfian parafang = 2 Gallic leagues	4831.044
Egyptian schœnc = 4 ancient Roman miles	6441.392
German league, or that of Scandinavia = 2 rafts	9662.088
The mile or league of Germany = 200 Rhenish yards	8239.846
Great Arabian mile, used in Palestine in the time of the crusades, rated at $1\frac{1}{2}$ ancient Roman mile	2415.713
Modern Roman mile	1628.466
Modern Greek mile of 7 Olympic stadia	1409.0545
Modern French league = 2500 toises	5328.75
Mile of Turkey, and the common werst of Russia, supposing it seven Olympic stadia	1409.0545
League of Spain = 4 ancient Roman miles	6441.392
Large league of Spain = 5 ditto	8051.74

For other measures of a mile, see Tables under MEASURE.

MILE-stone. This article is introduced solely for the purpose of suggesting an improvement under the title of *Mile-hut*. The comfort and convenience which travellers derive from mile-stones is well known, and the dilapidations which they are subject to, are very generally felt as a grievance. Instead, however, of pointing out remedies for the evil (which might easily be done), we wish to see them entirely superseded by substituting mile-huts in the place of them. In every new act of parliament for a turnpike-road, or in any amended act, let it be a standing order that a clause shall be introduced, obliging the trustees to erect mile-huts on the whole line of road.

They should be uniform and cheap; the whole cost not to exilt forty pounds; they should be lime-whitened in the manner of the buildings in South Wales. The door to be the place of measurement, over which a painted board, with letters and figures very legible, denoting the place, thus, { London 5 } and underneath the name of the cottager, "Jones," in a different character. Each hut should be furnished with hammers, a saw, a screw-wrench, nails, cords, twine, and sundry parts of harness to be paid for at low fixed rates by those requiring them, and the keepers to be under similar regulations for good behaviour as toll collectors. In winter each hut to have a lamp burning all night.

The advantages attending such a plan are more than can readily be conceived. It would insure a large supply of cheap cottages all over the kingdom, and would be particu-

larly convenient for the labourers who repair the roads, who would never be more than half a mile, when at work, from their home. The trustees would be sufficiently remunerated by an abatement in the wages, or an easy rent to the occupier. Coaches, horses, and every sort of travellers meeting with accidents, or needing assistance, would always be within half a mile of help, and a certain knowledge of where it was to be had. But it is needless to enlarge, and all we wish is, that some member of parliament would endeavour to get the experiment tried upon some one stage, and we have no doubt it would soon come into general use.

MILECZA, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 76 miles E. of Wilna.

MI-LEI, a town of China, of the second rank, in the province of Yun-nan. N. lat. $24^{\circ} 34'$. E. long. $103^{\circ} 14'$.

MILENT, a town of Prussia, in the province of Pomerelia; 5 miles S.W. of Marienburg.

MILES, a Latin term, which, in its general import, signifies *foldier*.

In our English laws and customs, miles is peculiarly appropriated to a knight, called also *eques*.

MILESARA, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 24 miles W. of Ourfa.

MILESBURY, a post-town of America, in Mifflin county, Pennsylvania; 262 miles from Washington.

MILEŞIMO, a town of France, in the department of the Stura; 10 miles N.E. of Ceva.

MILETIN, a town of Bohemia, in the circle of Koniggratz; 12 miles N.N.W. of Koniggratz.

MILETO, a town of Naples, in Calabria Ultra, the see of a bishop; said to have been built by the Milesians, after Darius

rians had destroyed their city. It was demolished by an earthquake in the year 1783; 22 miles S.S.W. of Squillace N. lat. 38° 25'. E. long. 16° 25'.

MILETS, anciently *Miletus*, a town of Asiatic Turkey, on the W. coast of Naxos, once a celebrated city of Asia Minor, in Ionia. It was situated on the southern bank of the gulf into which the Meander discharged itself; but this river gradually accumulated its deposit in this gulf, that the town of Miletus was removed, in process of time, more than a league within the land. The town of Miletus was N. of the Posidean promontory, S.E. of the promontory Trogium, and W.S.W. of the town of Myus. This town was one of those which the Greeks conquered on their arrival in Asia. The mouth of the Meander, which was very distant from this town, was in the time of Pausanias under the walls of Miletus. This capital of Ionia was adorned with superb edifices, and was celebrated for its commerce, sciences, and arts. It had a grand temple of Ceres. The tomb of Nellesus, the son of Codrus, king of Athens, by whom the town was founded, might be seen near the walls, upon the way that led to the temple of Apollo Didymæus. This temple was burnt by Xerxes, but rebuilt by the Milesians on so large a scale, that, as Strabo reports, it was equal to a village in extent, whence it remained uncovered, but was surrounded by a thick grove, which was inhabited by the priests who served the temple. The citadel constructed by Tissaphernes, was situated on the isthmus which separated the ancient town from the new. The theatre, though built of stones, was cased with marble, and enriched with sculptures. Of all these superb edifices, there now remain merely mutilated marbles, half buried in the ground. Miletus was the native place of Thales, one of the seven wise men of Greece, and of Aspasia, the wife of Pericles. Venus had a temple at Miletus, and another in its vicinity. This city was anciently called *Lelegeis*, from the *Leleges* who inhabited it; afterwards *Pitynda*, from the quantity of pines which its territory produced; at a later period *Anactoria*; and last of all, *Milefos*, and in Latin *Miletus*. This town became illustrious by the number of colonies which proceeded from it. The Milesians, when free from a foreign yoke, were often reduced to a state of miserable vassalage by domestic tyrants. In the time of Antiochus II., king of Syria, we find that a person named Timarchus reigned in Miletus, and exercised great cruelties on the citizens, till he was driven thence by that prince, who, on that account, was honoured by the Milesians with the surname of *Θεός*, or God. This town lies at the distance of 64 miles S. of Smyrna. N. lat. 37° 22'. E. long. 27° 13'.

MILFOIL, in *Botany*, and the *Materia Medica*. See *ACHILLEA*.

MILFORD, or *MILFORD Haven*, in *Geography*, a sea-port town situated in the parish of Stanton, hundred of Rhôs, and county of Pembroke, South Wales, is of very modern origin, having been founded since the year 1790, and raised to its present importance by the patriotic exertions of the honourable Mr. Greville, nephew to the late sir William Hamilton, on whose property it stands. Happening to be here with his uncle in 1784, the penetrating and scientific eye of Mr. Greville quickly perceived the many natural advantages which this situation offered for a naval and commercial establishment. He accordingly prevailed upon sir William to apply to parliament for an act to enable him to set out legal quays, establish markets, construct docks, and in general to do every thing necessary for insuring the prosperity of the intended town. This object being effected, the conduct of the undertaking was entirely committed to Mr. Greville, who immediately laid out the ground in allot-

ments, according to a regular plan, and began his labours by the erection of a large inn or hotel. Numerous purchasers quickly appeared, so that in less than ten years the town had made considerable progress, and began to assume an air of neatness and consequence. Since that period Milford has continued gradually increasing in extent and importance. Many improvements have been made in the haven for the greater safety and accommodation of the shipping; and a dock-yard has been formed at the suggestion of lord Spencer, where several large vessels of war have been built and others repaired.

The situation of this town is most singularly beautiful, being seated on a small promontory, the sides of which descend gently to the water. The principal haven stretches itself to the south, and presents the appearance of a spacious lake. This harbour is one of the safest and most commodious in the world, and contains sixteen creeks, five bays, and thirteen roads, where upwards of a thousand sail may ride in perfect security. The town at present consists chiefly of three streets, with crossings, running in a direction from east to west, and parallel with the shore of the haven. At the extremity of the lower row of houses stands the church, an handsome edifice, consisting of a nave, chancel, and two side aisles. Several of the windows in this church exhibit escutcheons of painted glass, displaying the arms of Barlow, Hamilton, and Greville. In the chancel stands an ancient vase of red porphyry, brought from Egypt by the learned Dr. Pococke, and intended for the baptismal font, but that idea not coinciding with the religious feelings of a considerable part of the congregation, another of Derbyshire marble was fixed opposite to it for that purpose. Near the vase is placed a trunk of the mainmast of the *L'Orient*, the French admiral's flag ship, which was blown up at the battle of the Nile. At a short distance eastward from the church stands the old chapel of St. Catharine, formerly dependent upon Stanton, the mother church. It is a very ancient building, having the nave vaulted into a pointed roof; and since the erection of the new chapel has been converted into a powder magazine. The market-house is a very neat structure, as is likewise the custom-house; the collection for which takes in both sides of the haven from Milford town to the harbour's mouth, and round the coast of Bride's bay to St. David's. Two batteries for the defence of the town and haven have been lately erected, each of them mounting seven guns.

Milford is now the regular port for the mails from England to Waterford, for the conveyance of which five packets are stationed here, so that a daily communication is thereby kept up with Ireland. The chief trade of the town is its South sea whale fishery, which is carried on with great success by a colony of Quakers from the island of Nantucket, who were invited to settle here by Mr. Greville. They are, like most of their brethren, an industrious and well-disposed people, and have greatly contributed by their exertions to the progress of the new establishment. There is, likewise, some trade in wood and other stores requisite for the equipment or supply of his majesty's ships, or other vessels which may find it necessary to put in here for repair or safety. There are two quays for the landing of goods, and extensive store-houses for their reception, under the management of established officers. Two markets are held in this town during the week, on Tuesday and Saturday, but there are no fairs. The family of Philips derive from hence the title of baron. For the encouragement of the science of ship-building a boat-race was some years ago established here under the auspices of lord Cawdor and Mr. Greville. The prize for the winning boat of the first class of twenty feet keel, is a cup

cup given by his lordship of the value of twenty-five or thirty pounds; and there is besides an inferior prize for boats of a second class from sixteen to eighteen feet keel.

The neighbourhood of Milford exhibits a well inclosed and highly cultivated country. Several elegant villas belonging to the merchants of Milford contribute much to its beauty. The old town of Haking stands on the W. side of the influx, call Priory Pill. Near it is an elegant observatory built by Mr. Greville, and, with the mathematical school contiguous to it, were placed under the direction of Mr. Firminger, who was for eight years sole assistant to Dr. Maskelyne. Here are likewise the ruins of the priory from whence the inlet derives its name. This religious establishment owed its foundation to Adam de Rupe, or de la Roche, who appears to have been a man of power and consequence in this district. It was dedicated to St. Mary and St. Buddoch for monks of the order of Tyrone, who in time forsook that strict rule and became Benedictines. A small portion of this edifice only now remains; most of the materials of which it was composed having been carried off within the memory of man, to assist in the erection of other buildings in the neighbourhood. The earl of Richmond, afterwards Henry VII., is said to have landed at this place, in his enterprise against Richard III., on the seventh of August, 1485. On the eastern side of the Pill, or influx, stands Castle Pill, which was formerly a fortification for its protection. In the reign of queen Elizabeth it was reckoned among the castles in Pembrokehire; and is mentioned, in 1644, as one of the strongest posts which the royalists maintained in this part of the country. From the misconduct of the garrison, however, it was subsequently taken, after a short resistance, by a force apparently inadequate to the undertaking. The village of Stanton, which gives name to the parish in which Milford is situated, lies on the road between that town and Haverford-west. The church here was garrisoned during the civil wars by the troops of the parliament, with the view of interrupting the communication between Haverford-west and the fort already mentioned. According to the parliamentary returns of 1801, the whole population of this parish amounted to 1291 persons, a great proportion of whom resided in Milford. Fenton's Historical Tour through Pembrokehire, 1 vol. 4to. Carlisle's Topographical Dictionary of Wales, 1 vol. 4^o.

MILFORD, a township of America, in Milflin county, Pennsylvania.—Also, a small town in Worcester county, Massachusetts, 18 miles from Worcester, containing 907 inhabitants.—Also, a post-town of the state of Delaware, pleasantly situated on the N. side of Maspilon creek, about 12 miles W. of its mouth in Delaware bay; containing more than 100 houses, inhabited by Episcopalians, Quakers, and Methodists.—Also, a town of Northampton county, Pennsylvania, laid out on the N.W. side of the Delaware, in an elevated situation, at Well's Ferry, 120 miles above Philadelphia. A paper-mill has been erected here by a Mr. Biddis, who has discovered the method of making paper and pasteboard by substituting a large proportion of saw-dust in the composition.—Also, a post-town of Connecticut, in Long-Island sound, and in New Haven county, 13 miles S.W. of New Haven. The Indians call this town "Æopowage;" and it was settled in 1638. It contains an episcopal church, and two congregational churches.

MILFORD Haven, a deep bay on the coast of Nova Scotia, to the S.W., round the point of the strait of Canso.—Also, a bay on the N. coast of Virginia. N. lat. 37° 26'. W. long. 76° 20'.

MILHAU, a town of France, and principal place of a district, in the department of Aveyron, seated on the Tarn.

In 1371, this town was taken by Edward III., king of England; 27 miles S.E. of Rodés. The place contains 6077, and the canton 10,443 inhabitants, on a territory of 297½ kilometres, in nine communes. N. lat. 44° 6'. E. long. 3° 10'.

MILHAUSEN, a town of the duchy of Stiria; 10 miles E. of Gratz.

MILI, a river of Sicily, which runs into the sea, seven miles S. of Messina.—Also, a town of Thibet; 45 miles N.E. of Tchiatam.

MILIANI, a town of Africa, in the kingdom of Algiers; 22 miles S.E. Shershell.—Also, a river of Africa, in the kingdom of Tunis, which runs into the Mediterranean, about 10 miles S.E. of Tunis.

MILIARENSIS, in *Antiquity*, a silver coin of the empire, substituted by Constantine in the room of the denarius; and so called because he fixed the price of the pound of gold at 1000 pieces of this new silver. But as he divided the pound of gold also into 72 solidi, each solidus really contained 13² miliarenfes, though it passed for 14; which difference between the real and current value of the solidus, in relation to the miliarenfes, must have occasioned disputes in the payment of small sums. To remedy this inconvenience, it was thought proper to alter the weight of the silver money, and having fixed the price of the pound of silver at five solidi, to coin sixty pieces out of it, which retained the name miliarenfes, though the pound of gold was worth but 864. It does not appear how many miliarenfes Constantine coined out of the pound of silver: but if the piece of gold was nearly the same in his reign, as when five solidi were worth a pound of silver, the pound must have been worth 14² pounds of silver; and 1000 divided by 14² gives 69⁺ for the number of miliarenfes coined out of the pound. Therefore it is probable, that Constantine's number was either 69 or 70. If the former, each piece should weigh 73⁸/₂₇ troy grains; if the latter, 72³/₁₈. According to the former estimate, the proportion of gold to silver was always 14¹/₂ to 1; according to the latter, 14²/₇ to 1. Phil. Trans. vol. lxi. part ii. p. 513. See **FOLLIS**.

MILIARES GLANDULÆ, in *Anatomy*, glandular bodies distinguished by their small size; such as the supposed glands of the skin, &c.

MILIARIUM, the name of a tall and narrow vessel, used in the bathing of the ancients, for heating water to any degree, to give warmth to the rest. See Mem. Acad. Inscrip. vol. i p. 127.

MILIARY ERUPTION, in *Medicine*, an eruption of minute vesicles, appearing in persons confined to bed, in hot and close apartments, especially after profuse sweating. The term has been adopted from ancient times, from the resemblance of the vesicles in size and appearance to *millet* seeds.

MILIARY Fever, a denomination given to fevers of every description, when accompanied by an eruption of miliary vesicles.

This is the light in which the more correct observation of our times has taught us to consider the *miliary fever*. The physicians of the seventeenth and the greater part of the eighteenth century describe the miliary fever, as a distinct eruptive fever, arising, like the small-pox, measles, &c., from a peculiar poison or acrimony, of the proper concoction and expulsion of which from the system the eruption was deemed evidence, according to the doctrines of the humoral pathology. Under this notion, the disease was described, by different observers, with a variety of titles, and no small degree of confusion arose from the misapplication of these titles to other diseases, which bore some resemblance to it.

Thus,

MILIARY FEVER.

Thus, it was called, the military disease (*Morbus miliaris*), the military fever, the vesicular fever, or simply *miliaria*, and *miliaris*, and others, confounding the vesicular appearances with the purple spots, or petechiæ of malignant fevers, or supposing them to be of a similar nature, applied the term *Purpura* to it; calling it *Purpura alba*, *Purpura miliaris*, *Febris purpurata*, &c. Again, another mistake, equally gross, was committed in places where the scarlet-fever was epidemic, in confounding the rash of this disease with the vesicular eruption of *miliaria*. This occurred particularly at Leipzig, where *scarlatina* was extremely prevalent and fatal, in the year 1672, and a history of which was published by Cbrill. Joan. Langius. (See his *Prax. Med.* part ii. cap. xiv. § 9.) This fever was extremely contagious, and spread over the greater part of the continent, and was called a military fever; it has been even considered by many writers as the prototype of all military fevers, and the first example of its appearance in Europe. See Macbride, *Method. Introductio. to the Theory and Pract. of Physic*, part ii. chap. xvii. Hamilton de *Febri Miliari*. Allioni *Tract. de Miliarium Orig. Progress. &c.* J Fordyce *Hist. Febris Miliaris*, &c.

These errors were corrected by De Haen (*De Divis. Februm*, § 4.); and the true nature of the military eruption, as always secondary or symptomatic, and as the result of perspiration and of a continued heating regimen, in various febrile diseases (of which, indeed, Sydenham had long before expressed his belief), was satisfactorily shewn by Mr. White (in his *Essay on the Management of Lying-in Women*), and by Dr. Cullen (*Nosol. Method. Gen.* xxxii. *note.*) In truth, the occurrence of this eruption, and of the severe and often fatal symptoms of fever, with which it was accompanied, affords a lamentable proof of the mischief resulting from mistaken hypothesis on medical subjects, when carried to the bedside of the sick. For this *military fever* has been, at different times and places, not only produced, but actually rendered epidemic, by the mal-practice of individuals. Mr. White asserts, that a midwife at Manchester, who had very extensive practice among all ranks of women, and was tolerably successful in other respects, had a remarkable number of her patients seized with the military fever, during their accouchement, which proved fatal to many, particularly to the wives of several of the principal tradesmen. This disease "became so alarming and notorious, both in this neighbourhood and in distant parts of the country, as to acquire the name of the Manchester fever." While at the same time, other practitioners of the place, who pursued a different plan of treatment, met with no such fever. So that the sarcasm of Dr. Shebbeare was but too correct, when he recommended gentle means of supporting the vital heat, "otherwise the military eruption may be rather a symptom of the physician than of the disorder, as it is to be feared that some, through mistaken practice, have discovered a way of making military fevers, and may be called a kind of manufacturers of that disease." (*Practice of Physic.*) "Quid verò demum generi humano calamitosius," says De Haen, "quam quod et plebe et medicis conspirantibus, tot millenni quotannis ægri, ab ipso principio acutorum, in sudores symptomáticos agitentur, ac veluti fundantur, ut coacta omnino crisis, in perisque aut letalis, aut periculosa saltem, producat; interea dum salutaria nature molimina turbantur, confunduntur, ac penitus sufflaminantur. Faxit Deus, ut demum sapiant Phryges!" *Februm Divis.* § 4. p. 84.

Hippocrates and the ancients have said little respecting this military fever, because they followed too steadily the dictates of nature in their practice to produce it. They do,

however, mention a casual appearance of military vesicles, in febrile diseases. (See Hippocrates *Epidem.* lib. i. § 3. *ægror.* 2. lib. ii. § 1. & § 3.) In like manner, those practitioners who have been conversant with the treatment of diseases during the last thirty years, have witnessed but casual and slight occurrences of these eruptions, and are totally unacquainted with the formidable military fever, described by the physicians of Leipzig, and subsequently very well known in this country.

It has been universally observed that women, during their puerperal confinement, although not exclusively, were the most frequently attacked by the military fever. This, no doubt, arose from the peculiar assiduity with which the hot and sweating regimen was enforced with puerperal women, of which Mr. White has given an impressive description. (*Loc. cit.* p. 6. et seq. 3d edit.) Under the suffocating heat and closeness of the room, in which was a large fire and a crowd of people, and every crevice, even the key-hole, closed; under an additional load of bed-clothes, from which the good woman was not allowed to put out her arm, or even her nose; and constantly supplied with heating liquors from the spout of a tea-pot to keep up the sweating; in such a situation, "a few days after delivery the patient is, perhaps, seized with a shivering fit, and the nurse is surprized, as she protests she has not had the least waft of cold; more clothes are heaped upon her; spirituous liquors and hot spices are given her, to throw off the cold fit, which most certainly increase the succeeding hot one. A warm room, plenty of clothes, and warm drinks are continued, to throw her into a sweat, but have frequently a contrary effect, by increasing and prolonging the burning fit; which at last terminates in a most profuse sweat, continuing many nights and days without giving relief." (*Ibid.* p. 13.) The tongue becomes dry and warm; the pulse quick, small, and creeping; and the patient complains of great anxiety and oppression about the præcordia, attended with sighings, lowness of spirits, lassitude, and extreme languor and debility. "If the hot regimen be continued," Mr. White proceeds to state, "with vinous spicy caudles, hot alexipharmic medicines, volatile alcalious salts and spirits, opiates, and a close room, so as to keep the patient in a perpetual sweat, vibices or petechiæ appear, or (military) eruptions, either of the white or red kind, or both, first upon the neck and breasts, afterwards extending themselves all over the body, one crop succeeding another till the patient is worn out; but they give no relief, are not in any way critical, nor is there indeed any crisis in this disorder, except the looseness." (P. 16.) In the military fever, which was epidemic among puerperal women at Leipzig, about the year 1650, many of the most violent symptoms, connected with malignant fever, concurred; such as extreme prostration of strength, restlessness, and delirium, tremors and convulsive motions of the limbs, dimness of sight, hæmorrhagies, &c. (See Gotofr. Welfsch, *Hist. Med. Nov. Morb. Puerp. qui der Friesel dicitur*:—in Haller, *Disput. Med.* tom. v. § clxxiv.) The disease is said to have been called *der Friesel*, from the resemblance of the rough state of the skin, to a sort of cloth called *friesel*.

The utmost irregularity seems to have prevailed, in respect to the period at which the military vesicles made their appearance. According to Welfsch, it appeared as early as the second day after parturition, or within the first week; but other writers have not seen it before the fifth day, and others again on the seventh, eighth, tenth, or eleventh, on the fourteenth, sixteenth, and even twenty-eighth day. This difference would, of course, be expected to happen, in consequence of the different degrees of the hot regimen adopted

in different instances, and of the variety of season and of individual constitution. It seems to be agreed, however, notwithstanding the hypothetical notions of the salubrity of such expulsions of supposed morbid matter from the body, that a favourable termination of the disease is not more certain from a copious eruption, or from its early appearance; but that, on the contrary, the fuller and earlier the eruption is, the greater is the danger.

The distinction that has been made by writers in general, respecting the two kinds of miliary vesicles, the *red* and the *white*, is futile; as these differences of colour are by no means specific, but depend entirely upon the size of the vesicles, their transparency, and the degree of inflammation accompanying them: inasmuch that the eruption which is *red* in the beginning, when the vesicles are perfectly diaphanous, becomes *white* in a day or two, when the inflammation of the surface is less, and the lymph contained in the vesicles becomes of a milky opacity.

Mr. White observes, that "the diseases, or rather the symptoms, which are said to succeed the miliary fever, are hectic heats, loss of appetite and of spirits, and swellings of the legs, feet, and thighs; but these are nothing more than what follow other putrid fevers. Those who have had this fever are particularly liable to returns of it during their whole lives; owing most probably to the skin being over relaxed, and its tone destroyed, by a too hot and forcing treatment."

Miliary eruptions have been produced in consequence of feverish complaints, which confined patients to bed, and occasioned a sweating condition of the skin, as well as in the puerperal state. Thus it has sometimes occurred in persons who became feverish after some important surgical operation, or remained in bed in consequence of some accident; it has occurred also in catarrhal and rheumatic fevers, where the natural tendency to sweating is considerable, and in various other febrile complaints. Hence we may explain the observations of some writers on the subject, who speak of the miliary fever as imitating or being disguised under the character of other febrile diseases; when, in fact, the eruption was secondary, and had supervened upon the hot and sweating state of the patient in those other fevers respectively; such as tertians, quartans, remittents, &c. (See *Memoires de la Soc. Royale de Medecine*, par M. Barailon, tom. i. p. 193.) Indeed there is scarcely any acute disease, with which the miliary eruption has not been described as combined, and with which it might be expected to be combined, while the mode of practice, which gave rise to it, continued to be pursued: thus it has been conjoined with typhus, gout, pneumonia, measles, small-pox, scarlet-fever, whooping-cough, the fever of dentition, asthma, &c. See Allionius *Traët. de Miliarium Orig. Progress. Nat. et Curat.* The *Cure of the Miliary Fever*, by a subject to Mithridates.

That excellent writer, Dr. Macbride, was misled, like his less intelligent brethren, by the prevalent hypothesis of the concoction and critical expulsion of morbid acrimony, and considered miliary fever as something specific, like the contagious eruptive fevers. He has accordingly described it, as occurring alone and uncombined, under the term *miliaris simplex*, seu *benigna*. "The febrile symptoms previous to the eruption," he says, "are not very high nor distressing; no great pain, thirst, or sickness; the pulse rather depressed than hard; they increase, however, gradually till the third or fourth day, when the eruption strikes out, chiefly on the neck, back, and breast, being preceded by a profuse sweat, of a sourish smell, and a particular tingling sensation in the skin, especially in the fingers, and an itching in those places where the miliary pustules (vesicles) are most plentiful. In

about thirty hours the eruption is full out, and replete with serum, with a slight inflammation round the basis of the little vesicles, occasioning a fulness and tension of the skin. The febrile symptoms now subside, the patient continues to sweat plentifully, and makes higher-coloured urine, the pulse gradually becomes full, soft, and equable, and by the end of the week the eruption dries up, and the cuticle falls off in scales." (*Methodical Introd. to Theory and Pract. of Physic*, part ii. chap. 17.) Sir Richard Blackmore gives a similar account of the progress of the miliary eruptions, the drying of which, "in the more kindly sort, is generally accomplished in seven days." (*Treatise on the Plague*.) But in the worse sorts, he says, the time is much protracted; and he avers, that he has seen the fever continue, and a second, and even a third crop of the eruptions appear, and go through the same course. And Dr. Brocklesby mentions a case, in which the low pulse, great prostration of strength, and other severe symptoms, continued *forty-six days*, in which time *four* successive crops of miliary vesicles occurred. See his *Paper on Seltzer Water*, *Med. Obs. and Inquir.* vol. iv. art. ii. p. 31.

Having stated these facts upon the authority of the best writers on the subject, it is scarcely necessary to enter into any detail of the discussion, relative to the origin of the miliary fever. The sagacity of Sydenham detected their efficient cause in the hot regimen generally practised in his time, and long afterwards. "*Licet sua sponte nonnunquam ingruant, sapius tamen levi calore et cardiacis extorquentur.*" (*Sched. Mon. de Nov. Febris Ingressu*.) And his opinion has been substantiated, and the arguments and hypothesis of those, who denied its truth, practically refuted by the almost total disappearance of the disease, even in puerperal women, since the rational method of ventilation and regimen, now practised, became generally prevalent among medical men.

It is scarcely necessary, therefore, to say any thing respecting the method of treatment. In all circumstances, under which a person is confined to bed, the room in which he lies should be as free from any disagreeable smell or closeness as any other apartment in the house; which can be readily effected by the constant admission of fresh air and by cleanliness: and his bed-clothes, whether he labour under fever or not, should be as light as may be, provided the skin is not cooled below the natural standard of temperature, and the patient experiences no actual sensation of chilliness. These rules should be strictly observed, even under a state of perspiration or profuse sweating; for, so long as no direct current falls upon the patient, coolness of the surrounding air will moderate, without suppressing, the cutaneous discharge. Even when the miliary eruption has appeared, in consequence of previous improper management, coolness of the apartment and bed of the patient, with a free access of fresh air, will be found the most effectual cordial, and will support the strength, and subdue the languor of body and mind more powerfully than "gallons of wine." Consult Mr. White's able treatise above quoted, in which references to all the writers on the subject are given, and from which, as well as the *Essay of De Haen, de Divisione Februm*, the most satisfactory information will be obtained.

MILICIA, in *Geography*, a river of Sicily, which runs into the sea; 10 miles E.S.E. of Palermo.

MILIEU HARMONIQUE, in *French Music*, is the name sometimes given to the 3d of a common chord or triad, as being the mean or middle between the key note or fundamental base and its 5th.

MILILLO, in *Geography*, a town of Sicily, in the valley of Noto; 8 miles S.S.E. of Lentini.

MILIN,

MILIN, a town of Bohemia, in the circle of Beraun; 4 miles from Pezibram.

MILIOIUM, in *Surgery*, a small tumour of the eyelids, so called, from its being of the size of a millet seed.

MILLOQUEAN CREEK, in *Geography*, a river of Upper Canada, which, running northerly, discharges itself into lake Simcoe, now called "Holland's river."

MILIS, a town of Sardinia; 12 miles from Oristagni.

MILITANT, a term used of the body of Christians, while here on earth.

The Romanists divide the church into militant, patient, and triumphant; the militant is on earth; the patient, or passive, they place in purgatory; and the triumphant in heaven.

MILITARE AERARIUM. See **AERARIUM**.

MILITARIS TOGA. See **TOGA**.

MILITARIS Via. See **VIA**.

MILITARY, something belonging to the militia, or soldiery. Thus,

Military Architecture denotes the art of fortification. See **ARCHITECTURE**, and **FORTIFICATION**.

Military Art, is the art or science of making or sustaining war to advantage. See **WAR**.

Military Column. See **COLUMN**.

Military Court. See **COURT of Chivalry**.

Military Discipline. See **DISCIPLINE**.

Military Estate includes the whole of the soldiery; or such persons as are peculiarly appointed among the rest of the people for the safeguard and defence of the realm. Although the laws and constitution of this kingdom know no such state as that of a perpetual standing soldier bred up to no other profession but that of war, it has for many years past been judged necessary by our legislature, for the safety of the kingdom, the defence of the possessions of the crown, and the preservation of the balance of power, to maintain, even in time of peace, a standing body of troops, under the command of the crown, who are however *ipso facto* disbanded at the expiration of every year, unless continued by parliament; and if from experience past we may judge of future events, the army is now lastingly engrafted into the British constitution; with this singularly fortunate circumstance, that any branch of the legislature may annually put an end to its legal existence by refusing to concur in its continuance. (Bl. Com. b. i.) The military force of the kingdom comprehends regulars, including the royal marines, the militia, and volunteers. See **MARINES**, **MILITIA**, **SOLDIER**, and **VOLUNTEERS**.

Military Execution, the delivery of a city or country up to be ravaged and destroyed by the soldiers, upon its refusing to pay the contribution money imposed upon it. It denotes also the punishment inflicted by the sentence of a court martial. See **EXECUTION**.

Military Exercises are the evolutions or various manners of ranging and exercising soldiers. See **BATTALION**, **EVOLUTION**, **EXERCISE**, and **MANUAL Exercise**.

Military Feuds. See **FEE** and **FEUD**.

Military Fever, a kind of malignant fever frequent in armies, by reason of the ill food, &c. of the soldiers. See **FEVER**, and **TYPHUS**.

Military Government, is the supreme command and disposal of all the military power of a nation, by land and sea.

Military Law. See **LAW of Arms**, and **MARTIAL**.

Military Machine. See **MACHINE**.

Military Merit, Order of, in *Heraldry*, was instituted in France, in the year 1759, by Louis XV. in honour of those officers of his army who were Protestants. The

marks of honour are the same as those of the order of St. Louis. The ensign of the order is also of the same form as that of St. Louis, with this difference, that on one side it is a sword in pale; within this motto *PRO VIRTUTE MILITICA*; and on the reverse is a chaplet of laurel; within this inscription, *M. D. XV. INSTITUIT 1759*.

Military Music, before the introduction of fire-arms, served to animate the soldiers in battle and assaults of places, as well as for purposes of signals for the different manoeuvres and duties in camp and garrison; and, therefore there is no reason to doubt its having been used in our ancient armies. The common military instruments of music were the trumpet, drum, fife, and horns of different kinds. See an account of each under its proper title. In modern times, kettle-drums and trumpets have been chiefly appropriated to the horse. The dragoons long had the hautbois and side-drum, but about the year 1759 changed these for the trumpet: the infantry had only the drum, till the introduction of fifes. Since the introduction of light infantry, many of these companies have used the bugle-horn.

Of late years, in addition to the drums and fifes, each regiment of infantry has had its band of music. The instruments are chiefly hautbois, clarinets, French horns, bassoons, trumpets, cymbals, and in some the tabor and pipe. The band is usually composed of men borne upon the establishment of the regiment as privates, and allowed some additional pay from the non-effective fund of the field-officers and captains of companies. These officers also defray the charge for instruments, extra-clothing, music, &c. though in many corps the money paid for discharges has been applied to the support of the regimental band. Grose's Mil. Ant. vol ii.

Military Order. See **ORDER**, and **KNIGHTHOOD**.

Military Rewards. See **REWARDS**.

Military Tenures. See **TENURE**.

Military Testament, among the Romans, was what we call a nuncupative will; or a testament made only by word of mouth, in the presence of two witnesses.

This was a privilege peculiar to the soldiery, and to them only when in the field; for at other times they were subject to the common laws in this respect. See **SOLDIER**.

Military Townships, in *Geography*, townships of America, in the state of New York; deriving their appellation from the following circumstance. The legislature of the state granted $1\frac{1}{2}$ million of acres of land as a gratuity to the officers and soldiers of the line of this state. This tract, forming the country of Onondago, is bounded W. by the E. shore of the Seneca lake and the county of Ontario, N. by the part of lake Ontario near Fort Oswego, S. by Tioga county, and E. by Chenango county. This pleasant country is divided into 25 townships of 60,000 acres each, which are again subdivided into 100 convenient farms, of 600 acres, amounting in the whole to 2500 farms, well watered by a multitude of small lakes and rivers.

Military Ways, viz militares, are the large Roman roads, which Agrippa procured to be made through the empire, in the time of Augustus, for the more convenient marching of troops, and conveyance of carriages.

N. Bergier has wrote the history of the origin, progress, and amazing extent, of these military roads; which were paved from the gates of Rome to the extreme parts of the empire. See **WAY**.

MILITELLO, in *Geography*, a town of Sicily, in the valley of Demona, on the N. coast; 16 miles S.W. of Patì.

MILITES CANDIDATI. See CANDIDATI.

MILITIA, a collective term, understood of the body of soldiers, or persons who make profession of arms.

The word comes from the Latin *miles*, a soldier; and *miles* from *mille*, which was anciently wrote *mile*. For in levying soldiers at Rome, as each tribe furnished a thousand, *mille*, or *mile*, *men*; whoever was of that number, was called *miles*.

MILITIA, in its proper and more restrained sense with us, is used to signify the inhabitants, or, as they have been sometimes called, the *trained-bands*, of a town or county; who are armed on a short warning for their own defence. In which sense militia is opposed to regular stated forces. Soon after the restoration of king Charles II., when the feudal tenures were abolished, it was thought proper to ascertain the power of the militia, to recognize the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination; and the order in which the militia now stands by law, is principally built upon the statutes which were then enacted, viz. 13 Car. II. cap. 6. 14 Car. II. cap. 3. 15 Car. II. cap. 4.

It is true the two last of them are apparently repealed; but many of their provisions are re-enacted, with the addition of some new regulations, by the present militia laws; the general scheme of which is to discipline a certain number of the inhabitants of every county, chosen by lot, for three years, and officered by the lord-lieutenant, the deputy lieutenants, and other principal land-holders, under a commission from the crown. They are not compellable to march out of their counties, unless in case of invasion or actual rebellion, nor in any case compellable to march out of the kingdom. They are to be exercised at stated times; and their discipline in general is liberal and easy; but when drawn out in actual service, they are subject to the rigour of martial law, as necessary, to keep them in order. This is the constitutional security, which our laws have provided for the public peace, and for protecting the realm against foreign and domestic violence, and which the statutes 2 Geo. III. cap. 20. &c. 9 Geo. III. cap. 42. declare is essentially necessary to the safety and prosperity of the kingdom. Blackst. Com. book i.

By the 2 Geo. III. cap. 20. all former acts relating to the raising of the militia are repealed, except in such cases as are therein specially directed to be subject to the provisions of the former acts, or any of them; particularly with regard to the city of London, the Tower Hamlets, and the Cinque Ports. Several statutes were subsequently enacted, which it is needless to recite; because by the 42 Geo. III. c. 90. the chief former acts relative to the militia are from June 26, 1802, repealed; excepting such as relate to the city of London, Tower Hamlets, the Stannaries, and the Cinque Ports. The militia raised under such acts shall be subject to this act; and all deficiencies under the former militia laws are to be supplied, and the men so raised are to serve according to this act. It is first provided by this act that the king shall appoint lieutenants for the several counties, &c. with full power to call together, arm, array, and cause to be trained and exercised such persons, once in every year; and such lieutenants shall appoint 20 or more persons, duly qualified, to be deputy-lieutenants, and shall also appoint a proper number of colonels, lieutenant-colonels, majors, and other officers, qualified to train, discipline, and command the persons to be armed and arrayed. The names and ranks of all such officers to be certified to his majesty, and subject to his approbation. Every person, appointed to be a deputy-lieutenant, shall be either in law or equity, for his own use and benefit, in possession of a freehold, copyhold, or customary

estate for life, or for the life of his wife, she having a freehold, copyhold, or customary estate for her life, or for some greater estate, or of an estate for some long term of years determinable on one or more life or lives, in manors, messuages, lands, tenements, or hereditaments, in England, Wales, or the town of Berwick-upon-Tweed, of the yearly value of 200*l.*; or shall be heir apparent of some person in like manner possessed to the yearly value of 400*l.*; a colonel, to the yearly value of 1000*l.* or heir apparent to the yearly value of 2000*l.*; a lieutenant-colonel, to the yearly value of 600*l.* or heir apparent to the yearly value of 1200*l.*; a major, to the yearly value of 400*l.* or heir apparent to the yearly value of 800*l.*; a captain, to the yearly value of 200*l.* or heir apparent to the yearly value of 400*l.* or he shall be a younger son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 600*l.*; a lieutenant, to the yearly value of 50*l.* or personal estate alone to the amount of 1000*l.* or real and personal estate together of the value of 2000*l.* or he shall be son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 100*l.* or of a personal estate alone to the amount of 200*l.* or real and personal estate together of the value of 3000*l.*; an ensign, to the yearly value of 20*l.* or a personal estate alone to the amount of 500*l.* or real and personal estate together of the value of 1000*l.* or he shall be son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 50*l.* or who shall be, or at the time of his death was, possessed of a personal estate alone to the amount of 1000*l.* or of real and personal estate together of the value of 1500*l.*; one moiety of which said estates, excepting of lieutenants and ensigns, shall be situate within the respective counties, ridings, or places, in which they shall be appointed to serve.

Provided, that the immediate reversion or remainder of and in manors, messuages, lands, tenements, or hereditaments, which are leased for one, two, or three lives, or for any term of years determinable on the death of one, two, or three lives, on reserved rents, and which are to the lessees of the clear yearly value of 300*l.* shall be deemed equal to an estate herein before described, of the yearly value of 100*l.* and fo in proportion. s. 10.

Also, a person, either at law or equity, for his own use and benefit, in possession of an estate for a term originally granted for 20 years or more, of an annual value (over and above all rents and charges payable in respect of the same) equal to the annual value of such an estate as is required for the qualification of a deputy-lieutenant and commissioned officer respectively, and situate as aforesaid, shall be deemed sufficiently qualified.

In the counties of Cumberland, Huntingdon, Monmouth, Westmorland, and Rutland, and in every county and place in Wales, the qualifications shall be as follow, and of the like estates as before mentioned:

A deputy-lieutenant's shall be of the yearly value of 150*l.* or he shall be heir apparent to an estate of the yearly value of 300*l.*; a colonel's of the yearly value of 600*l.* or he shall be heir apparent to the yearly value of 1200*l.*; a lieutenant-colonel's or major commandant's shall be of the yearly value of 400*l.* or he shall be heir apparent to the yearly value of 800*l.*; a major's shall be of the yearly value of 200*l.* or he shall be heir apparent to the yearly value of 400*l.*; a captain's shall be of the yearly value of 150*l.* or he shall be son of a person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 300*l.*; a lieutenant's shall be of the yearly value of 50*l.* or a personal estate alone to the amount of 600*l.* or real and personal to-

MILITIA.

gether of the value of 1000*l.* or he shall be the son of a person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 600*l.* or a personal estate alone to the amount of 1200*l.* or a real and personal estate together of the value of 2400*l.*; an ensign's, of the yearly value of 200*l.* or a personal estate alone to the amount of 300*l.* or real and personal together of the value of 600*l.* or he shall be the son of a person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 300*l.* or of personal estate alone to the amount of 600*l.* or real and personal together of the value of 1200*l.*; of all which respective estates (except those for the qualifications of lieutenants and ensigns), one moiety shall be within the respective counties or places in which such officers shall be respectively appointed to serve.

In the Isle of Ely, a deputy-lieutenant's shall be of the yearly value of 150*l.* or he shall be heir apparent to the yearly value of 300*l.*; a captain's shall be of the yearly value of 100*l.* or he shall be heir apparent to the yearly value of 200*l.* or he shall be a younger son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 300*l.*; a lieutenant's shall be of the yearly value of 30*l.* or personal estate to the amount of 600*l.* or he shall be son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 600*l.* or personal estate to the amount of 1200*l.*; an ensign's shall be of the yearly value of 20*l.* or personal estate to the amount of 300*l.* or he shall be the son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 300*l.* or personal estate to the amount of 600*l.*; one-half of all which estates (except those for the qualifications of lieutenants and ensigns), shall be situate or arising within the said Isle of Ely, or some other part of the county of Cambridge.

In all cities or towns which are counties within themselves, and have heretofore used to raise and train a separate militia within their respective liberties, and which are united with and made part of any county for the purposes of raising the militia only, the lieutenant hereof, or, where no lieutenant, the chief magistrate, shall appoint the deputy-lieutenants, and also the officers of the militia, whose number and rank shall be proportionable to the number of men which such city or town shall raise as their quota towards the militia of the county to which they are united for such purposes; and all powers and provisions made with respect to counties at large shall take place in the said cities or towns. And the qualification for a deputy-lieutenant shall be 150*l.* a-year as aforesaid, or a personal estate alone, or real and personal estate together, to the amount or value of 3000*l.* Field officer 300*l.* or personal estate alone, or real and personal together, to the value of 5000*l.* Captain 150*l.* a-year, or personal estate alone, or real and personal together, to the value of 2500*l.* Lieutenant 30*l.* a-year, or personal estate of 750*l.* Ensign 20*l.* a-year, or personal estate of 400*l.* One-half of all which real estates (except those for the qualification of lieutenants and ensigns) shall be within such city or town, or within the county to which such city or town is united for the purposes aforesaid. f. 9.

The whole number of private men to be raised, exclusive of certain places that are excepted, is 39,572; in various proportions for the several counties. Such numbers shall continue to be the respective quotas, until the 25th day of June, 1805, and from thence until other quotas shall be appointed by his majesty's privy council; and the respective quotas that shall at or after the expiration of the said first mentioned period, and also from time to time at or after the

expiration of every successive ten years after such period, be to appointed by the privy council, shall from the appointment thereof continue until other quotas shall be appointed under this act.

By this act provision is made for a "Supplementary Militia;" for in case of invasion, or imminent danger of it, and also in case of rebellion, the king may (the occasion being first communicated to parliament if sitting, or declared in council, and notified by proclamation, if there be no parliament sitting) by his proclamation order and direct, in addition to the number of militia-men aforesaid required to be raised under this act, any number of men not exceeding one-half of the aggregate number of the militia to be raised and enrolled. These men shall, in pursuance of such proclamation, be raised by the lieutenants and deputy-lieutenants. His majesty may also, by proclamation, disembody the supplementary militia; and the privates so disembodied, or those enrolled and not embodied, shall remain liable to serve and to supply all vacancies. The lieutenants and deputy-lieutenants shall hold meetings, and issue precepts for returning lists, and settling of lists, for proportioning the numbers in the several hundreds, &c., and the deputy-lieutenants shall cause the number appointed to serve to be chosen by ballot out of the list returned for every parish, &c. Parishes are allowed to offer volunteers without balloting.

The persons exempted from serving in the militia, or providing substitutes, are peers of this realm; commissioned officers in his majesty's other forces, or in any of his castles or forts; non-commissioned officers and private men serving in any of his majesty's other forces; commissioned officers serving, or who have served four years in the militia; members of either of the universities; clergymen; licensed teachers of any separate congregations; constables, or other such peace officers; article clerks, apprentices, seamen or seafaring men; persons mustering and doing duty in any of his majesty's dock-yards; persons free of the company of watermen of the river Thames; persons employed and mustered at the Tower of London, Woolwich Warren, the several gun-wharfs at Portsmouth, Chatham, Sheerness, and Plymouth, or at the powder mills, magazines, or the houses under the direction of the board of ordnance; and poor men who have more than one child born in wedlock. And by 43 Geo. III. c. 123. a person serving or having found a substitute in the army of reserve; and by 44 Geo. III. c. 54. any effective volunteer. Persons balloted, that refuse to serve or provide a substitute, shall forfeit 10*l.* which, by 43 Geo. III. c. 50. is increased to 15*l.* and at the expiration of five years, be liable to serve again, in person or by substitute. Those who have served are to be returned home in due time, so that they may reach the county to which they belong, if absent from it, by the expiration of their term; unless they shall consent to serve again. The enlisting of persons enrolled to serve in the militia, for service in his majesty's other forces, shall be deemed null and void. The militia are required to be trained and exercised by regiment or battalion, once in a year for twenty-eight days together (43 Geo. III. c. 19.): and the penalty of not appearing, or deserting, is the immediate payment of 20*l.* or imprisonment for six months, or till the money is paid. In case of actual invasion, or immediate danger of it, or rebellion in this kingdom, his majesty, communicating the occasion to parliament, if sitting, or declared in council, and notified by proclamation, if parliament be not sitting, may order the militia to be embodied, put under the command of general officers, and led to any part of the kingdom, but not to go out of it; and they shall be subject to the acts against mutiny

and

MILITIA.

and desertion. And any person not appearing, shall be liable to be apprehended and punished as a deserter; and if any person shall harbour or conceal any such militia man, he shall for every such offence forfeit 100*l*. From the date of his majesty's command for drawing out the militia into actual service, the officers and privates shall be entitled to the same pay as those of other infantry. Officers of the militia, during the time of service, are exempted from the office of sheriff, nor does the acceptance of a commission in the militia vacate the seat of any member returned to serve in parliament (42 Geo. III. c. 90.): and private men from highway duty, from parish offices, and serving in his majesty's other forces by sea or land. Militia men, when sick, are entitled to relief; and their destitute families to a weekly allowance out of the poor rates of the parish, &c. to which they belong. If they are maimed or wounded in actual service, they are entitled to the benefit of Chelsea-hospital: they may set up trades in any part of the kingdom.

As the militia of the city of London are now raised and regulated under and by virtue of the 36 G. 3. c. 92. and 39 G. 3. c. 82: And as the militia of the Tower Hamlets are now raised and regulated by the 37 G. 3. c. 75. and c. 25. and the same are thereby respectively made subject to certain provisions in the 26 G. 3. c. 107. by this act repealed; it is enacted, that, from and after the passing of this act, all and every the clauses, provisions, powers, authorities, punishments, bounties, penalties, forfeitures, matters, and things in this act contained, in relation to any persons, acts, matters, and things as to which the 26 G. 3. c. 107. or any of the clauses or provisions thereof, were in force or applicable as to the said respective militias, shall, from and after the passing of this act, be applied, practised, and put in full force as to all such persons, matters, and things, as far as the same can be applied, and are not contrary to any of the provisions of the said respective acts, or any or either of them: But nothing in this act contained shall be construed to extend to repeal any of the provisions of the said acts, or either of them, other than such as are in and by the said acts made subject to the rules and regulations of the 26 G. 3. c. 107.

Nothing in this act shall extend to the tinnerns in Devon and Cornwall; but the lord warden of the stannaries for the time being in pursuance of his majesty's commission in that behalf, and such as he shall commissionate and authorize under him, shall use the like powers, and array, assesse, arm, muster, and exercise the said tinnerns as has been heretofore used, and according to the ancient privileges and customs of the stannaries.

The lord warden of the cinque ports, two ancient towns and their members, and in his absence his lieutenant or lieutenants, shall put in execution within the same all the powers and authorities granted by this act, in like manner as his majesty's lieutenants of counties and their deputy-lieutenants may do; and may keep up and continue the usual number of soldiers in the said ports, towns, and members, unless he or they find cause to lessen the same; and the militia of the said ports, towns, and members, shall remain separate from the militia of the several counties within which the said ports, towns, and members are situate; and the said warden, or his lieutenant or lieutenants, shall, in pursuance of orders from his majesty, in the manner prescribed by the 13 and 14 Car. 2. notwithstanding one or more months pay advanced be not reimbursed, raise and draw out the soldiers into actual service, and cause the persons charged as by the said act to provide their soldiers with pay in hand, not exceeding one month's pay, in such manner as if all the pay advanced and provided had been reimbursed; and shall use the like powers,

and array, assesse, and arm, muster and exercise the said soldiers, and make assessments, and issue warrants for the assessments made or to be made for raising any trophy money, and for defraying the necessary charges of trophies, and other incident expences of the militia of the said ports, towns, and members, as hath been heretofore used, and according to their ancient privileges and customs; any thing in the said act or this act to the contrary notwithstanding.

By 48 Geo. III. c. 111. and subsequent acts, a particular species of force is ordered to be raised under the name of the "Local Militia;" the provisions of which act regulate the mode of raising the same kind of force in the Cinque Ports, Stannaries, and some other privileged places. The number of men ballotted and enrolled under this denomination in any county, division, or part of any county, shall not exceed such number as will, including the effective yeomanry and volunteers then serving in such county, &c. exclusive of supernumeraries above the establishment of such corps, serving without pay, who shall have been enrolled therein after the 1st of April 1808, amount to six times the respective original quota or proportion of militia of such county, &c. under the 42 Geo. III. c. 90. The deficiencies in effective yeomanry and volunteers in any county, &c. shall be supplied from time to time by local militia men; so that the number in the whole of the local militia under this act, and effective yeomanry and volunteers, shall be equal to six times the amount of such quota or proportion. Volunteers are allowed to enter, whether any order be given for supplying deficiencies or not, until the local militia be completed; and such volunteers shall receive two guineas each, payable on their respective enrolment. By 49 Geo. III. c. 40. this is repealed, except as to members of volunteer corps. Volunteers transferring themselves into the local militia, are not liable to serve in the regular militia, in consequence of any former ballot. The men to be raised under the act 48 Geo. III. c. 111. shall be ballotted out of the persons between the ages of 18 and 30 returned in the lists now existing, or hereafter returned, amended or corrected for the raising of the militia; and his majesty may direct the making out of new lists; and no person ballotted to serve in the local militia shall be allowed to find any substitute, or be entitled to any bounty or half bounty. Persons ballotted are to take a prescribed oath, and then to be enrolled to serve in the local militia of such county as a private local militia man for the space of four years. Persons unable to serve from illness or bodily infirmity shall be excused; and persons exempted are licensed teachers of any congregation in holy orders, or pretended holy orders, and not carrying on any other trade, or exercising any other occupation for his livelihood, except that of a school-master; such medical men actually practising as physicians, surgeons, or apothecaries; no person mustered, trained, or doing duty, or employed in his majesty's service in the Tower of London, the royal arsenal at Woolwich, or at any gun wharfs, or at any powder mills, powder magazines, or other storehouses belonging to his majesty, under the direction of the board of ordnance, shall be liable to be ballotted for the local militia, so long as they respectively continue within any of the aforesaid descriptions; and every person who shall have served, or is now serving in person in the additional military force, raised under an act passed in the forty-third year of the reign of his present majesty, or who shall have been ballotted, and have provided any substitute, or shall have paid any fine for not serving or finding a substitute in such additional force, shall be exempt from ballot and service in the local militia, in like manner, and for the same period, as such person was or is exempt from ballot and service in the regular militia during

during the continuance of the said act of the forty third year aforesaid; any thing in any act or acts of parliament to the contrary notwithstanding.

No person having served in the regular militia or such additional force, or provided any substitute, or paid any fine for not serving, or finding any substitute in the regular militia or such additional force as aforesaid, shall be entitled to exemption from being balloted under this act, for any longer period than four years after the expiration of his period of service, if he shall have served in person, or six years from the period of any such substitute being enrolled, or four years after having paid any such fine.

And no articed clerk or apprentice, nor any poor man who has less than three children born in wedlock, nor any person under the height of five feet four inches, who shall be of the height of five feet two inches, or upwards, shall by reason thereof, respectively be exempt under this act, notwithstanding they may, by reason thereof, respectively be exempt from the militia.

Provided that nothing in this act contained shall extend to authorize any apprentice ballotted under this act, to enlist in the army, navy, marines, or regular militia, or to enter as a volunteer in the local militia, without the consent of his master; provided also, that no ballot, enrolment, and service under this act, shall make void or in any manner affect any indenture of apprenticeship or contract of service between any master or servant, notwithstanding any covenant or agreement in any such indenture or contract, and no service under this act of any apprentice or servant shall be deemed to be an absence from service, or a breach of any covenant or agreement as to any service or absence from service in any indenture of apprenticeship or contract of service.

And every person claiming to be exempted from service under this act, upon payment of the fine of twenty pounds, or ten pounds, instead of thirty pounds, shall sign a declaration that the amount of his income does not exceed two hundred pounds or one hundred pounds as aforesaid, as the case may be, and shall deliver the same to the deputy-lieutenants before whom he shall appear to claim such exemption, or produce a certificate to the like effect, allowed by any commissioners under any act relating to the rates and duties arising on property, &c. or to any allowances made on any such rates and duties, within twelve months previous to the production of such certificate. Quakers, or united brethren, on production of certain certificates, shall not be enrolled, and may be adjudged to pay a proportion of the fines on persons ballotted, and not appearing. Persons serving in the local militia are entitled to the same exemptions as volunteers, and having served four years, are not liable to be ballotted for the regular militia for two years. Local militia officers shall not be exempt from serving the office of sheriff.

His majesty may order the local militia to be called out yearly to be trained; but they are not to be trained for more than 28 days in a year, nor to be ordered to march for that purpose further than some adjoining county. In case of invasion, or appearance of an enemy in force upon the coast of any part of the united kingdom, his majesty may order the local militia to be embodied and marched to any part of Great Britain, and continue there, so embodied, for any period not exceeding six weeks after the enemy shall have been prevented or repelled, or driven from the coast, or after any rebellion or insurrection shall have been suppressed. Lord lieutenants, &c. may call out the local militia for the suppression of riots, and those who do not appear are subject to certain penalties; but when so called out, they are not to be kept

assembled for more than 14 days in one year. Local militia assembled in time of war are subjected to the mutiny act. Every person enrolled to serve in the local militia shall, upon being assembled for training and exercise, be entitled to receive one guinea for the first year of his service, and 10s. 6d. for each succeeding year; and a further sum of one guinea in case such person shall be embodied under any order of council or proclamation. The local militia, when not drawn out and embodied, shall be entitled to the same pay, clothing and allowances, as the regular militia are when not embodied; and when drawn out and embodied, shall be entitled to the same pay, clothing, and allowances, for themselves and families, as his majesty's other militia forces when drawn out and embodied. Local militia men may enlist in the army, navy, or marines, or regular militia of the same county; and their vacancies shall be supplied as other vacancies. No person shall enlist a local militia man during the period of training, on penalty of 20*l.* Every county, hundred, or parish, is subject to a fine of 15*l.* for each man deficient at a certain period, but it shall be entitled to a return of part, for every man enrolled within a certain time.

MILITUM CURIA. See CURIA.

MILITUM *Expensis levandis.* See EXPENSIS.

MILTIUM, in *Botany*, an ancient name for a sort of corn or grass, remarkable for the abundance of its seeds; hence *Festus*, against whom we certainly can have no appeal, derives it from *mille*, a thousand. The plant of the Romans however was either a *Holcus*, or the *Panicum millicaeum*, or both; and our Linnæan genus has obtained this appellation from its resemblance in seed to those.—Linn. Gen. 33. Schreb. 47. Willd. Sp. Pl. v. 1. 358. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 75. Prodr. Fl. Græc. Sibth. v. 1. 44. Ait. Hort. Kew. ed. 2. v. 1. 147. Juss. 29. Leerf. 18. t. 8. f. 7.—Class and order, *Triandria Digynia.* Nat. Ord. *Gramina.*

Gen. Ch. *Cal.* Glume of two, nearly equal, ovate, tumid, pointed valves, inclosing a single flower. *Cer.* of two ovate valves, less than the calyx, permanent, finally cartilaginous, enfolding the seed; one of them smaller than the other. *Nectary* of two ovate, obtuse leaflets, tumid at the base. *Stam.* Filaments three, capillary, short; anthers oblong, versatile. *Pist.* Germen roundish; styles two, capillary; stigmas tufted. *Peric.* none, except the hardened and polished corolla, which closely invests the solitary roundish seed.

Eff. Ch. Calyx of two valves, single-flowered, tumid. Seed invested with the permanent hardened two-valved corolla.

1. *M. capense.* Cape Millet-grass. Linn. Mant. 185. Willd. n. 1.—“Panicum capillary. Calyx pointed. Corolla with a terminal curved awn.”—Native of the Cape of Good Hope. *Stems* four inches high, smooth and slender. *Leaves* narrow, clothed underneath with scattered hairs, and bearded at the top of their sheath. *Panicle* spreading every way; the flower-stalks finer than a hair. *Calyx* of two ovate, slightly swelling, pointed valves, of nearly equal length. *Seed* the length of the calyx. *Awn* terminal, curved, longer than the flower.” Such is the description Linnæus gives of this grass, which no botanist has ever been able to ascertain. Nothing in his herbarium bears this name, and yet there can be no doubt of his having described a specimen of his own. In writing the second *Mantissa*, he was often negligent about marking the plants he described. There is found in his genus *Avena*, confounded with the Spanish *A. Loeflingiana*, from which it is very distinct, a Cape specimen, which answers precisely to his description of the *Milium* in question, except that the calyx generally con-

MILIMUM.

tains two florets, each with the twisted awn of an *Avena*. This however is as good a *Milium* as *M. paradoxum*, and we have no scruple in considering it as what Linnæus intended. The hairy sheaths and backs of the leaves, as well as the bearded stipula, are remarkable. The corolla is externally hairy. We cannot refer this grass to any in Thunberg's *Prodromus*.

2. *M. punctatum*. Dotted Millet-grass. Linn. Sp. Pl. 91. Amoen. Acad. v. 5. 392. Swartz. Obs. 37. Brown. Prod. Nov. Holl. v. 1. 188.—Panicle of alternate, linear, simple clusters. Lower flowers in pairs; upper solitary. Flower-stalks jointed. Outer valve of the corolla with a short awn. Native of Jamaica, in moist meadows. Swartz. Gathered by Mr. R. Brown near Port Jackson, as well as in the tropical part of New Holland; by Dr. Rottler at Madras. A pale upright grass, with the habit of a *Leersia*, or a *Paspalum*. Stem from one to two feet high, simple, round, jointed, smooth, leafy. Leaves broadish, striated, slightly roughish, with long smooth sheaths. Panicle a span long, erect, close, with hairy stalks. Flowers crowded, turned one way, ovate, acute, hairy. Corolla included, elliptical; its outer valve tipped, as Dr. Swartz and Mr. Brown observe, with a short rough awn. A purple stain, like a dark dot, under each flower, seems to have given rise to the specific name.

3. *M. lendigerum*. Panick Millet-grass. Linn. Sp. Pl. 91. Schreb. Gram. v. 2. 14. t. 23. f. 3. Engl. Bot. t. 1107. Fl. Græc. Sibth. v. 1. 49. t. 65. (*Agrostis australis*; Linn. Mant. 30. A. ventricosa; Gouan. Hort. 39. t. 1. f. 2. Knapp. t. 25. Gramen panicum serotinum, spicâ laxâ pyramidalî; Moris. v. 3. 189. n. 12. Herb. Bobart.)—Panicle close, somewhat spiked. Corolla awned, fringed.—Native of fields in the south of Europe, where water has stagnated; rather rare in England. Dr. Sibthorp found it on the sandy sea-shore of Asia Minor. It is annual, and flowers in the latter part of summer. The tufted fibrous roots produce many stems, from ten to twenty inches high. Leaves rough, with slightly swelling sheaths, and long, white, torn stipulas. Panicle pale, erect, acute, from one to four inches long, of innumerable crowded flowers; the base of their calyx tumid, smooth and polished. The permanent hardened corolla, which invests the seed, makes this species more certainly a *Milium*, than an *Agrostis*.

4. *M. compressum*. Compressed Millet-grass. Swartz. Ind. Occ. 183. Willd. n. 4.—Spikes two or three together, linear, on a very long stalk. Flowers alternate, close-pressed, awnless. Stem compressed, jointed in the middle.—Common in barren, rather alpine pastures in Jamaica; communicated by Dr. Swartz. Roots white, thread-shaped, perennial. Stems a foot high, or more, smooth, compressed quite flat, with a downy joint about the middle. Leaves long, linear, smooth, finely striated, radical; except one from the joint in the middle of the stem, which is broader, with a very long compressed sheath, bearded at its orifice. Flower-stalks from four to eight, from the sheath of the stem-leaf, about a foot long, thread-shaped, smooth, each bearing a pair of terminal, erect, linear, slender spikes, about two inches long, sometimes accompanied by a third at some distance, all together resembling some of the genus *Panicum*. The common stalk of each is zigzag and acutely angular. Flowers small, elliptic-oblong. Calyx ribbed, brownish, minutely fringed.

5. *M. digitatum*. Fingered Millet-grass. Swartz. Ind. Occ. 181. Willd. n. 5.—Spikes finger-like, about four together, nearly sessile. Florets acute, awnless, close-pressed, in pairs, directed one way. Leaves with cartilaginous ferratures.—Gathered by Dr. Swartz in barren

pastures, in the south of Jamaica. This appears to be still more akin to *Panicum* than the last, having sometimes a minute third valve to its calyx. The stem is a foot high, simple, slender, upright, smooth. Leaves lanceolate, short, striated, with compressed bearded sheaths. Spikes terminal, slender, somewhat spreading, two inches long, purplish. Flowers in pairs, rather unequal, on ferrated stalks.

6. *M. panicum*. Panick-like Millet-grass. Swartz. Ind. Occ. 179. Willd. n. 6.—Spikes rather finger-like, alternate, spreading, thread shaped. Flowers triangular, awnless, stalked, in pairs, turned one way.—In dry sandy ground, in the southern part of Jamaica. Swartz. Stem a foot high, simple, slender, erect, roundish, smooth. Leaves linear, smooth; their sheaths hairy at the orifice. Spikes three or four, slender, alternate, but near together, at the top of a long slender stalk, spreading. Flowers minute. Glumes of the calyx somewhat fringed; the outer one convex; the inner flat. Corolla the shape and size of the calyx, smooth, brown and shining, finally blackish, containing the very small seed.

7. *M. effusum*. Spreading Millet-grass. Linn. Sp. Pl. 90. Curt. Lond. fasc. 4. t. 12. Engl. Bot. t. 1106. Knapp. t. 19. Willd. n. 7. (Gramen miliaceum; Ger. em. 6.)—Flowers loosely panicked, awnless. Glumes elliptical, pointless, sheaths of the leaves smooth.—Native of shady groves, where the ground is rather moist, throughout Europe, flowering in June or July. Roots creeping, perennial. Stems erect, two or three feet high, leafy, smooth. Leaves light green, broad, flat, roughish at the edges; their sheaths smooth and naked, crowned by an oblong membranous stipula. Panicle erect, lax and widely spreading, composed of several alternate fascicles of variously branched capillary flower-stalks. Flowers solitary, pale whitish-green, elliptical, rather acute, but not pointed; their calyx-glumes even, finely ribbed, generally quite smooth, sometimes minutely roughish, never hairy nor fringed. Corolla at length horny, quite smooth and finely polished.

8. *M. confertum*. Close Millet-grass. Linn. Sp. Pl. ed. 1. 61. ed. 2. 90. Willd. n. 8. (Gramen paniculatum alpinum latifolium, paniculâ miliacâ sparsâ; Scheuchz. Agrost. 134.)—Flowers closely panicked, awnless. Glumes elliptical, pointless. Sheaths of the leaves smooth.—Native of Switzerland. Haller asserts under his n. 1525. Hist. v. 2. 243, that this proved, on an inspection of Scheuchzer's specimen, a mere variety of the last. We know it not.

9. *M. arundinaceum*. Reed-like Millet-grass. Sm. Prodr. Fl. Græc. Sibth. v. 1. 45. Fl. Græc. t. 66. (*Agrostis miliacea*; Linn. Sp. Pl. 91. Willd. Sp. Pl. v. 1. 363.)—Flowers loosely panicked. Corolla awned, smooth. Calyx taper-pointed. Sheaths of the leaves smooth. Stipula very short, abrupt.—Native of Siberia, Spain, Portugal, Zante, and the neighbourhood of Athens. The modern inhabitants of Zante call it γερδαζα. The root is perennial, tufted, with tortuous, downy, strong fibres. Stems numerous, two feet high, round, smooth, most knotty in their lower part. Leaves spreading, acute, roughish, with close smooth sheaths. Panicle rather turned to one side, slender, constructed much like that of *M. effusum*, but the flowers are only half as large, with ovate, tumid, long-pointed calyx glumes, often reddish. Corolla ovate, the outer valve tipped with a rough awn, twice its own length. Seed coated with the hardened corolla, which makes the plant a true *Milium*, its resemblance to *Agrostis spica-venti*, hinted by Linnæus, chiefly regarding its first aspect, and disappearing on a close examination.

10. *M. angulosum*. Little Angular-husked Millet-grass.—Flowers closely panicked, awnless. Glumes ovate, acute, strongly

strongly ribbed and furrowed. Sheaths of the leaves hairy.—Gathered in the Sandwich islands, by Archibald Menzies, esq. This has the habit of the three preceding, but is distinguished by the hairiness of the backs of the leaves, and of their sheaths. The joints of the stem are densely bearded. Panicle rather close, at least in the dried specimen, drooping. Flowers smaller than even those of *M. arundinaceum*, their glumes all strongly ribbed, bluntly pointed, destitute of awns, and of long hairiness.

11. *M. jetyum*. Bristly-husked Millet-grass.—Flowers closely panicle, pointed, awnless. Calyx fringed with long hairs. Sheaths of the leaves hairy.—Gathered in the Sandwich islands, likewise by Mr. Menzies. Root of strong smooth fibres, probably annual. Stem branched, a foot or more in height, with numerous joints, under each of which it is rough and hairy. Leaves and their sheath very hairy, light green. Panicle much like the last, but shorter. Glumes of the calyx strongly furrowed, with a short but stout point, scarcely amounting to an awn; they are remarkably fringed, with a few fine long spreading hairs, at each side. Corolla elliptical, awnless, very smooth, smaller than the calyx.

12. *M. tenellum*. Small Tumid Millet-grass. Cavan. Ic. v. 3. 37. t. 27. f. 1.—Panicle ovate, dense, awnless. Calyx-glumes inflated, almost hemispherical, very smooth. Sheaths of the leaves swelling, ribbed, smooth.—Gathered in sandy ground in Spain by the late Abbé Cavanilles, to whom we are obliged for a specimen. This is a little annual vernal grass, in habit, size and colour like *Aira caryophyllea*, along with which it grows. The stems branch from the bottom, and are clothed with a few short, narrow, involute leaves, with long, inflated, ribbed, purplish, smooth sheaths. The upper part of each branch is naked, round, smooth, rigid, purple, bearing an ovate, dense, glittering panicle, an inch long. Glumes of the calyx rugose at the keel, ovate, almost hemispherical, concave, enclosing the much smaller corolla, which latter we have not seen in an advanced state, so as to judge of the generic character. The aspect of the glumes of the calyx is that of a *Briza*.

13. *M. globosum*. Globose Millet-grass. Thunb. Jap. 49. Willd. n. 9.—Panicle spreading, awnless; its partial stalks annulated. Calyx-glumes ovate, obtuse. Sheaths of the leaves fringed.—Gathered by Thunberg in Japan. Stem simple, erect, a foot high or more. Leaves lanceolate, striated, rough, bordered, spreading, hardly a finger's length; their sheaths fringed at the edges and orifice. Panicle somewhat ovate, spreading; its stalks capillary, zigzag, marked with a yellow ring near the top. Calyx ovate, obtuse, awnless, smooth, brownish-green. Thunb.

14. *M. paradoxum*. Black-seeded Millet-grass. Linn. Sp. Pl. 90. Scop. Carn. t. 1. Schreb. Gram. v. 2. 50. t. 28. f. 2. Hort. Gram. Austr. v. 3. 16. t. 23. Willd. n. 10.—Panicle spreading. Calyx ovate, taper-pointed, ribbed. Corolla long-awned, smooth. Sheaths of the leaves smooth. Stipula elongated, acute.—Native of the south of France, and of Caniola. A tall, slender, reed-like grass, with narrow, smooth, rather glaucous, taper-pointed leaves, whose sheaths are close and smooth, and their stipula long, white, thin, membranous, acute, torn at the point. Panicle with feathery, spreading, slender, compound branches. Flowers very large in proportion to all the foregoing, one-third of an inch in length. Calyx-glumes purplish, ovate, concave, keeled and ribbed, with a long membranous point. Corolla half the length of the calyx, finally becoming black hard and polished, its outer valve tipped with a long rough awn.

15. *M. racemosum*. Racemose Millet-grass.—Flowers in a simple upright cluster. Calyx elliptical, acute, ribbed.

Corolla long-awned, hairy. Leaves lanceolate, with smooth sheath.—Sent by the Rev. Dr. Mulletberg from Lancaster in Pennsylvania. The stem is slender, leafy, smooth. Leaves lanceolate, flat, taper pointed, half an inch broad. Flowers the size of the last, four or five, in a slender, erect, perfectly simple cluster, with finely downy stalks. Calyx many-ribbed, green. Corolla at length brown, clothed with a few fine hairs, and not much polished, bearing a long rough awn.

16. *M. carulifolium*. Bluish Millet-grass. Desfont. Atlas. v. 1. 66. t. 12. Sibth. Prodr. Fl. Græc. Sibth. v. 1. 45.—Panicle spreading. Calyx ovate, taper-pointed. Corolla smooth, with a slight awn shorter than the calyx. Sheaths of the leaves smooth. Stipula elongated, jagged.—Gathered by Desfontaines in the fissures of rocks on mount Atlas, and by Dr. Sibthorp abundantly in the Greek islands.—This has nearly the appearance of *M. paradoxum*, especially the panicle, but the leaves are more narrow and glaucous, the corolla smaller, with only a short deciduous awn.

17. *M. villifolium*. Slaggy-flowered Millet-grass. Swartz. Prodr. 24. Obs. 383. Willd. n. 11. (*Andropogon inflexus*; Linn. Sp. Pl. 1480. (*Gramen avenaceum*, panicula minus sparsa, glumis allâ ferocâ lanigine obductis; Sloan. Jam. v. 1. 43. t. 14. f. 2.)—Panicle slightly spreading, awnless. Calyx clothed with long hairs. Sheaths of the leaves smooth.—Native of Jamaica and the Brazils. The leaves are lanceolate, roughish. Panicle of very numerous angular branches. Flowers about half the size of the last, remarkable for the long silky hairs that clothe the calyx. Awns none. This species seems rather to belong to the genus *Saccharum*. We know nothing of its corolla.

18. *M. ramosum*. Branching Millet-grass. Reiz. Obs. fasc. 6. 22. Willd. n. 12.—Stem branched, compressed, decumbent. Flowers closely panicle, hairy, usually in pairs. Sheaths of the leaves smooth.—Native of the East Indies. Stems leafy, downy at the joints. Leaves linear, narrow, quite smooth as well as their sheaths. Panicles several, on long stalks, from the sheaths of the upper leaves, each a span long, close, simply branched. Flower-stalks thickened and fringed at the top, with a black ring under each flower. Calyx lanceolate, hairy. Corolla smooth, polished, hard, the outer valve with a rigid point shorter than the calyx. Stigmas long, feathery, brown. The nature of the corolla being considered, the doubts of the accurate Retz, whether this grass should be reckoned a *Milium* or *Agrostis*, vanish.

MILIMUM Arundinaceum, a name by which some authors call the lachrymæ Jobi, or Job's tears.

MILIMUM Indicum, a name by which some authors call the maize, or Indian wheat.

MILK, in *Rural Economy*, and *Animal Chemistry*, is a white opaque fluid, secreted by a certain organ existing in all lactiferous animals. This secreting apparatus is differently situated in different animals. In women it is placed in the anterior part of the breast: in the cow, the mare, the ewe, and some others, it is situated in the lower part of the abdomen. While in the sow, the bitch, and several other quadrupeds, it is arranged through the whole course of the abdomen. The glandular substance which constitutes this organ is called the mamma: that projecting portion of the mamma, from whence the milk issues, being called the papilla, or nipple. The mammae are more or less in number in different animals, according to their number of young, some having as many as ten, others but one. In the human subject the mammae are two, each having one nipple. In the cow but one mamma, with four nipples. This organ in all animals appears destined to furnish their

MILK.

young with nourishment, till their own digestive organs are capable of performing their functions. Hence we find the period of lactation in animals to commence when they bring forth their young. This shews a strong connection between the secretion of milk, and the uterine action. All this may easily take place from the great connection between those branches of nerves which are bestowed upon the mammæ and the uterus.

At the age of puberty, the same nervous connection which may induce the uterine action, may, at the same time, be also bestowed upon the mammæ, causing them to be enlarged. During pregnancy, the nervous influence which is expended in forming the secretions for the growth of the fœtus, is, after delivery, transferred to the mammæ to produce lactation. Since secretion is dependent upon nervous influence, all substances moderately stimulating must facilitate the formation of milk. Some have supposed that the mammary artery is too small to furnish the quantity of milk which is furnished during lactation, and have thought that the chyle has been the principal source of this fluid. Fourcroy is of opinion, that the more substantial part of milk only is secreted from the blood, and that the aqueous part is furnished from the lymphatic vessels. What renders this idea plausible is, the very different states in which we find cows' milk from different kinds of food.

Milk, as an article of food, and its products, are of such importance in domestic economy, as to render all the improvements in its production and management particularly valuable. Since the milk of the cow is the most abundant and in general use, we shall confine the analysis of this substance to cows' milk.

Milk, when drawn from the cow, is of a yellowish-white colour, and is the most yellow in the beginning of the period of lactation. The viscidty of milk is something greater than that of water. In this state it has a peculiar but pleasant odour, which becomes less by exposure to the air, but returns when exposed to heat. Its taste is peculiar, rather agreeable, and somewhat saccharine. This, however, varies in different animals, and in the same animal, from particular kinds of food. Cabbage and turnips, when eaten by cows, give each their peculiar flavour to milk; and if they eat the smallest quantity of wild garlic, the milk and butter become perceptibly flavoured with its peculiar odour.

The specific gravity of milk, on the average, is about 1.035, water being 1. According to Brisson, whose authority on this physical property of bodies stands high, the following are the specific gravities of the milk of different animals.

Women's milk	-	-	-	1.0203
Cows'	-	-	-	1.0324
Goats'	-	-	-	1.0341

The specific gravity of cows' milk varies from several causes. It is greatest at the beginning of lactation. It is the least when the milk appears the thinnest, or when it is the most aqueous. Cows feeding on grains, which is the case frequently in large towns, give poor milk, of little specific gravity.

When milk is exposed, in a cold situation more especially, it soon becomes covered with a substance, of greater viscidty than the milk, of a yellow colour, and having an unctuous feel. This is called cream. The quantity of this stratum bears different proportions to the milk under different circumstances. The milk now loses some of its viscidty,

and becomes of a bluer colour. In this state it is known by the name of skimmed milk. See DAIRYING.

When milk is exposed to heat, it first swells, and boils, it is said, at the temperature 199° of Fahrenheit. The surface soon becomes covered with a pellicle, which, if removed, is soon succeeded by another. This effect would take place till the residuum would become of an aqueous appearance, and incapable of furnishing any pellicle. This substance formed on the surface, is found no longer to possess the properties of milk, but is a peculiar substance called caseous matter, and is the same which constitutes the solid matter called cheese.

When milk is very slowly evaporated it forms a kind of thick extract of milk, which is called *franchipane*. This being mixed with sugar, almonds, and orange flowers, constitutes a sort of sweetmeat or custard.

When milk is distilled, a liquor comes over which has the odour of milk, but does not possess any other of its properties. It soon becomes putrid, depositing white flakes. If the heat be raised and continued, the thick part of the milk undergoes the destructive distillation. Empyreumatic oil, zoonic acid, and ammonia, are formed, with the disengagement of carburetted hydrogen gas. After the process, a voluminous coal is found in the still.

When milk has been exposed for several days in a temperature from 60° to 70°, it becomes a thick coagulum, so solid as not to be capable of pouring. During this change it is found that an acid has been formed which has separated the milk into two portions, the one the coagulable part, called curd, or caseous matter; the other the serous part, called whey. This change is also effected by other acids and by alcohol. The mineral acids are not proper for this purpose, because they re-dissolve the curd. Hence the vegetable acids are said to produce more curd than the mineral acids. The substance generally employed by cheesemakers to separate the curd, is a small portion of the inner coat of the stomach of the calf, which is salted, dried, and kept for that purpose.

By a particular management milk may be made to undergo the vinous fermentation, by which a quantity of alcohol is formed. It will be easy to infer, however, that this change is occasioned by the saccharine matter which it contains.

The Tartars have long been in the practice of making a vinous liquor, from which they distilled a species of brandy. This they procure from mares' milk, which is known to contain more sugar than that of the cow. By exposing it in large open vessels, the fermentation takes place. The mass being large, no doubt contributes to this change. A quantity both of the lactic and acetic acids are formed at the same time, which are separated from the vinous spirit by repeated distillations. The curdy or caseous part of milk above alluded to, is pressed into molds for cheese. (See DAIRYING and CHEESE.) Although acids separate the curd when added in small quantity, yet when in considerable quantity, the curd becomes re-dissolved. It is remarkable, that dilute vegetable acids separate the curd without re-dissolving it, while these acids, concentrated, dissolve the same. The curd is, on the contrary, easily dissolved by the dilute mineral acids, but not by these acids in their concentrated state.

Many other substances coagulate milk, such as alcohol, molasses, gelatine, and all astringent vegetables. The effect is supposed to arise from the affinity of the coagulating substance to water, the curd, which is principally albumen, having very little affinity for the same. The alkalis dissolve curd with great facility, owing to their great affinity

affinity for that substance. If ammonia be added to milk which has curdled, it will restore it to the appearance of milk, by dissolving the curd. Lime has also the power of dissolving curd. If quick-lime be boiled with curd into the form of pulp, it forms a most powerful cement. A similar property may perhaps belong to barytes and strontian.

When curd is freed from cream, kneaded, and pressed to expel the liquid matter, it becomes very hard with time, assumes a degree of transparency, and possesses many of the properties of dried coagulated albumen. Exposed to heat, it softens and becomes glutinous. The heat being continued, it becomes brown, exhales fumes, which contain ammonia; and lastly, inflames, leaving a dense coal behind.

The dried curd does not change by exposure to the air, but if it contains moisture, it soon putrefies, giving a disagreeable fetid odour. This change would take place in cheese, if it were not for muriat of soda, which also acts as a seasoning. It is likely that certain proportions of nitre, muriat of soda, and sugar, would make an agreeable seasoning for cheese, and would be a better preservative than salt alone.

If curd remains in cold water for a length of time, its properties become changed; it becomes fat, unctuous, and soft, having, at the same time, a fetid smell. It is, doubtless, to a certain degree of this change that we may attribute what is called the ripening of cheeses, by laying them in a damp place, and turning them from time to time. The cheeses absorb a quantity of water, and gain much weight. Their bulk is increased, and the interior is much altered, and is said to be ripe or mellow. Instead of allowing the cheese to absorb water, it is not uncommon for epicures to saturate it with port wine, or strong ale.

The white colour of milk, after the cream has been separated, is owing to the curd. This substance, in numerous minute particles in a state of coagulation, constitutes its white opaque appearance, since the whey, after the last portions of curd and cream have been separated, becomes transparent and limpid.

The clear liquor last mentioned is what we shall now examine under the name of whey, or the serum of milk. It differs from the whey of dairies, since the latter always contains a portion of oily matter, as well as some unseparated curd. To get the serum or whey sufficiently pure for chemical examination, a small quantity of fresh membrane of the calf's stomach must be employed to coagulate the milk. This will be more effectually done by boiling them together till the change takes place. Previous, however, to this, the milk must be perfectly freed from its cream, by placing it in a cool situation, and skimming it frequently. When the curd is separated, first strain it through a coarse cloth; afterwards filter it through unglazed writing paper.

In this state the whey is limpid, and of a greenish-yellow colour. It has a peculiar sweetish smell when hot, which it loses on cooling. Its taste is rather sweet, and not disagreeable. When exposed to a boiling heat, a whitish scum rises to the surface, the liquid becoming rather turbid. If it be boiled a little while, and then set to cool, that which rendered it turbid falls, leaving the liquor clear, and almost as colourless as water. This residuum last named, is a small portion of curd which remained in the whey. The clear liquor thus obtained is of less specific gravity than milk, being 1.0193. By slow evaporation, it affords crystals of a substance much resembling sugar, but much less soluble. This has been called sugar of milk. Near the end of the evaporation, crystals of the muriats of potash and soda are deposited, and some phosphat of lime.

The circumstance of muriat of potash being afforded in this analysis, is strongly in favour of the idea that milk is not wholly secreted from the blood, since potash is never found in that fluid. The sugar of milk is in the form of crystals of a brown-yellow colour. These, when purified by several successive solutions and evaporations, become white, of a prismatic shape, or rather paralleloipedons.

This substance is soluble in about four parts of boiling water, and twelve of cold. It is manufactured and sold in Switzerland, under the name of salt or sugar of milk.

When treated with nitric acid, with a view to obtain oxalic acid, a smaller portion of this acid is obtained than from the same weight of sugar. Scheele, however, who first made this experiment, found that a quantity of white powder was separated, which he found to be a peculiar acid, and which he denominated the acid of sugar of milk. This has been altered into *Saccharic acid*, which see. Fourcroy found that the same acid was afforded by treating gum arabic with nitric acid. On this account he called it the mucous acid. It was from this latter fact that this sagacious chemist inferred that sugar of milk was a substance of a middle nature between gum and sugar. It is the opinion of Deyeux and Parmentier, that sugar of milk consists of sugar combined with the saccharic acid.

The mother water, from which the sugar of milk is obtained, is of a brown colour, and of a thick gluey consistence, which, on cooling, assumes the appearance of animal jelly. If this be diluted and slowly evaporated a second time, an additional quantity of the muriat of potash is separated in crystals, and also of phosphats of soda and lime. The presence of phosphat of lime in the serum of milk, may be detected both by precipitating its acid and its base. If oxalat of ammonia be poured into the clear whey, a precipitate of oxalat of lime is formed. On the other hand, when nitrat of lead or nitrat of mercury is employed as a test, the phosphats of lead and mercury are precipitated. The great quantity of phosphat of lime in milk, in order to supply oxidizing matter, so essential to young animals, is a remarkable provision of nature.

The remaining part of the whey chiefly consists of gelatine. If when whey has been evaporated to the consistency of syrup, a quantity of alcohol be poured upon it, a starchy precipitate is formed, consisting of gelatine and sugar of milk. The gelatine may be separated by tannin. Thus we see that whey consists of sugar of milk, gelatine, muriats of potash and soda, and phosphats of lime and soda, with a certain quantity of water. It is also said that whey contains sulphat of potash, and the phosphats of iron and magnesia.

Whey is exceedingly liable to turn sour. The acid which is formed, was thought by Scheele to be what he termed the lactic acid; the same which is formed when milk coagulates spontaneously. It is, however, now found to be the acetic acid, arising from the acetous fermentation which has succeeded the vinous; the latter being induced by the saccharine matter which the milk contains.

Having given the analysis of milk deprived of cream, or the oily part, we shall now give some account of the latter, which is also denominated the butyraceous part of milk.

Cream, the mode of separating which we have already given, gradually thickens by exposure to the air, and ultimately becomes a soft unctuous solid, called cream cheese. When cream is exposed to its boiling heat, and oil soon appears upon its surface, the rest of the cream consists of caseous matter and whey. This oil, by the operation of churning, is converted into a solid fatty substance, so well

MILK.

known under the name of butter. See **BUTTER** and **DAIRY-ING**.

If milk, when newly taken from the cow, be agitated for some time, the oily matter becomes concrete, and is dispersed through the fluid in small grains. These being collected, constitute butter. It was formerly thought, that the agitation of the milk merely collected and pressed the small particles of butter together. It is now believed that the butter does not exist ready formed in the milk, but in a state of oil, which requires to combine with oxygen before it can become hard. This idea is rendered plausible by several circumstances. The more acid the cream has become before churning, the sooner butter is formed. It has also been ascertained, that the presence of fresh atmospheric air facilitates the formation of butter. The frequent instances which occur in practice, of not getting butter at any rate, may doubtless be traced to the want of a supply of oxygen. This may be a hint of some importance in the management of large dairies.

When butter has been obtained from cream, the liquid remaining consists of milk, containing minute particles of butter. If cream has been kept till it shall have become sour, the curd becomes precipitated. In this case it becomes of a thicker consistence. This is known by the name of butter-milk.

Butter, prepared as above, is of a yellow colour, and more yellow as the cream has been kept longer. Its taste is very unlike any other fatty substance, and extremely agreeable. This, however, is not always the case, since its flavour is sometimes altered by the food of the cow. When it has been exposed to the air for a certain time, it acquires a rancid taste. Its flavour sometimes becomes changed, and rendered disagreeable, by a portion of the butter-milk which has not been washed out of it.

Butter, when newly made, fuses in about 99° of Fahrenheit. Its specific gravity is about .96, water being 1. When it is exposed to the heat of boiling water in a glass tube, a portion of curd and whey is separated from it. By this process the butter becomes almost transparent; but it will be found to have lost much of its agreeable taste. Hence it would seem, that its flavour either depends upon the small portion of serum and curd, which is always a constituent of butter, or that its aroma is expelled by the heat. Butter is not changed by a heat which merely fuses it.

When butter is distilled from a small glass retort, some drops of water first appear, and the greater part of the butter comes over. This is accompanied by a disagreeable smell, and an inflammable gas. A small quantity of coaly matter is left at the bottom of the retort, which contains phosphat of lime. By repeated distillation, the oily substance which comes over becomes lighter and more volatile. This is probably owing to the separation of carbon. If the retort be large, the oxygen, being more abundant, causes the formation of more water with the hydrogen from the butter. Another portion of the hydrogen and a portion of carbon combine with the oxygen, forming sebatic acid.

Butter combines with most of the substances which combine with fat, such as sulphur, phosphorus, the alkalies, and several metallic oxyds.

By collecting the different parts which have been given, we shall find the constituents of cows' milk as follows: curd; serum or whey, which consists of water; gelatine; sugar of milk, or mucaceous saccharine matter; muriats of soda and potash; sulphat of potash, and the phosphats of lime; magnesia and iron; butter, consisting of an oxygenated oil, combined with a little serum and caseous matter.

In cases where the milk of animals is taken away periodi-

cally by milking, as in the cow, the supply is continued, and hence the great value of that animal, in particular, to man, who is indebted to her for three of the most useful articles of food, milk, butter, and cheese. But in respect to the quality of milk, it differs considerably in different circumstances and situations, and from the manner in which the cows are fed and managed. In order to have an abundant supply, it is necessary to have recourse to constant plentiful feeding of the animals with rich luxuriant green food of different sorts, given in a proper varied manner, as well as other kinds of food. In comparing the qualities of the milk of different cows, the time in which they have been in milk should be fully considered, as the milk, soon after calving, is always much thinner than it is afterwards. The properties of milk, so far as they regard the dairy, and the management of it in respect to the making of butter and cheese, will be taken notice of in another place. In cases where the mother is lost, or the young animal is too feeble to have recourse to her teats, milk with sugar, gruel, and a small quantity of spice, is sometimes given as a means of support. See **DAIRYING**, **LACTOMETER**, **BUTTER**, and **CHEESE**.

The milk of different animals differs considerably.

Women's milk is much thinner than cows' milk; is of a bluer colour, and contains more saccharine matter. It does not afford butter till some time after delivery, although it contains some oily matter. It contains less curd than the milk of the cow. The milk of women is liable to greater changes from disease than any other. Spasms, which are not uncommon to those who suckle, so change the milk, as to be unpleasent and unwholesome to the infant. It is observed by Deyeux and Parmentier, that when the milk is drawn from the breast at short intervals, it is constantly watery and poor, and is of but little service to the infant. They therefore recommend, that the intervals of suckling should be as great as possible, without inconvenience to the infant or the nurse.

The milk of the ass is also different from cows' milk: it contains more saccharine matter, and, like women's milk, is thinner than that of the cow. There is nothing in this milk more than in others, to warrant the medical qualities which some ascribe to it.

Asses' milk is said to be a great beautifier and preserver of the skin. Poppæa, wife of the emperor Nero, used it for that purpose; having four or five hundred asses constantly in her retinue, to furnish her every morning with a fresh bath. The receipt for making what is called artificial asses' milk is as follows:

R limac. terrest. contus. xviii. Rafur. C. Cervi, Hordei perlati, Rad. eryngii, sing. unc. i. aquæ puræ lib. vi. coque leni igne in vase figulino vitriato ad lib. iii; dein cola et adde syrupi balsamici fescunciam. Capiat æger mane et vesperi quotidie unc. iv. hujus liquoris mistas cum lactis vaccin. recentis p. æ. Med. Transf. vol. ii. p. 341.

Goats' milk is something thicker, and appears richer than even the cows' milk. It has a peculiar aroma, which, from the black goat, is so strong as to be disagreeable. It affords butter and cheese: the former is of a whiter colour than that from the cow, and is said to keep longer.

Ewes' milk has the appearance of cows' milk. It affords a much larger quantity of cream, forming a soft and very fusible butter. Its caseous matter is very soft and unctuous, and is sometimes mixed with that from the cow, to give it a rich appearance.

Mares' milk is the next to women's milk in quantity of saccharine matter: it affords little cream; and does not easily coagulate.

coagulate. It is from the quantity of sugar contained in this milk, that it affords alcohol by fermentation.

Milk, in the *Wine Trades*. The coopers know very well the use of skimmed milk, which makes an innocent and efficacious forcing for the lining down of all white wines, cracker, and small spirits; but it is by no means to be used for red wines, because it discharges their colour. Thus if a few quarts of well skimmed milk be put to a hoghead of red wine, it will soon precipitate the greater part of the colour, and leave the whole nearly white; and this is of known use in the turning red wines, when pricked, into white; in which a small degree of acidity is not so much perceived.

Milk is, from this quality of discharging colour from wines, of use also to the wine-coopers, for the whitening of wines that have acquired a brown colour from the cask, or from having been hastily boiled before fermenting; for the addition of a little skimmed milk in these cases precipitates the brown colour, and leaves the wines almost limpid, or of what they call a water whiteness, which is much coveted abroad in wines as well as in brandies.

MILK-Abcess. See *Abcess of the Breast*.

MILK-Fever, a fever frequently attacking women the second or third day after being delivered, occasioned probably by some circumstance attending the secretion of the milk into the breasts. It is of short duration, and not attended with danger. For the treatment and cure, see *LACTATION, Natural*.

MILK of the Moon, lac lune, a name given by naturalists to fossil agaric, a white light marble. See *LAC lune*.

Some say, it is chiefly found in silver mines, and that it is a flower sublimed from the ore of that metal; whence its denomination, *flower of silver*.

MILK of Sulphur, lac sulphuris, a preparation of flowers of sulphur and salt of tartar; prescribed by physicians as a sudorific. See *SULPHUR Precipitatum*.

MILK-Vetch, in *Botany*. See *ASTRAGALUS*.

MILK-Vetch, *Barlard*. See *VETCH*.

MILK-Vetch, or *Coat's-thorn*, in the *Materia Medica*. See *TRAGACANTH*.

MILK, Virgin's, lac virginale, composed of rock alum, spring-water, lycharge, and vinegar; used as a cosmetic, to drive in pimples, and check any cutaneous eruptions, by its cooling, restringent quality. See *VIRGIN'S Milk*.

MILK-Water. See *WATER*.

MILK-Wood, in *Botany*. See *TRUMPET-flower*.

MILK-Wort. See *POLYGALA*.

MILK-Wort, or *Wart-wort*. See *SPURGE*.

MILK-Wort, Sea. See *GLAUX*.

MILK, in *Geography*, a river of Jamaica, which runs into the sea, four miles N.W. of Maccree bay.

MILK Cove, a creek of Ireland, on the S.E. side of the entrance into Ross bay, near Gully Head.

MILK Haven, a small harbour of Ireland, in the county of Sligo, S. of Donegal bay.

MILK River, a river of Canada, which runs into lake Erie, N. lat. 42° 28'. W. long. 82° 22'.

MILKING, the means or operation of drawing the milk from the cow or other animal. The proper milking of cows is a matter of much consequence to the cow and dairy farmer. And it has been observed, that more care is necessary in this business than is generally supposed, in order to obtain the largest possible quantity of milk. "On the physiological principle of the secretions of animals being increased in proportion as the secreted fluid is more frequently withdrawn, it has been, it is said, recommended to have recourse to more frequent milkings in order to augment the quantity

of that fluid in cows. And there can be little doubt but that by accustoming the secretory organs to a more frequent secretion, such a habit may be established in them as will afford a large proportion of milk in a given time. But in order to effect this in the most perfect manner, it will be necessary to have the cows highly fed, and to observe the greatest regularity and exactness in the periods of milking, and to be careful that every drop of milk is drawn away each time, and without due regard in these respects the desired effect will not be produced. This is fully shewn to be the case by the few experiments that have been instituted with the view of deciding the matter; as while the cows were continuing the more juicy spring food, there appears to have been an increase in the quantity of milk both by three and four milkings in the day; but in the autumnal season there seems to have been rather a decrease under the same circumstances." But "in order to ascertain the advantages to be obtained in this way with accuracy, the following experiments were made by Mr. Marco, and the results stated in the twelfth volume of the *Annals of Agriculture* to be these:

		Pints.
1789—May 21,	First meal	9½
	Second ditto	13
		22½
22,	First meal	13
	Second do.	8
	Third do.	5
		26
23,	First meal	12
	Second do.	7
	Third do.	6
	Fourth do.	1
		26
October 22,	First meal	11
	Second do.	6
		17
23,	First meal	11
	Second do.	3
	Third do.	3
		17
24,	First meal	10
	Second do.	1½
	Third do.	1½
	Fourth do.	3
		16

But it is evident, that "such trials, to afford any satisfactory conclusions, should have been continued for a much greater length of time, being varied considerably in the times of milking, and nicely compared with the nature and quantity of the food employed; as it is only by ascertaining how much depends upon the simple operation of taking away the milk, and how much upon the quality and proportion of food that is taken in, that the question can be fairly decided.

decided. The deterioration of the animal should also be considered. It is not to be supposed that merely increasing the number of milkings for a few days can have much influence in altering the state of the secretion in the animals. Some, with the intention of increasing the quantity of milk, have recommended milking, when the cows are fully fed in the summer season, three times in the course of the day at equal distances, as the convenience of the business will admit as the most proper. Early in the morning, about the middle of the day, and in the evening before it is too late. The exact proportion of increase in the milk that may be produced in this way over that of milking in the morning and evening only, which is the usual mode, has not, that we know of, been ascertained with any degree of accuracy; but some suppose that it may approach to nearly one-half of the whole, while others contend that it cannot be any thing near so much. If a third were gained, by such means, it would amply repay the cow-keeper for his additional trouble and expence."

With respect to "the method of milking adopted by cow-farmers in most cases, it is only to have their milking performed twice in the course of twenty-four hours. In such cases the most proper times would seem to be about seven o'clock in the morning, and five in the afternoon; but in the neighbourhood of London, according to the Report of Middlesex, and in other large towns, it is the practice to have this work performed from four to half-past six in the morning, and from half-past one to three in the afternoon. It is, therefore, probable, that more frequent milking in the business of cow-farming, especially when conducted upon an extensive scale, would not only be inconvenient but impracticable. In such cases it is supposed, that all that can be done is, perhaps, that of having the operation executed with as much care as possible, in respect to the whole of the milk being taken away each time, and by persons who are careful and perfectly accustomed to the work. Where this is neglected, much loss may be sustained not only in the immediate produce of the milk, but in the cows becoming much more quickly dry, as well as their being more subject to affections of the udder. The best advice is, to have the business performed in an expeditious manner, in regard to the whole of the animals, and with the utmost attention in respect to cleanness. A sufficient number of persons should of course be employed in proportion to that of the cows. An expert milker is capable of performing the operation on from six to seven or eight cows in the course of an hour." It is proper that the number of milkers employed should constantly be such as to have the business performed in about the course of an hour at the farthest. See DAIRY, and DAIRYING.

MILKING Pail, in *Rural Economy*, the vessel made use of for containing the milk as it is drawn from the cow. These pails are made of wood, and sometimes hooped with iron at the bottom. They are made of different sizes, and should be kept well seasoned by frequent scalding.

MILKNESS, a provincial term applied to a dairy. See DAIRY.

MILKOVAIA DERVINA, in *Geography*, a town of Kamtschatka, settled by a colony of Russians; 15 miles N. of Verchnei Kamtschatka.

MILKY GROTT. See GROTT.

MILKY Way, *via lactea*, or *galaxy*. See GALAXY.

MILL, JOHN, in *Biography*, a learned English divine and biblical critic, was born at Shapp, in Wiltmorland, about the year 1645. He was entered of Queen's college, Oxford, where he took his degrees in arts, and of which

college he afterwards became a fellow and eminent tutor. As soon as he entered into holy orders he distinguished himself by his pulpit talents, and was much followed as an eloquent preacher. He published one of his sermons preached at St. Martin's-in-the-Fields about the year 1676, intended to shew that there was no sort of foundation for the worship of the Virgin Mary, and at this period the bishop of Exeter appointed Mr. Mill one of his chaplains, and gave him a prebend in his cathedral church. In 1680 he took his degree of B.D., and in the following year was presented by his college to the rectory of Blechingdon, in Oxfordshire, at the same time proceeded doctor in divinity, and was nominated chaplain in ordinary to king Charles II. Dr. Mill had been some years employed in preparing for the press his valuable edition of the "New Testament," which is now as rare as it is excellent. This great work he undertook by the advice and with the encouragement of Dr. Fell, bishop of Oxford, at whose expence it was to be printed. At an early stage of the business the liberal-minded prelate died, and his executors being unwilling to proceed with the work, Dr. Mill, with a noble spirit, refunded to them the sums of money which his departed friend had advanced, and determined to complete it at his own risk. To this work, which cannot fail to transmit his name with distinguished honour to posterity, he devoted the thirty last years of his life, with the most patient assiduity, as well as scrupulous care, and he had the satisfaction of seeing his useful labours brought to a close, and the fruits of them presented to the world. In 1685, Dr. Mill was elected principal of St. Edmund's hall, Oxford, which preferment was the more acceptable, as it gave him an honourable settlement in the university, and enabled him to prosecute his design to the utmost advantage. In 1704 he was, by the interest of Dr. Sharp, archbishop of York, presented with a prebendary of Canterbury. His work was published in 1707, an event which he did not survive more than a fortnight, being carried off by an apoplectic stroke in the sixty-third year of his age. Of his great learning his work gives ample proofs: it is founded upon, and is an improvement of, Robert Stephens' elegant folio edition, published at Paris in the year 1550, which has in the inner margin the collation of sixteen manuscripts, and of bishop Fell's neat and accurate edition, published at Oxford in 1675. To the various readings of the former, Dr. Mill added those of sixteen MSS. out of the English Polyglot bible. He also collated himself all the valuable MSS. in England, and procured collations of the most esteemed ones at Rome, Paris, Vienna, and other places, as well as of the ancient translations of the New Testament. This edition of the New Testament was reprinted at Rotterdam in 1710, in folio, by the learned Kulter, who augmented it with the collation of twelve new MSS. It was also reprinted at Leipzig in 1723. Dr. Mill's labours gave very general satisfaction to the learned of this country, and to biblical scholars every where; but there were some few who doubted if it might not tend to unhinge the minds of people, by countenancing the notion that the text was precarious, as the author had collected thirty thousand various readings. On this account Dr. Whitby made it the subject of an attack, which was ably answered by Mr. Whiston, and still more fully by Dr. Bentley, in the thirty-second section of his "Remarks" upon it, under the assumed title of "Phileatherus Lipsiensis." Biog. Brit.

MILL Bay, in *Geography*, a bay on the E. coast of the island of Stronfa. N. lat. 58° 59'. W. long. 2° 20'.

MILL Creek, a river of Virginia, which runs into the Ohio, N. lat. 40° 36'. W. long. 80° 36'.

MILL Gaut, a town of Hindoostan, in the circar of Hindia, on the left bank of the Nerbudda; 10 miles E. of Hindia.

MILL Islands, four small islands in Hudson's bay. N. lat. $64^{\circ} 30'$. W. long. $78^{\circ} 30'$ to $79^{\circ} 40'$.

MILL, in propriety, denotes a machine for grinding corn, &c. but, in a more general signification, is applied to all machines whose action depends on a circular motion.

Of these there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c.

Few people are ignorant, that corn is ground by two mill-stones, placed one above the other, without touching.

The lower mill-stone is immoveable, but the upper one turns upon a spindle. The opposite surfaces of the two stones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one swells up; each of them being of a conic figure, whose axis indeed is very short, in proportion to the diameter of its base; for the upper one being six feet in diameter, is hollowed but about one inch at its centre; and the lower one rises but about three-fourths of an inch. These two mill-stones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to insinuate between them as far as two-thirds of the radius, which is the place where it begins to be ground, and where it makes the greatest resistance that it is capable of; the space between the two stones being in that place about but two-thirds or three-fourths of the thickness of a grain of corn. But as the millers have the liberty of raising or sinking the upper stone a little, they can proportion its distance from the lower one, according as they would have the flour finer or coarser.

In order to cut and grind the corn, both the upper and under mill-stones have channels or furrows cut in them, proceeding obliquely from the centre towards the circumference. And these furrows are each cut perpendicularly on one side, and obliquely on the other, into the stone; which gives each furrow a sharp edge, and in the two stones, they come, as it were, against one another, like the edges of a pair of scissars; and so cut the corn to make it grind the easier, when it falls upon the places between the furrows. These are cut the same way in both stones when they lie upon their backs, which makes them run cross-ways to each other, when the upper stone is inverted by turning its furrowed surface towards that of the lower. For if the furrows of both stones lay the same way, a great deal of the corn would be drove onward in the lower furrows, and so come out from between the stones without ever being cut. When the furrows become blunt and shallow by wearing, the running stone must be taken up, and both stones new dret with a chissel and hammer. But, by this repeated operation, their thicknesses, and consequently their weight, diminish; and it is observed, that when they come to have but three-quarters, or half of the thickness which they had when new, they produce but three-quarters or half the flour which they yielded at the beginning.

The circular motion of the upper mill-stone brings the corn out of the hopper by jerks, and causes it to recede from the centre towards the circumference, where, being quite reduced to flour, it is thrown out of the mill, by the centrifugal force of the stone, through a hole provided on purpose.

The diameter of common mill-stones, according to Dr. Defaguliers, is from five to seven feet, and their thickness, twelve, fifteen, or eighteen inches: they last thirty-five or forty years, and when they have been long used, so that

their thickness is considerably diminished, they are cut anew, to give their surface a contrary figure to what they had before; so that the upper mill-stone is made the lower.

In water-mills, the momentum of the water is the moving power, and the attrition of the two stones in grinding is the force to be overcome. Of these there are two kinds, *viz.* those where the force of the water is applied above the wheel, and those where it is applied below the wheel; the former being called over-shot, and the latter under-shot mills; and to these we may add a breast-mill, where the water strikes against the middle of the wheel.

In a common breast-mill, where the fall of water may be about ten feet, A A, (*Plate XXIII. Mechanics, fig. 1.*) is the great wheel, which is generally about seventeen or eighteen feet diameter, from *a* the outermost edge of any float board, to *b*, that of its opposite float. To this wheel the water is conveyed through a channel, and falling upon the wheel, turns it round. On the axis B B, of this wheel, and within the mill-house, is a wheel D, about eight or nine feet diameter, having sixty-one cogs, which turn a trundle E, containing ten upright staves or rounds; and when this is the number of cogs and rounds, the trundle will make $6\frac{1}{10}$ revolutions for one revolution of the wheel. The reason of adding an odd cog, called the hunting cog, to the wheel, is this; that, as every cog comes to the trundle, it may take the next staff or round behind the one which it took in the former revolution, and thus it will wear all the parts of the cogs and rounds which work upon one another equally, and to equal distances from one another in a little time; and make a true uniform motion throughout the whole work. The trundle is fixed upon an iron axis called the spindle, the lower end of which turns in a brass foot, fixed at F, in the horizontal beam S T, called the bridge-tree; and the upper part of the spindle turns in a wooden bush fixed into the lower mill-stone, which lies upon beams in the floor Y Y. The top part of the spindle above the bush is square, and goes into a square hole in a strong iron cross, *abcd*, (*fig. 2.*) called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd. The rynd is let into grooves in the under surface of the running mill-stone G, (*fig. 1.*) and so turns it round in the same time that the trundle E is turned round by the cog-wheel D. This mill-stone has a large hole quite through its middle, called the eye of the stone, through which the middle part of the rynd and upper end of the spindle may be seen; whilst the four ends of the rynd lie hid below the stone in their grooves.

The end T of the bridge-tree T S (which supports the upper mill-stone G upon the spindle) is fixed into a hole in the wall; and the end S is let into a beam Q R called the brayer, whose end R remains fixed in a mortise: and its other end Q hangs by a strong iron rod P, which goes through the floor Y Y, and has a screw-nut on its top at O; by the turning of which nut, the end Q of the brayer is raised or depressed at pleasure; and, consequently, the bridge-tree T S and upper mill-stone. By this means the upper mill-stone may be set as close to the under one, or raised as high from it, as the miller pleases. The nearer the mill-stones are to one another, the finer they grind the corn; and the more remote from one another, the coarser.

The upper mill-stone G is inclosed in a round box H, which does not touch it any where; and is about an inch distant from its edge all around. On the top of this box stands a frame for holding the hopper *kk*, to which is hung the shoe I, by two lines fastened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the

crook.

crook-string K fastened to the fore-part of it at *i*; the other end being twisted round the pin L. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

If the shoe be drawn up quite to the hopper, no corn can fall from the hopper into the mill; if it be let a little down, some will fall: and the quantity will be more or less, according as the shoe is more or less let down. For the hopper is open at bottom, and there is a hole in the bottom of the shoe, not directly under the bottom of the hopper, but forwarder towards the end *i*, over the middle of the eye of the mill-stone.

There is a square hole in the top of the spindle, in which is put the feeder *e* (fig. 2.); this feeder (as the spindle turns round) jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper, through the shoe, into the eye of the mill-stone, where it falls upon the top of the rynd, and is, by the motion of the rynd and the leather under it, thrown below the upper stone, and ground between it and the lower one. The violent motion of the stone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a spiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a spout M, called the mill-eye, into the trough N. When the mill is fed too fast, the corn bears up the stone, and is ground too coarse; and besides, it clogs the mill so as to make it go too slow. When the mill is too slowly fed, it goes too fall, and the stones, by their attrition, are apt to strike fire against one another. Both which inconveniencies are avoided by turning the pin L backwards or forwards, which draws up or lets down the shoe; and so regulates the feeding as the miller sees convenient.

Sometimes, where there is a sufficient quantity of water, the cog-wheel in fig. 1. turns a large trundle, on whose axis is fixed a horizontal wheel, with cogs all around its edge, turning two trundles at the same time; whose axis or spindles turn two mill-stones. When there is not work for them both, either may be made to lie quiet, by taking out one of the staves of its trundle, and turning the vacant place towards the horizontal cog-wheel. And there may be a wheel fixed on the upper end of the great upright axle of this wheel for turning a couple of boulting-mills; and other work for drawing up the sacks, fanning and cleaning the corn, sharpening of tools, &c. As the water acts upon an over-shot mill both by impulse and weight, so does it likewise upon a breast-mill, or that where the water comes upon the breast or middle part of the wheel: and here, though the weight of the water is not so great as in the over-shot mill, being contained in the buckets of the lower quarter only; yet the impulse of the water is much greater, the height of the water being increased nearly the semi-diameter of the great wheel, all other things being equal. If the height of the water remain the same, the aperture of the penstock must be enlarged to nearly twice the area, that the force may be the same; so that to produce the same effect, twice as much water is necessary for the breast-mill as for an over-shot one, every thing else being the same.

Mr. Ferguson observes, that where there is but a small quantity of water, and a fall great enough for the wheel to lie under it, the bucket or over-shot wheel is always used. But where there is a large body of water, with a little fall, the breast or float-board wheel must take place. As to the under-shot mill, it is evident there can be only the impulse from the water; and therefore, the height of the water re-

maining the same, there must be a larger aperture of the penstock for the discharge of a greater quantity of water in the same time, in order to produce the same effect as the over-shot or breast-mill; whence a greater expence of water will be made here than in any other mill, and can only be supplied for a constancy by a river; and where this can be had, the under-shot is the easiest, cheapest, and most simple structure, of which a mill is capable. Dr. Defaguliers, having had occasion to examine many under-shot and over-shot mills, generally found that a well made over-shot mill ground as much corn, in the same time as an under-shot mill with ten times less water; supposing the fall of water at the over-shot to be twenty feet, and at the under-shot to be about six or seven feet: and he generally observed, that the wheel of the over-shot mill was of fifteen or sixteen feet diameter, with a head of water of four or five feet, to drive the water into the buckets with some momentum.

Mr. Ferguson has given the following directions how to construct water-mills, so as to be in the greatest degree of perfection; and also a table calculated from his rules, for the sake of those mill-wrights who either cannot calculate, or do not like to take the trouble.

When the float-boards of the water-wheel move with a third part of the velocity of the water that acts upon them, the water has the greatest power to turn the mill: and when the mill-stone makes about sixty revolutions in a minute, it is found to do its work the best. For, when it makes but about forty or fifty, it grinds too slowly, and when it makes more than seventy, it heats the meal too much, and cuts the bran so small, that a great part thereof mixes with the meal, and cannot be separated from it by sifting or boulting. Consequently, the utmost perfection of mill-work lies in making the train so, as that the mill-stone shall make about sixty turns in a minute when the water-wheel moves with a third part of the velocity of the water. To have it so, observe the following rules:

1. Measure the perpendicular height of the fall of water, in feet, above the middle of the aperture, where it is let out to act by impulse against the float-boards on the lowest side of the under-shot wheel.
2. Multiply this constant number 64.2882, by the height of the fall in feet, and extract the square root of the product, which shall be the velocity of the water at the bottom of the fall; or the number of feet the water moves *per* second.
3. Divide the velocity of the water by 3; and the quotient shall be the velocity of the floats of the wheel in feet *per* second.
4. Divide the circumference of the wheel, in feet, by the velocity of its floats; and the quotient shall be the number of seconds in one turn or revolution of the great water-wheel on whose axis the cog-wheel that turns the trundle is fixed.
5. Divide 60 by the number of seconds in a turn of the water-wheel or cog-wheel; and the quotient shall be the number of turns of either of these wheels in a minute.
6. By this number of turns divide 60 (the number of turns the mill-stone ought to have in a minute) and the quotient shall be the number of turns the mill-stone ought to have for one turn of the water or cog-wheel. Then,
7. As the required number of turns of the mill-stone in a minute is to the number of turns of the cog-wheel in a minute, so must the number of cogs in the wheel be to the number of staves in the trundle on the axis of the mill-stone, in the nearest whole number that can be found. By these rules the following table is calculated; in which the diameter of the water-wheel is supposed to be 18 feet, (and consequently

quently its circumference 56; feet,) and the diameter of the mill-stone to be five feet.

Perpendicular height of the fall of water in feet.	Velocity of the water in feet per second.	Velocity of the wheel in feet per second.	Number of turns of the wheel in a minute.	Required number of turns of the mill-stone for each turn of the wheel.	Nearest number of cogs and flaves for that purpose.	Number of turns of the mill-stone for one turn of the wheel by these cogs and flaves.	Number of turns of the mill-stone in a minute by these cogs and flaves.

Example.—Suppose an under-shot mill is to be built where the perpendicular height of the fall of water is nine feet: it is required to find how many cogs must be in the wheel, and how many flaves in the trundle, to make the mill-stone go about 60 times round in a minute, while the water-wheels float move with a third part of the velocity with which the water spouts against them from the aperture at the bottom of the fall.

Find 9 (the height of the fall) in the first column of the table; then against that number, in the sixth column, is 70, for the number of cogs in the wheel, and 10 for the number of flaves in the trundle: and by these numbers, we find in the eighth column that the mill-stone will make $59\frac{3}{5}$ turns in a minute, which is within half a turn of 60, and near enough for the purpose; as it is not absolutely requisite that there should be just 60 without any fraction: and throughout the whole table the number of turns is not quite one more or less than 60.

The diameter of the wheel being eighteen feet, and the fall of water nine feet, the second column shews the velocity of the water at the bottom of the fall, to be $24\frac{1}{5}$ feet per second; the third column the velocity of the float-boards of the wheel to be $8\frac{1}{5}$ feet per second; the fourth column shews that the wheel will make $8\frac{1}{5}$ turns in a minute; and the sixth column shews that for the mill-stone to make exactly 60 turns in a minute, it ought to make $7\frac{1}{5}$ (or seven turns and five hundred parts of a turn) for one turn of the wheel.

VOL. XXIII.

Dr. Barker has invented a water mill, that has neither wheel nor trundle: this is represented in *fig. 1.* in which A is a pipe or channel that brings water to the upright tube B. The water runs down the tube, and thence into the horizontal trunk C, and runs out through holes at *d* and *e* near the ends of the trunk on the contrary sides thereof.

The upright spindle D is fixed in the bottom of the trunk, and screwed to it below by the nut *g*; and is fixed into the trunk by two cross-bars at *f*: so that if the tube B and trunk C be turned round, the spindle D will be turned also.

The top of the spindle goes square into the rynd of the upper mill-stone H, as in common mills; and as the trunk, tube, and spindle turn round, the mill-stone is turned round thereby. The lower, or quiescent mill-stone, is represented by I; and K is the floor on which it rests, and wherein is the hole L for letting the meal run through, and fall down into a trough which may be about M. The hoop or case that goes round the mill-stone rests on the floor K, and supports the hopper, in the common way. The lower end of the spindle turns in a hole in the bridge-tree G F, which supports the mill-stone, tube, spindle, and trunk. This tree is moveable on a pin at *b*, and its other end is supported by an iron rod N fixed into it, the top of the rod going through the fixed bracket O, and having a screw-nut *o* upon it, above the bracket. By turning this nut forward or backward, the mill-stone is raised or lowered at pleasure.

Whilst the tube B is kept full of water from the pipe A, and the water continues to run out from the ends of the trunk; the upper mill-stone H, together with the trunk, tube, and spindle, turns round. But if the holes in the trunk were stopp'd, no motion would ensue; even though the tube and trunk were full of water. For,

If there were no hole in the trunk, the pressure of the water would be equal against all parts of its sides within. But, when the water has free egress through the holes, its pressure there is entirely removed; and the pressure against the parts of the sides which are opposite to the holes, turns the machine. See Defaguliers's *Exp. Phil.* vol. ii. p. 417, &c. p. 431, &c. p. 459, &c. Fergufon's *Mechanics*, p. 45, &c. 4to. ed. and Supp. p. 10. See also on this subject, an elaborate paper of Mr. Smeaton, containing an account of a number of experiments, in order to estimate the natural powers of water and wind to turn mills, in the *Phil. Trans.* vol. li. art. 18 p. 100, &c.

The description of a mill, which we have given above in the words of the late ingenious Mr. Fergufon, is very correct. The improvements of late years, which have been made in mills for grinding corn, relate to the manner of their construction, and the proportions of the wheel-work, for giving motion to the mill-stones, by which the grinding is performed in the manner described. The late Mr. John Smeaton, F.R.S., was celebrated for his accuracy and judgment in the proportions of his mills, particularly those turned by water. We shall, under the article *WATER-WHEELS*, give some account of his principles; and under this head we shall describe a steam flour-mill, which was erected from his designs, at the victualling house for the navy at Deptford, in 1781. This was before the steam-engine of Mr. Watt was brought to the perfection it has since attained; and as the old atmospheric engine was thought to be unfit for producing a rotatory motion, Mr. Smeaton erected a common steam-engine to pump up water for the supply of a large overshot water-wheel, which actuated the mill. *Fig. 1.* of *Plate XXXIV. Mechanics*, represents the whole mill, by a longitudinal section of the house; and *fig. 2.*

another section, taken perpendicular to the former. The mill is double, that is, the water-wheel, A A, is situated between two buildings, only one of which is represented in *fig. 2*; and the wall, B B, of the other is one side of a house, containing exactly the same machinery as that which is delineated. Over the water-wheel two large cisterns, or troughs, C, D, are placed, communicating with each other by a large iron pipe E, *fig. 1*; and one of these troughs, C, has a pipe or trough, leading water into it, from the pump of the steam-engine supplying the water for the mill: in the other trough, D, is a shuttle *a*, which being raised up, permits the water to issue from a hole in the end of the trough, and fly forwards horizontally through a proper chute, or pentrough, into the buckets of the wheel A. The form of these buckets is shewn by *fig. 1*, a portion of the wheel being represented in section for that purpose. The buckets, which are thus filled at the top of the wheel, descend by their weight, turning the wheel round, till they come to the lowest part of the wheel; and here, by the buckets becoming inverted, the water is discharged from them, and they go up empty to the top of the wheel, where they are filled again from the trough. In this manner, one side of the wheel being always loaded by the buckets full of water, and the other side being empty, it has a constant tendency to turn round. The axis of the wheel has a large spur-wheel, E, fixed upon its extreme end, which being furnished with a double row of cogs, as shewn in *fig. 2*, communicates motion to the lanterns or trundles, F, G, one above, and the other below it: the latter, G, is fixed upon the end of an horizontal shaft H H, extending beneath the mill-stones, situated at I I and L: it actuates the upper stone of each pair, by means of crown or face-wheels K, which turn the pinions fixed at the lower ends of the respective spindle *dd*. The upper trundle, F, is fixed upon a shaft, which carries two face-wheels, *e, f*: the teeth of these wheels are opposite to each other, and either of them can be made to work a pinion, *g*, *fig. 1*, fixed upon the end of an axis *b*, which at the other end has a cog-wheel turning a pinion at *k*, on the end of the spindle of a machine, M, for dressing flour. This machine consists of a hollow cylinder or frame, covered with wire-cloth of different degrees of fineness; the finest being at the end A, which is the most elevated, for the axis of the cylinder is inclined in the direction of the dotted line: every one of the lengths, as it goes towards the other end, is covered with a coarser kind of wire-cloth, for sifting the flour. Within this cylinder, which is stationary, a reel is situated; its axis being exactly in the centre of the cylinder, and turned round by the pinion *k*: the rails of this reel are provided with hair brushes, which, as they revolve, brush against the interior wire surface of the cylinder. The machine is provided with a shoe or jigger, very similar to that of the mill-stones, to bring down the flour or meal through a trough, from the floor above, where it is kept after being ground: the meal, being by this means gradually fed into the cylinder, is, by the motion of the brushes on the reel, sifted or rubbed through the wire: the finest of the flour will of course go through at the upper end, but no other kind; the second through the next division, and so on till the bran falls out at the end of the cylinder, being too coarse to go through any of the wires. The cylinder is enclosed in a tight and close box M, to prevent waste by the flour flying about; and the box has partitions, which divide it into as many lengths as the cylinder has different kinds of wire. Thus each division of the box receives a different quality of flour; and spouts being fixed, which go down into the floor beneath, sacks can be filled at them without waste or inconvenience.

The pinion *g*, for turning the dressing machine, can be

made to turn either way about, by engaging it with the teeth of either of the cog-wheels *e, f*, which acting on the opposite sides of the pinion *g*, give the means of turning it in either direction at pleasure. The pinion is of such a diameter, that it cannot be engaged with both wheels at once; and the upright lever *r*, which supports the pivot of its axis *b*, can be thrown to either side, as is shewn in *fig. 2*: for its lower end moves on a centre at the floor, and at top it is guided by a groove in a piece of wood, fixed to the ceiling, and can be fastened at either side by a pin, so as to throw the pinion in gear with either *e* or *f*. The object of this contrivance is, that when the machine, M, has for a long time been running in one direction, and its brushes become worse, or bent on one side, its motion may be reversed, to give them an equal wear on the opposite side. The wheel, *e*, has another fixed to it at the back (see *fig. 2*), which actuates a cog-wheel N, upon the end of a roller R, having a rope wound round it, for drawing up sacks of corn or flour from one floor of the mill to another. This rope passes upwards from the roller to the roof of the building, where it passes over a pulley, and thence descends through square holes in the several floors to the ground. These holes are covered by double doors, opening upwards, so that a sack, being drawn up, opens the door, which falls down as soon as it has passed. The wheel, N, of the sack-roller can be disengaged at pleasure from the cog-wheel, *e*, which turns it; and then the rope can be unwound and run down again, to fetch up another sack. This disengagement of the wheel is effected by the same means as described of the upright lever *r*; and a line being conducted from the top of the lever, over proper pulleys, into various parts of the mill, the miller can, by pulling this line, disengage the roller at pleasure, to draw up or let down a sack. A pinion and shaft, similar to *g* and *b*, *fig. 1*, may be placed on the opposite side of the wheels, *e* and *f*, to work another dressing machine at the opposite side of the mill, or what is called a bolting machine. This is rather of a different construction, being the original flour-dressing machine: it consists of a reel like the former, but without any brushes; and upon this, instead of a wire-cylinder, a cloth like a sack, cut open at the bottom, is fastened, and revolves with it; the flour, being introduced by a feeding-shoe into this, is sifted round in the revolving cloth, and the fine flour passes through. To prevent the flour accumulating at any one side of the cloth into a bag, and swinging round with it, without sifting, four rails are fixed in the machine, parallel to the axis; and if the cloth swings out by the weight of the flour within it, the cloth strikes against these rails, and the flour is thus shaken through it into the chest or case of the machine.

The lower figures of the plate contain the development of the parts of the mill, tending to explain their construction. *Figs. 3, 4, and 5*, shew the cast-iron axis for the water-wheel; N is the cylindric shaft, and *b, b*, its two necks, which lay on bearings in the wall of the mill, and bear the weight: beyond these necks the axis has a square box, O O, at each end, for framing the great cog-wheels upon. The manner of attaching the arms of the great water-wheel to the shaft is this: two circular plates or saunches, P, P, *fig. 3*, are cast upon the axis; and against each of these 12 arms, Q, Q, are bolted: they are placed against the saunch, tending to the centre, and the spaces between them are filled up by wooden pieces, as shewn by *r, r, r*, *fig. 4*: two iron rings, R and S, are placed over the arms, and a bolt put through each arm, to attach it to the saunch, and to the axis; the wooden pieces, *r, r*, are kept in their places by a wedge driven through each, within the great hoop R, and by means of these wedges the pieces, *r, r*, can

at any time be drawn up towards the centre, to hold all the arms fast in their places.

This method of framing water-wheels was used with great success by Mr. Smeaton in many instances, and was found to answer the purpose extremely well, being a great improvement upon the old method of mortising the arms into a wooden shaft.

Fig. 6, 7, and 8, shew one of the spindles for the mill-stones H and L, *fig.* 2: it is a straight iron axis, *d*, formed to a pivot, *s*, at the lower end, which rests and turns in a piece of brass: near the upper end of the spindle another neck or pivot, *t*, is formed, and runs in a collar, in the centre of the nether or lower mill-stone, whilst the upper one is hung upon the arms of an iron cross T: see also *fig.* 7, fitted with a square upon the top of the spindle. On the lower part of the spindle the pinion Z, which gives it motion, is fixed: it has a square hole through it, fitting on the square spindle, and iron crosses are fixed both at top and bottom of the block of wood forming the body of the pinion: in this iron are two screws (see *fig.* 8.), which, being screwed fast, fix the pinion firmly to the spindle, its weight being supported by a wedge, *v*, put through a hole in it; but when this wedge is withdrawn, and the screws slackened, the pinion falls down so low upon the spindle, that its teeth are clear of the teeth of the cog-wheels *k*, *fig.* 2, and in this state the spindle and mill-stone upon it will stand still, though the mill is going. The spindle foot, *s*, rests in a brass socket, fixed in a lever *w*, *figs.* 1 and 2, called the bridge-tree: its fulcrum is in the solid wall, W, *fig.* 1, at one end, and the other rests on the middle of a second lever X, perpendicular to the former, called the brayer, one end of which has a fulcrum in the framing, *fig.* 2, and the other is supported by a screw, which the miller turns round, to elevate or depress the upper stone, and adjust the distance between them at pleasure, according as he wishes to grind finer or coarser flour. The upper part of the mill before us is used as a store-house for corn, which is drawn up in sacks by the tackle into the roof, and there emptied into bins, or different compartments, of the upper floor: from these it is let down to the mill-stones, and ground into meal. The spouts from the stones lead the meal into sacks, which, when full, are drawn up to the top of the house again, and emptied out into a flour bin, situated over the dressing machine M, which separates it into various qualities for use.

The mills which grind for the London market use three dressing machines: the finest flour is that which has been passed through a wire-cloth of 64 *per* inch, when the meal is dressed the first time; the other part of the cylinder is coarse wire, which suffers a coarse meal, called middlings, to pass through it; but the bran and coarse pollard fall out at the end of the cylinder. The middlings are ground over again in a pair of mill-stones, which are rather dull, and become unfit for grinding corn, without dressing them again: then, after this second grinding, the meal is dressed in the cloth machine, called the bolting cloth, which takes out the second flour, and the pollard comes out at the end of the cloth: the bran and the pollard together are now put into the clearing-off machine, which is a coarse wire-cylinder of the kind we have described, and by it is separated into hog pollard, which is the finest sort; 2d, horse pollard; and, 3d, bran. A pair of mill-stones will grind five bushels of wheat *per* hour, when in good condition; but require to be taken up and dressed once a week, if used constantly. This dressing is done by picking the surface of the stone over with the mill-pick, to cut the grooves and furrows sharp, that they may grind and cut the corn between them.

Persons riotously assembling and destroying, or maliciously burning, any wind-law mill, water-mill, or water-mill, &c. shall be guilty of felony, without benefit of clergy, by 9 Geo. III. c. 29. Prosecution to be commenced within eighteen months after the offence committed. By 41 Geo. III. c. 24. the damages occasioned by demolishing any wind-mill by persons riotously assembled, may be sued for and recovered in the manner provided for by 1 Geo. Stat. 2. c. 5. respecting the demolishing of churches and other buildings. (See Riot.) By 43 Geo. III. c. 58. any person who shall maliciously set fire to any mill in the possession of any other person, or of any body corporate, shall be guilty of felony, without benefit of clergy.

Water-mills have long been great nuisances to agriculture, by preventing the use of the streams on which they stand, in many cases, in irrigating and flooding the adjoining land, by which much improvement is kept back, that would otherwise take place. They are also injurious by obstructing and damming up the water in numerous instances, so as to render it stagnant on the ground above. Wind and steam may, however, be applied as the moving powers of mills without producing any such effects, and are, of course, the most proper powers to be employed.

The ancient feudal custom of obliging tenants to grind at the lord's mills, is now almost wholly done away. Draining or lifting-mills are often extremely useful in discharging water from low flat lands in many situations. The moving power in these is commonly wind. See MILL, in *Mechanics*.

By an ancient ordinance the toll for grinding shall be taken either to the 20th or 24th corn; and yet, in some places, millers claim and take the 16th part: but Mr. Dalton says, that the miller should take but one quart for grinding one bushel of hard corn, and if he carry back the grist to the owner he may take two quarts of such corn, *i. e.* wheat rye, and meslin, (wheat and rye mixed.) For malt he shall take half as much as for hard corn. By Holt ch. just. the toll of a mill must be regulated by custom, and if the miller take more than the custom warrants, it is extortion: but if it be a new mill, the miller is not restrained to any certain toll. (1 L. Raym. 149.) In some places the tenants are bound to have their corn ground at the lord's mill. When a miller, upon information given on oath to any magistrate, is suspected of adulterating meal or flour, the house, mill, &c. of such miller may be entered under the authority of a warrant of a magistrate, at all reasonable times of the day, to search for discovery, and if such adulterated meal or flour be found, it may be seized by the officer executing the warrant, seized by the magistrate to whom it is carried, and disposed of at his discretion. (31 Geo. III. c. 29.) A miller who hath corn given him to grind, and who charges for that which is bad, is indictable; and he may be guilty of felony by taking away any part with an intent to steal it. (Hawk. c. 33.) Millers are not to be common buyers of any corn, with a view to sell the same again, either in corn or meal. (Dalt. c. 122.) By 36 Geo. III. c. 85, every miller shall keep balances and weights according to the standard of the exchequer, which may be examined by a person appointed for this purpose by 35 Geo. III. c. 102; and in default thereof the miller shall forfeit not exceeding 20s. &c. &c. Millers may be required to weigh corn, and, on refusal, shall forfeit not exceeding 40s. Millers are to deliver the whole produce of corn when ground, if required, allowing for waste in grinding and dressing, and for toll when taken; and if such

corn shall weigh less than the full weight, such miller shall, for every bushel of corn deficient in weight, forfeit not exceeding 1s. and also treble the value of such deficiency. When toll is taken, it shall be deducted before the corn shall be put into the mill. No miller shall demand corn for toll, but in lieu thereof shall be entitled to payment in money, under penalty of forfeiting not exceeding 5l.: excepting when persons shall not have money to pay for grinding, and also, that this shall not extend to mills called "Soke-mills," or such ancient mills as are established by custom and the law of the land, which mills shall continue to take toll as they have been accustomed to do. Every miller is required to put up in his mill a table of the prices in money, or of the amount of toll or multure, on pain of forfeiting 20s. for every such offence.

MILLS, *Wind*, are, with respect to their working parts, little different from those of water-mills; but they are turned by the force of wind gathered in their sails.

Of these, some are called *vertical*, others *horizontal*, according to the position of the sails; or, rather, according to the direction of their motion, with regard to the horizon.

For the best form of horizontal sails, and also for determining the position of the axis of wind-mills, see WIND-mill and MECHANICS.

MILLS, *Portative* or *Hand*, are those kept in motion by the hand; or else whose mill-stones are turned, or pistons driven by the force of horses or other beasts. Thus, if the cog-wheel D, (*Plate XXXIII. Mechanics, fig. 1.*) be made about eighteen inches diameter, with thirty cogs, the trundle as small in proportion, with ten staves, and the mill-stones be each about two feet in diameter, and the whole work be put into a strong frame of wood, as represented in the figure, the engine will be a hand-mill for grinding corn or malt in private families. And then it may be turned by a winch instead of the wheel A A; the mill-stone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will assist greatly in regulating the motion.

If the cog-wheel that turns the trundle or trundles of a mill be placed horizontally, horizontal levers may be fixed into its vertical axis, and horses applied to these for turning the mill; which is often done where water cannot be had for that purpose.

The use of mills and mill-stones, according to Pausanias, was first invented by Myla, son of Meleges, first king of Sparta; though Pliny attributes the invention of every thing belonging to bread and baking, to Ceres: Polydore Virgil was not able to discover the author of so useful a machine. It is doubted whether or not water-mills were known to the Romans, there being no mention made, in the Digest, but of mills turned by slaves and asses. Salmasius, however, and Gothofred, will not allow water-mills to have been unknown to the ancient Romans, though they were not in ordinary use. Wind-mills are of much more modern invention; the first model of these was brought from Asia into Europe in the time of the holy wars.

MILL is also used for any machine, which being moved by some external force, serves to give a violent impression on things applied to it.

Mills, in this sense, are machines of vast use in the manufactures, arts, and trades; for the making and preparing divers kinds of merchandizes. The principal are those which follow.

MILL, *Colour*. Colours for the use of painters, paper-

stainers, &c. are prepared, in the large way, by grinding them, either with oil or water, in mills worked formerly by horses, but now frequently steam-engines are used for such purpose in London. These colour-mills consist of a large toothed-wheel, or cog-wheel, worked by the horses, or steam-engine, &c. which gives motion to several trundles and upright spindles of small mill-stones placed round its circumference. The construction and use of these will be readily comprehended from the following description of a single pair of stones to be worked by hand, *Plate XXXV. fig. 1.* The winch-handle A gives motion, by the labour of a man, to the spindle B and fly-wheel C, fixed thereon; and which also carries a small spur-wheel D, having eighteen bevelled teeth, which work into those of the crown-wheel E E, of twenty-six teeth, fixed upon the upright spindle F, working in a brass collar at top, fixed to the piece of wood G, which is adjustable by means of the wedge H, so as to keep the teeth of the wheels properly in gear: the bottom of the spindle works in the end of a brass screw R, working in the bottom framing of the machine, and passing up through the centre of the lower stone, the turning of which screw, occasionally, adjusts the distance of the stones, which are of the common construction, exactly like those for grinding flour, but smaller, each being sixteen inches diameter and three inches thick. The upper stone I is supported on the upright spindle F by a shoulder and crow, the same as mill-stones in general; it has a hopper K affixed to it, and which revolves with it, into which the semi-fluid colours intended to be ground are put, and when ground they are protruded through a spout from the tub M, nineteen inches diameter, which contains the stones.

After the above process, colours for the use of painters, &c. were ground by hand with oil or water, on a polished marble slab with a pebble muller; but this process being tedious and expensive, as well as highly prejudicial to the health of the workman, Mr. James Rawlinson of Derby, some years ago contrived a mill for this purpose, which is represented in *fig. 2*, a model of which he presented to the Society of Arts in the Adelphi, London, in 1804. A is a roller or cylinder of black marble, truly formed and well polished, 16½ inches diameter and 4½ inches broad; B is a concave muller, covering one-third of the roller, of the same kind of marble, well polished, and fixed in the wooden case or frame b, which is hung on hinges at i, for use when the muller requires to be lifted off the cylinder. C is a crooked bar of iron, about an inch broad, moveable on a pin at f, in order to turn down out of the way when the muller is to be lifted off: near the end of this bar is a thumb-screw c, whose end acts in a hole in the wooden case b, and serves to keep that and the muller steady, and to increase the pressure of the muller as occasion may require. D is a scraper or taker-off, made of a piece of clock-spring fixed in an iron frame K, in the manner of a frame-saw, and turning on centres d d, so that when in use the taker-off lies in an inclined position against the cylinder, and at other times is turned back out of the way. H is a plate set under the taker-off to catch the colour when sufficiently ground, which stands upon a sliding board that can occasionally be drawn out, to remove any colour which may accidentally drop from the cylinder. F is a drawer under the mill for holding carriers' shavings, for cleaning the cylinder and muller, when a fresh colour is wanted to be ground. The colour, roughly ground in a large colour-mill above described, is applied in proper quantities, by means of a knife, to the front of the cylinder above the taker-off, and by means of the winch-handle G the mill is worked, until the colour, by passing between the revolving stone

stone and muller, is sufficiently ground; when the taker-off D, which during the operation lay back, is turned against the stone, the winch-handle is turned the reverse way for a few revolutions, in order to scrape off the colour which falls into the dish H.

In the Philosophical Transactions, No. 87, a mill is described as having been used by Dr. Langelot, for grinding leaf gold to powder, for the fanciful purpose of preparing *Aurum potabile*: the principles of this mill were, some years ago, found applicable to the grinding of dry indigo in Mr. Taylor's manufactory at Manchester, and were also found by Mr. Rawlinson, above mentioned, to be the best adapted for finely pulverizing the dry colours intended to be ground with oil or water in his colour-mill. This simple mill is represented in *fig. 3*, where L is a marble mortar, nicely formed and polished; M is a muller nearly in the form of a pear, having an iron axis fixed into its upper end, which is bent into the form of a crank at P to serve as a handle for turning the muller: the axis is fixed, when in use, into two collars O, O, in beams of wood N N, so as to revolve easily and truly in the axis of the mortar. This muller is shewn separately at *fig. 4*, which shews a slit that is made through it, almost dividing it into two parts: this slit is of use in collecting the colour which is grinding, and bringing it continually under the muller. A circular board in two halves, with a centre-hole to fit the axis, is used to lay over the mortar, to prevent the dust of the colours from flying out, to waste the same and injure the health of the workmen. By means of the flat perforated weights R, on the top of the axis, any required pressure can be applied upon the muller.

For preserving the health of such colour-men and painters as still prefer the common stone and muller for grinding their colours, M. Boulard, in the Journal de Physique, recommends an apparatus represented in *fig. 5*, wherein the stone, and its table A B, is surrounded by a close-sided casing of boards C, C, fitted to the floor of the room, and leaving a space of about $\frac{1}{2}$ th of an inch wide all round the table supporting the stone; this is for emitting a current of fresh air, which is to be supplied by a pipe D D extending from a hole in the floor under the case, to the outward air in some most convenient place. Over the stone a glazed pyramid E E and metal tube F is supported by the irons G and braces H, H, H, or by other more convenient means, so that the pyramid E E projects, on all sides, about three inches beyond the stone; and at a height above the same no greater than is sufficient for the free admission of the workman's arms to work the muller, and with his pallet knife to scrape together the colour when requisite, and which he will be able perfectly to see to do, through the glass in the frame, without inhaling the vapour from the colours, but which are to be made to ascend through the tube F, and pass off into the open air through the tube M M, by means of a small stove I I closely jointed to the tubes F and G, which is to be kept burning during the hours of work, in order to produce a current between the pipes D and M, that may effectually carry off the contaminated air which has been in contact with the colours on the stone, along with their effluvia. K represents the door of the fire-place, and L that of the ash-hole of the stove, both contrived to shut very close. In the pipe F a register N should be made for regulating the turning of the stove, by the admission of more or less air hereto through the pipe F. If desirable, the close pipe F may be conducted into the fire-place of any stove or fire in the apartments above, or it may even descend by a proper curvature, so as to admit of the stove I I being placed on the ground, and applied to any useful purpose, as the boiling of oil, or heating an adjoining room, &c.

MILL, Cotton. See MANUFACTURE of Cotton.

MILL, Flood, that sort of mill which is contrived for the purpose of raising water in order to discharge it from fens, marshes, and other similar kinds of land.

MILLS, Forge, turned by water, serve to raise and let fall one or more huge hammers, to beat and form the iron into bars, anchors, and other massive works. They are also called tilt-mills. See FORGE, IRON, and STEEL.

MILL, Fulling, is a water-mill which raises and beats down large wooden pistons in proper vessels called *poils*, or *troughs*; in order to full, scour, and cleanse woollen stulfa. See FULLING-Mill.

MILL, Gunpowder, is that used to pound and beat together the ingredients whereof gunpowder is composed.

This is done in a kind of iron or brass mortar, by means of iron pestles wrought by a wheel, without-side the mill, turned by the water falling on it. See GUNPOWDER.

MILLS, Leather, are used to scour and prepare with oil, the skins of stags, buffaloes, cows, bullocks, &c. to make what they call *buff-leather*, for the use of the soldiery.

This is effected by means of several large pistons, rising and falling on the skins, in large wooden troughs, by means of a wheel without-side, turned by the force of water.

MILLS, Linen, do not differ much from fulling-mills. Their use is, to scour linens, after their having been first cleansed when taken out of the lixivium, or ley. Some of these go by water, and the generality by horses.

MILLS, Oil, when turned by men, water, hand, or horse, serve to bruise or break the nuts, olives, and other fruits and grains, whose juice is to be drawn, by expression, to make oil. See OIL.

MILL, Paper, a water-mill, furnished with engines containing cylinders furnished with teeth which cut and grind the rags or cloth in a kind of wooden trough; and thus, by reducing them to little pieces, turn them into a kind of pulp, by means of water conveyed into the troughs by a pipe for that purpose. See PAPER.

MILL, Sawing, is a water-mill, serving to saw several planks or boards at the same time.

These are frequent in France, especially in Dauphiné.

They were lately prohibited in England, where they were begun to be introduced, from a view to the ruin of the sawyers, which must have ensued. See SAWING, also MACHINERY, Block.

There are also *silk* mills, for spinning, throwing, and twisting silks; which are large round machines in form of turrets, five or six feet high, and six yards in diameter; which, being turned, either by the force of water or that of men, work at the same time an infinity of bobbins fastened thereto, whereon the silk had been wound to be here spun and twisted.

There are abundance of mills of this kind in France, especially about Lyons and Tours, some of which are so disposed, as that three of them will go at the same time, and by the same wheel wrought by water or by strength of hand. That in the Hôpital de la Charité at Lyons, is wonderful, a single man working no less than 48 of these mills. See SILK, and WINDING of Silk.

MILL, Stamping. See STAMPING.

MILL, Sugar, is a machine that serves to bruise the sugar-canes, and express the liquor or juice contained therein. The sugar-mills are very curious contrivances. Of these there are four kinds, being turned either by water, wind, men, or horses.

Those turned by the hand were first in use; but they are now laid aside, as being an intolerable hardship on the peo-

negroes who were doomed thereto, besides the slowness of their progress.

Wind-mills are the most modern: but they are yet somewhat rare, excepting in St. Christopher's and Barbadoes, and among the Portuguese. These make good dispatch, but have this inconvenience, that they are not easily stopped; which proves frequently fatal to the negroes who feed them. See SUGAR.

MILLS, *Tan or Bark*, wrought by water or horses, serve to cut certain barks into a coarser sort of powder, proper for the tanning of hides, &c.

MILLS for *Sword-blades* are likewise moved by water. They are frequent at Vienne, in Dauphiné. By working heavy hammers they forge those excellent sword-blades, called *blades of Vienne*.

The uses and operations of these several mills, more at large, see under PAPER, FULLING, SUGARS, &c.

MILL, *Threshing*, such a machine as is contrived for the purpose of threshing grain or other sorts of seed crops. See THRESHING Machine.

MILL, in *Coinage*, is a machine used to prepare the laminæ, or plates of metal, and to give them proper thickness, hardness, and consistence, before they be struck, or stamped.

This machine has not been long known among us; but is of some standing in Germany. It consists of several wheels dented like those of clocks, &c. which move two cylinders of steel, between which the metal is passed to be brought to its proper thickness. It was first turned with water, since with horses. See COINAGE.

MILL, in *Commerce*, a money of account in the United States of America; 1000 mills being = 100 cents = 10 deniers = a dollar.

MILL, among *Gold Wire Drawers*, is a little machine consisting of two cylinders of steel, serving to flatten the gold or silver wire, and reduce it into laminæ, or plates. See GOLD Wire.

They have also mills to wind the gold wire or thread on the silk: these are composed of several rows of bobbins all turned at the same time.

MILL-*Reek*, in *Medicine*, an appellation given by the miners, employed at the Leadhills in Scotland, to those affections of the bowels, and of the nervous system, which are occasioned by the poison of the lead. The melting-houses, in which the operations are carried on, are called *mills*, because the bellows there are worked by water-wheels; and the *reek*, or smoke, arising from the melted lead, is believed to be the chief cause of the disease: whence the term *mill-reek* has been appropriated to the malady. See *Essays and Obs. Phys. and Liter.* vol. i. art. xxii. Edinburgh.

MILL-*Dams*, in *Rural Economy*, the basons which contain the water for supplying mills. A very firm way of making these in a quick or running sand; which is usually found a very troublesome circumstance in the making of them, is by laying the foundation with unslaked lime; which, by slaking among the sand, runs together into a hard stone, which gives a very firm and sure foundation. Plott's Staffordshire, p. 336.

MILL-*Holms*, a term applied to the low meadows, and other fields in the vicinity of mills, or watery places about mill-dams. The soils in these cases are generally of a good quality.

MILL-*Pool*, a stock or pond of water, by the force of which the motion of a water-mill is effected.

The dam of a mill-pool is raised much in the same manner as directed for *fish-ponds*; which see.

MILL-*Stones*, in *Rural Economy*, the prepared stones made use of in grinding grain and other substances, which are of

different kinds, according to the purposes for which they are employed, but those chiefly used in grinding wheat into flour, were formerly imported from France, and termed *burrs*. Lately, however, stones proper for this use have been discovered in different parts of this kingdom, as in Wales and Scotland. In the first of these places they were found by Mr. Bowes, in a quarry which is "situated within the corporation liberties of Conway: the stone appears within a quarter of a mile of that town, and extends from east to west for the distance of two miles, appearing in most places upon the surface within that distance. Such an immense body of the stone has been left bare and exposed to view, that the industry of ages would scarcely lessen it. A deep chasm intervenes at the end of two miles; and, on examining the same line across this valley, he found the stone mixed up with various other fossil substances, to which it seems to bear no relation. In the next rise of mountains it resumes its quality, and takes a southerly direction, passing through a range of hills to the distance of two miles more, where the vein disappears. It is every where the highest stratum; and when disengaged from the quarry where now worked, it tumbles down the side of the mountain to the plain within five hundred yards of the shipping-place, where small vessels may lie safely in all weathers at a natural quay, completely calculated for this business." The quarry lies on the decline of a hill: the vein now is about eight yards wide; but he has reason to suppose it wider below. At the depth he has sunk, which is at least twenty-five feet, the stone mends in quality. When first taken from the quarry it is much softer and easier wrought into shape, than when exposed to the air: even a day makes a difference. The vein appears to him quite inexhaustible, and contains every variety of the stone, cellular, close, hard, or soft. The right in this tract of country has been presented to him, by Mr. Sneyd of Staffordshire, under the hope that he might be able to make this discovery, and carry it vigorously into effect, in which he has not been disappointed.

It would appear from the evidence sent to the Society for the Encouragement of Arts, &c. that the stones raised from this quarry are capable of being employed in most cases where those imported from France have been in use, and that the stone, from its external appearance, seems to be constituted of quartz and cherts.

And in the latter of the above situations stones fit for this use were discovered by James Brownhill, miller, "who, when the late unfortunate war had rendered the getting of the French burr extremely difficult, as he was passing by the great basaltic rock of the Abbey Craig, near Stirling, examined the texture of several masses of the stones; and found one species, which appeared to him fit for the grinding of wheat, and brought home a sample of them, which he shewed to Mr. Alexander Ball, agent of the Alloa Mills, who agreed to make trial of a pair. They were built under his direction in the same manner as the French burr; and, on their being put to work, gave such satisfaction to the customers of the mills, as induced the Alloa Mill company to have another pair built, and totally lay aside the French burr mill-stones." It is suggested, that "the French burr stones are so porous, as to make it necessary to fill up the cavities with a preparation of alum: this considerable expence is saved by the uniform texture of the basaltes; and their superior excellence is so apparent, that upwards of 60 pair are now at work in several parts of the kingdom, and the demand for them is daily increasing." In addition it is stated, that "the basaltes mill-stones are not only excellent for manufacturing of flour, but for all kind of grist. The distillers give them a decided preference, and they grind oats

in a very complete style, as the meal is returned quite free of sand, which is a great desideratum for those places where oat bread is in use. The discoverer of this use of the basaltæ, builds mill-stones of all sizes on moderate terms, and is careful, from his experience as a miller, to build them of such a grain as is most suitable for the particular purposes for which they are intended.

The following remarks are offered by Mr. Ferguson on the size and velocity of mill-stones. The diameter of the upper stone is generally about six feet, the lower stone about an inch more; and the upper stone, when new, contains about 22½ cubic feet, which weighs somewhat more than 19,000 pounds. A stone of this diameter ought never to go more than 60 times round in a minute; for if it turns faster, it will heat the meal. But according to Mr. Ingham, the mill-stone should turn twice round in a second of time, and should only be four feet and a half in diameter. It may probably be imagined, that the meal will be much heated by such a rapid motion as he has recommended, but the effect is counteracted by diminishing the size of the mill-stone from six feet to four and a half. The velocity of the circumference of the small mill-stone moving twice round in a second, is only one-third greater than the velocity of the large mill-stone moving once round in a second.

It may be noticed, that in the former of the above quarries mill-stones are raised which are of much larger sizes than the French burrs, which may probably be an advantage in some cases.

The modes of preparing mill-stones for the purpose of grinding have been described already, and *fig. 6. of Plate XXXV.* represents the surface of the under grinding mill-stone, the way of laying out the wads or channels: the wooden bush is fixed into the hole in the middle, in which the upper end of the iron spindle turns round; and the case or hoops that surround the upper one, which ought to be two inches clear of the stone all round its circumference. B shews the upper grinding mill-stone, and iron cross or rynd in its middle, in the centre of which is a square hole that takes in a square on the top of the iron spindle, to carry the mill-stone round; when the working sides or faces of the mill-stones are laid uppermost, the wads must lie in the same direction in both, that when the upper stone is turned over, and its surface laid on the under one, then the channels cross each other, which assists in grinding and throwing out the flour; the wads are also laid out according to the way that the upper stone revolves. In these the running mill-stone is supposed to turn *sunways*, or what is called a right-handed mill; but if the stone revolves the other way, the channels must be cut the reverse of this, and then it is termed a left-handed mill. See **MILL**.

The mill-stones which we find preserved from ancient times, are all small, and very different from those in use at present. Thoresby mentions two or three such found in England, among other Roman antiquities, which were but twenty inches broad; and there is great reason to believe that the Romans, as well as the Egyptians of old, and the ancient Jews, did not employ horses, or wind, or water, as we do, to turn their mills, but made their slaves and captives of war do this laborious work; they were in this service placed behind these mill-stones, and pushed them on with all their force.—Sampson, when a prisoner to the Philistines, was treated no better, but was condemned to the mill-stone, in his prison. The runner, or loose mill-stone, in this sort of grinding, was usually very heavy for its size, being as thick as broad. This is the mill-stone which it is expressly prohibited in Scripture to take in pledge, as lying loose it was more easily removed. The Talmudists have a story,

that the Chaldeans made the young men of the captivity carry mill-stones with them to Babylon, where there seems to have been a scarcity at that time; and hence, probably, their paraphrase renders the text "have borne the mill, or mill-stones;" which might thus be true in a literal sense. They have also a proverbial expression of a man with a mill-stone about his neck; which they use to express a man under the severest weight of affliction. This also plainly refers to this small sort of stone.

MILL-Work. Under this head we intend to treat of the parts and mechanical contrivances used in mills. Under the article **MACHINERY**, the reader will find observations of a similar nature to those of the present article, but applied to smaller and more delicate machines than those which are usually denominated mills.

The object of this article will therefore be, to give a general account of the most important pieces of mill-work, as cog-wheels, shafts, bearings, &c.; which parts being common to mills of all kinds, would, if minutely described under every head where they are employed, introduce a great many needless repetitions.

The different first movers of mills will be treated of, and described under their several heads of **STEAM-Engine**, **WATER-Wheels**, and **WIND-Mill**; and the acting machines of several kinds of mills, as clay-mill, grinding-mill, under **CUTLERY**; fulling-mill, flour-mill, iron-mill, under **MANUFACTURE of Iron**; oil-mill, cotton-mill, under **MANUFACTURE of Cotton**; rolling-mill, spinning-mill, silk-mill, thrashing-mill, water-mill, sawing-mill, under **MACHINERY for manufacturing Ships' Blocks at Portsmouth**; **TILT Mill**, &c. &c.

Cog-wheels are the most important and numerous parts of mill-work, few mills being without them, to modify the direction, and adapt the power of the first mover, which actuates the mill, to the working point, or the machine which performs the operations the mill is intended for. Most mills contain several different kinds of machines, or operative parts, all deriving their motions from the same source, or first mover. Thus, a flour-mill contains stones for grinding; dressing machines for sifting the flour; sack tackle, for drawing up the sacks, &c.; all which are moved by the same first mover as a water-wheel, wind-mill, steam-engine, or horse-wheel. But each of these machines requires to be moved with a different velocity to perform its work in the best manner; and it is the object of the mill-work to obtain these different velocities from the same first mover, chiefly by the means of wheels; which, therefore, from their importance, deserve the first notice. There are a variety of cog-wheels, as spur-wheels, (or *gear* in the technical phrase,) bevil-wheels, face-wheels or crown-wheels, pinions or nuts, trundles or lanterns; with a variety of other names which are local, but have the same signification with some of the above.

Spur-wheels are those in which the teeth project from the periphery of the wheel, in the direction of radials (see *Plate 1. fig. 1. of Mill work*): they are so called, from the resemblance to the rowel of a spur. A spur-wheel is used to communicate motion by its teeth to another, situated in the same plane; consequently, the axes of the two are parallel to each other. The spur-wheel, at other times, works with a pinion, or nut (see *fig. 2.*), which is in fact a spur-wheel of small size: at other times with a *trundle* or *lantern*. This is a pinion of peculiar construction, consisting of two circular boards A, A, (*fig. 3.*) fixed, at some distance apart, upon its axis of motion or shaft B B, and united by a number of cylindrical pins *a, a*, called *staves*, or *rounds*, which are arranged in a circle, and fixed parallel to the axis of the trundle between the two boards of it. The teeth of the wheel

act upon these rounds to give motion to the trundle; the rounds, therefore, must be the same pitch or distance asunder as the cogs of the wheel. The number of the rounds of the trundle of course determine its diameter. Trundles have of late years fallen into disuse among mill-wrights, cast iron pinions being found much more preferable: they were sometimes used to work with spur-wheels, but more commonly with

Face-wheels, see *fig. 4*. In these, the teeth or cogs are fixed perpendicularly to the plane of the wheel, parallel, therefore, to its axis: they were used to work with another similar wheel, or with a trundle with a spur-wheel, or with a pinion, when the two axes were required to be perpendicular to each other, as shewn in *figs. 3* and *4*.

The crown or face-wheel has of late years been almost wholly superseded by bevil-wheels, which, in all situations where a wheel is required to turn another in a direction perpendicular or inclined to itself, are found vastly superior.

Bevilled or Mitre-wheels, see *fig. 5* of the plate, have their teeth formed upon a conical surface, the angle of the cone being the same as the angle the axes C, D, of the two wheels A, B, make with each other. The introduction of this class of wheels into machinery is a very essential improvement, which has been wholly made within these thirty years. Bevil-wheels are of course always used to work with others of the same kind.

The manner of setting out the teeth of cog-wheels, in such a form that they shall act in the most equable manner upon each other, and with the least friction, has been a subject of much investigation among mathematicians and theoretic mechanics; but the practice and observation of the mill-wrights have produced a method of forming cog-wheels, which answers nearly, if not fully as well in practice, as the geometrical curves which theory has pointed out to be the most proper. This they have effected by making the teeth of the modern wheels extremely small and numerous. In this case, the time of action in each pair of teeth is so small, that the form of them becomes comparatively of slight importance; and the practical method of the mill-wrights (using arcs of circles for the curves) approximates so nearly to the truth, that the difference is of no consequence: and this method is the best, because it so easily gives the means of forming all the cogs exactly alike, and precisely the same distance asunder, which, by the application of any other curve than the circle, is not so easy. The method, which is extremely simple, is explained by *fig. 1*. The wheel being made, and the cogs fixed in much larger than they are intended to be, a circle, *aa*, is described round the face of the rough cogs upon its *pitch diameter*, that is, the geometrical diameter, or acting line of the cogs; so that when the two wheels are at work together, the pitch circles, *aa*, of the two are in contact. Another circle, *bb*, is described within the pitch circle for the bottom of the teeth, and a third, *dd*, without it, for the extremities. After these preparations, the pitch circle is accurately divided into the number which the wheel is intended to have: a pair of compasses are then opened out to the extent of one and a quarter of these divisions, and with this radius arcs are struck on each side of every division, from the pitch line *a* to the outward circle *dd*. Thus, the point of the compasses being set in the division *e*, the curve *fg* on one side of the cog, and *no* on one side of the other, are described; then the point of the compasses being set on the adjacent division *k*, the curve *lm* is described. This completes the curved portion of the cogs *e*, and this being done all round completes every tooth: the bounding portion of the cog within the pitch circle, *a*, is bounded by two straight lines drawn from the points *g* and *m* towards the centre;

this being done to the cogs all round, the wheel is set out, and the cogs, being dressed or cut down to the lines, will be formed ready for work, every cog being of the same breadth; and the space between every one and its neighbour is exactly equal to the breadth, provided the compasses are opened to the extent of one division and a quarter, as first described.

Many different methods of forming teeth have been proposed, among them the following: Let the tooth *a* (*fig. 6*) press on the tooth *b* in the point C; and draw the line F C D E perpendicular to the touching surfaces in the point C: draw A F, B E, perpendicular to F E, and let F E cut the line A B in D. It is plain from the common principles of mechanics, that if the line F E, drawn in the manner now described, always pass through the same point D, whatever may be the situation of the acting teeth, the mutual action of the wheels will always be the same. It will be the same as if the arm A D acted on the arm B D. In the treatises on the constructions of mills, and other works of this kind, are many instructions for the formation of the teeth of wheels; and almost every noted mill-wright has his own nostrums. Most of them are egregiously faulty in respect to mechanical principle. Indeed, they are little else than instructions how to make teeth clear each other without sticking. Dr. Hooke was, we think, the first who investigated the form of teeth which procured this constant action between the wheels; and in a very ingenious dissertation, published among the Memoirs of the Academy of Sciences at Paris, 1668, this gentleman shews that this will be ensured by forming the teeth into epicycloids. Mr. Camus, of the same academy, has published an elaborate dissertation on the same subject, in which he prosecutes the principles of M. De la Hire, and applies it to all the varieties of cases which can occur in practice. There is no doubt as to the goodness of the principle, and it has another excellent property, "that the mutual action of the teeth is absolutely without any friction." The one tooth only applies itself to the other, and rolls on it, but does not slide or rub in the slightest degree. This makes them last long, or rather does not allow them to wear in the least. But the construction is subject to a limitation which must not be neglected. The teeth must be so made, that the curved part of the tooth *b*, is acted on by a flat part of the tooth *a*, till it comes to the line A B in the course of its action; after which the curved part of *a* acts on a flat part of *b*, or the whole action of *a* on *b* is either completed, or only begins at the line A B, joining the centres of the wheels.

Another form of the teeth secures the perfect uniformity of action without this limitation, which requires very nice execution. Let the teeth of each wheel be formed by evolving its circumference; that is, let the acting face G C H of the tooth *a* have the form of a curve traced by the extremity of the thread F C, unrolled from the circumference. In like manner, let the acting face of the tooth *b* be formed by unrolling a thread from its circumference. It is evident that the line F C E, which is drawn perpendicularly to the touching surfaces in the point C, is just the direction or position of the evolving threads by which the two acting faces are formed. This line must, therefore, be the common tangent to the two circles or circumferences of the wheels, and will, therefore, always cut the line A B in the same point D. This form allows the teeth to act on each other through the whole extent of the line F C E, and, therefore, will admit of several teeth to be acting at the same time; (twice the number that can be admitted in Mr. De la Hire's method.) This, by dividing the pressure among several teeth, diminishes its quantity on any one of them, and, therefore diminishes the dents or impressions which they unavoidably make

make on each other. It is not altogether free from sliding or friction, but the whole of it can hardly be said to be sensible. The whole side of a tooth three inches long, belonging to a wheel of ten feet diameter, acting on the tooth of a wheel of two feet diameter, does not amount to $\frac{1}{16}$ th of an inch, a quantity altogether insignificant. Conical wheels, or bevelled gear, may be considered as consisting of two cones rolling on the surfaces of each other: let B and C, (*fig. 7.*) be the bases of two cones turning on their centres, having teeth cut on them diverging from the apex A to the bases B and C. These teeth will work freely into one another from the apex A to the bases B and C, when turned round; but the teeth near the point of the cone being small and of little use, may be cut off at G and H. These teeth may be made of any breadth, according to the stress they are intended to bear; and this is of vast importance, because by this method they may be made to overcome a much greater resistance, and work smoother than a face-wheel and trundle of the common form. Besides, these kind of wheels are of singular use to communicate motion in any direction, or to any part of a building, with less trouble and friction than wheels of any other construction.

We shall now venture some remarks upon the manner of constructing wheel-work. Cog-wheels were formerly made of wood, and some are still constructed of that material; but of late years cast-iron wheels have been substituted, and found much superior in strength, accuracy, and durability. Wooden wheels are framed together in segments usually of three thicknesses, to break the joints upon each other. (See *fig. 1.*) The middle thickness is made in six or eight pieces, and left on the inside with straight sides, *x, x*, into which the arms are fitted, and bolted against it. On each side this middle thickness, another is (*XX, fig. 1.*) placed with break joints, and all the three are bolted together to make a solid rim, in which the cogs are to be fixed by mortises, the tenons or tails of the cog being held in their places by a pin driven through each. The arms of wooden wheels are made in different ways; sometimes they are mortised through the shaft, and the ends are notched in the middle of the sides of the octagonal pieces *x, x*, and laying against the face of them behind, are bolted to them to make all fast. This manner of uniting the arms with the rim is shewn at *l* (*fig. 4.*); but this method is not the best, because the mortises weaken the shaft very materially, and it is difficult to get such a wheel off if ever it is required, on a failure of the shaft, &c. On this account, the method called clasp arms is much preferable: it is shewn in *fig. 1.* Four arms *E E, F F*, are used, which are halved into each other, and form a frame as in the figure, leaving a square opening in the centre, and holding the rim of the wheel by their ends, which are bolted to the middle thickness of the rim, as shewn in *fig. 4.* To fit on such a wheel as this, the shaft is made up to a square, by fixing pieces of wood upon its sides; and the wheel being hung upon this, is made fast by wooden wedges driven in all round, the square formed between the arms being rather larger than the shaft, by which means the wheel can be adjusted to come quite true by the wedging. Face-wheels, like *fig. 4.* have sometimes stays or braces proceeding from the back of the rim to some distance along the shaft, where they are received in mortises, as shewn by the dotted lines: these make the wheel exceedingly strong, and keep it very stiff in the square upon its axis, which is very necessary, as the action of the teeth of a face-wheel meeting a trundle, is to throw the wheel back upon its shaft, which tendency these stays effectually counteract. At other times, two sets of clasp arms are used for the same end, one bolted on each side of the middle thick-

ness of the wheel, by the same bolts which pass through both, as well as the wheel, and unite the two sets like one, but of considerable depth, so that the wedging will have a greater effect to keep the wheel in the square. Small wheels are frequently made of plank, solid, without any arms. In this case the middle thickness is made of four pieces, leaving a square hole between them, and they are kept together by a circular ring of segments, bolted on at each side all round, and the joints overlapped. The construction of trundles (*fig. 4.*) has been sufficiently explained, except that they usually have an iron hoop fitted round the circular boards to prevent them from splitting: indeed many large face-wheels have the same. Small pinions are made out of one block of wood, and the cogs are fitted into it much in the same manner as the spokes are let into the nave of a coach-wheel. Iron-wheels either have the cogs cast in the same solid piece with the rim, or mortises are left in the castings for the reception of wooden cogs, as these are found to work much better. The wheel and its arms are sometimes cast in one piece, but for large wheels the rim and its arms are formed in two separate pieces and screwed together. The reason of this is, that in casting a large and extended piece of iron, it frequently happens that some parts will cool in the mould, and become solid before the others: consequently, from their contraction, these parts will be shorter than others which have retained their heat and fluidity longer. This circumstance happening to the arms of a wheel, will either warp the rim out of a true circle, or set the metal of one part upon a strain against another, so that the slightest blow or jar will cause them to snap in such parts. All this danger is avoided by making them in separate pieces, as in *fig. 8*: the end of each arm, as *A B*, has a flat expanded part, which lays against a proper socket within the rim *C D*, and is bolted to it. One-half of this wheel is delineated, with wooden cogs fitted in, at *C D*; and the other half, *F F*, shews the form of a rim, where the cogs and the arms *e f* are cast all in one piece. In the latter case the rim has a rib *g* within it for strength, in the same manner as all the arms have, and which is evidently shewn by the figure. In some situations it is necessary to fix wheels upon long shafts while they are in their places, and cannot conveniently be taken down: in this case such wheels may be made in two halves bolted together. *Fig. 9.* is drawn as if it were two halves of different kinds put together in this manner; the joint being up the middle of the arms *L, L*, and the connecting bolts are plainly shewn. By this method one wooden pattern, if very accurately made, will serve for casting both halves of the wheel. Cog-wheels are found to work with least friction, wear, or noise. When one has wooden, and the other iron cogs, dressed exceedingly smooth and true, the small wheel is usually made with the iron teeth, and the large one with the wooden ones. When such wheels are first set to work, the cogs are smeared with black lead mixed with tallow: this gives them a glossy surface, which greatly diminishes the friction. Hornbeam is found to be the best wood for the cogs, as it is not liable to split or splinter away by long wear. The cogs are held in by a pin driven through the tenon or tail, within the rim of the wheel. The wooden cogs are dressed by chisels to the marks set out, in the same manner as wooden wheels; but the iron cogs are first chipped with a cold chisel and hammer, and then filed true. The great labour of doing this induced Messrs. Boulton and Watts, some years ago, to erect machinery for dressing cogs. The wheel was provided with apparatus to hold it fast at the several divisions, and a strong slider, with a chisel fixed in it, was forced between the rough cogs by the revolution of a cam or heart,

with a sufficient power to cut away a shaving, and form the cog perfectly at twice repeating the operation. Some mechanics dispute the propriety of dressing iron cogs at all; they say, that the exterior surface of the castings have a kind of case-hardening, which is removed by the dressing, and a softer substance of metal exposed for the acting surfaces. This is true, and the objection would have its full force, if it were possible to make castings of wheels perfectly true in the circle, and all the cogs precisely the same size: but as the present state of the founder's art cannot insure this, it is best to chip and file the cogs; accuracy in the form of the teeth being a superior consideration to any quality of their substance. The wheel being made in either of these methods, must next be fixed, or *hung*, upon its shaft. Wheels are generally fixed fast upon their shafts or axes before their teeth are set out; or, if this is not convenient, they are fixed on a temporary spindle to set them out. When the wheel is made of wood, it is fixed upon the shaft, or a temporary axis, and turned round upon its pivots, while a chissel is laid on some fixed support to cut or turn its circumference to a true circle, or else to make a mark to which its rim may be reduced all round. The circumference is then divided, and mortises cut out for every cog; and when these are fixed in they are much larger than they are intended to be, that they may be set out, as above directed, and reduced to their true figure, without absolutely depending upon the accuracy of the mortises which receive them. Iron wheels are, as before-mentioned, treated in a different manner, being cast in the impression of a truly circular pattern made of wood; the cogs cast solid, with the rim or else mortises left all round for the reception of the wooden cogs: in either case the rim is a true circle, and must be fixed upon the shaft exactly by its centre, instead of forming the circumference to the centre, as in the wooden wheel. To do this, the centre hole through the iron wheel is made much larger than the shaft which is to go through it, and the space all round is filled up by iron wedges driven in; so that by means of these the wheel can be fixed exactly true in the centre (or in the round), and also in the flat that is truly perpendicular to the axis. The manner of arranging the wedges is shewn in *fig. 8*, where eight wedges are shewn by *a, a, a, a*, &c. round the shaft R. It is needless to explain how the wheel can, by means of these, be set exactly true, when it is found by turning round upon the pivots of its shaft that any one side of the circumference is farther from the centre than another. For the purpose of setting it square upon the shaft, each wedge-hole is provided with two wedges, one driven in from each side of the wheel, the two laying over each other in the notch or hole in the manner shewn at G. Thus, by gently driving one in, and the other a little outwards, the wheel may be very correctly rectified, if it has any deviation from the perpendicular. This is the usual manner of hanging wheels, and for large wheels it is the only applicable method. *Plate II, figs. 9 and 10*, is a far superior plan for such iron wheels as are not too large or heavy to be turned in a lathe upon a chuck, so that the centre is exposed, and may be bored through with a truly circular hole, and rather conical: of course the wheel is fixed upon the chuck, so that its circumference runs truly; and at the same time the centre is bored, the pitch circle is described upon the cogs, and sometimes the ends of the cogs are turned to reduce them to a true circle, and also the sides, that they may be exactly flat: for, as we have before observed, iron wheels, however true their teeth may be cast, should always have their cogs rather too large, and then be set out and dressed, by chisseling and filing, to make them perfectly correct to the lines thus

described. But to return to *fig. 9*; the wheel being prepared, and its centre bored out, the shaft is turned, as usual, to form its pivots, and, at the same time, the part which is to receive the wheel is turned conical, to fit the hole through the wheel, which being jammed thereon will certainly be true at once: and to prevent it from slipping round upon its axis various means are in use; sometimes a mortise is formed through the shaft A, at the small part of the cone, and a wedge *r* driven through, which is received in notches at the sides of the hole through the central part of the wheel, so that it holds the wheel from turning round on the shaft, at the same time that it drives it hard, and fixes it upon the conical fitting. Another method is to cut a channel along the conical part of the shaft parallel to the axis of it, and another similar one within of the hole through the wheel; then a fillet or feather of iron *s*, (*fig. 10*.) being inserted into the two grooves, effectually prevents the wheel from turning, unless the strain is so great as to cut the feather in two through its whole length, which is easily prevented by making it of a proper thickness. Another method of fixing a wheel is to have a flaunch, or flat shoulder, formed upon the shaft, and the wheel is drawn up against this by two, three, or four screw-bolts going through it, and also through the central part of the wheel, parallel to its axis. This plan is neither so neat, simple, nor strong as the former. When a wheel is required to be sometimes disengaged from its axis, the conical or cylindrical fitting is very convenient. In this case, the wheel should fit up against a flat shoulder, as *a*, in *fig. 11*, and at the opposite side should have a collet, or ring *b*, to confine it, and kept up by a key going through to the shaft R. In this way the wheel will slip round freely upon its axis, and communicate no motion thereto, though it is in constant motion itself: but when they are required to be connected, a locking bayonet, or clutch-box, is used. These pieces of mechanism are constructed in different forms; one of them is shewn in the figure. Strong arms A, A, are fixed fast on the shaft R, just before the wheel either by a circular fitting with a fillet, by a square, or they may be cast with it. Through the extremities of these arms holes are drilled to receive the shanks *f, f*, of the locking bayonet, which are fixed by nuts fast to an arm D, very nearly similar to A A, but it slides on the shaft, and has a central part *g*, with a circular groove round it, in the manner of a pulley, and a fork embracing the central piece in this groove gives the means of sliding the bayonets *f, f*, and D, upon the shaft, so that the points of its shanks intercept the arms of the wheel, so as to carry it round with them and the shaft; but when the points of *f, f* are drawn back clear of the arms of the wheel, it slips round freely upon the shaft. The clutch-box is rather different from this; it is a piece fitted upon the shaft with a fillet, so that it cannot slip round, but will slide endways upon it. The end of the piece is formed with several notches, or indentations across its face, which meet similar indentations in the face of the central part of the wheel, and thus unites the wheel and the shaft when the clutch is slid up to it; but the wheel is disengaged when the clutch is drawn from it. The construction of bearings for the support of pivots at the ends of shafts or spindles, is a matter of great importance in mill-work. The old kind of bearing called brasses is shewn in *fig. 12*. A lump of brass *a*, with a semicircular notch in it, was let into the piece of timber A, which was to support it; and two screw-bolts *b, b*, were fixed through the timber, being half received in notches formed in the sides or ends of the brass *a*: the upper brass, *b*, was exactly similar to the lower, and over it a plate of iron, *d*, was placed, with two holes through it to receive the two bolts *b, b*, and keep them

them together: the nuts *c, c*, upon the tops of the bolts confined the upper brads down, and made all fall neat tight. This kind of brads is not sufficiently strong or steady for all purposes, and, therefore, the bearing shewn in *fig. 13*, has taken its place: in this, *aa* is a cast-iron plate, which is held by two or more bolts *r, r*, down upon the timber or framing of the mill: this piece of cast-iron has two pieces *b, b*, rising up from it, between which a piece of brad, *z*, is brided, and has a semicircular notch in it. Another similar piece of brad is fixed into the cast-iron cap-piece B, which is fitted into the space between the two pieces *b, b*, and is drawn down by nuts upon the two bolts *c, c*. The brasses are prevented from getting out sideways by small fillets projecting from the middle of them, which are received into proper notches in the cast-iron work. In the same manner the cap B is fitted between the pieces *b, b*, with a tongue or fillet, and groove, so that it cannot deviate sideways, and then the bolts have only to draw the brasses down together. Sometimes a bearing of this kind is fitted up, so that it is adjustable in its position a little to adjust two wheels to work accurately with each other, or for other purposes where nicety is required. In this case, an iron plate, D, is bolted down to the framing, and the bearing, *aa*, lays upon it, the same bolts *r, r*, going through both, and also through the framing beneath; but the holes through which they pass in the piece *aa* are oblong, to admit the whole bearing being adjusted sideways. This is done by two wedges *o, o*, inserted at the ends of the piece *aa*, between the two ends of D, which rise up for the purpose, as at *nn*. The bearing rests upon two wedges at *g, g*, and is drawn down upon them by the bolts *r, r*. By these two wedges it can be raised up at pleasure, and by the other two, *o, o*, at the ends, it can be adjusted endways to set the bearing in the exact position required; and the bolts *r, r*, when screwed fast, hold all tight. The best way to make the interior surface of the brasses for a bearing exactly true, is to have them cast solid, that is, the two halves of the brads in one, with a notch which very nearly, but not quite separates them. In this state it can be chucked in a chuck-lathe, and the inside bored or turned out true: then it may be sawn in two halves, and put into its place, to which it should have been previously fitted. Sometimes the bearing is all fitted together and screwed down in its place, and a borer is used to bore or broach out the hole for the brasses, the same as is employed to bore pump barrels. Brads is found, by experience, to be the best substance to form bearings for a cast-iron gudgeon, having the least friction, and, consequently, least wear, of any other substance which can be used. To diminish this friction still farther, friction-wheels are sometimes used. The manner of constructing these, when merely required to support a gudgeon, leaving its own weight to keep it down in its place upon them, is shewn in *fig. 14*. Here *AA* is an iron plate, which is to be bolted down upon the framing: it has holes through it to receive the friction-wheels B, B, and supports bearings *a, a*, for their pivots raised up to a proper height, and provided with sockets for brasses, in which the pivots of the friction-wheels are to lie. The two friction-wheels B, B, as is evident, lie by the side of each other, and the gudgeon, D, of the shaft they are to bear lies upon and between them, so that when it turns round it rolls upon them, or rather, their circumferences move with it, and, consequently, the pivots of the friction-wheels move so slowly, as to diminish the friction very materially, the proportion depending on the relation between the diameters of the wheels B and the gudgeon D. This is not the best kind of friction-wheels, though the simplest. *Plate II.*

fig. 15. of Mill-work, contains a view of another kind, called

friction-rollers: here *AA* is an iron plate bolted down to the framing, and an iron ring, B, rises up from it, all cast in one piece. The interior surface of this ring is turned in the lathe with the greatest accuracy, and the pivot or gudgeon C, which is also turned true, rests in the centre thereof, being supported by its rollers *a, a*, &c. arranged at equal distances round it, and of such a diameter as to exactly fill up the space all round between the gudgeon and the ring. The rollers, it is evident, must be made all of one exact diameter, and extremely true, and they must fill up the space: then the gudgeon being turned round acts upon these rollers, and turns them round also at the same time by this motion. As they have no fixed centre, they also roll round within the ring B, in the same direction as the motion of the gudgeon, but with a very slow motion, which will be in proportion to the relative diameters of the gudgeon C and the ring B. By this means nearly all the friction is avoided, nothing like the sliding of a gudgeon round upon its bearing taking place here; it is all rolling of one surface upon another: and as the contact of two cylinders, supposing them hard, is but a line, the friction, or more properly adhesion, is exceedingly small; and at the same time that the gudgeon is as strongly supported as possible: but this depends upon the hardness of the matter of the gudgeon, the rollers, and the ring B. If the ring and gudgeon are made of hard cast iron, and the rollers of steel at a spring temper, it will act extremely well, though the strain or weight upon the rollers be very great. For light strains softer substances might be used, but not to so good an effect.

The manner of keeping all the rollers at their relative distances from each other, in the ring B, that they may not run against each other, is yet to be explained. Each roller, as shewn at *z*, has a groove turned in it in the middle of its length, so as to reduce it to a small neck in the centre: then an iron ring, L, is provided, which has six holes drilled in it, in the proper positions for the centres of the rollers, that is at equal distances round a circle, which is as much less than the ring E as the diameter of the rollers, or the same quantity larger than the diameter of the gudgeon C. These holes are made to fit the small neck in the centre of the rollers, and to get them in, the holes are cut open from the outside of the ring, so as to become notches; then the rollers being put into them, are all in one cluster, and in this state are introduced into the ring E. They will now be kept at their proper distances asunder, and when the gudgeon C is introduced between them, they will all take their proper places, and lie truly parallel. It is to be observed that the holes or notches in the ring L, do not exactly fit the necks of the rollers, which have therefore considerable play, and but very little friction, for it is not essential to keeping the rollers at their relative distances that this ring should be used, but it will prevent the danger of their getting wrong by accident. To prevent any dust or dirt getting in, which would completely destroy the action of this ingenious mechanism, a circular iron plate is fitted into the ring B, on each side, and both are fixed by small screws going through the ring. One of the plates N must of course have a hole through the middle, to admit the gudgeon. The joints of these plates should be water tight, and then a quantity of oil being poured in, will remain in the bottom of the ring B, and every roller, as it passes, will be kept oiled; though this is no ways necessary to their action. The end plate, which is not perforated, will make a stop to prevent the gudgeon moving endways, and the two plates will keep the rollers from shifting their position on end; but to prevent friction, if ever they come in contact, the ends of the roller should be rather convex, as shewn at *z*, that they may touch in the

centre rather than the outsides; but they will never bear hard against the plate, having no drift that way.

A patent was taken out for these friction rollers many years ago, and a large manufactory was established for making them for various purposes, as carriage and waggon-wheels, the gudgeons of heavy water-wheels, &c.: they were found to possess great advantages, having scarcely any sensible friction when in motion, but were liable to get out of order chiefly from the entrance of dust, which occasioned the rollers to wear out of the round more on one side than the others; and if once by this accident the rollers stood still for an instant, the gudgeon wore a flat place in the two rollers beneath it, and they would never run round again: a very little time would wear this flat side so deep as to stop the rollers, because of the very small surfaces in contact with the gudgeons. For delicate purposes, where hardened steel can be employed for all the rollers and the ring, they are a most admirable contrivance, and the above objections will then apply very slightly; but, as before mentioned, their perfection and durability will ultimately depend upon the hardness of the substances employed.

Fig. 16. represents a fruit of friction rollers for supporting the weight of a heavy vertical shaft, as a horse-wheel, a horizontal wind-mill, a capstan fugar-mill, &c. *A A* is a plate supporting the weight of the shaft; it has a conical eminence upon it, and a hole in the centre of this, which exactly fits the pivot or gudgeon *c*, at the bottom of the shaft *R*: upon this gudgeon a conical plate *B* is formed, exactly of the same shape and size as the conical part of the plate *A*, and between these two plates three or four rollers *a, a*, are situated, and bear the weight of the shaft *R*, or whatever presses upon the plate *B*. The rollers are kept at proper distances asunder by a ring, shewn separate at *L*, with three arms, *n*, projecting from it, which being formed into spindles, pass through the centres of the rollers *a*, and have collets and cross keys to keep them on. In this manner, as the gudgeon and plate *B* turn round, the plate rolls upon the rollers *a, a*, keeping always in the true centre, by the end of the gudgeon *c* fitting the hole in the centre of the plate *A A*; but the weight is supported by the rollers *a, a*, which, at the same time that the upper plate rolls upon them, they roll upon the lower, and thus very considerably diminish the friction which any other kind of gudgeon would have in such a situation.

Shafts.—In almost all modern mills, the shafts or spindles for the conveyance of motion, and support of wheels, are made of iron, either wrought or cast. Square shafts are the most common, but sometimes octagon and round ones are used; and if they are very large, they are cast hollow, like pipes, and the gudgeons fixed in at the ends by wedges; but the pivots should always, if possible, be formed of the same piece of metal, as the slightest possible deviation from the straight line causes them to strain, and work very irregularly in their bearings. In wooden shafts this is impracticable, and it is one of the greatest objections to the use of them. The best method of fixing gudgeons into wooden shafts is shewn in *fig. 17*. Here *A* is the gudgeon, made in cast iron, turned true; it has four leaves, *a, b, c, d*, forming a cross, which is let into the end of the wooden shaft *R*: the front edge of each leaf is considerably thinner than the back, so that a pair of strong iron hoops *r r* being driven tight on the end of the shaft, closes the wood round the cross, and holds it fast, and the back of the leaves being wider than the front, it will not come out. As an additional security, screws are sometimes put in: these are put through holes in the arms of the cross, which are then made flat the other way, and do not go so far into the wood. The screws go into the timber a considerable distance, where a mortise is cut into the wood, to meet

the end of the bolt, and an iron nut is dropped in, to screw the bolt into, when it is turned round by a screw driver. By this contrivance a gudgeon may be fitted into a wooden shaft very fast, but still it will never come into competition with iron shafts, when the gudgeon is made all in one solid piece with the whole of the shaft. A judicious mechanic will never make more than two bearings upon any one shaft, if it can be avoided, because if the three, by any means, as the warping of the frame work, or other cause, get the smallest possible quantity out of the straight line, they can never work well afterwards, but will always strain and wear the bearings with great friction. In very extensive mills, such as woollen and cotton mills, breweries, &c. when the buildings are of great length, it becomes necessary to join several shafts together in length, to reach from one end to the other of a mill. The manner of making the joinings is of some consequence: it is necessary that every shaft should have a bearing at each end, and consequently that the connection of the ends of every one should be made by uniting the ends of the shafts which project beyond their bearings. This can be done in various ways: one is by having the ends of each of the shafts provided with circular heads (see *A B fig. 18.*), which have teeth in one, and corresponding indentations in the other, to receive them, and thus one is made to turn the other about, at the same time that if any slight settlement of the building or other cause depresses one of the bearings, or raises another, so as to put the two shafts out of the perfect straight line they ought always to preserve; these joints will admit the slight flexure, and still communicate the motion of one shaft to the other.

As this accidental settlement in large buildings is almost unavoidable in some degree, care should be taken to make such joints as will admit of a trifling bending. Sometimes the ends of the shaft are made circular, and turned quite true in the lathe; then a metal tube or collar is fitted truly upon both to cover the joint, and connect them, a bolt being put through each end, which unites both shafts with the collar, and thus by means of it causes one to turn the other round. This method is sometimes used to save the great expence of having a bearing at each end of every length of shaft, one bearing to each length being then sufficient, the other end of the shaft being supported by this collar, connecting it with the end of the adjacent length just where it projects beyond its bearing. But this is not a good method, as the shafts are apt to bend and work with so much friction in the bearings, if they get the least out of the straight line, because these kind of joints will not admit any flexure of the shaft, or if they do, they will only bend on one side, whereas it is necessary for the joint to bend successively on all sides, when the bearings are not precisely in a straight line. *Plate III. fig. 19.* represents a coupling-box, used by Mr. Murray of Leeds, for connecting the lengths of a long line of shaft which are to carry a heavy strain: it is so made that it will communicate the motion in the manner of an universal joint, if they should be out of the line. Let *A, B*, be the two shafts to be united; *C, D*, their necks or collars which lay in the bearings: the ends projecting beyond these have boxes *E, F*, fixed on them, either by a square with wedges, or by a round part with a fillet: one of these boxes, *E*, has a piece projecting from the inside of it on each side, and extending into the other box, as is shewn at *a a*, (*No. 2.*), which is an inside view: the other box, *F*, has two similar pieces projecting from it at *b b* into the other box *E*: within the boxes an iron cross *c c d d* is situated; it has screws fixed into the ends of the cross, and by these the motion is communicated: thus, the pieces *a, a*, when the shaft *A* and box *E* are turned round in the direction of the arrow (*No. 2.*) act against the screws *c, c*, of the cross, and turn it

it about : at the same time the other two screws *d, d*, at the other arms of the cross press against the pieces *b, b*, which belong to the box *F* and shaft *B*, thus turning them round : the cross is placed quite detached in the boxes, and thus acts as an universal joint, to communicate the motion of one to the other : the screws *c, d, d*, at the ends of the crosses are only put in that the acting points may be made of steel, and made smooth to have but little friction in these parts. Another method of uniting shafts by Mr. Murray is shewn at *fig. 20* : it has the advantage of requiring only one bearing for every length of shaft, whereas the above method requires one for each end of every length. *A, B*, represent the two shafts ; each has a pivot formed at the end : these pivots are fitted into a coupling piece *C D E*, which is bored out truly to fit them inside, and the outside turned true, with a neck *D D*, which is received and fitted into a bearing : the two shafts *A, B*, are connected with the coupling piece *D*, at *C* and *E*, by means of a cross key *lm*, put through each shaft, and the ends of them received in notches made within side of the coupling piece at *C* and *E*, where it receives the ends of the shafts. It is to be observed that the shafts do not fit tight in these parts *E* and *C*, but only in the pivots *a, b*, within, by which means they have liberty of a little motion, and this without straining the bearing in which *D* runs, because it is only the short coupling piece which is received therein ; and consequently, any trilling deviation from the straight line will not strain it, because of the play allowed in the fittings.

The universal joint, called also Hooke's joint, from its inventor Dr. Hooke, is a method of uniting shafts, which permits them to be rather inclined to each other. This is shewn in *fig. 21*, where *A, B*, are the two shafts, with necks to be received in bearings : each shaft beyond this is formed into a fork, as *C* and *D* ; and these are united by a cross of iron *E*, or sometimes a ring, in which four pins are inserted, and pass through holes in the ends of the forks. On one or other of these pins the joint will bend in any direction, on the same principle as a compass hangs in its gombals, and will communicate a rotative motion from one shaft to the other, when they are rather inclined ; but this inclination should be small, or else the joint will not act well, or without great friction, and irregularity of motion. If an angle of more than 15 degrees from the straight line is required, a pair of slightly bevelled wheels are best.

The regulation of the velocity of a mill is a matter of considerable importance, to preserve an uniformity of motion, either when the force of the first mover is fluctuating, or when the resistance or work of the mill varies in its degree : either or both of these causes will occasion the mill to accelerate or diminish its velocity ; and in many instances it will have a very injurious effect upon the operations of the mill. Thus, in a mill for spinning cotton, wool, flax, &c. driven by a water-wheel, are a multiplicity of movements, many of which are occasionally disengaged, in different parts of the mill, for various purposes. This tends to diminish the resistance to the first mover, and the whole mill accelerates. Or, on the other hand, the head of water, which drives the wheel, may be liable to rise and fall suddenly, from many causes, which great and rapid rivers are subject to, and cause similar irregularities in the speed of the wheel. For such cases, judicious mechanics have adopted contrivances, or regulators, which counteract all these causes of irregularity ; and a large mill, so regulated, will move like a clock, with regard to its regularity of velocity. These regulators are usually termed *governors*, and are made on different principles. Those most generally used are called flying-balls, operating by the centrifugal force of two heavy balls, which are connected and revolve with a vertical axis. *Fig. 22.* re-

presents the simplest form of this ingenious apparatus : *A A* is the vertical axis, which is constantly revolving by the machinery ; at *a a* two arms or pendulums, *a b, a b*, are jointed, and carry at their extremities a heavy metal ball each, as *b b* ; from the pendulums two chains or iron rods, *d, d* proceed, and suspend a collar *e*, which slides freely up and down the axis, and has a groove formed all round it, in which the end of a forked lever, *D*, is received ; and thus the rising and falling of the collar, *e*, produces a corresponding motion of the end of the lever *D* ; but the collar is always at liberty to turn round with the axis freely within the fork, at the extremity of the lever. The operation of the governor is this : when the vertical axis is put in motion, the centrifugal force of the balls, *b, b*, causes them to recede from the centre ; and as this is done both together, they cause the collar, *e*, and the end of the lever to rise up : the balls fly out to a certain height, and there they continue as long as the axis preserves the same velocity ; as it is the property of a pendulous ball, like *b*, to make a greater effort to return to the perpendicular, in proportion as it is removed farther from it, in consequence of the suspending rod being more inclined, and bearing less of its weight. The weight of the balls to return to the axis may be considered as a constantly increasing quantity ; while the quantity of the centrifugal force, causing them to recede from the axis, depends exactly upon the velocity given them. But this velocity increases as they open out, (independently of any increased velocity of the axis,) in consequence of their describing a larger circle. The combination of these oppositely acting forces causes the governor to be a most sensible and delicate regulator. Thus : suppose the balls hanging perpendicular, put the axis in motion with a certain velocity, the centrifugal force will cause the balls to fly out ; and this increasing their velocity, (by putting them farther from the centre, and causing them to revolve in a larger circle,) gives them a greater centrifugal force, which would carry them still farther from the centre, but for the counteracting force, *viz.* the weight of the balls tending to return. This is, as before stated, an increasing quantity, and consequently these opposite forces come to a point where they balance each other ; that is, the balls fly out till their weight to return balances the centrifugal force. But if the slightest alteration takes place in the velocity of the axis, the equilibrium is destroyed by the increase or diminution of the centrifugal force, and the balls alter their distance from the centre accordingly, and by elevating or depressing the end of the lever, operates upon some part of the mill to rectify the cause of the irregularity. In a steam-engine, the lever acts upon a vane or door situated in the passage of the steam from the boiler to the cylinder ; and if the mill loses in velocity, from an increase of resistance, the balls fall together a little ; and the consequent fall of the lever opens the door, or throttle valve a little wider, and gives a stronger supply of steam to restore the mill to its original velocity. On the other hand, if the mill accelerates, the balls open out and then close the vane, so as to moderate the supply of steam. See a more full description of this under *STEAM-Engine*.

A water-wheel is not so easily regulated by the governor, because the shuttle of a large wheel requires a much greater force to raise or lower it, when the water is pressing against it, than the lever, *D*, can at any time possess ; it therefore becomes requisite to introduce some additional machinery, which has sufficient power to move the shuttle, and this is thrown, in or out of action, by the flying balls. The simplest contrivance, and that which we believe was the regulator first used for a water-wheel, was erected at a cotton mill at Belper, in Derbyshire, belonging to Mr. Strutt.

MILL-WORK.

A square well, or large cistern, was situated close by the water-wheel: it had a pipe leading from the mill-dam into it, to admit water; and another pipe from it to the mill-tail, to take the water away: both were closed at pleasure by cocks or sluices. Within the well was a large floating chest, very nearly filling up the space: it of course rose and fell with the water in the cistern, and had a communication by rack and wheel-work with the machinery for drawing the shuttle, so that the rise and fall of the floating chest elevated and depressed the shuttle of the wheel. The lever of the governor was connected with the cocks in the two pipes, in such a manner that when the mill was going at its intended velocity, both of the cocks were shut; but if the water-wheel went too slowly, the falling of the balls and descent of their lever, D, opened the cock in the pipe of supply, and, by letting water into the well, raised the float, and, with it, the shuttle, to let more water upon the wheel, till it acquired such a velocity that the balls began to open out again, and thus shut the cock: on the other hand, if the mill went too fast, the balls opened the pipe of exit from the well, and then the sinking of the float closed the shuttle till the true velocity was restored.

Since this first application of the regulator to the water-wheel, the manner of its operation has been greatly varied; and as the same mechanism is applicable to any kind of mill-work, we shall give a slight sketch of it. Suppose A, *fig. 23*, an axis, receiving its motion from the mill by wheel-work; it is provided with a pair of governors, *ab, ab*, constructed like those before described; and at the lower part of the spindle is a bevilled wheel, R, turning two others, B and C, situated upon one spindle, D, which goes away, and communicates motion to the racks of the shuttle; the wheels, B and C, are neither of them fixed to the spindle D, but both slip round freely upon it, turning in contrary directions, as they receive motion from the opposite sides of the wheel R. A locking clutch, *d*, is fitted upon the spindle between these two wheels, B, C, and can, by moving it one way or the other, be made to lock either one of the wheels to the spindle D, at the same time that it leaves the other disengaged. The locking-box is moved by means of a lever, shewn in *fig. 24*; the arm *m*, having a fork to embrace a groove in the box; the lever is fixed on a vertical axis *n*, which has at the upper end two other levers, *o, p*: these lay one on each side of the vertical axis A, but at different heights, as is evident from the figure. The collar *e*, which is raised up when the balls fly out, is fitted upon a square part of the spindle A, and is formed like a snail or cam, which will act upon either of the levers, *o* or *p*, according to the height at which it hangs upon its spindle. Now when the mill is going with its true velocity, this cam, *e*, is at such a height that it is beneath one lever, *o*, and above the other, *p*, so as to interfere with neither; consequently the locking-box, *d*, remains detached: but on any alteration in the velocity of the mill and the axis A, the balls open or shut, as before explained, and the cam, *e*, either rises or falls, and then it presses against one of the levers, *o* or *p*, and by pushing it away from the axis, it moves the lever *m*, and the locking-box *d*, up to one of the wheels, B or C, which it locks to the axis D, and turns it round in the direction of that wheel's motion, by which it either raises or depresses the water-wheel's shuttle, as is required. This apparatus may, it is plain, be applied to any other kind of mill-work.

Governors or flying-balls are very frequently used in the wind-mills employed for grinding flour: the variable force of this first mover renders some such regulator necessary, to increase the resistance, by allowing a greater feed of corn,

when the mill moves too quickly, and thus in some degree counteracting the irregularity. If the mill moves too slowly, the balls tend to diminish the feed, and at the same time they raise the upper stone, to set them at a greater distance asunder, that they may require less power to drive them, and consequently suffer the mill, as nearly as it can, to retain its full velocity, though the motive force is greatly diminished. This application of the governor was, we believe, first made by the ingenious captain Hooper of Margate, who invented the horizontal wind-mill. (See *WIND-MILL*.) It is a very great advantage, and no wind-mill should be without them. Many wind-mills are provided with flying-balls, which, by very ingenious mechanism, clothe and unclothe the sails just in proportion to the strength of the wind.

In many mills it is of consequence to be able to detect small variations in the velocity, and to ascertain the quantity of them; for the governor only corrects the irregularities, without shewing any scale of them. In cases where this is required, it may be done by a very ingenious instrument, invented by Mr. Bryan Donkin of Fort-Place, Bermondsey. He received a gold medal from the Society of Arts, Manufactures, and Commerce, in 1810, for this instrument, which he calls a tachometer.

A front view of this instrument is represented in *fig. 25*, and a side view in *fig. 26*, of *Plate II*. XYZ, *fig. 25*, is the vertical section of a wooden cup, made of box, which is drawn in elevation at X, *fig. 26*. The whiter parts of the section, in *fig. 25*, represent what is solid, and the dark parts what is hollow. This cup is filled with mercury up to the level LL, *fig. 25*. Into the mercury is immersed the lower part of the upright glass tube AB, which is filled with coloured spirits of wine, and open at both ends, so that some of the mercury in the cup enters at the lower orifice, and, when every thing is at rest, supports a long column of spirits, as represented in the figure. The bottom of the cup is fastened by a screw to a short vertical spindle D, so that when the spindle is whirled round, the cup (whose figure is a fold of revolution) revolves at the same time round its axis, which coincides with that of the spindle.

In consequence of this rotation, the mercury in the cup acquires a centrifugal force, by which its particles are thrown outwards, and that with greater intensity, according as they are more distant from the axis, and according as the angular velocity is greater. Hence, on account of its fluidity, the mercury rises higher and higher as it recedes from the axis, and consequently sinks in the middle of the cup; this elevation of the sides and depression in the middle increasing always with the velocity of rotation. Now the mercury in the tube, though it does not revolve with the cup, cannot continue higher than the mercury immediately surrounding it, nor indeed so high, on account of the superincumbent column of spirits. Thus the mercury in the tube will sink, and consequently the spirits also; but as that part of the tube which is within the cup is much wider than the part above it, the depression of the spirits will be much greater than that of the mercury, being in the same proportion in which the square of the larger diameter exceeds the square of the smaller.

Let us now suppose, by means of a cord passing round a small pulley F, and the wheel G or H, or in any other convenient way, the spindle, D, is connected with the machine whose velocity is to be ascertained. In forming this connection, we must be careful to arrange matters, so that when the machine is moving at its quickest rate, the angular velocity of the cup shall not be so great as to depress the spirits below,

C, into

C, into the wider part of the tube. We are also, as in the figure, to have a scale of inches and tenths applied to A C, the upper and narrower part of the tube, the numeration being carried downwards from zero, which is to be placed at the point to which the column of spirit rises when the cup is at rest.

Then the instrument will be adjusted, if we mark on the scale the point to which the column of spirits is depressed when the machine is moving with the velocity required. But, as in many cases, and particularly in steam-engines, there is a continued oscillation of velocity; in those cases we have to note the two points between which the column oscillates during the most advantageous movement of the machine.

Here it is proper to observe, that the height of the column of spirits will vary with the temperature, when other circumstances are the same. On this account the scale ought to be moveable, so that, by slipping it upwards or downwards, the zero may be placed at the point which the column reaches when the cup is at rest, and thus the instrument may be adjusted to the particular temperature with the utmost facility, and with sufficient precision. The essential parts of the tachometer have now been mentioned, as well as the method of adjustment; but certain circumstances remain to be stated.

The form of the cup is adapted to render a smaller quantity of mercury sufficient than what must have been employed either with a cylindrical or hemispherical vessel. In every case two precautions are necessary to be observed. First, that when the cup is revolving with its greatest velocity, the mercury in the middle shall not sink so low as to allow any of the spirits in the tube to escape from the lower orifice; and that the mercury, when most distant from the axis, should not be thrown out of the cup. Secondly, that when the cup is at rest, the mercury shall rise so high above the lower end of the tube that it may support a column of spirits of the proper length.

Now, in order that the quantity of mercury, consistent with these conditions, may be reduced to its minimum, it is necessary, first, that if M M (*fig. 1.*) is the level of the mercury at the axis when the cup is revolving with the greatest velocity, the upper part M M X Y of the cup should be of such a form as to have the sides covered only with a thin film of the fluid; and secondly, that, for the purpose of raising the small quantity of mercury to the level L L, which may support a proper height of spirits when the cup is at rest, the cavity of the cup should be, in a great measure, occupied by the block K K, having a cylindrical perforation in the middle of it for the immersion of the tube, and leaving sufficient room within and around it for the mercury to move freely, both along the sides of the tube and of the vessel.

The block, K K, is preserved in its proper position in the cup or vessel X Y Z, by means of three narrow projecting slips or ribs, placed at equal distances around it, and is kept from rising or floating on the mercury by two or three small iron or steel pins inserted into the underside of the cover, near the aperture through which the tube passes. It would be extremely difficult, nor is it by any means important, to give to the cup the exact form which would reduce the quantity of mercury to its minimum; but we shall have a sufficient approximation, which may be executed with great precision, if the part of the cup above, M M, is made a parabolic conoid, the vertex of the generating parabola being at that point of the axis to which the mercury sinks at its lowest depression, and the dimensions of the parabola will be determined in the following manner. Let V G (*fig. 27.*) represent the axis of the cup, and V the point to which the mer-

cury sinks at its lowest depression: at any point, G, above V, draw G H perpendicular to V G; let n be the number of revolutions which the cup is to perform in t'' , at its quickest motion; let v be the number of inches which a body would describe uniformly in t'' , with the velocity acquired in falling from rest through a height m to G V,

and make $G H = \frac{v}{314 n}$. Then the parabola to be deter-

mined is that which has v for its vertex, V G for its axis, and G H for its ordinate: at G the cup has a lid to prevent the mercury from being thrown out of it, an event which would take place with a very moderate velocity of rotation, unless the sides were raised to an inconvenient height; but the lid, by obstructing the elevation of the sides of the cup, will diminish the depression in the middle, and, consequently, the depression of spirits in the tube: on this account, a cavity is formed in the block immediately above the level L L, where the mercury stands when the cup is at rest, and thus a receptacle is given to the fluid which would otherwise disturb the centrifugal force, and impair the sensibility of the instrument.

It will be observed, that the lower orifice of the tube is twisted upwards. By these means, after the tube has been filled with spirits, by suction, and its upper orifice stopped with the finger, it may easily be conveyed to the cup, and immersed in the quicksilver, without any danger of the spirits escaping, a circumstance which otherwise it would be extremely difficult to prevent, since no part of the tube can be made capillary, consistently with that free passage to the fluids which is essentially necessary to the operation of the instrument.

We have next to attend to the method of putting the tachometer in motion, whenever we wish to examine the velocity of the machine. The pulley F, which is constantly whirling during the motion of the machine, has no connection whatever with the cup, so long as the lever, Q R, is left to itself. But when this lever is raised, the hollow cone T, which is attached to the pulley, and whirls along with it, is also raised, and, embracing a solid cone on the spindle of the cup, communicates the rotation by friction. When our observation is made, we have only to allow the lever to drop by its own weight, and the two cones will be disengaged, and the cup remain at rest.

The lever, Q R, is connected, by a vertical rod, to another lever S, having at the extremity, S, a valve, which, when the lever, Q R, is raised, and the tachometer is in motion, is lifted up from the top of the tube, so as to admit the external air upon the depression of the spirits. On the other hand, when the lever, Q R, falls, and the cup is at rest, the valve at S closes the tube, and prevents the spirits from being wasted by evaporation.

It is, lastly, to be remarked, that both the sensibility and the range of the instrument may be infinitely increased; for, on the one hand, by enlarging the proportion between the diameters of the wide and narrow parts of the tube, we enlarge, in a much higher proportion, the extent of scale corresponding to any given variation of velocity; and, on the other hand, by deepening the cup, so as to admit, when it is at rest, a greater height of mercury above the lower end of the tube, we lengthen the column of spirits which the mercury can support, and, consequently, enlarge the velocity which, with any given sensibility of the instrument, is requisite to depress the spirits to the bottom of the scale. Hence the tachometer is capable of being employed in very delicate philosophical experiments, more especially as a scale might be applied to it indicating equal increments of velocity.

velocity. But, in the present account, it is merely intended to state how it may be adapted to detect, in machinery, every deviation from the most advantageous movement.

MILLAH, in *Geography*, a mountain of Algiers; 15 miles S.W. of Tiffesh.

MILLAINS, according to Mr. Wingate, are the third subdivision of the primes in Gunter's line; and express the thousandth part of such primes.

MILLAR, JOHN, in *Biography*, professor of law in the university of Glasgow, was born, in 1735, in the parish of Shorts, in Lanerkshire. He received his grammar education at the school of Hamilton, whence he was removed at the age of eleven to Glasgow. He was designed for the church, but the freedom of his enquiries having inspired him with a disinclination to fetter himself by subscription to articles of faith, he turned his thoughts to the bar, and his father acquiesced in the change. After he had finished his studies at Glasgow, he passed about two years in the family of lord Kames as tutor to his son, and derived much information and improvement from his connection with that eminent lawyer. At this period he contracted an acquaintance with David Hume, to whose metaphysical opinions he became a convert, though he materially differed from him upon political topics. In 1760 Mr. Millar began to practise at the bar. He was regarded as a rising young lawyer, when he thought proper to terminate his professional career by becoming a candidate for the vacant professorship of law at Glasgow. To this post he was appointed in 1761, and immediately began to execute its duties. Previously to his appointment the students of the law-course seldom exceeded four or five in number, but his reputation produced such an accession in a few years, that they frequently amounted to forty, and the pupils upon his lectures on government were much more numerous. He lectured in English, and spoke fluently with the assistance of mere notes only. By this method his lectures were rendered full of variety and animation, and at the conclusion of each he was accustomed to explain the difficulties and objections that had presented themselves to his pupils, in a free and familiar conversation. His business as professor was that of commenting upon the institutions and pandects of Justinian, but to this he subjoined a course of lectures on jurisprudence, or the general principles of law, as existing in the codes of all civilized nations: he likewise employed an hour thrice a week in lectures on government, and twice a week on the law of Scotland. A spirit of investigation had given birth to a literary society among the clergy and professors of Glasgow, of which Mr. Millar became an active member. Few men were more ready at discussions of the philosophical kind, and all the branches of science connected with the study of the human mind were extremely familiar to him. In 1771 he published a treatise on "The Origin of the Distinction of Ranks," which contained a view of the changes produced in the several relations of society by the gradual progress of civilization and improvement. It was well received by the public, and has gone through several editions. The copy now before us is one of the third edition, and was published in 1781. The treatise is divided into distinct chapters, which are subdivided into several sections, and in these subjects of much interest and great importance are discussed. The first chapter treats "Of the Rank and Condition of Women in different Ages;" the second "Of the Jurisdiction of a Father over his Children;" the third and fourth "Of the Authority of Chiefs and Sovereigns;" the fifth "Of the Changes produced in the Government of a People, by their Progress in Arts and in polished Manners;" the sixth "Of the Authority of a Master over his Servants."

Mr. professor Millar's enquiries into the English government, which made an important part of his lectures, together with a zealous attachment to the principles of liberty, led him to publish in the year 1787 the first volume of an "Historical View of the English Government," in which he traces the progressive changes in the property, the state of the people, and the government of England, from the settlement of the Saxons to the accession of the house of Stuart. This volume, which is replete with ingenious and profound speculations, would have been followed by a second, bringing down the history to the present time, had not the events which, soon after the publication of this work, passed on the theatre of Europe, so completely arrested the attention of the public, as almost to sink the importance of past forms of government, in the superior interest of those which were expected to arise!

Mr. Millar was an early, active, and persevering advocate for the abolition of the slave-trade, which, in his opinion, could never be palliated, far less justified, by any regulations, either respecting the transport of slaves from Africa to the West Indies, or their treatment, however mild, after their arrival. While he considered domestic slavery as the greatest curse that can befall a nation; as equally subversive of the morals of all ranks in society, he was by no means indifferent to the evils of political slavery. He viewed the attempt to tax America, as an attack on the just rights of the Colonies, and he dreaded the subjugation of that country, as a decisive step towards the overthrow of British freedom. When the French revolution, to which we have already alluded, astonished the world, he was one of those who, without entering into the wild speculations it occasioned, saw in prospect the benefits it apparently promised to Europe; and on that account hailed it as the happiest event that could have happened to the human race. To the deep regret, excited by succeeding horrors, there was, we are told, always joined in his mind, a sentiment of the most profound indignation against that coalition of continental kings, to which he thought they might be justly ascribed.

Among the parties that have divided the present reign, Mr. Millar attached himself to that of the Whigs, and particularly to that branch of them which had first the marquis of Rockingham, and afterwards Mr. Fox at their head. He always warmly supported their principles through all the vicissitudes of administration and public opinion. He was ever suspicious of power, and was a zealous friend to all attempts for restraining the increase of the power of the crown. It was probably in consequence of his jealousy of authority, that, in the limited degree in which he still followed the profession of an advocate, he made it a constant practice to appear on the circuits as counsellor for criminals; and few pleaders surpassed him in the acuteness with which he examined evidence, and the force with which he addressed the feelings of juries. Mr. Millar's researches were by no means confined to politics and law. He was an able and profound metaphysician: his acquaintance with the works of imagination, both ancient and modern was also very extensive, and his criticisms were at once ingenious and solid, evincing an admirable union of acuteness of understanding with an elegant and correct taste. He died on the 30th of May 1801, at the age of 69, leaving behind him several manuscripts, from which, in 1803, were printed, in two volumes, his posthumous works, consisting of an historical view of the English government from the accession of the house of Stuart, and some separate dissertations connected with the subject. Of the style of Mr. Millar's works, it is sufficient praise to say in the words of his biographer, that, "perhaps it would be impossible to find a sentence which can require

require a second perusal to be distinctly understood." Monthly Magazine, vol. ii. See also "An Account of the Life and Writings of John Millar," esq. prefixed to the fourth edition "Of the Origin of the Distinction of Ranks."

MILLARES, or MILLAS, in *Geography*, a town of Spain, in the province of Valencia, on the Xucar; 18 miles N.W. of St. Felipe.

MILLAS, a town of France, in the department of the Eastern Pyrenees, and chief place of a canton, in the district of Perpignan; 9 miles W. of Perpignan. The place contains 1361, and the canton 7029 inhabitants, on a territory of 137½ kilometres, in 9 communes.

MILLEA, in *Botany*, a genus named by Cavanilles in honour of Mr. Julian Milla, head gardener of the Royal Botanical Garden at Madrid.—Cavan. Ic. v. 2. 76. Willd. Sp. Pl. v. 2. 62.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronaria*, Linn. *Lilia*, Juss.

Gen. Ch. *Cal.* Perianth none. *Cor.* of one petal, funnel-shaped; tube elongated, straight; limb spreading, deeply cloven into six, ovate segments, the alternate ones narrower, and tipped with a short, hooked appendage. *Stam.* Filaments scarcely discernible; anthers six, oblong, erect and approaching each other, almost sessile, opposite to the segments of the corolla, and inserted into the upper part or throat of the tube. *Pist.* Germen superior, on a very long stalk, triangular, inclosed in the tube; style thread-shaped, prominent; stigmas three, globular, covered with thick hairs. *Peric.* Capsule oblong, triangular, of three valves and three cells. *Seeds* many in each cell, ovate, pointed, compressed into the shape of a little bag.

Obf. Cavanilles says that the germen being superior, the tube elongated and straight, the anthers nearly sessile and approaching each other, added to the deficiency of a calyx and nectary, are sufficient marks to render our present plant distinct from *Panacratium*, *Amaryllis*, *Crinum* and *Agapanthus*, to all which genera in other respects it seems to have some affinity.

Ess. Ch. Corolla funnel-shaped; with a flat limb, deeply six-cleft. Anthers inserted into the throat of the tube. Germen stalked. Capsule of three cells, with many seeds.

1. *M. biflora*. Willd. n. 1. Cavan. Ic. v. 2. t. 196.—A native of Mexico. It flowers and bears seed in the garden at Madrid in October. *Root* an ovate bulb, with very fleshy oblong fibres, covered with a thin, reddish skin. *Radical-leaves* a foot high or more, awl-shaped, sometimes furrowed on the inner side, smooth and generally longer than the scapus. *Stalks* scarcely a foot high, round, stiff, generally forked and two-flowered. *Braçtes* at the division of the stalk, three, short, acute, withering. *Corolla* white, each segment of the limb streaked at the lower part with green. *Seeds* numerous, black. The analogy of the *Tigridia Pavonia* helps us to understand this root, which Cavanilles appears to have incorectly described.

MILLEFOLIUM, Millefoil or Yarrow, so denominated from *mille*, a thousand, in allusion to the multitude of divisions which compose its leaves. (See *ACHILLEA*.) The name is likewise, for the same reason, applied to an aquatic genus, called Water Millefoil. See *MYRIOPHYLLUM*.

MILLENARII, MILLENARIANS, in *Ecclesiastical History*, a sect among Christians, chiefly in the primitive church, who hold that Jesus Christ is to come again, and reign on earth for the space of a thousand years; during which time, the faithful are to enjoy all manner of temporal blessings; and at the expiration of this term, the day of judgment is to take place.

The Millenarii are also called *Chilists*, *Chilistæ*, from the Greek *χίλις*, *mille*, a thousand.

This opinion of the Millenarii is very ancient, and may be traced back almost as far as the time of the apostles. It had its origin from a passage in the Apocalypse too literally understood, in which mention is made of Christ's reign on earth, &c.

The opinion of S. Papias, in the second century, to whom Eusebius ascribes the origin of this notion of a millennium, says M. Launois, touching the new kingdom of Jesus Christ on earth, after the resurrection, was held for near three centuries, before it was charged as erroneous; as appears from ecclesiastical history. It was allowed of, and followed, under various interpretations, by several of the greatest men among the primitive fathers, as Irenæus, Justin Martyr, Lactantius, Tertullian, &c. Papias, to whom this opinion is ascribed, is represented by Eusebius himself a very credulous person, and it is certain his authority deserves no implicit confidence. From the second dialogue of Justin Martyr with Trypho, we have evidence that the doctrine of the millennium had not in his time the universal reception which Mr. Gibbon the historian, with a view of serving his own purpose, has supposed. Many Christians of pure and pious principles rejected it. This appears from the testimony of Justin, in a passage which has been misunderstood by Mede and Tillotson in consequence of the substitution of *ε* for *ου*. See Thirlby's ed. of Justin, A.D. 1722, and Jebb's ed. A.D. 1719.

Towards the close of the second century, the credit of this opinion began to decline, principally through the influence and authority of Origen, who opposed it with the greatest warmth, because it was incompatible with some of his favourite sentiments.

Nepos, an Egyptian bishop, endeavoured to restore this opinion to its former credit, in a book written "against the Allegorists," for so he called, by way of contempt, the adversaries of the millenarian system. But Dionysius of Alexandria, a disciple of Origen, stopped the growing progress of this doctrine by his private discourse, and also by two learned and judicious dissertations concerning the "divine promises." Jerom is also said to have opposed this millenary reign of Christ. The ancient Millenarians generally held, according to the account of the learned Dr. Whitby, that the temple, or the city of Jerusalem, should be rebuilt, and that the land of Judea should be the habitation of those risen saints, who were to reign on earth a thousand years; that this resurrection was not to be confined to the martyrs only, but that all the just were then to rise and reign with Christ; and that this reign should also extend to the just who were found alive at this first resurrection; that Jesus Christ shall then come down from heaven, and be seen on earth, and there reign with his servants; and that they shall then fare deliciously, and enjoy the richest wines and most delicious fruits, build houses, plant vineyards, and eat the fruits of them, and propagate their species.

Dr. Whitby has clearly proved, that this opinion of the millennium was never generally received in the Christian church, and that there is no just ground to think it was derived from the apostles. Indeed, if we examine their writings critically and candidly, we shall find that they never predicted this event to others, nor cherished the expectation of it in themselves. The passages which seem to countenance this opinion are contradicted by others, which are altogether inconsistent with it; so that the apostles never entertained the delightful hope of seeing their master coming again into the world. It is evident that St. John, who survived all the other apostles, could not have had any such expectation; since in the book of the Revelation the future events of the Christian church, which were not to take place,

many of them, till a long period of years after his death, and some of which have not yet been accomplished, are there minutely described. St. Peter likewise strongly intimates, that the day of the Lord might be said to be at hand, though it was at the distance of a thousand years, or more. St. Paul, in his second epistle to the Thessalonians, labours to remove the erroneous opinion that had been adopted by some, who expected the speedy coming of Christ; he describes a great corruption of the Christian church, which was to happen before the day of the Lord, and this appears by the express language of his prophecy to comprehend circumstances, which did not occur till many ages after they were predicted. But allowing, says bishop Watson, that the apostles did expect that Christ would come in their own time, their mistake in this respect ought not in anywise to diminish their authority as preachers of the gospel. They might be proper witnesses of the life and resurrection of Christ, though they were not acquainted with every thing which might have been known, though, in particular, they were ignorant of the precise time when our Lord would come to judge the world. It can be no impeachment, either of their integrity as men, or their ability as historians, or their honesty as preachers of the gospel, that they were unacquainted with what had never been revealed to them; that they followed their own understandings, where they had no better light to guide them; speaking from conjecture, when they could not speak from certainty; of themselves, when they had no commandment of the Lord. There is therefore no ground for the reflections of Mr. Gibbon, tending to invalidate the truth of Christianity and the doctrine of a future state, and founded on what he conceives to have been the opinion of the apostles and of ancient Christian writers, concerning the millennium. Watson's Apology for Christianity.

The millennium, according to the learned commentator Dr. Whitby, is a glorious state of the church, commencing after the fall of antichrist; and the subsequent conversion of the Jews to the Christian faith, in which it shall flourish in peace and plenty, in righteousness and holiness, and in a pious offspring, for a thousand years, under the undisturbed, though not personal government of Christ, over both Jews and Gentiles, which shall then be united into one church.

MILLENBACH, or MILBACH, in *Geography*, a town of Transylvania; 20 miles W. of Hermanstadt. N. lat. 46° 6'. E. long. 23° 14'.

MILLENNIUM, compounded of *mille*, a thousand, and *annus*, a year, a term literally signifying a thousand years; chiefly used for the time of our Saviour's expected second appearance, and reign on earth.

Mr. Whiston, in several of his writings, has endeavoured to support the notion of a millennium. According to his computation it was to have commenced about the year 1720. See MILLENARIUM.

MILLEPEDA, in *Conchology*, the name given by authors to a species of *Strombus*; which see.

MILLEPEDES, or SLATERS, in *Zoology*, well known insects, formerly used on many occasions in medicine. This insect is otherwise called *asellus*, being a species of *oniscus*, in English the *wood-louse*. (See ASELLUS and ONISCUS.) Mr. Ray describes seven different species of this insect, some of which we see every day, others are more rare. The blue kind, which rolls itself up into a ball, is the proper medicinal kind; though there is another sort of a pale brownish-grey, smaller, flatter, and thinner than the former, and having the last division of the body not annular but pointed, and a forked tail, which is of the same quality. They are

found in cellars, on roofs of houses, old walls, and under stones and logs of wood in cold moist places. They are rather more than half an inch in length, whitish on the belly, with seven pairs of legs, each terminated by a sharp horny claw. The head is somewhat pyramidal, and furnished with two articulated feelers; and the upper part is guarded by a callous, brownish, livid-coloured, jointed armour, consisting of 14 semicircular plates, within which the insect rolls itself like a ball when touched; like some other insects it casts the skin, and carries the young in valvular follicles under the abdomen.

Millepedes are so generally known among the vulgar, that most persons seem to be masters of their medicinal uses, and take them in many cases without any other direction. They were formerly regarded as expectorant, diuretic, and absterfive, and occurred frequently in prescriptions for disorders in the kidneys, and also in obstructions of the viscera, and particularly in the jaundice; and in many other diseases. Although they are retained in the list of *Materia Medica*, the good sense of modern practitioners has nearly exploded the use of them.

The *millepedes preparatae* of the shops, when they were considered as a medicine of importance and beneficial efficacy, were reduced to powder, either by inclosing them in a thin canvas cloth, and suspending them over hot spirit of wine in a close vessel, till they were killed by the steam and rendered friable; or by including them in a proper vessel and drying them with a very gentle heat. The prepared millepedes, or slaters as they are called, have a fetid odour, and a sweetish nauseous taste.

There were also several chemical preparations of millepedes, as spirit, volatile salt, oil, and wine of millepedes.

The college of Edinburgh formerly directed two ounces of live millepedes to be slightly bruised, and digested for a night in a pint of Rhenish wine, after which the liquor is to be pressed through a strainer.

MILLEPORA, in *Natural History*, a genus of the class Vermes, and order Zoophyta. The animal is an hydra or polype; coral mostly branched, and covered with cylindrical turbinated pores. There are 34 species, chiefly inhabitants of the Mediterranean; but some are found on our own coasts, especially in Cornwall, and a few are scattered through the seas of America, India, and Polynesia.

Species.

ALCICORNIS. This species is branched, compressed, straight, with scattered and scarcely visible pores. It inhabits the Indian and American seas, and is frequently found incrusting pieces of rock, gorgonia, and cocoa-nuts; dull white with sometimes a yellowish tinge, smooth, solid, stony, sometimes brittle, with very minute pores.

CERULEA. This is flat, rough, divided into thick plates bending different ways, the tops of which are sometimes lobed, and both sides furnished with cylindrical substellate pores. It is found in vast masses in the Indian ocean; the laminæ or plates are generally half an inch thick, and full of minute pores between the star-like cells. It appears to be an intermediate species between the madreporæ and the milleporæ.

ASPERA. Somewhat compressed, with eminent pores, which are sometimes cleft. It inhabits the Mediterranean seas. It is erect, pointing two ways, roundish, with crowded pores at the branches, cleft on the lower side.

SOLIDA. Turbinate, with crowded angular pores. Found on the shores of Gothland. Tubes of pores with transverse divisions within.

TRUNCATA. Dichotomous, erect, with truncate branches.

MILLEPORA.

It inhabits the Mediterranean and North seas. Is of a yellowish-grey colour, and appearing as if covered with a coat of varnish, very brittle, within greyish, the branches are divaricate, the pores are placed in a quincunx order.

MINIACRA. Very minute, branching into small lobes, and covered with small pores. This species is found in the Mediterranean and Indian seas. It is a beautiful little coral, and the smallest of its genus, being seldom above a quarter of an inch high; the whole surface, when magnified, appears full of minute, white, blind spiracles, and on the tops of the lobes are several scattered holes surmounted with a margin; the base is broad, and with this it adheres to shells, rocks, and other corals.

* **CERVICORNIS.** This is a little compressed, dichotomous, with cells on both sides, tubular, and prominent forests. It inhabits the Mediterranean and Cornish coasts; is from five to six inches high; is of reddish or yellowish-brown, within whitish, branched like the horns of a stag, and appearing as if covered with a varnish; a few of the pores are divided at the base, which are narrow, and of a brittle texture.

* **SKENEL.** Compressed, and slightly branched, with cells on both sides, disposed in alternate rows; cells turbinate, with a gaping mouth and covered with a helmet, the under lip furnished with a small tooth. It is found near Aberdeen, adhering to the rocks; of a bright shining white colour, and appearing as if covered with silver varnish.

PUMILA. This is depressed, with scattered irregular retuse branches every where porous and roughish. It inhabits the Mediterranean, on shells and rocks; is about three inches high, solid, and very much branched, pale grey, and within whitish.

COMPRESSA. This species is furnished with a stem slightly branched, and a little compressed, branches distant, pores every where a little prominent and rough. It inhabits the Mediterranean.

* **LICHENOIDES.** Caulicent, decumbent, with waved nearly opposite denticulate branches; pores a little prominent on the upper side, and striate beneath. It inhabits the Mediterranean and European coasts, on stones and other marine substances; milk-white, very brittle, and about two inches long.

VIOLACEA. Flat, branching, with erect flexuous round branches, a little compressed, with a porous suture encompassing the margin. It inhabits the South-sea islands; is about three inches high; fine violet blue, with two rows of small pores each side the margin, besides the line of larger ones surrounding it; the surface is rough with a few clusters of little studs.

TUBULIFERA. This species is solid, branched, with tubular scattered pores; the branches are confluent, with tapering rough extremities. It inhabits the Sicilian seas; is about four inches high, white, solid; the trunk and branches smooth.

* **FASCIALIS.** Membranaceous, flat, narrow, branched, flexuous, with pores on both sides. It is found on the coast of the Isle of Wight, as well as in the Mediterranean, and grows in irregular masses; the branches are flat, narrow, and irregularly subdivided, which coalesce, twist, and branch out again, leaving hollow spaces between them. It is about six inches in diameter.

* **FOLIACEA.** This is, as its name imports, foliaceous, flexuous, uniting sometimes at the extremities, and is covered with pores on both surfaces, so small as to be scarcely visible. Found growing to an oyster-shell at the Isle of Wight; is from three to twelve inches long, white and stony.

ZRYLANICA. This is composed of thin concrescent irregularly divided membranes, with rows of oblong cells on each side. It is of a white colour, and is found in the Indian ocean.

FORNICULOSA. Crustaceous, with rows of vaulted cells furnished with a small ringent lip, and closed by a membrane. Is found in South America, adhering to other corallines; resembles the *Phylira foliacea*, and is thought by some to be a cedeopore.

CRISTULENTA. Crustaceous, somewhat branching, and irregularly shaped, with rows of oblong cells closed by a membrane, and very entire divisions. It inhabits the salt dykes of Holland, and the Atlantic; is of a greyish-white colour, and forming sub-globular masses.

EUSIA. This also is crustaceous, with open cells pectinate at the lateral margin. It is found in the American ocean, affixed to rocks; the cells have erect subulate teeth, about four on each side.

RETICULATA. Membranaceous, with depressed linear branches rough on the upper surface, with prominent pores. It inhabits the Mediterranean and West Indies; is white, brittle, horizontal, convolute, and much branched; the reticulate branches growing in an undulate manner, and coalescing occasionally; the upper surface is rough, with pointed pores, the under surface is striate.

* **CELLULOSA.** Membranaceous, reticulate, funnel-formed, irregularly waved, and plaited at the margin, with numerous pores on one side. It is found in the Mediterranean and European seas, fixed to marine substances, and resembles a piece of lace, consisting of a flat erect undulated membrane covered with large regular perforations, sometimes disposed in a cup-shaped form, at other times running into loose folds with a waved margin like a ruffle; is about three inches high, solid, brittle, white or yellowish-grey, with very vivacious polypes.

CLATHRATA. Umbilicate, reticulate, with flat branches that are porous on one surface. It inhabits the Indian ocean, and is thought to be an intermediate species between the *Cellulosa* and *Lichenoides*; it is white and seated on a solid centre.

RETICULUM. Composed of branched cancellate threads. It is found in the Mediterranean, covering the surface of shells and the roots of fuci; resembles a spider's web, and is composed of fine capillary threads.

SPONGITES. Caulicent, erect, with angular imbricate branches; it resembles a sponge; is about a foot long; the pores are not visible.

CORIACEA. Sub-membranaceous, semi-orbicular, and nearly horizontal, with a few pores on the lower surface. It inhabits the Atlantic and Numidian seas, covering the stems of the *Fucus cartilagineus*, and forming covers for the chambers of other corals.

CALCAREA. Branched, milk-white, solid, with tapering sub-divisions. It inhabits the Mediterranean; is four inches high. The branches grow smaller towards the end, and are usually regularly sub-divided.

* **POLYMORPHA.** Crustaceous, solid, irregularly shaped, but generally branched and tuberculate, and without visible pores. This is found in most of the European seas, and is the common coral of the shops: in many places it grows in such abundance, that it is burnt for manure; its colour is either red, yellowish, or greenish, and is but seldom white! It was formerly much used in medicine as an absorbent. It is sometimes shaped like the kernel of a walnut, often in large compressed masses, sometimes like a small bunch of grapes, but most frequently in short and rather irregular

ramifications of a chalky tuberculate appearance, and stony substance.

DECUSSATA. Composed of cretaceous erect laminæ, or plates, crossing one another, and uniting differently in different places. It is found on the coast of Portugal, in masses about five or six inches wide.

* **ALGA.** This consists of thin semicircular plates, disposed horizontally: it inhabits the Cornish coast, adhering to and frequently entirely covering the Polymorpha, and is either red, purplish, yellow, or whitish; extremely thin and brittle, with semicircular plates of various sizes, constantly growing horizontally, with their margins bending over, rendering them convex on the upper side, and concave beneath.

* **PUMICOSA.** Irregularly shaped, brittle, rough, and composed of sharp-pointed roundish cells. It inhabits the British coasts, and is frequently found incrusting many of the Sertularia in small irregular masses, appearing very like white sand strongly united together; the branches are generally cylindrical, each about half an inch long; the cells are placed round about in alternate order, shaped like an helmet just opening, with a hole in the middle.

* **TUBULOSA.** This is a parasitic plant, crustaceous, pale purple, with small tubular cells disposed in transverse rows or whorls. It inhabits the Mediterranean and British coasts, and is found frequently encompassing the stem of the Sertularia falcata.

PINNATA. Dichotomous, erect, with tubular pores disposed in a pinnate order. Inhabits the Mediterranean: when fresh caught it is greyish, though sometimes green, is about an inch high, and very brittle.

* **LILIACEA.** Creeping prostrate, in obtuse linear divisions, with tubular pores on the upper surface disposed in transverse rows. It inhabits the Mediterranean and Cornish coasts, and resembles, in some respects, the Tubulosa, but is white.

CARDUNCULUS. This is irregularly shaped, membranaceous, with concentric wrinkles, and central triangular pyramidal tubes. It is found in the Mediterranean, adhering to the Sertularia; it is minute, white, sub-pellucid, and resembling the flower of a thistle.

MILLER, PHILIP, in *Biography*, a celebrated gardener and botanist, was born in 1691. His father had the superintendance of the Physic Garden at Chelsea, belonging to the Apothecaries' Company, and founded by sir Hans Sloane; to which appointment he himself succeeded in the year 1722. In this situation he became distinguished by his practical knowledge of plants, and especially by his skill in their cultivation. The latter was evinced in a paper, communicated by himself to the Royal Society in 1728, and printed in the 35th volume of the Philosophical Transactions, on "a method of raising some exotic seeds," which had been judged almost impossible to be raised in England. This consisted in allowing them to germinate in a bark bed, previously to their being planted in earth. By this means alone, several hard-shelled nuts can be made to vegetate in our stoves; and indeed the practice is founded on a judicious observation of nature's operations. Two years afterwards, Mr. Miller made known, for the first time, the present popular mode of causing bulbous plants to flower in water.

In 1730 he published anonymously a thin folio, accompanied with twenty-one coloured plates, after the drawings of Van Huysum, entitled "A Catalogue of trees, shrubs, plants, and flowers, both exotic and domestic, which are prepared for sale in the gardens near London." The preface is signed by a society of gardeners, amongst whom the name of Miller appears. The work is much more than a mere catalogue, the generic characters being given in

English, and many horticultural and economical remarks subjoined. Most of the plates contain figures of several different plants. This publication is mentioned by Haller, who was uninformed respecting its real author, in his *Bibl. Bot.* v. 2. 229.

In 1731 appeared the first edition of the "Gardener's Dictionary," in folio, the most celebrated work of its kind, which has been translated, copied and abridged, at various times, and may be said to have laid the foundation of all the horticultural taste and knowledge in Europe. It went through eight editions in England, during the life of the author, the last being dated 1768. This forms a very thick folio volume, and follows the nomenclature and style of Linnæus; the earlier ones having been written on Tournefortian principles. A much more ample edition has been published within a few years, making four large volumes, under the care of the Rev. Prof. Martyn. In this all the modern botanical discoveries are incorporated with the substance of the 8th edition. Linnæus has justly remarked, that Miller's was a botanical as well as a horticultural dictionary. We cannot but think that it has proved a powerful means of introducing a taste for scientific botany, amongst those who at first had recourse to it merely as cultivators.

This work had been preceded, in 1724, by an octavo of two volumes, called "The Gardener's and Florist's Dictionary," and was soon followed by "The Gardener's Kalender," a single octavo volume, which has gone through numerous editions. One of these, in 1761, was first accompanied by "a short introduction to a knowledge of the Science of Botany," with five plates, illustrative of the Linnæan system. Miller had been trained in the schools of Tournefort and of Ray, and had been personally acquainted with the great English naturalist, of which he was always very proud. No wonder therefore if he proved slow in submitting to the Linnæan reformation and revolution, especially as sir Hans Sloane, the Mecænas of Chelsea, had not given them the sanction of his approbation. At length more intelligent advisers, Dr. Watson and Mr. Hudson, overcame his reluctance, and, his eyes being once opened, he was no longer behind-hand in deriving advantage from so rich a source. He became a correspondent of Linnæus, and one of his warmest admirers. Although it does not appear that he had any direct communication with Micheli, he was chosen a member of the Botanical Society of Florence, which seems to indicate that they were known to each other, and probably communicated through Sloane and Sherard, as neither was acquainted with the other's language. Miller maintained an extensive communication of seeds with all parts of the world. His friend Houston sent him many rarities from the West Indies, and Miller but too soon inherited the papers of this ingenious man, amongst which were some botanical engravings on copper. Of these he sent an impression to Linnæus; and such of them as escaped accidents, afterwards composed the *Reliquiæ Houstonianæ*. See **HOUSTONIA**.

In 1755 our author began to publish, in folio numbers, his "Figures of Plants," adapted to his dictionary. These extended to three hundred coloured plates, making, with descriptions and remarks, two folio volumes, and were completed in 1760. They comprehend many rare and beautiful species, there exhibited for the first time. The commendable design of the writer was to give one or more of the species of each known genus, all from living plants; which as far as possible he accomplished. His plates have more botanical dissections than any that had previously appeared in this country.

Miller was a fellow of the Royal Society, and enriched its Transactions

Transactions with several papers. The most numerous of these were catalogues of the annual collections of fifty plants, which were required to be sent to that learned body, from Chelsea garden, by the rules of its foundation. These collections are preserved in the British Museum, and are occasionally resorted to for critical enquiries in botany. He wrote also on the Poison Ash, or *Toxicodendrum*, of America, which he believed to be the Japanese Varnish tree of Kämpfer; a position controverted by Mr. Ellis. (See ELLIS.) The latter appears to have been most in the right, which may account for a certain degree of ill humour betrayed by Mr. Miller in the course of the dispute. It is scarcely consistent with the usual candour of the amiable Dr. Pulteney, that in his "Sketches of the Progress of Botany in England," he rather discovers a partiality to Miller on this subject. We cannot account for his omitting all account of so great a man as Ellis, in that valuable work.

Miller continued to attend to his duties and his favourite pursuits to an advanced age, but was obliged at length, by his infirmities, to resign the charge of the garden. He died soon after, at Chelsea, December 18, 1771, in his 81st year, and was interred in the burying-ground in the King's road, with his wife, by whom he had, if we mistake not, several children. One of them, Mr. Charles Miller, spent some time in the East Indies, where he acquired a handsome fortune, and is, we believe, now living in England. This gentleman made some experiments on the cultivation of wheat, an account of which was given by Dr. Watson to the Royal Society. They were intended to shew the wonderful produce to be obtained by division and transplantation, and have often been repeated. An account of the island of Sumatra, by Mr. C. Miller, is printed in vol. 68th of the Philosophical Transactions. The sister of Philip Miller married Ehret, and left one son. See EHRETIA.

In the course of his residence at Chelsea, Miller collected, principally from the garden, an ample herbarium, which was purchased by Sir Joseph Banks. He sent many dried specimens to Linnæus. Pulteney's Sketches. Haller Bibl. Bot. Works of Miller. Dryandr. Bibl. Baekes.

MILLER, JAMES, an English dramatic writer, was born in the year 1703. He was designed for business, and received an education suitable to it, but feeling a repugnance to that sort of employment he went to Wadham college, Oxford, and having completed the usual course he took orders. While at the university he wrote a famous comedy, entitled "The Humours of Oxford," which was performed in 1729. He was author of several other pieces, of which the last was a tragedy, entitled "Mahomet." This had a considerable run, and before its popularity was at all abated, the author died in 1743. He published a volume of sermons, and poems. Biog. Dram.

MILLER, Lady, an accomplished woman, of some literary talents, who published letters from Italy, six vols. 8vo. She resided at Bath-Eaton, near Bath, where she entertained several ingenious persons, who composed a collection of poems, which was afterwards published. She died in 1781.

MILLER, an admirable performer on the bassoon, who flourished in the middle of the last century. The concertos which he performed during many years, at Vauxhall, Hickford's Room, the Swan, Castle, and King's Arms concerts, and the solo parts allotted him by Handel in his oratorios and concertos, always excited attention, were heard with delight, and justly applauded for the sweetness of his tone, and neatness of his execution.

MILLER'S, in *Geography*, a settlement in Kentucky, on a branch of Licking river; 32 miles N.E. of Lexington.

MILLER'S Bay, a bay on the S. coast of Jamaica, N. of Portland Point.

MILLER'S Town, a town of Northampton county, in Pennsylvania, pleasantly situated on a branch of Little Lehigh river; 47 miles N.W. by N. of Philadelphia; containing about 40 houses.—Also, a town in Shenandoah county, in Virginia; 32 miles S. of Winchester.

MILLER'S Thumb, in *Ichthyology*, an English name for the fish called also the bull head, and by authors the cottus; being the *COTTUS gobio* of Linnæus; which see.

MILLERIA, in *Botany*, received its name from Dr. Houston, and was first published by Prof. Martyn, sen., in honour of their common friend, the celebrated curator of Chelsea garden. (See MILLER.) Linnæus, in adopting the name, observes, *Crit. Bot.* 80, that "this American plant, whose close-shut calyx entirely surrounds and protects its one or two seeds, is well bestowed on a man who spared no pains in procuring rare American seeds, and in contrivances for preserving and communicating them."—Linn Gen. 443. Schreb. 579. Willd. Sp. Pl. v. 3. 2328. Mart. Mill Dict. v. 3. Aut. Hort. Kew. ed. 1. v. 3. 266. Juss. 187. Lamarck Illustr. t. 710. Gärtn. t. 168. Hoult. Ic. ined. f. 13. (Randia; *ibid.* f. 14.)—Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ oppositifoliae*; Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* of one leaf, very large, in three deep segments, closed together in a flattish-triangular form, permanent; the two *innermost* equal, nearly ovate, acute, flat; the *outer* one twice as large, roundish, pointed, flat, heart-shaped at the base, most deeply separated. *Cor.* compound, half radiant: *united florets* two, within the smaller segments of the calyx: *female* solitary, within the larger one: the former of one tubular, erect, five-toothed petal: the latter ligulate, erect, obtuse, concave, with one or two notches. *Stam.* (in the united florets) Filaments five, capillary; anthers as many, erect, linear, connected laterally by the middle, acute, as long as the corolla. *Pist.* (in the same) Germen oblong, very thin; style thread-shaped, the length of the petal; stigmas two, linear, weak, obtuse, spreading: (in the female floret) Germen large, triangular; style thread-shaped, the length of the petal; stigmas two, brittle-shaped, long, reflexed. *Peric.* none, except the closed common calyx, become coriaceous and coloured. *Seed* to the united florets none: in the female ones solitary, oblong, obtuse, triangular, tapering downward. *Down* none. *Receptacle* very minute, naked.

Obf. *M. quinqueflora* has the female floret three-cleft; the united ones four in number; calyx accompanied by five membranous internal leaves; style simple in the united florets, cloven in the female.

Ess. Ch. Receptacle naked. Down none. Common Calyx of three permanent valves. Corolla semi-radiant.

1. *M. quinqueflora*. Five-flowered *Milleria*. Linn. Sp. Pl. 1301. Mant. 478. (*M. dichotoma*; Cavan. Ic. v. 1. 58. t. 82. *M. annua erecta, foliis conjugatis, floribus spicatis luteis*; Mart. Decad. 41. t. 41.)

2. *M. maculata*. Mill. Dict. ed. 8. n. 2. (*M. annua erecta ramosior, foliis maculatis, profundius ferratis*; Mart. Decad. 47. t. 47. f. 2.)

Leaves heart-shaped. Flower-stalks forked. Calyx double.—Native of Vera Cruz, Panama and Mexico. Sent to Chelsea garden in 1731 by Houston, but now lost, having no beauty to secure the attention of cultivators in general. Linnæus had it at Upsal, and Cavanilles at Madrid. This is an annual stove plant, flowering in autumn. *Stem* five or six feet high, square, branched, leafy. *Leaves* opposite, stalked, heart-shaped, broad, ribbed, roughish, slightly toothed

toothed or serrated, tapering at the base. *Flowers* small, yellow, in terminal, leafy, slender, forked panicles. The *leaves* of the variety β are more strongly serrated, of a darker green, and blotched with black. The number of *florets* varies.

2. *M. biflora*. Two-flowered *Milleria*. Linn. Sp. Pl. 1301. Hort. Cliff. t. 25. (*M. annua erecta minor, foliis parietaria, floribus ex foliorum alis*; Mart. Decad. 47. t. 47. f. 1.)—*Leaves* ovate. Flower-stalks simple, terminal, aggregate. Calyx single.—Native of the country near Campeachy, from whence it was sent by Houlton in 1730.—Rather smaller, and less showy than even the former. The *leaves* are ovate and triple-ribbed. *Flowers* pale yellow, very small, in terminal tufts.

Willdenow's *M. Contrayerba*, n. 3. Cavan. Ic. v. 1, 2. t. 4, is our *Flaveria capitata* (see FLAVERIA); and his *angustifolia*, n. 4. Cavan. Ic. v. 3. 12. t. 223, is of the same genus. Perhaps *Flaveria* ought to be sunk in *Milleria*, Cavanilles having found a radiant floret. Their habits however are not similar. S.

MILLE-ROCHES, ISLE AU, in *Geography*, a small island of Upper Canada, in the river St. Laurence, containing from 6 to 700 acres of good soil. N. lat. $45^{\circ} 5'$. W. long. $75^{\circ} 40'$.

MILLEROLLE, in *Commerce*, an oil measure at Marseilles = 4 escandaux = 64 Paris pintes, or $15\frac{3}{4}$ English gallons nearly, and weighing about 136 poids de table, or 122lb. avoirdupois. The wine measure of the same denomination is = 4 escandaux = 60 pots; and 4 millerolles of wine = 63 English gallons nearly; and $3\frac{1}{2}$ millerolles are reckoned = a Bourdeaux hoghead.

MILLERS, or PAYQUAGB, in *Geography*, a river of the Massachusetts, which runs W. by S. and falls into Connecticut river, between Northfield and Montague.

MILLERY, a town of France, in the department of the Rhone and Loire; seven miles S. of Lyons.

MILLES, JEREMIAH, in *Biography*, a learned divine and antiquary, was born at High Cleer, in Hampshire, in 1713, of which place his father was minister. He succeeded Dr. Lyttleton as dean of Exeter, and also as president of the Society of Antiquaries, to whose *Archæologia* he was a great contributor. Dr. Milles was a zealous champion for the genuineness of the Rowley poems, of which he printed an edition in 4to., with glossarial annotations. This work laid him open to the attacks of the critics, who were sceptical on these supposed relics of antiquity. The dean died in 1784.

MILLESSOW, in *Geography*, a mountain of Bohemia, in the circle of Leitmeritz.

MILLET, in *Botany*. See MILIUM.

MILLET, the common name of a plant which grows naturally in India, whence it was first imported into Europe. It is greatly cultivated in Italy, Spain, and the southern parts of France, for the food of men as well as that of poultry. It may also be raised in this climate. This is a plant that delights in a light sandy soil, prepared in the same manner as for maize; and in each land it branches out into many stalks, sometimes thirty or forty, not unlike reeds either in their shape or leaves, of which there is one at each joint. The top of each stalk is terminated by a large, loose panicle, which hangs on one side, with a chaffy flower, which is succeeded by a small round seed, about the bigness of turnip or cabbage seed, of a yellowish-white colour in one variety, and of a dark red inclining to black in another, which are the small millet, and the large, a distinction which some make, as only varieties of the same species. It is likewise said to thrive extremely well in strong land; but will

not do in stony ground, or where the bottom is of either a chalky or clayey nature.

Miller advises, that it should be sown in the beginning of April, that it may ripen in August; but in warmer climates, the general rule is to sow it either between the middle and the end of May, or about Midsummer. The former crop is reaped at the end of September, and the latter about the end of October. The seed is usually sown in furrows, very thin, and covered with the plough or rake. The largest sort should be sown thinnest, because it branches most. When the plants are about a month old, the ground should be stirred round them with a hand-hoe, as well to lay fresh earth to their roots, as they require much nourishment, as to clear them from weeds, which they afterwards prevent by over-topping them. At the same time, the millet plants should be thinned out wherever they grow too close, so as to leave, in general, about six inches between each plant. Nothing more is necessary to be done till harvest, except that, when it begins to ripen, great care must be taken to protect it from birds, which would otherwise soon devour it. The returns of this crop are very great; it is not easily hurt by drought or rain, nor is it subject to blight. Frequent showers of rain are of great service to it whilst in its young growth.

As soon as the crops are ripe, the panicles of the plants are cut off near the uppermost joints of the stalks with a knife, and put into baskets or sacks, in which they are carried home, when they are then laid up in heaps covered with old cloths, and after remaining in that situation five or six days, spread upon the barn floor, threshed out with a flail, and cleansed like other sorts of grain. Great care must be taken to dry it well in the sun, before it is laid up in the granary; as it soon spoils if the least moisture be left in it; being of all grains the most difficult to keep, unless it be thoroughly dry; but on the other hand, none keeps longer, or better, after it has been well dried. It is not liable to the weevil; but it should be turned from time to time in the granary. It has been constantly found that the late sown crops are the most defective, and that their panicles are smaller than those of the same grain sown at an earlier period.

But the small white millet is the most delicate, and the best for puddings, &c. The red is larger and coarser, and used for pigeons, poultry, and swine, after being ground to meal; it is very good fodder for cattle, either green or after its grain is threshed out. From its numerous roots, large size, and quick growth, it is a sort of crop that exhausts the soil greatly, and of course must be well guarded against in that respect.

The common millet was originally brought from the eastern countries, where it is still greatly cultivated: from whence we are furnished annually with this grain, which is by many persons greatly esteemed for puddings, &c. This is seldom cultivated in England, but as a curiosity in small gardens, or for poultry, as its seeds generally ripen well.

Millet is reckoned by Pliny the most fertile of all grain; one grain of it producing three Roman sextaries.

Millet is cooling, drying, and binding, somewhat windy, and not easily digested; a strong decoction of it with figs and raisins, mixed with wine, and drank warm in bed, is a very good sudorific, though it is seldom used.

Millet, by consent of authors both ancient and modern, is refrigerating and drying; it is of bad juice, difficult of digestion, binds the belly, and generates flatulencies; it is however well known to be a very grateful food to many nations at present. In former times it served to make bread, under a dearth of better corn, as we are assured by Dioscorides,

corides, Pliny, Galen, and others of the ancients. Among the Italians, says C. Boehne, leaves are made of millet, which are yellow, and eaten hot by many, not out of necessity, but for their sweetness; but when this bread is grown hard, it is quite black. Of the flour of millet and milk, the Italians make fine cakes, which must be eaten as soon as dressed, or else they become glutinous, and ungrateful to the taste.

A pudding prepared of millet, boiled in milk, with an addition of butter, and sugar sprinkled over it, is much in request among the Germans at present; and these puddings have been long ago introduced into England, and are still in fashion.

The flour of millet was formerly used in fomentations, for the gripes, and for pains of the head and nerves; it was applied externally in bags, because the use of it in cataplasms was difficult, on account of its friability. If the membrane of the brain happens to be wounded, it is excellently coagulated, says Aëchigenes, by infusing thereon the juice of calaminth, and sprinkling it with dry flour of millet. A decoction of millet, with figs and raisins, is called, by Heurnius, a noble sudorific and diuretic. Or, take of a decoction of millet, boiled till it bursts, four ounces; white wine, two ounces: let the patient take it hot. Chesneau.

Millet is diuretic and astringent; the seeds are of extraordinary service in diseases of the lungs, and exulcerations of the kidneys: made into a cataplasin, they are anodyne and resolvent. Hist. Plant. adscript. Boerhaave.

MILLET, *Indica*. See HOLCUS.

MILLEVANT, in *Geography*, a town of Prussia, in the province of Pomerelia; 16 miles S. S. E. of Dantzic.

MILLEVILLE, ALESSANDRO, in *Biography*, an excellent organist, born at Ferrara, much celebrated in Italy at the beginning of the seventeenth century. He was successively patronized by the king of Poland, the emperor of Germany, and the duke of Ferrara. He was also a voluminous composer, as appears by all the catalogues of the time; in which we find the following list of his works: Messe e Salmi a 3 voci. Concerti a 2, 3, & 4 voci, libro 1. Motetti a 3, 4, 5, & 6 voci, libro 7mo. Novelli fiori a 2 & 3 voci, libro 6. Litanie di B. V. a 3 voci: and, lastly, he published at Venice, 1622, a work intitled "Gemme Sacre," and in the same city, 1629, another book of motets. Walther.

MILLEVILLE, in *Geography*, a town of Sweden, in the province of Warmeland; 25 miles S. of Carlstadt.

MILLIARE, or MILLIARIUM, among the Romans, denoted a *mile*, consisting of a thousand paces, *mille passus*; whence the name.

In the Roman empire, the milliaria, in all the great roads, were marked with stones, or columns erected for that purpose; commencing from a column in the heart of the city, called *milliare aureum*.

Those columns were also hence denominated *milliary columns*.

MILLIARIA CANTONS. See CANTONS *Equitata*.

MILLICO, GIUSEPPE, of Naples, in *Biography*, arrived in England 1772, from Vienna, where he had acquired great applause as a singer and actor, in Gluck's operas of "Orfeo," "Alceste," and "Paride ed Elena," and as a singing master, by making Gluck's niece one of the most expressive singers then alive.

This judicious performer and worthy man, who was not an Adonis in person, and whose voice had received its greatest beauties from art, found the musical part of our nation in no favourable disposition towards him. The admirers of Tenducci and Guadagni, as well as the Cocchi, Guglielmi, Giardini, Vento, and Bach parties, however hostile in other

particulars, all agreed in decriing every part of that opera in which their favourite had no concern. Sacchini, who arrived here soon after, was involved in these cahals. None of the friends of their predecessors would allow that Millico could sing or the new master compose. Violent and virulent means were used to prison, or at least to shut the ears of the unprejudiced public; but not with much success. Indeed, at first both the music and performance were frequently hissed; but, at length, Sacchini's compositions were generally allowed to be admirable, and Millico's importance was manifested by a crowded house at his benefit, composed of the first persons for taste and rank in the kingdom; and at the end of the next season, several who had boldly pronounced that neither Sacchini could compose nor Millico sing, would have given a hundred pounds if they could have recalled their words, or made their acquaintance forget they had been guilty of such manifest injustice and absurdity.

The cauzonets of his composition, in singing which he used to accompany himself on a small harp slung over his shoulder, are still as *muscadei camera*, elegant and pleasing. Not many years after he left this country, where he remained two seasons, he was afflicted with blindness; but being received in the chapel royal at Naples, he performed in that melancholy state a considerable time, till other infirmities came on, when he threw himself into a convent to end his days. He was living when the French invaded Naples; but whether the turbulence of the times suffered him to live or die in peace, we are unable to affirm.

MILLIGRAMME, in *Commerce*, a French measure of weight = .0154 English grains. See WEIGHT.

MILLILITRE, a French measure of capacity = .06103 English cubic inches. See MEASURE.

MILLIMETRE, a French measure of length = .03937 English inches. See MEASURE.

MILLING, in the *Manufactories*, an operation called also *fulling*.

MILLING, or *throwing of silk*, is the last preparation of silk before dyeing; serving to twill it, more or less, according to the work for which it is intended.

To prepare the silk for milling, they first put it in boiling water, inclosed between two linen cloths. The mill is a square machine, composed of several pieces of wood, mortised in each other, so as to form a kind of large cage, in the centre of which are two wheels placed parallel over each other, whose axis bears on two posts. When the machine is simple, a single man turns these wheels by means of a little cog, in which they catch, and a large handle.

The wheels, put in motion by the handle, communicate their motion to eight windles, or reels, or even more, according to the largeness of the machine; on the flights or arms of which the silk is wound from off two rows of bobbins placed on each side of the machine; each row at the height of one of the two wheels in the centre. These bobbins have their motion by means of leathern thongs, which bear on little cylinders of wood that support them, and turn at length on the two wheels at the centre; so that the silk on each bobbin twirls as it winds, and forms its separate skin.

The smallest wheel moves two hundred of these bobbins, over which a single person is sufficient to inspect, to put new bobbins or spoils in lieu of those discharged of their silk, and to knot the ends when they break. See WINDING of *Silk*.

MILLINGTONIA, in *Botany*, a supposed new genus, consecrated by the younger Linnæus, to the memory of sir

Thomas

Thomas Millington, Savilian professor at Oxford, who is recorded by Grew to have first suggested to him that the anthers of plants were their male organs.—Linn. Suppl. 45. Schreb. 425. Willd. Sp. Pl. v. 3. 382. (where the name is thrice written *Mallingtonia*, by mere inattention.) Juss. 138. Class and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Bignoniæ*, Juss.

The fruit being unknown, the generic character in the *Supplementum* has always been incomplete, and is now found insufficient to distinguish the plant in question from *Bignonia*, to which genus it is referred by Dr. Roxburgh.

Bignonia suberosa. Roxb. Coromand. v. 3. 11. t. 214. (*Millingtonia hortensis*; Linn. Suppl. 291.)—Koenig first observed this fine tree in the gardens of the Rajah at Tanschuur, or Tanjore, but did not meet with the fruit. His manuscript however does not imply that none is ever produced there. From hence some plants were brought to Madras, and one to Calcutta, where Dr. Roxburgh informs us it is now an elegant tree, about thirty feet in height, blossoming at the close of the rainy season, and ripening seeds in March. The *trunk* is straight, with a light ash-coloured, deeply cracked, spongy bark. *Leaves* opposite, repeatedly pinnate, about two feet long; leaflets ovate, pointed, smooth, serrated in Roxburgh's figure, but in his description, like the Linnæan specimens, entire, and conveying some idea of the foliage of Catalonian Jasmine. *Panicles* terminal, large, cross-branched, many-flowered, smooth. *Flowers* two inches long, tubular, slender, white, delightfully fragrant; their upper lip erect, cloven half-way down; lower in three equal, ovate, three-ribbed, reflexed segments. *Pod* a foot long, not an inch broad, compressed, nearly smooth, pointed at each end. *Seeds* winged.—The native country of this plant has not yet been ascertained.

MILLINGTONIA is now applied as the name of a new East India genus in *Diadelpbia Decandria*, by Mr. Donn in *Hort. Cant.* ed. 5. 180. Of this we presume Mr. Brown to be the author, and that it will be defined in the new edition of Mr. Aiton's *Hortus Kevenfis*. Three species are enumerated by Mr. Donn, *M. trinervia*, *striata*, and *semialata*; all stove shrubs, which seem not yet to have flowered at Cambridge. This genus is placed between *Hedysarum* and *Indigofera*.

MILLION, in *Arithmetic*, the number of ten hundred thousand; or a thousand times a thousand.

A million of gold, or million of money, is sometimes understood of a million of pounds; and sometimes of a million of crowns.

MILLION *Bank*. See *BANK*.

MILLMOTH, in *Natural History*, the name of an insect approaching to the nature of the beetle, but having no sheath wings. It is common in the abode of millers and bakers, and other persons who deal in meal.

MILLOT, CLAUDE-FRANÇOIS-XAVIER, in *Biography*, a well-known French writer, was born at Befançon in 1726. He was brought up among the Jesuits, and devoted himself to the duties of the pulpit; but when the period for public exertion arrived, either the weakness of his voice, or a natural timidity, convinced him that he could not make progress as a public orator. He, therefore, undertook a professorship of history at Parma, by the recommendation of the prince. He filled this office with high reputation, and upon his return to France was appointed preceptor to the duke d'Enghien. He died in the year 1785, at the age of 59. D'Alembert said of the abbé Millot, that he was the person of all others whom he had known, that had "the fewest prepossessions and the fewest pretensions." In society he was modest and rather reserved in his manners, but every

thing which he said was sensible and judicious. His works also exhibit the same candour and cool judgment which were visible in his conversation. They are chiefly historical abridgments, written with care and correctness, in a natural and rather elegant style. The principal are: "Elemens de l'Histoire de France, depuis Clovis jusqu'à Louis XV.," 3 vols. 12mo.; "Elemens de l'Histoire Univerfelle," 9 vols. 12mo.; "Memoires Politiques et Militaires pour servir à l'Histoire de Louis XIV. et de Louis XV.," &c. He published also "L'Histoire des Troubadours," in 3 vols. which work was chiefly drawn from the papers of M. de Sainte Palaye; some "Discourses" read before the academy of which he was a member, and a translation of select harangues from the Latin historians.

MILLOWITZ, in *Geography*, a town of Bohemia, in the circle of Saatz; 10 miles W. of Saatz.

MILLSTREET, a post-town of Ireland, in the county of Cork, chiefly remarkable for a good inn, at which travellers to Killarney usually pass a night. It is 134 miles S.W. from Dublin.

MILLTOWN, a town of America, in the state of Delaware; two miles from Wilmington.—Also, a town in Northumberland county, Pennsylvania, on the E. side of the W. branch of Susquehannah river, containing about sixty houses; 14 miles N. by W. of Sunbury.

MILLTOWN, a post-town of Ireland, in the county of Kerry, which promises to become a good market town by the exertions of sir William Godfrey, and the convenience of water carriage, the tide bringing sloops up the Mang very near to this town. It is 169 miles S.W. by W. from Dublin, and nine miles N.W. from Killarney. Carlisle.

MILLVILLE, a post-town of Cumberland county, New Jersey; 196 miles N.E. from Washington.

MILLWOOD, a post-town of Frederick county, Virginia; 68 miles from Washington.

MILNTHORP, or MILTHORP, a sea-port and market-town in the parish of Heversham, Kendal ward, Westmoreland, is situated near the mouth of the Can, at the distance of five miles from Kendal, and 251 from London. It consists chiefly of one street, which is pretty well built; and at the E. end there are some good houses, in pleasant and open situations. This town is the only sea-port in the county, and has several vessels belonging to it, which trade principally to Liverpool, Port Glasgow, and Annan in Scotland. Here are three rope-yards, two paper-mills, one flax-mill, and one cotton-mill. The market day is Friday, and there is an annual fair on Old May day. A very handsome bridge is thrown across the river Betha, which flows through the town. The resident population here, according to the parliamentary returns of 1801, amounted to 968 persons; 459 males, and 509 females, of which number 113 were returned as employed in agriculture, and 170 in trade and manufactures.

The country around this town is pleasingly diversified with hill and dale, and embellished by a variety of elegant mansions. Of these that of Dallam Tower, the seat of Daniel Wilson, esq. is the most conspicuous. It is situated at the foot of a hill, which rises rapidly from its base, and is covered to the summit by a profusion of trees. In front extends a fine park, adorned with wood, the ground of which rises as it recedes from the house. At Beerham-hill, near this mansion, is a waterfall on the river Beele, well deserving the attention of the curious traveller. Housman's Topographical Description of Cumberland, Westmoreland, &c. 8vo. Carlisle's Topographical Dictionary, 4to.

MILO, in *Biography*, a name that frequently occurs in the Roman classics: we shall notice three persons of note.

Our

One was celebrated at Crotona, in Italy. It is said that he carried on his shoulders a young bullock four years old, and afterwards killed it with a single blow of his fist. He was seven times crowned at the Pythian games, and six times at Olympia.—The second was Titus Annius, a native of Lanuvium, who attempted to obtain the consulship at Rome. Clodius the tribune opposed his views, yet Milo would have succeeded, had not an unfortunate circumstance taken place between his furie and that of Clodius as he was going to the country. Clodius and eleven of his servants were killed, and the body of the murdered tribune was carried to Rome and exposed to public view. Cicero, as is well known to every classical student, undertook the defence of Milo, but with no effect; he was condemned and banished to Massilia.—A third of this name was a general of the forces at Parennum, and that he might not forget the duty and allegiance which he owed to his sovereign, Pyrrhus sent him, as a present, a chain, which was covered with the skin of Nicias the physician, who had perfidiously offered the Romans to poison his sovereign for a sum of money.

MIL0, anciently *Milos*, in *Ancient Geography*, one of the largest and most elevated islands in the southern part of the Grecian Archipelago. According to Thucydides, it was independent, and enjoyed perfect freedom long before the Peloponnesian war. The inhabitants, strongly solicited by the Athenians on the one hand, and on the other attached to the Lacedæmonians, from whom they had descended, wished, in the midst of this terrible war, to remain quiet and to observe a wise neutrality. At this conduct the Athenians were so irritated, that they dispatched Nicias with a fleet of sixty ships, and 2000 land forces to punish them for refusing to furnish their quota of troops. Nicias ravaged this island, but failed with his feeble army to take the town, which was defended by all the inhabitants, assembled for this purpose. Some time after the Athenians sent two other generals, with a more numerous army, who were not more successful than Nicias; but at length, when Philocrates brought fresh troops, the Milots were reduced to the greatest extremity, and obliged to surrender. The Athenians, implacable in their resentment and ferocious in their vengeance, massacred, without discrimination, all the men who were capable of bearing arms, and made slaves of the women and children, whom they carried away to Attica. They then sent 500 persons to repeople the island, and to take possession of the property of those whom they had murdered. In the mean time, the Athenians, conquered in their turn by Lysander, commander of the Lacedæmonian troops, and compelled to surrender at discretion, found themselves constrained to recal their colony; and those who remained of the unfortunate Milots were then enabled to return, and to reinvest themselves with the property which had been taken from them. This island, like all those of the Archipelago, passed under the dominion of the Romans; it afterwards made part of the empire of the East. Marco Santo united it, with all the Cyclades, to the duchy of Naxos; and it was in process of time detached from this duchy in favour of Francesco Crispo; and at length subjected to the Ottoman empire, under which it has lost, together with its liberty, its importance.

Milo is about sixty miles in circumference; it is divided in its middle, and almost through its whole breadth, by a deep bay: this is one of the finest harbours in the Mediterranean, sufficiently spacious to contain a fleet, and to keep the ships belonging to it sheltered from all winds. The anchorage is excellent, particularly at the head of the gulf and near the E. coast; the bottom has a fine sand, and vessels come to anchor there in from 12 to 18 fathom water. Small

craft can approach nearer the coast, and carry out moorings to the rocks of one of the grottoes. Another anchorage, more convenient, and also less exposed to the action of the winds and the violence of the sea, lies on the W. coast, in a cove called "Patricha."

The entrance of the harbour first mentioned faces the N.W.; it is very wide, and ships approach very near to the coasts that form it, without risk. To the starboard, or right, they have Cape Veni, and to the left Cape Lerida; the gulf then contracts between Cape San Dimitri and Cape Bombarda. At the latter, a high mountain, in the form of a sugar-loaf, bears on its summit a village, called "Sifour," surrounded by walls, whence it has the name of Castro: here the pilots for the Archipelago reside. As the air here is pure and wholesome, it is more populous than the capital of Milo, and the inhabitants exhibit signs of vigour and health, not common in other parts of the island. It is not improbable that the principal place of the isle of Milo was near the site of Sifour, which commands an extensive prospect; more especially as the ancient habitations of the Archipelago are built on eminences the most lofty, and the most rugged of access. Near this place are considerable ruins, fragments of columns of Parian marble, and subterraneous galleries, antique catacombs, which furnish funeral inscriptions, vases, idols, and medals, and other remains of a considerable city. The women of Sifour, or Sefours, employ themselves the whole year in knitting cotton stockings, and making coarse calicoes. The men cultivate the earth, or are mariners. Near this place, on the summit of a hill, is at present a church of Caloques, built, as Olivier conceives, on the ruins of a temple. However, the capital of the island is a town of the same name, situated on a plain formerly not inferior to any other of the Archipelago, but now presenting scarcely any thing but ruins. Scarcely do forty families drag on their unfortunate existence, with consumptive aspects, in a town which reckoned 5000 inhabitants within its walls. At the beginning of the last century, Tournefort discovered, in 1700, that the air of Milo was insalubrious, and that the inhabitants were subject to dangerous disorders; but the unwholesomeness of the air must have increased very much since that epoch. In traversing the island to the monastery of St. Marino, Mount St. Elias, the most lofty point in the island, and the volcanic mountain of Calamo, the country presents various traces of its volcanic origin. At the distance of a quarter of a league from Milo alum is formed, which has been mentioned both by ancient and modern writers. In the same grotto that furnishes this alum, are also found crystals of gypsum, but the heat is such as not to admit its being examined for any long time. The baths called "Loutra" were also situated in this quarter. The water is strongly charged with alum and marine salt. These baths were anciently much frequented by Greeks, who repaired hither from all the Cyclades in order to obtain relief in disorders of the skin, as well as in rheumatism and palsy. Spacious grottoes occur frequently, and in these are subterraneous caverns, full of turnings and twinings, and into which the descent is steep and laborious. The chambers which they contain appear to have been formerly used as habitations and places of concealment.

Near the site of an ancient town, called "Clima" by the modern Greeks, are sepulchres or catacombs, in which, at an unknown period, the inhabitants of Milo deposited their dead. Each of these catacombs generally contains seven sarcophagi five and a half or six feet long, and a foot or fifteen inches deep, surmounted by an arch and dug in the rock. The whole island indicates a subterraneous configura-

gration; and in several places the ground which rebounds under your feet apprizes you that it covers vast cavities. Every appearance testifies, that the stones and pebbles which are found here have been thrown up by the explosion of a volcano; boiling waters issue on all sides; pumice stones are scattered abroad; sulphur is formed in abundance, and shews itself on the surface of the ground. Nevertheless, the vegetable earth, which mostly covers the island, gently warmed by subterraneous heat, is very productive. Corn and cotton are here of an excellent quality; the vines yield good wine, and the trees afford delicious fruits; but the quantity of lands that lie fallow announces an excessive diminution in the population, as well as the criminal indifference of the government. Ships still come to Milo to fetch away a great quantity of the solid lava, of which mill-stones are made, which are transported to several countries of the Levant, particularly to Egypt and Constantinople. The island likewise contains many mines of iron and ferruginous pyrites, from which no advantage is derived. Under a liberal administration other valuable articles might be found, and the island might even cease to be an unhealthy abode. The whole population at present does not amount to 500 persons, and this small number would daily decrease, if it was not kept up by emigrants from the Morea, where distress constrains them to seek new habitations, and who are attracted to Milo with a view of cultivating the lands. The captain-pacha has some difficulty in levying 2500 piastrres by way of impost. N. lat $36^{\circ} 40'$. E. long. $24^{\circ} 30'$. Sonnui and Olivier.

MILOPOTAMO, in *Geography*, a town and fortress of the island of Candia; 28 miles W.N.W. of Candia.

MILORRA, a small island in the East Indian sea, between Ternate and Tidor.

MILOSŁAW, a town of the duchy of Warsaw; 20 miles S.S.W. of Gnesna.

MILPHOSIS, $\mu\lambda\phi\sigma\iota\varsigma$, a Greek word used by the ancient medical writers, as a name of the disease of the eye-lids, by which the hairs fall off from them, and the edges become red and tumid.

MILREA, or MILREE, in *Commerce*, a money of account in Portugal, so called, because 1000 reas, or rees, are = 1 milree. In the notation of accounts, the milrees are separated from the rees by a crossed cypher, called "Cifraon," and the milrees from the millions by a colon; thus, Rs. 2 : 700 \oplus 500, means two thousand seven hundred mil. and five hundred rees. As the crusado of exchange, or old crusado, is 400 rees, the new crusado, 480 rees, the testoon, 100, and the vinten or vintem, 20 rees; the milree is = $2\frac{1}{2}$ old crusados = $2\frac{1}{2}$ new ditto = 10 testoons = 50 vintens. The milree valued in gold is worth $67\frac{1}{2}d.$ sterling, and the same in silver is worth $68\frac{3}{4}d.$ sterling. The milree is also a gold coin, struck for the Portuguese possessions in Africa in 1755; it weighs 19 $\frac{1}{2}$ grains, and contains, in pure gold, 18.1 grains, and is valued at $3s. 2\frac{1}{2}d.$ sterling. See COIN.

MILSTATT, or MUHLSTADT, in *Geography*, a town of the duchy of Carinthia, situated on the Militatter see; 40 miles N. of Goritz. Militatter see is a lake of Carinthia, 9 miles E. of Saxenburg.

MILT, in *Anatomy*, a popular name for the spleen.

MILT, or Melt, in *Natural History*, the soft roe in fishes; thus called because it yields, by expression, a whitish juice resembling milk. See ROE.

The milt is properly the seed, or spermatic part of the male fish.

The milt of a carp consists of two long whitish irregular bodies, each included in a very thin fine membrane.

M. Petit considers these as the testicles of the fish wherein the seed is preserved: the lower part, next the anus, he takes for the vesiculae feminales. Vide Mem. Acad. R. Scien. anno 1733, p. 291.

In the milt of a living cod-fish there are such incredible numbers of those small animalcules found in the male-seed of all animals, that in a drop of the juice of it, no more in quantity than a small grain of sand, there are contained more than ten thousand of them; and, considering how many such quantities there are in the whole milt of one such fish, it is not exceeding the bounds of truth to affirm, that there are more animals in one milt of it, than there are living men at one time upon the whole face of the earth. However strange and romantic such a conjecture may appear at first sight, a serious consideration, and calculation, will make it appear very plain. A hundred such grains of sand as here mentioned, will make about an inch in length; therefore in a cubic inch there will be a million of such sands.

The milt of one of these fishes is frequently about the quantity of fifteen cubic inches, it must therefore contain fifteen millions of quantities as big as one of these sands; and if there be ten thousand animals in each of these quantities, there must be, in the whole, a hundred and fifty thousand millions: which is a number vastly exceeding the number of mankind, even though we were to suppose the whole earth as populous as Holland. See Philosophical Collections, p. 4. See *Fecundity of FISH*.

MILT *Wasse*, or *Ceterach asplenium*, in *Botany*. (See ASPLENUM.) The leaves are recommended as a pectoral similar to maidenhair, or Asplenium trichomanes; to which they have been frequently joined in infusions and apozems; and likewise as an aperient in obstructions of the viscera. They possess likewise a diuretic virtue, and appear to gently carry off sand, cleanse the kidneys, and allay pains in the urinary passages. The way of using them is to drink infusions of them in the morning, as tea, with the addition of such other medicines as particular cases may require. See CETERACH, ASPLENUM, and TRICHIOMANES.

MILTENBERG, in *Geography*, a town of Germany, on the Maine; 26 miles N.E. of Heidelberg.

MILTHORP. See MILNTHORP.

MILTIADES, in *Biography*, a celebrated Athenian general, the son of Cimon, and grandson of Miltiades, who founded an Athenian colony on the Thracian Chersonesus. After the assassination of Stefagoras, in the colony, Miltiades was sent from Athens to take the command, and having got into his power the principal men of the Chersonesians, he made himself master of the whole district, and married the daughter of the king of Thrace. When Darius I., king of Persia, undertook an expedition against the Scythians, and throwing a bridge across the Danube marched into their country, he entrusted the guard of the bridge to the Ionian Greeks, the commanders of whom he had attached to himself, by raising them to the supreme authority in their several cities. Miltiades, who was one of them, excited by that spirit of Grecian patriotism, to which every other duty was made subservient, urged the other leaders to break down the bridge, in order that a prince so entirely inimical to Grecian liberty might never return in safety. His counsel was approved by all the rest except Hylliaeus the Milesian, who had influence enough to prevent its taking effect. Miltiades, judging it imprudent to await the monarch's return, embarked for Athens, and in his way took possession of the isle of Lemnos for his countrymen. Darius, after his return from his Scythian expedition, having retolved upon the conquest of Greece, sent Mardonius at the head of a powerful army to invade it. When he had arrived at

the

the plains of Marathon, within ten miles of the capital, Athens, the alarm of the citizens became extreme, and in their despair they took the resolution to march out to meet the foe, with such troops as they could assemble, soliciting, at the same time, succours from the other Grecian states. But of the battle of *Marathon*, we have already given an account under that article. Miltiades, who was unquestionably the grand instrument in obtaining this victory, was next entrusted with a strong armament fitted out for the reduction of some of the islands which had taken part with the Persians. He sailed to Paros, and laid siege to its capital, but either a false alarm of the approach of the Persian fleet, or an unsuccessful attempt to gain the place, in which he was wounded, caused him to return without effecting his purpose. The disappointment of the Athenians was so great, that Miltiades was accused of treason before the assembly of the people, who, forgetting his past services, by which they had been delivered from a foreign yoke, condemned him to death. Upon, however, the payment of a heavy fine, he was exempted from capital punishment, but was thrown into prison, where, to the everlasting disgrace of his countrymen, he died of a broken heart, in the year after the battle of Marathon. Corn. Nepos. Univer. Hill.

MILTON, JOHN, in *Biography*, the father of our great poet, though a scrivener (or banker) by profession, was a voluminous composer, and equal in science, if not genius, to the best musicians of his age; in conjunction, and on a level with whom, his name and works appeared in numerous musical publications of the time, particularly in those of old Wilbye; in the "Triumphs of Oriana," published by Morley; in Ravenscroft's "Psalms;" in the "Lamentations," published by Sir William Leighton; and in MS. collections, still in the possession of the curious. The late Mr. T. Warton, in his notes on the *Minora* of Milton, tells us, from the MS. Life of the Poet, by Aubrey, the antiquary, in the *Mus. Ashm. Oxon.* that "Milton's father, though a scrivener, was not apprenticed to that trade: having been bred a scholar, and of Christ-church, Oxford; and that he took to trade in consequence of being disinherited." Mr. Warton therefore observes, that Milton, in his Latin epistle to his father, addresses him in a language which he understood. Aubrey adds, "that the elder Milton died very old in 1647, and was interred from his house in Barbican, in St. Giles's church, Cripplegate; where the great poet was afterwards buried, near his father, in 1674."

His son celebrates his musical abilities in an admirable Latin poem, "Ad patrem," where, alluding to his father's musical science, he says, that Apollo had divided his favours in the sister arts between them; giving music to the father, and poetry to the son.

"Nec tu perge, precor, sacras contemnere musas,
Nec vanas inopesque puta, quarum ipse peritus
Munere, mille sonos numeros componis ad aptos,
Millibus et vocem modulis variare canoram
Doctus, Arionii merito sis nominis hæres.
Nunc tibi quid mirum, si me genuisse poetam
Contigerit, charo si tam prope sanguine juncti
Cognatas artes, studiumque affine sequamur?
Ipse volens Phœbus se dispertire duobus,
Altera dona mihi, dedit altera dona parenti,
Dividuumque Deum genitorque puerque tenemus."

Ver. 56. usque 66.

His effusions of gratitude for the education he had received from his parent's bounty, and his apology for cultivating poetry, of which he gives a charming eulogium,

seem to contain ideas as beautiful and sublime, as any in his *Para-life Loll.*

MILTON, JOHN, the most illustrious of English poets, was descended from an ancient family settled at Milton, in Oxfordshire. His father, who had been brought up in the Roman Catholic religion, and by embracing the Protestant faith had been disinherited, came to London and followed the profession of a scrivener, and marrying a woman, exemplary for her numerous virtues and extensive charities, had two sons and a daughter; viz. John, the subject of this article, Christopher, and Anne. Of the two latter, Christopher, applying himself to the study of the law, became a benchler of the Inner Temple, and at an advanced period of his life was knighted, and raised by James II., first to be a baron of the exchequer, and afterwards one of the judges of the court of Common Pleas. During the civil war he followed the royal standard, and effected his composition with the victors by the prevailing interest of his brother. In his old age he retired from the fatigues of business, and closed, in the country, a life of study and devotion. His sister, Anne, married Mr. Edward Philips, a native of Shrewsbury, who, coming to London, obtained the lucrative place of secondary in the crown office in chancery: by him she had several children, of whom Edward and John only survived to maturity; the former became the biographer, after having, with his brother, been the pupil of his uncle, our author. By a second husband, Mr. Agar, she had two daughters, of whom Mary died young, and of the other, Anne, nothing more is known, than that she was living in the year 1694.

John Milton, the subject of the present article, was born at his father's house, in Bread-street, London, on the 9th of December, 1608. His promise of future excellence was made at a very early period: every incitement to exertion, and every mode of instruction adapted to the disposition and powers of the child, were employed, and no means, probably, were omitted to expand the intellectual Hercules of the nursery into the full dimensions of that mental amplitude for which he was intended. The portrait of him was painted, when he was only ten years old, by the celebrated Cornelius Jansen; hence we may infer that the son, who was made the object of so flattering a distinction by a father, in competent, but by no means in affluent circumstances, could not have been a common child. Of himself, at this period, he gives the following account. "My father destined me, when I was yet a little boy, to the study of elegant literature, and so eagerly did I seize on it, that from my twelfth year, I seldom quitted my studies for my bed till the middle of the night. This proved the first cause of the ruin of my eyes; in addition to the natural weakness of which organs, I was afflicted with frequent pains in my head. When these maladies could not restrain my rage for learning, my father provided that I should be daily instructed in some school abroad, or by domestic tutors at home." "How great," says Dr. Symonds, "are the obligations of Britain and the world to such a father, engaged in the assiduous and well directed cultivation of the mind of such a son." Some part of his early education was committed to the care of Mr. Thomas Young, a puritan minister, and native of the country of Essex, afterwards chaplain to the English merchants at Hamburgh, a man whose merits are gratefully commemorated by his pupil in a Latin elegy. About the age of fifteen he was sent to St. Paul's school, of which Mr. Alexander Gill was then master, and there he began to distinguish himself by his intense application to study, and his poetical talents. Ardent in his love of knowledge, he was regardless of pleasure, and even of health, when they came

into competition with the prevailing passion of his soul, and we are consequently not surprized by the extraordinary and brilliant result which soon flashed upon the world. It is conjectured that it was at this early period he imbibed the spirit of devotion which actuated his bosom to his latest moments. For this he was probably indebted to his father, who would naturally be solicitous to stamp upon the tender bosom of his son, that conviction and feeling of duty which were impressed so deeply on his own, and which he had exhibited in his abjuration of those errors in which he had been educated. He intended his son for the church, and on that account would be more anxious to incline him to devotional principles and practice. The sentiments and the warmth thus communicated to the mind of the youth, would unquestionably be strengthened by the lessons and example of his preceptor, Mr. Young, in whom religion was carried to enthusiasm. To Milton's devotional turn of mind we are probably indebted, not merely for the subject, but for a great part of the sublimity of the *Paradise Lost*. On the 12th of February, 1624-5, he was entered a pensioner at Christ's college, Cambridge, under the tuition of Mr. W. Chappel. Of his course of studies in the university little is known, but he gave proof of the extraordinary skill he had acquired in writing Latin verse, by several exercises preserved among his works, and which are of a purer classical taste than any preceding compositions of the kind by English scholars. It appears that some part of his conduct brought upon him academical punishment; but whatever were the cause, he felt no shame on account of it, but refers spontaneously to the circumstance in the following lines:

“Nec duri libet usque minas perferre magistri
Cateraue ingenio non subeunda meo.
Si sit hoc exilium patrios adiisse penates
Et vacuum curis otia grata sequi.”

Which have been translated by his biographer.

“And ill my soul a master's threats can bear,
With all the fretting of the pedant's war.
If this be banishment—all cares aloof—
To live my own beneath a father's roof—
Still let an idle world condemn or not,
Mine be a truant's name,—an exile's lot.”

From these lines, the enemies of Milton have inferred that he was subjected to corporal punishment, and that he was dismissed from his college for irregularity of conduct. Dr. Symmons has, with a proper degree of indignation, vindicated completely the character of Milton from these vile aspersions. Our limits will not permit us to follow him through the steps of the arguments, but they appear perfectly satisfactory. The doctor, speaking of the calumnies spread on this subject, says, “In opposition to this pretended evidence, stand the records of our author's university, and the force of his own positive declarations. By the former of these, which prove that he took his bachelor's degree as soon as it could be taken, it is made highly probable, if not absolutely certain, that he lost no term; and by the latter we are assured that he was not only exempted from punishment during his continuance at Cambridge, but in that seat of learning was an object of affection and respect.”—And again, “With respect to Milton, we may be confident that no immorality could be the cause of his punishment. Religion, as we know, took early possession of his bosom, and he who, with weak eyes and an aching head, could consecrate one-half of the night to study, cannot be suspected of stealing the other half from repose, for the purpose of confounding it with excess, or of polluting it with debauch.

A mind, indeed, like his, exulting in the exercise of its higher powers, and intent on the pursuit of knowledge, could not, without a violation of its nature, submit to licentious indulgencies. The cultivation of intellect not only diverts the attention from sensual pleasure, but inspires a pride which subdues its fascination: and while the spectacle of the world exhibits innumerable instances of men of genius hurrying into excessive gratification, it scarcely presents us with one, under the influence of the same unfortunate error, among the assiduous votaries of knowledge.”

Milton probably became obnoxious to the governors of his college by the bold avowal of his puritan opinions, which he had imbibed from his tutor Young, or by his dislike to the discipline of the established religion, or to the plan of education pursued in the university; hence he might lose the favour of his superiors in the college, and be exposed to their censures without incurring the slightest loss of character, or sustaining the most trifling diminution of general esteem.

He took the degrees of bachelor and master of arts, the latter in 1632, when he left the university. In the seven years of his academical life, his vigorous and ardent genius broke out in frequent flashes, and evidently disclosed the future author of “*Comus*” and “*Paradise Lost*.” He was a poet when he was only ten years old, and his translation of the 136th psalm evinces his progress in poetic expression at the early age of fifteen. He renounced his original purpose of entering the church, for which he assigns as a reason, “that coming to some maturity of years, he had perceived what tyranny had pervaded it, and that he who would take orders, must subscribe slave, and take an oath withal, which, unless he took with a conscience that could retch, he must either strain, perforce, or split his faith; I thought it better to prefer a blameless silence before the office of speaking, bought and begun with servitude and forswearing.” This denotes a mind resolved to think and act for itself, and it cannot be doubted that Milton was already marked with that firm unyielding temper, which, in some degree, is a necessary concomitant of a superior mind. He now returned to his father, who had retired from business, to a residence at Horton, in Buckinghamshire, and there passed five years in a course of classical study, and in the composition of some of his finest miscellaneous poems. This was the period of his *Allegro* and *Penseroso*, his *Comus* and *Lycidas*. “*L'Allegro* and *Il Penseroso*,” says Dr. Symmons, “were certainly written at Horton, and probably at no long period before the *Lycidas*, which was the last of our author's works while he resided with his father. They were composed in the happiest humour of the poet's mind, when his fancy was all sun-shine, and

————— no cloud, or, to obstruct her view,
Star interposed.

We may contemplate them not as the effects or qualities, but as the very substance of poetry, as its “hidden soul untied, and brought forward to our sight.” In comparing the merits of these pieces, Dr. S. gives the preference to *Il Penseroso*. “The portrait of contemplation,” says he, “the address to Philomel; the image of the moon wandering through heaven's pathless way; the slow swinging of the curfew over some wide-watered shore; the flaming of the night lamp in some lonely tower; the unsphering of the spirit of Plato to disclose the residence of the unbodied soul; the arched walks of twilight groves; the mysterious dream by the murmuring waters; the sweet music of the friendly spirit of the wood; the pale studious cloister; the religious light thrown through the storied windows; the pealing organ, and finally the peaceful hermitage—

form together such a mass of poetic imagery as was never before crowded into an equal space: the impression made by it on the imagination is to be felt and not explained." The pale and studious cloister having been objected to, in one of Mr. Wharton's criticisms, Dr. Symmons remarks, that the word *pale*, as an epithet to cloister, is most happily poetic, and as holding a large and animated picture to the imagination. It shews the ghastly light of the place, the sickly cheek of timorous superstition, and the wan and faded countenance of studious and contemplative melancholy.

In 1638, having obtained his father's consent to improve himself by foreign travel, Milton set out for the continent. At Paris he was received with distinction by lord Sendamore, the ambassador from England, by whom he was introduced to the notice of the illustrious Grotius, who then resided in the French capital, as the minister of Christina, the queen of Sweden. After the delay of a few days at Paris, he renewed his progress, and pursued the direct road to Nice, where a vessel received and landed him at Genoa. From this city he passed immediately through Leghorn and Pisa to Florence, and on the banks of the Arno he made what may be regarded as his first pause. Here he resided two months, and by the brilliancy of his conversation, and mildness of his manners, made himself the object of very general admiration. Here he obtained admission into those private academies, which had been instituted by the Medici for the advancement of literature, and for the cementing of friendships among its votaries. The English bard could in this place enumerate in the list of his friends all the great, the respectable, and deeply learned men of Italy, who appear to have been lost in surprise at the spectacle, presented to them, of a native of Britain, a country just emerging, as they imagined, from barbarism, who to an acquaintance, not superficial, with all the sciences, united a profound knowledge of classical and Italian letters; whose mind was at once sublime and deep, accurate and comprehensive, powerful and acute; patient to follow judgment in the gradual investigation of philosophical truth, yet delighted to fly with the more aerial offspring of the brain on the high and expatiating wing of imagination. During this visit to Florence he saw and conversed with the great Galileo, that memorable victim of priestly ignorance and superstition. "There it was," says Milton, "that I found and visited the famous Galileo, grown old, a prisoner to the Inquisition, for thinking in astronomy otherwise than the Franciscan and Dominican licensers thought." On his leaving Florence, our traveller proceeded through Sienna to Rome, and then visited Naples, where he was kindly received by Manfo, marquis of Villa. At Rome he was introduced, by Holstenius, the learned keeper of the Vatican library, to the attentions of cardinal Barberini, who at that time possessed the whole delegated sovereignty of Rome under his uncle, Urban VIII. At a great musical entertainment which the cardinal gave, he looked for our traveller among the crowd at the door, and brought him, almost by the hand, into the assembly. It is supposed, that it was at this concert Milton was first struck with the charms and the inimitable voice of Leonora Baroni, which had been made the general theme of their praise by the contemporary poets of Italy: and she is probably the person who has been celebrated by Milton in her own language, and who was the object of his love in his Italian sonnets.

At Naples the attentions paid to Milton were of the most flattering nature; the marquis of Villa not only conducted him through the viceroy's palace, and to a sight of all that was worthy to be shewn in the city, but honoured

him also with some familiar and very friendly visits. The imprudent freedom, with which Milton had discovered his sentiments on the subject of religion, was the only circumstance which deprived him of a still more unreserved intercourse with this elegant and accomplished nobleman. Having completed his intended residence at Naples, he began to make preparations for the execution of the remaining part of his plan of travel, which extended to Sicily and Greece; but while he was engaged in this business he received letters from England, acquainting him with the distracted state of his country, and with the near prospect of a civil war; he determined to return. "As I was desirous," he says, "to pass into Sicily and Greece, the melancholy intelligence from England of the civil war recalled me; for I esteemed it dishonourable for me to be lingering abroad, even for the improvement of my mind, when my fellow-citizens were contending for their liberty at home." He, however, resolved to revisit Rome, where he remained two months; and whenever his religion was attacked, he scrupled not to vindicate its principles with spirit and ardour, even within the precincts of the sacerdotal palace. From Rome he went to Florence, and his second visit to this city, which the kindness of his friends made a species of home to him, was of equal duration with his first. When he departed from Florence, he crossed the Apennines, and travelled through Bologna and Ferrara to Venice. He spent a month in viewing the curiosities of this celebrated city, and then pursued his returning course through Verona and Milan, over the Alps, and by lake Lemanus to Geneva. Here he contracted an acquaintance with two learned divines, John Diodati and Frederic Spanheim. He now returned through France to England, having been absent about fifteen months. On his arrival he found the civil commotions of his country hastening to a crisis, and as he had expressed impatience to be present on the theatre of these disputes, it has been thought extraordinary that he did not instantly take upon himself some active part. But his tastes and habits were altogether literary, and he had been long pondering upon some subject of English poetry worthy of his genius, and capable of being made a passport to the immortality to which he aspired. For the present, therefore, he fixed himself in the metropolis, undertook the education of his sister's sons, of the name of Philips. Shortly after he was applied to by several parents to admit their children to the benefit of his tuition, to which he assented, and by this means he has exposed himself to the title of school-master, which his enemies, and the enemies of human happiness and intellectual improvement, who employed it as a term of reproach, conceived to be of a nature to degrade him. He took a house in a garden in Aldersgate-street, and opened an academy for board and education. Here, in his little circle of scholars, he was usefully, if not splendidly, engaged; and he could not perhaps conceive, while he was essentially promoting the highest interests of some of his species, that he was degrading himself in the estimation of the rest. In his conduct to his pupils, he was familiar and free where he could be so, and was never rigid but by compulsion. His form of instruction respected things more than words, and attempted to communicate knowledge when the understanding was, perhaps, incapable of receiving more than the key which opened the important gate. Instead of the common classics, he put into the hands of his scholars such Latin and Greek authors as treated on the arts and sciences, and philosophy. These were ill calculated to render learning pleasant to beginners, and from the imperfect state of ancient science, such a course was as likely to inculcate error as truth. He performed the duties

Duties of instruction with great assiduity, and set the example of hard study and spare diet to his pupils, whom he seems, in some respects, to have disciplined with the severity of old times.

Milton did not very long continue inactive in the public cause, and his principles made it no matter of doubt which side he should espouse in the contentions of his country. Conscious of his own proper strength, and sensible that genius armed with knowledge was a power of far greater and more extensive efficiency than the bodily force of any individual, he accordingly decided in favour of the pen against the sword; and stationed himself in the closet, where he was himself a host, rather than in the field, where every muscular private man would have been his superior. In the year 1641 he published four treatises relative to church government, in which he attacked episcopacy, and supported the cause of the Puritans. These were followed by another in the next year, relative to the same controversy, and he reckoned among his antagonists such men as bishop Hall and archbishop Usher. His father, who had been molested in his residence by the king's troops, came to live with him, and spent his latter years, in tranquillity, under his son's roof. In 1643, Milton married Mary, daughter of Richard Powell, esq., a magistrate in Oxfordshire. This was a very unsuitable connection, for the father-in-law was a zealous royalist, and the daughter had been accustomed to the jovial hospitality of the country gentlemen of that party. After a month's experience of her new life, the lady sighed for the gaieties which she had left, and obtaining permission, by the earnest request of her relations, for a short absence, she revisited her native place. Here she continued during the remainder of the summer, nor could the letters, messages, and remonstrances of her husband bring her back. Incensed at her neglect and ill treatment of him, he began to consider her conduct as a desertion of the nuptial contract, and resolved to punish it by repudiation. He soon found arguments to justify it to the world, and published, in 1644, "The Doctrine and Discipline of Divorce," which was followed by "The Judgment of Martin Bucer concerning Divorce." By these writings the fury of the Presbyterian clergy was instantly kindled, and they procured the author to be summoned before the house of lords, but that body did not choose to enter into the question, and soon dismissed him. The Presbyterians were now left without any consolation for the loss of an able friend, and the excitement of a formidable enemy. Milton now was irrevocably alienated from their cause, and he soon fully discovered that many of these pretended zealots of liberty fought only their own aggrandizement, and the power of imposing upon others a yoke which they had themselves been unable to bear. On the subject of divorce he makes out a strong case, and appealed to the whole tenour of the scripture; the laws of the first Christian emperors; the opinions of the most eminent among the early reformers; and endeavours to shew that by the laws of God, and by the inferences of the most virtuous and enlightened men, the power of divorce ought not to be rigidly restricted to those causes which render the nuptial state unfruitful, or which taint it with spurious offspring. Regarding mutual support and comfort as the principal objects of this union, he contends, that whatever defrauds it of these ends essentially vitiates the contract, and must necessarily justify its dissolution.

Milton, in conformity to this theory, resolved practically to act upon it, and began to pay his addresses to a young lady of great accomplishments, the daughter of a Dr. Davies. The rumour of the intended alliance effected what his re-

monstrances had been unable to do; as he was paying a visit to a neighbour, he was surprised with the sudden appearance of his wife from another room, who threw herself at his feet and implored forgiveness. After a short struggle of resentment, he relented, and took her again to his bosom. The reconciliation was lasting and sincere, and Milton nobly sealed it by opening his house to her father and brothers, when they had been driven from home by the triumph of the republican arms. He was now obliged to take a larger mansion, and removed to Barbican. In this asylum his wife's relations continued, till the question respecting their property was adjusted with the government, and till a period subsequent to the death of Milton's father. Under the pressure of these domestic embarrassments, and of the public interest, the intellect of our author, obedient to a heart actuated by the purest benevolence, was busy in promoting the welfare of the human race. In the year 1644, he imparted to the world his ideas on the subject of education, and defended, with a power which has never been exceeded, that guardian of liberty and truth, the freedom of the press.
