His "Tractate on Education," addressed to Mr. Hartlib, the friend of sir William Petty, contains his thoughts on that important subject. From this it appears, he conceived it possible to initiate the young student into science and language by the same process, and to make an acquaintance with things the immediate result of an acquaintance with words. Between the years of twelve and twenty-one, the pupil is to be led through various languages from grammar to ethics, logic, rhetoric, politics, law, theology, criticism, and the practice of composition. Geography was to exhibit to him the surface of the globe, and the principles of astronomy were to unfold to him the heavens; natural philosophy, comprehending anatomy and physiology, was to make him conversant with the phenomena of nature, and with the wonders of his own frame; the mathematics were to introduce him to the sciences of architecture, engineering or gunnery, fortification, and navigation. With this kind of education, Milton's pupil was to be accomplished, and fit for any duty to which his country might summon him, in the pulpit or at the bar, in the senate or the field. During the course of these studies, the body of the student was to receive its due share of cultivation, to be maintained in health by temperance, and to be invigorated by exertion. This little piece is written in an easier and purer style than the preceding works of its author; but in every species of merit it must yield to another composition, produced nearly at the same time, by the same pen, and addressed to the parliament, with the title of "Areopagitica, or a speech for the liberty of unlicensed printing." The Presbyterians, on their rising into power, forgot the principles which they had professed in their adversity; and, declaring against unlimited toleration, discovered by their readiness to violate the rights of others, that their tenderness was only for their own. Against these apostates to the cause of liberty, Milton advanced as the champion of free discussion; and the effect of his zeal in this instance, for the interests of genuine liberty, has received the unanimous acclamation of the world. Though his controversial, and other engagements, had for some time suspended the exertion of his poetical talents, yet he did not suffer his character as a poet to sink into oblivion, and in 1645, he published his juvenile poems in Latin and English. In 1646, Milton's wife produced her first child, and in the following year, in which his father died, the Powells returned to their own mansion, and his house was resigned once more to literature. In this house, in which his second daughter Mary was born, he did not continue long, but exchanged it for one of smaller dimensions.

in High Holborn. His next removal was occasioned by his acceptance of the office of Latin secretary, which rendered a situation nearer to Whitehall an object of convenience.

Milton's principles of the origin and end of government, carried him to a full approbation of the trial and execution of the king, which was the final catastrophe of the civil wars; and in order to conciliate the minds of the people, which were agitated by the outcries, as well of the Presbyterians as the loyalists against that act, he published early in 1649, a work, entitled "The Tenure of Kings and Magistrates," proving that it is lawful, and that it hath been so held through all ages, for any who have the power, to call to account a tyrant or wicked king, and, after due conviction, to depose and put him to death, if the ordinary magistrates have neglected or denied to do it. He soon after attempted to support the new order of things, by a pamphlet animadverting upon the revolt of the Scotch Presbyterians, settled at Belfast, from the parliament. With the view of preserving the republican spirit of the nation, he also employed himself in composing "A History of England" from the earliest periods, of which he wrote six books, but left the work unfinished. His progress was stopped by an appointment to the Latin secretaryship to the council of state. Scarcely was Milton seated in his new office, when he was summoned by the government to the discharge of a duty, well adapted to the extent of his powers, and one of considerable importance; it was to write an answer to the famous royal work, as it was then supposed to be, entitled "Icon Basilikè," or the portraiture of his sacred majesty in his solitudes and sufferings. Milton chose for the title of his work "Iconoclastes," or Image-breaker: this piece, says his biographer, Dr. Symmons, "may be regarded as one of the most perfect and powerful of Milton's controversial compositions. Pressing closely on its antagonist, and tracing him step by step, it either exposes the fallacy of his reasoning, or the falsehood of his assertions, or the hollowness of his professions, or the convenient speciousness of his devotion. In argument, and in style compressed and energetic, perspicuous and neat, it discovers a quickness which never misses an advantage, and a keenness of remark which carries an irresistible edge." This work was first printed in 1649, and a second edition of it appeared in the following year; it was published again in London in 1652, in a French translation, and was answered in 1651, in a work, entitled "Icon-oclastes," or the Image unbroken, and also forty years afterwards in another piece, called "Vindiciæ Carolinae." We have in the article GAUDEN shown that the "Icon-Basilikè" was written by that prelate, and not by king Charles, to whom it was generally imputed. This has been satisfactorily proved by the assertions of the two sons of the king, viz Charles II. and James II.; by letters of the Lord chancellor Hyde, and Dr Gauden himself; and by the specific depositions of the doctor's friend Dr. Walker, and of his widow. Doubts of the real author of the "Icon Basilikè" were entertained almost immediately upon its publication by Milton, and by other persons. Milton probably had no doubt whatever of its spuriousness, but was without any specific evidence to bring home the charge, he therefore answered the book, and its arguments, without regard to the writer, for he expressly says, "But the matter, here considerable, is not whether the king, or his household rhetorician, have made a pithy declamation against tumults, but first, whether there were tumults or not, &c." It was also, in the year 1649, attacked as the work of a clergyman who was looking to preferment as a reward, in an able piece, entitled "Icon-alethinè," or the true image. To this work is prefixed a frontispiece, in which, on a curtain being drawn

aside, is discovered a digressary of the church of England in his full canonical dress, and beneath are inscribed the following lines:

"The curtain's drawn; all may perceive the plot,
And him, who truly the black base brought.
Whose fable mantle makes us bold to say,
A Phaeton Sol's chariot ruled that day.
Presumptuous priest! to step into the throne;
And make the king, his ballard issue own!
The author therefore hath conceived it meet,
The doctor should do penance in this sheet."

On the appointment of Milton to the office of Latin secretary, he removed to a lodging at Charing Cross, and afterwards to apartments in Scotland Yard. Here his wife presented him with a third child, a son, who died in his infancy. In 1652 he changed his residence to Petty France, which he occupied for eight years, till the crisis of the restoration, a handsome house opening into St James's park.

Scarcely had Milton finished his reply to the "Icon Basilikè," than he was called upon to justify the principles of the commonwealth in England, in opposition to Salmastius, an honorary professor in the university of Leyden, who had been hired by Charles II. to write a work in favour of the royal cause, which he entitled "Defensio Regia." Salmastius was, by much, a more powerful antagonist than Dr. Gauden, and the contest was to be decided in a more ample field, than that in which Milton had engaged with the "Icon Basilikè." The powers of his mind were now to be exhibited to Europe; and the whole circle of the civilized and Christian community was to witness his triumph or defeat. In 1651, he performed the task allotted him in a work under the title of "Defensio pro Populo Anglicano;" in this he exercised all the powers of Latin rhetoric, as well to justify the republican party, as to confound and vilify the celebrated scholar against whom he took up his pen. By this, notwithstanding the party virulence, with which, by the custom of the times, it was debased, he acquired a high reputation both at home and abroad. He was visited on the occasion by all the foreign ambassadors then in London, was complimented by several eminent scholars on the continent, and received, as a remuneration for his labours, a thousand pounds from the English government. His book was generally read by literary enquirers of all parties, while, on the other hand, the work of Salmastius was condemned and suppressed by the states of Holland. One source of triumph arose to Milton's enemies; in consequence of this controversy, his intense application to study deprived him of that sight, which had been for some years declining. His physicians had warned him, that the exertion necessary to accomplish such a work would probably induce total blindness, but his attachment to the public cause of his country and the world, made him readily submit to any privations which were merely personal, so that he might render that service which the exigencies of the times required.

That such were his motives, we have his own declarations, in a fine sonnet addressed to his friend Cyriac Skinner, which our readers will thank us for transcribing.

"Cyriac, this three years day, these eyes, though clear
To outward view, of blemish or of spot,
Bereft of light, their seeing have forgot;
Nor to their idle orbs doth sight appear
Of sun, or moon, or star throughout the year,
Or man or woman;—yet I argue not
Against Heaven's hand or will, nor bate a jot
Of heart or hope; but still bear up and steer

Right

Right onward What supports me, dost thou ask?

The conscience, friend, to have lost them overplied

In liberty's defence, my noble task,

Of which all Europe rings from side to side:

This thought might lead me through the world's vain mask,

Content, though blind, had I no better guide."

And in plain prose he says, in his "Second Defence," "When the task of replying to the defence of the king was committed to me, at a time when I had to contend with ill-health, and when one of my eyes being nearly lost, my physicians clearly predicted, that if I undertook the laborious work, I should soon be deprived of both; undeterred by the warning, I seemed to hear a voice, not of a physician, but of some internal and more divine monitor; and conceiving that by some fatal decree, the alternative of two lots was proposed to me, that I must either lose my sight, or must desert a high duty, the two destinies occurred to me, which the son of Thetis reports to have been submitted to him by his mother, from the oracle of Delphi. Reflecting, therefore, with myself, that many had purchased less good with greater evil, and had even paid life as the price of glory, while to me the greater good was offered at the expense of the less evil, as merely by incurring blindness, I might satisfy the most honourable demand of duty; which, intrinsically of more worth even than glory itself, ought to be the first and dearest object of every man's regard; I determined to dedicate the short enjoyment of my eye-sight, with as much effect as I could to the public advantage."

Among the attentions paid to Milton at this time, he was particularly pleased with those of Leonard Philarus, a learned Athenian, who had attained to high rank in Italy, and was now employed by the duke of Parma on an embassy to the court of Paris. Struck with the ability and spirit of Milton's composition, this illustrious Greek sent him his portrait, with a letter of panegyric to the defender of the English commonwealth. On a visit which Philarus soon afterwards made to England, he waited upon Milton, then reduced to a state of total blindness, and mutual friendship was the consequence of their personal intimacy. When Philarus returned to Paris, he was led, by the celebrity of Thevenot, the physician, particularly renowned at that time for his acquaintance with the diseases of the eye, to communicate a hope to Milton of the recovery of his sight. The letters in which our author acknowledges the kindness of his friend on this and other occasions are preserved in Dr. Symmons' life of him.

His intellectual powers, however, suffered no diminution from this abridgment of the sensitive faculties, and he pursued, without intermission, both his official and controversial employments. In 1652 a book was published at the Hague, entitled "Regii sanguinis clamor ad cælum adversus parricidas Anglicanos;" the author was Peter Moulin the younger. Milton replied to it in his "Second Defence," to which we have already referred, and which was entitled "Defensio secunda pro Populo Anglicano." In this was a high panegyric upon Cromwell, who had now assumed the supreme power with the title of Protector. "Milton's subservience and attachment to this usurper," says one of his biographers, "is the part of his conduct which it is the most difficult to justify. When the wisest and most conscientious of the republicans had become sensible of his arts, and had openly opposed his ambitious projects, it might have been expected that the mind of Milton would neither have been blinded by his hypocrisy, nor overawed by his power. If the general tenour of his character will exonerate him from the suspicion of interested motives on this occasion, it must be supposed that he was dazzled with the greatness of Cromwell's actions,

and was convinced that his superiority alone could allay that contention of parties which threatened ruin to the cause that had proved victorious in the field. Milton, besides, was a zealous friend to religious liberty, for which he saw no refuge from the intolerance of the Presbyterians, except in the moderation of the protector. It may be added, that the very passage in which he addresses Cromwell with the loftiest encomium, contains a free and noble exhortation, that he should respect that public liberty, of which he considers him as the guardian."

Milton's office as Latin secretary, chiefly regarded transactions with foreign nations, in which it is admitted that Cromwell was meritoriously attentive to the honour and interest of his own. In 1652 he lost his wife, and his blindness, in a short time, induced him to marry again. His second wife was Catharine, the daughter of captain Woodcock of Hackney, who, unfortunately for him, died within a year in child-bed, greatly regretted by her husband, who has consecrated her memory by a beautiful sonnet, supposed to be the result of a dream, immediately after her decease, in which are the following lines:

Methought I saw my late espoused saint,

* * * * *

Came, vested all in white, pure as her mind:

Her face was veiled, yet to my fancied sight

Love, sweetness, goodness in her person shined

So clear, as in no face with more delight.

But Oh! as to embrace me she inclined,

I waked;—she fled, and day brought back my night.

Employment was his resource against the gloom of his condition; and after he had concluded his controversial warfare, he took up his suspended "History of England," which he carried on to the conquest: he also collected materials for a Latin Thesaurus, intended as an improvement upon that of R. Stephanus.

In the business of his office he had coadjutors; but the most important matters were still committed to him, and from his pen proceeded a Latin memorial of great strength and elegance, stating the reasons for the war which the protector declared against Spain. A remonstrance which he drew up concerning the persecution of the Protestants in Savoy, strongly expressed his detestation of religious tyranny.

After the death of Cromwell, when the fluctuations of government threatened general anarchy, he was induced to give his advice on civil and ecclesiastical topics in some small publications, one of which was entitled "A Ready and Easy Way to establish a Free Commonwealth, and the Excellence thereof, compared with the Inconveniences and Dangers of re-admitting Kingship." This, as its title imports, was intended rather to expose the evils necessarily consequent to the nation's relapse into its old vassalage under kings, and to demonstrate the preference of a republican to a monarchical government, than to propose any just model of a popular constitution. In this work, as well as in another, entitled "Brief Delineations, &c." he shews that he was fearful of an unqualified appeal to the people, and deems them incapable of determining with wisdom for their own interests. It was, however, in vain to contend by pamphlets against the national inclination. The king returned in triumph, and Milton was discharged from his office, and for a time lay concealed in the house of a friend in St. Bartholomew's Close, near Smithfield. Here his privacy from the world was perfect, till after the passing of the act of oblivion, in the exceptions of which he was not comprehended, ascer-

tained

tained his safety, and re-inflated him in society. To whom he was indebted, in this emergency, for his preservation, is not known with certainty; but it seems probable that his life was saved principally by the earnest and grateful interposition of sir William D'Avenant, who had himself been formerly preserved by the mediation of Milton, when ordered by parliament, in 1651, to trial, before the high court of justice. (See D'AVENANT, WILLIAM.) Milton's name first occurs in the proceedings of the new government, in an address from the house of commons to his majesty, that he would issue his proclamation to call in Milton's "Defences of the People," and "Iconoclastes," together with a book of Goodwyn's, and cause them to be burnt by the common hangman, and also that the authors should be prosecuted by the attorney-general. The books were accordingly burnt, but the authors were returned as having absconded.

Now, reduced in his circumstances, and under the discountenance of power, Milton removed to a private habitation, near his former residence in the city. But scarcely had he left his concealment when he was taken into custody, by an order of the house of commons, from which he was dismissed by paying his fees. In 1662, he was residing in Jewin-street, and from thence he removed to a small house in the Artillery-Walk, adjoining Bunhill Fields, where he continued during the remaining part of his life.

While living in Jewin-street, he married his third wife, Elizabeth Minshull, the daughter of a gentleman of Cheshire. He was now to resume that poetical character which, for many years, had been sunk in that of the controversialist and politician. Undisturbed by contentions and temporary topics, his powerful mind was left in repose, to meditate upon the great ideas which had indistinctly risen to its view, and the result of its energies was the "Paradise Lost." Much discussion has taken place concerning the original conception of this grand performance, but hitherto it has not been traced. It is certain that at the time when he first formed the resolution of writing an epic poem, which was at an early period, he thought of some subject in the heroic times of English history; but the religious turn of his mind, and his assiduous study of the Hebrew scriptures, produced a final preference of a story derived from the Old Testament. He composed in blank verse, on account of the facility with which he could pour forth the strains that rushed into his mind with the force and rapidity of inspiration. His nephew Philips had the perusal of it, from the very beginning, in parcels of ten, twenty, or thirty verses at a time, which, being written by any person that was near at hand, probably wanted correction as to the orthography and pointing. This gentleman says, upon the authority of Milton, that his vein never happily flowed but from the autumnal equinox to the vernal, and that whatever he attempted at other times was never to his satisfaction. The exact time occupied in the composition of the *Paradise Lost* is not known; it was finished in 1665, when Milton, to avoid the contagion of the plague, through the kindness of his friend Elwood, a quaker, made a retreat to Chalfont, in Buckinghamshire. It was first printed in 1667, in ten books, and he received from the bookseller five pounds for the copyright, with a contingency of ten more, depending on the sale of two other editions, and which he lived to receive. These fifteen pounds, however, purchased only the bookseller's right to the several editions for which they were paid, as Milton's widow sold the irrevocable copyright of the work which had been bequeathed to her, for eight pounds, to the same bookseller, Samuel Simmons, who, almost immediately, disposed of what was thus wholly transferred to him, for twenty-five pounds to Aylmer, another bookseller, from whom it passed, at a con-

siderable advance, to Jacob Tonson. Much has been said of the deplorably low price advanced for this immortal work, "but," says Dr. Symonds, "if we would regard ourselves placed in the middle of the seventeenth century, and immersed in all the party violence of that miserable period, we should rather be inclined to wonder at the venturous liberality of the bookseller, who would give even this small consideration for the poem of a man living under the heaviest frown of the times, in whom the poet had long been forgotten in the polemic, and who now tendered an experiment in verse, of which it was impossible that the purchaser should be able to appreciate the value, or should not be suspicious of the danger. It is certain that the world was, at that period, incapable of doing it justice, and it was long before it took a secure place among those productions which continually rise in estimation, and are unlimited by time or place. Milton, conscious of its merits, anticipated his final success, and was, in that expectation, supported amidst temporary discouragements." The thirteenth edition was printed, with a life by the author, in 1727, by Elisha Fenton, who was a scholar, a poet, and a man of worth, though not without his failings. See FENTON.

In 1671 Milton published his "*Paradise Regained*," written upon the suggestion of his friend Elwood, who, on having read the *Paradise Lost* in manuscript, and being asked by the author how he liked it, answered, in his quaint way, "Thou hast said much here on *Paradise Lost*; but what hast thou to say of *Paradise Found*?" When the latter poem was finished, he put it into the hands of Elwood, saying, in a pleasant tone, "this is owing to you, for you put it into my head by the question you put to me at Chalfont." This was probably regarded by the author as the theological completion of the plan commenced in *Paradise Lost*, and he viewed it with the partial fondness of an aged parent for his latest offspring. But in point of grandeur and invention its inferiority is extremely apparent, yet modern criticism has pronounced it by no means unworthy of the genius of Milton, allowance being made for the narrow compass of the subject, and his particular purpose in writing it.

At the same time that this was published, appeared his tragedy of "*Sampson Agonistes*," composed upon the ancient model, and never intended for the stage. It cannot be said to entitle the author to a place among those dramatic writers who have distinguished themselves by the talent of moving the passions, or of delineating the character; but its moral and descriptive beauties are not inconsiderable. The impression made on the author's mind by the sufferings of his party, and by his own depressed state, may be distinctly traced in some of its pathetic and animated strains, such as in those that follow:

"God of our fathers! what is man!
That thou towards him with hand so various
Or, might I say, contrarious,
Temper'st thy providence through his short course
Not evenly, as thou rulest
The angelic orders, and inferior creatures mute,
Irrational and brute.
Nor do I name of men the common rout,
That wand'ring loose about
Grow up and perish, as a summer fly.
Heads without name, no more remembered;
But such as thou hast solemnly elected,
With gifts and graces eminently adorned,
To some great work, thy glory,
And people's safety, which in part they effect:

MILTON.

Yet towards these, thus dignified, thou oft
Amidst their height of noon,
Chang'’t thy countenance and thy hand, with no regard
Of highest favours past
From thee on them, or them to thee of service.
Not only dost thou degrade them, or remit
To life obscured, which were a fair dismissal,
But throw’st them lower than thou didst exalt them high.”

With the Sampson Agonistes Milton’s poetical account closes; but writing was become so much a habit with him, that he was continually making additions to his works in prose. In 1672 he published “A System of Logic, after the Manner of Ramus;” and in the following year he ventured again in the field of polemics, with “A Treatise of true Religion, &c. and the best Means to prevent the Growth of Popery.” The latter was become the dread of the nation, and Milton was among the most zealous of its opponents. The principle of toleration which he lays down is agreement in the sufficiency of the scriptures; and he denies it to the Papists, because they appeal to another authority. So imperfect was Milton’s notion of religious liberty: it is, however, to his credit, that even in this he was contending with popery, avowedly patronized by the duke of York, and secretly countenanced by the king. “The danger,” says his biographer, “which at this instant awakened the fears of Milton, became not long afterward so palpable and striking as to excite the nation, united in one great effort for its safety, to depose the Catholic bigot who occupied and abused the throne.”

In the same year Milton published a second edition of his youthful poems, with his “Tractate on Education,” in one volume, in which he included some pieces not comprehended in the edition of 1645. In 1674 he gave the world his familiar letters and some college exercises, the former with the title of “Epistolarum Familiarum Liber unus,” and the latter with that of “Prolusiones quedam oratoriz in Collegio Christi habitæ.” The next exercise of his pen, was, it is said, to translate into English the declaration of the Poles, on their elevating John Sobieski to their elective throne, but Dr. Symmons is doubtful of the fact; thinking it much more certain that in some part of the same year he wrote “A brief History of Muscovy,” which was published at a period of about eight years after his death. With this work terminated his literary labours; for the gout, which had for many years afflicted him, was now appointed to terminate his valuable life. He sunk tranquilly under an exhaustion of the vital powers on the eighth of November, 1674, when he had nearly completed his sixty-sixth year. His remains were carried from his house in Bunhill Fields to the church of St. Giles, Cripplegate, with a numerous and splendid attendance, and deposited in the chancel near those of his father. No monument marked the tomb of this great man, but one was erected to his memory in Westminster Abbey, in 1737, at the expence of Mr. Benson, one of the auditors of the impress. His bust has since been placed in the church where he was interred, by the late Samuel Whitbread, esq.

In the July preceding his death, Milton had requested the attendance of his brother Christopher, and in his presence made a disposition of his property by a formal declaration of his will. This mode of testament, which is called *nuncupative*, was set aside, on a suit instituted by his daughters. By this nuncupative will he had given all his property to his widow, assigning nothing to his daughters, but their mother’s portion, which had not yet been paid. On this account, and from exacting from his children some irksome

services, such as reading to him in languages which they did not understand, which were necessities resulting from his blindness and his indigence, he has been branded as an unkind father. But the nuncupative will, discovered some years since, shews him to have been amiable, and injured in that private scene, in which alone he has generally been considered as liable to censure, or rather, perhaps, as not entitled to affection. In this will, published by Mr. Warton, and in the papers connected with it, we find the venerable parent complaining of “unkind children,” as he calls them, for leaving and neglecting him because he was blind, and we see him compelled, by their injurious conduct, to appeal against them even to his servants. By the deposition of one of those servants, it is certain, that his complaints were not extorted by slight wrongs, or uttered by capricious passion on trivial provocations: that his children, with the exception of the youngest, would occasionally sell his books to the dunghill women, as the witness calls them. That these daughters were capable of combining with the maid-servant, and of advising her to cheat her master, and their father, in her marketings; and that one of them, Mary, on being told that her father was married, replied, “that was no news; but if she could hear of his death that would be something.”

We cannot better conclude our account of Milton than in the words of his liberal and eloquent biographer, Dr. Symmons, to whose work we have already acknowledged our obligations, and to which we earnestly refer the readers of the New Cyclopedia, in order that they may see how much more is recorded of our illustrious countryman, than can possibly be compressed in this article. Milton, says Dr. Symmons, was “a man in whom were illustriously combined all the qualities that could adorn, or elevate the nature to which he belonged; a man, who at once possessed beauty of countenance, symmetry of form, elegance of manners, benevolence of temper, magnanimity and loftiness of soul, the brightest illumination of intellect, knowledge the most various and extended, virtue that never loitered in her career nor deviated from her course;—a man who, if he had been delegated as a representative of his species to one of the superior worlds, would have suggested a grand idea of the human race, as of beings affluent with moral and intellectual treasure, who were raised and distinguished in the universe as the favourites and heirs of heaven.”

Of the three daughters of Milton, Anne, the eldest, married a master-builder, and died with her first child in her lying-in. Mary, the second, died in a single state: and Deborah, the youngest, married Abraham Clarke, a weaver in Spitalfields. She had seven sons and three daughters, but of these she left, at her decease, only Caleb, who marrying in the East Indies, had two sons whose history cannot be traced; and Elizabeth, who married Thomas Foster, of the same business with her father, and had by him three sons and four daughters, who all died young and without issue. Mrs. Foster died in poverty and distress, on the ninth of May, 1754, “and with her, it is highly probable, expired the last descendant of the immortal Milton.” Symmons’s Life of Milton. Biog. Brit. Gen. Biog. Bayle’s Dict. Newton’s Life of Milton, and Milton’s Works.

MILTON, in *Geography*, a parish in the lower half hundred of Toltingtrough, lathe of Aylesford, and county of Kent, England, is situated 22 miles from London, and forms the east side of the town of Gravesend, with which it was incorporated in the reign of queen Elizabeth. Milton was returned, under the population act of 1801, as containing 322 houses, occupied by 2056 inhabitants. The church, which stands near the sea-shore, about a mile from Gravesend,

end, is built of flints and rag-stones round it formerly stood the village of Milton, of which only one house is now left. See GRAVESEND.

MILTON, or *Middletun*, as anciently called, a market town and parish in the upper half hundred of Milton, in the lath of Seray, and county of Kent, England, is of very remote antiquity, and formed part of the demesnes of the Saxon kings. It is situated 12 miles from Maidstone, and 30 from London, on the acclivity of a hill, about half a mile from the high road, sloping down to a small creek which falls into the river Swale, about two miles to the north-west. The vicinity of this town to the Swale, which separates the Isle of Sheppey from the main land, was the cause of its being frequently plundered by the Danes during their piratical incursions in the ninth century. Here their veteran chief, Hasting, endeavoured to establish himself in the time of Alfred; and the remains of his encampment or fortrefs are still to be seen in the marshes of Kemsey Downs, between Milton church and the mouth of the creek. It consists of a high rampart and broad ditch, enclosing a square area, the sides of which are nearly parallel with the cardinal points of the compass. It measures about an hundred feet each way, and has obtained the name of Cattle-Rough, from its having been long overgrown with trees and underwood.

Milton is supposed to have originally stood in the vicinity of its church, which is considerably to the north of the present town; and near it the Saxon kings had a palace, which was burnt, together with the town, by earl Godwyn, during his quarrel with Edward the Confessor, about the year 1052. Notwithstanding this, Milton appears to have been a place of considerable importance for the time, in the days of William the Conqueror, who, in the Domesday survey, is recorded to have then held the manor. It remained vested in the crown till the time of Charles I., though frequently granted for life, or a term of years, to different persons; particularly to several queens in dowry, and others of the royal blood, who procured various privileges for the inhabitants. The grant of the market, which is kept on Saturdays, was obtained by queen Isabella, in the 13th of Edward II., together with the liberty of holding an annual fair for four days. The town is governed by a portreeve, who is chosen on St. James's day, by such inhabitants of the parish as pay the church and poor's rates. The market-house and shambles stand near the middle of the town; and at a small distance northward is the court-house, an old timber building, where manor courts and other public meetings are held; beneath it is the town gaol. The church is a spacious fabric, and consists of two aisles and two chancels, with a massive embattled tower at the west end, which, together with the south chancel, is composed of squared flints, laid in even rows. The east windows are large, and pointed; that of the north chancel is divided into five lights, with numerous crockets above; the other has four trefoil-headed lights below, with three ranges of quatrefoil lights above. The south chancel, which belonged to the ancient family of Northwood, contains a piscina, and several tombs and sepulchral memorials.

The number of houses in this parish, as returned in the year 1801, under the population act, was 322; that of inhabitants 2056. The Oyster Fishery furnishes the principal source of employment to the latter, and has done so for many centuries. In the reign of king John, the right of this fishery in the manor and hundred of Milton was granted to the abbey at Faversham, to which it appertained at the dissolution. It then was held by the crown till the reign of Charles I.: since that period it has been

granted, with the manor, to various persons successively; and is now held on lease by a company called Free Dredgers, who are governed by their own particular rules or bye-laws, made, according to ancient custom, at the court-baron of the manor. The oysters produced within the limits of this fishery are in high estimation, under the name of "Native Miltons." There are four wharfs belonging to this town; and considerable quantities of corn, and other produce of the adjacent country are shipped here for the London markets, commodities of every kind being freighted in return.

In the western part of this parish and its vicinity is a large tract of woodland, called Chestnut Woods, from the great plenty of those trees which grow therein: and in a presentment made of the customs of Milton, in 1575, it is mentioned, that the occupiers of three mills holden of the manor, should gather yearly for the lord of it nine bushels of "chellenottes" in Chestnut Wood, or pay eighteen-pence by the year to the queen.

In the marshes in the north-west quarter of the parish is a decoy for wild fowl, of which great numbers are taken, and principally sold in the markets of the metropolis. Halled's History of Kent, vol. vi. Beauties of England and Wales, vol. viii. by E. W. Brayley.

MILTON, a township of America, in Chittenden county, New York, on the E. side of lake Champlain, opposite to South Hero island; divided into nearly equal parts by La Moille river, which discharges itself into the lake in Colchester. The township contains 786 inhabitants.—Also, the "Uncataquisset" or "Unquaty" of the ancient Indians, a post-town in Norfolk county, Massachusetts, adjoining to Dorchester; 7 miles S. of Boston: containing 1143 inhabitants, three paper-mills, and a chocolate-mill. It was incorporated in 1662; and affords one of the finest prospects in America.—Also, a town in the county of Saratoga, in New York, containing 2123 inhabitants.—Also, a post-town in Cayuga county, New York, on the N.E. side of Cayuga lake, 40 miles N. of Tioga river; incorporated in 1794, and containing 3553 inhabitants.—Also, a small post-town in Albemarle county, Virginia, on the S.W. side of the Rivanna, about 80 miles N.W. by W. of Richmond.—Also, a post-town of Northumberland county, Pennsylvania: 219 miles from Washington.

MILTOWN-MALBAY, a post-town of Ireland, in the county of Clare. It is built on a bank running down to the sea, facing the south-west. There are here hot and cold baths, and it is much frequented as a bathing-place. It is 128 miles W.S.W. from Dub'in. Carlisle. Wakefield.

MILTSCHIN, a town of Bohemia, in the circle of Bechin; 10 miles N. of Tabor.

MILTUS, in *Betany*, so called by Loureiro, from *μύθος*, red lead, or vermilion, the whole plant being as that author says of a beautifully vivid red colour.—Loureir. Cochinch. 303.—Cials and order, *Dodiceandria Pentagynia*. Nat. Ord. *Caryophyllei*; Linn.? *Ficoideæ*, Juss.?

Gen. Ch. *Cal.* Perianth inferior, of five, ovate, concave, rugose, coloured, spreading, permanent segments. *Cor.* none. Nectary none. *Stam.* Filaments twelve, affixed to the bottom of the calyx, and shorter than it; anthers ovate, twin, erect. *Pist.* Germen superior, roundish, furrowed; style none; stigmas five, linear, bent backwards. *Peric.* Capsules five, approaching each other, ovate, rough, single-seeded. *Seed* ovate, shining.

Ess. Ch. Calyx of five leaves, inferior. Corolla none. Capsules five, single-seeded.

Obs. Loureiro remarks that the difference between this genus and *Glinus* is not very great.

1. *M. africana*. Loureir.—A native of dry places at Mozam-

Mozambique, an African island.—All that we know of this plant is from the description of the above quoted author, which is as follows. *Stem* shrubby, much divided, about four feet long, slender, prostrate, smooth. *Leaves* oblong, entire, obtuse, thick or fleshy, smooth, the lesser ones nearly sessile, opposite, and crowded. *Flower-stalks* simple, many together, lateral.—The stems, flowers, and leaves are all of a remarkably striking red or vernilion colour.

MILVAGO, in *Ichthyology*, a name given by Gesner and some others, to a fish called by authors in general *milvus*, and by some *lucerna*, and the *flying-fish*. It is a species of the trigla, and is called, by Artedi, the trigla with a snout bifid at the extremity, and the side-lines forked near the tail.

MILVERTON, in *Geography*, a market-town in the hundred of the same name, and county of Somerset, England. It is situated in a woody fertile country, pleasingly diversified with hill and valley, at the distance of eight miles from Taunton, and five from Wellington. The buildings are chiefly arranged in three irregular streets; and the church stands on an eminence in the centre. This town was anciently a borough, the manor whereof is now vested in the crown, and long possessed a good trade in ferges and druggets. The manufacture of these articles, however, is now almost entirely dropped, but an extensive manufactory of flannels has been established of late years. Though entirely deprived of its privileges as a borough, it continues to be governed by a portreeve; and searchers and sealers are still annually appointed. The petty sessions are held here. Friday is the market day, and there are two fairs during the year, one on the 25th of July, and another on the 10th of October. The population of the town and parish, according to the returns of 1801, was 1667 persons.

Milverton is remarkable in history as having given name to John de Milverton, the Carmelite friar of Bristol, who was celebrated for his zealous opposition to the doctrines of Wickliff, the first English reformer. Collinson's *History and Antiquities of Somersetshire*, vol. iii. 4to.

MILUS, *μῖλος*, a name given by the Greek writers to a plant used in garlands, and sometimes to a tree. Theophrastus evidently uses it as the name of a tree, and Crato as that of the garland-herb.

MILVUS, in *Ichthyology*. See *FLYING-FISH*, *CALYONIMUS Lyræ*, and *DRAGONET*.

MILVUS, in *Ornithology*, the name of the kite and buzzard. See *FALCO*.

MILWALDE, or MIDWALDE, in *Geography*, a town of Holland, in the department of Groningen; 8 miles S.S.E. of Dam.

MIMA, a town of Japan, in the island of Xicoco; 23 miles N.W. of Awa.

MIMANSA, in *Philosophy*, is the name of a theory upheld by a numerous sect of Hindoos, among whom, however, even of this school, there is considerable diversity of opinion. The word Mimanfa denotes, in Sanscrit, the operations and conclusions of reason. The doctrines are divided into the first and second. The first, called Purva Mimanfa, or Karma Mimanfa, is said to have been promulgated by Jaimini in twelve chapters; it discusses questions of law, and moral and religious duties. (See *JAIMINI*.) The second division is called Vedanta, and is attributed to Vyasa, who is sometimes said to have been the master or preceptor of Jaimini. (See *VEDANTA* and *VYASA*; and the articles *MURTY* and *MYSTICAL Poetry* for some of the tenets of the Vedanti school.) Both the Mimanfas profess to shew what acts are pure or impure, what objects are to be desired or avoided, and by what means the soul may ascend to the First

Principle. Compared with the Grecian schools, the Mimanfa approaches nearest the Platonic, having, indeed, many consonant ideas and doctrines.

MIME. MIMUS, a term in the ancient comedy, signifying a *buffoon*, or *mimic*, who acted by postures suitable to the person or subject he represented.

The word comes from the Greek *μιμῶν*, *imitator*; formed of *μιμῶμαι*, *I imitate*. The same comedians were also sometimes called *pantomimes*, because of their counterfeiting all manner of postures and gestures.

According to Lucian (de Saltatione), a single dancer, or mime, was able to express all the incidents and sentiments of a whole tragedy or epic poem by dumb signs, but still to music, as in the ancient recitation, and in modern pantomime entertainments; though Aristotle expressly says, that dancers want neither poetry nor music; as by the assistance of measure and cadence only, they can imitate human manners, actions, and passions. See *BATHYLLUS* and *Pylades*.

Plutarch (Sympos. l. vii. probl. 8.) distinguishes two kinds of pantomime: one was called *εὐβήσιον*, the subject of which was decent and decorous, as well as the manner of expressing it, and this nearly approached to comedy. Buffoonery and indecency constituted the other.

Sophon of Syracuse, who flourished in the time of Xerxes, was reputed the inventor of serious and decorous pantomime, replete with lessons of morality. Plato had great pleasure in the perusal of the pantomimes of this author. But the Greek drama was scarcely formed, ere theatrical writers and actors endeavoured more to divert the people by farces and representations of vicious scenes and characters, than to improve their morals. Such were the means by which interludes on the stage were rendered agreeable to the people of Greece.

The Romans were equally pleased with pantomime, and formed of it a fourth species of drama. The actors distinguished themselves by a licentious imitation of the manners of the times, as appears by the following verse of Ovid.

“Scribere si fas est imitantes turpia Mimos.”

The mimes usually acted without socks or stockings, whereas the three others wore socks or buskins. Their heads were close shaved, like the fools on mountebank stages; their dress, like that of our harlequins, was composed of bits of cloth or linen of different colours. This dress was called *Panniculus centumculus*. They sometimes also appeared in magnificent senatorial robes of purple, to divert the people by the ridicule and contrail of a senator's robe, and a shaved head and socks. Thus harlequin sometimes on our stage is bedight in the garb of a gentleman. To this dress they joined licentious language, and all kinds of ridiculous postures, neglecting nothing that could amuse the populace.

This kind of diversion was given even at funerals, and the actors were called *Archimimes*. They went before the coffin, and described by their gestures the actions and manners of the deceased: his virtues and vices, all were exhibited. The propensity which the mimes had to raillery, inclined them rather to reveal their frailties, than paint their virtues, or any thing that could redound to their honour.

The applause given to the pieces of Plautus and Terence, did not prevent even the better sort from admiring these pantomimic farces, when enlivened by wit, and not debased by indecency. The Mimographic poets of the Romans, who chiefly distinguished themselves in these dramatic exhibitions, were Sænius Mattius, Decimus Liborius, Publius Syrus, under Julius Cæsar; Philistion, under Augustus; Silo, under Tiberius; Virgilius Romanus, under Trajan;

and Marcus Marcellus, under Antoninus. But the most celebrated of all these was Decimus Liberius, and Publius Syrus. The first directed Julius Cæsar so much that he made him a Roman Knight, and conferred on him the privilege of wearing gold rings. He had such a wonderful talent at teasing ridicule, as to make every one draw his abilities. To the Cæsar allude, in writing to Trebatius, when he was in Britain with Julius Cæsar, telling him, that "if he is absent much longer inactive, he must expect to be attacked by the name Liberius." Publius Syrus, however, gained so much more applause, that he retired to Puzzoli, where he comforted himself for his disgrace and the inconsistency of the people, and the transient state of human affairs, by the following admirable verse :

"Cecidi ego : vadet qui sequitur ; laus est publica."

We with difficulty can imagine some of the grave and judicious reflections of Syrus to be extracted from the pantomimes which he exhibited on the stage : we should rather take them for maxims moulded on the sock or buskin. *Eneycl. 1st edit.*

"Sweet Polhymnia, see advance,
Mother of the graceful dance :
She who taught th' ingenious art
Silent language to impart :
Signs for sentiment she found,
Eloquence without a sound :
Hands loquacious gave her lungs,
All her limbs are speaking tongues."

MIMESIS, μιμησις, in *Rhetoric*, a figure, whereby the words, gestures, speech, actions, &c. of another person are imitated. See IMITATION.

MIMEPES, in *Botany*, so called by Mr. Salisbury (according to Mr. Brown) ; apparently from μιμησις, a mimic, but we know not its particular application. *Brown Tr. of Linn. Soc. v. 10. 105. Aut. Hort. Kew. ed. 2. v. 1. 197. (Hypophyllocarpodendron ; Boerb. Lugd-Bat. ed. 2. v. 2. 205. t. 205, 206.)—Class and order, Tetrandria Monogynia. Nat. Ord. Proteas, Juss.*

Ess. Ch. Corolla regular, in four deep segments. Stamens in the concave tips of the segments. Nectary four scales beneath the germen. Nut superior, sessile, smooth. Common receptacle flat, many-flowered. Scales deciduous.

Eleven species of this genus, all from the Cape of Good Hope, are described by Mr. Brown, four of which, introduced by Mr. Masson between the years 1774 and 1795, are cultivated at Kew. They are all *shrubs*, of a stout tortuous habit ; their *leaves* either entire, or furnished with callous teeth. *Flowers* aggregate, generally axillary, sometimes embraced by a sort of hooded leaf, sometimes terminal. *Involucrum* of many imbricated, membranous, rarely coriaceous, leaves, sometimes turned all to one side. *Pistils* longer than the corolla, which becomes laccid after its expansion. *Stigma* cylindrical, slender, for the most part acute. In *M. capitulata* however, Mr. Brown's second species, it is thickened and conical at the summit. In *M. purpurea*, his last, the *receptacle* is destitute of scales.

The following examples are sufficient.

M. hirta. Hairy Mimetes. Br. n. 1. (*Protea hirta ; Linn. Mant. 188. Lepidocarpodendron foliis sericeis brevibus, confertillimè natis ; fructu gracili longo ; Boerb. Lugd-Bat. v. 2. 194. t. 194. Leucadendron hirtum ; Linn. Sp. Pl. 136.*)—*Involucrum* equilateral, coloured, pointed, eight or ten-flowered. *Stigma* awl-shaped. *Corolla* feathery. *Leaves* acute, entire.—Grows in moist

situations. *Flowers* in the greenish use from June to August. A woody *shrub*, with numerous, imbricated, silky *leaves*. *Flowers* red-lith.

M. cucullata. Three-toothed Mimetes. Br. n. 4. (*Protea cucullata ; Linn. Mant. 189. Leuca enlroa africana, five Scolymocephalus angulorolatus, spicibus tridentatis ; Pluk. Almagell. 212. t. 3. 4. f. 6. Hypophylla arpodendron ; Boerb. Lugd-Bat. 206. t. 206. Leucadendron cucullatum ; Linn. Sp. Pl. 136.*)—*Involucrum* unequally directed, pointed, nearly smooth. *Leaves* linear-oblong, three-toothed, smooth : the floral ones dilated below, with recurved margins. *Stigma* awl-shaped, very acute.—Native of low marshy places, a mile and a half from the Cape. The *leaves* are crowded, tipped with three blunt red teeth. *Flowers* leathery, their long prominent styles reaching far beyond the corolla.

M. thymelaeoides. Daphne-leaved Mimetes. Br. n. 8. (*Leucadendron thymelaeoides ; Berg. Cap. 1.*)—*Stem* erect. *Leaves* oval, obtuse, downy, small. *Flowers* terminal, rather clustered. *Style* downy below the middle.—*Stem* shrubby, with round, purplish, downy, upright, compound branches. *Leaves* about half an inch long, crowded, spreading, downy, finely tinged ; the lower ones becoming smooth. *Flowers* sessile, the size of a small cherry, mostly in pans. *Leaves* of the *involucrum* elliptical, inclining to lanceolate. *Scales* of the *receptacle* all over densely woolly. *Corolla* silky. *Stigma* rather acute. Of this we find no figure, nor is any thing said of the colour of the flowers.

MIMIZAN, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan. The place contains 413, and the canton 2821 inhabitants, on a territory of 415 kilometres, in 6 communes.

MIMNERMUS, in *Biography*, a Greek elegiac poet, a native of Colophon, who flourished in the sixth century before Christ, was contemporary with Solon. He was the inventor of the pentameter verse : his compositions were of the elegiac kind, according to the ancient acceptation of the word, which by no means confined it to mournful topics. His talents led him to treat of very different subjects : he was a votary of love and pleasure, and is so distinguished by a line in Propertius :

"Plus in amore valet Mimnermi versus Homero :"

Horace likewise refers to him in a similar connection, though in much stronger terms :

"Si, Mimnermus uti censet, sine amore jocisque
Nil est jocundum, vivas in amore jocisque."

"If, as wise Mimnermus said,
Life unblest with love and joy,
Ranks us with the senseless dead,
Let these gifts each hour employ."

His manners are thought to have corresponded with his philosophy. Of his poems only a few remain, which have been published with the "Novem Feminarum Græcarum Carmina," by Ursinus in 1568, and by Wolfius in 1734.

Mimnermus, according to Plutarch, has rendered himself remarkable, by playing upon the flute a nome called *Cradias*, which, Hesychius tells us, was an air for that instrument usually performed at Athens, during the march, or procession, of the victims of expiation. His elegies, of which only a few fragments are preserved, were so much admired in antiquity, that Horace preferred them to those of Callimachus. (*Epist. hb. ii. ep. ii. v. 101.*) He composed a poem of this kind, as we learn from Pausanias, upon the battle

battle fought between the people of Smyrna, and the Lydians, under Gyges. He likewise was author of a poem in elegiac verse, quoted by Strabo (lib. xiv. p. 633, 634. ed. Par.), which he entitled "Nanno," and in which we may suppose he chiefly celebrated a young and beautiful girl of that name, who, according to Athenæus, was a player on the flute, with whom he was enamoured in his old age. Horace bears testimony to his abilities in describing that seducing passion; alluding to some much admired lines of this Greek poet, which have been preserved by Stobæus:

" Τις δε βίος, τι δε τέρπον ατερ χρυσι; Ἀφροδίτης, &c.
 What is life and all its pride,
 If love and pleasure be denied?
 Snatch, snatch me hence, ye Fates, whene'er
 The au'rous blis I cease to share.
 Oh let us crop each fragrant flow'r,
 While youth and vigour give us pow'r;
 For frozen age will soon destroy
 The force to give or take a joy;
 And then a prey to pain and care,
 Detested by the young and fair,
 The sun's bleit beams will hateful grow,
 And only shine on scenes of woe!"

MIMOSA, in *Botany*, so called from *mimos*, an actor or imitator. *Herba, or arbor, mimosa*, meaning a sort of imitative plant, whose motions mimic the sensibility of animal life. The Sensitive Plant.—Linn. Gen. 548. Schreb. 734. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 438. Juss. 346. Tourn. t. 375. Lamarck Illustr. t. 846. Gærtn. t. 155. (Acacia; Tourn. t. 375. Inga; Plum. Gen. 13. t. 19.)—Class and order, *Polygamia Monoecia*. Nat. Ord. *Leguminosæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very small, with five teeth. *Cor.* of one petal, funnel-shaped, regular, more or less deeply five-cleft, sometimes wanting. *Stam.* Filaments capillary, very long, usually very numerous, sometimes united below; anthers incumbent, sometimes partially abortive. *Pist.* Germen superior, oblong; style thread-shaped, shorter than the stamens; stigma abrupt. *Peric.* Legume long, with numerous transverse partitions. *Seeds* numerous, of various roundish shapes.

Obs. Many of the flowers are male, soon falling off; others are female; others furnished with both stamens and pistil, each occasionally more or less imperfect; all which circumstances vary in different species.

Mimosa of Tournefort has a jointed legume, and apparently sensitive, or irritable, leaves.

Acacia of the same author has a cylindrical legume; the leaves not moving when touched.

Inga of Plumier has a fleshy legume.

No part of the fructification in the genus before us is constant.

The *calyx*, usually five-toothed, in some species is three-cleft.

Corolla usually of one petal, in some is of five, in others altogether wanting.

Stamens in some very numerous, in others ten, five, or four; in some monadelphous; in some abortive.

Pericarp a legume, but in some species fleshy, in others membranous; in some winged, in others jointed; in some composed of four valves.

Seeds of a different shape in different species.

Ess. Ch. *Calyx* five-toothed. *Corolla* regular, five-cleft. *Stamens* five or more. *Pistil* one. *Legume* superior, with many cells. Some male flowers.

This vast genus labours under great uncertainty of cha-

rafter, as appears by the above remarks of Linnæus. For some of its near allies, see *GLEDITSIA* and *GYMNOCALADUS*. Jussieu has hinted at the propriety of dividing it, according to the number of stamens, and the structure of the legume. This Willdenow has attempted; but to accomplish it fully, an examination of numerous species in a living state would be necessary; and as most of them are tropical shrubs or trees, rarely seen, and still more rarely flowering or fruiting, in the gardens of Europe, this desirable end is not at present attainable. The foliage is of the pinnate kind, more or less compound; in some irritable, and folding up when touched or shaken; in all, we believe, drooping and folding together in the dark. A number of paradoxical species as to habit, uniform enough in fructification, have been found in the southern hemisphere. These have only a few pinnated leaves when young, bearing subsequently nothing but simple, vertical, oblong or linear, dilated and defoliated footstalks, which have all the appearance of leaves, and doubtless perform the functions of such. A few species bear, in their adult state, nothing but angular thorns, still less like foliage. Yet we know not of any difference in the fructification, between these and various uniformly pinnate kinds of *Mimosa*, found likewise in New Holland, which have the habit as well as characters of numerous species heretofore described, natives of Africa, or of the East or West Indies.

It is difficult to form a calculation of the species of *Mimosa*. The 14th edition of *Syst. Veg.* contains fifty-three only, scarcely any of the New Holland ones being there included. Of these last five are figured by Labillardiere, and several in Curtis and Andrews; two in Smith's Specimen of the Botany of New Holland. Much more information may be expected from Mr. Brown on this subject.

The genus is for the present subdivided, by the composition of its leaves, into several sections, of which we shall offer a few examples.—Some species are furnished with thorns, others not.—The roots in general have a strong alliaceous scent.

Section 1. Leaves simply pinnate.

M. Inga. Sweet-bean *Mimosa*. Linn. Sp. Pl. 1498. (*Inga* flore albo fimbriato, fructu dulci; Plum. Ic. 14. t. 25. *Arbor sylvestris*, Belgis *Zoete-boontjes*; Merian. Surin. 51. t. 51.)—Thorns none. Leaves pinnate, of five pair of ovate leaflets, with a jointed bordered stalk—Native of South America. A tree, with broad, smooth, serrated, ribbed leaflets. *Flowers* corymbose, large, green, with many united stamens. *Legumes* often a foot long, tortuous and furrowed; the seeds lodged in sweet eatable pulp. The last circumstance shews an affinity to *Ceratonia*.

Section 2. Footstalk divided, bearing two or three distinct pair of leaves.

M. bigemina. Pointed Twin-leaved *Mimosa*. Linn. Sp. Pl. 1499. (Katou-Conna; Rheede Hort. Malab. v. 6. 21. t. 12.)—Thorns none. Leaves pointed, in a double pair.—Native of Malabar. A tall tree, with a fetid though insipid root. *Leaflets* ovate, entire, three inches long, smooth. *Flowers* small, white, monadelphous. *Legumes* spiral, compressed, their polished globose seeds suspended by a thread.

Section 3. Leaves conjugate, consisting of two pinnate leaves, or a common footstalk.

M. sensitiva. Broad-leaved Sensitive plant. Linn. Sp. Pl. 1501. (*M. spinosa prima*, &c.; Breyn. Cent. t. 16.)—Prickly. Leaves conjugate; each with two pair of half-ovate leaflets; the innermost lower one very small. Petals none.—Native of the Brasils; and of hedges at Lima. This very interesting plant, whose sensibility, on account of the large size of its leaflets, is so striking, was formerly introduced by Houston into the gardens of England, but is

no longer to be met with. We have seen it at Turin. The *footstalks* have a large succulent knot at their base, which appears the chief seat of irritability, and on which the *leaflets* turn, as on a hinge, at the slightest touch. The largest *leaflets* are near an inch and half long; all semi-ovate, bristly beneath. *Flowers* in globular dense heads, on simple axillary stalks. *Legumes* flat, radiating from a centre, bristly and downy.

M. pudica. Common Sensitive plant, or Humble plant. Linn. Sp. Pl. 1501. (*M. spinosa* *tertia*, &c.; Breyn. Cent. t. 18.)—Prickly. Leaves to somewhat fingered, pinnate. Stem hispid. Legumes jointed, fringed.—Native of South America, and of the title of Bourbon.—This is naturally shrubby, though raised as an annual in our stoves, where it is kept for the sake of its wonderful sensibility. The *leaflets* are very numerous, oblong, obliquely elliptical, rather bristly. If one of them be cut, the shock is communicated, with gradually accelerated rapidity, along the *footstalks*, to the rest, who all fold softly together, after which the common and partial stalks droop and become pendent. These have the same tumid pulpy texture at their base as the former. (See LEAVES.) The *flowers* are pale purple, in round, axillary, stalked tufts. *Legumes* near an inch long, composed of three or four orbicular fringed joints.

Section 4. Leaves at least doubly pinnate.

M. glauca. Glaucous Mimosa. Linn. Sp. Pl. 1504. (*Acacia* non *spinosa*, flore albo, foliorum pinnis latiusculis glabris, siliquis longis planis; Trew. Ehret. 9. t. 36.)—Thorns none. Leaves doubly pinnate, in six principal divisions, and very numerous partial ones. *Legumes* long, lanceolate, flat.—Native of South America. Cultivated in our stoves, from the time of king William. The delicate glaucous *foliage* is very handsome. *Flowers* white, decandrous, in globular stalked axillary heads, either solitary or in pairs. *Legumes* a span long, acute at each end.

M. farnesiana. Sweet-scented Yellow Mimosa. Linn. Sp. Pl. 1506. *Acacia indica farnesiana*; Ald. Hort. Farnes. 3. t. 2. 4.)—Spines in the place of stipulas, awl-shaped, distinct. Leaves doubly pinnate, in eight principal divisions, and numerous partial ones. *Legumes* tumid, curved.—Native of Hispaniola. First raised at Rome in 1611. It is scarcely now seen in our stoves. The *leaflets* are small and smooth. *Flowers* deep yellow, in stalked heads, (not sessile as Linnæus says,) valuable for their exquisite fragrance, which excels almost every thing of the kind.

M. nilotica. Egyptian Mimosa. Linn. Sp. Pl. 1506. Woodv. Med. Bot. t. 67.—Spines in the place of stipulas, needle-shaped, divaricated. Leaves doubly pinnate, with glands on their common stalk. Heads of flowers on downy stalks, several together.—Native of the Levant. Linnæus mistook this for the true Gum Arabic plant, whose legumes were pasted along with his specimens, and which is another species of *Mimosa*, not well known to us. At least this was the opinion of the late learned Mr. Dryander. Several species, akin to these, produce different sorts of Gum Arabic, or Gum Senegal.

M. pubescens. Hairy-stemmed Mimosa. Vent. Hort. Malm. t. 21. Curt. Mag. t. 1263.—Thorns none. Branches hairy. *Legumes* doubly pinnate, without glands. *Leaflets* numerous, crowded. Heads of flowers numerous, in long axillary clusters.—Native of New South Wales. A beautiful and fragrant acquisition to the conservatory, remarkable for its rich downy *foliage*, and copious golden *flowers*.

Of the New Holland species with denudated *footstalks*, assuming the aspect of simple leaves, and which make a fifth most distinct *section*, examples are

M. myrtifolia. Curt. Mag. t. 302.

M. strita. Ibid. t. 1121. Andr. Repos. t. 53.
Of those which bear spines only.

M. verticillata. Curt. Mag. t. 110.

MIMOSA, in Gardning, comprehends plants of the shrubby and under shrubby kinds, of which the species cultivated are, the double-flowered annual sensitive mimosa (*M. plena*); the lively mimosa (*M. viva*); the quadrivalve-podded humble mimosa (*M. quadrivalvis*); the sensitive plant (*M. sensitiva*); the humble plant (*M. pudica*); the long-twiggd mimosa (*M. virgata*); the spotted-stalked mimosa (*M. punctata*); the slothful mimosa (*M. pernambucana*); the hairy-podded mimosa (*M. alperata*); the slow American sensitive plant (*M. pigra*); the glaucous mimosa (*M. glauca*); the horned mimosa, or cuckold tree (*M. cornigera*); the horrid mimosa (*M. horrida*); the Farnesian mimosa, or sponge tree (*M. farnesiana*); the Egyptian mimosa (*M. nilotica*); the whorled-leaved mimosa (*M. verticillata*); the rough tree mimosa (*M. arborea*); the Lebbeck, or Egyptian mimosa (*M. lebbeck*); the broad-podded mimosa (*M. latifolia*); the tamarind-leaved American mimosa (*M. tamarindifolia*); the spiral mimosa (*M. circinalis*); the small-leaved mimosa (*M. pennata*); the broad-leaved mimosa (*M. latifolia*); the purple mimosa, or soldier wood (*M. purpurea*); the netted mimosa (*M. reticulata*); the climbing mimosa (*M. scandens*); the myrtle-leaved mimosa (*M. myrtifolia*); and the sweet-scented mimosa (*M. suaveolens*.)

Method of Culture.—These plants are all capable of being increased by seed, and some of the sensitive kinds by layers and cuttings, but the first is by much the best method. The seed procured from the nurseries or seed-shops should be sown in pots of light rich mould early in the spring, covering it with fine earth, a quarter of an inch deep, and plunging the pots in the hot-bed; if in a common hot-bed under frames and glasses, managing them nearly in the manner of tender annuals, and when in a bark-bed in the stove little trouble is required. But moderate sprinklings of water should be given; and when the plants are two or three inches high, they should be planted out singly into small pots, preserving the earth to their roots, replunging them in the hot-bed, &c. giving water and occasional shade till they are well rooted, repeating the waterings frequently. The plants should afterwards be continued either in the hot-bed under glasses, or plunged in the bark-bed of the stove, to facilitate their growth, preserve them in vigour, and increase the sensibility of the sensitive kinds; admitting fresh air pretty freely.

It is proper that the perennial sorts, both shrubby and herbaceous, should be kept in the stove all winter, and principally the year round. And they must be frequently removed into larger pots to prevent the roots from getting through the pots, which they are apt to do, and by that means are often destroyed.

The *Acacia* kinds are the most tender, requiring the stove almost constantly, except a little in the heat of summer, when they must be placed in a warm situation. They should always have a bark hot-bed, and be put in very small pots filled with sandy mould, the heat of the stove being kept up to above temperate: as the leaves of some of them are shed, they have the appearance of being dried when that is not the case.

Where there is not the convenience of a stove, those who are curious to have the plants, may have them in summer, by the aid of a common dung, or tan-bark hot-bed, under frames and glasses, though not in winter; by raising some of the annual, or any of the other kinds, by seed in spring, in a hot-bed under a frame, &c. keeping up the heat of the bed until the middle of June, and continuing the plants always

always under the frame, raising one end of the lights a little, occasionally, in warm days, to admit fresh air; and as they rise in height, raise the frame at bottom, to allow them full room to grow. About Midsummer, or soon after, some of the low spreading kinds may likewise be turned out with balls, or plunged in their pots into a warm sunny border, and covered with large hand-glasses, which may be lifted off occasionally just to view the plants. By these methods, the plants may be preserved through the summer in their sensitive quality, though not in equal perfection to those in stoves; nor can they be preserved alive in winter out of the stove.

The shrubby kinds that afford spreading branches may be laid any time in summer, in pots plunged in the bark-bed, where they then take root, and are ready to pot off singly in the autumnal season.

The sensitive and humble sorts often branch out profusely, so as to furnish plenty of young shoots for cuttings, which should be planted in pots in the summer season, plunging them in the bark-bed, whereby they often readily take root, and form good plants.

These modes should, however, only be practised when feed cannot be procured.

The general culture of all the species is afterwards to keep them always in pots placed in the stove, being plunged occasionally in the bark-bed, especially the spreading sensitive kinds, frequent waterings being given in summer and winter, but considerably the most in the summer season; shifting them into larger pots as they increase in growth. And although most of the sorts will live in the open air in the heat of summer, it is the best practice to expose them but sparingly.

The fourth and fifth sorts are held in high estimation on account of the singular sensibility lodged in their leaves; which, in consequence of being touched or shaken, either by the hand, a stick, or the least wind blowing upon them, the wings of the leaves suddenly close, and the footstalks fall down. The period of time which the leaves, &c. require to recover themselves, after falling from any irritation, are according to the vigour of the plant, the hour of the day, the serenity of the atmosphere, and the temperature of the heat of the stove, &c. being often from ten or fifteen minutes to an hour or more.

The plants also, every evening, naturally contract themselves, and expand again in the morning. They are all ornamental and curious in their nature.

MIMULUS, in *Botany*, a name borrowed from Pliny, whose plant however could not be the same with Linnæus's American genus. The word is derived from *Mimus*, a masked actor among the Romans, and alludes to the form of the corolla.—Linn. Gen. 323. Schreb. 423. Willd. Sp. Pl. v. 3. 360. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 2. 361. Juss. 122. Brown Prodr. Nov. Holl. v. 1. 439. Lamarck Illustr. t. 523. Gærtn. t. 53. (Cynorrhynchium; Mitch. 3.)—Clas and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Scrophularia*, Juss. and Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, oblong, prismatic, five-sided, five-toothed, nearly equal, permanent. *Cor.* of one petal, ringent; tube the length of the calyx; limb two-lipped; the upper erect, cloven, rounded, reflexed at the sides; the lower broader, with three rounded segments, the middle one smallest; palate convex, cloven, protruded from the base of the lower lip. *Stam.* Filaments four, thread-shaped, within the throat, two of them shorter; anthers cloven, kidney-shaped. *Pist.* Germen superior, conical; style thread-shaped, the length of the stamens; stigma

ovate, cloven, compressed. *Peric.* Capsule oval, of two cells, opening transversely at the top; partition membranous, contrary to the valves. *Seeds* numerous, small. *Recept.* oblong, affixed to the partition on each side.

Eff. Ch. Calyx five-toothed, prismatic. Corolla ringent; the upper lip folded back at its sides. Capsule with two cells and many seeds.

1. *M. ringens*. Oblong-leaved Monkey-flower. Linn. Sp. Pl. 884. Curt. Mag. t. 283.—Stem erect. Leaves oblong, linear, sessile.—A native of Virginia and Canada, growing in wet places, and flowering in the summer.—*Root* perennial. *Stem* annual, about two-feet high, square, jointed, occasionally branched at the base. *Leaves* two at each joint of the stem, opposite, serrated, acutely pointed. *Flowers* solitary, on long, opposite stalks which spring from the joints of the upper part of the stem; they are of a delicate violet colour and without smell. *Seeds* pale straw-coloured, and tipped at each end, according to Gærtner, with a small, prominent, reddish point.—This plant was referred to several different genera by old authors. Linnæus first called it *Mimulus*, assigning the following explanation of the term in his *Philosophia Botanica*, “*MIMULUS, mimus personatus.*”

2. *M. glutinosus*. Orange Monkey-flower. Willd. n. 2. (*M. aurantiacus*; Curt. Mag. t. 354.)—Stem erect, shrubby, round. Leaves sessile, ovato-lanceolate, rather obtuse.—Gathered by Mr. Archibald Menzies in California. It flowers in our greenhouses, to which it is extremely ornamental, during the greatest part of the summer.—*Stem* nearly three feet high, much branched, jointed, viscid. *Leaves* opposite, sessile, serrated, much blunter than in the last species, revolute, smooth above, veiny. *Flowers* very showy, twice as large as those of *M. ringens*, of a beautiful orange colour, on solitary stalks, two at each joint of the stem. The whole plant is glutinous.

3. *M. alatus*. Oval-leaved Monkey-flower. Willd. n. 3. Vahl. Symb. p. 2. 72.—Stem erect, square, winged. Leaves oval, on stalks. A native of North America. It flowers at Kew in July and August.—We know of no figure of this plant, which very much resembles the first species in appearance.—*Stem* simple, smooth, slightly branched at the top, winged with a membrane at each angle. *Leaves* oval, veined, unequally serrated. *Flowers* on axillary, solitary, opposite, square stalks, swelling upwards. *Corolla* but little exceeding the calyx in length.

4. *M. luteus*. Yellow Monkey-flower. Linn. Sp. Pl. 884. Curt. Mag. t. 1501. (*Gratiola foliis subrotundi nervosis, floribus luteis*; Feuill. Peruv. v. 2. 745. t. 54.)—Stem creeping. Leaves roundish or ovate, on short stalks embracing the stem.—Found originally at Chili by Feuillé; and lately in California, and at Nootka, by Mr. Archibald Menzies. Dr. Langsdorff also, one of the Russian embassy to China, found it at one of the Fox Islands.—*Stems* creeping in the lower part, angular, thick at the base, the flowering branches ascending. *Leaves* opposite, at the joints of the stem. *Flowers* on solitary stalks, two at each joint, of a bright yellow colour, their throat spotted with red. The whole plant is massy and magnificent, being thickly set with foliage and flowers.

5. *M. gracilis*. Slender Monkey-flower. Brown Prodr. Nov. Holl. v. 1. 439.—Very smooth, erect. Leaves oblong, somewhat linear, obtuse, nearly entire. Flower-stalks elongated.—Found by Mr. R. Brown near Port Jackson, as well as in the tropical part of New Holland.

6. *M. repens*. Creeping Monkey-flower. Brown Prodr. Nov. Holl. v. 1. 439.—Smooth, creeping. Branches ascending. Leaves oval, obtuse. Flower-stalks shorter than the

the calyx.—Native of New South Wales and Van Diemen's Land. *Brown*.

MIMULUS, in *Gardening*, comprehends plants of the herbaceous flowery ornamental kind, of which the species cultivated are, the oblong leaved monkey-flower (*M. ruscus*); the wing stalked mimulus (*M. alatus*); and the orange monkey flower (*M. aurantiacus*).

M. of Culture.—This is a plant which is very hardy in respect to cold, but should have a loamy soft soil, rather moist than dry, and not too much exposed to the sun.

In the first sort the plants may be increased by parting the roots, not too small, and planting them in autumn, or the early spring, but the former is the better season. It may also be raised by seeds, which should be sown in autumn, soon after they become perfectly ripe, on a border exposed to the morning sun. And the second sort may likewise be increased in the same manner.

With respect to the third kind, it is best propagated by planting cuttings of the young shoots or branches in the early spring in pots of fresh mould, plunging them in a mild hot-bed, being afterwards managed as the other sorts.

The first and the second sort may be introduced in the borders and clumps, and the third among other potted plants of the less tender kinds.

MIMUSOPS, in *Botany*, so called by Linnæus, who seems to have taken the idea of the name from Hermann's *Museum Zeylanicum*, p. 23. This tree is there called *Munamal*, *Muna* being said to signify the human face in the Cingalese language, because the flowers have somewhat of the resemblance of a human face, of which however we seek in vain for any trace in the plates of authors. As this author says the highly fragrant flowers are worn by young women to adorn the neck and head, may not the above appellation allude to their being used as an ornament for the face?—Linn. Gen. 190. Schreb. 252. Willd. Sp. Pl. v. 2. 325. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 2. v. 2. 349. Brown Prodr. Nov. Holl. v. 1. 530. Juss. 152. Lamarck Illustr. t. 300. Gærtn. t. 42 (Imbricaria; Juss. 152. Binectaria; Forsk.)—Class and order, *Olandria Monegyia*. Nat. Ord. *Holoraceæ*, Linn. *Sapotæ*, Juss. and Brown.

Gen. Ch. *Cal.* Perianth inferior, of eight deep segments in two rows, ovate, acute, coriaceous, permanent. *Cor.* of one petal, wheel-shaped, its segments in two rows, numerous, oblong, entire or divided, the length of the calyx. *Stam.* Filaments eight, awl-shaped, hairy, very short; anthers oblong, erect, as long as the calyx. *Pist.* Germen superior, roundish, rough; style cylindrical, smooth, the length of the corolla; stigma simple, very blunt. *Peric.* Berry of one cell, oval, pointed. *Seeds* one or two, oval, hard.

Obs. Mr. Brown describes an equal number of abortive filaments, alternate with the stamens, and the calyx as in some instances six-cleft. The germen has originally six or eight cells. Dr. Roxburgh also found the abortive filaments.

Ess. Ch. Calyx of eight segments in two rows. Corolla of one petal, in numerous segments, in a double row. Berry with one or two seeds.

1. *M. Elengi*. Linn. Sp. Pl. 497. Fl. Zeyl. 57. Roxb. Coromandel. v. 1. t. 14. (Elengi; Rheed. Hort. Mal. v. 1. 33. t. 20.)—Leaves alternate, remote, ovate, pointed.—A native of sandy places in the East Indies, and much cultivated for its highly fragrant blossoms, which expand chiefly in the hot season. These flowers are sacred to the Hindoo gods. The root of this tree is thick and fixed deeply in the earth. *Trunk* branched, many feet in cir-

cumference, covered with a brown and frosty bark. *Leaves* alternate, on short stalks, somewhat drooping, veined, very firm, of a deep shining green, three or four inches long and about half as broad. *Flowers* stalked, two or three at the base of the leaf stalks, slightly drooping, white or yell with, very fragrant. *Seed* compressed, shining, chestnut-coloured. The wood of this plant is said by Rheed to be remarkably durable in water, but on the contrary very subject to become rotten if exposed to the air.

2. *M. parviflora*. Brown Prodr. Nov. Holl. v. 1. 531.—A native of the tropical part of New Holland.—Leaves oval, pointed, smooth on both sides. Flower-stalks erect to three, downward, longer than the downy leaf stalks.—All that we know of this species is from its discovery by Mr. Browne, who says that it is very nearly allied to *M. Elengi*, but that the flower-stalks of the latter are more numerous, and shorter than the leaf stalks, which are smoothish.

3. *M. Kauli*. Linn. Sp. Pl. 497. Fl. Zeyl. 57. Brown Prodr. Nov. Holl. v. 1. 531. Willd. n. 3. (*Metrilideros macassarensis*; Rumph. Ambon v. 3. t. 8.)—Leaves on shortish stalks, crowded together at the ends of the branches, ovate, obtuse, silvery beneath.—A native of the East Indies and Arabia, as well as of the tropical parts of New Holland.—The branches of this tree are thicker than those of *M. Elengi*, having small scars scattered all over them. *Leaves* crowded together at the ends of the branches. *Flowers* very similar in structure, but larger than those of the first species.—The berries are eaten in their crude state by the natives of Macassar, and are said to have a pleasant flavour. The foliage is extremely ornamental, and the wood useful for the handles of tools and such purposes.—Mr. Brown hazards a doubt whether the *Manil-kara*, Rheed. Hort. Mal. v. 4. t. 25, can possibly be cited as a synonym of *M. Kauli* on account of its six-cleft flowers, though they agree precisely as to foliage.

4. *M. hexandra*. Willd. n. 2. Roxb. Coromandel. v. 1. t. 15.—Leaves alternate, obovate, emarginate. Flowers hexandrous.—Native of the East Indies in the mountainous, uncultivated parts of the Circars. It flowers towards the beginning of the wet season.—The trunk of this large tree is erect, and much branched, with an ash-coloured bark. *Leaves* alternate, on stalks, wedge-shaped, deeply emarginate, very hard, of a deep shining green, three to five inches long, and about a third as broad. *Flowers* several together, axillary, stalked, variegated with white, lilac and yellow. *Berry* the size and shape of an olive.

5. *M. Imbricaria*. Willd. n. 5. (Imbricaria; Juss. et Lamarck' Illustr. t. 300.)—Leaves crowded together at the ends of the branches, ovate, obtuse, remote. *Berry* with many seeds.—A native of the Isle of Bourbon.—We are inclined to believe that this is very near *M. Kauli*, or perhaps a variety of that species, although we have adopted it on the authority of Willdenow.

MINA, $\mu\upsilon\alpha$. The Attic mina was either nummular or ponderal; in the first acceptation it was the sixtieth part of a talent, and contained a hundred drachmæ, or denarii, amounting in our coin (if we allow nine-pence for the value of the drachma), to three pounds fifteen shillings. The mina of Athens contained, at first, seventy-three drachmæ; but Solon gave it a hundred. Mina, considered as a weight, was also divided into a hundred drachmæ. It was regarded as a pound weight of the country to which it belonged; and the Attic pound is considered as the same with the Roman, and very nearly one pound troy. See **DRACHM**.

Mina was also a medicinal weight, consisting of twelve Roman ounces; but as in coinage eight drachms were allowed to the ounce, the mina, or pound, contained ninety-six, *i. e.*

the pound in weight consisted in fact of ninety-six drachmæ, while the pound in tale had a hundred. Dr. Arbuthnot asserts that the common Attic pound contained sixteen ounces, and was equal to our pound avoirdupoise; but this assertion seems to be contradicted by ancient testimony. See COIN and WEIGHT.

MINA, or *Mine*, in *Commerce*, a corn measure of Genoa, equal to 8 quarte, or 96 gombette: 100 English quarters = 233 mina, and a moundino of salt = 8 mine. See MEASURE.

MINA, in *Geography*, a town of Algiers; 50 miles S.E. of Oran.—Also, a river of Algiers, which runs into the Sheliff, 12 miles E. of Mustyganim.

MINA, or *Minau*, a sea-port town of Persia, in the province of Kerman, at the entrance of the gulf of Persia, at the mouth of the river Ibrahim, the air of which is insalubrious. It is surrounded with walls, and defended by towers, and has medicinal springs and baths; 42 miles W. of Ormus. N. lat. 27 8'. E. long. 56 40'.

MINADA, a town of Japan, in the island of Nippon; 20 miles N. of Xenday.

MINADAH, a river of Bengal, which runs into the Ganges at its mouth, N. lat. 22 45'. E. long. 91° 3'.

MINAES GERAES, a jurisdiction of South America, in Brazil, situated between the 15th and 22d degrees of S. lat., and the 25th and 33d degrees of W. long. The number of inhabitants is computed to be about 35,180 whites, 26,075 Indians, and 108,400 slaves. The fifth part of the gold found in this jurisdiction, and formerly paid to the king of Portugal, is estimated yearly to be about five millions of livres.

MINAGGNHINIM, a pulsatile instrument of music among the Hebrews, which was a square table of wood, fitted with a handle; over this table was stretched an iron chain, or hempen cord, passing through balls of wood or brass, which struck against the table when the instrument was shook, and occasioned a clear sound, which might be heard at a great distance.

MINARES, in *Geography*, a river of Spain, which waters the province of Aragon.

MINAS, *Basin of*, or *Les Mines bay*, sometimes called "Le Grand Praye," a gulf on the S.E. side of the bay of Fundy, into which its waters pass by a narrow strait; about 30 leagues from the entrance of Annapolis, and ten from the bottom of Bedford bay; 12 leagues in length and three in breadth.

MINAS, or *De las Minas hill*, the middlemost of the three hills, serving as inland marks for Bonaventura bay and river, on the coast of Peru, in South America; S. of Panama bay. N. lat. 3 20'. W. long. 75° 18'.

MINAS des Rixas, a town of Brazil, in the government of Goya; 85 miles N. of Villaboa.

MINASCOU BAY, a bay in the river St. Mary, between lake Superior and lake Huron; containing several islands. N. lat. 46. W. long. 84.

MINATO, Count NICOLA, of Bergamo, in *Biography*, a dramatic poet of great fertility. The reputation which he had acquired in writing for the theatres of Venice, occasioned his being engaged at Vienna as imperial poet laureate. He furnished the emperor's lyric theatre with a great number of serious operas, and still more small occasional dramas and poems for music. On every birth-day and occasion of joy and festivity, an analogous piece or two, besides the fixed operas for winter and autumn. These operas passed into Italy, where they were new set and performed with success. This poet possessed a perfect knowledge of history, his fable was generally well planned, and his cha-

raeters well sustained. He had genius and invention, and gave good opportunities for decoration and machinery. He flourished from about 1650 to 1683.

MINATTA, *Isle la*, in *Geography*, lies on the N. coast of lake Superior, in Upper Canada, near to, and E. of, the grand Portage, extending to Thunder bay.

MINAYA, a small town of Spain, in the province of La Mancha: it was formerly considerable, but is now almost reduced to the size of a village. The entrance to the parish church, which is of a moderate size, and has three chancels, is through a portico supported by two pillars of the Corinthian order, of white marble; 2½ leagues from La Roda.

MINAZZO, CAPE, a cape of Spain, on the W. coast of Galicia. N. lat. 42 51'. W. long. 91° 20'.

MINCA, a name given by the ancients to a very coarse and bad kind of myrrh.

MINCH, in *Geography*, a channel of the North sea, between the Hebrides and the main land of Scotland.

MINCHA, in the *Jewish Customs*, offerings of meal, cakes, or biscuits, made in the temple of the Lord. The Seventy have sometimes preserved this word in their translation; but instead of *mincha* they read *mana*, which doubtless was the received pronunciation in their time. We find *mana* in the same sense in Baruch, i. 10. Levit. ii. 3, &c. See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings, viii. 5. 9. xvii. 7. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5, 9, &c. Calmet. Dict. Bibl.

MINCHIN-HAMPTON, in *Geography*, a market-town in the hundred of Longtree, and county of Gloucester, England, is situated on the declivity of a gentle eminence, and consists of four irregular streets, intersecting each other at right angles. The chief trade of this town is a manufacture of cloths, which is carried on to a considerable extent, the many brooks and rivulets in the vicinity being extremely favourable for the purpose. The church, which is built in the form of a cross, was founded by the nuns of Caen, in the reign of Henry III. Numerous monuments and sepulchral inscriptions diversify the interior of this fabric; and in the church-yard appears a brass plate, in honour of Mr. James Bradley, the celebrated astronomer, who was a native of Gloucestershire, and died in 1762. Here are three market-houses, two of which were erected by P. Sheppard, esq. in the year 1700, with the view of establishing a wool-market, but the design failed of success. Here is likewise a respectable free-school. Leland says "there were nunnes" in this town; and Camden and Speed hence affirm it contained a nunnery. Bishop Tanner, however, considered this statement as erroneous, and says, "this place was called Minchin-Hampton, only because the manor was given to the nuns, or minchins of the Holy Trinity, at Caen, in Normandy, by William the Conqueror." The abbess of that monastery purchased for it the privilege of a weekly market, which continues to be held on Tuesday. According to the parliamentary returns of 1801, this town contained a population of 3419 persons, of which number 1549 were males, and 1870 females. To the west of this town lies an extensive common, called Amberley, remarkable for being the site of a very singular encampment. The great vallum of this work is irregular, and has smaller trenches branching from it. It extends nearly three miles in length, to a spot called Woeful-Dane-Bottom, probably in memory of some signal defeat sustained here by that people, whom Mr. Fosbrooke conjectures to have occupied this camp as a summer residence, during their abode at Cirencester in the year 879. At Rodmarton, a small village near the fols-way, which passes through this district, a tessellated pavement and other Roman remains were discovered about the

the middle of the seventeenth century. Horley, a dilapidated market-town, two miles from Minchin Hampton, contains some fragments of a priory, formerly dependent on the monastery of St. Martin's, at Troues, in Normandy. In a field adjoining to Catcombe park, the seat of Philip Sheppard, esq., is a large oval tumulus, now planted with firs, which had erect stones at each end of it. On its summit is placed a huge fragment of rock, evidently a sepulchral monument, which has been long distinguished by the appellation of Tingle-stone. At some distance from this tumulus appear two large stones, set upright in the ground; one has its top broken off, but the other is perfect, and rises ten feet above the surface. Tradition assigns one or both of these memorials to Long, a Danish chieftain, whence comes the name Long's stone, or pillar. Bigland's History of Gloucestershire, vol. ii. folio. Beauties of England and Wales, vol. v.

MINCHIVAVIDA, a small island in the South Pacific ocean, near the coast of Chili. S. lat. 44° 40'.

MINCIO, a river of Italy, which rises in lake Garda, forms the lake which surrounds the city of Mantua, and afterwards runs into the Po near Sassetta.—Also, a department or division of the new kingdom of Italy, consisting of what was before the revolution the duchy of Mantua, containing 123,649 inhabitants, who elect nine deputies. The capital is Mantua.

MIND, **MENS**, denotes a thinking or understanding being. See **SMITH**.

Philosophers generally allow three kinds of minds, *viz.* *God*, *angels*, and the *human soul*. For a thinking being must either be finite or infinite: if infinite, it is *God*; and if finite, it is either joined with a human body, or not; if the latter, it is an *angel*; if the former, a *soul*.

The *human mind* is properly defined a thinking rational substance; by *thinking* it is distinguished from body; and by *reasoning* from God and angels, who are supposed to see and know things intuitively, without the help of deduction and discourse.

MIND. *Affection of the*. See **AFFECTION**.

MINDANAO, or **MAGINDANAO**, in *Geography*, one of the Philippine islands, and interior only to Luçon in extent: it is of a triangular form, and in circumference about 900 miles, but so intersected with promontories and bays, that a person might cross it in a day and a half. It was discovered by the Spaniards who accompanied Magellan. It lies S.E. of Manila, at the distance of 600 miles. Although mountainous, the vales consist of a rich black mould, watered with the finest rivulets; it furnishes ample supplies of rice, and also palm-trees, the pith of which affords sago, and this, when reduced to meal, is used for making bread and biscuit throughout all the island. It has a variety of fruits in common with the other islands of this archipelago; but the cinnamon is peculiar to itself, and the trees that furnish it grow on the mountains without culture, and without being regarded as the property of any individual. By digging deep in the ground, and searching the rivers, the inhabitants find good gold. They also collect plenty of sulphur from the burning mountains. The scenery of Mindanao is beautiful, and it is fertile in a variety of productions. The chief Spanish settlement is at Sambuang, in the S.W. The "Lano" is a large inland lake, about 60 miles in circumference: horses and buffaloes have multiplied here to a surprising degree. In the south, there is a volcano of constant eruption, which serves as a sea-mark. In the strait between this island and that of Xolo, very large pearls are found. N. lat. 5° 40' to 9° 55'. E. long. 122° to 126° 27'.

MINDAY, a town of Pegu; 8 miles S. of Prome.

MINDELHEIM, a town of Bavaria, and capital of a lordship, about 8 miles square; 22 miles S.W. of Augsburg. N. lat. 48° 2'. E. long. 10° 27'.

MINDEN, a principality of Germany, in the kingdom of Westphalia, about 96 miles in circumference, consisting of good corn land, so that agriculture is carried on with great diligence and with such success, that from hence neighbouring countries are supplied with flax and corn, and particularly with wheat and barley. This principality has also wood, turf, coal, and a productive salt-work, and plenty of fish. The Roman Catholics only enjoy in the town of Minden, and the Calvinists every quarter of a year, at the citadel of Petershagen, their public worship; all other churches in the country belong to the Lutherans. This principality is now annexed to the kingdom of Westphalia.

MINDEN, a city of Westphalia, and capital of the fore-mentioned principality, and formerly one of the Hanse towns, is situated on the Weser. It is about two miles in compass, and surrounded with walls and ramparts. Its situation for commerce is advantageous, and some of the inhabitants carry on a considerable brewery; others are employed in agriculture and breeding of cattle. The cathedral is a considerable building, and the chapter consists of 18 persons, partly Roman Catholic and partly Lutheran. This town was an important place, even in the reign of Charlemagne; and it has since been contended for, and occasionally possessed by the Imperialists, Swedes, and French; 30 miles E. of Osnabruck. N. lat. 52° 18'. E. long. 8° 56'.

MINDEN, a post-town of America, in Montgomery county, New York; 472 miles from Washington.

MINDEPILLY, a town of Hindoostan, in Myfore; 8 miles W. of Veniatighery.

MINDERER, **RAYMOND**, in *Biography*, a physician of Augsburg, who was distinguished in the early part of the seventeenth century as a partizan of the chemical sect. He was also eminent as a military physician, in which capacity he served several campaigns, with universal esteem throughout all ranks in the army; whence he also rose to high reputation and practice in the courts of Vienna and Munich, and was consulted by the principal nobility. He published the result of his experience relative to the diseases of armies, in the German language; and this work was translated into Latin, with the title of "Medicina Militaris, seu, Liber Caltrensis, epositorista et facile parabilia Medicamenta continens," Vienna, 1620, 8vo. This work was several times reprinted, and was also translated into English in 1674. He was likewise author of the following works. "De Pestilentia Liber unus," *ibid.* 1608. "Alœdarium Marocoftinum," *ibid.* 1616, and afterwards republished. "De Calcantho, seu Vitriolo, ejusque qualitate, virtute, et viribus," 1617. "Threnodia Medica, seu, Planctus Medicinæ lugentis," 1619. His chemical reputation is evinced by the connection of his name in the shops, even at this day, with the neutral salt, the acetate of ammonia, which is called Mindererus' spirit. Eloy. Dict. Hist.

MINDERERI SPIRITUS. See **VINEGAR**.

MINDIGAUT, in *Geography*, a town of Hindoostan, in Dooab; 5 miles S.E. of Canoge.

MINDIUM, in *Botany*, Juss. 164. Medium Dioscoridis, Mindium Rhazis; Raaw. It. 284. See **MEDIUM** and **MICHAUXIA**.

MINDO, in *Geography*, a town of South America, in the audience of Quito; 20 miles N.W. of Quito.

MINDORO, one of the Philippine islands, about 27 miles S. from the island of Luçon, triangular in figure, and about 150 miles in circumference. It is high and

mountainous, abounding in cocoa and other fruit-trees, with some rice. A part of the sea adjoining this island is called the "sea of Mindoro." N. lat. $12^{\circ} 21'$ to $13^{\circ} 30'$. E. long. $120^{\circ} 24'$ to $121^{\circ} 24'$.

MINDOWLY, a town of Hindoostan, in the circar of Singrowl; 10 miles N. of Seipour.

MINDYGUR, a town of Hindoostan, in Oude; 5 miles S. Canage.

MINE, a town of Abyssinia; 170 miles S.W. of Gondar. N. lat. $0^{\circ} 4'$. E. long. $35^{\circ} 30'$.

MINE. This word is applied generally to all works carried on under ground, but seems principally to belong to such as have for their object the discovery and production of the metallic ores.

The construction of the works in various mines differs according to circumstances, such as the form of the hills in which they are situated, or the position of the ores, whether found in veins or beds. Some mines are formed by a level or drift entering the foot of a mountain, and extending to the deposits of metal within it, which may be taken away and carried out through this opening; and in this case *shafts* are only required for the purposes of ventilation.

This seems to be the simplest state of mining, and is, as well as such mines as have been formed by following ore from the surface to such depths as water would permit, to be ranked among the earlier efforts of this kind.

The more extended operations of mining are to be found where regular metallic veins, situated in primitive rocks, are worked to great depths below the level of the sea, where perpendicular *shafts*, drained of the constantly accumulating water by engines, form the means of communication from the surface to *levels* driven upon the *lode* or vein, at various and successive depths, so as to open all parts of it for the discovery of its contents.

A mine thus constructed, of any considerable extent, is one of the most extraordinary instances of human enterprize, patience, and ingenuity; especially if it be considered that its formation depends upon the application of two of the most wonderful discoveries on record, the expansive forces of gunpowder and steam.

Mines in Cornwall and Devon are generally worked by a company of proprietors, called adventurers, who agree with the owner of the land, or lord of the soil, as he is usually denominated, to work the mine for a certain term of years, paying him, by way of rent, a proportion of the ores raised, or an equivalent in money. The grant thus made to the adventurers is called a *feet*, and the lord's rent, if paid in ore, is called the *disb* (probably from the ancient practice of measuring it by a vessel of that sort), and when settled for in money, has the term *dues* applied to it.

The adventurers divide their undertaking into shares of different magnitude, but usually forming in the whole some even and easily divisible number. The smallest share usually held by one adventurer is one sixty-fourth part, though in some large mines this share is divided, and a person may then have only a one hundred and twenty-eighth part of the whole, while others may hold eighths, others sixteenths or thirty-seconds, and some larger proportions, but the whole added together make up sixty-four shares. Any part of the concern held by one person is generally called a *dole*, and distinguished as to its relation to the whole by adjoining to this word the denomination of its value, as an eighth dole, a sixteenth dole, &c.

Mines in Cornwall and Devon are usually named as soon as they are undertaken, and this practice seems to have been of considerable antiquity, as the word *wheal*, or *huel*, usually even now prefixed to these appellations, is derived from the an-

cient Cornish language, and signifies a work or mine. The other parts of the names of mines often relate to the situation, or have been given in compliment to some person connected with them, or adopted according to the fancy of the adventurers. Thus Wheal Rose is probably derived from the Cornish word *ros*, a valley, and means therefore the mine in the valley; Wheal Godolphin has the name of a family; and among the arbitrary appellations which are the most numerous, may be instanced Wheal Unity, Wheal Virgin, Wheal Jewel, &c.

The *bounds*, or limits of the set of a mine, are usually marked out upon the surface, and include the space of ground in which any company of adventurers have contracted for the right working. Bounds for working tin are recognized by the statutory laws of Devon and Cornwall, as a property in themselves distinct from the possession of the soil, and were probably originally granted to encourage the search for this metal by the laws of the duchy, that the revenue of the chief lord might not suffer by the unwillingness of the possessor of the soil to have its surface disturbed. Tin bounds that have been legally renewed, or possession retained, are even now in their original state in this respect; but copper mines, and also many tin mines, are now generally held of the possessor of the fee.

Mines are generally conducted in Cornwall and Devon by a manager appointed by the adventurers, who held meetings at the counting-house to revise and pass the accounts, and to debate and determine on all subjects relative to the prosecution of the works submitted to them.

Under the principal agent others are appointed, who are practical miners, and who superintend the various operations and settle the terms of the contracts with the workmen, which are made by a kind of public auction. These agents are called *captains*, and the number employed in a mine is in proportion to its extent and importance. Some attend principally to the works below, and are therefore called *under-ground captains*; others take charge of the operations on the surface, and are therefore distinguished by the appellation of *grafs captains*. It would be injustice to this useful and respectable body of men to pass them over without noticing the intelligence, activity, and skill by which the agents of the mines in the districts alluded to are distinguished.

The establishment of a mine further includes occasionally an engineer, a head carpenter and smith, who have each their workmen under their care; a *pitman*, who directs the fixing and repair of the pump-work; a *timberman* or *binder*, who superintends the construction of the woodwork under ground, for securing the shafts, ladders, levels, and so on; and besides these operative men, there are usually clerks to keep the accounts, and persons to receive and deliver to the workmen the materials used in their operations.

The miners working under ground are divided into two classes, according to the mode by which they are paid. Those of the first class are called *tributers*, who work on the productive parts of the mine, and receive a proportion of the ore which they procure and make merchantable, for their labour. This mode of payment, by its occasionally leading to unusual profit, stimulates to great exertion in the discovery of fresh deposits of ore, and is therefore conducive to the interests of the employer as well as the workman. To the reward thus held out to skill and intelligence, may probably be attributed the prevalence of these qualities, which may be observed more particularly in this class of Cornish miners. The other workmen employed under ground are denominated *tutwork-men*, who agree for sinking shafts, driving levels, and so on, at a certain price *per fathom*. These prices are exceedingly various, as the rock to be penetrated differs in degrees

gress of hardships, or the nature of the work exposes the men to more or less danger or inconvenience from water or bad air.

The people employed on the surface in dressing the ore, generally perform their labour by talk-work, the amount being charged to the account of the tributers, whose ore is undergoing this process.

The copper ores, when ready for sale, are sampled by agents of the smelting companies, who visit the mines for that purpose, and are sold on a fixed day by a public sale, called a *ticketing*, and afterwards weighed and carried to a port and shipped to Wales, where the copper smelting houses in general are. Tin ores are smelted in Cornwall, and are sold by the miner to the owners of the smelting houses by private contract, valuing them by an assay made by the buyer. In this respect the value of tin ores is determined by a mode much more uncertain and irregular than that employed for copper, the assay of which is conducted with extreme care, and wonderful accuracy.

The extent of the returns and costs of the mines in Cornwall and Devon, both collectively and separately, may be seen by referring to the history of mining in this district, where the tables of the state of these concerns exhibit a very interesting picture of the great increase of these extensive undertakings. See *Mining, History of*.

The king by his prerogative hath all mines of gold and silver to make money; and therefore those mines, which are properly royal, and to which the king is entitled when found, are only those of silver and gold. (2 Inst. 577.) By the old common law, if gold or silver be found in mines of base metal, according to the opinion of some, the whole was a royal mine, and belonged to the king; though others say that this was only the case, when the quantity of gold or silver was of greater value than the quantity of base metal. (Plowd. 336.) But by statute no mines of copper, tin, iron, or lead, shall be adjudged royal mines, though gold or silver be extracted. (1 W. and M. c. 30.) And persons having mines of copper, tin, lead, &c. shall enjoy the same, although claimed to be royal mines; but the king, or persons claiming royal mines under his authority, may have the ore (except tin-ore in Devon and Cornwall) paying to the owners of the mines, within thirty days after it shall be raised, and before removed, 16*l.* per ton for copper-ore washed, and made merchantable; for lead-ore 9*l.* per ton; tin or iron, 40*s.* &c. (Stat. 5 W. & M. c. 6.) If any person maliciously set on fire any mine, or pit of coal, he shall be guilty of felony, without benefit of clergy, by stat. 10 Geo. II. c. 32. If any person shall wilfully or maliciously set fire to, burn, demolish, pull down, or otherwise destroy or damage any fire-engine, or other engine erected for draining water from coal mines, or for drawing coals out of the same; or for draining water from any mine of lead, tin, copper, or other mineral, or any bridge, waggon-way, or trunk erected for conveying coals from any coal mine, or staith for depositing the same; or any bridge, or waggon-way erected for conveying lead, tin, copper, or any other mineral, from such mine, or cause the same to be done, he shall be guilty of felony, and transported for seven years. (9 Geo. III. c. 29.) Provided that no person be prosecuted under this act beyond 18 months after the offence committed. By 39 & 40 Geo. III. c. 77, destroying or damaging mines or roads leading to or from the same, &c. incurs the guilt of misdemeanor, and any one person so offending may, on conviction, be imprisoned for any time not exceeding six months. Colliers and miners working in a manner contrary to their agreement, or not fulfilling their contracts, shall, on conviction, forfeit not exceeding 40*s.* and on non-payment be imprisoned for a time

not exceeding six months, or until the penalty and costs shall be paid. Stealing ore out of mines is no larceny, except only those of black-lead, the stealing ore out of which is felony, punishable with imprisonment and whipping, or transportation not exceeding seven years, and escaping from such imprisonment, or returning from transportation is felony, without benefit of clergy, by 25 Geo. II. c. 10.

Mine-venturers Company of, had its first rise about the year 1600, when certain mines of lead and copper were found in South Wales, which were divided by the proprietors into twenty-four shares; and in 1603 sub-divided into four thousand and eight shares, for the term of twenty-two years and a half; to which term five years more were added in 1608, and the affairs of the company regulated by a new constitution. In 1704, queen Anne granted a charter of incorporation to this company; in consequence of which several new shares were added, so that the whole number amounted to six thousand and twelve. However, the interests of this corporation were so ill managed, that the proprietors and creditors petitioned parliament in 1710, and a committee of the house of commons was appointed to enquire into its state. The result of the enquiry was a censure on the principal managers; and though, in 1711, a law was passed for the better regulation of the company, and the relief of the creditors and proprietors, nothing could preserve it from sinking.

MINE, in the *Art of War*, denotes a subterranean canal or passage dug under the wall or rampart of a fortification intended to be blown up by gunpowder.

The passage of a mine leading to the powder is called the *gallery*. These passages or galleries made within the fortification, before the place is attacked, and from which several branches are carried to different places, are generally four feet wide, and five feet high, and the earth is supported from falling in by arches and walls, as they are to serve for a considerable time; but when mines are to be used in a short time, the galleries are only about three feet wide and five high, and the earth is supported with wooden frames or props. When the gallery is carried on to the place where the powder is to be lodged, called the *chamber*, the miners make this generally of a cubical form, large enough to hold the wooden box, which contains the powder necessary for the charge; this box is lined with straw and sand-bags, to prevent the powder from contracting any dampness. The chamber is sunk somewhat lower than the gallery, unless the besieged can raise the water in the ditch, and incommode the gallery; in which case the chamber is made higher than the gallery, that the water may not be let in and spoil the mine. The line, drawn from the centre of the space containing the powder, perpendicular to the nearest surface, is called the line of *least resistance*; the pit or hole, made by a mine when sprung, is called the *excavation*. The fire is conveyed to the mines by a pipe or hose, made of coarse cloth, whose diameter is about an inch and a half, called *saucisson*, extending from the chamber to the entrance of the gallery, to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber. In order to prevent the powder from becoming damp, the saucisson is laid in a small trough, called *auge*, with straw in it, and round the saucisson, with a wooden cover nailed upon it. There are various kinds of mines, which acquire different names; as *royal mines*, *serpentine mines*, *forked mines*, as their passages are straight, oblique, winding, &c. The mines made by the besiegers in the attack of a place are simply called *mines*, and those made by the besieged *counter-mines*. They are both made in the same manner, and for the like purposes, *viz.* to blow up their enemies and their works; only the principal galleries and mines of the besieged are usually made

before

before the town is besieged. The besieged generally make a great many small mines under the glacis, of about six, seven, or eight feet deep under ground, which are called *fougasses* or *fougades*. They make likewise another fort, called *coffers* or *caissons*, which are a kind of wooden boxes three or four feet long, and a foot or eighteen inches wide, which they bury four, five, or six feet under the glacis, and about four yards distant from each other.

MINES, History of. It is observed by writers on this subject, that mines were in use long before the invention of gunpowder; for the ancients made galleries or subterraneous passages under the walls of places, and supported them with strong props; filling the interval with all kinds of combustibles, which being set on fire burnt their props, and, the walls being no longer supported, fell, whereby a breach was made. The besieged also made use of similar passages from the town under the besiegers' machines, with which they battered the walls, in order to destroy them. But the art of mining has received great improvements since the invention of gunpowder. The first mines which we read of, since the discovery of gunpowder, were used, in 1487, by the Genoese, in the attack of Serezanella, a town belonging to Florence: however, as these failed, they were neglected for a considerable time. The first successful application of the blowing of mines in sieges was in the kingdom of Naples, in the year 1503; when Pietro de Navarre by this means possessed himself of a fort garrisoned by the French. But the first celebrated use of these mines in opposing the progress of the besiegers was in the years 1666, 1667, 1668, at the siege of Candia; though they had been often practised in the defence of places before, in a less memorable manner; for by the assistance of this invention principally, the city of Candia kept the whole power of the Ottoman empire at bay for three years successively. Since that time the advantage of counter-mines hath been better understood. The last eminent instance of their great utility was in the defence of Turin, in 1706: for so effectually were the besiegers traversed thereby, that, after near four months of open trenches, they were not in possession of more than the counter-scarp, and even then, eleven pieces of their cannon were blown up by the defendants but three or four days before the place was relieved.

The first professed writer on mines was the celebrated M. Vauban; he was succeeded by M. de Valliere, one of the greatest masters in the art of mining; who, uniting theory with experiment, discovered, by measuring several excavations, that the pit or hole made in the earth, when the mine was sprung, was not an inverted cone (*Plate VI. Fortification, fig. 10.*) nor a frustum of a cone (*fig. 11.*) as Vauban and others had supposed, but nearly a paraboloid (*fig. 12.*); and his tables were computed according to that figure. It has been generally admitted by miners, that the diameter of the pit or hole made by the mine was always twice the line of the least resistance, and that this diameter should never exceed this proportion. But M. Belidor undertook to remove this prejudice; and however generally it may still prevail, he seems to have proved by many experiments, which have since been repeated by others, that the diameter of the hole made by a mine may be increased to any length in regard to the depth of the mine.

MINES, Theory of. The estimation of the proper quantity of powder with which a mine is to be loaded in any kind of soil, or at any depth under ground, in order to produce any proposed effect, is the most difficult part of the whole art of mining. This depends not only on the quantity of earth to be blown up, but likewise on the tenacity of the different soils in which the mines are made. The quantity of earth

to be raised depends on the figure of the excavation; for if this is known, the solid content may be determined by geometry; and by weighing exactly a cubic foot of that soil, we can easily discover what weight is to be raised; and by knowing what quantity of powder is required to raise a certain weight, the tenacity of the parts may also be had, by making a mine so as to produce a good effect; and subtracting the quantity of powder, necessary to raise the weight of the solid from the charge of the mine, the remainder would be the quantity necessary to overcome the tenacity. It is, however, disputed, as we have already observed, what the figure of the excavation is: it was at first imagined to be an inverted cone, as *A C B* (*fig. 10.*) whose vertex is in the centre of the chamber, and the radius of its base *A D* equal to its axis *C D*; but this being found to allow too small a charge, it was next supposed to be a frustum of a cone, as *A E F B* (*fig. 11.*) whose lesser base *E F* is equal to the line *C D* of least resistance, and the greater *A B* equal to twice that line. On this last supposition, said to be confirmed by the experiments of M. Maigrigny, under M. Vauban, near Tournay, miners have computed their tables of the quantities of powder necessary for charging mines at different depths.

However, Mr. Belidor disputed the conclusions of Maigrigny; whose experiments were examined by direction of the chief commander of the artillery of La Fere, in the construction of more than a hundred and fifty mines between the years 1725 and 1730. In the course of this enquiry, seven mines were made, whose line of least resistance was ten feet, and loaded with the following quantities of powder, *viz.* the first with 120lb.; the second with 160lb.; the third with 200lb.; the fourth with 240lb.; the fifth with 280lb.; the sixth with 320lb.; and the seventh with 360lb. These mines being sprung one after another, and their excavations examined, the diameters of their bases were found to be as follow: that of the first 22 feet; the second, 26 feet; the third, 29 feet; the fourth, 31½ feet; the fifth, 33½ feet; the sixth, 36 feet; and the seventh, 38 feet. These experiments invalidated the principles of Maigrigny; nevertheless miners have still doubted, whether the diameter of the excavation can be made greater than double the line of least resistance, or whether the excavation itself will not become like a well or pit when overcharged. As to the true figure of the excavation, this was discovered by M. de Valliere, and ascertained by others after him to be very nearly a paraboloid, as *A E B* (*fig. 12.*) having the centre of the powder or charge in the focus *C*, *C D* the line of least resistance, *A B* the diameter, and *C A* the radius. Mr. Muller, however, observes, that though the figure of the excavation is a paraboloid, the quantity of the earth to be blown up should be estimated by the part *A L M B*, cut off by a plane *L M*, passing through the focus or centre *C* of the chamber, parallel to the horizon *A B*; the other part *L E M* being occasioned by the force of the powder pressing downwards; because, he says, the explosion of gunpowder, acting on all sides alike, must condense the solid under the chamber from *L* to *M*, by its pressure downwards, so long as it presses the earth above *L M* upwards; and it cannot be said, that any particle of earth under the horizontal line *L M* can be drove upwards. In order to find the content of this solid, let *E K = E C = ¼* of *P*, or the parameter; and it appears from the well known properties of the parabola, that $A D^2 = E D \times P$; $L M = P$; and $C A = K D$. And in the right-angled triangle *C D A*, $C D^2 + D A^2 = C A^2 = K D^2$; and, therefore, $\sqrt{C D^2 + D A^2} = K D$; whence, if *C D* and *D A* are given, the line *K D*,
and

and consequently CK, or its equal CL, will be known; and, therefore, if the line of least resistance CD, and the radius DA of the base are given, the parameter may be found. Moreover, the solid content of the paraboloid is equal to half the cylinder of the same base and altitude; if r expresses half the circumference, whose radius is unity; *i. e.* if $r = 3.57$; then, because $1 : 2r$, or the radius to the circumference as the squares of the radii CL, DA, are to the areas of their circles; we have $r ED \propto AD^2$ for the solid LEM; therefore, their difference $r ED \times AD^2 - r EC \times CL^2$, will express the solid required. But if P expresses the parameter LM, then will $P \times ED = AD^2$, and $P \times CE = CL^2$, and these value, substituted in the expression of the solid, give $rP \times ED^2 - rP \times EC$: or, because $ED = EC + CD$, and $KD = CD + 2EC$, we shall have this expression reduced to $rP \times CD \times KD$. But as r is a constant number, it may be neglected in comparing the solids; and then $P \times CD \times KD$ will be the expression of the solid. And when two excavations are compared together, which have the same line of least resistance CD, the solid will be expressed by the rectangle $P \times KD$. Hence if this solid, or the quantity of earth to be raised, and the line CD of the least resistance be given, the parameter P may be found; and having the parameter and the line CD, the equation $P \times ED = AD^2$, will give the radius AD of the base. For if $CD = c$, and the given solid ALMB = a , then because $CE = \frac{1}{2}P$, the expression $P \times CD \times KD$ will give

$$Pc \times \frac{1}{2}P + c - a, \text{ or } PPc + 2Pcc = 2a, \text{ and } PP + 2Pc = \frac{2a}{c},$$

$$\text{to which adding } cc, \text{ we shall have } PP + 2cP + cc = \frac{2a}{c} + cc; \text{ and } P + c = \sqrt{\frac{2a}{c} + cc}.$$

In comparing mines together, which have the same line of least resistance, the rectangle $P \times KD$ gives $PP + 2cP = 2A$, to which adding cc , we shall have $PP + 2cP + cc = 2a + cc$, whose square root is $P + c = \sqrt{2a + cc}$. By means of these equations, all the different problems relating to mines are easily solved, on the supposition, that the forces of powder are proportional to their quantities, and, therefore, the charges also proportional to the quantities of earth to be raised in the same sort of soil, *i. e.* in soil of the same density and tenacity. Some writers, however, assert, that the elastic force of powder is greater in proportion in larger quantities than in small ones, which Mr. Muller denies; and Mr. Belidor gives another reason for diminishing the charges of mines, as the earth to be raised increases; which is, that not only the weight of the earth to be raised is to be considered, but likewise the pressure of the atmosphere over the surface of the excavation, which pressure is as the bases of the excavation, and these as the squares of the diameters; whereas the weights of similar solids are as the cubes of these diameters; and, therefore, this pressure being less, in proportion, in larger bodies than in smaller, the charges ought rather to be lessened in large mines than in the small. But this reasoning seems to be contradicted by experiments.

In order to know the quantity of powder necessary for blowing up a mine in a particular soil, several mines are to be made in it, having their lines of least resistance equal, but loaded with different quantities of powder, till one is found to have the desired effect. When this is found, the diameter of its base must be measured with the greatest accuracy, and

likewise the line of least resistance; and when these lines are determined, the parameter P of the parabola is found by the equation $KD = \sqrt{AD^2 + CD^2}$; and, having the parameter given, the quantity of earth or solid is found by the solid $P \times CD \times KD$, or by the rectangle $P \times KD$, as the lines of least resistance are different or the same. Thus solid, and the charge of the mine, will serve to find the effect of any other mine made in the same soil when the charge is given; or to determine the charge, so that the diameter of the base shall be of any given length, by means of the equation $P \times ED = AD^2$. The same being performed in all the different soils, which generally occur in making mines, will serve to make mines of any depth, or placed in any soil.

The miners divide the different soils into five species.

|--|------|---|
| 1. }
2. }
3. }
4. }
5. }
6. } | into | { loose earth or sand.
{ common middling light soil.
{ loam or strong soil.
{ potters' clay, or stiff soil.
{ clay mixed with stones.
{ all kind of masonry. |
|--|------|---|

It has been found, that a cubic foot of the first weighs 95lb; of the second, 124lb.; of the third, 126lb.; of the fourth, 137lb.; and 160lb. of the fifth. But as to masonry, it cannot be determined to any degree of exactness, as depending on the different kinds of stones or bricks of which they are made.

It is pretended, that there are nine pounds of powder required to raise a cubic toise of the first kind; 11 of the second; 13 of the third; 15 of the fourth; 18 of the fifth; and 20 or 25 to raise a cubic toise of masonry above ground; and 35 or 40 for raising the same quantity under ground.

These are the French weights and measures, which being reduced into English, give 8lb. of powder for the first kind of soil; 9.8 for the second; 11.6 for the third; 13.4 for the fourth; 16 for the fifth; 18 or 22.3 for the masonry above ground; and 31 or 35 for raising the same quantity under ground.

In the second volume of M. Vauban's Attack and Defence of Places, he says, that the following rules never fail.

A cubic toise of common earth requires 14 pounds of powder to be raised.

Stiff sand or loam, which may be dug without being supported, requires 17 pounds *per* toise.

Mixed earth requires 18 pounds *per* toise.

Potters' clay or stiff soil, 19 pounds *per* toise.

Fat or stiff earth mixed with pebble stone, 22lb.

Wet sand, which cannot be dug without being supported, 15lb.

These rules of M. Vauban make, therefore, the charges greater than those of later miners.

But this is a matter which must be decided by experiments; and when these are made with sufficient exactness, it will be easy to find the proper charge of a mine, so as the diameter of its base be of any given length; or when that length is given, to determine the charge required. *E. gr.* Let it be required to find the diameter of a mine made in the second sort of soil; which being loaded with 100lb. of powder, say, if 11 pounds raise a cubic toise, or 216 cubic feet of earth, how much will raise 100lb.; the fourth term, which is 1964, will be = a ; and $2a = 3928$; and supposing the line of least resistance CD to be 10 feet, then

$$\text{will } c = 10; \text{ hence the equation } c + P = \sqrt{\frac{2a}{a} + cc},$$

will give $c + P = \sqrt{402.8} = 20$; or $P = 10$, and $EC = \frac{1}{2}P = 2.5$; $ED = 12.5$; whence the equation $P \times ED = AD^2$, gives $10 \times 12.5 = 12.5 = AD$, or $AD = 11.2$ nearly.

But to shew how far this theory agrees with the experiments mentioned before, we may suppose the first to be true, and from thence proceed to find what the diameters of the bases of the others will be. All the lines of least resistances of these mines were ten feet each, the diameter of the base of the first mine was found to be $22\frac{2}{3}$ feet; so that AD is $= 11.33$, or 11.4 $CD = 10$; these values being substituted in the equation $KD = \sqrt{CD^2 + AD^2}$, will give $KD = \sqrt{229.96} = 15.16$; and $2KC = P = 10.32$; hence these values being substituted in the rectangle $P \times KD$, because the line of least resistance is here always the same, gives $10.32 \times 15.16 = 156.5$, for the solid, which must be remembered, because it is the standard number whereby the other solids are determined.

Now if 120lb. gives 156.5, how much gives the charge 160lb. of the second for its solid, the fourth term gives $208\frac{2}{3} = a$, and $2a = 417\frac{1}{3}$; this value, as well as that of $c = 10$, being substituted in $P + c = \sqrt{2a + cc}$, gives $P + c = \sqrt{517.4} = 22.7$; hence $P = 12.7$, $EC = \frac{1}{2}P = 3.2$, and $ED = 13.2$. Now these values being substituted in $P \times ED = AD^2$, give $AD^2 = 167.64$, and $AD = 13$ nearly; and as AB has been found by measurement to be about 26, it shews that this computation answers very nearly the experiment.

If as the charge 120 of the first is to the charge 200 of the third, so is the solid 156.5 of the first to the solid of the third; we shall have $a = 260.84$, or $2a = 521.68$; and as $c = 10$, the equation $P + c = \sqrt{2a + cc}$ gives $P + c = \sqrt{621.68} = 24.93$ nearly; hence $P = 14.93$, $\frac{1}{2}P = EC = 3.73$, and $ED = 13.73$; these values being substituted in $P \times ED = AD^2$, give $AD = 14.32$, and $AB = 28.64$; which answers nearly the experiment; it was found that $AB = 29$ nearly.

If we proceed thus with regard to the 4th, 5th, 6th, and 7th experiments, we shall find the diameters of the base to be as follows; that of the 4th, 31.2; that of the 5th, 33.2; the 6th, 35.3; and that of the 7th, 37.4; which answers pretty near the experiments.

In this method of constructing mines, any opening may be made, whatever be the line of resistance; and by making this line small, and loading the mine with more powder, the inconvenience of a large excavation, which affords lodgment to the besiegers, is avoided: besides, the shafts and galleries are sooner made, and several mines may be placed under one another, by which the same spot of ground may be blown up several times.

If it were required to make a mine in the same sort of soil as that in which the seven experiments mentioned before were made, so that the line of the least resistance shall be equal to the radius of the base, and each of ten feet, and to find the quantity of powder necessary for its charge. Because $AD = CD = 10$, the equation $KD = \sqrt{AD^2 + CD^2}$, will give $KD = \sqrt{200} = 14.14$; hence $P = 8.28$; these values being substituted in $P \times KD$, will give 117, nearly, for the solid; then if we say, as the solid 156.5, of the first experiment, is to the solid 117, so is the charge 120 to the charge required, it will be 90lb. nearly. But if it was required to find the quantity of powder necessary to raise a cubic fathom, or 216 cubic feet of this soil; then because $CD = 10$ has been neglected in the solid 156.5, of the

first experiment, as likewise the ratio r , therefore the quantity must be multiplied by $r = 10$; or because $r = 1.57$ by 15.7, which will give 2457; then if we say, as 2457 requires 120lb. of powder, how much will 216 require; and the fourth term, which is 10.5lb, will be the number sought. From whence it appears, that the soil, in which these experiments were made, was a light sort of soil, somewhat lighter than that which is taken by the miners for the second sort.

M. De Valliere supposes, in his table, inserted below, that a mine, whose line of least resistance and radius of the base are each ten feet, requires 93 $\frac{1}{2}$ lb for its charge. Now, if it be required to find what kind of soil these mines are made in, by substituting the number for CD , AD , in the equation $KD = \sqrt{AD^2 + CD^2}$, we shall have $KD = \sqrt{200} = 14.4$, and $P = 8.28$; now these values being substituted in $rP \times CD \times KD$, we shall have $15.7 \times 8.28 \times 14.14 = 1838$; then if we say, as 1838 is to 93 $\frac{1}{2}$, so is 216 to 11. This fourth term will express the number of pounds of powder required to raise a cubic fathom of the same sort of soil, which therefore is the second sort.

The preceding computations have been made of French weights and measures, to shew how nearly the foregoing theory agrees with the experiments made at La Fere. It remains now to apply it to our own weights and measures; because eight pounds of powder will raise a cubic fathom of earth of the first sort; if we say a cubic fathom, or 216 cubic feet, is to eight pounds, as 1838 cubic feet is to 68.074 pounds, this fourth term will be the charge of a mine, whose line of resistance is 10 feet as well as the radius of the base: in the same manner are found the charges of the same mine in the rest of the soils. But the shortest way of computing tables is to subtract the logarithm of 216 from that of 1838, which gives 9298917; now if to this logarithm we add those of 8, 9, 8, 11.6, 13.4, 16; the weight of the powder required to raise a cubic fathom of the different soils, found before; we shall have 1° 83298, 2° 92112, 3° 99435, 4° 05699, 5° 14301 for the logarithms of the charges of a mine whose line of least resistance is 10 feet, and the diameter of the base 20.

Valliere's TABLE for the Charges of Mines.

Length of the line of least resistance.		Charge of Powder.		Length of the line of least resistance.		Charge of Powder.	
Feet.	lb. oz.	Feet.	lb. oz.	Feet.	lb. oz.	Feet.	lb. oz.
1	0 2	11	124 12	21	868 3	31	2792 4
2	0 12	12	162 0	22	998 4	32	3072 0
3	2 8	13	205 15	23	1140 10	33	3369 1
4	6 0	14	257 4	24	1296 0	34	3680 12
5	11 11	15	316 4	25	1559 9	35	4019 8

9	68 5	19	643 0	29	2256 7	39	5561 2
10	93 12	20	750 0	30	2530 4	40	6000 0

By this construction the radii of the bases being always equal to the lines of least resistance, the solids are similar, and therefore are to one another as the cubes of their axes; that is, as the cubes of the lines of least resistance. So that taking any one of the charges to be true, the others will be found by saying, as the cube of the axis whose charge is given is to its charge, so is the cube of the axis of any other mine to its charge.

For example, let the charge $93\frac{1}{2}$ of the mine, whose line of least resistance is 10 feet, be given; and it be required to find the charge of any other mine whose line of least resistance is given, suppose 15: then say, as the cube 1000 of 10 is to the cube 3375 of 15, so is the charge $93\frac{1}{2}$ to the charge required, which is 316.4, or 316 pounds 6 ounces, which is 2 ounces more than in the table. In the same manner is found the charge of a mine whose line of least resistance is 20; or because 20 is double of 10, the cube of 20 will be octuple the cube of 10; and therefore $8 \times 93\frac{1}{2}$, or 750 pounds, will be the charge of that mine.

A TABLE of the Charges of Mines according to Muller's Theory.

Diam.	Charge.	Diam.	Charge.	Diam.	Charge.
Feet.	Pounds.	Feet.	Pounds.	Feet.	Pounds.
22	150	42	639	62	1518
24	181	44	711	64	1621
26	217	46	773	66	1741
28	255	48	857	68	1842
30	297	50	946	70	1980
32	344	52	1020	72	2098
34	394	54	1115	74	2243
36	452	56	1205	76	2372
38	502	58	1299	78	2501
40	560	60	1406	80	2648

In this table the line of least resistance is supposed to be always 10 feet, and the charges producing the openings at the sides of them from 22 feet to 80. It is supposed that the charge $93\frac{1}{2}$ of a mine, whose line of least resistance and radius of the base are each 10 feet, is given, and from thence all the rest are computed by means of these equations, $KD = \sqrt{AD^2 + CD^2}$, and $P \times KD = a$; and by comparing the diameters of the bases found, by means of these equations, to be rather less than those found by experiments, it is presumed that the diameters marked in this table will not be found less, but rather greater in practice.

In order to find the size of the boxes, generally made cubical, in which the powder is lodged: as a cubic foot of common powder weighs about 55 pounds, if we say as 55 is to any other quantity to its cube; i. e. if the given quantity of powder be divided by 55, the quotient will be the cube required, and its cube root will be the length of the side of the box. The box must always be made a fourth bigger than it should be, on account of the straw and sand-bags put in it, for keeping the powder free

from wet; so that if the quantity of powder be 360 pounds, the fourth part of it, or 90, must be added, and the sum 450 divided by 55, whose quotient is 8.1818, and the square root of this, or 2.86 feet, or 34 inches, will be the size required. If the chamber happens to be placed on a rock, or any other hard substance, the force or action of the powder downwards, meeting with great resistance, will be employed in raising the earth upwards; and consequently the effect of the mine will be much greater than that produced by the same quantity of powder, placed on a softer substance. On which account, if a platform of strong planks were made under the chambers, there would be a less quantity of powder required for the charge of the mine. When the mine is properly loaded, the gallery is stopped up with stones, earth, and dung, well rammed, five or six feet farther from the chamber than the length of the line of least resistance. And for preventing the mine from bursting through the gallery, and to make it have its effect upwards, the gallery is made with one or two turnings, at right angles to each other, and strongly secured with buttresses and planks, and the intervals rammed with stones and earth.

Many writers have estimated the operation of mines on the false supposition, that their entonnoir, or excavation, is the frustum of a cone; and therefore, in order to estimate the weight of the matter to be blown up, they have only to compute the solidity of such a frustum in cubic fathoms, and to multiply the number of fathoms by the number of pounds of powder necessary for raising the matter it contains; and if this cone contains matters of different weights, to take a mean between them all; always having a regard to their degree of cohesion. As to the disposition of mines, there is one general rule, which is, that the side towards which one would determine the effect, be the weakest; but this varies according to occasions and circumstances.

MINES, Different Sorts of. A mine which has only one chamber is called a single mine, as A, *fig. 13*. If it has two chambers, it is called double, as *fig. 14*, and if it has three, triple, as *fig. 15*, &c. the names being taken from the number of chambers. If a single mine is made under the rampart, to make breach, the entrance O, *fig. 13*, must not be opposite to the place where the chamber is designed to be, but on one side or other; and the gallery with two turnings, that it may be stopped with greater security, and that the distance of the entrance O to the chamber A may be greater than the length of the line of least resistance: otherwise the mine would have its effect that way. It must also be observed, that the chamber is placed in the middle of a counterscarp, by which means it will make a greater breach than if it were placed in the earth behind the wall. When a double mine is made under the rampart for making breach, the entrance O, *fig. 14*, is made, as nearly as can be guessed, in the middle, between two counter-forts; the gallery being carried quite through the wall in a direct line, turns afterwards to the right and left, in the form of a T; from whence it is also called a T mine; and the chambers are also placed in the next counter-forts, but exactly at equal distances from the direct gallery: this double mine will make a much larger breach than the single one, and it is for that reason preferred to any other.

But when a triple mine is to be made under the rampart, the opening O, *fig. 15*, is to be made directly opposite to the counter-fort, if possible, and carried directly through the wall, and turned to the right and left in the same manner as the former; and the chambers A, B, at both ends, are placed in the two adjacent counter-forts. As to the gallery of the third, C, it is carried round the middle counter-fort, and the chamber placed under its extremity; this last is

generally charged with fifty pounds of powder more than either of the others; but great care must be taken to carry the auger of this last chamber in zig-zags, so as to be equal in length to that of the chamber B, otherwise the fire would not reach them all three at the same time, and thereby the chamber C not take fire, which sometimes happens, and then the effect does not answer the expectation.

There are seldom or ever more made than a triple under the ramparts in sieges; but when a work is to be demolished, they make then as many as will demolish a whole face at once; which is done by giving the fire to all at the same time; that is, all the saucissons are brought into one, and so contrived, as that their parts from the chambers to the common junction may be exactly equal. Muller's System of Artillery, &c. vol. vi. part iii. p. 206, &c.

MINE, *Chamber of a*. See CHAMBER and MINE.

MINE, *Counter*. See COUNTER-mine and MINE.

MINE, *Gallery of a*. See GALLERY and MINE.

MINE, *Knight of the*, is a military honour, anciently conferred on persons who had distinguished themselves in engagements in mines.

MINE-Ships, are ships filled with gunpowder, inclosed in strong vaults of brick or stone, to be fired in the midst of an enemy's fleet. See FIRE-ship.

MINE is also a French measure. See MEASURE.

MINE-Dial is a box and needle, with a brass ring divided into 360 degrees, with several dials graduated thereon; generally thus made for the use of miners.

MINEHEAD, in *Geography*, a township of America, in Essex county, Vermont, on Connecticut river; it is watered by Nulhegan river, and has only 27 inhabitants.

MINEHEAD, a cape of Ireland, in the county of Waterford, between Ardmore-head and Helwick-head, from the latter of which it is about four miles distant.

MINEHEAD, a sea-port town and borough, situated on the southern shore of the Bristol channel, in the hundred of Carthampton and county of Somerset, England. The town was first incorporated by queen Elizabeth, who endowed it with many valuable privileges. In the reigns of Charles II. and queen Anne, so great was the trade from this port to Ireland, that upwards of forty vessels were constantly engaged in it. Several were likewise employed in the West India, Virginia, and Straits trade; and not less than 4000 barrels of herrings were annually shipped here for the Mediterranean. The chief articles of import, besides colonial produce, were wool, linen, and cattle, and the exports consisted mostly of coals and grain. All this trade is now entirely lost; the herrings have deserted the coast, and there are at present only five or six vessels belonging to the port. In the time of its prosperity the government of this borough was vested in a portreeve, but since its decline it has been committed to two constables, who are chosen annually at the court leet of the lord of the manor. The arms of the town are a ship under sail and a wool-pack, emblematical of its pristine trade.

Minehead is divided into three parts; the Upper Town, consisting of several irregular streets, meanly built, and standing on the eastern slope of a vast hill, called Greenalagh or Minehead point; the Lower Town, situated half a mile from the beach to the south-east; and the Quay Town, placed under the brow of a lofty eminence close to the shore. The church, which is a large handsome structure, stands in the Upper Town, and is distinguished by a very elegant alabaster statue of queen Anne, on a pedestal four feet high. It was the gift of sir Jacob Banks, as appears from an inscription upon it, bearing the date 1719. At the entrance of the quay, in Quay Town, stands the Custom-house, which still con-

tinues furnished with a regular establishment of officers. A market continues to be held here every Wednesday; and there is a small manufacture of woollen cloths, which constitutes the chief support of the inhabitants. Fronting the market place is an alms-house, built and endowed by Robert Quirk, in 1630. Two members are sent from this borough to parliament, who are elected by the parishioners of Dunster and Minehead, being housekeepers and not receiving alms. The constables are the returning officers.

The country around Minehead is pleasing and beautiful, presenting to the view a series of lofty hills interspersed with rich and luxuriant vallies. The climate is so mild that vegetation is a month earlier here than in most parts of England. This circumstance has of late years induced many persons to resort hither during the bathing season, to the great benefit of the town. A peculiar species of limpet, found on the rocks here at low water, afford a very curious liquor used in marking linen, which, when first applied, exhibits a variety of changes in its colour, and ultimately, after washing, assumes a bright crimson hue, which no subsequent efforts will alter or eradicate. About six miles to the south of the town is the lofty mountain of Dunkerry, which rises 1770 feet above the level of the sea, and is 12 miles in circumference at the base. From the collections of stones bearing the marks of fire, which appear on different parts of it, it is conjectured to have been used as a beacon to alarm the country in the event of invasion. Collinson's History and Antiquities of Somersetshire, vol. ii. 4^{to}. 1791.

MINELLI, ANDREA, in *Biography*, a Venetian opera poet, and author of many dramas that were much applauded: such as "Orfeo," 1702; "Finezze d'Amore, et la forza vinta dall' Onore," 1703; "La Rodoguna," at Milan the same year; and "Il trofeo dell' innocenza," at Venice, 1704.

MINELLIUS, JOHN, was born at Rotterdam about the year 1625, and passed his life as a teacher of the learned languages. He died in 1683. He published notes upon Terence, Sallust, Virgil, Horace, Florus, Valerius Maximus, and Ovid's Tridlia, which have not only been very useful to students, but have been freely transcribed by more modern editors and commentators.

MINEO, in *Geography*, a town of Sicily, in the valley of Noto, near a lake of the same name; 24 miles S. of Catania.

MINERA, in *Medicine*, the seat, or rather matter of a disease.

The term is applied by some authors to those parts of the body wherein there are collections and coagulations of humours made; which, hardening, form obstructions, and produce diseases.

In this sense we say, the *minera morbi*, &c.

MINERALS, or FOSSILS, are those inorganic natural bodies of which the solid mass of the earth is composed. Their more remarkable properties and characters will be enumerated under the article ORYCTOGNOSY.

MINERAL, *Æthiops*. See ÆTHIOPS, and MERCURY.

MINERAL, *Turbith*. See TURBITH, and MERCURY.

MINERAL Oil See OIL.

MINERALE *Bzoardicum*. See BEZOARDICUM.

MINERAL, *Crystal*. See CRYSTAL Mineral.

MINERAL *Kermes*. See KERMES Mineral.

MINERAL Waters, are those which, at their springing for h t o m and r-ground, are found impregnated with some mineral matter; as salt, sulphur, vitriol, &c. See WATER

Such are hot baths, spas, purging, &c. springs.

MINERAL Waters, *Earth of*. See EARTH.

MINERAL Juices. See JUICES.

MINERAL Courts, *Curia mineralis*, in Law, courts for regulating the concerns of lead mines; as *flannary courts* are for tin.

MINERALOGY, the science which makes us acquainted with all the various relations under which minerals present themselves to us. This comprehensive branch of knowledge is by the illustrious Werner divided into five distinct doctrines, *viz.* 1. *Oryctology*, or that part of mineralogy which, with the assistance of well ascertained characters and fixed denominations, teaches us to determine fossil substances, and to arrange them according to their natural affinities. 2. *Geognosy*, which has for its object the structure, relative position, and formation of those substances of which the crust of the earth is composed. 3. *Mineralogical Geography*, which exhibits, in geographical order, the species of rocks that occur in different countries, together with the various species of minerals contained in them, and the circumstances under which they occur. 4. *Mineralogical Chemistry*, which makes us acquainted with the various chemical properties of minerals, and with the quality and quantity of their component parts. 5. *Economical Mineralogy*, in which mineral substances are considered merely with a view to the use to which they are applicable, which also determines their arrangement.

It is only within the last quarter of the elapsed century that the knowledge of minerals has made rapid strides towards perfection; not long before that period it could scarcely be said to have assumed the appearance of a science; and the ancients appear to have been totally unacquainted with any thing in the shape of scientific mineralogy.

The *ορυκτα* and *μιταλλευτα* of Aristotle can scarcely be considered as bearing testimony to this philosopher's knowledge of minerals, and are indeed only mentioned by him because he fancied the origin of the former might be derived from earth, and that of the latter from water. The few mineral substances treated on by Theophrastus, Pliny, Dioscorides, and Galen, intermixed with productions of art, are merely such as were employed for the common purposes of economy, and the study of these authors is far more important to the philologist and antiquary than to the mineralogist. On reading the sixth book of Dioscorides, we become indeed acquainted with part of the medical knowledge of the ancients, but it teaches us very little that might be deemed any way interesting in a mineralogical point of view. Pliny, where he treats on gems and metals, expatiates on the luxury prevalent among the Romans, and when speaking of marble, basalt, &c. enters upon the history of their productions of art, without at all adverting to the degree of knowledge they possessed of unorganized nature. Indeed, *scientific* knowledge of this kind was not among the acquirements of the ancients; and whatever may have the appearance of it in the writings of the authors above-mentioned, is so destitute of order and precision, that it is surprising how Wallerius, who well knew what is requisite for a mineralogical system, could mention Theophrastus, Pliny, Dioscorides, and Galen, as the first systematic writers in mineralogy. The knowledge of some mineral substances must, of course, be coeval with the earliest ages of the world; but to trace mineralogy, as a science, to Egypt, or to ancient Greece and Rome, is almost as absurd as to dignify Tubal Cain with the title of the first of chemists.

When the general lethargy of the sciences commenced, little regard was paid even to the scanty knowledge handed down in the works of the ancients; and it was not till the introduction of the chemistry, or rather alchemy, of the

Arabians into Europe, that a small share of attention was again bestowed on the study of unorganized bodies. Avicenna laid the foundation of the distribution of minerals, into stones, metals, sulphureous fossils, and salts; a division which was generally adopted by the chemists of those times, but not by the other naturalists; the former, to judge from a passage in Agricola (*De Nat. Fossilium*, l. i. p. xvii.), not being held in great esteem by the scholasts. "Avicenna," says Agricola, "non scienter, sed more dimissarum, sulphureo duas species subiecit: sulphur et arsenicum." Hence it is that Albertus Magnus, this superstitious transcriber of the ancients, followed quite a different distribution; for among other changes which he adopted, was that of throwing the lapa and sulphurea into one class, under the name of *Media*.

Such were the first attempts at introducing some order among the unorganized bodies. The chemists on one side proposed the component parts, which, however, far from being demonstrated, were only hypothetically assumed by them; the scholasts, on the other hand, were equally intent upon investigating and recommending the characters derived from the external form of minerals, their supposed medicinal properties and miraculous virtues. This twofold view of the subject characterizes the writings of almost all succeeding mineralogical authors, down to a period not far remote from the present; we find them either implicitly adopting the ideas of the chemists, or announcing themselves as mere empirical collectors of curiosities. Agricola, the first systematic mineralogical writer, may, indeed, be considered as an exception to this rule. He directed his thoughts to the uniting the views of these two classes of writers, although he certainly inclined more to those of the second.

Agricola was the first who paid attention to external characters, which were determined by him with tolerable precision, and employed for the distinction of the mineral substances then known. All fossils (*corpora subterranea*) are divided by him into simple, or such as consist of homogeneous particles; and into compounded, or such as are formed of heterogeneous parts, taken in a mineralogical acceptance of the terms. The minerals belonging to the former of these divisions are found in four different forms, which are, 1. Terra. 2. Succus concretus. 3. Lapis. 4. Metallum. *Terra* he defines as "corpus fossile quod potest manu subigi, cum fuerit asperum humore, aut ex quo, cum fuerit modofactum, fit lutum." These earths he divides partly according to some external characters, partly after their localities, in cases where their names are derived from the countries or places in which they are found. "*Succus concretus* est corpus fossile siccum et subdurum, quod aqua asperum aut non mollitur, sed liquefit, aut, si mollitur, multum vel pinguitudine differt a terra, vel materia ex qua constat." The fossils of this class Agricola divided into macra and pingua; the former consist of a juice partly mixed with earth (sal nitrum), partly with metal (chrysolita, arugo, ferrugo, caruleum), partly mixed both with earth and metal (atramentum iutorium, alumen, &c.): to the latter he refers sulphur, bitumen, fardarach, and auripigmentum. The ambiguity of this definition, and the impropriety of placing in one and the same class substances so very distinct from each other, require no comment. The stones are the third class of Agricola's system. "*Lapis* est corpus fossile siccum et durum, quod vel aqua longinquo tempore vix mollit, ignis vehemens redigit in pulverem; vel non mollit aqua, sed maximo ignis liquefit calore." The stones are subdivided into lapis, gemma, marmor, and saxum. His definition of metals, being his fourth class, is, "*corpus fossile natura vel liquidum vel durum quidem, sed quod*

MINERALOGY.

ignis liquefcit calore." He enumerates ten metals. The laft clafs of Agricola's fyftem comprehends mixed and compound foſſils. 1. Mixtures of ſtones and juices (*fucci*). 2. Of earth and metal. 3. Of ſtone and metal. 4. Of juice, ſtone, and metal. To the ſecond and third diviſion he refers the various ores. What has been ſaid may convey an idea of Agricola's ſyſtematic knowledge in mineralogy. Conſidered as a firſt eſſay, his ſyſtem is indeed very valuable, and more logical precision in its execution can ſcarcely be expected from its author; but, on the other hand, it cannot be denied that he was often ſtrangely led aſtray by his deficiency in chemical knowledge, nor did he even ſuſpect that the preſervation of unity is at all required in the conſtruction of a ſyſtem.

Moſt of the ſyſtematic mineralogical writers who ſucceeded Agricola were chemiſts, or rather alchemiſts; but even theſe adopted his ſyſtem, although it was more or leſs altered by ſome of them. Thus, Cardanus retained the "*fucci concreti*," but he followed the chemiſts in ſeparating the ſalts from the bitumens.

Kentmann, who published in 1569 his book "*De omni rerum foſſilium genere*," was a nomenclator who adopted Agricola's ſyſtem almoſt without making any alteration. The earths and the *fucci concreti* are, however, ſubdivided in a different manner, and a treatiſe on petrifications is added, entitled "*Alcyonia, conchæ et alia, quæ ex falſo liquore maris et ex ejus ſpuma, cum tenuiſſimis foribus permixta concreſcunt*."

The celebrated botaniſt, Cæſalpinus, was the firſt who properly ſeparated the ſalts from the inflammable foſſils. The diviſions of his ſyſtem are, 1. *Mineralia humore ſolubilia*, to which he refers the earths and ſalts. 2. *Oleo ſolubilia*, which contains the ſulphureous ſubſtances with orpiment. 3. *Illiquabilia*, comprehending the rocks, and all other ſtones, as alſo corals, animal calculi, &c. 4. *Liquabilia*, or metals.

Aldrovandus, that voluminous writer, compiled his ſyſtem from Agricola, Cardanus, and Cæſalpinus. With him the petrifications begin to be conſidered as objects of curioſity.

Befides the many authors of that period, who buſied themſelves by arranging the minerals of the ancients according to Agricola's ſyſtem, which they now and then altered conformably to the ſuppoſed diſcoveries of the day, there were ſome who, although not ſyſtematic writers themſelves, had conſiderable influence on the ſyſtems of ſucceeding periods. Among theſe was the famous Jeſuit, Athanaſius Kircher, who (in his *Mundus ſubterraneus*, Amſterd. 1678) ſurpaſſed all his precuſors in the amaſſing of wonderful curioſities and *luſus naturæ*; although Jonſton had not been remiſis in affixing much importance to the ſtrange forms repreſenting celeftial and ſublunary bodies, preſented to the world in his "*Notitia regni mineralis*," which appeared at Leipzig in 1661.

Of greater importance were the advantages which the ſcience of mineralogy derived from the investigations of Beccher. This mineralogiſt (in his "*Phyſica ſubterranea*," firſt published in 1667,) conſidered water and earth as the remote, and vitreous, inflammable, and mineral earths (ſal, ſulphur, mercurius), as the proximate conſtituent parts of all minerals, which he accordingly arranged under three claſſes; the firſt comprehending ſuch ſtones in which the vitreous earth conſtitutes the principal ingredient; the ſecond and third claſs containing the ſubſtances in which the two remaining earths predominate. Though the principles which thus formed the baſe of his ſyſtem were derived from gratuitous aſſumption, yet they ſerved to prove the poſſibility of a chemical arrangement of the genera, and of applying

the differences obſervable in the conſtituent parts of the earths and ſtones as fit characters for diſtinguiſhing them.

The ſtones Beccher divides into thoſe that either calcine or vitrify in the fire; thoſe that preſerve their ſolidity, or become friable when ignited; and thoſe that, when ignited and immerſed in water, either remain ſolid or crumble to pieces. In his work, we for the firſt time find antimony, zinc, and biſmuth, (though, indeed, alſo pyrites,) introduced as imperfect or ſemi-metals. The perfect metals, of which he has fix in number (for mercury he conſiders as a *decompoſitum*), are claſſed after the following characters: two of them (gold and ſilver) melt in a red heat; two (copper and iron) are red-hot before they melt; and two (tin and lead) melt before they can be heated to redneſs.

The next in ſucceſſion are the *decompoſita*, or ſuch minerals as are compoſed of ſeveral earths and ſtones, earths and metals, &c., or of ſeveral ſpecies belonging to the ſame claſs, ſuch as mixtures of metals; and they are divided into *terrea, lapidea, metallica, and aquea*.

Bromelius (who published a book intitled "*Catalogus rerum curioſarum*," Gothæburg, 1698,) began to refer to the ſame claſs ſulphur and the bituminous ſubſtances, which he called *ſulphurea* and *pinguia*: he retained Beccher's diviſion of metallic ſubſtances into perfect and imperfect metals.

Nor ſhould the Swediſh mineralogiſt Hiärne be left unnoticed here, who introduced ſeveral changes into the then prevailing ſyſtem of mineralogy: thus, for inſtance, he was the firſt who ſeparated the common from arſenical pyrites, which before him had conſtantly been united by authors. Like Bromelius he places ſulphur and the bituminous ſubſtances in the ſame claſs; an arrangement which has been retained by all ſucceeding ſyſtematic writers in mineralogy: and though the term "*fuccus concretus*" continued to be employed by ſome of them, it was always uſed as a ſynonym of ſalt.

Towards the cloſe of the 17th century Woodward publiſhed his catalogue of minerals. His knowledge of mineralogy was ſuperior to that of any other Engliſh author of his time.

Of the mineralogiſts of the beginning of the 18th century, the moſt celebrated were Beyer, Bütner, and Scheuchzer. Theſe authors, who were leſs ſuperſtitious and more to be depended upon than Aldrovandus and Kircher, principally preſented the world with their obſervations on petrifications. The two latter, however, were not quite free from prejudice; they introduced an exceſs of biblical teleology into the mineralogical ſcience, and moſt of their obſervations were made with a view to the univerſal deluge. But it is not to be denied that all three contributed largely towards directing the attention of mineralogiſts to the ſtructure of mountain rocks. All the mineralogical writers that had preceded them were chemiſts, practical miners, or at beſt mere oryctognoſtians: but about this period naturaliſts began to examine rocks with other than merely metallurgical views; mineralogy was found ſuſceptible of being treated in a ſcientific manner, and it began to go hand in hand with the other branches of phyſical knowledge. Even Scheuchzer and Beyer, and ſome other authors of thoſe times, by not conſining themſelves to the mere collecting of petrifications, but alſo conſidering them as veſtiges of important revolutions, had opened a new field of investigation to the thinking naturaliſt.

Magnus von Bromell, a Swede and pupil of Hiärne and Boerhaave, publiſhed a ſyſtem of mineralogy, (*Inledning til kundſcåb om Mineralier, &c.* Stockh. 1730,) in which he not only availed himſelf of all the improvements made by his maſters, but alſo propoſed a new chemical diviſion of ſtony ſubſtances into ſuch as are refractory (*apyri*), or calcinable,

or vitrescible, in the fire; to which were added the figured stones (*figurati*.)

After Von Bromell, Linnæus appeared, and it is chiefly from this period that the origin of systematic mineralogy may be dated, when our science, together with the other branches of natural history, acquired a degree of popularity which it had never before enjoyed. It has been questioned whether Linnæus himself contributed to the advancement of the science; and some writers have even denied him any knowledge in this department of natural history. But the fact is that in his earlier years Linnæus devoted a considerable share of time to the study of mineralogy, and whatever his merits in framing his mineralogical system may be, certain it is that it bespeaks the same acuteness and the same original mode of thinking, which we so much admire in the other works of this illustrious naturalist. His mineralogical arrangement cannot, indeed, be compared with the masterly systems of zoology and botany, and it even appears that he added it chiefly for the sake of completing his grand work of a general system of nature. It has been justly urged against the applicability of his system, that it is founded on an erroneous principle, *viz.* on the supposition that the crystalline form of mineral substances is due to different salts, and that they are to be classed accordingly; but even this erroneous notion served to direct the attention of the student to the important characters derived from the diversity of crystallization, of which subsequent mineralogists availed themselves with signal success, for the distinction and classification of mineral substances. (See *CRYSTALLIZATION*.) If, moreover, we consider the advantages which necessarily accrued to mineralogy by those general principles that were introduced into natural history by Linnæus, the precision of his terminology, his philosophical views of classification, &c., all of which were equally applicable to our science, it can no longer be a matter of doubt that the labours of the great Swedish naturalist have, at least indirectly, been of essential service to the advancement of this important branch of natural knowledge.

The chemical part of mineralogy began, about this period, to be cultivated with great success. The discoveries of Henkel and Pott, who (if we except Hiärne, and perhaps Beccher) may be looked upon as the first mineralogical chemists, had clearly demonstrated the important advantages which mineralogy may derive from chemistry. The external characters were almost entirely rejected by Henkel as vague and unsatisfactory. In his "*Idea Generalis de Lapidum Origine*," the inflammable mineral substances (to which, however, he refers also vegetable gum and phosphorus) constitute a separate class; the class of salts contains acids, alkalies, and neutral salts, and the alkaline are kept distinct from the earthy, and the latter from the metallic neutral salts; the earths he divides in the same manner as Beccher, and he subdivides them after the degree of heat required for their fusion; the class of stones comprises the calcareæ, siliceæ, calcareo-siliceæ or limosæ; a classification which he proposes with great modesty, although it may indeed be considered as a great step in mineralogical chemistry. Henkel's "*Kies-Historie*" (*History of Pyrites*), considering the period in which it was written, displays an uncommon degree of accuracy, and contains, as well as others of his works, valuable contributions towards the natural history of various metallic substances, and their ores.

More accurate chemical knowledge marks the works of the celebrated Pott, who, on account of the valuable discoveries illustrative of mineralogy, may justly be called the Klaproth of the period in which he flourished. No mineralogist before him had so clearly demonstrated that it is the

degree of hardness alone which distinguishes earths from stones, and that this property, infinitely variable in various substances, cannot furnish a principal distinctive character for their classification. Profound chemical knowledge and uninterrupted application enabled him to subject the simple earths to a closer examination, to determine their character with greater precision, and also to augment their number. His classification of the earths, which, with some alterations, justly became a standard for his successors, is the following:—
1. *Alcaline earth*, which may be burnt into quick-lime, and is soluble with effervescence in the acids. 2. *Siliceous earth*, little alterable by calcination, and insoluble in acids: this he considered as the principal cause of hardness of the stones in which it predominates. In his "*Lithogeoognosie*," Pott called this latter "*vitrescible*" earth; but finding afterwards that the property which gave rise to it is common to all the earths, he discontinued the name. 3. *Argillaceous earth*, which, on account of its viscidness and ductility, is susceptible of being turned on the lathe, becomes hard in the fire, and is insoluble in the acids. 4. *Gypsous earth*, which by burning is converted into gypsum, which resists the acids, and is difficultly vitrifiable. The species of earthy fossils were distributed among these classes, according as one or the other of the above earths formed the predominant constituent part in them. Had this great chemist lived to extend to the metals the same strict examination to which he subjected the earths and stones, mineralogy would undoubtedly, in his time, have arrived at that perfection which afterwards resulted from the laborious experiments of succeeding chemical mineralogists.

Nearly about the same time Wallerius published his system of mineralogy (*Mineral-rike indelt och beskrievit*, Stockholm 1747), in which, as the discoveries of Pott were not then known to him, he adopts the classification of the older mineralogists, separating earths from stones, the former of which he divided into pulverulent earths (*terræ macræ*), argillaceous earths (*terræ pingues*), mixed earths (*terræ minerales s. compositæ*), and sand (*arenæ*); the latter (with Bromell the younger) into lime-stones (*calcarei*), vitrifiable stones (*vitrescentes*), refractory stones (*apyri*), and rocks (*saxa*). The substances of the third class of his system are called *minera*, comprehending saline ores (*salia*), inflammable substances (*sulfura*), and metals. The fourth class contains the concretions (*concreta*), which are subdivided into stactical substances (*pori*), petrifications (*petrificata*), figured stones (*figurata*), and calculi.

This work of Wallerius was a welcome present to the mineralogical world. The genera before its appearance were extremely vague, and the external characters pointed out in the descriptions were insufficient for the determination of a given fossil substance; it was indeed required to be previously acquainted with minerals in order to understand the systematic works, and the knowledge of fossils was propagated more by tradition than by scientific instruction. One of the chief objects of *oryctognoy*, the determining a given fossil from description alone, even without any previous practical knowledge of mineral substances, was in a great measure attained by this new work of Wallerius; the utility of which was greatly enhanced by the addition of a correct and critical synonymy of preceding mineralogists. But however great the advantages which accrued to the science by the labours of this excellent mineralogist, his system was still, in many parts, essentially defective: thus, for instance, the characters of the first, second, and fourth classes were derived from the external form, those of the third, on the other hand, from the mode of occurrence of the substances which it contains; the orders are chemically determined in the three first

classes, while those of the fourth class are derived from the form, and even the origin of the minerals referred to it. Nothing can be more vague than the definition he gives of concretions, which to him are "mineral substances composed of a fossil and common matter, formed in the usual manner, but hardened, and, as it were, cemented, either by fire or water, and therefore different from other minerals in their origin, figure, and the localities in which they occur."

Woltersdorf, a pupil of Pott, proposed to frame a system, embracing the whole mineral kingdom, in the manner of his master's system of lapideous substances; but his chemical knowledge appears to have been inadequate to the task which he undertook: his system, therefore, not being sufficiently supported by experiments, shared the fate of all attempts at natural arrangement not founded on actual observation, and proved abortive.

Pott's discoveries had paved the way to a more judicious and proper mode of framing classes and orders in mineralogy. In the same manner as botanists, in former times, separated trees from plants, mineralogists, equally misled by an apparently important external character, had kept the stones distinct from the earths; it was principally Pott who shewed the impropriety of this separation, and also that both earths and stones are divisible into several genera, according to the greater or less proportion they contain of the several chemically simple earths. The idea now presented itself, that perhaps in future the genera might be successfully determined after the number of earths which enter the composition of each, and that this principle of classification might be made subservient to the preservation of unity of the system. The salts were already arranged, also in the mineralogical systems, according to their more obvious chemical differences. To the class of metallic substances all such minerals were referred as chiefly contained metals, and the mineralized ores were no longer separated from the native metals. On the other hand, the writers on petrifications, Bourguet, d'Argenville, &c. still followed closely the footsteps of Scheuchzer. *Lusus nature*, fossil productions imitative of organic structure, still occupied a conspicuous place in their arrangements, from which no systematic writer had yet dared to exclude them. To do this was reserved for Cronstedt.

With Cronstedt begins the second principal era of the science of mineralogy, if the first is to be dated from Agricola. In his work (*Forfög til Mineralogie, &c. Stockh. 1758*), he sets out with giving some highly interesting and important observations on the gradual effects of fire and water on minerals, and on the slow but unintermitted changes they experience by physical and chemical agents in the bowels of the earth.

The minerals are divided by Cronstedt into earths, bitumens, salts, and metals. The earths are subdivided according to the difference in their mixture, as far as it was then known, into the following nine orders:—1. Calcareous stones; to which order also gypsum is referred. 2. Siliceous substances. 3. Granitic substances (garnet, basalt, shorl.) 4. Argillaceous substances. 5. Micaceous substances (mica, talc.) 6. Fluoric substances (fluor spar.) 7. Asbestine substances. 8. Zeolite, to which he refers also the lapis lazuli. 9. Manganesian substances (manganese, wolfram.) The salts are classed according to the acids or alkalis. The class of inflammables, which till then had been but little elucidated, has hardly undergone any alterations. He has, however, added the plumbago or graphite to it. The class of metals comprehends as many genera as simple metals were known in the author's time. For the first time we find here the then newly discovered platina, and also nickel, one of Cronstedt's own discoveries.

One of the principal and most striking advantages of this system, is the strict unity observed in the principle of classification, which is throughout chemical; and the principles on which these classes and orders are established are still pretty generally acknowledged as genuine by the systematic mineralogists of the present day. The garnets were not separated by Cronstedt, from supposing them to contain a peculiar earth; on the contrary, he himself considers them as a mere variety of iron-shot quartz, and the separation was suggested by some peculiarities of external and physical characters presented by the garnets and shorls, the component parts of which were not as yet known to him. This unacquaintance with the constituent parts, and their peculiar chemical properties, likewise induced him to separate mica, talc, asbest, fluor, zeolite, and azur stone, manganese and wolfram from the other earths: though he actually suspected that the two former of these substances contained argillaceous earth, and that manganese and wolfram were known metals. Soon after, a new acid was discovered in fluor spar, a new earth in talc and asbest, and new metals in manganese and wolfram. In some instances he has deviated from the unity of his classification, particularly in the class of inflammable substances, to which, probably, on account of its use, iron pyrites is referred, though it does not display those properties which are mentioned as characteristic of that class. As, on one hand, Cronstedt's system is enriched with many new species, so, on the other hand, this mineralogist properly rejected a great number of substances, which occupied a conspicuous place in the writings of his predecessors; for instance, the *lusus nature*, figured stones, &c. He also shewed that petrifications cannot claim a separate place in the system merely because they have retained part of their original form; as also that compound mountain rocks are not admissible into a system which comprehends mineralogically simple substances. Both these natural productions are treated on in an appendix.

No work on mineralogy ever created greater sensation than that of Cronstedt. A short time after its appearance, it was translated into almost all European languages, the system was studied in all civilized countries, and with some occasional, often unnecessary deviations, was adopted by all writers on mineralogy. Yet with all this, Cronstedt's system is not without its great defects: thus, for instance, it is a matter of great difficulty to become acquainted with a mineral substance by consulting the description he gives of it. Cronstedt improved the classification of minerals, but the task of giving the greatest possible perfection to description, so indispensably necessary for the diagnosis of fossils, was reserved for succeeding mineralogists. He even neglected those external characters which were known and adopted in his time; but these, it must be confessed, were, for the greatest part, unsettled and vague.

At the same time with Cronstedt's Mineralogy, or immediately after, Lehmann and Vogel published their Systems, which, however, did not contribute much to the advancement of the science.

Marggraf demonstrated the peculiar nature of magnesian earth, which became the foundation for a new order of earthy substances. His writings contain, moreover, many discoveries highly important to chemistry, but which it is not necessary to detail in this place.

Wallerius was the first by whom the principles on which systematic writers had hitherto arranged mineral substances, were subjected to a strict examination. He rejected all characters derived from the value, use, and geognostic situation, and established it as a rule, that the orders and genera should be founded on chemical characters alone, while the species

MINERALOGY.

species should principally be determined by their external characters. This principle has been employed in the new edition of his "Mineralogical System," published at Stockholm in 1772. This is a measure of so mineralogical writer before him had been equally correct and precise. His external characters, combined with the chemical ones then known enabled the student, at least in some measure, to discriminate minerals by means of these improved determinations. The genera, too, were distinguished by him with greater precision, and augmented with many new ones. In these respects Wallerius holds a most distinguished place among mineralogical writers, and his work still deserves to be consulted by the student in oryctognosy. It cannot, however, be denied that his terminology is still much too vague, and his external characters far from being sufficiently complete; for, as Werner very justly remarks, description is one of the principal objects of oryctognosy, and it is better to see a mineral badly arranged and well described, than well arranged and badly described. But even in his arrangement Wallerius has fallen into errors, which latter discoveries might have taught him to avoid. In separating earths from stones he is not even faithful to his own principles of classification; and the reasons he assigns for so doing are, indeed, very unsatisfactory. His retaining the faulty division into vitreous and fixed stones, his referring to one and the same class the salts, the sulphureous and bituminous substances, together with the metals, were among the more important defects in his classification.

It was about this time that Engström, by pointing out a more convenient method of trying some of the chemical properties of minerals by subjecting them to the flame urged by the blowpipe, greatly contributed toward facilitating the diagnosis of minerals, especially that of metallic substances.

Werner now published his classical work on the external characters of minerals, (*Von den äussern Kennzeichen der Fossilien*, Leipzig 1774,) upon the appearance of which the vague terminology which had, till then, rendered description almost useless, gave way to a settled and determinate language, and the foundation was laid of a system which has deservedly procured its framer the title of the father of systematic mineralogy. In the work just mentioned, all characters are described with uncommon precision, which may appear pedantic to those who are ignorant of the salutary effects which this very circumstance has on the discrimination of minerals. In 1780, Werner published a German translation of Cronstedt's Mineralogy, accompanied with notes, in which he makes us acquainted with his ideas respecting a system of oryctognosy. This was followed, in 1791, by a descriptive Catalogue of the Mineral Collection of M. Pabst von Oheim, in which we have the first authentic sketch of his system. These two works, and some highly interesting memoirs in "The Bergmännische Journal," and some other periodical publications, is all that has been published by this great and modest mineralogist. All the explications of his system which we possess are by his pupils; they are of various merit, and some of them are but ill calculated to convey an adequate idea of its excellencies. The late Mr. Kirwan, in his "System of Mineralogy," (a work of peculiar merit, on account of the many original observations which it contains) was the first who made the Wernerian system known in England; and after him professor Jameson, a distinguished pupil of the Freiberg school, has published an elaborate work in three volumes, the two first of which contain the system of oryc-

to-gnosy according to the method of Werner, the third giving a complete exposition of his system of geognosy.

The fundamental principle laid down by Werner, in the systematical arrangement of bodies, is their natural affinity, which he all ways to be founded on the chemical mixture of their component parts. These may be distinguished into essential and accidental component parts; the former of which alone are considered in the classification of mineral substances. The essential component parts are subdivided into predominant and characteristic ones; and generally the characteristic happen to be, at the same time, the predominant constituents. By Humboldt the former are called the essential constituent parts. All mineral substances are distributed by Werner into four classes, which are founded on what is called the fundamental constituent parts, *viz.* the earthy, saline, inflammable, and metallic; each class being called after that fundamental constituent part which predominates in and characterizes it. Thus we have the earths, the salts, the inflammables, and the metals. These classes are subdivided into genera, which are derived from the variety in the component parts of the minerals comprehended in each class; there being as many distinct genera as there are predominating, or, at least, characteristic constituent parts discovered in their mixture. Werner has himself disregarded this rule in several instances, and we suppose has now even entirely discontinued the division into genera; at least, several of his pupils have, in their systematic works, introduced *families* as the only division between class and species; each family being a group of species that manifest close affinity to each other, such as the "Feldspar family," the "Zeolite family" &c. By this means the system is so far freed from the shackles of chemistry, and the contradictions are avoided, which so frequently strike the student of the Wernerian system. In the same manner perhaps, also, the species might in some measure be made independent of chemistry. The character of the species, according to the original idea of the founder of this system, was to be derived from the chemical mixture, and from the differences in the quantity and quality of the constituent parts. But in most cases, where no analyses existed of minerals, or no satisfactory ones, external characters were substituted the more readily, as it is an axiom with Werner that a difference in external characters is indicative of a corresponding difference in the component parts, whether it be in their quantity and quality, or in the particular state of their chemical combination. If, therefore, a mineral differs from another related substance in three or more external characters, it is now considered as a distinct species. This circumstance accounts for the considerable number of species in the Wernerian system, compared with those of Haüy's, whose characters employed for specification are confined within a far more narrow compass. We shall shew in another place, that the laws for framing species in mineralogy, whatever the characters may be on which they are founded, must always be arbitrary: but fortunately for the science, the different opinions entertained by different schools respecting the nature of the species, is a mere matter of speculation, exerting little or no influence either on the diagnosis or the arrangement of mineral substances: for, provided the natural connection between two mineral substances remain undisturbed, it is certainly of no great importance whether one of them be degraded into a mere variety of its neighbour, or raised to the rank of a distinct species. Werner enumerates three different kinds of affinity of minerals, *viz.* the chemical, depending on the similarity of their constituent parts; the oryctognostical, consisting in the approximating

MINERALOGY.

resemblances of their external characters; and the geognostic affinity, denoting similarity in occurrence, relative age, &c. The species is subdivided by Werner into *subspecies* and *variety*: by the former are meant fossils belonging to the same species with another, but differing from it in two or three particular external characters; the latter is produced by the difference in any single external character, such as colour, fracture, &c.

The following is a tabular view of the Wernerian oryctognostic system, according to the improvements it has experienced up to 1803; to which are subjoined the additions lately made by its founder.

Class I. EARTHY FOSSILS. A. *Diamond Genus*: 1. Diamond. B. *Zircon Genus*: 2. Zircon. 3. Hyacinth. 4. Cinnamon-stone. C. *Flint Genus*: *Chrysolite Family*: 5. Chrysoberyl. 6. Chrysolite. 7. Olivine. 8. Cocco-lite. 9. Augite. 10. Pistacite. 11. Vesuvian.—*Garnet Family*: 12. Leucite. 13. Melanite. 14. Garnet; noble, common. 15. Staurolite. 16. Pyrope.—*Ruby Family*: 17. Spinelle. 18. Sapphire. 19. Emery. 20. Corundum. 21. Diamond spar. 22. Ceylanite. 23. Topaz.—*Shorl Family*: 24. Euclase. 25. Emerald. 26. Beryl; noble, shorlous. 27. Shorl; common. Tourmaline. 28. Axinite.—*Quartz Family*: 29. Quartz amethyst; (common, thick fibrous). Rock crystal. Milk quartz. Common quartz. Prase. 30. Iron flint. 31. Hornstone; splintery, conchoidal, wood-stone. 32. Flint slate; common, Lydian-stone. 33. Flint. 34. Calcedony; common, carnelian. 35. Hyalite. 36. Opal; noble, common, semi-opal, wood-opal. 37. Menilite. 38. Jasper; Egyptian (red, brown), striped, porcelain, common (conchoidal, earthy). 39. Heliotrope. 40. Chrysoptase. 41. Plasma. 42. Cat's-eye.—*Pitch-stone Family*: 43. Obsidian. 44. Pitch-stone. 45. Pearl-stone. 46. Pumice.—*Zeolite Family*: 47. Prehnite; fibrous, foliated. 48. Zeolite; mealy, fibrous, foliated, radiated. 49. Cubicite. 50. Cross-stone. 51. Lomonite. 52. Schmelzstein (Dipyre, H.) 53. Natrolite. 54. Lazulite. 55. Azure-stone.—*Feldspar Family*: 56. Andalusit. 57. Feldspar; adularia, Labrador, common, (fresh, disintegrated), compact, hollow spar. 58. Scapolite. 59. Arctizite. 60. Spodumene. 61. Ichthyophthalmite.—D. *Clay genus*: *Clay Family*: 62. Pure clay. 63. Porcelain earth. 64. Common clay; loam, pipe-clay, potters' clay, (earthy,) variegated, and slate-clay. 65. Clay-stone. 66. Adhesive slate. 67. Polishing slate. 68. Tripoli. 69. Float-stone. 70. Alum-stone.—*Clay-slate Family*: 71. Alum-slate; common, glossy. 72. Bituminous shale. 73. Drawing-slate. 74. Whet-slate. 75. Clay-slate.—*Mica Family*: 76. Lepidolite. 77. Mica. 78. Pinite. 79. Pot-stone. 80. Chlorite; chloritic earth, chlorite slate, common and foliated chlorite.—*Trap Family*: 81. Hornblende; common, Labrador, basaltic, hornblende slate. 82. Basalt. 83. Wacke. 84. Clink-stone. 85. Iron-clay. 86. Lava.—*Lithomarge Family*: 87. Green earth. 88. Lithomarge; friable, indurated. 89. Rock-soap. 90. Umbra. 91. Yellow earth.—E. *Talc Genus*: *Soap-stone Family*: 92. Native magnesia. 93. Bole. 94. Meerschaum. 95. Fullers'-earth. 96. Steatite. 97. Bildstein.—*Talc Family*: 98. Nephrite; common, axe-stone. 99. Serpentine; common, noble, (conchoidal, splintery). 100. Schillerstein. 101. Talc; earthy, common, indurated. 102. Asbest; rock-cork, amianth, common asbest, rock-wood.—*Asimote Family*: 103. Kyanite. 104. Strahlstein; asbestous, common, glassy. 105. Tremolite; asbestous, common, glassy. 106. Salite.—F. *Lime-stone Genus*: *Carbonats*: 107. Rock-milk. 108. Chalc. 109. Lime-stone; compact, (common, roe-stone), foliated, (granular, calc. spar), fibrous, (com-

mon, calc. sinter,) pea-stone. 110. Lime-tuff. 111. Foam earth. 112. Slate-spar. 113. Brown spar; foliated, fibrous. 114. Schaalstein. 115. Dolomite. 116. Rhomb spar. 117. Stink-stone. 118. Marl; marl-earth, indurated m. 119. Bituminous marl-slate. 120. Arragon.—*Phosphats*: 121. Appatite. 122. Asparagus-stone. 123. Phosphorite.—*Fluats*: 124. Fluor; compact, F. spar.—*Sulphats*: Gypsum; earthy, compact, foliated, fibrous. 126. Selenite. 127. Anhydrite. 128. Cube spar.—F. *Baryte Genus*: 129. Witherite. 130. Heavy spar; earthy, compact, granular, curved lamellar, straight lamellar, columnar spar, prismatic spar, Bolognese spar.—G. *Strontian Genus*: 131. Strontian. 132. Celestine; fibrous, foliated.—H. *Halite Genus*: 133. Boracite. 134. Cryolite.

Class II. FOSSIL SALTS.—*Carbonats*: 135. Natural soda.—*Nitrats*: Natural nitre.—*Muriats*: Natural rock-salt; rock-salt, (foliated, fibrous,) lake-salt. 138. Natural sal-ammoniac.—*Sulphats*: 139. Natural vitriol. 140. Hair-falt. 141. Rock-butter. 142. Natural Epfom-salt. 143. Natural Glauber-salt.

Class III. INFLAMMABLE FOSSILS.—*Sulphur Genus*: 144. Natural sulphur; common, volcanic.—*Bituminous Genus*: 145. Mineral oil. 146. Mineral pitch; elastic, earthy, slaggy. 147. Brown coal; bituminous wood, earth coal, alum earth, common brown coal, moor coal. 148. Black coal; pitch coal, columnar, slaty, foliated, coarse, cannel coal.—*Graphite Genus*: 149. Glance coal; conchoidal, slaty, scaly, compact. 151. Mineral charcoal.—*Resin Genus*: Amber; white, yellow. 153. Honey-stone.

Class IV. METALLIC FOSSILS.—*Platina Genus*: 154. Native platina.—*Gold Genus*: 155. Native gold; gold-yellow, brass-yellow, greyish-yellow.—*Mercury Genus*: 156. Native mercury. 157. Native amalgam; semi-fluid, solid. 158. Mercurial horn-ore. 159. Mercurial liver-ore; compact, slaty. 160. Cinnabar; dark, light-red.—*Silver Genus*: 161. Native silver; common, auriferous. 162. Antimonial silver. 163. Arsenical silver. 164. Corneous silver-ore. 165. Silver black. 166. Silver glance. 167. Brittle silver glance. 168. Red silver-ore; dark, light. 169. White silver-ore. 170. Black silver-ore.—*Copper Genus*: 171. Native copper. 172. Copper glance; compact, foliated. 173. Variegated copper-ore. 174. Copper pyrites. 175. White copper-ore. 176. Grey copper-ore. 177. Copper black. 178. Red copper-ore; compact, foliated, capillary. 179. Tile ore; earthy, indurated. 180. Copper azure; earthy, indurated. 181. Malachite; compact, fibrous. 182. Copper green. 183. Iron-shot copper green; earthy, slaggy. 184. Copper emerald. 185. Copper mica. 186. Lenticular ore. 187. Olive ore. 188. Copper muriat.—*Iron Genus*: 189. Native iron. 190. Iron pyrites; common, radiated, hepatic, capillary. 191. Magnetic pyrites. 192. Magnetic iron-stone; common, arenaceous. 193. Iron glance; common, (compact, foliated,) micaceous. 194. Red iron-stone; red iron-froth, ochrey and compact red iron-stone, red hematite. 195. Brown iron-stone; brown iron-froth, ochrey and compact iron-stone, brown hematite. 198. Clay iron-stone; reddle, columnar, lenticular, jaspersy, common, reniform, and piliiform clay-stone. 199. Bog iron-ore; morafs-ore, swamp-ore, meadow-ore. 200. Blue iron-earth. 201. Pitchy iron-ore. 202. Gadolinite. 203. Green iron-earth. 204. Cube-ore.—*Lead Genus*: 205. Galena; common, compact. 206. Blue lead-ore. 207. Brown lead-ore. 208. Black lead-ore. 209. White lead-ore. 210. Green lead-ore. 211. Red lead-ore. 212. Yellow lead-ore. 213. Lead-vitriol. 214. Lead-earth; coherent, friable.

friable.—*Tin Genus*: 215. Tin pyrites. 216. Tin-stone. 217. Wood-tin.—*Bismuth Genus*: 218. Native bismuth. 219. Bismuth glance. 220. Bismuth ochre.—*Zinc Genus*: 221. Blende; yellow, brown, black. 222. Calamine.—*Antimony Genus*: 223. Native antimony. 224. Grey antimony; compact, foliated, radiated, plumose. 225. Black antimony. 226. Red antimony. 227. White antimony. 228. Antimony ochre.—*Cobalt Genus*: 229. White cobalt ore. 230. Grey cobalt ore. 231. Cobalt glance. 232. Black cobalt ochre; earthy, indurated. 233. Brown cobalt ochre. 234. Yellow cobalt ochre. 235. Red cobalt ochre; cobalt crust, cobalt bloom.—*Nickel Genus*: 236. Copper nickel. 237. Nickel ochre.—*Manganese Genus*: 238. Grey manganese ore; radiated, foliated, compact, earthy. 239. Black manganese. 240. Red manganese.—*Molybdena Genus*: 241. Molybdena.—*Arsenic Genus*: 242. Native arsenic. 243. Arsenical pyrites; common, argentiferous. 244. Orpiment; yellow, red. 245. Arsenic bloom.—*Scheele Genus*: 246. Tungsten. 247. Wolfram.—*Menachine Genus*: 248. Menachan. 249. Octahedrite. 250. Rutile. 251. Nigrine. 252. Iserine.—*Uran Genus*: 253. Pitch ore. 254. Uran mica. 255. Uran ochre.—*Sylvan Genus*: 256. Native sylvan. 257. Graphite ore. 258. Yellow sylvan ore. 259. Black sylvan ore.—*Chrome Genus*: 260. Acicular ore. 261. Chrome ochre.

Werner has since added several new species to this list, and from the place assigned to one or two of them in the arrangement, it follows that this latter must also have undergone some slight alterations. Thus zoisite is placed between pistacite and axinite, which in the above tabular view are placed at some distance from each other. Augite is divided into common, foliated, conchoidal, and granular; and, as next species to it, the coccolite is added. The Siberian green garnet forms a distinct species next to garnet, under the name of grossular. To the same natural family, Werner has now also added the cinnamon stone, (which, after Lam-padius' incorrect analysis, had before been placed in the zircon genus,) and the allochroit of d'Andrada. Between plasma and cat's eye, the festslein or elæolite of Klaproth is placed. The species pumice is divided into three sub-species, common, glassy, and porphyritic p. The dichroïte of Cordier is added, as iolite, to the pitch-stone family. The blue feldspar of Stiria now forms a species distinct from, but next to feldspar, under the name of blau-spath. A variety of compact feldspar (jade of Saussure) is called variolite. Porcelain earth now stands next to feldspar, from which it originates. Also the meionite and sommit are united with this family. Potters' clay is now sub-divided into earthy (formerly called pipe-clay) and slaty. To the three sub-species of strahlstein or actinote is added a fourth, the granular. Silver-black is divided into friable and indurated. What was called capillary iron pyrites, has, by Klaproth's analysis, proved to be native nickel. The menachine genus has received two additional species in the brown and the yellow menachan, inserted after iserine.

Having given this general idea of Werner's system, we cannot proceed to that of Haüy, without making honourable mention of the celebrated Romé de l'Isle, whose indefatigable researches so eminently contributed to the progress of the science of mineralogy in general, and whose "Crystallographie" (of which the first edition appeared in 1773) is deservedly characterized as the result of labours immense in their extent, almost entirely novel in their object, and of the highest importance on account of their utility. His classification of minerals has nothing peculiar; but for the accuracy, completeness, and elegance of his descriptions, and particularly his scientific method of determining the crystal-line forms, he stood unrivalled among the mineralogists of

his time. For an account of the labours of this father of crystallography, the reader is referred to the article **CRYSTALS**.

Several memoirs of Haüy, illustrative of his theory of the structure of crystals, were followed, in 1801, by that celebrated professor's great work, entitled "Traité de Minéralogie." In this important and truly classical production, the new theory (of which a detailed view is given under the article **CRYSTALLOGRAPHY**) is also made subservient to the classification of mineral substances. Haüy has defined the mineralogical species "an assemblage of bodies, the integrant molecules of which are similar to each other, and have the same composition." According to his mode of viewing the subject, minerals have both a geometrical and a chemical limit; the former consists in the invariable form of the molecule; the other in the composition of the same molecule. Haüy prefers making use of the geometrical limit for determining the species, not only because minerals being in general more or less mixed with heterogeneous matter, it often happens that the chemical limit is but imperfectly represented by the results of the analysis, whereas mechanical division invariably furnishes the same form of the molecule; but principally because the geometrical limit is far more obvious and palpable, since to obtain it nothing is in many cases required but the mechanical division of the crystal. In cases where the integrant molecule belongs exclusively to a determined combination of component principles, it alone is sufficient to distinguish the species; but there are forms of molecules which are common to several distinct species; and these forms, as far as they are known, happen to possess the peculiar character of symmetry and regularity, constituting, as it were, limits with respect to other forms. As in this latter case the character derived from the integrant molecule is not sufficient, Haüy adds to it another, chemical or physical, character for the discrimination of the species: thus, for instance, the property of dissolving in water, super-added to the cubic form determines muriate of soda, or common salt; but if the same form is united to the property of becoming electric by heat, we have borate of magnesia, or boracite. The type of the species, according to Haüy, being once determined, it is comparatively easy to arrange the varieties of crystallization belonging to the same substance, by ascertaining, with the assistance of the theory of decrements, whether all their forms, even those which no longer retain a trace of the primitive form, are in exact correspondence with the latter. With regard to the varieties, such as those composed of fibrous, granular, or compact masses, of which the type, though it still exists in them, can no longer be determined, their discrimination depends on the physical and chemical properties of the substance, such as hardness, specific gravity, electricity, &c. What regards the genera and upper divisions, the distribution is made after the component parts or chemical properties common to all the substances contained in the same division. The method adopted by Haüy, in his description of the mineral species, is the following. At the head of the description of each mineral is placed the essential character, founded on the most constant properties which distinguish its individuals; after which follow the physical, the geometrical (comprehending the cleavages and primitive form of the substance), and the chemical character; to which is added the distinctive character, in which the differences are pointed out which distinguish the substance in question from others which might be easily mistaken for it. These general characters are followed by the enumeration of the varieties of form (divided into determinable and undeterminable), the varieties depending on light, such as colour, transparency, &c.

MINERALOGY.

The following outline of Haüy's distribution is principally taken from his "Tableau comparatif des Résultats de la Crystallographie, et de l'Analyse chimique," Paris, 1809. The names included in parentheses are those of the Wernerian school.

Class I. Acidiferous Substances. Order I. Disengaged acidiferous substances. 1. Sulphuric acid. 2. Boracic acid. *Order II.* Earthy acidiferous substances. A With simple base:—*First Genus*: Chaux (lime), sp. 1. 3. Chaux carbonatée, (comprising all the Wernerian species of carbonates of lime, with the exception of the following species). 4. Aragonite. 5. Chaux phosphatée (apatite). 6. Ch. fluatée (fluor). 7. Ch. sulfatée (gypsum and selenite). 8. Ch. anhydro-sulfatée (anhydrite). 9. Ch. nitratée. 10. Ch. arseniatée (arsenic bloom; pharmacolite, Klapr.)—*Second Genus*: Baryte. 11. Baryte sulfatée (barytes or heavy spar). 12. Baryte carbonatée (witherite).—*Third Genus*: Strontian. 13. S. sulfatée (celestine). 14. S. carbonatée (strontian).—*Fourth Genus*: Magnésie. 15. M. sulfatée (natural Epsom or bitter salt). 16. M. boratée (boracite). 17. M. carbonatée (native magnesia or talc earth).—*Fifth Genus*: Lime and silica. 18. Chaux boratée filiceuse (datholite).—*Sixth Genus*: Silica and alumine. 19. Silice fluatée aluminéuse (topaz and pycnite, or stonr beryl).

Order III. Acidiferous alkaline substances.—*First Genus*: Potasse. 20. P. nitratée (natural nitre).—*Second Genus*: Soude. 21. S. sulfatée (natural Glauber salt). 22. S. muriatée (rock-salt). 23. S. boratée (tinkal, K.). 24. S. carbonatée (natural soda or natron).—*Third Genus*: Ammoniaque. 25. A. sulfatée (mascagnin, K.). 26. A. muriatée (natural sal ammoniac).

Order IV. Acidiferous alkaline-earthly substances. 27. Alumine sulfatée alcaline (alum)—*Appendix*. 28. Alumine fluatée alcaline (kryolite). 29. Glauberite.

Class II. Earthy substances. (No subdivision into orders) 30. Quarz (the whole of Werner's quarz family comprising fourteen of his species). 31. Zircon (zircon and hyacinth). 32. Corindon (corundum, sapphires, diamond-spar, emery). 33. Cymophane (chrysoberyl). 34. Spinelle (spinel, ceylanit). 35. Émeraude (emerald, beryl). 36. Émelase. 37. Grenat (garnet, melanite). 38. Amphigène (leucite). 39. Idocrase (Vesuvian). 40. Meïowite. 41. Feld-spath (feldspar). 42. Apophyllite (fish-eye stone, or ichtyophthalmite). 43. Triphane (spodumen). 44. Axinite. 45. Tourmaline (stonr). 46. Amphibole (all the sub-species of hornblende, except Labrador hornbl., actinote, augite and tremolite partly). 47. Pyroxène (augite, fahlite). 48. Yenite. 49. Staurotide (staurolite). 50. Épidote (pistazite, zoisit). 51. Hypersthène (Labrador hornblende). 52. Wernerite (arktazit). 53. Paranthine (scapolite). 54. Diallage (var. of actinote, schillerstein). 55. Gadolinite. 56. Lazulite (azur-stone). 57. Mefotype (fibrous and mealy zeolite, made stein). 58. Stilbite (radiated and foliated zeolite). 59. Laumonite (lomonit). 60. Prehnite. 61. Chabasie (schabasit). 62. Analcime (kubizit). 63. Nepheline (nephelin; sommit, K.). 64. Harmotome (cross-stone). 65. Peridot (chrysolite, olivine). 66. Mica (glimmer or mica). 67. Pinite. 68. Dithène (cyanite). 69. Dipyre (schmelz-stein; dipyr, K.) 70. Asbeste. 71. Talc. 72. Marle (hollow spar; chialsteite, K.)

To this class are appended the following substances, the characters of which are not sufficiently well understood to assign them their respective places in the system.

Allochroite (splintery garnet, K.) Alumine pure (pure clay). Amianthoïde. Antophyllit, Schum. and Wern. Aplome. Bergmannit, Schum. Diaspore. Feldspathopyre, H. (andalusit). Feld-spath bleu (var. of compact feldspar).

Fibrolite, Bourn. Gabbronite, Schum. Jade (common nephrite, axe-stone). Jolithe, W. and K. Kancel or cinnamon stone, W. Lazulit, W. Latialite (Haüyne). Lepidolite, W. Mellite, Fleuriau. Natrolite, W. Pseudo-sommit, Fleur de B. Spath en tables (schaalltein). Spinellane. Spinelle zincifère? (automalite). Spinhère, H. Talc? granuleux (earthy talc), and T. glaphique (bildstein; agalmatolite, Kl.)

Class III. Combustible not metallic substances.—*Ord. I.* Simple. 73. Soufre (sulphur). 74. Diamant (diamond). 75. Anthracite (kohlenblende, glanz-kohle).—*Ord. II.* Compounds. 76. Graphite. 77. Bitume (mineral oil; mineral pitch). 78. Houille (black coal). 79. Jayet (pitch coal). 80. Succin (amber). 81. Mellite (honey-stone).

Class IV. Metallic substances.—*Ord. I.* Not immediately oxidable, except by a very high degree of heat, and immediately reducible.—*First Genus*: Platina. 82. P. natif ferrifère (native platina).—*Second Genus*: Or. 83. O. natif. (native gold).—*Third Genus*: Argent. 84. A. natif (native silver). 85. A. antimonial (antimonial silver); as appendix to it, A. antimonial ferro-arsénifère (arsenical silver). 86. A. fulfuré (vitreous silver-ore). 87. A. antimonié sulfuré (red-silver-ore); and as appendix to it, A. antimonié sulfuré noir (brittle vitreous silver). 88. A. carbonaté. 89. A. muriaté (horn-ore or horn-silver).—*Ord. II.* Immediately oxidable and reducible: Mercure. 90. M. natif (native mercury). 91. M. argental (native amalgam). 92. M. fulfuré (cinnabar); and as appendix, Mercure sulfuré bituminifère (mercurial liver-ore). 93. Mercure muriaté (mercurial horn-ore).—*Ord. III.* Oxidable, but not immediately reducible: a, sensibly ductile.—*First Genus*: Plomb. 94. P. natif volcanique. 95. P. sulfuré (galena) by way of appendix, P. sulf. antimonifère, and P. sulf. antimonifère et argentifère (weissgultig-erz). 96. P. oxydé rouge. 97. P. arseniaté (flokken-erz, K.). 98. P. chromaté (red lead-ore). 99. P. carbonaté (white lead-ore); and, as appendix, P. carb. noir (black lead-ore, lead earth), and P. carb. cuprifère. 100. P. phosphaté (brown and green lead-ore). 101. P. molybdaté (yellow lead-ore). 102. P. sulfaté (natural lead vitriol).—*Second Genus*: Nickel. 103. N. natif (capillary iron pyrites). 104. N. arsenical (copper nickel). 105. N. oxydé (nickel ochre).—*Third Genus*: Cuivre. 106. C. natif (native copper) 107. C. pyriteux (copper pyrites); and, as appendix, C. pyr. hépatique (variegated copper ore). 108. C. gris (grey copper ore). 109. C. sulfuré (vitreous copper ore). 110. C. oxydulé (red copper ore and tile ore). 111. C. muriaté (faltz-kupfer). 112. C. carbonaté bleu (copper azur). 113. C. carb. vert (malachite; copper green). 114. C. arseniaté (lenticular copper ore; olive ore); as appendix, C. arsen. ferrifère (cupreous arseniate of iron, Bourn.) 115. C. dioptase (copper emerald). 116. C. phosphaté. 117. C. sulfaté (copper vitriol, K.).—*Fourth Genus*: Fer. 118. Fer natif (native iron). 119. F. oxydulé (magnetic iron-stone); and, by way of appendix, F. oxydulé granu-liforme (iron-sand). 120. F. oligiste (specular iron, iron mica, red iron froth, red hematite; compact red iron-stone, columnar clay iron-stone). 121. F. arsenical (common arsenical pyrites); and, as appendix, F. arsenical argentifère (weiss-erz, W. noble arsenical pyrites, K.) 122. F. sulfuré (common pyrites); and, as appendix, F. sulfuré épigène (leberkies, but not of Werner), and F. sulfuré ferrifère (magnetic pyrites). 123. F. oxydé (brown hematite; reniform and lenticular clay iron-stone; green iron-earth); and, as appendix, F. oxydé résinite (eisenpech-erz, or pitchy iron-ore); also part of F. oxydé carbonaté (sparry iron-stone). 124. F. phosphaté (blue iron earth). 125. F. chromaté (eisen-chrom, K.) 126. F. arseniaté (cube ore). 127. F. sulfaté

sulfaté (native vitriol).—*Fifth Genus*: Etain. 128. E. oxydé (tin-stone); and, as appendix, E. oxydé concrétionné (Cornish tin ore, or wood-tin). 129. E. sulfuré (tin pyrites).—*Sixth Genus*: Zinc. 130. Z. oxydé (calamine). 131. Z. carbonaté. 132. Z. sulfuré (blende). 133. Z. sulfuré (zinc vitriol, K.)—*b*, not ductile.—*Seventh Genus*: Bismuth. 134. B natif (native bismuth). 135. B sulfuré (bismuth glance); and, as appendix, B. sulf. plumbo-cuprifère (needle ore). 135. B. oxydé (bismuth ochre).—*Eighth Genus*: Cobalt. 137. C. arsenical (white and grey cobalt-ore). 138. C gris (cobalt glance). 139. C. oxydé noir (black cobalt ochre). 140. C. arseniaté (red cobalt ochre).—*Ninth Genus*: Arsenic. 141. A. natif (native arsenic). 142. A. oxydé (arsenic bloom). 143. A. sulfuré (yellow and red orpiment).—*Tenth Genus*: Manganèse. 144. M. oxydé (grey and black manganese ore); and, as appendix, M. oxydé carbonaté (red manganese ore). 145. M. sulfuré (manganese glance, K.) 146. M. phosphaté ferrifère (phosphor. mangan, K.)—*Eleventh Genus*: Antimony. 147. A. natif. (native antimony). 148. A. sulfuré (grey antimony ore). 149. A. oxydé (white antimony ore; antimony ochre). 150. A. oxyde sulfuré (red antimony ore).—*Twelfth Genus*: Uran. 151. U. oxydulé (pitch ore). 152. U. oxydé (uran mica; uran ochre).—*Thirteenth Genus*: Molybdène. 153. M. sulfuré (molybdène).—*Fourteenth Genus*: Titane. 154. T oxydé (rutile; menakan). 155. T. anatase (octaedrit). 156. T. siliceo-calcaire (sphen).—*Fifteenth Genus*: Scheelien. 157. S. ferrugine (wolfram). 158. S. calcaire (tungsten).—*Sixteenth Genus*: Tellure. 159. T. natif; auro-ferrifère (native sylvan), argentifère (graphic ore); auro-plombifère (nagyag ore).—*Seventeenth Genus*: Tantale. 160. T. oxydé ferro-manganésifère (tantalit, K.) and yttrifère (yttro-tantalit, K.).—*Eighteenth Genus*: Cerium. 161. C. oxydé silicifère (cererit, K.)

Two appendices contain, the one, all the compound rocks; the other, the volcanic productions. As neither of these classes of minerals form a prominent or distinctive feature in the system, it is only necessary in this place to mention the subdivision of those assemblages. The rocks are divided into aggregates of primary, secondary, and tertiary formation, and into those composed of fragments or detritus cemented together subsequent to the formation of the substances to which they belonged. The volcanic productions are divided into six classes: 1. Lavas, (subdivided into lithoid, glassy, and scorified). 2. Thermautides, or substances presenting only slight traces of volcanization. 3. Products of sublimation, such as sulphur, &c. 4. Altered lavas. 5. Volcanic tuftas. 6. Substances formed in the interior of lavas, such as mesotype, &c. Conf. Anon. über das Studium der Mineralogie. Häuy's Tabl. comparatif. Lucas' Tabl. des Espèces minerales.

MINERVA, LA, in *Geography*, a town of Naples, in the province of Otranto; 20 miles E.S.E. of Matera.

MINERVA, in *Mythology*, derived according to some à *minis*, from the threats of her stern countenance, otherwise called *Pallas*, is the goddess of wisdom and the arts; and the only one of the offspring of Jupiter to whom pertain the prerogatives of the supreme rank of divinity. Minerva is represented, both by the painters and poets of antiquity, as a beauty of the severer kind: the distinguishing character of her face is dignity and a certain sternness, which has more of masculine than feminine in it: and, therefore, more apt to strike one with awe and terror, than to charm one, at first sight. Her dress and attributes are adapted to the characters of her face; she most usually appeared with a helmet on her head, and a plume that nodded formidably in the air; in her right hand she shook her spear, and in her other grasped

her shield, with the head of the dying Medusa upon it; the same figure appears also on her breast plate called *Egis*, which was the skin of a goat, or, as others say, of a monster so called, which vomited fire and committed dreadful havoc in Phrygia, Phœnicia, Egypt and Libya, and which was killed by Minerva, and hence she wore its skin upon her buckler; and sometimes the goddess herself is represented as having living serpents about her breasts, and about her shoulders; she is also accompanied with a cock, which is a fighting bird, and corresponding to her character as the inventress and president of war, and an owl, which sees in the dark, and, therefore, is the image of wisdom. It is probable that the Romans considered Jupiter, Juno, and Minerva, as one and the same divinity, under three different names: among which names, that of Jupiter might signify supreme goodness; that of Minerva, supreme wisdom; and that of Juno, supreme power: thus the learned Dr. Cudworth observes, *Intell. Syst. b. 1. c. 4. p. 450*, that the three Capitoline gods, Jupiter, Juno, and Minerva, may be understood to have been nothing else but several names and notions of one supreme deity, according to its several attributes and manifestations. Cicero mentions five goddesses of the name of Minerva, and Clemens Alexandrinus admits also the same number. Several cities were distinguished by the worship which they paid to Minerva; among others Rhodes and Athens, but Sais in this respect rivalled all the cities in the world, for here this goddess had a magnificent temple, which Herodotus has particularly described. The same author also speaks of temples consecrated to this goddess in several cities of Greece; but the island Dio, or Naxos, though consecrated to Bacchus, was more remarkable for the worship of Minerva, which appears by her representation on three medals of that city. At Athens she had a magnificent temple, called "Parthenos," the virgin, which Phidias adorned with a statue of gold and ivory, reckoned his master-piece. The worship of Minerva was rendered still more solemn by a festival, called "Atheneia," celebrated to her honour, and the pomp of which invited spectators from all Greece. This festival afterwards took the name of "Panathœnaia," in which was a procession, when the people carried about the "peplus" of Minerva, which was a white robe without sleeves, wrought with gold, on which were represented the combats and great achievements of Minerva, Jupiter, and the Hermes.

Minerva is also ranked among the musical deities, to whom the invention of the flute is ascribed. See *FLUTE*.

MINERVALIA, among the Romans, called also *Quinquatria*, were feasts celebrated in honour of Minerva. One of these feasts commenced on the 3d of January, and another on March 19th, and lasted five days. The first day was spent in prayers to the goddess; the rest in offering sacrifice, seeing gladiators fight, acting tragedies upon mount Albanus, and reciting pieces of wit, wherein the conqueror had a prize given him. Scholars had then a vacation, and made a present to their masters, which was called *Minerval*.

MINEUR, Fr., MINOR, Lat., a musical term applied to such concords and intervals, as are rendered as flat or small as possible, without being false and out of tune. Mineur is said also of a key or mode in which the third above the key note is minor or flat. See *MODE*, *MAJOR*, and *INTERVAL*.

MINGALLA, in *Geography*, one of the small western islands of Scotland, the largest of those called "Bishop's islands," about three miles long and one broad. N. lat. 56° 48'. W. long. 7° 35'.

MINGAN ISLANDS, a cluster of islands near the south

coast of Labrador, in the gulf of St. Laurence, so called from the name of the principal of them. N. lat. 50° 15'. W. long. 64°.

MINGHIOL, signifying "Thousand Springs," a mountain in the northern part of Armenia, abounding with springs; from which the Euphrates originates.

MINGO, an Indian town on the W. bank of the Ohio river, 40 miles south-westerly of Pittsburg. In the creek, where it is situated, there are springs, that yield the "petrol," a bituminous liquid.

MINGOES, an Indian nation, inhabiting the vicinity of the southern branch of the Scioto river. The number of warriors is 40.

MINGOLZHEIM, a town of the duchy of Baden; 14 miles S.E. of Spire.

MINGOTTI, REGINA, in *Biography*, a female opera singer and actress of great abilities and celebrity, was born in Carinthia, a German province, in the dominions of Austria, and though a native of a transalpine country, she became one of the most eminent vocal performers on the Italian opera stage during the last century. After seeing and hearing her frequently in England, where she arrived in the year 1754, we met with her, in 1772, at Munich, in Bavaria, and in conversation obtained from her the following sketch of her active professional life.

Her parents were Germans; her father, an officer in the Austrian service, being called to Naples upon duty, his wife travelled with him thither during her pregnancy, and was there brought to bed of this daughter; who, however, was carried to Gratz, in Silesia, before she was a year old; and her father dying while she was young, her uncle placed her in a convent of Ursulines, where she was educated, and where she received her first lessons of music.

She told us, that during her childhood, she remembers being so pleased with the music performed in the chapel of her convent, particularly with the Litany sung there one festival, that she went to the abbess, with tears in her eyes, and trembling, both with fear of anger, and of a refusal, to intreat her to teach her to sing, as *she* did in the chapel. The abbess put her off, with saying, that she was very busy that day, but would think of it. The next day she sent one of the elder nuns to ask her who bid her make that request, when the little Regina, as she was then called, replied, that nobody had bid her, but that it was merely her own love for music which inspired the thought. After this the abbess sent for her, and told her, that she had very little time to spare; but if she would promise to be diligent, she would teach her herself; adding, that she could only afford her half an hour a day; but with that, she should soon find what her genius and industry were likely to produce, and she should go on with, or discontinue her instructions accordingly.

Regina was in rapture with this compliance of the abbess, who began to instruct her the next day, *à table sec*, as she expressed it, without a harpsichord, or any other instrument. She applied to the harpsichord several years after, and still accompanied on it very well. But it was perhaps owing to her manner of learning to sing *without* an instrument, that she acquired the firmness in performance, for which she has always been remarkable.

In this manner she was taught the elements of music and *solfeggi*, with the principles of harmony, and was obliged to sing the treble, while the abbess sang the base. She shewed us a very small book, in which all her first lessons were written: the explanations were in the German language.

She remained in this convent till she had attained her

14th year, at which time, upon the death of her uncle, she went home to her mother. During the life of her uncle, she had been intended for the veil. When she quitted the convent, she appeared, in the eyes of her mother and sisters, to be one of the most useless and helpless of beings; they looked upon her as a fine lady, brought up in a boarding school, without knowing any thing of household concerns; and her mother neither knew what to do with her, or her fine voice, which both she and her sisters despised, not foreseeing that it would one day be productive of so much honour and profit to the possessor.

Not many years after she quitted the convent, signor Mingotti, an old Venetian, and manager of the opera at Dresden, was proposed as a husband for her. She detested him, but was at length worried into a compliance, which was the sooner extorted from her, perhaps, as she, like other young women, imagined that by losing, she should gain her liberty.

People talked very much of her fine voice and manner of singing. Porpora was at this time in the late king of Poland's service, at Dresden: he had heard her sing, and spoke of her at court as a young person of great expectations; which occasioned a proposal to her husband for her entering into the service of the elector: he had before marriage promised never to suffer her to sing on the stage; however, he came home one day, and asked her, if she should like to engage in the service of the court. She thought this was done in derision, and gave him a short and peevish answer; but he continuing to teize her on the subject, at length convinced her that he was in earnest, and had a commission to treat with her. She liked the thoughts of singing, and turning her voice to some account, and therefore gladly entered into articles for a small stipend, not above 3 or 400 crowns a-year.

When her voice had been heard at court, it was supposed to raise a jealousy in Faustina, who was then in that service, but upon the point of retiring; and consequently, in Hassé, her husband, particularly when he heard that Porpora, his old and constant rival, was to have 100 crowns a month for teaching her. He said it was Porpora's last stroke; the only twig he had to catch at; *un clou pour s'accrocher*. However, her talents made such a noise at Dresden, that the fame of them reached Naples, to which place she was invited to sing at the great theatre. In her way thither from Dresden she passed through Vienna, where she visited unexpectedly Metastasio, in whose "Attilio Regolo" she had distinguished herself; of which visit he gives the following account to the princess di Belmonte.

"Signora Regina Mingotti, one of the principal ornaments of the vocal band at Dresden, being engaged at Naples in the same rank, has not escaped the epidemic desire of bringing with her a letter from me to your excellence. This request, however, would have been fruitless, had she not most wickedly and maliciously hit upon the following expedient, for vanquishing my well-known repugnance to give way to such applications. When she left the court of Dresden, what does she do but post away to Vienna; and without giving me the least previous notice of my danger, early one fine morning presents herself in my room, and in a military habit, preceded only by her fame, and accompanied by all the graces of youth, vivacity, talents, and what is still worse, entitled to the chief credit of the successes of my "Attilio" in Dresden. Now tell me madam, with your usual candour, if ever you heard of so cunning a musical trick, it was like putting a knife to the throat of a poor Christian. I know not what Socrates, Cato, or Aristotle would have done in such a case; but this I know, that

that I could not help writing the letter, and even devoutly thanking heaven, that she had the moderation to limit her pretensions to a letter only."

This letter has no date, but it must have been written in 1751, when "Attilio" was first represented at Naples.

At this time she knew but little Italian; however, she now went seriously to work in studying it.

The first character she appeared in was Ariftea in the opera of the "Olimpiade," set by Galuppi. Montecelli performed the part of Megacles. On this occasion her talents, as an actress, gained her as much applause as her singing: she was bold and enterprising; and, seeing the character in a different light from what others had done before her, would, in spite of the advice of old actors, who durst not deviate from custom, play it in a way quite different from any one of her predecessors. It was in this original and courageous manner, that our Garrick first surprised and charmed an English audience, and, in defiance of contracted rules, which had been established by ignorance, prejudice, and want of genius, struck out a style of speaking and acting, which the whole nation has ever since continued to approve, with acclamation, rather than applause.

After this success at Naples, Signora Mingotti received letters from all parts of Europe, to offer her terms for engaging at different operas; but she was not then at liberty to accept of any of them, being obliged to return to the court of Dresden, in which service she was still a pensioner; however, her salary was considerably augmented, and she frequently expressed her gratitude to that court, and said she owed to it all her fame and fortune. Here she repeated, with great applause, her part in the "Olimpiade;" every one agreed, that in point of voice, execution, and acting, her powers were very great; but many thought that she was wholly unfit for any thing pathetic or tender.

Haffe was now employed to set "Demofonte;" and she imagined that he kindly gave her an adagio, accompanied by the violins, Pizzicati, merely to expose and shew her defects. But suspecting the snare, she studied hard to escape it; and in the song, "Se tutti i Mali Miei," which she afterwards sung in England with great applause, she succeeded so well, as to silence even Faustina herself. Sir Ch. H. Williams was English minister here at this time, and being intimate with Haffe and his wife, had joined their party, publicly declaring that Mingotti was utterly unable to sing a slow and pathetic song; but when he had heard her, he made a public recantation, asking her pardon for doubting of her abilities, and ever after remained her firm friend and adherent.

She went next to Spain, where she sung with Gizziello, in the operas under the direction of Fariuell; who, she said, was so rigid a disciplinarian, that he would not allow her to sing any where but in the opera at court, or even to practise in a room next the street. She was requested to sing at private concerts by many of the first nobility and grandees of Spain, but could not obtain permission from the director; who carried his prohibition so far, as to deny a pregnant lady, of great rank, the satisfaction of hearing her, though she was unable to go to the theatre, and declared that she longed for a song from Mingotti. The Spaniards have a religious respect for these involuntary and unruly affections in females thus circumstanced, however they may be treated as problematic by M. Buffon and others. The husband, therefore, of the lady, complained to the king of the cruelty of the opera director, who, he said, would kill both his wife and child, if his majesty did not interfere. The king lent a favourable ear to the complaint, and ordered Mingotti to receive the lady at her house, in which his majesty was implicitly obeyed, the

lady's desire was satisfied, and the child prevented, perhaps, from being marked in some part of its body with a music paper, or from having an Italian song written with indecipherable characters on its face.

Mingotti remained two years in Spain, whence she came to England, for the first time, in 1754. How much her performance was then admired many persons now living can well remember, and tradition has told the rest. She afterwards sung in every great city of Italy: but always regarded Dresden as her home during the life of Augustus, the late king of Poland. She was now settled at Munich, more it was thought from economy than attachment. She had no pension from the court of Bavaria, as was reported; but with care and prudence, she had just sufficient from her savings to bring her safely through the year. She seemed to live very comfortably, to be well received at court, and to be esteemed by all such as were able to appreciate her understanding, and enjoy her conversation.

It gave us great pleasure to hear her speak concerning dramatic music, which she did with more intelligence than any maestro di cappella with whom we ever conversed. Her knowledge and experience in singing, and powers of expression in different styles, were still astonishing, and must have delighted all such as could receive pleasure from song unaccompanied with the blandishments of youth and beauty. She spoke three different languages, German, French, and Italian, so well, that it was difficult to say which was her own. English she likewise spoke, and Spanish, well enough to converse in them, and understood Latin; but in the three languages first mentioned she was truly eloquent.

Her style of singing was always grand, dramatic, and such as discovered her to be a perfect mistress of her art; she was a most judicious and complete actress, extending her intelligence to the poetry, decorations, and every part of the drama. Yet her greatest admirers allowed that her voice and manner would have been more irresistible, if nature had allowed her a little more female grace and softness. Her performance of male parts, however, obviated every objection that her greatest enemies could make to her perfection, either as a singer or actress.

The first time Mingotti came to England, she remained here three years; during part of which time she and Giardini were joint managers; by which their celebrity was more increased by their talents, than their fortune by the profits of the theatre.

MINGRAY, in *Geography*, a town of Spain, in Catalonia, near the mouth of the Tet; 15 miles E. of Gerona.

MINGRELIA, a country of Asia, the ancient *Colchis*, (which see), is bounded on the N. by Circassia, on the E. and S.E. by Imeritia, on the S. by Guriel, and on the W. by the Black sea and Abascia. This country is woody, intermixed with a small proportion of arable land, which is so soft as scarcely to bear the plough. The climate as well as the soil is relaxed by moisture; and it is said that in many places the ground sounds hollow, from which circumstance originates an opinion, that the Euxine and Caspian are connected by a subterraneous communication. Mingrelia is watered by the Phasis, and a great number of other rivers. The chief food of the inhabitants is "gom," a grain resembling millet; wheaten bread is used only by the prince and nobility. This country was originally rich in gold, and hence, it has been said, the Argonauts fetched the golden fleece; but the mines of precious metals are now unwrought. Ancient Colchis, of which Mingrelia is a part, contained a great number of cities and towns, most of which have long since sunk into oblivion. The present capital of this part of Turkey in Asia, called Cotatis or Cutais,

Cutais, comprehends hardly 200 houses, though it is the residence of the prince. The air is rendered infalubrious by frequent rains, and the inhabitants seldom protract their lives beyond 60 years. The vines of the country produce excellent wine, and the pastures, which are excellent, feed many horses. The men, as well as women, are generally well formed and handsome; but they are reckoned, in general, to be thievish, perfidious, cruel, drunken, and licentious in their amours. Infants, that have no means of support, are often put to death, as well as sick persons, of whose recovery there is no reasonable expectation. The people are generally employed in the chase, and they think themselves peculiarly happy, if they possess a horse, a good dog, and a well-trained falcon. The peasants are slaves to the nobility; who have the power of life and death over their vassals in Mingrelia, as well as Imeritia, Guriel, and Georgia. Their religion is that of the Greek church: The principality is hereditary, and the prince or chief of Mingrelia and Guriel assumes the title of "Dadian," or the chief of justice; and the tribute exacted by the Turks is a quantity of linen cloth, manufactured in the country. The principal commerce is in slaves.

MINHO, Lat. MINIUS, which is said to derive its name from "Minium," or vermilion, found in its neighbourhood, is a river of Spain, that rises on the E. of the Sierra Mondonado, in the province of Galicia, receives the waters of the Cuytella and the Ouaría, passes to Lugo, receives the Chouro, and at San Martino de Coba the Sil, and then pursuing the boundary of Galicia, separates it from Portugal, whence it proceeds and falls into the ocean near the port of Guardia; its course is about 52 leagues, first from N. to S., then to the S.W.

MINIACI, or CASALINO, a town of Sicily, in the valley of Demona; 10 miles S.W. of Randazzo.

MINIATO, ST., a town of Etruria, on the Arno, the see of a bishop, containing four churches besides the cathedral and nine convents; 20 miles W. of Florence. N. lat. 43° 44'. E. long. 10° 40'.

MINIATURE, in *Painting*, a word borrowed of the French, and derived, as some say, from the Latin *minimum*. It properly signifies the representation of natural objects, by figures drawn and painted in small proportions; but there is something arbitrary in its present use, as it is almost entirely confined to portraits painted with water-colours on paper, vellum, or ivory; and is not applied to small figures painted in oil, on wood, stone, or canvas. Thus, Gerard Dow's and Adam Elsheimer's very finely executed works, wherein sometimes are figures not more than two or three inches high, and consequently far smaller than miniature portraits are usually painted, which ought therefore, according to the preceding etymology of the word, to be called miniatures, never are so, but are constantly spoken of as small pictures. But we conceive that the term miniature is derived, agreeably to the statement of other writers, from *minium*, vermilion, whence the persons who put the red letters, and illuminations in ancient manuscripts, were called *miniatores*.

In this branch of the art of painting, the same feeling of character, the same taste and understanding of drawing and chiaro-scuro are requisite, as in oil painting; but the use of its materials is more facile, and less likely to produce, in unskilful hands, such discordant and unpleasant effects, though the process is more tedious. It requires great ingenuity and patience in the artist, as it is wholly performed with the point of the pencil, either applied in the manner termed hatching, which consists of fine strokes crossing or intermingling with each other; or that of stippling, or laying dots of various colours over the surface of the picture. One

of these modes of proceeding is necessary to produce softness, with fullness and richness in miniature; because ivory and vellum, from the peculiarity of their textures and surfaces, do not admit of the system called washing, or blending the colours together in a broad soft manner, like aqua-tint; and in works like these, whose beauties are not discernible but on a near inspection, great neatness and perfection in the finishing are imperiously demanded.

The miniatures which are of the oldest date in England were chiefly wrought on vellum, though the cabinets of our nobility and gentry contain some few in oil colours on thin copper-plates: and this latter system might well have been adopted generally, but for the difficulty of producing the essential beauties of miniature, *viz.* clearness and purity, with so gross a vehicle as oil is, when compared with water; and also, that there is much danger, if the picture be worn, of some of the colours changing, and becoming dark: otherwise, and if merely hung up for ornament, a decided preference must be given them for their durability over those painted in water colours.

The adoption of ivory for miniature painting, in preference to vellum, which, although limited in size, is now almost universal, is founded on three circumstances, *viz.* its being so much less likely to be affected by damp, capable of receiving a smoother texture, and having a more agreeable hue of colour, which greatly blends with the fresher hue of the flesh, and gives it warmth and harmony. It also possesses a degree of absorption, which renders the colours less likely to fade. So great is the effect of damp upon vellum, or of the substances employed to smooth and prepare its surface for the artist, that there are few miniatures painted upon it, of recent date, even the colours of which are not in some measure impaired; and in many they are almost totally destroyed.

The colours best adapted for miniature painting are those that have the least body, and that work clear and clean in hue; such as lakes, carmine, ultramarine, browns, yellows, and greens made of the juices of certain herbs and flowers. Most of the earthy colours, as the ochres, by no means are easily applied to this purpose: their opacity and body render them unfit agents, where all should be light, splendid, and clear. The vehicle which best suits the purpose is water, in which either gum Arabic or gum tragacanth is dissolved. The colours should be first ground in pure water, and the gum-water added afterwards, in sufficient quantity to give them tenacity, that they may not easily rub off the surface of the ivory or vellum; but if too much gum be used, there is great danger of the colours cracking and falling off.

In the process of miniature painting, our modern artists cover the ivory with colours more than was usually done by those of an early period, who were accustomed to leave the naked ground or colour of that substance in a large proportion in the fleshy parts, and contented themselves with little more than drawing very delicately the features of their sitters on it, and rounding the extremities with shadows. Though much more rotundity and richness of effect is gained by the present process, when skilfully employed; yet in hands less ingenious, there is great danger of heaviness, and loss of character and simplicity, those prime and inimitable qualities in all works of art, the want of which cannot be compensated for by all the colour and delicacy of finish the utmost stretch of art, without them, is capable of producing. But, in fact, the capabilities of water colours are become far more known and understood of late, as well as the best modes of applying them. A new school in that branch of art has arisen in the course of the last ten or fifteen years; since when, effects have been produced by them, which leave all former experience of their power far behind, and of

which nothing could have been expected. Of this more under the article *Water-Colours*.

The most successful artists in miniature in this country, till the present period, were Nicholas Hilliard and Isaac Oliver, in the time of Elizabeth; and P. Oliver and S. Cooper, in that of Charles I. The works of the latter are particularly striking, and worthy of observation, for the extraordinary breadth of manner, which he appears to have caught of Vandyke; many of whose pictures he copied in miniature, and which his own pictures resemble so much, that a magnifying glass only exhibits to greater effect the simplicity of the style in which they are wrought.

We now possess a great number of very ingenious artists in this branch of the profession: but to particularize any one, when so many stand on nearly the same level, would be invidious; and the public have ample opportunities of deciding on their respective merits.

For the method of preparing ivory for miniatures, see *Ivory*.

MINICULATOR, among the Romans, a servant who embellished any writing with minium.

MINIET, or **MINIEN**, in *Geography*, a small but somewhat handsome town, compared with other places in the same country, in Upper Egypt, on the west banks of the Nile. Its streets, however, are narrow and dusty: the houses are built of unbaked bricks, cemented with mud; and many of its edifices are clumsy and irregular. The house occupied by the kiaschef or cashief, as well as those of some other persons, are built of stone, and their whiteness relieves the uniform reddish-grey of the rest. The bazars, or places where the merchants meet, are tolerably commodious; and the crowds which frequent them announce a numerous population, as well as some briskness of trade. Government has here established a toll for loaded vessels, which is easily collected, as the Nile is not wide at this place. Here are manufactured earthen vessels, called "bar-dacks," formed of clay in the neighbourhood, and serving to preserve the water cool. Columns of granite, broken and thrown down, and some still standing, besides heaps of rubbish, intimate that Miniet occupies the place of a more ancient city; which, according to some, was "Hermopolis," and, according to others, "Cynopolis," where the dog was worshipped. Mr. Bruce supposes Miniet to be the ancient "Phile." It is about 50 leagues from Cairo, 22 miles S. of Abu Girgê, and 14 N. of Ashmuneim, or Achmounim.

MINIET Rabiné, a town of Egypt; 6 miles S. of Gizeh.

MINIET Selamé, a town of Egypt; 10 miles S. of Faoué.

MINIET Semannud, a town of Egypt; 8 miles S. of Manfora.

MINIM, in *Music*, from *minimus*, Lat., the least. In the first time-table that was framed, where the semibreve was the shortest note, and the first in a round form, the rest were square. But as the art of counterpoint was improved, and different parts in notes of different value were attempted, it was found necessary to divide the semibreve in two equal

parts, ; diminishing the length of a semi-

breve one half, by adding a tail to it. This invention has frequently been ascribed to Vitriaco; but it seems more properly to belong to Franco, as appears by a manuscript tract in the Bodleian library at Oxford. Franco flourished 200 years before Vitriaco. See *MUSICA Mensurabilis*, **TIME**, **MEASURE**, and *Musical CHARACTERS*.

MINIM, *Sextuple of the*. See **SEXTUPLE**.

MINIMA NATUREÆ, or *Minima Naturalia*, among *Philosophers*, the primary particles of which bodies consist;

the same with what are otherwise called *corpufcles*, and *atoms*.

MINIMA, in the *Higher Geometry*, the smallest quantities attainable in any given case. See **MAXIMA**.

MINIMA, *Per*. See **PER MINIMA**.

MINIME, in old French *Music*, was the same character for time as is now called *une blanche*. See **MINIMI** and **TIME-TABLE**.

MINIMENTS, or **MUNIMENTS**. See **MUNIMENTS**.

MINIMI Digni Extensor. See **EXTENSOR**.

MINIMI Digni Pedis Abductor. See **ABDUCTOR**.

MINIMS, **MINIMI**, an order of religious, instituted about the year 1440, by S. Francis de Paulo, confirmed in 1473, by Sixtus IV., and by Julius II. in 1507. See **BONS-HOMMES**.

These have improved on the humility of the *Minors*, by terming themselves *Minimi* or *Minims*, *q. d.* least, or smallest.

MINIMUS GLUTEUS. See **GLUTEUS**.

MINING, *History of*. To trace this subject up to its earliest stages, and to exhibit the various combinations of human ingenuity which it has in successive periods produced, though an inquiry which might afford matter for curious speculation, would be one which, if we were to take into the view the progress of mining in all the different countries where metals have been found, would extend the subject to a length hardly admissible in any work not wholly devoted to this object.

From the simplest operations, mankind have been gradually led, by following the pursuit of the metals, to efforts the most complex and astonishing. At first it may be assumed, not only from the probability of the thing, but from evidence which even this country affords, in the remains of ancient works of this kind, that metals were procured from detached fragments of the ores, such as had been separated by various causes from the upper parts of the veins in which they were originally deposited: and in this manner is gold yet procured, by washing the sands of certain rivers; and tin even now sought after, under beds of gravel, in the vallies of Cornwall and Devon.

The pursuit of scattered pieces of ore naturally would conduct the persons, who were thus employed, to the beds from which they had been detached; and in turning over the soil to procure the loose fragments, the backs of the veins would be laid open and discovered. This is a process which is even now daily going on in mining districts, only with a different object: for having found an accidental stone of ore, the miner does not row dig over the earth on the surface, for the sake of these casual deposits; but reasoning from their appearance that a vein is near at hand, goes at once to work in order to find it.

If we allow that this account of the origin of mining be true, it ought to follow that those metals were most anciently worked, whose ores are most attractive in their appearance, most easily reduced into a metallic state, or such as are most usually found near the surface of the earth. As far as the English mines afford us the means of judging, all this may be asserted to be true. The tin of Cornwall was undoubtedly the first metal sought after in Britain, and probably the first article of commerce with other nations; and the ores of tin, from their great weight, indicate their metallic contents, and yield them to the simplest treatment with fire, and are still found at inconsiderable depths. It may also be observed, that the traces of the most ancient tin works exhibit no symptoms of their having been pursued, but in situations where the soil, with which it was mixed, could be easily and expeditiously removed; or where it

could

MINING.

could be washed away by streams of water, conducted over it for the purpose, and which, by carrying off the lighter parts of the soil, laid bare the ores, which are kept from moving by their superior specific gravity.

This latter was an ingenious improvement upon the first ruder efforts, and is still the mode employed in many of the tin stream works; while there are numerous traces of these attempts accompanied with circumstances, which prove them of very considerable antiquity.

Lead is another metal, which not only is often found near the surface, but the ores exhibit to the eye the appearance of metal, and in general yield their contents to the heat of a moderate fire. This metal, therefore, was probably an object of pursuit in the early ages of mining.

Copper, on the other hand, is seldom found without penetrating the earth to considerable depths; and the proportion of metal in most of the ores is so small, that a certain progress in the arts of mining and smelting must be presumed to have been made, before it could have become an object of research. We believe this to have been the fact in most countries, as well as in this, where copper was certainly discovered by working mines in pursuit of tin or lead.

From the processes for finding and separating metallic ores from alluvial matter in which they were casually mixed, the next step was to procure them by digging out the veins themselves, and following them into the solid rocks in which they are formed. At first this could only have been done, where, by the elevation of the mountains, it was possible to work high enough for the waters to discharge themselves by conduits or adits from the works; and where the rock was not so hard but to yield to tools rudely formed, or perhaps to the agency of fire, which would, however, produce but a limited effect in most cases.

It was not until machines were applied to pump the waters, that the metals could be followed to any considerable depth, and not until gunpowder had furnished the means of splitting the hardest rock, that man was enabled to penetrate strata of every description that opposed his progress.

These inventions, therefore, form most important epochs in the history of mining; for, since mankind have called in the assistance of such powerful agents, neither the influx of constantly flowing water, nor the barriers which the most indurated rock can present, are obstacles in the way of the miner, where rich and productive veins of ore tempt the pursuit.

The first important era was the period in which the application of gunpowder to the purposes of mining took place, which happened in Hungary, or Germany, about the year 1620, and was first introduced into England at the coppermine at Ecton, in Staffordshire, about the year 1670, by some German miners brought over by prince Rupert. It was in use in Somersetshire about 1684, and it was not until after this period, probably, that the Cornish miners became acquainted with this powerful assistant to their operations.

Its importance may be judged of by the amount of the present consumption in the mines of Cornwall alone, which has been calculated at an annual value of about forty thousand pounds sterling.

There are many mines which could not possibly have been worked without the aid of gunpowder, and, until it was used, subterranean operations must have been difficult and very uncertain. The hammer and wedges were probably the first instruments employed for splitting rocks, and the pick followed, which is used both as a hammer and a wedge. The change of form in these instruments observed in those which have been found in old works, as well as the materials of

which they are sometimes made, offer evidence of considerable antiquity.

Many tools of oak have been occasionally met with, which tradition among the Cornish tanners make to have belonged to the Saxons or Danes, but it is probable that they were employed before the time of their having a footing in the country, and most likely when iron was little known here.

Wedges of dry wood were made use of by driving them into clefts of the rock, and then wetting them, so as to cause them to swell, and thus by repeated similar insertions to force the ground asunder.

Agricola describes the application of fire to the splitting of rocks, but there is no tradition of its having been applied to this purpose in England.

The means employed for raising or throwing up the ores and waste stuff to the surface, were at first as rude as the other operations of mining. The *windlafs and bucket* may be reckoned an improvement which took place in a later stage of mining, as simple a one as it certainly is, and now in a great measure superseded by more effective machinery. It was, however, at the time an important addition to the apparatus of mines, as water as well as ore could thus be raised to moderate heights; and by the employment of much manual labour with a number of such machines, even considerable excavations were kept free from water, and had their produce lifted to the surface.

The windlafs, probably, like most of the early improvements in mining, had its origin in Germany, and before it was introduced here from that country, the mode adopted for throwing up the stuff dug in the bottom of the deeper pits, was by making successive steps, or stages, which were called in Cornwall *shammels*; upon each of which men were placed, who raised the excavated matter from one to the other, until it thus reached the highest point.

In South America the windlafs is even yet hardly known, and the ores are either carried up by the Indians employed in the mines, or, where the situation admits of sloping roads being made to the bottoms, are conveyed to the surface on the backs of mules.

When mines were worked deep, the labour of raising the water which was constantly collecting, became too great for mere manual exertion, and hydraulic machines were invented or employed for the purpose. Pumps were adapted to the shafts, and their constant action secured by giving motion to their pillars by wheels turned by descending streams of water. Where supplies of this agent can be obtained, and the force of the country admits of its application with considerable falls, nothing better can be desired, as it is a more regular power than steam, and infinitely less expensive; it has, therefore, continued in use to the present day, where circumstances admit of its being applied.

The German miners seem in all probability to have had the merit of these inventions, as they appear to have been completely in use among them when Agricola wrote, who fully describes their construction and application.

But though Germany may fairly claim the invention of these engines for this purpose, yet nothing more has been done there; but, on the contrary, they are said to remain now there in nearly the same state as at their original introduction. The English miner has improved the pump-work and the water-engines to their present high state of perfection in this country.

It is in some degree owing to necessity that this has been the case, as there are single mines in England which require that as much water be discharged from them, as the pumps of a whole province of German mines could effect. There

is, indeed, no need to prove the capacity of English artists for mechanical improvement.

Hydraulic machines, however, as they require falls of water to put them into motion, can only be erected where the circumstances of a country afford the means of working them; and if nothing farther had been done, many of our most valuable mines in Cornwall, not to mention our galleries and lead mines, would have remained unexplored and unproductive. The invention of the *steam-engine* gave to the miner a power capable of universal application, and of an effect that added, as it were, new regions of subterranean country to his control. Depths hitherto unattainable are now placed at his command, and no limit can be assigned to his exertion, but that of the expence compared with the value of the produce.

The history of the steam-engine will be a subject for another place; but we may here observe, that the invention very early excited the attention of the mine owners of Cornwall, who successively adopted and encouraged the improvements of Savary, Newcomen, and Watt.

In this district some of the earliest efforts of these ingenious men were seconded and rewarded, and in return the mines have gained such assistance as could not have been formerly anticipated or imagined.

The general history of mining in England has never been very accurately traced; the districts famous for their mineral products have no communication with each other on this account, and have no common mineral laws or customs.

In other countries mining has been fostered and protected by the state, immunities have been granted, the workmen have been surrounded by particular privileges, and their operations encouraged by grants of timber from royal forests, or the free use of lands and waters. Thus peculiar systems of laws have often arisen where the mines were important as a source of revenue to the state. Something of this sort is indeed to be traced in the stannary laws of Cornwall; these laws, however, are not operative in the other mining districts of England, but are confined to the counties of Devon and Cornwall, which are both included in the royal duchy which bears the name of the latter. Here the stannary laws still existing, now afford the miner but scanty assistance, though they effectually provide for the secure payment of the mineral revenue to the duke of Cornwall. To this object, and to the adjoining disputes touching the affairs of tin mines, the present administration of these laws may be said to be directed. The protection to the person of the tinner, as to military service and processes from other courts, has been gradually removed, and the rights of embounding lands for his pursuits, and of obtaining water-courses for his engines, have been questioned, and, in some cases, rendered doubtful. It cannot, perhaps, be contended that these laws could now be exercised in their former construction in the present state of property; but a revision, accommodating them to the fair wants of the miner, without prejudice to the land owner, would be attended with much benefit to the mining interest.

The copper-mines, being altogether of later date than those of tin, partake of none of the advantages which the stannary laws afford, and are therefore governed more by custom than any thing else; an extension of the privileges of the tin mines to these, and a legal provision for the peculiar arrangements which such undertakings require, would remove many serious obstacles to their prosecution.

Mining in England had a very early origin, compared with the progress of other arts in the country; it was in all probability the first source of trade to these islands, and the tin of Britain was known in distant parts of the world at a very remote period. It is generally believed that the Phœnicians were the nation principally engaged in trading to

Britain for the metal. Tin works were carried on before iron was in use in England, as may be presumed from the tools of oak which have been found in ancient mines. Ctesero affirmed that no silver was to be found in Britain, and though it has since been proved that he was wrong in that respect, yet the notice taken of the subject serves to shew that the metals of the country were the principal temptation to the Roman conquerors.

The Saxons neglected the pursuit of the metals, but the Normans appear to have worked for them to advantage, and from this time, until the reign of king John, the mines were mostly in the hands of Jews, when they are said not to have been successful, but in the reign ensuing they were worked by the same people with more effect. Edward I. caused the Jews to be banished, and the mines were, in consequence, neglected, until Edmund, the elder son of that king, and earl of Cornwall, willing to restore what had produced so large a proportion of the revenues of his domain, made grants important to the miner, which were confirmed by the king, by a charter in the 33d year of his reign; which states that

“For the advancement of the stannaries, he frees the tanners from all pleas of the natives touching the court, and from answering before any justices, &c. save only the keeper of the stannaries; (pleas of land, life, and member excepted) neither are they to be kept from work but by the said keeper.” And it further “indemnifies them from tolls, &c., gives them libertie to dig tin and turf any where in the said countie, and to turn water-courses for their works at pleasure; with many other privileges.”

It is from this time that the enactment of laws for the government of the stannaries may principally be dated.

Power to search for other metals besides tin was granted to individuals immediately from the crown, and we find that various persons held the right of searching for mines in the reigns of Edward III. Richard II. Hen. IV. and Hen. VI. In some of these grants, gold, silver, and copper are mentioned as well as lead.

The privileges of the tanners were not interfered with by any question relating to these metals, nor, on the other hand, did the jurisdiction of the stannaries extend to affairs connected with them.

Thus we find an appeal to the exchequer in the reign of Henry VI. relative to lead mines. *From the records. Easter term, anno 36. Regni. Devon Memorand.* “That John Bottwright, governor of the mines of Bury Ferrers in Devon, complains to this court that Robert Glover, at the command of Roger Champernown, took away 144 boules of glance oar, valued at 15*l.* 6*s.* 8*d.* and made profit of the same without any thing allowed to the king, to the king's damage of 100*l.* and thereupon desireth the advice of the court.”

The mines continued to be protected by the crown, and particularly by Henry VII., until Edward VI. when they were neglected; and fell into complete decay during the disastrous government of Mary.

When Elizabeth succeeded to the crown, the mines of the kingdom partook of the attention which this enterprising queen bestowed on every object from which an increase to the resources, or an addition to the strength of her government, might be derived.

The failure of the mines had diminished the number, and annihilated the skill, of the English miners; the queen therefore invited over Germans, and made extensive grants in different parts of England to Houghseter and Thurland, and likewise others to William Humphreys and Christopher Shutz. She also established, in 1568, a corporation, which still exists, called “The Society for the Mines Royal,” which had certain grants and privileges in several counties, and of

MINING.

which William, earl of Pembroke, was the first governor. It does not appear that this society, which was originally a mining company, though now engaged in smelting ores only, produced any important effect upon the discovery of metals in England; the tin mines of Cornwall were not worked by them, but remained in the hands of private adventurers, under the jurisdiction of the stannaries, and increased in produce and value in proportion to the demand for this metal. The whole amount of tin annually raised in Devon and Cornwall, in the following reigns of James I. and Charles, was from fourteen hundred to sixteen hundred tons. It is probable that the civil wars which succeeded injured the workings of the mines, as in the reign of Charles II. it appears from a note of Mr. Scawen, of Molinek, who was vice warden of the stannaries, and quoted by Dr. Pryce, that the tin revenues were very small.

In the reigns of Anne and George I. the produce of tin had again become considerable, and amounted, one year with another, to something more than sixteen hundred tons; so that in the space of 110 years its mean proportion was equal to fifteen hundred tons *per annum*.

Since the foregoing time a gradual increase took place in the ensuing thirty years; for in the year 1742 a proposal was made by the Mines Royal Company in London to raise one hundred and forty thousand pounds to encourage the tin trade by farming that commodity for seven years at a certain price. A committee of Cornish gentlemen were appointed to consider of the proposal; and they reported, "That the quantity of tin raised yearly in Cornwall, at an average for many years last past, hath been about two thousand one hundred tons;" and resolved, "That three pounds nine shillings for grain tin, and three pounds five shillings *per hundred*

weight for common tin, are the lowest prices for which such tin will be sold to the contractors, exclusive of all coinage duties and fees."

The produce of the tin mines was much more considerable afterwards, and from 1760 to 1780 it was reckoned at about two thousand eight hundred tons a-year, which was worth the annual sum of about 180,000*l*.

Copper began to be worked in Cornwall in the beginning of the 18th century, and the amount had attained at the period just quoted to about the same annual sum of 180,000*l*. making the mineral returns of this district at this period, *viz.* about 1780, to be of the yearly value of 360,000*l*.

The tin mines have not been so important to the Cornish miners since the discovery of copper as they were before, the produce of the latter having increased most rapidly, while the former have not made any proportional progress. As the subject is very interesting in estimating the power of this country to supply raw materials for its numerous manufactures, we shall give statements of the produce and other particulars of the tin and copper mines of Cornwall and Devon, from the early part of the last century to the present time.

We shall first state the produce of the tin mines, and afterwards give a more detailed account of the effect of the discovery of copper on the mining interest as well as the trade of the country.

The chief part of the tin in the following statement was produced from the mines of Cornwall alone, as although Devon had anciently yielded a large proportion of tin, yet before this period the mines, or rather the stream works of the latter county had become exhausted, and were incapable of producing any notable proportion of ore.

Account of the Quantity and Value of Tin raised in Cornwall and Devon, from 1700 to 1800.

Dates.	Number of Blocks 6½ to a Ton.	Number of Tons.	Price <i>per</i> Ton.		Periods.	Annual Quantity in Tons.	Annual Value.	
			£.	s. d.			£.	s. d.
1700 to 1720	208,000	32,000			20 years	1600		
1720 to 1740	273,000	42,000	66	0 0	20 years	2100	138,600	0 0
1740 to 1750	162,500	25,000	65	0 0	10 years	2500	162,500	0 0
1750 to 1760	172,779	26,580	63	7 6	10 years	2658	168,450	15 0
1760 to 1770	177,302	27,277	66	6 8	10 years	2728	180,957	6 8
1770 to 1780	178,737	27,498	60	2 0	10 years	2750	165,275	0 0
1780 to 1790	192,295	29,583	68	2 0	10 years	2958	201,439	8 0
1790 to 1800	210,928	32,450	73	1 0	10 years	3245	227,047	2 6

From this table we may observe a regular increase in the quantities raised, the improvements in mining which took place having contributed, without doubt, to produce this effect. The price of the metal did not advance in proportion to the increase of the charges on labour, and the enhanced value of the articles used in the mines, and therefore we cannot account for the greater produce from increased demand, but from the power derived by improved means of working, and thus of bringing the metal to market at a cheaper rate. About the year 1770 the quantity raised appears to have been greater than the demand required, and the price seems to have been lower than at any former period, which was probably likewise affected by the war, and by the influx of tin imported into Europe by the Dutch from their possessions in the East Indies, where it is raised as well as in England. The advance in price that followed in the next period, may be attributed to the revival of trade, in consequence of the

peace which followed the American war, but this again produced an over quantity in the market, followed by a depression in value, very injurious to the miners, which was severely felt about 1789, when, by the exertions of Mr. G. Unwin, an export of tin to China, through the East India company, took place, that absorbed the surplus which the European market did not require, and thus the price advanced again to a rate higher than any preceding one. This export to India has continued ever since, and may probably increase notwithstanding that tin is found in some considerable quantity in Asia.

From 1800 to the present time the tin mines of Cornwall have rather declined, and are probably gradually exhausting, this metal not being found to penetrate so far into the earth as copper, and therefore but few mines have been found to continue productive at very considerable depths.

Any decline that may have taken place in the tin mines of Cornwall has, however, been more than compensated by the rapid

MINING.

rapid advances which the copper mines have made in that and the neighbouring district, which of late years have been so great as to render them of the highest consideration, and to give these concerns the precedence over all similar undertakings of any country. For whether we consider the quantity of their produce, the immense capitals invested, the power and number of their engines, the skill with which they are conducted, or the spirited and rapid execution of the works, they will probably be found to take the rank here assigned to them.

Cornwall possesses many eminent advantages as a mining country, of which its maritime situation is among the most important, but another is that it is peopled by a race of men peculiarly fitted for this employment. The Cornish miners unite great courage to personal strength and activity, while we may observe in their character intelligence mixed with persevering enterprize, and patience of fatigue with a considerable independence of spirit.

There is no doubt but that the system of management adopted in the mines, which long usage has matured into a system as beneficial to the mine owners as stimulating to the exertions of the workmen, has tended much to render the latter what they now are, though their insulated situation has likewise probably preserved to them much of their original character as a people.

With such advantages, and with a sufficient quantity of the metallic ores distributed throughout it, a district only requires capitalists of sufficient wealth, intelligence, and enterprize, to render it of consequence as a mining country, and it has happened to Cornwall to have gentlemen possessed of all these requisites.

The statements which follow will shew how the discovery of a valuable metal has been followed up, and an intimate acquaintance with the Cornish mines would prove how great the exertions must have been, to have produced effects in a short time which the labour of ages in other countries have scarcely equalled.

We have before observed that copper began to be sought after in Cornwall about the beginning of the eighteenth century, and, as might be expected, we have no exact accounts of the success of the undertakings for its pursuit in their earliest stage. In a few years, however, the quantity produced had attained to a considerable amount, and we shall be enabled to trace pretty accurately the progress afterwards made.

The first document on the subject is the following:
Statement of the Returns of Copper Ores in Cornwall, from 1726 to 1775.

Years.	Tons of Ore.	Average Price per Ton.	Amount.	Annual Quantity of Fine Copper.
		£ s. d.	£	(Probably)
1726 } 10 } 1735 }	64,800	7 15 10	473,500	700 Tons.
1736 } 1745 }	75,520	7 8 6	560,106	830
1746 } 1755 }	98,790	7 8 0	731,457	1080
1756 } 1765 }	169,699	7 6 6	1,243,045	1800
1766 } 1775 }	264,273	6 14 6	1,778,337	2650

This account is taken from Pryce's "Mineralogia Cornubiensis," excepting the last column of the quantities of metal produced from the ores, which it was desirable to exhibit, in order to compare the increase of late years, of which the quantity of *fine copper* is the only true criterion, the ores often differing materially in their metallic content. The statement is, however, given as respects this part of it only as a near approach to the truth, as we have no certain data to calculate from; the assay and price of copper, by which the value paid to the miner was determined, being in a great part of the period above quoted not easily ascertained. The amount of metal is, however, calculated from the most probable supposition.

From the table we see, that in Cornwall the produce of copper increased in fifty years from about 700 tons of fine metal *per annum* to 2650 tons.

Copper mines were not attended to in England much before the dates in the preceding table, the discovery of this metal probably having taken place in working the tin mines, which had been wrought time immemorial. Soon after that discovery, in 1691, a charter was granted to Sir Joseph Herne and others, merchants of London, who were thereby incorporated as a company for the purposes of refining and purifying copper ores.

This company still exists, and is now commonly called the English Copper Company.

The Mines Royal Company, which had been incorporated near 100 years before this time, appear originally to have designed to apply their resources to the opening and working mines in various parts of the kingdom, and they had grants for searching for copper among other metals, although it does not appear that any important discovery of this metal took place in consequence of their exertions, nor is mining one of those pursuits which is ever likely to flourish in the hands of large companies.

In 1694, a copper coinage of halfpence and farthings took place, and government paid at the rate of 18*d.* a pound for the copper, which was of Swedish produce.

In 1717, a further coinage took place, to the amount of 700 tons of English copper, for which government paid at the rate of 15³/₄*d.* per pound, or 147*l.* per ton.

In 1702, the first brass work in England was erected near Bristol, which has continued to this time, but with great additions and improvements. Many other copper and brass houses have been since erected in this country, and by that spirit, energy, and enterprize, for which the people of it are so distinguished above all others, the most valuable branches of the copper and brass trade have been established in England, which had before been altogether, and for ages, carried on in Germany and Holland.

For the first twenty or thirty years of the last century, and always before, most of the copper and brass utensils for culinary and other purposes of this country were imported from Hamburgh and Holland, procured from the manufactories immemorially established at Nuremberg and various other parts of Germany; even brass pans for the purposes of the dairies of our country could not be procured but of the German make.

So late as 1745, 1746, and 1750, copper tea-kettles, saucepans, and pots of all sizes were imported here in large quantities from Hamburgh and Holland; but through the persevering industry, capitals, and enterprising spirit of our miners and manufacturers, these imports became totally unnecessary, being all made here, and far better than any other country could produce.

During all this time the price of copper will be found to have been as high as it has been in the last three or four years;

MINING.

years, 1808, 1809, 1810, and 1811, notwithstanding the great difference in the value of money, and consequent advance of price on materials used in mining, and of the wages of labour employed therein.

It appears above that government paid for copper used in their coinages in the year 1694 at the rate of 18*l.* a pound, or 168*l.* a ton for metal the produce of Sweden; and in 1717, they were supplied with English copper at the rate of 15³/₄*l.* a pound, or 147*l.* a ton.

The reduction here specified in value may fairly be accounted for by the increasing produce of the English mines, and accordingly the price went on to lower nearly in proportion to the quantity which was thus brought into the market.

In the year 1720 copper was sold for about 130*l.* a ton, and declined towards the year 1772 to the price of 100*l.* a ton.

About the year 1773, new copper mines being discovered in Derbyshire and Wales, and fresh supplies of fine copper coming from thence to market in competition with the Cornish copper, the price of it fell gradually until 1781. In this year the East India company first paid so little as 79*l.* a ton for cake copper. This great reduction was owing to a warm contest which took place between the owners of the Cornish mines and those of the Paris Mountain mine in Anglesea, which had become amazingly productive, and so as to alarm the fears of the former.

Arrangements were afterwards made between the parties principally concerned in the mines of these two districts, by which the price was somewhat advanced, but did not exceed at any time 84*l.* a ton, and continued at nearly the same rate until the year 1791.

By this time England, instead of depending upon foreign mines for a supply of copper, had become one of the principal sources from which the world at large was furnished with this useful metal.

Accordingly, in the year 1791 we find that the exports of different articles in which copper either formed the whole or the principal ingredient, amounted to a very considerable branch of trade, and that these articles went in large quantities to those very countries upon which England had formerly depended for a supply. Among these may be noticed Holland, Germany, and even Sweden itself.

The total exports were, in 1791,

	Tons.	C.	qrs.	lbs.	£	s.	d.
Wrought copper	3082	3	3	11	value 358,844	9	1
Brass and plated goods	2324	2	0	11	209,769	8	9
	5406	5	3	22	568,613	17	10

Comparing this with the produce of copper in Cornwall in the year 1775, as above quoted from Dr. Pryce, which was only 2650 tons, and allowing for what might be brought to market from Anglesea, we may, in some measure, judge of the increase in the quantity of metal from the Cornish mines in this period of sixteen years, even under the discouraging circumstance of great competition and reduced prices.

Besides this vast export, a new source of consumption for copper had in the mean time arisen at home in the use of it very extensively in sheathing and fastening ships, and this alone would require considerable quantities.

The demand having apparently kept pace with the quantity brought to market, the question will naturally be asked, how it happened that the price continued to fall, or at least to remain at a rate so much under what it brought 100 years before? Though the answer to this question must include other considerations than those connected with mere mining, it may be proper to go a little out of our way to answer it, particularly as it relates to the mines of Corn-

wall, which were at one time threatened almost with ruin, from the value of their produce not bearing any proportion to the increase in their expenses, from the diminished value of money, and the rapidly accumulating charges occurring from the great depths to which most of the productive mines were by this time worked.

The reason, then, of the price of copper not bearing a proportion to the cost of procuring it, and the demand of the article, appears to have been simply this. Neither the miners nor the great consumers of the copper were smelters of the ore; but this business was in the hands of a very few companies, employing immense capitals in their works, who thus had the power of managing the market, and of preventing that salutary competition, which alone can regulate fairly the due course of trade.

The principal smelters, by a contract which had been entered into improvidently with them by the majority of the miners, had possessed themselves of the greater part of the copper ores of the county of Cornwall at a fixed price; and this price being found inadequate to meet the increasing charges of working the mines, discontents arose, which spread among the labouring miners, who feared the loss of their employ by the ruin of the mines, which was anticipated. Many of the proprietors, or adventurers as they are usually called, who were not personally parties to the contract, refused to be bound by the act of their co-adventurers, and considerable confusion ensued.

The small proportion of the ores, not included in the contract, continued to go to public sale, where the price was advancing; but these sales were attended by a few smelting companies only who had not joined the others, until the following circumstance occurred, which materially contributed to open a free market to the miner for the sale of his ores, upon a plan that ensures a fair and equitable price, according to the demand, as far as is possible, where the number of buyers must be necessarily small.

Many of the principal manufacturers of Birmingham, who were large consumers of copper, had observed the difference between the price of the metal in the ore paid to the miner, and the price at which they bought it when smelted. They saw no other reason for the intervention of a third party between the miner and consumer, but the capital necessary for the erection of smelting works; and this being easily raised by shares, a company was formed under the name of the Birmingham Mining and Copper Company: their object being to encourage the production of copper, by adventuring in the mines, as well as to procure it for their manufacture, by purchasing and smelting the ores.

As soon as the company was established, they proposed to revive the old mode of the sale of ores, which had, owing to the contract, nearly fallen into disuse, called a *ticketing*; by which, on certain days, the ores of any number of mines, being previously sampled and assayed, are offered for sale by tenders or tickets, produced by the agents of each smelting company, and delivered to the chairman of the meeting which is held for the purpose, who declares the offer of each, and the highest the buyer.

This revival of the ticketings was effected by the Birmingham company joining the small number of smelting companies who were not concerned in the contract, and the competition was rendered complete. A new spirit was infused into the working mines, by an increase of the price of their produce. Other smelting companies were afterwards formed upon similar principles; and the demand for copper advancing rapidly, while the quantity produced in Anglesea and other parts of England lessened, the mines of Cornwall flourished in proportion.

MINING.

The advance on copper began to be felt about 1792, when it had attained the price of 100*l.* per ton; and in a very few years after (1799), it had reached 124*l.*: being still, however, much lower than it was in the beginning of the 18th century.

We may recollect that the quantity of copper raised in Cornwall, in the year 1775, was about 2650 tons a year; in 1789 it had increased to about 3000 tons; which increase was progressive, as in the year 1797, according to the report laid before the house of commons, the quantity amounted to 5093 tons; and in the following year (1798), was 5427 tons.

So that we see in the period of about 70 years from 1726, the annual quantity produced by this district had risen from 750 to 5427 tons; and that the aggregate amount of an article, valuable as a raw material, affording, after it passes from the hands of the miner, the means of subsistence and profit to thousands, had risen from the sum of 47,35*l.* to about 600,000*l.* a-year. Even this great increase of produce was far exceeded in the course of the next eight or nine years, when, as we shall see hereafter, half as much more was added to the quantity, and more than that proportion to the value.

Early in the year 1799 the Birmingham manufacturers, finding the price of copper rapidly increasing, began to be alarmed lest a diminution of their trade should be the consequence, and having apparently overlooked the plain rule of commerce, that, without unfair restraint, demand must govern price, applied to government to impose prohibitions on the export, and other regulations, which would have amounted in effect to the fixing a maximum on the price, and consequently a ruinous restraint on a valuable source of national wealth, and laudable enterprise and exertion. It may be justly wondered at, that any ministry should have listened to such a proposal; but great as were the boasted talents of the then premier, he appears to have been led to the warm support of it, by the narrow consideration which was held out to him, of supplying the navy with copper at a somewhat lower price; not looking forward to the probability that any step which might ruin the British copper mines, must eventually make the British navy dependent on other countries for this essential article of equipment.

The contest that ensued between the miners and the manufacturers produced many curious documents, which were laid before the committee of the house of commons appointed to investigate the subject, and from which we are now enabled to state particulars of the mines of Cornwall, more exactly than could have been obtained, had not such an occasion called them forth.

The matter came fully before parliament, the good sense of which defeated the impolitic wishes of the proposers of the restrictions, and left a ministry unaccustomed to defeat in a minority on the question.

That the predictions of the manufacturers were groundless may be inferred from what took place afterwards: the price of copper advanced 50 per cent. in the next seven years, and the Birmingham trade, notwithstanding, increased in activity and consequence. The high price stimulated the enterprise of the miner, until an over-supply began to operate; and in the last few years, this, together with the unfortunate state of foreign trade, has again reduced the price of copper, so as once more to endanger the existence of a great proportion of the copper mines.

From the documents before alluded to, we find that, in February 1799, there were in Cornwall then working sixty copper mines, which were divided into classes, to shew their relative conditions. The accounts are made up for the six months preceding the statement.

Class 1. Includes the old deep mines, which produced in the six months more than half of all the copper raised in Cornwall.

2. Includes the profitable mines, which produced about three-eighths of the copper.

3. The new mines which were carrying on in the hopes of their improvement, and the greater number of which, in fact, had not begun to yield any ore.

The result of the statement is as follows, in which it is to be observed that the value of the ores is accounted for, after deducting the proportion paid to the owner of the soil, and therefore does not exhibit an account of all that was raised. The first column of loss refers to the money sunk in the six months for which the account is taken; and the last column of unrecovered loss includes all the money laid out from the commencement of each mine, which had not been paid off by adequate returns.

State of the Copper Mines of Cornwall for six Months, to the end of February 1799.

MINING.

By this statement we see, that the total profit of the six months, in all the mines, exceeded the loss by the sum of 18,683*l.* 4*s.* 0*d.*, and in the loss is included a considerable amount, which it does not seem clear should have been placed there, *viz.* the sums expended on the new mines in the period, as this may more properly be called an investment of capital with a view to future expected profit.

The unrecovered loss is subject to the same remark, though it is usual to reckon in mining the expenditure as loss until the profits have repaid it. The capital, however, which means the value of stock upon the mines, ought to be deducted from this unrecovered loss; and if this be done, and a fair allowance be made for the value of such new mines as might have been supposed likely to become profitable, the

account gives no unfavourable impression of the general result at that time.

Another observation may be made on this account which seems necessary, as it does not appear on the face of it. Credit is only given for the adventurers' part of copper ores; but several of these mines returned tin as well as copper, of which no account is taken, and which must, in all probability, have increased the profits of the six months, if stated.

The next table shews the general receipts and disbursements on the copper mines of Cornwall for seven years, ending the 31st December, 1798, which cannot be deemed so favourable as the former, which related to the latter part of this same period.

General State of the Copper Mines of Cornwall for Seven Years, ending the 31st of December, 1798.

N. B.—The columns of labour and materials, added together, do not make up the total cost, because the accounts sent from some mines do not distinguish the amount of labour from materials; and, therefore, could be no otherwise arranged than by being carried at once to the column of total cost.

The average annual cost of working the copper mines of Cornwall for this period appears to have been 313,589*l.* Out of this sum the labour appears to have cost about 197,640*l.*, and the materials employed about 115,950*l.* The proportion of the one to the other being nearly as 5 to 3.

The great amount of the latter may be attributed to the great depth of many of the mines, whereby the charge for coals for the steam-engines, and the wear and tear in the shafts of cordage and other articles, is prodigiously increased.

If, taking the amount of labour at the above sum, we allow 40*l.* as the annual earnings of each man employed, which is nearly the usual proportion, we shall find it would shew that there are about 5000 men employed. But as a certain proportion belongs to the boys working under ground, and the women and children who dress the ores on the surface, who altogether are paid after a much lower rate, the whole number of hands, including men, women, and children, may

not, at this period, perhaps be over-rated at from 6 to 7000.

In order to shew the respective state of each mine at this time, we insert the following table, which exhibits the name of each, with the particulars of their expenditure and returns, as far at least as copper is concerned; for, as was remarked before, no notice is taken of the tin produced from any of them.

We take the year 1798, the last of the seven years to which the statement given above refers to.

Such is the fluctuation of concerns of this sort, that at the present time, 1812, very few of those which appear at the head of the following list as most important in consequence and produce, are now working to much extent, while others, which either then lay neglected, or in which discoveries had not been made, have succeeded to supply their places.

MINING.

State of the Copper Mines in Cornwall for the Year 1798.

About this period a part of the county of Devon began to attract notice as a mining district, although it might rather seem to belong to Cornwall, if a division had been made between the counties by a line that an observer of the geology would have chalked out, rather than by the arbitrary limit of a river. The mines of Devon may, therefore, fairly be ranked as a branch of the great mineral country adjoining, as their features are nearly alike, the products very similar, and the system of working derived from Cornwall. A space of no inconsiderable extent indeed is to be found lying between the western and most considerable mines in Cornwall, and those on its eastern limits, which intervening tract is comparatively unproductive in mineral treasures.

The tin mines of Devon have been before alluded to, and we have seen that they had gradually declined into insignificance. Copper had now been found, and pursued with some success, and though the quantity was not very great at this period, it soon led to greater exertion, which in turn was repaid by the discovery of new mines and an enlarged return of valuable produce.

It is probable that before 1800 the mines of Devon, which are mostly situate within a few miles of the town of Tavistock, did not yield more in any one year than about 100 tons of fine copper, and even this was a very recent discovery; we shall now see that they went on, together with those of Cornwall, augmenting in importance.

From 1798 to 1804, the produce of the Cornish mines appears to have continued pretty steadily at about 5500 tons of fine copper a-year; while the Devon mines in the same period increased their returns very rapidly, which had reached, about this time, to about 300 tons of fine copper a-year.

The price of the metal we mentioned to have been, in 1799, about 124*l.* a ton, and until 1804 a gradual increase was experienced, although the supply was at least somewhat larger. In the following year, however, owing to the flourishing state of the export trade, the value of copper rose very rapidly, and reached the unprecedented price of 180*l.* a ton to the miner. The consequences of this were soon felt, and, by the exertion produced by this stimulus, the returns of the Cornish and Devon mines reached to more than 7000 tons of fine copper, fetching, at the first hand, the sum of 1,260,000*l.*

From this time to the present, the value of copper has experienced violent and rapid fluctuations, being, at one time, at half the price of the year 1805; and as this has proved a cause of great embarrassment and loss to the adventurers in the mines, so it has tended to reduce again the quantity of copper raised.

The year or two following 1805 were, as might be expected, even more productive than that in which the price attained its highest pitch, for the exertions it caused operated long after the price began to decline.

MINING.

The following Table exhibits a Statement of the Quantity of Copper Ores and Fine Copper produced by the Mines of Cornwall and Devon during the last four Years, taken up to the End of June in each Year, and the Value calculated according to the Average Standard, or Miner's Price of the Metal

		Copper Ores.			Fine Copper.				Average Standard <i>per Ton.</i>			Annual Amount after deducting Charges of Smelting.

	Devon -	3540	0	0	323	13	0	0						
		73,579	0	1	6272	0	0	22						

We have now brought the history of the copper mines up to the present period, and we have found what has been done in one district in the space of about 100 years after the discovery of the metal. We may observe, that in the beginning of the 18th century the annual produce of the mines consisted of about 6500 tons of ore, and 700 tons of fine copper, yielding to the miners, who, from their ignorance of the subject, did not then receive from the smelters a price for their ores adequate to the value of the metal they contained, no more than 45,000*l.* a-year. And we have found this produce increased, at the early part of the present century, to the annual quantity of near 80,000 tons of ore, yielding more than 7000 tons of fine copper, worth to the miners an annual sum little short of 1,000,000*l.*

The copper mines now working in Cornwall and Devon may be known from the following list, which contains such only as are more or less productive, and does not include such as make no returns, but may, notwithstanding, be prosecuting with a view to future discovery, many of which kind were stated in the former account of the mines working in Cornwall in 1798.

By referring to that statement, we shall find the productive mines to be forty in number, and the unproductive to amount to thirty-six.

The following list will be found to contain sixty-one productive mines, with the quantity of ores estimated from the account of sales at the ticketings, where the computed weight of each parcel of ore is stated, and the exact quantity determined after the sale has taken place.

It is possible that some few mines may exist which do not appear in this list, and which sell their ores by private contract, but they are not important.

We subjoin to the list the Devon mines, with their quantities of ore, taking account, as in Cornwall, of such only as are productive; and the whole is made up to the end of December 1811.

VOL. XXIII.

A list of Copper Mines, with the Quantities of Ore offered for Sale at the Ticketings from each; in the Year 1811.

In the county of Cornwall there are 61 mines.

Hence it will appear, that the copper mines have of late been declining in their produce, which is to be referred to the general state of trade rendering the price of the metal unequal to the charge of producing it.

The present value of copper, as was observed in a former part of this article, is as low as it was 100 years ago, and we may account for the possibility of this happening without absolute ruin to the mines, by the facilities which the great improvements in all the various operations of mining have given for lessening manual labour and consequent expence.

This very improvement has, however, contributed to a more rapid exhaustion of the ores, and though discovery has hitherto in this district kept pace with the gradual waste, yet it is impossible not to foresee that as the country is even now very fully explored, a time must arrive when the quantity of metal produced will grow less, and the price in consequence must advance.

This period we conceive is not so distant as some may imagine, but it is a subject not easily reduced to any very probable calculation.

The history of the mining of a particular district would naturally lead to an interesting enquiry on this subject, and to the discussion on the probability of a future and continuing supply of the metals which the bowels of the earth have hitherto yielded so abundantly. As this question regards one country, it may be assumed that the supply must have its limits; as it regards the whole world, it becomes difficult even to conceive what extent or number of deposits of metal may exist.

That certain districts may become exhausted is more than probable, but others now unexplored by the hand of man may be found. New powers, as far surpassing those of the steam engine as they did all former ones, may give the means of penetrating the earth to depths now unattainable, and veins may hereafter be followed to situations which are forbidden at present by the value of their produce or the want of sufficient exertion.

The stores which the earth yields from its bowels are unlike those which its surface produces; the former are limited and are not renewed, the latter are constantly produced by the encouraging hand of industry. The one are gradually exhausting, and seem to demand frugality in their expenditure, the other grow and increase in proportion to our care and exertion.

The result of a gradual exhaustion of mines now existing seems likely to be this; at first the price of metals will increase in proportion to their scarcity, this advance in value will lead to a greater produce by new efforts even in the districts which are exhausting, and after these begin again to fail, which they will do more rapidly from the increased exhaustion, new districts will be sought after, and perhaps uncultivated countries even become peopled by the want of what is now become so necessary to human life.

The variation in these affairs may at some time make material changes in the state of civilization, a position which will not be denied by those who duly consider the effects that the stores of coal and metal have had on the prosperity of Britain.

MINING Processes, according to the practice of the mineral districts of Cornwall and Devon.

The means pursued for the discovery of veins containing metal, and the appearances which serve as indications of the probable quantity which may be found in them, are treated of in a former article. See *LODE*.

The works which follow the discovery are at first but simple and limited, but they increase afterwards in proportion as the prospects of future success become more certain; or, on the contrary, they are discontinued when the trial offers but little encouragement to proceed with the adventure.

By a reference to the article above quoted, it will be understood how the deposits of metal are usually situated in the veins; and as the miner's object in his first operations is to get at some shoot or bunch of ore as quickly as possible, and to open as much of the lode as he conveniently can, the most promising part on the surface is chosen for the commencement of a *shaft*, which is either sunk upon the vein so as to follow its dip or underlay, or otherwise is carried down perpendicularly from some spot on the side to which it dips, so as to intersect it at a given depth, and then is usually called an *underlayer*.

As water is commonly soon met with in such quantities as to impede the workmen, means for removing it must be provided, and it speedily becomes necessary to take steps for this purpose. Where the elevation of the ground will admit of an *adit* or water-level being made, this is usually first had recourse to, particularly when it may be obtained by driving a moderate

a moderate distance, or when it can be pursued on the course of the lode, and to serve the double purpose of a drain and a level for trying the appearance of the vein.

When the shaft becomes deeper than the adit, or indeed when the latter cannot well be had, machinery to draw out the water is erected and employed, such as steam-engines, or overshot water-wheels where streams to drive them can be obtained: in both cases these engines are employed to work pumps to raise the water.

As soon as a shaft is sunk sufficiently deep, and it becomes desirable to pursue the lode horizontally, it is stopped for a time, and a level is commenced on each side of it, and this is usually continued in two opposite directions upon the course of the vein. The ends of this level being driven out of the way of the shaft, sinking may again be undertaken, and continued until it is deemed proper to drive another level; and thus a succession of these galleries or drifts are opened under each other, and the vein is divided into parallel portions, which are left to be worked for the ore contained therein, and which portions are called *backs*.

New openings to the surface from these levels are afterwards made by sinking more shafts at proper distances, and communications from one level to another are formed by sinking a kind of small underground shaft, called a *winze*, probably because the only machine employed in their execution for hauling the stuff is the common windlafs, which, in Cornwall, has generally the same abbreviated or corrupt appellation.

When a mine is put into this state, and any quantity of ore discovered, proper engines provided with sufficient power to admit the constant deepening of the mine by keeping the bottom of the engine shaft, called the *sump*, dry, so as to be regularly sinking: when the ventilation is completed by proper means for that purpose, and machines constructed for hauling up the ores and waste to the surface called *whims*, a mine, in the technical language of Cornwall, is said to be in due course of working.

The agents who attend daily to the works are called *captains*; they contract with the different classes of miners, and direct the operations, under the orders either of the principal adventurers, or a manager appointed by them.

The shafts and levels are kept regularly sinking and driving to lead to further discovery, or to open more of the lode for working, and the parts of the vein or lode left between the passages thus made are worked away, where the ore will pay the expence of so doing, by men, who contract for this work within certain limits, being paid a proportion of the value when merchantable, which is called a *tribute*, and which varies with the degrees of facility with which the ore can be procured, either from the different states of richness of the lode, or the hardness or softness of the rock which must be broken to obtain it.

The ore is usually conveyed in wheelbarrows through the levels under ground by boys to the nearest shaft, and there raised in buckets or *kibbles* to the surface. These kibbles are wound up by the whims, which are turned either by horses, steam, or water.

In preparing the ores for smelting, a variety of processes is employed, which require the labour of many hands; these are carried on upon the surface, and chiefly by women and children. The object being to separate from the ore both the stony and sparry waste, and the mundic or other useless metallic mixtures with which it is combined, considerable skill is required, from the different specific gravities of the various substances, which render it impossible by mere washing to separate the ores entirely from the different mixtures which accompany it.

To dress ore properly, it is essential that the whole should first be brought into such a state of division, that the different parts may be separated by washing or sifting: and, therefore, the richer the slate in which the whole is raised from under ground, the less the labour required in breaking or stamping. The better parts of the ore are broken to a proper size for smelting, either by flat hammers, or, as is now usual in the mines in Devon, by iron cylinders driven by water. For the coarser parts much more labour is required in stamping, sifting, and washing, the particular detail of which will be found under the article *Ore*.

The stamping-mills, and other apparatus for dressing the ores, are usually fixed as near the mouths of the shafts on the surface as possible, consistently with the power of leading streams of water to them. And plots, or *floors*, are prepared near them for receiving the merchantable ores until they are sold to the smelting companies.

The management of these processes is usually confided to a *dresser* or *grafs captain*, who regulates the whole, the expence being borne by the men who raise the ore on tribute, who take their proportion of the value according to the amount of the sales, and, therefore, pay every previous charge.

The erections on the surface of a mine comprize, besides steam or water-engines, whims, stamping-mills, and sheds on the dressing floors, a suitable counting-house for the captains and clerks, where the people are paid monthly, and the bargains or contracts made by a kind of public auction. A forge, or blacksmith's shop, accommodated to the extent of the mine, where men are generally at work by night as well as by day, to sharpen tools as well as to make or repair the iron-work of the different engines. A carpenter's shop, or *timber-house*, for work of that description, which is always going on to a considerable extent.

From the account given in the *History of MINING*, and the statement of the disbursements and returns there exhibited of all the concerns of that description in Cornwall and Devon, it may be seen how extensive some of them are in that respect. It may further be here observed that great depth has been attained in many of the older ones; in Dolcoath, which we believe is rather the deepest, the lowest part is somewhat more than 220 fathoms from the surface. Some individual mines in Cornwall employ near 1000 persons, and have several steam-engines working for the different purposes of pumping the water and raising the ore. In the county of Devon, streams of water being at hand, large overshot wheels are employed for working the pumps, and several have been erected of late years equal in power to the larger steam-engines. Within a very late period, the same economical means have been applied in a very ingenious manner to the winding up the ores from under ground, which, from the crookedness of the shafts of copper mines, was a work of more difficulty than might at first appear.

We propose to give more detailed accounts of the processes of breaking, raising, and dressing the *Ores*, under the article bearing that title; and shall describe the operations of sinking shafts and driving the levels from them under the head of *SHAFT*. The pump-work of mines, and the means for ventilating drifts, will be treated of in their proper places.

MINION, in *Geography*, a small island in the straits of Mozambique, near the W. coast of Madagascar. S. lat. 12° 40'. E. long. 49° 32'.

MINION, a sort of cannon, or piece of ordnance, of which there were formerly two kinds; large and ordinary, answering to our six-pounders. See *CANNON*.

MINION is also the name of a type used by printers.

MINISH, or MYNISH, in *Geography*, one of the many islands on the west coast of the county of Galway, Ireland. It belongs to the barony of Ballinahinch.

MINISINK, a town or rather village of America, in New Jersey, in the N.W. corner of the state, and on the W. side of Delaware river; 57 miles N.W. of Brunswick. —Also, a township of Orange county, New York; containing 3594 inhabitants.

MINISTER, one that serves or conducts the public worship of God.

In the reformed church, priests, or those ordained to preach and do the other functions of the priesthood, are called absolutely and simply ministers.

In which sense, bishops, &c. are said to be ministers of God, ministers of the Word, of the Gospel, &c. In some churches they are also called *pastors*.

MINISTERS of the *Altar* are properly those who attend and assist the priest at the administration of the eucharist. See DEACON and SUBDEACON.

Officers of state, &c. are called the king's ministers; as administering the affairs of justice, policy, &c. for him.

MINISTER of *State*, is he with whom a prince entrusts the administration of his government; or to whom he commits the care and direction of the principal affairs thereof.

Boethius is proposed as a model for ministers of state.

The grand vizier is the prime minister of the Ottoman empire.

MINISTERS, *Foreign*, or the ministers of foreign princes, are their ambassadors, envoys, agents, or residents in the courts of other princes.

There are two kinds of foreign ministers. Ministers of the first rank, who are also called *ambassadors*, and *envoys extraordinary*.

And ministers of the second rank, who are the ordinary residents.

Those of the first rank have a representative character, which the others have not; though these last are sometimes invested with fuller powers than the former.

MINISTER is also the title which certain religious orders give to their superior.

In this sense we say, the minister of the Mathurins, or Trinitarians.

MINISTER, among the *Jesuits*, is the second superior for each house; thus called, as being an assistant to the superior, or rector.

The general of the Cordeliers order is also called the *minister-general*. See JESUITS.

MINISTRY, or MINISTRY, a profession, office, or employment, which a person discharges for the service of God, the public, or some particular person.

In which sense we say, a bishop must account to God for his ministry, &c.

MINISTRY is also used for the government of a state, by some great minister, under the sovereign authority.

In which sense we say, the ministry of the cardinal de Richelieu, &c.

MINISTRY is also frequently used as a collective word, signifying the ministers or officers of state.

Thus we say, the ministry opposed a thing; meaning the ministers opposed it.

MINITOBA, in *Geography*, a lake of Canada, 100 miles long, and from 10 to 15 wide. N. lat 50° 40'. W. long. 100 20'.

MINIUM, in the *Natural History of the Ancients*, a name given to what we now call cinnabar, or native mineral of a shining red colour, out of which quicksilver was extracted. See MERCURY.

As the prepared cinnabar is much preferable to the native as a pigment, it has long been a considerable article of chemical manufacture; and the Dutch having had the reputation of making the best, we shall subjoin their method of proceeding, given by M. Tuckert (*Ann. de Chem. iv. p. 25.*) cited in Aikin's Dictionary. This manufacture consists of two distinct operations, the one being the preparation of the æthiops, the other the conversion of the æthiops into cinnabar. To make the æthiops, a boiler of iron polished on the inside, and about 2½ feet in diameter, and 1 in depth, is charged with 1080lbs. of mercury, and 150lbs. of sulphur (or *per cent.* 87.8 mercury, and 12.2 sulphur); a moderate heat is then applied gradually increasing, and accompanied by suitable stirring of the ingredients till the whole appears to be thoroughly mixed and combined. The black sulphuret of mercury thus formed, is then removed from the boiler and pulverized. In order to convert this into cinnabar, three large earthen subliming pots are placed in a furnace, and gradually brought to a red heat by means of turf: at this time the cover of each (which consists of a simple square plate of iron) is removed, and the contents of an earthen vessel, holding about a pint and a half of æthiops, are poured into each pot. In a few seconds a column of flame rises out of the pots, to the height of five or six feet, and, as soon as it begins to lessen, the further escape of the contents is prevented by putting on the iron cover. In a short time after a second charge is poured in, to which succeeds a third, and so on, till at the end of thirty-four hours the whole of the æthiops has been equally divided between the three pots, making 410lbs. for each. The fire is now kept up as steadily as possible for thirty-six hours longer, in order to accomplish the sublimation, care being taken to stir up the materials at the bottom of the vessels at least once every half hour, by an iron rod made for the purpose and introduced at the top. At the same time the workman ascertains how the process is going on by the flame which appears when the cover is removed; if it rises to the height of two or three feet, the heat is too great, as on the other hand it is too feeble if the flame only lightly quivers about the mouth of the pot; the proper temperature is marked by the flame rising vigorously, yet not exceeding three or four inches in height. When the last thirty-six hours are expired, the furnace is extinguished, and the whole allowed to cool: the subliming pots are then taken out, the iron hoops with which they are bound are knocked off, and the pots themselves are broken; the cinnabar is found sublimed in the upper part of the vessel to the amount of 400lbs. being 10lbs. less than the æthiops that was put in: or, in other words, the loss of weight sustained by the conversion of æthiops into cinnabar, amounts to 2½ *per cent.*

Minium, or red lead, is a calx of lead of a vivid yellowish-red colour, which colour it acquires by a slow calcination and reverberation.

The method in which minium is made in large quantities with us, is concisely described in our article LEAD.

The process by which minium is prepared is described in the following manner by M. Jars. The furnace is of the reverberatory kind, with two fire-places at the ends; each fire-place being separated from the area, or body of the furnace, by a wall twelve inches high. The fire-places are fifteen inches broad, and their length is equal to the breadth of the whole furnace, which is about eight or nine feet. The length of the area from one place to the other is nine or ten feet. The quantity of lead used in one operation is about 1500 pounds, of which nine parts are lead obtained from furnaces where the ore is smelted, and one part is lead extracted from the scoria which is formed in smelting the ore.

This

This latter kind is said to be necessary, as the former could not alone be reduced into powder. All the lead is at once put into the area, the bottom of which is level. The calx, as fast as it is formed, is drawn to one side by means of a rake suspended by a chain before the mouth of the furnace. In four or five hours the whole quantity of the lead is calcined; or, if any pieces remain uncalcined, they are separated and kept for the next operation. The heat employed is that of a cherry-red, and the fire-places and mouth are kept open, that the air may accelerate the calcination. The powder or calx is to be frequently stirred to prevent its concreting, and when this operation has been continued about twenty-four hours, the matter is taken out of the furnace, and laid on a flat pavement. Then cold water is thrown on it, to give it weight, as the workmen say; but rather (as M. Jars thinks) to make it friable. It is then to be ground in a mill, and the finer part is separated by washing, while the coarser part, reserved for some following operation, is to be placed at the mouth of the furnace in order to retain the melted lead. The fine powder, which is now of a yellow colour, is again put into the same or a similar furnace, and exposed to a very moderate fire, from thirty-six to forty-eight hours: during which time it is stirred frequently to prevent its concreting; and the powder gradually acquires its proper red colour. The minium is then to be taken out of the furnace, cooled, and sifted through an iron sieve placed in a cask. Mem. de l'Academie Royale à Paris, 1770. In Holywell, Flintshire, minium is made from litharge, which saves the previous calcination.

A portion of the lead during the operation is lost by volatilization; part of it being dissipated in the air and part settling in the chimnies, and on the roofs of the furnace, in form of a yellowish-white foot, with crystallized lumps intermixed: this is collected from time to time, and either reduced into lead, or mixed with the lead in the subsequent calcination. The quantity of sublimate thus collected cannot be accurately ascertained. Dr. (bishop) Watson, in his "Essays," estimates it at about $\frac{1}{100}$ th of the minium produced. From the circumstances above recited it is not possible to determine the full increase of weight which lead should acquire by its conversion into minium. On an average the actual increase is about $\frac{1}{10}$ th; 20 cwt. of lead producing 22 cwt. of minium.

MINIUM, in the *Materia Medica*, and the *Arts*, &c. For medical purposes it is used externally; it obtunds the acrimony of the humours, allays inflammations, and is excellent in the cleansing and healing of old ulcers: it is used on these occasions in many of the plasters and ointments of the shops; it is an ingredient in the officinal composition, called *emplastrum de minio*, used as a desiccative and cicatrizer; though more rarely than that made in the same manner with litharge, because it does not stick so well, and is more difficult of preparation. See EMPLASTRUM, LEAD, in *Medicine*, and UNGUENT.

It was with minium the ancient Roman and Grecian ladies tinged their nails and faces of a red colour. For, as to our modern paints, without doubt, they were not known in those days.

The bright orange colour of minium might render it valuable in painting, if it could stand with certainty in either oil or water. But as it is subject to become black, it cannot be safely trusted, except in hard varnishes: and is, therefore, seldom used in oil, or even in water, unless for very gross purposes, or as a ground for vermilion. The goodness of the minium may be distinguished by the brightness of its colour: and the adulteration to which it is liable may be detected, by putting an ounce of it into a crucible, with an

equal quantity of charcoal-dust, well mixed together, and placing the crucible in a common fire sufficient to melt lead, which is to be covered with another small crucible inverted into it. When it has been continued for some time on the fire, take it out and strike it against the ground, the minium will thus be reduced to its metallic state; and its diminished weight, when freed from the charcoal-dust and cold, will indicate the proportion of adulterated matter. Minium is also used as a flux in forming the enamel for grounds, and in glazing, &c.

MINNIGAFF, in *Geography*, a town of Scotland, in the county of Kircudbright; 15 miles S.W. of New Gal-loway.

MINNIN, a stringed instrument of music among the ancient Hebrews, having three or four chords to it. Though there is reason to question the antiquity of this instrument; both because it requires a hair-bow, which was a kind of plectrum not known to the ancients, and because it so much resembles the modern viol. Kircher took the figure of this, the *machul chinnor*, and *psaltery*, from an old book in the Vatican library. Hawkin's Hist. Music, vol. i. p. 255.

MINO, in *Geography*, one of the smaller Philippine islands, near the E. coast of the island of Bool. N. lat. $10^{\circ} 6'$. E. long. $124^{\circ} 30'$.

MINOMEIT, a town of Prussia, in Oberland; 13 miles W.N.W. of Heilsberg.

MINONG, or ISLE ROYAL, an island of Canada, in lake Superior, 30 miles long and 10 broad. N. lat. 48° . W. long. 89° .

MINOR, a Latin term, literally denoting *less*, used in opposition to *major*, greater.

Thus we say, St. James Minor, Asia Minor, the minor excommunication, &c.

MINOR *Ædilis*. See *ÆDILE*.

MINOR *Anticus Serratus*. See *SERRATUS*.

MINOR *Barons*. See *BARON*.

MINOR, *Canis*. See *CANIS*.

MINOR *Gastricus*. See *GASTRIC*.

MINOR *Oculi Obliquus*. See *OBLIQUUS*.

MINOR *Orders*. See *ORDERS*.

MINOR, *Rectus*. See *RECTUS*.

MINOR, *Teres*. See *TERES*.

MINOR, *Urfa*. See *URSA*.

MINOR, in *Law*, denotes a person under age, or who, by the laws of the country, is not yet arrived at the power of administering his own affairs, or the possession of his estate.

Among us, a person is a minor till the age of twenty-one; before which time his acts are invalid. See *AGE* and *INFANT*.

It is a maxim in the common law, that in the king there is no minority, and therefore he hath no legal guardian: and his royal assents and grants to acts of parliament are good, though he has not in his natural capacity attained the legal age of twenty-one.

The minority of the kings of Sweden, Denmark, and the provinces of the empire, terminates at eighteen years; and that of the kings of France at fourteen, by an ordinance of Charles V. in 1374.

It is also provided by the custom and law of parliament, that no one shall sit and vote in either house, unless he be twenty-one years of age. This is likewise expressly declared by stat. 7 & 8 Will. III. cap. 25. with regard to the house of commons.

MINOR, in *Logic*, is the second proposition of a formal or regular syllogism, called also the assumption.

MINOR, in *Music*, is applied to certain concords, which differ

differ from, or are lower than, others of the same denomination by a lesser semitone, or four commas.

Thus we say, a third minor, or lesser third: or a fifth major and minor.

Concords that admit of major and minor, *i. e.* greater and less, are said to be imperfect concords.

MINORS, or *Friars Minors*, an appellation which the Franciscans assume, out of show of humility; calling themselves *fratres minores*, *i. e.* lesser brothers; and sometimes Minorites.

There is also an order of regular Minors at Naples, which was established in the year 1588, and confirmed by Sixtus V.

MINORBINO, in *Geography*, a town of Naples, in the province of Bari, the see of a bishop; 85 miles S. of Naples. N. lat. $41^{\circ} 5'$. E. long. $15^{\circ} 59'$.

MINORCA, *INSULA MINOR*, the lesser, when compared with Majorca, and the second of the Balearic isles, an island of the Mediterranean, is long and narrow, forming part of a circle from the S.E. end to the N.W., the hollow part being towards the S. It is thought to be 13 leagues in length at the longest part, and near 38 leagues in circumference: it lies about ten leagues to the N.E. of Majorca, and 50 E. from the mouth of the Ebro. Minorca has successively fallen under the dominion of the Carthaginians, the Romans, the Vandals, the Moors, the Aragonese, and the Castilians; and for a century, from 1708, it has been in the possession of the house of Austria, the English, French, and Spaniards, by turns. This island is situated in the middle of a number of small rocks, banks, and islands; on the south the shore is level. The air is moist, and the soil dry. The administration is divided into districts, or terminos, the chief towns of which are Ciudadella, Mahon, Alayor, Ferarias, and Mercadal. The principal ports are Mahon, on the E.; Fornella, on the N.; and Ciudadella, on the W. The isle is level, and there is only one mountain distinguished by its elevation, *viz.* Monte Toro. Ciudadella, or Samna, the capital, is situated at a small distance from the coast, towards the N.W., 11 leagues from Mahon; it was in the fifth century the see of a bishop, and the residence of the governor of the island, and also the seat of civil and ecclesiastical jurisdiction. In the time of the Carthaginians and Romans it was a considerable place; but its splendour has declined; and port Mahon disputed with it the superiority, when the English established their tribunals and seat of government in the island. (See *PORT MAHON*.) The port is small and marshy, formed by a canal, bounded by rocks. On the right and left are towers, corresponding to each other, to repeat the signals, and two cannons of a large calibre, upon swivels, sufficient to stop a privateer. The entrance is difficult of access. The city is surrounded in part with ancient walls, erected by the Moors; the rest is modern, formed of bastions and curtains of hewn stone. The streets are of ancient form, being narrow and shady, paved with large unhewn stones; and in the city are a cathedral, flanked by a beautiful square tower, and supposed to be built in the third century, two churches, three convents, and an hospital. The termino, of which Ciudadella is the capital, bearing its name, is above $5\frac{1}{2}$ leagues long, and $2\frac{3}{4}$ wide; and its total population amounts to about 800 persons. Alayor is situated about $4\frac{1}{2}$ leagues from Mahon, being the chief town of the termino of that name, containing about 112 hamlets or manors, and rather more than 4000 people. The streets are uneven, narrow, crooked, and ill paved: but the houses are well built. At the entrance into the town is a church, built of free stone, in a simple Gothic style of architecture without, and within decorated with sculptures and

paintings. The monastery of Cordeliers has a handsome church. Here are also an hospital, and a barrack capable of accommodating 250 men. The town is well provided with cisterns, and the water is fresh and salubrious. About one league from Alayor is *Mercadal*; which see. The most remarkable ports of this island, besides those of Mahon and Ciudadella, are Fornella and Adaya. Port Fornella is about six miles from mount Toro, of a circular form, with a narrow entrance, and facing the north. The bay is capable of containing the largest fleet, perfectly sheltered, and defended at the entrance by a small square fort, with bastions and fosses. The establishment is capable of containing 300 men. The entrance to the port of Adaya is concealed by eminences towards the north; it is only used for fishing. The strength of the island depends upon circumstances. When the English retook it, in 1798, the Spaniards had in it 6000 troops, and the English, exclusive of their naval force, disembarked only 3000 soldiers. When the Spaniards, four years after, were reinstated, they left a garrison with 3000 infantry, 1500 light infantry, 500 engineers and miners, and 90 heavy cavalry.

Of the islands, or islets, surrounding Minorca, the most considerable are to the S., about $\frac{2}{3}$ of a mile from Cabo Bufara. The island of Coloms is elevated, and forms with the cape a narrow canal. Near it are two small islets. The large and small islands of Adaya are near the port of the same name. To the S.E. is situated the large island of Aguida. The isle of Sanitge is near the port of the same name on the W. coast; at some distance is an islet, and beyond that the island of Bleda. Beyond the rocks of Alayor, are a small island named Galera, and an islet called Codrell. The isle of Layre de Mahon is within reach of the ancient fort of St. Philip, and there are several small islands near Mahon.

Monte Toro is at a little distance from Mercadal, and by its elevation commands the whole island: at its base it is some miles in circumference, and its form is that of the frustum of a cone. Mount St. Agatha is situated N.W. of Mercadal, and rises above several mountains that surround it. Upon the summit is a chapel, held in great veneration. The whole of this canton is inhabited by shepherds, whose flocks subsist upon a part of the mountains, and the valley beneath is abundantly fertile.

Minorca is not sheltered from the north winds, which check vegetation; nevertheless snow is seldom seen here in winter, and in the spring the air is always temperate and pure; the heat of summer is great, and the drought is productive of inconvenience. In the autumn there is much rain. The soil of the plains is less fertile than that of the coast; and the earth upon the mountains, though thinly spread over the rocks, is rich and fertile. In the vallies and plain, the soil is argillaceous and thin, but it is fertilized with that which is washed down from the mountains. Upon the whole, this island is, in many parts of it, rich in vegetation. The principal grains cultivated in the island are wheat, barley, and a small quantity of maize. Red and white wines are exported; olive trees are numerous, and here is abundance of every kind of fruit, such as oranges, pomegranates, lemons, figs, &c; and the island furnishes great variety of garden and culinary vegetables. The water-melons are very fine; and the honey of the island, some of which is exported, is reckoned very good. The horses, mules, and asses, are estimated at about 2000; the horned cattle at 7000; the sheep, goats, and small animals, at about 45,000; the pigs at nearly 10,000. Poultry is scarce, but birds of different species are very numerous. The fish all round the island is abundant at all seasons, and very good. The inhabitants have

have no manufacture or fabric for furnishing articles of exchange in commerce. Their export trade consists of a small quantity of cheese sent into Italy, and a small surplus of wool, which produce about 2500 *l.* sterling; salt, wine, honey, and wax produce from about 17,083 *l.* to 17,921 *l.* The island receives from abroad corn, brandy, rice, sugar, coffee, tobacco, spices, linen, fine cloths, boards, pitch, cordage, &c. and some pieces of furniture. The natural history of this island presents to us a natural and very interesting grotto, called La Cava Perella, two miles to the S. of Ciudadella; and also a subterranean lake; a quantity of coral is found near the sea-shore, and a small variety of shells. In many parts of the island are mines of iron and lead, and quarries of stone and marble. The inhabitants are a quiet, peaceable people, attached to their own customs, and little disposed to change. They regard with reverence the ceremonies of religion. The same language is spoken in Minorca and Majorca. In this island, and particularly in the territory of Añazor, they have some altars of ancient date. It has also furnished Phœnician, Macedonian, Carthaginian, Celtiberian, Grecian, Roman and Spanish medals, in gold, silver, and large and small bronze. In this island, also, a small Gothic bronze coin has been discovered, the impression on which is a crowned head in the centre of a circle, with these words, "Alphonfus Rex;" supposed to belong to the end of the 13th century. The island also has presented to the antiquarian ancient sepulchres, vases, lamps, urns, lacrymatories, composed of a reddish earth, and marked with illegible inscriptions. N. lat. 39° 59'. E. long. 3° 45'.

MINOREA, *Cape*, a cape on the E. coast of Majorca. N. lat. 39° 50'. E. long. 3° 12'.

MINORE, Ital., the same as *minor*, Engl.

MINORESSES. See *St. CLARE*.

MINORI, in *Geography*, a town of Naples, in Principato Citra, the see of a bishop, suffragan of Amalfi, near the sea; three miles N.E. of Amalfi. N. lat. 40° 37'. E. long. 14° 26'.

MINOS, a small island near the coast of South Carolina. N. lat. 33° 48'. W. long. 78° 38'.

MINOS, *Is.*, a town on the N. coast of Masbate, one of the Philippine islands. N. lat. 12° 33'. E. long. 123° 10'.

MINOS, in *Mythology*, one of the three judges of hell, of rank superior to the other two, *viz.* Æacus, who, according to Plato, judged the Europeans; and Rhadamanthus, who, having left Crete, and fixed his residence in Asia, had the Asiatics and Africans for his lot; and Minos, as chief president of the infernal court, decided the differences that arose between the two other judges. All the poets are agreed in assigning to him the superiority over his colleagues. Homer represents him as sitting with a sceptre in his hand, in the midst of the ghosts of departed mortals, who plead their respective causes in his presence. Virg. *Æn.* vi. v. 432, places an urn by him, containing the several lots of mankind; while the stern Rhadamanthus sees to the execution of the sentences which his brother pronounces. The particular district of Aides, over which he was supposed to preside, was Erebus; and it was his office to determine the character and final condition of the spirits cited to his tribunal. Minos, it is said, was the first king of Crete, and considered as the wisest legislator of antiquity; on which account he obtained the honour of being judge in the invisible world. This Minos, whose institutes are said to have served as a model for those of Lycurgus, flourished, according to Selden, and others, who refer for authority to the Arundelian marbles, 1462 years, but, according to the abbé Banier, only 1340 years before Christ.

Minos, with a view of giving greater authority to his laws, retired into a cave at Crete, where he feigned that Jupiter, his father, dictated them to him, and every time he returned from the cave he announced some new law. Hence, Homer (*Olyss.* 19.) gives him the title of Jupiter's disciple, Διὸς μύθηος ἀκούων, which is thus expressed by Horace (*Olyss.* 10.), "Et Jovis arvens Minos admissus." Josephus is the only ancient writer, who says that Minos had received his laws from Apollo, and that he had travelled to Delphi to receive them from that god. (Lib. ii. against Appian.) This Jewish writer owns, that Minos was the only one among the ancients who deserved to be compared to Moses. If we give credit to Hæstius, Minos was the same with Moses, and he alleges that they lived about the same time. But the opinion of the learned prelate is contradicted by the decisive testimony of all antiquity; nor is the parallel which he has ingeniously drawn between these eminent lawgivers sufficient to convince impartial and candid inquirers. Banier allows, that some confused knowledge of the laws of Moses furnished Minos with a model for those of Crete.

Minos, after having governed his subjects with a mild and gentle sway, died in Crete, and being interred there, had this epitaph inscribed upon his tomb, ΜΙΝΟΣ ΤΟΥ ΔΙΟΥ ΤΑΦΟΣ; Minos F. Jovis Sepulchrum; when in process of time the name of Minos was defaced, and there remained only the two last words of the epitaph, the Cretans gave out that this was the tomb of Jupiter. This inscription, it is said, was defaced by the malice of the Cretans, who boasted of possessing the tomb of the father of the gods, whom they pretended to have brought up in his infancy. Accordingly, Callimachus, in a hymn addressed to Jupiter, sharply reproaches them on this account; for he says thus to the following purpose: "The Cretans are always liars, since they vaunt that they have thy tomb, O great king, who livest for ever!" To this passage the apostle alludes, when he upbraids the same people in the words of Callimachus, with the vice of lying.

MINOTAUR, MINOTAURUS, in *Antiquity*, a fabulous monster, much talked of by the poets; feigned to be half man and half bull.

The minotaur was brought forth by Pasiphae, wife of Minos II., king of Crete. It was shut up in the labyrinth of that island; and at last was killed by Theseus.

The fable of the minotaur was invented by the Greeks to make Minos odious. The occasion was this. Minos, having laid siege to Athens, reduced the inhabitants to great distress; when, consulting an oracle, they were directed to supplicate peace of Minos, the king of Crete. This he granted to them on condition that every ninth year, according to Plutarch and Ovid, or every seventh year, according to Diodorus Siculus and Apollodorus, the Athenians should send to him seven youths, and as many virgins. This article being agreed to, Minos raised the siege and withdrew to Crete, carrying with him those who were chosen by lot to be the first victims to the preservation of their country. Hence the fable originates. The Greeks said, that the king of Crete condemned the Athenian youths, who were sent to him, to fight in the labyrinth which Dædalus had built, with the minotaur, that was the offspring of the infamous passion of Pasiphae, his queen, for a white bull which Neptune had produced from the sea; that Dædalus, who was obliged to leave Athens, and remove to Crete, had favoured that monstrous passion of the queen; that from the conjunction sprung the minotaur. It was, without doubt, the hatred of the Greeks against Minos that made them invent this fable; for Plato says, that

that the favourable character which Homer and Hesiod had given of this great prince was of no avail against the malice of his enemies; and Plutarch adds, that it is dangerous to provoke a knowing people, who have it always in their power to take revenge. Servius gives us the following explanation of this fable. He says, that a secretary of king Minos, named Taurus, *bull*, had an intrigue with the queen Pasiphae, in the chamber of Dædalus; and that she was at length delivered of twins, one of which resembled Minos, and the other Taurus. This occasioned the production to be reputed monstrous.

In order to account for that part of the fable, that ascribes the destruction of the minotaur to Theseus, we observe, that this young hero, having obtained his father's permission, prepared with the other youths, who had cast lots, to set out for Crete. After the performance of certain rites, Theseus set sail, and with a favourable wind speedily arrived at Crete. His fine address attracted the notice of Ariadne, Minos's daughter (see the article *ARIADNE*), who gave him a clue, which he happily made use of to find his way out of the labyrinth, after vanquishing the minotaur: that is, Ariadne taught her lover to vanquish Taurus, furnishing him with arms; and by the clue we may understand the draught and plan of the labyrinth which the princess gave him, and of which he made use to find his way thence after the encounter. Some indeed have said, that Theseus encountered Taurus, not in the labyrinth, but in a public place; and that this young hero, animated by the presence of the fair Ariadne, defeated Taurus, an event which gave great joy to all, even to Minos himself, who thus got rid of a formidable rival. Our author says, that the son of Pasiphae and Taurus making great desolation in the mountains to which Minos had confined him, this prince sent all the Athenian slaves to combat with him; and Theseus having gone thither in his turn, put him to death with the sword which his mistress Ariadne had given him.

MINOVERY, formed of the French *main-œuvre*, *q. d.* *handy-work*, a trespass committed in the forest, by something that is a man's handy-work; as an engine to catch deer, &c.

MINOW, or **MINIM**, in *Ichthyology*, a name given by the English to the small fish, called by authors the *poxinus*. See *CYPRINUS Poxinus*.

MINROW, in *Geography*, a town of Hindoostan, in the Doob; 50 miles W. of Paltiar.

MINSFELDEN, or **MUNZFULDEN**, a town of Germany, with a citadel; 25 miles E. of Coblenz.

MINSK, a town of Russian Lithuania, and capital of a palatinate of the same name, situated on the Swilocz; 250 miles N.E. of Warsaw. N. lat. 53° 43'. E. long. 27° 40'.

MINSTER, a town of Lower Bavaria; seven miles N.E. of Brannau.

MINSTER, *Saxon*, *Mynster*, or *Mynstre*, anciently signified the church of a monastery or convent.

MINSTREL, an ancient term for a fiddler, or player on any other kind of musical instrument.

Borel derives the word from *manus* and *histrion*, one who diverts with the hand; or from *minor histrion*, *little buffoon*: Du-Cange from *ministrillus*, a diminutive of *minister*, because the minstrels were anciently ranked among the lower officers, ministers, or servants.

According to Dr. Percy, in his *Essay on the Ancient English Minstrels*, the word is derived from the French *menestrier*; and was not in use here before the Norman conquest: and it is remarkable, that our old monkish his-

torians do not use the words *cytharæodæus*, *cantator*, or the like, to express a minstrel in Latin; but either *minus*, *histrion*, *joculator*, or some other word that implies gesture. Hence it should seem that the minstrels set off their singing by mimicry or action; or, according to Dr. Brown's hypothesis, united the powers of melody, poem, and dance. These minstrels were probably the genuine successors of the ancient bards, who joined the arts of poetry and music, and sung verses to the harp of their own composing. After the conversion of the Saxons to Christianity, the poets and minstrels became two separate professions: and the latter continued to be a distinct order of men, and got their livelihood by singing verses to the harp at the houses of the great: where they were hospitably and respectfully received, retaining many of the honours shewn to their predecessors, the Bards and Scalds. And though some of them only recited the compositions of others, many of them still composed songs themselves, and all of them could probably invent a few stanzas on occasion.

Mr. Ritson, in his Introduction to "Ancient English Metrical Romances," blends the English minstrels with the jugglers, whose tricks of legerdemain formed another branch of the amusement of our ancestors. Although it be allowed, that the same person might occasionally practise both arts, yet we see no reason for doubting, that they were separate and distinct professions; nor can we admit the supposition of Mr. Ritson, that the minstrels, whose profession was music and the recitation of poetry, were not frequently themselves poets. Their daily bread depended upon their stock of tales and songs; and it must have been as natural for them to have composed the romances which they sung, as for a modern musician to compose the pieces which he performs. Above all, we cannot see why the arts of composition, which are admitted to have been exercised by the minstrels of France, should be supposed unattainable by those of England. Subsequent to the reign of Edward III., most of the popular French romances were translated into English, which then became the language, as well of the nobles as of the vulgar. Why the minstrels, who were most interested in these translations, should be deemed unequal to the task of accomplishing them, we can see no good reason for believing. As a wandering and idle race of men, attendant on the barons who went to war in France, they had time to acquire both languages; and the art of rhyming must have been easy to persons who almost every day of their lives were employed in poetical recitation. Minstrels and bards are often employed as synonymous terms, although the poetic powers of the bards are indisputable. As late as the reign of queen Elizabeth, this combination occurs in the poem of a Scottish satirist describing London.

"Bot yet the menstrallis and the bairdis,
Thair trowand to obtain rewardis,
About his ludgene loudlie played."

Legend of the bishop of St. Androis.

A proof how far the task of the poet and of the reciter were required from the minstrel, occurs in a very ancient poem, of which there is one MS. in the British Museum, and another in the library of Peterborough cathedral. It contains the history of an intrigue betwixt Thomas of Erceldoune, called the Rhymer, and the queen of fairies, by whom, as every one knows, he was transported to the "Lond of Faerie," and gifted with those supernatural powers of poetry and prophecy, by which he was afterwards distinguished. The following dialogue passes be-

twixt the hard and his faery leman upon this memorable occasion.

“ Fare wel Thomas, I wend my way,
I may no longer stande with the —
Gif me sum tokyn, lady gaye,
That I may say I spake with the. —

To harp and carpe, Thomas, wher so ever ze gon,
Thomas, take the these with the. —

Harping, he said, ken I non,
For tong is cheife of mynstralcie. —

If thu wil spelle, or talyz telle,
Thomas thu shal never make lye ;
Wher so ever thu goo, to sayth or felle,
I pray thu speke never non ille of me.”

From this decisive declaration, which a poet and minstrel made on the nature of his own profession, it appears plainly, that, in more ancient times, the minstrel's principal and most honourable occupation referred to poetry, rather than music; and the Rhymer might have been justly described as one “who united the arts of poetry and music, and sung verses to the harp, of his own composing,” if he had not disdained the musical skill to which it was Mr. Ritson's persuasion that the talents of the minstrel were exclusively limited. See Edinb. Rev. No. XIV. p. 304, &c.

Mr. Ellis, in the Introduction to his “Specimens of early English Metrical Romances,” has given us a plain and comprehensive view of the rise and progress of the minstrels and their poetry. Of his account we shall avail ourselves in the compilation of this article.

Normandy appears to have been the cradle of minstrelsy. The Northmen who wrested that province from the feeble successors of Charlemagne, had, doubtless, like all other barbarous people, especially the Scandinavian tribes, their national poets, under the name of scalds, or by whatever other term they were distinguished. On their settling in Neustria, their native speech speedily melted down into the more commodious and extended language used by the inhabitants of Northern France, which was called *romance*, being, in fact, a corrupted Latin, introduced by the Romans into their Gallic province. In this language, the minstrels composed most of their works, until, from that circumstance, the word *romance*, from signifying the early Norman-French, came at length to mean those chivalrous tales usually composed in that tongue.

“It appears likely,” says Mr. Ellis, “that they were carried by Rollo into France, where they probably introduced a certain number of their native traditions; those, for instance, relating to Ogier le Dancis, and other northern heroes, who were afterwards enlisted into the tales of chivalry; but that, being deprived of the mythology of their original religion, and cramped, perhaps, as well by the sober spirit of Christianity, as by the imperfection of a language whose tameness was utterly inapplicable to the sublime obscurity of their native poetry, they were obliged to adopt various modes of amusing, and to unite the talents of the mimic and the juggler, as a compensation for the defects of the musician and poet. Their musical skill, however, if we may judge from the number of their instruments, of which very formidable catalogues are to be found in every description of a royal festival, may not have been contemptible; and their poetry, even though confined to short compositions, was not likely to be void of interest to their hearers, while employed on the topics of flattery or satire. Their rewards were certainly, in some cases, enormous, and prove the esteem in which they were held; though this may be partly ascribed

to the general thirst after amusement, and the difficulty experienced by the great in dissipating the tediousness of life; so that the gift of three parishes of Gloucestershire, assigned by William the Conqueror for the support of his *joeculator*, may, perhaps, be a less accurate measure of the minstrel's accomplishments, than of the monarch's power and of the insipidity of his court.

“To the talents already enumerated, the minstrels added, soon after the birth of French literature, the important occupation of the *décor*, or *déclaimer*. Perhaps, the declamation of metrical compositions might have required, during their first state of imperfection, some kind of chast, and even the assistance of some musical instruments, to supply the deficiencies of the measure; perhaps, the aids of gesture and pantomime may have been necessary to relieve the monotony of a long recitation: but at all events it is evident, that an author who wrote for the public at large, during the eleventh, twelfth, and thirteenth centuries, was not less dependent for his success on the minstrels, than a modern writer of tragedy or comedy on the players of the present day. A copyist might multiply manuscripts for the supply of convent-libraries; but while ecclesiastics alone were able to read, there was no access to the ears of a military nobility, without the intervention of a body of men who travelled in every direction, and were every where welcomed as the promoters of mirth and conviviality.

“The next step was easy. Being compelled to a frequent exercise of their talent in extemporaneous composition, the minstrels were probably, like the *improvvisatori* of Italy, at least equal, if not superior, to more learned writers, in the merely mechanical parts of poetry; they were also better judges of the public taste. By the progress of translation they became the depositaries of nearly all the knowledge of the age, which was committed to their memory: it was natural, therefore, that they should form a variety of new combinations from the numerous materials in their possession; and it will be shewn hereafter, that many of our most popular romances were most probably brought by their efforts to the state in which we now see them. This was the most splendid era of their history, and seems to have comprehended the latter part of the twelfth, and perhaps the whole of the thirteenth century. After that time, from the general progress of instruction, the number of readers began to increase; and the metrical romances were insensibly supplanted by romances in prose, whose monotony neither required nor could derive much assistance from the art of declamation. The visits of the minstrels had been only periodical, and generally confined to the great festivals of the year; but the resources, such as they were, of the ponderous prose legend were always accessible. Thus began the decline of a body of men, whose complete degradation seems to have been the subsequent result of their own vices. During the period of their success they had most impudently abused the credulity of the public; but it is a whimsical fact, that the same fables which were discredited while in verse, were again, on their transfusion into prose, received without suspicion. It should seem that falsehood is generally safe from detection, when concealed under a sufficient cloak of dulness.”

This history solves a difficulty which Mr. Ritson, already cited, found in reconciling the degraded state of the minstrels to the high rewards and countenance which they sometimes received, even in preference to those of the clerical profession. It appears, on one occasion, that two mendicant friars soliciting hospitality at the gate of a convent, were received with acclamation under the idea of their being minstrels, and kicked out again when they announced their

real character. It is also proved, we believe, that one minstrel received four shillings for his performance, and six priests only sixpence, at the same festival. But such instances of extravagant reward to individuals of a class which dedicates personal exertions to public amusement, are consistent with the general disrespect to which this body in general is condemned.

There are two remarkable facts in history, which prove that the profession of a minstrel was held in great reverence among the Saxon tribes, as well as among their Danish brethren. In the year 878, when king Alfred wished to learn the true situation of the Danish army, which had invaded his realm, he assumed the dress and character of a minstrel, *singens se joeuatorem, assumpta ciithara*, &c. and under this character, though he could not but be known to be a Saxon, obtained an honourable reception. About sixty years after, a Danish king made use of the same disguise to explore the camp of our king Athelstan. The minstrel was, therefore, a privileged character with both these people: and so late as the reign of Edward II. the minstrels were easily admitted into the royal presence; an instance of which is mentioned by Stow (Survey of Lond. 1703, p. 469.) In the fourth year of Richard II. John of Gaunt erected at Tutbury, in Staffordshire, a court of minstrels, with full power to receive suit and service from the men of this profession within five neighbouring counties, to enact laws and determine their controversies, &c. for which they had a charter. See Plott's Hist. Staff. p. 435, &c.

The minstrels continued down to the reign of Elizabeth; in whose time, however, they had lost much of their dignity, and were sinking into contempt and neglect; yet still they sustained a character far superior to any thing we can conceive at present of old ballads. Towards the end of the sixteenth century this class of men lost all credit, and were sunk so low in the public opinion, that in the thirty-ninth year of Elizabeth, a statute was passed by which minstrels, wandering abroad, were included among rogues, vagabonds, and sturdy beggars, and were adjudged to be punished as such. This act seems to have put an end to the profession, for after this time they are no longer mentioned. Judge Blackstone observes, that in some manors, the copyholders were bound to perform many servile offices for the lord, who found them meat and drink, and sometimes (as is still the use in the Highlands of Scotland) a minstrel or piper for their diversion. Comm. b. ii.

The first compositions of the minstrels, according to Mr. Ellis (ubi supra), seem to have been unadorned annals or histories, reduced to measure for the convenience of the reciter, who was to retain them upon his memory. This field, however, soon became too barren and uninteresting. Other sources of narration were sought for. Some occurred in the ancient songs of the scalds, the legitimate productions of the minstrels. Others of Arabian origin found their way to France through Spain. But a much more numerous class was derived from the tales of the Armoricans, the neighbours of the Normans, who derived themselves from a Welsh colony. From this source, the minstrels probably drew their first accounts of

“ ————— What refounds
In fable or romance, of Uther's son,
Begirt with British and Armoric knights.”

This theme, however, acquired its chief popularity after the acquisition of England by William the Conqueror. It is now completely proved, that the earliest and best French romances were composed for the meridian of the English court, where that language continued to be exclusively used,

at least till the time of Edward III. When the Norman race of monarchs had once secured themselves on the throne of England, and identified the honour of that country with their own, they began to feel an interest in its early history, and to listen with applause to the feats of its heroes. The legends of the Welsh, on these occasions, were much more acceptable than those of the Saxons. The latter were the people whom the Normans had conquered, and whose kings they had dispossessed: the praise, therefore, of their departed heroes revived sentiments of discord, better forgotten by all parties. But the exploits of the British were carried back to so ancient a period, and so intermingled with Celtic fable, that they recalled no sentiments of ancient independence, and suggested no ideas dangerous to the Norman race. The exploits of Arthur were therefore unanimously adopted as the subject of tales and romances without end; and these were drawn by the Norman minstrels from the British traditions flowing from Wales, and floating in what had lately been the British kingdom of Cumberland; but especially from the works of Geoffrey of Monmouth.

Mr. Ellis shews, that the state of Wales, during the eleventh, twelfth, and thirteenth centuries, was favourable to an exchange of literary materials betwixt the bards of that country and the Norman minstrels, as well as between the former and their brethren of Armorica.

But as there is reason to believe that the British lays were seldom if ever committed to writing, it might be expected that different minstrels would tell the same story with some variations; that, unable to retain in their memory the whole of a long narrative, they would carry off, in the first instance, detached adventures, which they would afterwards connect as well as they were able; and that a system of traditional history, thus imperfectly preserved through the medium of a very loose translation, and already involved in much geographical and chronological confusion, would assume the fabulous appearance which we find in the French narratives called romances. See ROMANCE.

MINT, the place in which the king's money is coined. Anciently there were mints in almost every county in England; but as it is one of the prerogatives of the king to coin the money of the realm, the business of coining was carried on principally in the Tower of London, from the time of William the Conqueror to the year 1811. At this latter period a very elegant building was completed on the eastern side of Tower-hill, in which the coinage is now performed with a simplicity, dispatch, and accuracy that can scarcely be conceived by any who have not been witnesses of the several operations.

Coining metallic money was originally performed by the hammer, and afterwards by what was called the screw-press, or mill and screw. These operations have been amply described under the word COINAGE, to which we beg to refer our readers. In this place we shall endeavour, in very few words, to conduct them through the several offices of the New Mint, and describe, as well as we can, the business and processes carried on in each.

Almost all the money, now coined in this kingdom, is from bullion received from the Bank of England; from which it is sent to the “master of the mint's assay-office:” here it is received into what is called the strong-hold, and there kept till its fineness is ascertained, in order that its true value may be computed.

This being ascertained, the parties concerned are desired to attend at the office of receipt and delivery to witness its weight, and to be informed of its fineness, and, consequently, of its value; the standard weight of the bullion being determined by the calculation of the respective offices.

A mint-

A mint-bill is now made out and given to the owner of the bullion, by which he knows the exact value of his deposit. The next thing is to deliver the bullion to the melting-house, which is furnished with a variety of apparatus, adapted, not only to the melting of the gold and silver, but the lifting in and out the pots containing the precious metals, with safety, ease, and expedition. The silver is melted in pots of cast-iron, but the gold is melted in smaller pots manufactured from black-lead, which, according to the modern chemistry, is a carburet of iron. The silver is run into plates ten inches long, seven wide, and about five-eighths of an inch thick: the gold-plates are ten inches in length, four in breadth, and three-eighths of an inch in thickness. While the metal is pouring into the moulds, there are three portions taken, from the top, the middle, and bottom of each pot, and carried to the king's assay-office, there to be examined by the maffer of that office, and not permitted to pass into work until the fineness of the metal is accurately determined. The furnaces used are air-furnaces, and the fuel is coke.

In the process of melting there will necessarily be waste: every thing, therefore, that can possibly contain any portion of the precious metals, such as the sweepings of the melting-house, &c. are collected and carried to another apartment, in which are erected two grinding and two triturating mills, where the sweep is worked up, and the fine metals in part recovered, in the manner practised by refiners and gold-smiths.

The sweep, thus brought together, is ground into a powder, and passed through a fine sieve, by which the larger grains of metal are obtained. The sweep is then put, in small portions, into a wooden bowl, having two iron handles, by which it is carefully washed: the lighter particles, being absorbed by the water, are collected in a large tub; the heavy or metallic ones are found deposited at the bottom of the bowl. By these means the most considerable of the particles of gold and silver are obtained. The powdered sweepings, however, which have been collected after the washing process, still contain portions of metal; to obtain these, the sweep, in certain portions, is put into a mill, containing generally about one hundred weight of mercury, the remainder of the mill being filled with water: this is commonly called the triturating mill, and each charge is agitated about four hours with an iron instrument, having four arms placed horizontally, in the shape of a cross, and fixed to the centre of the mill; and for the better agitation of the sweep and mercury, the motion of this mill can be reversed at pleasure.

From the melting-house, the plates above described, provided they are found by the assay-maffer to be of the exact degree of fineness, are carried to the *ROLLING-Mill*, (which see.) They are first hot-rolled, that is, made red-hot, in a furnace adapted to the purpose, and then passed through a pair of cast-iron rollers. In the room in which this operation is performed there are four pair of rollers, which (as they require an immense power) are put in motion by a steam-engine, of a power equal to that of thirty horses. The rollers are placed very near the furnaces, and the metal, being brought to what is called a blood-red heat, is taken out by a man with a pair of smith's tongs, and immediately returned by another man, and again passed through while hot two or three times, by which it is greatly extended: after this, it is annealed. See *NEALING*.

This process is called the breaking-down rolling, and when finished the plates of silver are about $\frac{3}{16}$ ths of an inch thick. They are then cut into slips by a pair of circular shears attached to the shafts, by which the rollers are worked,

after which they are finished in what are called the adjusting-rollers, which are also made of cast-iron, and very finely polished. In this process the slips are rolled cold, and when a piece cut from the middle of each is found of the proper standard weight, they are carried to another apartment, called the cutting-out room, containing twelve machines worked by a steam-engine of the power of sixteen horses. With these machines the blank pieces are cut out from the slips or lamine just mentioned with great ease and velocity. The only manual labour required, is that performed by a boy nine or ten years old at each machine; he quickly learns the art of presenting the lamine to the cutters, which instantly cut out the blank pieces of metal; these so struck fall through a hole that conducts to a box placed below to receive them. Each machine will cut 60 pieces in a minute, of course the twelve will produce 720 in a minute, or 43,200 in an hour. Formerly these machines were worked by hand by a man or boy at each cutter, but no manual labour can operate so accurately and well as the power obtained by the steam-engine. The instruments with which the blanks are cut (called a bed and punch), are made of steel, of the exact diameter of the piece of money required.

From this apartment the blanks are carried to the adjusting-room, where every piece is most accurately weighed, the gold twice, at least, and the silver once: those pieces that are found too heavy are reduced by the file, called a float, and those that are found too light, which occasionally occurs, are re-melted.

The blanks, now properly adjusted, are carried to the milling-room. Into this, the writer of the present article was not allowed to enter; the process of milling being a secret by the very constitution of the mint. This has always been the case since the time of Peter Blondeau, who introduced the milling in 1662, as appears from an extract from Mr. Folkes, in his "Tables of English Silver Coins," in which he observes, and the observation holds good even now, though at the distance of sixty-five years; that "it may be noted that this practice of keeping secret the manner of edging the money, is still observed in our mint, all those who are entrusted with it being sworn not to discover it: notwithstanding, the manner in which the same operation is performed in several foreign mints, is there publicly shewn."

The blanks, when milled, are annealed, or softened, in order that they may be fitted to receive the impression.

The next operations are pickling and cleaning. The process of pickling is to throw the pieces of gold, thus annealed, into a strong solution of super-sulphat of alumine, those of silver into a solution of the super-sulphat of potash.

When the pieces are properly blanched, they are taken into another room to be dried and cleaned, which operation is performed by agitation in sieves, containing saw-dust, over a gentle heat.

They are now taken to what is properly called the coining-room. In this apartment there are eight coining-presses worked by a ten horse-power steam-engine; the apartment also is, in the winter months, heated with steam, so as to be kept to an uniform temperature. The machines are worked with the most perfect accuracy, and with such rapidity, that each will produce about 60 in a minute; and on the average, allowing for the necessary delays in working forty pieces of money, that is 320 guineas, &c. will pass through the eight machines in a minute, or about 19,200 in an hour. These machines require also one boy of ten or twelve years of age to each, who, by supplying the machine with the planchets, runs no risk of injury to his fingers, as the machine contains in itself a self-feeder or layer-on; the busi-

ness of the boy being only to fill the layer-on, through a tube with the blanks. From this tube, the machine places the blanks upon the dye, and when struck, displaces one piece and replaces another, and so on as long as the steam-engine is kept at work. The coin thus completed is carried to the mint-office, where the king's assayer attends, and where the process called *Pixing*, (which see,) takes place, to ascertain the weight and fineness of the monies before delivery.

The two faces of the coin are struck at once, the upper and under dye being both engraved for the purpose. The dyes are the workmanship of some capital engraver; he, of course, makes the pattern upon soft steel: from this, many others are taken at an office in the mint, and hardened, as is described under the article *CASE-HARDENING*. The engraver is called upon to verify the accuracy of the dyes made use of, with the pattern or mould which he has finished.

In the time of Charles II., when the English coins were brought to great perfection, John Roetier, a native of Antwerp, and Thomas Simon, were engravers to the mint. They were both called upon to make models or pattern pieces of money, to be exhibited at court; his majesty is said to have given the preference to those by Roetier, which were ordered to be followed in the punches or dyes to be made for the new money. "Which preference," says Mr. Folkes, "so far exasperated Simon, who did not value his performances less than they deserved, nor knew how to submit to a foreign rival; that he thereupon immediately quitted the mint, or, for some apprehended misbehaviour upon the occasion, was soon after removed from the office of one of the chief engravers."

It was in the year 1663, that he produced that inimitable crown, with the petition round the edge, that is now valued by the curious as a master-piece in this sort of workmanship. It resembles what were the common milled five shilling pieces, but the king's head is larger; the face and the garment are covered with a sort of frosted work. The letters are expressed by outlines frosted in the middle, and under the head is the name of Simon: upon the reverse there is a centre, instead of the usual star, the figure of St. George on horseback, encircled with the garter. The date is 1663, and upon the edge is the artist's petition, *viz.* "Thomas Simon most humbly prays your majesty, to compare this his trial-piece with the Dutch, and if more truly drawn and embossed, more gracefully ordered, and more accurately engraven, to relieve him." It is said, there were not more than twenty of these pieces struck off with the petition, and a small number without. We have seen one of the twenty in possession of the Rev. Dr. Disney, from the collection of the late Mr. J. Hollis; it is in the highest state of preservation: and in the memoirs of Mr. Hollis is a fine engraving of the medal, a little magnified. It is not ascertained what relief Simon obtained upon this petition, but it is pretty clear he was never afterwards employed in the mint.

MINT, Officers of the, are, 1. The warden, who is the chief, and is to receive the bullion, and oversee all the other officers. This officer has under him a deputy and two clerks. 2. The master-worker, with three clerks; he receives the bullion from the warden, causes it to be melted, and delivered to the moniers; and takes it from them again when coined. 3. Comptroller, with a deputy and clerk, who is to see that the money be made to the just assize, and to oversee the officers. 4. The assay-master, who weighs the silver and gold, and sees whether it be

standard. (See *REMEDY*.) This officer, called the king's assay-master, has under him a clerk. 5. The master's assay-master, and the probationer assayer. 6. The surveyor of the melting, who is to see the silver cast out, and that it be not altered after it is delivered to the melter, *i. e.* after the assay-master has made a trial of it. 7. The clerk of the irons, who is to see that the irons be clean, and fit to work with. These two offices are united in one person, who has a deputy and clerk. 8. The chief engraver, who engraves the dyes and stamps for the coinage of money: there is also an assistant engraver, and a probationer engraver, with a smith, assistant to the engravers. 9. The melters, who melt the bullion before it comes to coining. 10. The blanchers, who anneal, or boil and cleanse the money. 11. The porter and office-keeper, who keep the gate, &c. of the mint. 12. The provost to the company of moniers, acting as engineer, who provides for all the moniers, and oversees them. And, lastly, the company of moniers; some of whom shear the money, some forge it, some stamp or coin it, and some round and mill it. In this office, there are also the weigher and teller; receiver; king's clerk, and clerk of the paper; surveyor of the money-presses; solicitor and assistant; warden's deputy, master's deputy, comptroller's deputy, and subordinate clerks. See *COINAGE*, and the preceding article.

MINT, Roman, has been justly regarded as one of the most essential ornaments and sinews of the state. It derived great importance from the extent of the empire through which its produce was to circulate. The "*Quæstor*" seems at first to have had the direction of the mint, as well as of the treasury. About the time of the first coinage of silver in Rome, or 266 years B. C., the "*Triumviri Monetales*" seem to have been created; though Pomponius ascribes their first creation to the year of Rome 463, or 289 B. C. These were at first of the senatorial rank, until Augustus appointed them from the equestrian, which alteration seems to have continued. The title "*Triumviri*," however, remained till after Caracalla, as appears from inscriptions given us by Gruter, and by Bouteroc. Under Aurelian, it is probable there was but one master of the Roman mint, called the "*Rationalis*;" a change suspected by Pinkerton to have taken place under Gallienus. Aurelian, having conquered the revolted provinces, and united the whole empire again, seems to have altered the form of the mints in the capital provincial cities, and to have ordered them all to strike money with Latin legends, and of the same forms; for with him first appear coins on this plan with mint-marks of cities and offices. He seems also to have permitted the provincial cities to strike gold and silver as at Rome: and we know from his coins that the "*Aureus*," which had diminished by degrees to about 80 grains, was by him restored to 100. On this occasion, the moniers, who lost half their profits, and three-fourths of whom lost their work, caused commotions, which terminated in a rebellion, the suppression of which was attended, on the part of Aurelian, with the loss of 7000 of his best troops. About this time, the "*Procurator Monetæ*" seems to have succeeded the "*Rationalis*." In the Roman colonies, the direction of the mint appears to have been committed to the "*Duumviri*," or two annual magistrates, elected in imitation of the consuls at Rome. The engraving of the dye was a work of labour and of genius; and at Rome Greek artists were usually employed in it. The engravers of the dye were called "*Cælatores*:" other officers employed in the mint were the assayers of the metal, "*Speçtatores*," "*Expectatores*," or "*Nummularii*." The refiners were denominated "*Cenarii*;"

narii;" the melters "Fufarii," "Flaturarii," "Flaturarii." The "Equatores Monetarum" adjusted the weight. The "Suppolltores" put the pieces in the dye, and the "Mallectores" struck it. A "Primitivus" was at the head of each office; and there was a foreman, called "Optio et Exactor." Pukerton's *Ess. on Med.* vol. i.

MINT was also a pretended place of privilege in Southwark, near the king's bench, put down by statute. If any persons, within the limits of the mint, shall obstruct any officer in the serving of any writ or process, &c. or assault any person therein, so as to receive any bodily hurt, the offender shall be guilty of felony, and be transported to the plantations, &c. Stat. 9 Geo. I.

MINT, in *Botany*, &c. See MENTHA.

MINT, *Corymbiferous*, a name given by some to a species of tansy.

MINT, *Cat's*, the English name of a genus of plants, called by botanical writers *catarris*. See CATMINT.

MINTERS, or MONEERS. See MONEVERS and MINT.

MINTING is sometimes used for the coining of money.

MINTON, in *Geography*, an island in the Indian sea, near the W. coast of the island of Sumatra, a little S. of the line. E. long. 97° 8'.

MINTURNÆ, in *Ancient Geography*, a town of Italy, in Latium, upon the Appian way, near Formie on the W., and Sueffa Arunca on the E. situated on the Liris, at some distance from its mouth. Livy speaks of it as a very ancient city. The Romans gained possession of it by treason, in the year of Rome 439, and planted a colony in it. But the event which rendered it particularly memorable, was the imprisonment of Marius in this town, and his escape, in consequence of striking terror into the mind of the soldier who was sent to assassinate him. See MARIUS.

MINUARTIA, in *Botany*, so called by Læfing in commemoration of a Spanish botanist of the name of Minuart, an apothecary at Madrid, with whom Læfing was acquainted while in Spain, and from whom he received many botanical observations; as appears by various passages in his letters published by Linnæus.—Læf. It. 48. Linn. Gen. 42. Schreb. 58. Willd. Sp. Pl. v. 1. 492. Mart. Mill. Dict. v. 3. Ant. Hort. Kew. ed. 2. v. 1. 184. Juss. 300. Lamarck Illust. t. 52.—Class and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllæ*, Linn. and Juss.

Gen. Ch. *Cal.* Perianth inferior, erect, long, compressed, of five, awl-shaped, rather stiff, permanent leaves. *Cor.* none. Nectary composed of a few depressed glands within the calyx. *Stam.* Filaments three, capillary, short, inserted into the receptacle; anthers roundish. *Pist.* Germen superior, triangular; styles three, short, thread-shaped; stigmas thickish. *Peric.* Capsule oblong, triangular, a little shorter than the calyx, of one cell and three valves. *Seeds* not numerous, roundish, compressed.

Obs. *Minuartia montana* is said occasionally to be found with traces of five minute petals, which are possibly what Læfing described as nectariferous glands.

Ess. Ch. Calyx of five leaves. Corolla none. Capsule with one cell and three valves. Seeds few.

1. *M. dichotoma*. Linn. Sp. Pl. 132. Læf. It. t. 1. f. 3.—Leaves bristle-shaped. Stem simple, erect. Flowers sessile, crowded together in a forked manner.—Very plentiful on the hills about Madrid.—This little annual scarcely exceeds an inch in height. The stem is simple, erect, rarely branched, dichotomous at the upper part. Leaves opposite, awl or bristle-shaped, erect, so close as to cover the whole stem. Flowers sessile, cymose, forming a little square head, closely forked. Bractæas long, awl-shaped, rigid, twice or

thrice as long as the flower. Seeds from five to eight, kidney-shaped. The whole plant assumes a brownish-herbaceous colour.

2. *M. montana*. Linn. Sp. Pl. 132. Læf. It. t. 1. f. 4.—Flowers crowded, lateral, alternate, shorter than the bractæa.—Found in wet sandy situations on the sides of hills about Madrid.—Root annual, fibrous, very small. Stem simple, scarcely an inch in height, jointed, smooth. Leaves opposite erect, bristle-shaped, broader at the base, striated, acute, rigid. Flowers sessile, about three together, rarely solitary. Seeds from three to seven, small.

3. *M. campestris*. Linn. Sp. Pl. 132. Læf. It. 122.—Flowers crowded, terminal, alternate, shorter than the bractæa.—Found in situations similar to the two last species.—Root annual, very slender and simple, somewhat twisted. Stem quite simple, and very short, covered with leaves, round. Leaves opposite, flat, awl-shaped, striated, rigid, close to the stem, numerous. Flowers terminal, forming a compact little head, partially forked, but not universally so, and in this respect the plant chiefly differs from *M. dichotoma*. Seeds five or six, compressed, kidney-shaped.—The whole plant has a sealy or husky aspect.

MINUCCIO D'AREZZO, in *Biography*, according to Boccaccio, an exquisite singer and player on the viol, in great favour with Peter of Roan, king of Sicily.

MINUET, or MENUET, in *Music*, a composition answering to a kind of dance of the same name, said to be invented at Poitou; the motion of which is triple, with three crotchets in a bar $\frac{3}{4}$, though it is commonly performed in the time $\frac{4}{4}$. It has commonly two strains, each played twice over; the first has four or eight bars, the last note of which should be either the dominant or mediant of the mode, never the final; and the second has eight bars, it usually ends on the final of the mode, with a pointed minim or whole bar.

The word is said to be derived from the French *menu*, little, and signifying a small pace.

It seems as if the air and dance of that name, in such high favour and use during the last century in all the courts of Europe, as well as that of France, whence it was adopted, was either unknown to Broffard, or its character must have been very much changed since his time. In his *Dict. de Mus.* he defines *minuetto*, or *menuet*, *Danse fort gaye*, a very lively dance. But so far from lively and gay was this dance, that its characteristics were grace and gravity. It has been even said to be the only grave dance since the disuse of the *louvre*, fit for persons of high rank and dignity to dance alone at courts or great balls. But as the country-dance, at the latter end of the last century, was supplanted by the cotillon, the cotillon by the waltz, the instrumental minuet by the jig, the dance itself of the slow minuet is wholly abolished. For a further account, see MENUET.

MINUETTO *per Ballo*, Ital. a dancing minuet.

MINURI, in *Geography*, a town of Naples, in Principato Citra; 9 miles S.W. of Salerno.

MINUS, in *Algebra*. See CHARACTERS, in *Arithmetic*.

MINUS Quo, in *Law*. See QUO MIMUS.

MINUSCULÆ, in *Printing*, denote the small and running letters; as contradistinguished from *majuscule*, or capitals.

MINUTE, from the Latin *minutus*, small, in *Geography* and *Astronomy*, is the sixtieth part of a degree.

In which sense minute is also called *prime*, or *prime-minute*.

The divisions of degrees are fractions, whose denominators increase in a sexagesimal ratio; that is, a minute or prime is $\frac{1}{60}$ th; a second, or second minute, $\frac{1}{3600}$ th, &c.

In astronomical tables, &c. minutes are expressed by acute accents, thus, ' ; the seconds by two, " ; the thirds by three, "".

MINUTE, in *Computation of Time*, is used for the sixtieth part of an hour.

MINUTE, in *Architecture*, usually denotes the sixtieth, sometimes only the thirtieth, part or division, of a module.

MINUTE is also used to signify a short memoir, or sketch of any thing hastily taken in writing.

In this sense we say, the minutes of the proceedings of the house of lords, &c.

MINUTES of *Emerson*. See EMERSON.

MINUTES, *Meridional*. See MERIDIONAL.

MINUTE *Tithes*, *Minores Decime*, small tithes of wool, lambs, pigs, butter, cheese, &c. See TITHE.

MINUTIUS, FELIX, MARCUS, in *Biography*, an able apologist for Christianity in the third century, probably a native of Africa, who flourished towards the close of the reign of the emperor Septimius Severus, or about the year 210. He was educated to the profession of the law, and became an eminent pleader at Rome; where he renounced the heathen religion, and embraced that of Christ. He was author of an excellent defence of Christianity, entitled "Octavius," written in the form of a dialogue, between a heathen and a Christian, in which Minutius himself sits as judge and moderator. By this contrivance, he replies to the objections and arguments brought forward by the adversary, and refutes the calumnies cast upon Christians by the heathen philosophers, and at the same time exposes the absurdities of their creed and worship, powerfully demonstrating the reasonableness and excellence of the Christian religion. This work was, for a considerable time, attributed to Arnobius; but in the year 1560, Francis Baldwin, a learned lawyer, published it at Heidelberg, and made the discovery, in a preliminary dissertation, that Minutius was its true author. It has, since that time, gone through many editions, of which the best is that printed at Cambridge in 1712, with the dissertation of Baldwin prefixed, and "Commodiani Instructiones adversus Gentium Deos," added in the way of appendix. Gen. Biog. Lardner.

MINUZIANO, ALESSANDRO, a learned printer in the 15th century, was born at St. Severo, in Puglia. After studying under George Merula at Milan, he succeeded him as professor of rhetoric, and held that chair, with the professorship of history, several years. He interested himself very much in the editing of the learned works that issued from his press, and at length established a printing-press of his own. The first specimen that he gave was a fine edition of all Cicero's works, in four vols. folio. After this, he published editions of various authors, ancient and modern, to many of which he prefixed learned prefaces, written in an elegant style. He was a diligent collator of old manuscripts, and took vast pains to establish the most authenticated readings. He was not free from the unfair practice, at that period but too common among printers, of pirating each other's works: and when Leo X. caused the "Annales" of Tacitus to be printed for the first time at Rome, he found means, by bribing some of the workmen employed upon it, to obtain the sheets as they were worked, and brought out a rival edition. On account of this he incurred the pope's displeasure, and involved himself in troubles from which he was scarcely able to extricate himself.

MINX, in *Zoology*, is the name of an animal in North America, very much resembling the otter. See MUSTELA *Vison*.

MINYA, in *Ancient Geography*, a town of Greece, in Thessaly, called also "Almonia."—Also, a town of Asia,

in Phrygia.—Also, a town of the island Amorgos, situated in the most western part of the island.

MINYÆ, MINYANS, an ancient people of Greece, who were dispersed through different countries. The most ancient people of this name were settled in Bœotia, and the inhabitants of Orchomené are said to have derived it from Minyas, one of their kings. Some of these Minyans conducted a colony to Iolcos, and hence the Argonauts have been sometimes denominated Minyans. Others of them joined themselves to a colony which the sons of Codrus conducted to Ionia; and they established themselves, under the direction of Athamas, at Theos, a town situated to the south of the isthmus which connects the peninsula with the continent, W. of Smyrna. Others of them, tracing their derivation from the Argonauts, settled in the isle of Lemnos, whence they were driven by the Pelasgians. These fugitives failed to Laconia, and having encamped on mount Taygetus, the Lacedæmonians gave them land, and they intermarried with the Lacedæmonians. Of these Minyans, some in process of time aspired to the government, and rebelled against the powers that enforced the existing laws; and they were arrested, thrown into prison, and threatened with death. But their wives, having obtained permission to visit them in prison at the time when they were to be executed, changed clothes with them, and thus afforded them the means of rescue. They then retired to mount Taygetus, where they must have perished, if Theras, of the race of Cadmus, had not obtained their pardon.

MIOGA, in *Botany*, the Japanese name of a plant of the natural order of *Scitamineæ*, called by Kämpfer *Djooka*, vulgarly *Mjoga*, *Miougua*, or *Megga*, *Amœn*. Exot. 826. (*Anomum* Mioga; Thunb. Jap. 14. Kämpf. Ic. t. 1. Willd. Sp. Pl. v. 1. 7. *Zingiber* Mioga; Roscoe Tr. of Linn. Soc. v. 8. 348.)—Kämpfer describes it as "one of the eatable kinds of Ginger, of a mild taste, with a reedy stem and leaves, resembling those of wild Ginger (*Zingiber Zerumbet* of Roscoe). Its flowering bulb grows from the root near the stem, at the surface of the ground. The flowers are produced in succession, each proceeding from between scales, hooded, two inches long, of a pale colour, resembling the flowers of Ginger, with a faint smell of *Petasites*, or *Butter-bur*."

This curious plant was sent to Kew garden in 1796, by the right hon. sir Joseph Banks, but has not yet flowered. By Kämpfer's plate the flower-stalk appears remarkably short for a *Zingiber*, and more resembling a true *Anomum*, but there is no essential difference. The coincidences between the characters of the flowers, and the qualities of the roots, in these several species, confirm the solidity of Mr. Roscoe's arrangement, which is one of the happiest efforts that have been made in scientific botany. See SCITAMINEÆ.

MIOKECK, in *Geography*, a town of Sweden, in West Gothland; 36 miles S.E. of Gotheborg.

MIOLENS, a town of France, in the department of Mont Blanc, at the conflux of the Arche and Isere; 10 miles E. of Chambéry.—Also, a town and fortress of France, in the department of the Lower Alps; 9 miles W. of Barcelonetta.

MIOLLON, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 4'. E. long. 18° 20'.

MIONI KIALLE, a town of Persia, in the province of Mazanderan; 42 miles S. of Fehrabat.

MIOSS, a lake of Norway, in the government of Aggerhuus, about 50 miles long from N. to S., and from 2 to 16 broad, containing one island, 8 miles in circuit: the southern extremity is 30 miles N.E. of Christiania.

MIOUPOILON, a small island in the Indian sea, near the coast of Africa.

MIPARTY, *Chamber of*. See **CHAMBER**.

MIPROVEITZ, in *Geography*, a town of Bulgaria, the see of a Greek archbishop; 52 miles N.W. of Sophia.

MIQUELIPS, a kind of foot soldiers, inhabiting the Peruvian mountains: armed with pistols under their belts, a carbine, and a dagger. The miquelips are dangerous people for travellers to meet.

MIQUELON, in *Geography*, a small island in the Atlantic ocean, eight miles S.W. of Cape May, in Newfoundland. It is not more than three fourths of a league in length, and its soil is indifferent. It was ceded to the French by the peace of Paris in 1763. The English destroyed the settlement in 1778, and kept the island till the year 1783, when it was restored by the peace; and in 1793 it was retaken by the English, and restored at the peace of Amiens. N. lat. 46° 30'. W. long. 50° 5'.

MIR, a town of Lachuania, in the palatinate of Novogrodek; 24 miles S.E. of Novogrodek.

Miu N'fir, a town of Persia, in the province of Adirbeizan; 30 miles W.N.W. of U-mia.

MIRA, a town of Italy; 10 miles E.N.E. of Padua; eight miles W. of Venice.—Also, a town of Moldavia; 44 miles S.W. of Burlat.—Also, a town of South America, in the province of Chocos; 50 miles N. of Zitara.—Also, a town of Portugal, in the province of Beira; 16 miles N.W. of Coimbra.—Also, a river of Para, which runs into the Pacific ocean, N. lat. 1° 40'.

MIRABAT, or **MIRBAT**, a town of Arabia, in the province of Oman; 200 miles S.W. of Mascat.

MIRABAUD, **JOHN BAPTIST**, in *Biography*, a man of letters, was descended from a family of Provence, and born at Paris in 1675. He was intended, in early life, for the military profession, and was present at several battles. After this he became a member of the congregation of the Oratory, to which society he continued warmly attached through the remainder of his life. Having spent many years in literary pursuits he engaged in the service of the house of Orleans, and was entrusted with the education of two young princesses of that family. As an author he was first known by his translation of Tasso's "Jerusalem Delivered." This work gave him an entrance into the French academy in the year 1726, though not without some murmurs from original writers, who did not scruple to say that the patronage of the house of Orleans had more contributed to procure him this distinction, than his merit as an author. He next translated the "Orlando Furioso," which was also favourably received by the public. In 1742 he was elected perpetual secretary of the French academy, on the acceptance of which post, he insisted upon renouncing the right to a double fee of attendance, which his predecessors had enjoyed. In return for this disinterestedness, the academy procured for him an apartment in the Louvre, and a pension was attached to the secretaryship. Having occupied the place for several years, he resigned it to Duclos, who, however, insisted upon Mirabaud's retaining the pension and apartment in the Louvre, where he died, with perfect tranquillity, in 1760, at the age of 86. He was of a mild and equal temper, and a true philosopher in his conduct and sentiments. He had composed various works on interesting topics of literature, history, and philosophy; to the "Système de la Nature," published in 1770, his name is prefixed, but it is now generally believed that he was not the author.

MIRABEAU, **VICTOR RIQUETTI**, marquis of, a French political writer, and one of the leaders of the sect of Economists, was born of an ancient family of Provence. His

first literary work, entitled "L'Ami des Hommes," published in 1755, in three volumes, contains many useful ideas on rural and political economy, and displays liberal and judicious views of the great interests of society. It obtained to much public approbation and celebrity, that the name of the work became an epithet of the author, who is distinguished as "Mirabeau l'ami des hommes." He afterwards wrote in favour of provincial administrations, and published "Théorie de l'impôt:" all his writings are said to breathe a spirit of improvement and reform, which, together with his strictures on the financiers, was so little agreeable to the court, that he was for a short time imprisoned in the Bastille. He is variously represented, according to the different notions and feelings of the persons who have spoken of him and his works. He died in 1790, at the commencement of the revolution, after he had shewn an attachment to the court, while his son was a most distinguished leader among the popular party. All his writings were published collectively in eight volumes 12mo., with the exception of one, entitled "Hommes à célébrer," in two volumes 8vo., which he sent in manuscript to his friend, father Boscovich, by whom it was printed at Bassano.

MIRABEAU, **HONORE-GABRIEL RIQUETTI**, count of, son of the preceding, was born in 1749. The impetuosity of his temper led him to disdain the ordinary pursuits of youth, though it has been thought that a contempt for these pursuits was the principal cause of his want of application, for when Locke on the "Human Understanding," was put into his hands, he sat down to the perusal of it with the closest attention, and after making some progress in it, exclaimed "This is the book I wanted." While he was still a stripling he exhibited an ungovernable and daring spirit, with a propensity to almost every irregularity. Between him and his father there was the most irreconcilable difference, so that the marquis, who has been charged by La Harpe with tyranny in his family, obtained a lettre de cachet against his son, then only seventeen years old, and had him closely confined in the isle of Rhè for two years. On his liberation he procured a commission in the regiment of dragoons, with which he served a year in Corsica. On his return to France he precipitated himself into every extravagance, and became involved in great difficulties. He married a young lady of family and great fortune, but his father contributed, on the occasion, nothing more than his consent to this union, and his dissipations soon brought him into new difficulties. His conduct towards his wife was brutal, and his irregularities became so excessive and notorious that he was several times imprisoned, and once, on account of his seducing a lady, the wife of the marquis de Monnier, he was committed to the castle of Vincennes, where he was confined nearly four years. These imprisonments, by checking his career of dissipation, tended to improve and strengthen his mind, as he found in them no employment so interesting as laying in stores of information and reflection, and acquiring the habit of composition. At Vincennes he became an author, and published an abridgment of French grammar, and some licentious productions. These were followed by his celebrated "Essai sur les Lettres de Cachet, et les Prisons d'Etat," in which he pleaded for the right of every citizen to personal liberty, until he had been deprived of it by a legal trial, with all the energy and eloquence of one who had been a sufferer under uncontrolled authority. He next commenced an action against his father for maintenance and arrears, in which he was successful. With the assistance of Chamfort, a man of letters of some celebrity, he composed a work entitled "Considérations sur l'Ordre de Cincinnatus," the subject of which was a projected society in the United States of North America, which the friends of republicanism looked

looked upon with jealousy. During its composition, he frequently consulted Dr. Franklin, then at Paris. He now became a writer by profession, and with a view to his maintenance went to London, where he published some volumes of a work called "Le Conservateur," in which an analysis was given of the most valuable current publications. In London he met with very small encouragement, and returned to Paris, where he wrote some tracts on public finance. In 1786 he went to Berlin, to observe the politics of the court, and was admitted into the presence of, and had a conversation with, Frederic the Great, who was then attacked with his last illness. From his observations he wrote two very free and important letters of advice, or memorials, to the next king on his accession. He probably had some views to employment in the new reign, but his hopes were frustrated by his licentious character, and his open profession of atheism. He chiefly occupied his time at Berlin, with laying in materials for his statistical account of the Prussian and Saxon states, and for his secret and satirical history of the court of Prussia; he became a member of the society of *Illuminati*, and published an "Essay on the sect of *Illuminées*," which appearing to disclose its secrets, is thought to mix with them so many absurd fictions as to involve the whole in ridicule.

Upon the assembling of the Notables he returned to Paris, and by the freedom of some of his remarks, in a pamphlet against stock-jobbing, an order was issued for his apprehension, which he fortunately evaded by a temporary concealment near Liege. He did not continue long there, but on his return to the metropolis ingratiated himself with the minister Brienne, by writing against Neckar. In 1787 he visited Berlin, and was employed, in conjunction with his friend Mauvillon, in preparing for the press the work entitled "Histoire de la Monarchie Prussienne," which was published in the following year, in four volumes 4to. and in eight of the 8vo. size, and obtained for the author a high reputation for political and satirical knowledge. In 1789 appeared "Histoire Secrete de la Cour de Berlin," in which the reigning king of Prussia, and several other great personages in his court, were treated with so much disrespect, that the work was ordered, by the parliament of Paris, to be burnt by the common hangman.

The assembling of the States-General excited in Mirabeau's mind the highest expectations, and he, without doubt, viewed the approaching troubles of the kingdom as pregnant with events, in which his abilities would lead him to take a very conspicuous part. At the time of the elections he went to Provence, with the hope of being chosen one of the deputies of the noblesse for that province, but being rejected as not possessing any property in it, he opened a grocer's shop at Aix, put on an apron, sold his wares, and rendered himself so popular, that he was elected, with the greatest acclamations, a deputy of the tiers état of that city. On the meeting of the states, he set up a daily paper, which he entitled "Lettres de Mirabeau à ses Commettans," which gave such an account of the debates as might serve the interests of the popular party. Some feeble attempts were made to crush it, but without any effect, and its circulation became very extensive. He soon distinguished himself as the most eloquent speaker, and took a leading part in those disputes between the different orders, which ended in the assumption of the character of "National Assembly" by the tiers-état. It was on this occasion that a declaration was issued by the assembly, which among other subjects observed, that "the denomination of 'National Assembly' is the only one befitting the assembly in the actual situation of affairs, because the members composing it are the only representatives lawfully and publicly acknowledged and verified; be-

cause they are sent by almost the whole nation, and because the Representation being one and indivisible, none of the Deputies chosen, in whatever order or class, has a right to exercise his functions separately from the present Assembly." On another occasion, after a royal sitting, as it was called, the deputies were ordered by the king to depart, and the order was repeated by M. de Brèze, grand-master of the ceremonies. Mirabeau rose, and addressing Brèze in authoritative language, bid him go and acquaint those who sent him, that they were assembled by the will of the people, and that nothing but the bayonet should separate them. This speech confirmed the tiers-état in their resistance to the royal authority, and Mirabeau followed it by proposing and carrying a decree, declaring the inviolability of the persons of the members. About this time he attached himself to the duke of Orleans, but finding that prince incapable of carrying into effect any great designs, he withdrew from his councils. The death of his father in 1790 was of no advantage to his fortune, on account of the embarrassment in which he left his affairs, yet he found means to pay off large debts, and to live in a splendid style, which was generally attributed to the donations of the duke of Orleans. His motions were sometimes of a popular kind, sometimes tending to the support of authority. Though apparently a friend to order, he was thought secretly to have been the instigator of the worst outrages committed by the mob, over whom he possessed a greater influence than any other individual. In the infancy of the Jacobin club he was a constant attendant upon its meetings, but when the members seemed desirous of over-setting the whole system, he deserted and opposed them. In May 1790 he was the warm advocate for the right of peace and war as inherent in the executive power; from this period it was generally said that he had sold himself to the court, and his popularity was for some time much impaired. He had however enough of art and management to recover his influence, though he still treated the Jacobins with great contempt. It is imagined that he was engaged in a plan to procure the dissolution of the national assembly, and the liberty of the king, by means of an appeal to the nation, when he was attacked by a violent disease which proved fatal. The danger of no individual ever excited so universal an alarm; all Paris, as it were, crowded round his door, with eager enquiries, and the king himself sent messages to learn the state of his health. He died April 2d, 1791, at the age of 42. The honours paid to his memory were almost unprecedented. All public spectacles were suspended till his funeral, which was attended by all the ministers and deputies, and a vast number of other persons, to the Pantheon, where his body was deposited by the side of that of Descartes. His bust was placed in the halls of most of the municipalities of the kingdom, and funeral services were performed for him in several of the provincial capitals. Such, however, were the mutations of the public mind, that in the very next year, when republicanism was triumphant, his busts were destroyed, and his remains dissipated. Besides the works already mentioned, he published a variety of pamphlets. In his person, Mirabeau was gross and repulsive; in his manners, passionate and brutal. He was the most splendid figure in the earlier scenes of the French revolution, but, like a meteor, he dazzled and disappeared without leaving any lasting traces of his existence. No man of the time was perhaps equally qualified to shine in political warfare. Possessed of great eloquence, he was capable of bearing all before him in popular debate, and of a presence of mind which no emergency could disconcert; accustomed to lead the opinions of the public, and deriving more popularity from the boldness of his writings, than he lost by the dissoluteness of his morals, he was perfectly fitted

to act on the tumultuary theatre of revolutionary politics. His want of principle must exclude him from the rank of a real patriot, yet he was probably, on conviction, a friend to those public rights upon which all just and enlightened government is founded. Gen. Biog. Rabaut's Hist. of the French Revolution.

MIRABEL, in *Geography*, a province of Crete or Candia, lying to the E. of that of Candia, is populous, fertile, and abounding with oil, grain, and fruit. Formerly this province supplied several French vessels with oil, and thus kept up its price for the benefit of the inhabitants; but they have since been obliged to carry it, at a great expence, to Candia, and to sell it at a low price to the Turkish proprietors of the soap houses established in that town. In consequence of this reduction of price, the cultivation of olive trees, and the manufacture of oil, have declined. The road of Mirabel faces the east, and affords to vessels a tolerably safe anchorage. It is sheltered and defended by two small islands situated in front. The town is greatly diminished since commerce has taken another direction. Here are still reckoned 1500 inhabitants, most of whom are Greeks and cultivators. South of Mirabel lies the province of "Hierapetra," or "Gera-Petra," which produces, like the other province, oil, grain, various fruits, honey, wax, flax, &c. but it suffers equally with Mirabel from the prohibition, issued by the pacha, of selling commodities any where but at Candia. Olivier.

MIRABEL, a town of France, in the department of the Lot; nine miles N. of Montauban.

MIRABELLE, a town of Naples, in the county of Molise; 14 miles S.E. of Molise.—Also, a town of Naples, in Principato Ultra; 10 miles S.E. of Benevento.—Also, a town of Sicily, in the valley of Noto; four miles N.E. of Piazza.

MIRABILE, RETE. See RETE.

MIRABILIS, in *Botany*, a name which originated with the Spaniards, who applied to the beautiful plant, which still bears this name, the appellation of *Marabillas del Peru*, the Wonder, or Marvel, of Peru, on account of the great diversity of colour in its flowers, even on the same root. At first, as professor Martyn observes, every thing that came from the new continent was thought wonderful. The French call the plant of which we are speaking *Belle de nuit*, because the flowers expand, and smell sweet, at night only. Indeed the botanists of that nation seem to have taken a violent dislike to the original name, and all that belongs to it. Tournefort called this genus *Jalapa*, which is founded in error; and Jussieu *Nyctago*, derived from the French idea. The latter is unexceptionable, but superfluous.—Linn. Gen. 96. Schreb. 114. Willd. Sp. Pl. v. 1. 999. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 382. Stokes Mat. Med. v. 1. 311. Lamarek Illustr. t. 105. Gært. t. 127. (Nyctago; Juss. 90. Jalapa; Tourn. Init. 129. t. 50.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Aggregatz*, Linn. *Nyctaginez*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five erect, rather deep, unequal segments, permanent. *Cor.* of one petal, funnel-shaped; tube slender, long, gradually dilated upwards, its base permanent, hardened, investing the seed; limb somewhat spreading, plaited, in five slight equal segments. Nectary spherical, fleshy, surrounding the germen, obscurely five-toothed at the margin. *Stam.* Filaments five, inserted into the edge of the nectary, attached to the tube of the corolla, thread-shaped, inclining, unequal, extending rather beyond the tube; anthers roundish, ascending; pollen glutinous. *Pistl.* Germen turbinate, superior, within the nectary; style thread-shaped, the length and position of the

filaments; stigma globose, rough, ascending. *Peru.* none, except the permanent hardened base of the corolla. *Seed* solitary, ovate, obscurely five-sided.

Ess. Ch. Calyx inferior, five-cleft. Corolla funnel-shaped, its base inflated and permanent. Nectary a gland surrounding the germen. Seed solitary, coated.

1. *M. dichotoma*. Forked Marvel of Peru. Linn. Sp. Pl. 252. (Jalapa officinarum; Mart. Decad. 1. t. 1.)—Flowers nearly sessile, axillary, solitary, erect. Native of Mexico, from whence its seeds were brought very early to Europe. The plant is naturally perennial, having a thick oblong fleshy root; but if raised on a hot-bed, it will flower and feed the same season, like the usual race of tender annuals. It kept in a green-house, or planted in the open air close to the wall of a hot-house, it will endure many years, and flower more abundantly throughout the summer. The stem is herbaceous, succulent, very bushy, forked, knotty at the joints, three feet high, round, smooth except a narrow hairy line at the two opposite sides. Leaves opposite, stalked, ovate, somewhat heart-shaped, pointed, entire, very slightly downy or hairy at the margin and ribs. Flowers from the forks of the stem, on very short stalks, sweet-scented, of a scarlet red; their tube one and a half inch long. Calyx bell-shaped, a quarter of an inch in length.—This plant was by some botanists mistaken for the Jalap of the shops, which is now known to be a *Convolvulus*, and has blossomed this season, 1812, in the garden of A. B. Lambert, esq. at Boyton, Wilts; a rare occurrence in Europe, since the plant was sent over by Houston, 80 years ago.

2. *M. Jalapa*. Striped Marvel of Peru. Linn. Sp. Pl. 252. Curt. Mag. t. 371. (Admirabilis peruana, rubro flore; Clus. Hist. v. 2. 89. Mirabilia peruviana, flore luteo; Ger. em. 343.)—Flowers crowded, stalked, erect. Leaves nearly smooth.—Native of the East and West Indies. Very closely related to the foregoing, except that the calyx is longer, and the flowers more crowded together, on longer stalks. The leaves are not quite smooth at the edges. The corolla varies remarkably in colour, on which account, as well as its fragrance in the evening, the plant is highly desirable. What is said above of the treatment of *M. dichotoma*, is equally applicable to this. Some flowers are of a uniform scarlet red, others striped or speckled with red and white, in endless variety, on the same plant. On some they are all of an uniform very delicate yellow; while other individuals bear parti-coloured red and yellow blossoms. Most botanists, and among them Linnaeus, have believed this to be the real officinal Jalap; a mistake to which we have already alluded. See also CONVULVULUS, sp. 90, *Jalapa*.

3. *M. longiflora*. Long-flowered Marvel of Peru. Linn. Sp. Pl. 252. Stockh. Transf. for 1755. 176. t. 6. Sm. Exot. Bot. v. 1. 43. t. 23. (Atzoyatl, Mirabili Mexicana; Hernandez. Mex. 170.)—Flowers crowded, terminal, sessile, very long, slightly drooping. Leaves downy.—Native of the more cool and mountainous parts of Mexico, flowering in September. The seeds of this elegant species were sent by the French astronomers, about the middle of the last century, from South America, to M. le Monnier at Paris, by whose liberality they were dispersed throughout Europe. The plant has ever since been preserved, either as a tender annual, or the roots taken up, and kept from year to year in sand, they being, like those of the two former, truly perennial, and very large, externally black. The stem is three or four feet high, round, repeatedly forked, downy. Leaves opposite, heart-shaped, entire, soft, downy, and viscid, foetid when bruised; the lower ones stalked; the rest sessile. Flowers sessile, many together at the leafy top of each branch. Calyx very clammy and foetid. Corolla four inches long.

long, with a downy green and purplish tube; limb white, with a purple eye. *Antbers* orange. *Stigma* large, hairy, of a rich purple. *Seed* with a curiously tessellated dark brown coat, as big as the kernel of a filbert.

The flowers are highly scented. A few of them gathered in an evening, when they expand, without the foetid calyx, and placed in a glass of water, will perfume a large apartment all night. We do not however recommend them for a bed-chamber, or any close room. Each flower lasts only one night, but there is a copious succession till the close of autumn.

MIRABILIS, in *Gardening*, furnishes plants of the flowery perennial kind, of which the species cultivated are, the common marvel of Peru (*M. jalapa*); the forked marvel of Peru (*M. dichotoma*); and the sweet-scented marvel of Peru (*M. longiflora*).

The first sort has several varieties in the colour of the flowers, as purple and white, and variegated purple and yellow, but which resolve themselves into two principal varieties; as with purple and white flowers, which are variable; some being plain purple, others plain white, but most of them variegated with the two colours, and all found occasionally on the same plant; and with red and yellow flowers, generally mixed, but sometimes distinct on the same plant; some plants having only plain flowers, others only variegated; but the plants which are raised from seeds of the purple and white never produce red and yellow flowers, or the contrary.

All these varieties are highly ornamental during the months of July, August, and September, and, when the season continues mild, often last till near the end of October. The flowers opening only towards the evening, while the weather continues warm, but in moderate cool weather, when the sun is obscured, they continue open almost the whole day, and are produced so plentifully at the ends of the branches, that when expanded the plant seems entirely covered with them, and from some being plain, others variegated on the same plant, have a fine appearance.

The second species is common in the West Indies, where it is termed the *Four-o'clock flower*, from the circumstance of the flowers opening at that time of the day.

Method of Culture.—In all these sorts the propagation is effected by sowing the seed in the spring season, either on a warm border or on a hot-bed; but the latter method produces the plants considerably more early, and in the greatest perfection. When cultivated on warm south borders, in the places where the plants are to remain, the seed should be sown about the middle of April, either in patches or in shallow drills, half an inch deep, and six inches asunder: and when the places can be covered with hand-glasses, or a frame and lights, or the seed be sown in pots under those protections, or any other occasional shelter during the night time or in cold weather, it will greatly forward the germination of the seed, as well as the growth of the young plants afterwards. In the latter mode about June, the plants will be fit to plant out into the borders or into pots. Moist weather should be chosen for this purpose, and water and occasional shade be given till well rooted: they then readily grow, and acquire a tolerable size; but they do not attain to a large size, or flower so early by a month or six weeks as those forwarded in the hot-bed.

But in the latter method of raising them, a hot-bed should be prepared in March, or early in April, under frame and lights, and earthed over about six inches deep, then sowing the seed in the earth of the bed in shallow drills half an inch deep, as directed above, or in pots of rich earth the same depth, plunging them in the earth of the bed. The latter is the better method. The plants soon rise; when they should have fresh air daily, in common with the other plants of the bed,

and frequent refreshings of water; and when nearly two inches high, be planted out into another fresh hot-bed to forward them, placing them either in the earth of the bed, four or five inches asunder, or singly in small pots (thirty-two), plunging them in the bed; water and shade should be immediately given till fresh rooted, continuing the care of admitting fresh air every mild day; and about the middle or latter end of May, when they have acquired a good size and strength, they should be inured by degrees to the full air, so as that they may be removed into it fully about the beginning of June, choosing mild cloudy moist weather, if possible, for the business; taking up such as grow in the beds with balls of earth about their roots, and planting them in the borders; but those in the pots may be turned out with the whole ball entire, and planted in that way. Some should also be removed into large pots for moving into particular situations. Water should be directly given, and occasional shade to such as require it, repeating the waterings to the whole, till they have struck fresh root and begun to grow, when they will not require any further culture, except the occasional support of sticks, which is most necessary in the last sort.

As the seed ripens well, it will frequently prevent the trouble of preserving the roots. But when these are taken out of the ground in autumn, and laid in dry sand during the winter, secure from frost, and planted again in the spring, they grow much larger and flower earlier than the seedling plants: or when the roots are covered in winter with tanners' bark to keep out the frost, they often remain secure in the borders, where the soil is dry. When the roots thus taken out of the ground are planted the following spring in large pots, and plunged into a hot-bed, under a deep frame, they may be brought forward, and raised to the height of four or five feet, and flower much earlier in the season.

It should be noticed that in collecting the seeds, care should be taken not to save any from the plants which have plain flowers; and in order to have variegated flowers, the plain flowers should be pulled off from those plants which are intended to stand for seed. As the second sort is less hardy than the first and third, unless the plants are brought forward in the spring they seldom flower till very late, and their seeds do not ripen perfectly.

All the sorts are proper for the principal borders of pleasure grounds, being very ornamental in their large branchy growth, as well as in their extensive flowering.

MIRABILIS *Aqua*. See WATER.

MIRABOLANS, or MIROBALANS, in *Pharmacy*. See MYROBALANS.

MIRACHOW, or MIRCHAU, in *Geography*, a town of Prussian Pomerelia; 12 miles W. of Dantzic.

MIRACLE, in a popular sense, is a *prodigy*, or an extraordinary event, that surprises us by its novelty.

MIRACLE, in a more accurate and philosophical sense, is an effect that does not follow from any of the regular laws of nature; or which is inconsistent with some known law of it; or contrary to the settled constitution and course of things: accordingly all miracles presuppose an established system of nature, within the limits of which they operate, and with the order of which they disagree.

Spinoza denies that any power can supersede that of nature; or that any thing can disturb, or interrupt, the order of things; and accordingly defines a miracle to be a rare event, happening in consequence of some laws that are unknown to us.

Divines define a miracle, an extraordinary and wonderful effect above the power of nature, wrought by God, to manifest his power or providence; or to give credit to some messenger

essenger sent from himself. Thus Jesus Christ evinced the truth of his mission, and his doctrine, by miracles; and thus also did Moses. But there are scarcely any theological writers, that precisely agree in their definition of a miracle. Mr. Locke defines it to be a sensible operation, which being above the comprehension of the spectator, is, in his opinion, contrary to the course of nature, and taken by him to be divine. Dr. Clarke's definition of a miracle, in the theological sense of the word, is this: that it is a work effected in a manner unusual, or different from the common and regular method of Providence, by the interposition either of God himself, or of some intelligent agent superior to man, for the proof or evidence of some particular doctrine, or in attestation to the authority of some particular person. According to Dr. Sykes, a miracle is a designed effect, sensible, unusual in itself, beyond the art and power of man to do. Dr. Chandler says, that a miracle is an action done, or an operation visibly performed by any being, which is really and truly above the reach natural power, and capacity of that being who does it, of himself, and without the assistance of some superior agent to perform. With this Dr. Hutcheson's definition nearly coincides, *viz.* that it is a work far exceeding human power, yet performed by the command, or upon the volition of a man. And the same writer further observes, that though miracles may prove the superintendency of a voluntary agent, and that the universe is not guided by necessity or fate; yet that mind must be weak and inadvertent, who needs them to confirm the belief of a wise and good Deity; since the deviation from general laws, unless upon very extraordinary occasions, must be a presumption of inconstancy and weakness rather than of a steady wisdom and power; and must weaken the best arguments we have for the sagacity and power of the universal mind. Inquiry into the Original of the Ideas of Beauty, &c.

Mr. Farmer, a late ingenious and learned writer, objects to all those definitions of miracles, which represent them as effects unusual, above human power, and manifesting the interposition of superior power: because, he says, the term unusual does not distinguish real miracles from many things which are not miraculous, such as the rare and uncommon appearances of nature: nor does the calling a miracle an effect above human power, distinguish it from all other effects equally above human power, produced by superior beings, when acting within their usual sphere, which, for that reason, cannot be miraculous. Besides, as this definition comprehends many things, which are not miraculous, and to which no persons apply the term; so it excludes many things which are allowed by all to be proper miracles. For there seems to be a difference between effects above human power, or which argue a higher degree of power, and effects which argue a power barely different from human, and in no manner superior to it. According to this definition, beasts and birds may work miracles; for they do many things that are above the power of man. Moreover, this definition, instead of describing miracles by the nature of the works themselves, describe them by their author, and the degree of power necessary to their performance. To which it may be added, that works which argue only a power more than human, can be no absolute proofs of a divine interposition: and farther, the last part of the definition, manifesting the interposition of superior power, is superfluous; because it is only saying effects above human power must be produced by a power above it.

This writer considers the contrariety or conformity of the event itself to those laws by which the world is governed in the course of God's general providence, as the only circum-

stance which denominates and constitutes it a proper miracle or not: and, therefore, before we can pronounce with certainty any effect to be a true miracle, it is necessary (and nothing more is necessary than) that the common course of nature be in some degree first understood. Miracles, in this view, are not impossible to the power of God, nor necessarily repugnant to our ideas of his wisdom and immutability. Neither do they imply any inconsistency in the divine conduct, or a defect or disturbance of the laws of nature: so that in the general idea of miracles, considered as variations from the common course of nature, there is nothing that can furnish a certain universal proof against their existence; and there is a power superior to nature, which is ever able, and which in certain circumstances may reasonably over-rule what was at first established. The writer, now cited, farther maintains, that miracles are neither the effects of natural causes, nor of superior created intelligences, acting from themselves alone; but that they are always to be ascribed to a divine interposition; *i. e.* that they are never wrought, but either immediately by God himself, or by such other beings as he commissions and empowers to perform them. In proof of this proposition, he alleges, that the same arguments which prove the existence of superior created intelligences, do much more strongly conclude against their acting out of their proper sphere. Farther, the supposition of the power of any created agents to work miracles of themselves, in this lower world, is contradicted by the observation and experience of all ages; there being, in fact, no proper evidence of the truth of any miracles, but such as may be fitly ascribed to the Deity. Moreover, the laws of nature being ordained by God and essential to the order and happiness of the world, it is impossible God should delegate to any of his creatures a power of working miracles, by which those divine establishments may be superseded and controlled. Besides, the ascribing to any superior beings, God excepted, and those immediately commissioned by him, the power of working miracles, subverts the foundation of natural piety, and is a fruitful source of idolatry and superstition. It is further urged, that if miracles were performed in favour of false doctrines, mankind would be exposed to frequent and unavoidable delusion: and, if they may be performed without a divine permission, and in support of falshood, they cannot be credentials of a divine mission, and criterions of truth. So that, upon the whole, if superior beings really possess the miraculous powers which some writers have ascribed to them, the exercise of those powers, by good and evil agents, would either expose mankind to necessary and invincible error, or entirely destroy the credit and use of miracles, under the idea of criterions of truth and authentic credentials of a divine mission. If we appeal to the evidence of revelation, on this subject, we shall find, that the view which the scripture gives us of good angels, of the devil and his angels, as also of the souls of departed men, is inconsistent with their liberty of working miracles: and the view which the sacred writers give us of the gods of paganism is also absolutely inconsistent with their possessing a power of working miracles. Nevertheless, it has been much disputed, how far it may be in the power of the devil to work miracles? or wherein the specific difference lies between the miracles of Moses, and those of Pharaoh's magicians? those of Jesus Christ and the apostles, and those of Simon Magus and Apollonius Tyaneus? Whether the latter were any more than mere delusions of the senses; or whether any super-natural and diabolical power concurred with them. See MAGICIAN; under which article it is shewn, that the magicians, diviners, and forcerers of antiquity, who pretended by the assistance of

the heathen deities, &c. to foretel future events, or to work miracles, are branded in scripture as mere impostors, incapable of supporting their pretensions by any works or pretensions beyond human power or skill. The scripture likewise reproaches the pretences to inspiration and miracles, made by false prophets, in support of error and idolatry, as the sole effects of human craft and imposture. And, therefore, since angels, whether good or evil, the spirits of departed men, the heathen deities, magicians, and false prophets, are the only agents, who have ever been conceived as capable of working miracles, either in opposition to God, or without an immediate commission from him; and the scripture denies to all these the power of performing any miracles; it does in effect deny, that any single miracle has ever been performed without the immediate interposition of God. It is likewise alleged, that the scriptures represent the one true God, as the sole creator and sovereign of the world, which he governs by fixed and invariable laws; that to him they appropriate all miracles, and that they urge them as demonstrations of his divinity and sole dominion over nature, in opposition to the claims of all other superior beings. The scriptures also uniformly represent all miracles, as being, in themselves, an absolute demonstration of the mission and doctrine of the prophets, at whose instance they are performed; and never direct us to regard their doctrines as a test of the miracles being the effect of divine interposition. Accordingly, the miracles of Christ, in particular, were a demonstration (not a partial and conditional, but a complete and absolute demonstration) of his mission from God: and they were farther designed to evince his peculiar character as the Messiah or anointed; *i. e.* his regal commission and power, or his right by divine designation to dominion and judicature over mankind. And it may be observed, with respect to all the miracles of the New Testament, that their divinity, considered in themselves, is always either expressly asserted, or manifestly implied; and they are accordingly urged as a decisive and absolute proof of the divinity of the doctrine and testimony of their performers, without ever taking into consideration the nature of the doctrine, or of the testimony to be confirmed. It is also shewn, that the scriptures have not recorded any instances of real miracles performed by the devil; in answer to the objections drawn from the case of the magicians in Egypt, from the appearance of Samuel, after his decease, to Saul, which was either the work of human imposture or a divine miracle, and from our Saviour's temptation in the wilderness, which the writer, to whom we now refer, considers as a divine vision. Miracles, considered as the peculiar works of God, afford a divine testimony to the person on whose account they are wrought, and to that doctrine or message, which he delivers in the name of God. And this proof from miracles of the divine commission, and doctrine of a prophet, is in itself decisive and absolute. It is also the most natural and agreeable to the common sense of mankind in all ages. It is the most easy and compendious proof of a new revelation. Miracles are farther a very powerful method of conviction, making a strong impression upon the heart, at the same time that they carry light to the understanding. Nor is the necessity of miracles less evident than their propriety and advantage, in attesting a divine commission and propagating a new revelation. They also serve to revive and confirm the principles of natural religion, and to recover men from those two opposite extremes of atheism and idolatry. Finally, the evidence of miracles, whether of power or knowledge, is the fittest to accompany a standing revelation; because it is not confined to one age or nation, but may be extended over the whole globe, and con-

veyed to the most distant generations. On the nature and design of miracles, already illustrated in this article, see Farmer's Dissertation on Miracles, &c. 8vo. 1771, passim. On the other hand, Dr. Clarke, who allows that miracles may be wrought by other agents besides the Deity, observes that it cannot certainly be distinguished, by the miracle itself, whether any extraordinary interposition of some power superior to men be the immediate interposition of God himself, or of some good angel, or of some evil angel. The only possible ways, says this learned writer, by which a spectator may certainly and infallibly distinguish whether miracles be indeed the works either immediately of God himself, or of some good angel employed by him; and consequently the doctrine witnessed by the miracles be infallibly true and divinely attested: or whether, on the contrary, the miracles be the works of evil spirits, and consequently the doctrine a fraud and imposition upon men, are these: if the doctrine attested by miracles be in itself impious, or manifestly tending to promote vice; then, without all question, the miracles, how great soever they may appear to us, are neither wrought by God himself nor by his commission. If the doctrine, attested by miracles, be in itself indifferent, or such as cannot, by the light of nature and right reason alone, be certainly known whether it be true or false; and at the same time, in opposition to it, and in proof of the direct contrary doctrine, there be wrought other miracles, more and greater than the former, or at least attended with such circumstances as evidently shew the power, by which the latter are wrought, to be superior to the power that produced the former: then that doctrine, which is attested by the superior power, must necessarily be believed to be divine. This, he apprehends, was the case of Moses and the Egyptian magicians. (See MAGICIAN.) If, in the last place, the doctrine attested by miracles be such as, in its own nature and consequences, tends to promote the honour and glory of God, and the practice of universal righteousness among men; and yet nevertheless be not in itself demonstrable, nor could, without revelation, have been discovered to be actually true; and there is no pretence of more or greater miracles, on the opposite side, to contradict it: which is the case of the doctrine and miracles of Christ; then the miracles are unquestionably divine, and the doctrine must, without all controversy, be acknowledged as an immediate and infallible revelation from God. In order to obviate the objection, that we prove in a circle the doctrine by the miracles, and the miracles by the doctrine; he adds, that the miracles, in this way of reasoning, are not at all proved by the doctrine; but only the possibility and the good tendency, or at least the indifferency of the doctrine, are a necessary condition or circumstance, without which, the doctrine is not capable of being proved by any miracles. The doctrine must be in itself possible and capable of being proved, and then miracles will prove it to be actually and certainly true. Boyle's Lecture, Sermons, &c. p. 226, &c. The sufficiency of the argument in attestation to the truth of Christianity, deduced from miracles, has been controverted by several sceptical writers; and particularly by Mr. Hume. It has been alleged, that experience is the ground of the credit we give to human testimony. Having found in past instances that men have informed us right, we are disposed to believe them in future instances; but this experience is by no means constant; for we often find that men prevaricate and deceive. On the other hand, what assures us of those laws of nature, in the violation of which the notion of a miracle consists, is, in like manner, experience. But this is an experience that has never been interrupted. A miracle, it has been said, is an event which, from

from its nature, is inconsistent with all the experience we ever had, and in the highest degree incredible and extraordinary. In the falshood of testimony, on the contrary, there is no such inconsistency, nor any such incredibility, scarcely any thing being more common. No regard, therefore, can be due to the latter, when it is applied as a proof of the former. According to this reasoning, applied to the case of miracles, we are to consider which is most likely, that such events should happen, or that men should either deceive or be deceived. And as there is nothing more unlikely than the former, or much more common than the latter, particularly where religion is concerned, it will be right to form a general resolution, never to lend any attention to accounts of miracles, with whatever specious pretext they may be covered." "It is," says Mr. Hume in his "Essay on Miracles," "a maxim worthy of our attention, that no testimony is sufficient to establish a miracle, unless the testimony be of such a kind, that its falshood would be more miraculous than the fact which it endeavours to establish. And even in that case, there is a marked distinction of arguments, and the superior only gives us an assurance suitable to that degree of force, which remains after deducting the inferior. When any one tells me that he saw a dead man restored to life, I immediately consider with myself, whether it be more probable that the person should either deceive or be deceived, or that the fact he relates should really have happened. I weigh the one miracle against the other, and according to the superiority which I discover, I pronounce my decision, and always reject the greater miracle. If the falshood of his testimony would be more miraculous than the event which he relates, then, and not till then, can he pretend to command my belief or opinion." For such reasons as these Mr. Hume asserts, "that the evidence of testimony, when applied to a miracle, carries falshood on the very face of it, and is more properly a subject of derision than of argument;" and that whoever believes the truth of the Christian religion "is conscious of a continued miracle in his own person, which subverts all the principles of his understanding, and gives him a determination to believe what is most contrary to custom and experience." The principles on which this objection is founded, says an excellent writer, Dr. Price, are chiefly, "that the credit we give to testimony is derived solely from experience;" "that a miracle is a fact *contrary* to experience;" "that the previous improbability of a fact is a proof against it, diminishing, in proportion to the degree of it, the proof from testimony for it;" and "that no testimony should ever gain credit to an event, unless it is more extraordinary than it should be false, than that the event should have happened." Our author, in his examination of these opinions, begins with considering the nature and foundation of that assurance which experience gives us of the laws of nature. After a variety of ingenious observations on the nature and degree of the assurance with regard to future events, which we derive from past experience of the course of nature, this writer states the result of the whole in the following manner. "Upon observing, that any natural event has happened often or invariably, we have only reason to expect that it will happen again, with an assurance proportioned to the frequency of our observations. But we have no *absolute proof* that it will happen again in any future trial; nor the least reason to believe that it will always happen. For aught we know, there may be occasions on which it will fail, and secret causes in the frame of things which *sometimes* may counteract those by which it is produced." In examining the ground of the regard we pay to human testimony, our author concludes,

that it is not experience only, or that kind of experience to which we owe our expectation of natural events, the cause of which are unknown to us. We feel in ourselves, that a regard to truth is one principle in human nature; and we know, that there must be such a principle in every reasonable being; and to this chiefly owing the credit we give to human testimony. It is plain and capable of the most satisfactory proof, that there is a great difference between the conviction produced by testimony, and the conviction produced by experience, and the one is capable of being carried much higher than the other. Besides, the greatest part of what is commonly called experience is merely the report of testimony. "Our own experience," says Dr. Adams, "reaches around, and goes back but a little way; but the experience of others, on which we chiefly depend, is derived to us wholly from testimony." In proportion, therefore, as we weaken the evidence of testimony, we weaken also that of experience; and in comparing them we ought in reason to oppose to the former, only what remains of the latter after that part of it which is derived from the former, that is, after much the greatest part of it, is deducted. From this reasoning it follows, that there is no absurdity in using *testimony* for proving a *miracle*. This is not using a *weaker* experience to overthrow another of the same kind, which is *stronger*; but using an argument to establish an event, which yields a direct and positive proof, and is capable of producing the strongest conviction, to overthrow another founded on different principles, and which, at best, can prove no more than that, previously to the event, there would have appeared to us a presumption against its happening.

Moreover, a miracle cannot, with propriety, be styled an event *contrary* to experience; as Mr. Hume asserts. A miracle, says our author, is more properly an event *different* from experience than *contrary* to it; nor can it be proper to assert, as Mr. Hume does, that in every case of a miracle supported by testimony, there is a contest of two opposite experiences, the strongest of which ought always to determine our judgments. In Mr. Hume's argument there is, as Dr. Price intimates, a fundamental error: it is where he declares, that, "if, previously to an event, there was a greater probability *against* its happening, than there is *for* the truth of the testimony endeavouring to establish it, the former destroys the latter, and renders the event unlikely to have happened in proportion to its superiority." This is evidently a fundamental point in Mr. Hume's objection; or, in other words, in the principle, that no testimony should engage our belief, except the improbability in the falshood of it is greater, than that in the event which it attests. In order to evince the erroneousness of this principle, what our author wishes to be considered is, the degree of improbability which lies against almost all the common facts, independently of the evidence of testimony for them. In many cases of particular histories, which are immediately believed on the slightest testimony, there would have appeared to us, previously to this testimony, an improbability of almost infinity to one against their reality, as any one must perceive, who will think how sure he is of the falshood of all facts, that have *no* evidence to support them, or which he has only *imagined* to himself. It is then very common for the slightest testimony to overcome an almost infinite improbability. That this is the case our author has rendered evident by a train of satisfactory reasoning, which we have not room to introduce. For further particulars we must refer to the author himself, *ubi infra*.

Archdeacon Paley has, with his usual perspicuity, examined the objection of Mr. Hume against the credibility of miracles,

miracles, which we have above stated. Having premised that there is no antecedent improbability of a revelation from God, but that the contrary is the case; and that there is no way in which such a revelation can be made but by miracle, it is not improbable that miracles should be wrought. The improbability which arises from the miraculous nature of the things related is not greater than the original improbability that such a revelation should be imparted by God. Admitting then, that a revelation is not improbable, and that if there be a revelation, there must be miracles, the objection that no human testimony can render miracles credible must appear to be unfounded. Mr. Hume's principle, concisely stated, is this; that the truth of a miracle is contrary to experience, but it is not contrary to experience that testimony should be false. Our author observes that the term "experience," and the phrases "contrary to experience," or "contradicting experience," are ambiguous, and require explanation. Strictly speaking, the narrative of a fact is *then* only contrary to experience, when the fact is related to have existed at a time and place, at which time and place, we, being present, did not perceive it to exist. In this case the assertion is contrary to experience, properly so called; nor is it of any consequence, whether the fact be of a miraculous nature or not. This is a contrariety which no evidence can surmount. But this is not the experience, nor contrariety, which Mr. Hume meant to express in his objection; short of this, no intelligible signification can be affixed to the term "contrary to experience," but one, *viz.* that of not having experienced any thing similar to the thing related, or such things not being generally experienced by others. Now the improbability which arises from the want of experience, not contradiction to it, is only equal to the probability there is, that if the thing were true, we should experience things similar to it, or that such things would be generally experienced. Supposing then that miracles were wrought upon the first promulgation of Christianity, when nothing but miracles could decide its authority, is it certain that such miracles would be repeated so often, and in so many places, as to become objects of general experience? Is it a probability approaching to certainty? Is it a probability of any great strength or force? Is it such as no evidence can encounter? And yet this probability is the exact *converse*, and therefore the exact measure of the improbability which arises from the want of experience, and which Mr. Hume represents as invincible by human testimony. The force of experience, continues our author, is founded in the presumption, either that the course of nature is invariable, or that, if it be ever varied, variations will be frequent and general. Has the necessity of this alternative been demonstrated? Calling the course of nature the agency of an intelligent Being, is there any good reason for judging this state of the case to be probable? Ought we not rather to expect, that such a Being, upon occasions of peculiar importance, may interrupt the order which he had appointed, yet that such occasions should return seldom; that these interruptions consequently should be confined to the experience of a few; that the want of it, therefore, in many, should be matter neither of surprise nor objection? But it is said, that in our account of miracles, we assign effects without causes, or we attribute effects to causes inadequate to the purpose, or to causes of the operation of which we have no experience. Of what causes, we may ask, and of what effects, does the objection speak? If it be answered that, when we ascribe the cure of the palsy to a touch, of blindness to the enointing of the eyes with clay, or the raising of the dead to a word, we lay ourselves open to this imputation; we reply, that we ascribe no such effects to such causes. We perceive no virtue or energy in these things more than in other

things of the same kind. They are merely signs to connect the miracle with its end. The effect we ascribe simply to the volition of the Deity; of whose existence and power, not to say of whose presence and agency, we have previous and independent proof. We have therefore all we seek for in the works of rational agents, a sufficient power and an adequate motive. In a word, once believe that there is a God, and miracles are not incredible. Mr. Hume, as our author proceeds, states the case of miracles to be a contest of opposite improbabilities, that is to say, a question whether it be more improbable that the miracle should be true, or the testimony false. In this statement, however, there is a want of argumentative justice; because, in describing the improbability of miracles, he suppresses all those circumstances of extenuation, which result from our knowledge of the existence, power, and disposition of the Deity, his concern in the creation, the end answered by the miracle, the importance of that end, and its subserviency to the plan pursued in the works of nature. As Mr. Hume has represented the question, miracles are alike incredible to him who is previously assured of the constant agency of a divine Being, and to him who believes that no such being exists in the universe. They are equally incredible, whether related to have been wrought upon occasions the most deserving, and for purposes the most beneficial, or for no assignable end whatever, or for an end confessedly trifling or pernicious. This surely cannot be a correct statement. In adjusting also the other side of the balance, the strength and weight of testimony, the author has provided an answer to every possible accumulation of historical proof, by telling us, that we are not obliged to explain how the story or the evidence arose. The archdeacon thinks that we are obliged to do this. The existence of the testimony is a phenomenon: the truth of the fact solves the phenomenon. If we reject this solution, we ought to be able to recur to some other; and none even by our adversaries can be admitted, which is not consistent with the principles that regulate human affairs and human conduct at present, or which makes men *then* to have been a different kind of beings from what they are now. Our author adds; the short consideration, which, independently of every other, convinces me, that there is no solid foundation in Mr. Hume's conclusion, is the following: when a theorem is proposed to a mathematician, the first thing he does with it is to try it upon a simple case; and if it produce a false result, he is sure that there must be some mistake in the demonstration. Let us proceed in this way with what may be called Mr. Hume's theorem. "If 12 men, whose probity and good sense I had long known, should seriously and circumstantially relate to me an account of a miracle wrought before their eyes, and in which it was impossible that they should be deceived; if the governor of the country, hearing a rumour of this account, should call these men into his presence, and offer them a short proposal, either to confess the imposture, or submit to be tied up to a gibbet; if they should refuse with one voice to acknowledge that there existed any falsehood or imposture in the case; if this threat were communicated to them separately, yet with no different effect; if it was at last executed; if I myself saw them, one after another, consenting to be racked, burnt, or strangled, rather than give up the truth of this account; still, if Mr. Hume's rule be my guide, I am not to believe them. Now I undertake to say, that there exists not a sceptic in the world who would not believe them; or who would defend such incredulity."

Having explained the nature and evinced the credibility of miracles in general, we might take occasion to illustrate the evidence which the miracles, that are recorded by the founders and advocates of Christianity, afford in attestation of its truth and

and divine origin. Admitting the credibility of miracles in general, and of the Christian miracles in particular, we might allege many direct, collateral, and presumptive arguments in proof of their reality. The miracles which the New Testament records, are in their own nature and design worthy of the wisdom, power, and benevolence to which they are ascribed. If we consider these miracles in themselves, in their number and variety as well as their nature, in the state and circumstances of those who were the objects of them, in the mollifications and yet public manner of their being wrought, in the multitude and also the disposition and character of those who witnessed them, in the extent and permanence of their effects, and in their connection with the reception and prevalence of the religion which they were intended to introduce and establish, we cannot question their reality: we cannot discover any traces of collusion and deceit; we cannot hesitate in allowing them to be such as the evangelical historians have described and recorded. As for the historians themselves, their character and conduct, their labours and sufferings undergone and endured in attestation to the truth of the facts which they relate, and the death which they preferred to the infamy of renouncing their belief of them, evince, in the most satisfactory manner, their integrity, and preclude every suspicion of fraud and imposture. This testimony, transmitted to us with every attendant circumstance of credibility, claims our confidence, and whilst we believe the reality of the miracles which they record, we cannot demur in tracing the religion which, by their writings and teaching, they have communicated to the world, to a divine origin. But we must desist from enlarging, and refer our readers to Price's *Four Dissertations*, Diss. 4. Paley's *View of the Evidences of Christianity*, vol. i. Adams's *Ess. on Miracles*. Bishop Douglas's *Criterion*. Campbell's *Dissertation on Miracles*. See *CHRISTIAN RELIGION, REVELATION, NEW TESTAMENT*, and other similar articles in the *Cyclopædia*.

The Romans attribute miracles to their emperors Adrian and Vespasian. The church of Rome abounds in miracles: if we believe their writers, some of their monks have wrought more miracles than all the apostles; and this without any visible necessity for them.

Mr. Hume has confronted the miracle of Vespasian related by Tacitus, that performed in a Spanish church, and related by cardinal de Retz, and the cures said to be performed at the tomb of the abbé Paris, in the early part of the last century, with those of the New Testament. With respect to the latter miracles, we observe, that the patients who frequented the abbé's tomb were so affected with their devotion, their expectation of relief, the place, the solemnity, and above all, by the sympathy of the surrounding multitude, that many of them were thrown into violent convulsions, which convulsions, in certain instances, produced a removal of disorders, depending upon obstruction. The above account may now be admitted with less difficulty, because the same or similar effects have been experienced in the operations of *animal magnetism*. See on the subject of these miracles, Douglas's *Criterion*.

As full as the Romish church has pretended to be of saints, it has been a rule with them, that none should be ever canonized till there be a good proof of their having wrought miracles. So that were all those allowed to be good miracles, and to have happened out of the common order of nature, they are so numerous, that one would be tempted to think there was no order or law of nature at all.

Some Protestant writers have maintained, that the power of working miracles was exercised in the Christian church during the three or four first centuries; in proof of which they allege that of the thundering legion, &c. But Dr.

Madleton, in his *Free Inquiry into the miraculous Powers*, which are said to have subsisted in the Christian church, &c. has maintained a very different opinion. And it must be acknowledged, that the evidence of the facts is, to say the least of it, very doubtful.

The many and stupendous miracles which are said to have been wrought by the Christian missionaries, who were sent to convert the barbarous nations, in the eighth century, have lost, in our times, the credit they obtained in former ages.

St. Augustine is a strong advocate for miracles. He mentions several, of which he was an eye-witness; and others, of which he was informed by those that were. In the single city of Hippo, he tells us there were seventy miracles wrought in the space of two years, on the building of a chapel in honour of St. Stephen. There are those, however, who set aside the authority of all miracles; thinking it unbecoming the wisdom of God to establish such laws, as that he should find it frequently necessary to supersede. And as the former, from the avowed authority of some miracles, fetch an argument for the truth of all, pleading those which are allowed as well as those which are questioned; so these allege the false ones very unfairly, as conclusions against all.

MIRADOUX, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure; 7 miles N.E. of Lectoure. The place contains 1655, and the canton 6343 inhabitants, on a territory of 157½ kilometres, in 12 communes. N. lat. 44°. E. long. 0 50'.

MIRAFLORES, a town of South America, in the province of Tucuman, on the Salado; 50 miles N.N.E. of St. Miguel de Tucuman.—Also, a town of Peru, in the audience of Lima; 8 miles S. of Lima.

MIRAGE, the name given by the French sailors to an optical phenomenon, on which M. Monge read a memoir to the institute at Cairo, during the French invasion of Egypt. It often happens at sea, that a ship seen at a distance appears as if painted in the sky, and not to be supported by the water. A similar effect was observed by the French in the course of their march through the desert; the villages seen at a distance seemed to be built on an island in the middle of a lake. In proportion as they approached, the apparent surface of the water became narrower; when they were only at a small distance, it disappeared, and the same illusion began, in regard to the next village. M. Monge ascribes this effect to a diminution of the density of the lower stratum of the atmosphere. This diminution in the desert is produced by the increase of heat, arising from that communicated by the rays of the sun to the sand, with which this stratum is in immediate contact. At sea it takes place when, by particular circumstances, such as the action of the wind, the lower stratum of the atmosphere holds in solution a greater quantity of water than the other strata. In this state of things the rays of light, which come from the lower parts of the heavens, having arrived at the surface that separates the less dense stratum from those above it, do not pass through that stratum, but are reflected, and paint in the eye of the observer an image of the heavens, which appearing to him to be below the horizon, he takes it for water, when the phenomenon occurs at land. If he is at sea, he thinks he sees in the heavens all the objects which float on that part of the surface occupied by the image of the heavens. This phenomenon has been considered and explained by several English philosophers. See *Horizontal REFRACTION*.

MIRAGOANE, in *Geography*, a town on the north side of the south peninsula of the island of St. Domingo, and south side of the bight of Leogane, at the head of a bay of its name; 15 miles W. of Petit Goave.

MIRALETUS, in *Ichthyology*, a name given to the species of ray, commonly called by others *raja oculata*. See RAJA *Miraletus*.—Also, a name given by Bellonius and others to the RAJA *Oxyrinchus*; which see.

MIRAMACHI, or MIRACHI, in *Geography*, a port, bay, and river, on the north coast of New Brunswick. The port is at the entrance of the bay. In the river there is a salmon fishery.

MIRAMBEAU, a town of France, in the department of the Lower Charente, and chief place of the district of Jonzac; 12 miles S. of Pons. The place contains 2170, and the canton 15,117 inhabitants, on a territory of 242½ kilometres, in 19 communes.

MIRANA, a small island in the North Pacific ocean. N. lat. 62° 35'. E. long. 190° 34'.

MIRANDA, a town of Spain, in Navarre; 13 miles S.E. of Estalla.—Also, a town of Naples, in the country of Molise; 11 miles W. of Molise.

MIRANDA de Corvo, a town of Portugal, in the province of Beira, containing about 2700 inhabitants; 15 miles S.E. of Coimbra.

MIRANDA de Duero, a town of Portugal, in the province of Tras-los-Montes, situated in a barren mountainous country on the Duero, on the frontiers of Spain; the see of a bishop. It is but a poor mean town; 28 miles S.E. of Braganza. N. lat. 41° 24'. W. long. 5° 56'.

MIRANDA d'Ebro, a small town of Spain, in Old Castile, beautifully situated on the Ebro, over which is a noble bridge of eight arches. It contains a large square, embellished with fountains. It is environed by mountains, on whose brow are the remains of a castle, and the ruins of several towers, which formerly guarded access to it. A copious stream flows from the mountain, which serves to work several mills in its vicinity. The town was erected into an earldom, in the 14th century, by Henry IV., in favour of Don Diego de Zuniga, and is now governed by its alcade; 32 miles N.E. of Burgos.

MIRANDE, a town of France, and principal place of a district, in the department of the Gers. The place contains 1558, and the canton 10,316 inhabitants, on a territory of 292½ kilometres; in 49 communes. N. lat. 43° 31'. E. long. 0° 28'.

MIRANDELA, a town of Portugal, in the province of Tras-los-Montes; 30 miles S.W. of Braganza. N. lat. 41° 25'. W. long. 6° 58'.

MIRANDOLA, *Duchy of*, a small principality of Italy, almost surrounded by the duchy of Mantua. This principality shared the fate of Modena, and became a part of the Cisalpine republic, now the kingdom of Italy.—Also, a city of Italy, in the department of Panaro; lately capital of a duchy united with Modena, strong, and defended by a citadel; the see of a bishop. It contains, besides the cathedral, 15 churches; 14 miles N.N.E. of Modena. N. lat. 44° 50'. E. long. 11° 5'.

MIRANO, a town of Italy, in the Paduan, on the river Musan, containing about 3120 inhabitants; 12 miles N.E. of Padua.

MIRAPORVOS, a rocky islet among the Bahamas, near the south-west coast of Crooked island. N. lat. 21° 55'. W. long. 74° 46'.

MIRAPOUR, a town of Bengal; 30 miles E. of Burdwan.—Also, a town of Hindoostan, in the circar of Schaurunpour; 15 miles N. of Merat.

MIRASOLE, a town of Italy, in the department of the Mincio; 9 miles S.S.E. of Mantua.

MIRAVALLS, a town of Spain, in the province of Biscay; 9 miles S. of Bilbao.

MIRAVEL, a town of Spain, in New Castile, on the side of a hill, defended by a strongly fortified castle; 12 miles S.S.W. of Placencia.

MIRAW, or MEROW, a town of Moravia, in the circle of Olmutz; 22 miles N.W. of Olmutz.

MIRAY BAY, a bay on the coast of the island of Cape Breton. Large vessels may go up six leagues, have good anchorage, and lie secure from all winds. N. lat. 46° 5'. W. long. 59° 49'.

MIRBELIA, in *Botany*, named by the writer of this article, in honour of Monf. Mirbel, Superintendent of the botanic garden at Malmaison, member of various learned academies, and author of several excellent works on the anatomy and physiology of vegetables. His elucidations of their reticulated structure having excited much attention, the present plant, remarkable for the reticulated aspect of its leaves, was judged more particularly suited to perpetuate his name. Smith in *Smith and Konig's Annals of Botany*, v. 1. 511. Brown in *Ait. Hort. Kew. ed. 2. v. 3. 21.*—Class and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, sect. 4. Juss.

Gen. Ch. *Cal.* Perianth inferior, bell-shaped, two-lipped, without appendages; somewhat angular at the base: upper lip of two abrupt, oblique, parallel segments; lower of three lanceolate, acute, equal ones, dilated at the base, rather shorter than the upper: permanent. *Cor.* papilionaceous, of five petals, about twice the length of the calyx; standard inversely heart-shaped, recurved, with a short, broad, linear claw; wings lanceolate-oblong, rather shorter than the standard, with a tooth at the upper edge; keel shorter than the wings, of two cohering, half-ovate petals, with linear claws. *Stam.* Filaments ten, awl-shaped, equal, contained within the keel, inserted into the receptacle; anthers roundish, incumbent. *Pist.* Germen superior, ovate-oblong; style thick and short, bent upwards; stigma capitate. *Peric.* Legume heart-shaped, pointed, tumid, with a groove at each side, of two cells, at length separating from each other; the partition double, from both the inflexed margins of each valve. *Seeds* solitary, attached to the lower edge of each valve, oval, compressed, with a circular bordered scar.

Ess. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Style reflexed. Stigma capitate. Legume of two cells, tumid, with two seeds; the partition double.

1. *M. reticulata*. Reticulated Mirbelia. Sm. as above. Tr. of Linn. Soc. v. 9. 265. Venten. Malmaif. t. 119. (*Pultenæa rubicifolia*; Andr. Repof. t. 351.)—Leaves linear-lanceolate, veiny.—Native of the neighbourhood of Port Jackson, New South Wales. *Dr. White*. It was very early raised from seeds in this country, and is kept in the green-house, in light sandy peat earth, with little water in winter, but as much air as possible; flowering from May to August, the second year after being sown. The stem is shrubby, much branched, and very bushy, smoothish, leafy, angular; the branches mostly ternate, straight, and spreading. *Leaves* almost always three in a whorl, rarely opposite only, on very short broad footstalks, spreading, an inch long, linear-lanceolate, sometimes elliptical and shortened, smooth, revolute, slightly crenate or wavy, tipped with a spine, furnished with one rib and many transverse veins; paler and most opaque beneath. *Flowers* in little axillary and terminal tufts, on short stalks; with a pair of linear bractæas in the middle of each stalk. *Corolla* light purple, with a radiating reddish stain at the base of the standard. *Legume* a quarter of an inch long, grey, smooth, transversely veined. It is curious that this shrub should ever have been mistaken

mistaken for a *Rubia*, which was actually the case before it flowered.

2. *M. dilatata*. Lobed-leaved *Muhelia*. Brown in Ait. Hort. Kew. n. 2. — Leaves wedge shaped, dilated and three cleft at the extremity. — Found by Mr. Brown on the fourth-west coast of New Holland. This species was sent to Kew, in 1803, by Mr. Peter Good and flowers in the green-house in May and June. The stem is shrubby. We have seen no specimen, nor is any account given of the colour of the flowers.

MIRCHOUR, in *Geography*, a town of Hindoostan, in Golconda; 20 miles S. E. of Canoul.

MUREBALAIS, an interior town in the French part of the island of St. Domingo; 30 miles N. of Port au Prince.

MIREBEAU, a town of France, in the department of the Cote d'Or, and chief place of a canton, in the district of Dijon; 13 miles N. E. of Dijon. The place contains 1100, and the canton 8,78 inhabitants, on a territory of 257½ kilometres, in 27 communes. — Also, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Poitiers; 12 miles N. N. E. of Poitiers. The place contains 221, and the canton 7096 inhabitants, on a territory of 192½ kilometres, in 14 communes. N. lat. 46° 47'. E. long. 0° 16'.

MIRECOURT, a town of France, and principal place of a district, in the department of the Vosges; 13 miles N. W. of Epinal. The place contains 5084, and the canton 11,757 inhabitants, on a territory of 175 kilometres, in 28 communes. N. lat. 43° 18'. E. long. 0° 13'.

MIREMONT, a town of France, in the department of the Dordogne; 10 miles S. W. of Montignac. Also, a town of France, in the department of the Upper Garonne; 7 miles S. E. of Muret.

MIRENI, a town of Walachia, on the Ardgis, near its confluence with the Danube; 30 miles S. of Bucharest.

MIREPOIX, a town of France, and principal place of a district, in the department of the Arriege; 18 miles N. E. of Tarascon. The place contains 2819, and the canton 13,589 inhabitants, on a territory of 335 kilometres, in 37 communes. N. lat. 43° 5'. E. long. 1° 56'.

MIREVELT, MICHAEL JANSON, in *Biography*, a portrait painter, born at Delft in 1568. The extreme resemblance of his pictures, the freshness of their colour, and the neatness of their execution, procured Mirevelt a most extraordinary influx of professional occupation; so much, that he is reported by Houbraken to have painted 5000 portraits: for the smallest of which, merely a head, he was paid about 15*l.* sterling; and those of larger sizes in proportion.

He certainly was a very ingenious artist, and, where the talents of Rubens were unknown, must have appeared a luminary of his day; but the superior taste and freedom exhibited in the works of the latter, and afterwards in those of his extraordinary pupil Vandyke, render the works of Mirevelt tame and insipid. He died in 1641.

MIREVELT, PETER, son of the former, and a painter of the same taste, style, and study. By many he is thought fully equal to his father.

MIRGONDA, in *Geography*, a town of Hindoostan, in Dowlatabad; 25 miles S. W. of Beder.

MIRGOROD, a town of Russia, in the government of Kiev; 100 miles E. S. E. of Kiev. N. lat. 50°. E. long. 32° 54'.

MIRIAM, in *Sacred History*, the sister of Aaron, and a prophetess. When Moses had finished his pious effusions in the first hymn on record, after the safe passage of the Red sea, at the head of the whole people of Israel, just escaped

from bondage, he was crowned on this occasion by Miriam, "who took a timbrel in her hand, and all the women went out after her with timbrels and with dances, and Miriam answered them, Sing ye to the Lord," &c.

Here is an early instance of women being permitted to bear a part in the performance of religious rites, as well as of vocal music being accompanied by instrumental, and by what was called *dancing*, which was probably nothing more than moving or marching in regulated steps and gesture.

MIRJANAGORE, in *Geography*, a town of Bengal; 15 miles S. of Moorley.

MIRICK, CAPE, a cape on the west coast of Africa. N. lat. 19°. W. long. 6° 5'.

MIRIOSITO, a town of European Turkey, in Romania; 24 miles N. E. of Gallipoli.

MIROBRIGA, in *Ancient Geography*, a town of Spain, the site of which is now occupied by CIVIDAD Rodrigo; which see. This town of Leon was built in the reign of Ferdinand II, about the 13th century, and was made a rampart against Portugal. It is situated in a flat and tolerably beautiful country, producing abundance of the necessaries of subsistence. Its plains extend five leagues to the north, and are terminated by a chain of mountains, which are branches of those of Bejar, Pena de Francia, and Geta. The town is fortified, and is the see of a bishop. It has seven gates, and its streets are tolerably regular. Its population amounts to about 10,000 inhabitants. It has a cathedral, a collegiate church, six parish churches, five convents of monks, four of nuns, one seminary, and two hospitals. The river Ague passes close to the town. The ancient Roman aqueduct is destroyed; but the inhabitants have constructed another, which conveys the water requisite for the town and watering of the trees, through the space of three leagues. There are also some fountains out of the walls; and in the extent of the diocese are some medicinal waters, copper, lead, iron, and even gold mines.

MIROPEL, in *Geography*, a town of the duchy of Warsaw; 40 miles W. N. W. of Berdiczow.

MIRROPOLBE, a town of Russia, in the government of Cherkov; 88 miles N. N. W. of Charkov. N. lat. 51° 22'. E. long. 34° 34'.

MIROUETTE, in the *Manege*, is used for a dapple-bay.

MIROW, in *Geography*, a town of the duchy of Mecklenburg; 44 miles N. of Spandau.

MIROWITZ, a town of Bohemia, in the circle of Prachatitz; 18 miles N. N. E. of Strakonitz.

MIRROR, a *speculum*, or body, which exhibits the images of objects presented to it by reflection.

The use of mirrors is very ancient. Mention is made of brazen mirrors, or looking-glasses, in Exodus, xxxviii. 8. where Moses is said to have made a "brazen laver, or basin, of the looking-glasses of the women continually assembled at the door of the tabernacle." It is true some modern commentators will not allow the mirrors themselves to have been brass; but of glass, only set or framed in brass. But the most learned among the rabbins do all allow, that in those times the mirrors made use of by the Hebrew women in dressing their heads were of metal; and that the devout women, mentioned in this passage, made presents to Moses of all their mirrors, to make the brazen laver. See the Jesuit Bopferius's comment on this text. See GLASS.

It might likewise be proved, that the ancient Greeks made use of brazen mirrors, from divers passages among the ancient poets.

MIRROR, in the more confined sense of the word, is peculiarly used to signify a smooth surface of glass, tinned and

quicksilvered on the back-side; which exhibits the images of objects opposed to it. See LOOKING-GLASS.

MIRROR, in *Catoptrics*, denotes any polished body impervious to the rays of light, and which of consequence reflects them equally.

Thus water in a deep well or river, and smooth polished metals, are ranked among the number of mirrors.

In this sense, the doctrine of mirrors makes the subject of catoptrics.

Mirrors are made either of glass, coated with an amalgam of mercury and tin, or of metal, as of platina, of silver, or of an alloy of copper and tin, to which a little arsenic and silver are sometimes added. Mirrors of metal are more perfect than those of glass, because they are free from the inconvenience of a double reflection; but they are more expensive, and are liable to tarnish. Where a large mirror is required, with only a weak reflection, we may employ a single surface of glass, the back of the piece being covered with a black coating of some substance differing little from glass in its refractive density, by means of which the second reflection is avoided. See SPECULUM.

The doctrine of mirrors is founded on the following general principles.—1. Light reflected from any mirror, or speculum D E, makes the angle of incidence equal to that of reflection; which see demonstrated under the word REFLECTION.

Hence, a ray of light, as H B. (*Plate XIII., Optics, fig. 1.*) falling perpendicularly on the surface of a speculum D E, will be reflected back upon itself: as we find by experience it actually is.

From the same point of a mirror, therefore, B, there cannot be several rays reflected on the same point; since, in that case, all the angles of incidence must be equal to the same angle of reflection C B G, and therefore to each other; which is absurd. Nor can the ray A B be reflected to two or more points; since, in that case, all the angles of reflection would be equal to the same angle of incidence A B F; which is likewise absurd.

2. From every point of a mirror, are reflected rays thrown on it from every point of a radiant object. Since then rays coming from different parts of the same object, and striking on the same point of the mirror, cannot be reflected back to the same point; the rays which flow from different points of the same radiating object are again separated after reflection: so that each point shews whence it came.

Hence it is, that the rays reflected from mirrors exhibit the objects to view. Hence also, it appears, that rough uneven bodies must reflect the light in such a manner as that rays coming from different points will be blended or thrown confusedly together.

Mirrors may be divided into *plane, concave, convex, cylindrical, conical, parabolical, and elliptical.*

MIRRORS, *Plane*, are those which have a plane or flat surface.

These, by a popular name, we call *looking-glasses.*

For the manner of making plane mirrors, or specula, see LOOKING-GLASS.

MIRRORS, *Laws and Phenomena of Plane.* 1. In a plane mirror, every point of an object, as A, (*Plate XIII., Optics, fig. 2.*) is seen in the intersection B, of the cathetus of incidence A B, with the reflected ray C B.

Let C D and F E be two reflected rays, corresponding to the incident rays A D, A E: then, since the vertical angle C D G = E' D B; and the angle of reflection C D H = A D G the angle of incidence, A D H will be = C D G = E D B. And H E F = D E B, and H E F = A E G, therefore D E B = A E G. But A E G + A D E, as

well as B E D + B D E, are less than two right angles; consequently the reflected rays F E and C D meet in B, and in the equiangular triangles A D E and D E B, having D E common, D B = D A. Wherefore, since the angle B D G = C D H = A D G, the angles at G will be equal, and consequently A B perpendicular to H G: *i. e.* A B is the cathetus of incidence: and, therefore, the reflected rays F E and C D meet with the cathetus of incidence A B in the same point B: and the radiant point A is seen in B.

Hence, 1. As all the reflected rays meet with the cathetus of incidence in B; by whatever reflected ray the radiant point A be seen, it will still appear in the same place. Consequently, any number of persons, viewing the same object in the same mirror, will all see it in the same place behind the mirror. And hence it is, that the same object has only one image, and that we do not see it double with both eyes.

Hence, also, the distance of the image B, from the eye C, is compounded of the ray of incidence A D, and the reflected ray C D: and the object A radiates reflectedly in the same manner as it would do directly, were it removed into the place of the image.

2. The image of a radiant point, B, appears just so far behind a plane mirror, as the radiant point is before it: because A G = B G.

Hence, if the mirror H G be placed horizontally, the point A will seem so much below the horizon, as it is really elevated above it; consequently, erect objects will appear as if inverted; and therefore men standing on their feet, as if on their heads. Or, if the mirror be fastened to the ceiling of a room, parallel to the horizon, objects on the floor will appear above the ceiling as much as they really are below it; and inverted.

3. In a plane mirror the images are perfectly similar, and equal to the objects; for every point of the object is seen in the cathetus of incidence, and the mirror bisects that part of it which is intercepted between the radiant point and its image. And hence the use of mirrors as looking-glasses.

4. In a plane mirror, things on the right hand appear as on the left; and *vice versa.*

Hence, also, we have a method of measuring any inaccessible altitude, by means of a plane mirror. Thus, the mirror being placed horizontally in C (*fig. 3.*), retire from it till such time as the top of the tree be seen in it. Measure the height of the eye D E, the distance of the station from the point of reflection E C, and the distance of the foot of the tree from the same: then to E C, C B, and E D, find a fourth proportional A B. This is the altitude sought.

5. If a plane mirror A E (*fig. 4.*) be inclined to the horizon E H, in an angle of 45 degrees, an object C B perpendicular to it will appear parallel, I K, and the horizontal object L B perpendicular in M K.

For produce B C till it meets the mirror in A; then as H is a right angle, and E = 45°, A will be = 45°: therefore, if from B be drawn B G perpendicular to the mirror A E, A B G will be = 45°; and A G = G B. Let G K be = G B, and the image of B will be in K; draw K A, and because K G = G A and G a right angle, K will be = 45°, and therefore K A parallel to E H. In the same manner it may be shewn, that the point C would appear in I, and consequently the image I K will be parallel to the horizon E H; and *vice versa.* Hence, the eye being placed beneath the mirror, the earth will appear perpendicularly over it: or if placed over the earth will appear

appear perpendicularly under it. Hence, also, a globe descending down a plane a little inclined, may, by means of a mirror, be exhibited as mounting up a vertical plane, to the great surprize of such as are unacquainted with catoptrics. And hence we have a method of representing ourselves as if flying: for a mirror inclined to the horizon under an angle of 45° , we have observed, will represent vertical objects as if horizontal; consequently, a large mirror being so disposed, as you advance towards it, you will seem to move horizontally; and nothing will be wanting to the appearance of flying, but to strike out the arms and legs. It must be added, however, that as the floor is elevated along with you, your feet will still be seen to walk as along a vertical plane. To deceive the eye entirely, therefore, it must be kept from the feet.

6. If the object AB (fig. 5.) be parallel to the speculum CD , and equally distant from it, with the eye; the reflecting line CD will be half the length of the object AB .

Let the eye O be in the object AB , or let the spectator view himself in a glass. Since AB is parallel to CD , the image $G H$ will be parallel to it likewise. From O let fall OL perpendicular to CD , which, continued to I , will be also perpendicular to $G H$; therefore, OL and $O I$ will be the respective altitudes of the triangles $O C D$ and $O G H$, which triangles, having the angles $x = o$ and $u = y$, are similar: consequently $C D : G H :: O L : O I$; and as $O L = \frac{1}{2} O I$, by art. 2. above, $C D$ will be $= \frac{1}{2} G H = \frac{1}{2} A B$.

And hence, to be able to see the whole body in a plane mirror, its height and breadth must be half your height and breadth. Consequently the height and breadth of any object to be seen in a mirror being given, we have also the height and breadth of the mirror in which the whole object will appear, at the same distance with the eye.

Hence, also, as the length and breadth of the reflecting part of the speculum are subdupla of those of the object to be reflected; the reflecting part of the mirror is to the surface reflected in a subquadruple ratio. Consequently, the reflecting portion being a constant quantity, if in any place you see the whole body in a mirror, you will see it in every other place, whether you approach nearer or recede farther from it.

7. If an object AB (fig. 6.) be parallel to the mirror $I F$; the length of the reflected line AB is to the reflecting part of the speculum CD as the sum of the incident and reflected rays $B D + D O$ to the reflected ray $O D$; or as the sum of the distances of the eye and of the object from the speculum, *viz.* $O I + B F$ to the distance of the eye $O I$. For $G E : C D :: O E : O D$; *i. e.* because $G E = A B$, and $D E = D B$. $A B : C D :: O D + D B : O D$. Moreover, $O E : O D :: O K : O I$, therefore $G E : C D :: O K : O I$; consequently, since $I K = F E = B F$, and $G E = A B$, we shall have $A B : C D :: O I + B F : O I$.

8. A spectator will see his own image as far beyond the speculum as he is before it; and as he moves to or from the speculum, his image will, at the same time, move towards or from him on the other side, but apparently with a double velocity, because the two motions are equal and contrary. In like manner, if while the spectator is at rest, an object be in motion, its image behind the speculum will be seen to move at the same rate. And if the spectator moves, the images of objects that are at rest will appear to approach or recede from him, after the same manner as when he moves towards real objects.

9. If several mirrors, or several fragments or pieces of a mirror, be all disposed in the same place, they will only exhibit an object once.

10. If two plane mirrors, or specula, meet in any angle, the eye, placed within that angle, will see the image of an object placed within the same, as often repeated as there may be cathecti drawn determining the places of the images, and terminated without the angle.

Hence, as the more cathecti, terminated without the angle, may be drawn as the angle is more acute; the acuter the angle, the more numerous the images. Thus *Z. Traber* found, at an angle of one-third of a circle, the image was represented twice, at $\frac{1}{3}$ thrice, at $\frac{1}{4}$ five times, and at $\frac{1}{7}$ eleven times.

Farther, if the mirrors be placed upright, and so contracted; or if you retire from them, or approach to them, till the images reflected by them coalesce, or run into one, they will appear monstrously distorted: thus, if they be at an angle somewhat greater than a right one, the image of your face will appear with only one eye; if the angle be less than a right one, you will see three eyes, two noses, two mouths, &c. At an angle still less, the body will have two heads. At an angle somewhat greater than a right one, at the distance of four feet, the body will be headless, &c. Again, if the mirrors be placed, the one parallel to the horizon, the other inclined to it, or declined from it, it is easy to perceive that the images will be still more romantic. Thus, one being declined from the horizon to an angle of 144 degrees, and the other inclined to it, a man sees himself standing with his head to another's feet.

Hence it appears, how mirrors may be managed in gardens, &c. so as to convert the images of those near them into monsters of various kinds; and since glass mirrors will reflect the image of a lucid object twice or thrice, if a candle, &c. be placed in the angle between two mirrors, it will be multiplied an infinite number of times. On these principles are founded various catoptric machines, some of which represent objects infinitely multiplied and distorted; others infinitely magnified, and set at vast distances.

MIRRORS, *Burning.* See *BURNING-Glass.*

MIRRORS, *Convex,* are those whose surface is convex.

Note, by *convex* surfaces, authors generally mean such as are *spherically convex.*

Manner of preparing or making convex Specula, or Mirrors.

—There are various methods used by divers artists; particularly as to the matter or composition for the silvering. One of the best that is known is given us by *Wolffius*, thus:

Melt one part of tin, another of bismuth, together; and to the melted mass add two parts of mercury: as soon as the mercury begins to evaporate into smoke (which it presently does), the whole compost is to be thrown into cold water, and when well cooled the water decanted off. The mixture is then to be strained through a linen cloth two or threefold; and what is thus separated, poured into the cavity of a glass sphere: this sphere is to be turned gently round its axis till the whole surface is covered, the rest being reserved for future use.

If the sphere were of coloured glass, the mirror will be so too. And in the same manner may conic, elliptic, cylindrical, and other mirrors, be made.

How they may be made of metal, see under *Concave MIRROR.* See also *SPECULUM.*

MIRRORS, *Laws or Phenomena of Convex.* 1. In a spherical convex mirror $H C I$ (fig. 7.), the reflected ray $E M$

concur with the cathetus of incidence DL , and the incident ray DN with the cathetus of reflection EL , between the tangent AB , and the centre L . For the perpendiculars, or catheti of incidence, obliquation, and reflection, are in the plane of reflection, and, therefore, in the plane which touches the speculum in the point of incidence C ; the tangent AC makes a right angle with the cathetus of obliquation FC ; but the reflected ray EC , or CM , makes with it an acute angle u , and, therefore, falls between the tangent AC , and the cathetus of obliquation CL . Wherefore, since CL and DL meet in the centre L , the reflected ray EM ought to intersect the cathetus of incidence DL between the tangent and the centre. In the same manner it is shewn, that the incident ray DN ought to meet with the cathetus of reflection between the tangent and the centre. Hence, the image of a radiant point appears between the centre and the tangent, because it appears in the concurrence of the reflected ray and cathetus of incidence.

2. In a spherical convex mirror, the cathetus of incidence DL (*fig. 7.*) is to DB , the distance of the object from the tangent at the point of reflection C , as LM , the distance of the image from the centre, is to MP , the distance of the image from the tangent. Since $o = x$, and $r = m$, o will be equal to m , and, therefore, the right line CP bisecting the angle DCM , cuts the base DM into two parts, which are in the same proportion with the sides; consequently, $DP : PM :: DC : CM$; and if DF be drawn parallel to CM , u will be $= \beta$, and, as $u = y$, $\beta = y$, and $DF = DC$. Therefore, since $DF (DC) : MC :: DL : ML$, DL will be to $ML :: DP : PM$; and, therefore, $DL : DP :: ML : PM$. Hence, because $DL > DP$, and $ML > PM$; and, therefore, ML much greater than PM , the distance of the image from the centre is greater, but from the tangent less than half the semidiameter; and the image is nearer to the tangent than the centre.

Hence, also, the distance of the object from the tangent is greater than that of the image, and, consequently, the object is farther distant from the speculum than the image.

3. If the arc BD (*fig. 8.*) intercepted between the point of incidence D , and the cathetus AB ; or the angle C , formed in the centre of the mirror by the cathetus of incidence AC , and that of obliquation FC , be double the angle of incidence, the image B will appear on the surface of the speculum.

4. If the arc intercepted between the point of incidence and the cathetus; or the angle C , formed in the centre of the mirror by the cathetus of incidence, and the cathetus of obliquation, be more than double the angle of incidence, the image will be without the mirror.

5. If the arc intercepted between the point of incidence, and the cathetus; or the angle, formed in the centre of the mirror by the cathetus of incidence, and that of obliquation, be less than double the angle of incidence, the image will appear within the speculum.

6. In a convex mirror, a remoter point A (*fig. 9.*) is reflected from a point F , nearer the eye O , than any nearer point B in the same cathetus of incidence.

Hence, if the point of the object A be reflected from the point of the mirror F , and the point of the object B from the point of the mirror E ; all the intermediate points between A and B will be reflected from the intermediate points of the speculum between F and E ; and, consequently, FE will be the line that reflects AB .

Hence, also, a point of the cathetus B seems at a greater distance Cb from the centre C , than a more remote one, A .

7. A nearer point B (*fig. 10.*) not in the same cathetus with a remoter H , is reflected to the eye O , from a nearer point of the speculum, than the remoter H .

Hence, if the point of an object A be reflected from the point of a mirror C , and the point of the object B from the point of the speculum D , all upon the same point O ; all the intermediate points between A and B will be reflected from all the intermediate points between C and D . Consequently, the image FG of the object BA is contained between the cathetus BE and AE .

8. In a spherical convex mirror the image is less than the object.

And hence the use of such mirrors in the art of painting, where objects are to be represented less than the life.

9. In a convex mirror, the more remote the object the less its image; and, again, the smaller the mirror the less the image.

10. In a convex mirror, the right hand is turned to the left, and the left to the right; and magnitudes perpendicular to the mirror appear inverted.

11. The image of a right line, perpendicular to the mirror, is a right line; but that of a right line either oblique to the mirror, or parallel to it, is convex.

12. Rays reflected from a convex mirror diverge more than if reflected from a plane mirror.

Hence light, by being reflected from a spherical mirror, is weakened; and, consequently, the effects of reflected light are weaker than those of direct. Hence, also, myopes see remote objects more distinctly in a convex mirror, than they do directly.

Rays reflected from a convex mirror of a smaller sphere diverge more than those reflected from a larger. Consequently, the sight is more weakened, and its effects are less considerable in the former case than in the latter.

MIRRORS, *Concave*, are those whose surface is concave. These are generally made of a mixed metal.

Note, by *concave*, authors commonly mean *spherically concave*.

MIRRORS, *Manner of preparing or making Concave*. First, a mould is to be provided for casting them. In order to this, take clay well dried, pulverize and sift it; mix it up with water, and then strain or filter it; with this work up horse-dung, and hair shred small, till the mass be sufficiently tough; to which, on occasion, may be added charcoal-dust, or brick-dust, well sifted.

Two coarse moulds are then prepared of a gritty stone, the one concave the other convex; which are to be ground by one another with wet sand between, till such time as the one perfectly fits the other. By this means, a perfect spherical figure is acquired.

The mass, prepared before, is now to be extended on a table, by means of a wooden roller, till it be of a thickness proper for the mirror; and then being strewed with brick-dust to prevent its sticking, it is laid over the convex mould, and so gets the figure of the mirror. When this is dry, it is covered with another lay of the same mass; which once dried, both the covers, or segments of the clay, are taken off. The innermost of the two being laid aside, the stone mould is anointed with a pigment prepared of chalk and milk, and the outer cover again put over it.

Lastly, the joining being covered over with the same clay of which the cover is formed, the whole mould is bound together with an iron wire, and two holes are cut through the cover, the one for the melted matter of the mirror to be poured through, the other for the air to escape at, to prevent the mirror's being spoiled with bubbles.

The mould being thus prepared, eight parts of copper, one

one of English tin, and five of bismuth, are melted together; a little of the mixture is taken out with a ladle, and if it be too red, when cold, more tin is put in; if too white, more copper; the mass is then poured into the mould before prepared, and so assumes the figure of a mirror.

Some with ten parts of copper mix four of English tin, and a little antimony and sal ammoniac, stirring the mass about a long time any fumes arise in it: others have other compositions, many of which are described by Schottus and Zahnus.

The mirror, being thus cast, is cemented to a wooden frame, and thus worked to and fro over the convex side of the mould, first with water and sand, and, lastly, without sand till it be fit for polishing; the same mould is then covered with paper, and that is smeared over with tripoli dust, and calx of tin, over which the mirror is worked to and fro till it has got a perfect polish. And in the same manner are glass mirrors polished, excepting that the convex surface is there worked in the concave mould. When the mirrors are very large, they are fixed on a table, and first ground with a gritty stone, then with pumice, then with fine sand, by means of a glass cemented to a wooden frame; and, lastly, they are rubbed with calx of tin, and tripoli dust, on a wet leather.

For concave mirrors of glass, the mould is usually made of alabaster; the rest is as in metal mirrors. See SPECULUM, GRINDING, and POLISHING.

MIRRORS, *Laws and Phenomena of Concave.* 1. If a ray, as KI (fig. 11.), fall on a concave mirror EI , under an inclination of 60 degrees, and parallel to the axis AB , the reflected ray IB will concur with the axis AB , in the pole of the glass B . Since $m = 60^\circ$, n also will be $= 60^\circ$, and because KI is parallel to the axis AB , $i = 60^\circ$, and $u = 60^\circ$; therefore $CB = CI$, the radius. Consequently the point B , in which the reflected ray IB concurs with the axis, is in the surface of the speculum. If the inclination of the incident ray be less than 60 degrees, as that of EH , the reflected ray EF will concur with the axis at the distance BF , which is less than a fourth part of the diameter. Since $o = x$, and, on account of the parallels HE and AB , $o = y$, we shall have $x = y$, and, therefore, $EF = FC$; but $CF + EF > EC$, and $CE = CB$; therefore $CF + EF > CB$; consequently $CF > FB$; *i. e.* FB is less than half the radius CB , or a fourth part of the diameter. And, universally, the distance of the point F , in which the ray HE concurs with the axis, from the centre C , is to half the radius CD in the ratio of the whole sine, to the cosine of inclination. For by the last demonstration it appears, that FE is $= FC$; therefore if from F a perpendicular FD be let fall on EC , LC will be $= \frac{1}{2} CE$; but if CF be taken for the whole sine, CD will be the sine of the angle DFC , or the cosine of the angle DCF ; *i. e.* of the inclination DEH ; and, therefore, CF is to CD as the whole sine is to the cosine of the inclination.

Hence it is inferred, by calculation, that in a concave spherical mirror, whose breadth subtends an angle of six degrees, parallel rays meet, after reflection, in a part of the axis less than the one thousand four hundred fifty-seventh part of the radius; if the breadth of the concave mirror be 12, 18, 24, 30, 36 degrees; the part of the axis in which the parallel rays meet, after reflection, is less than $\frac{1}{363}$, $\frac{1}{106}$, $\frac{1}{56}$, $\frac{1}{37}$, $\frac{1}{26}$, the radius.

And on this principle it is, that burning glasses are formed.

For since the rays diffused through the whole surface of the concave mirror, after reflection, are contracted into a very small compass, the light and heat of the parallel rays

must be prodigiously increased thereby; *viz.* in a duplicate ratio of the breadth of the mirror, and the diameter of the circle in which all the rays are collected; and hence the sun's rays are, as to any purposes on earth, parallel to us, wonder that concave mirrors should burn with so much violence.

From this same principle is likewise deduced a method of representing the images of objects in a dark room; which see under CAMERA *obscura*.

2. A lucid body being placed in the focus F , of a concave mirror EI (fig. 12.), the rays, after reflection, become parallel. For parallel rays are by reflection united to a focus; but if the luminous body b be in the focus F , that which was before the reflected ray IF will be now the incident ray, and *vice versa*; therefore the reflected ray IE will now become parallel to the axis AB , and all the reflected rays parallel to one another.

Hence an intense light may be projected to a vast distance, by a lighted candle, &c. placed in the focus of a concave mirror.

Hence also, if the parallel rays be received by another concave mirror, they will again concur in its focus, and burn.

Zahnus mentions an experiment of this kind made at Vienna, where two concave mirrors, the one six, the other three feet diameter, being placed about twenty-four feet apart, with a live coal in the focus of the one, and a match and tinder in the other, the rays of the coal lighted the tinder.

3. If a lucid body be placed between the focus F (fig. 13.) and the mirror HBC , the rays, after reflection, will diverge from the axis BA . If the lucid body were in F , the reflected ray CE would be parallel to the axis AB , and, therefore, it would constantly preserve the same distance from the axis. But since $DCG > FCG$, KCG will be $> ECG$; and, therefore, CK will fall beyond CE , and cannot be parallel to the axis, but must continually diverge from the axis, the distance from it increasing; whence it follows, that light is weakened by reflection.

4. If a lucid body be placed between the focus F , and the centre G , as in I , the rays, after reflection, will meet in the axis beyond the centre. In this case $IHG < FHG$, and, therefore, $GHA < GHL$; consequently, the reflected ray HA recedes from the parallel towards the axis, and its distance from the axis will be continually diminished, till at length it concurs with the axis. But if the lucid body be placed in A , that which was before the reflected ray AH will now become the incident ray, and *vice versa*. If, therefore, the lucid body be placed beyond the centre G , the rays after reflection will concur with the axis between the focus F and centre G .

Hence, if a candle be placed in I , the image will appear in A ; if it be placed in A , its image will be in I : in the intermediate points between I and A , the section of light will be a circle; and that so much the greater, as it is nearer the point of concurrence.

5. If a luminous body be placed in the centre of the mirror, all the rays will be reflected back upon themselves; for as they fall perpendicularly on the speculum, they will be reflected into themselves.

Hence, if the eye be placed in the centre of a concave mirror, it will see nothing but itself, and that confusedly through the whole mirror.

6. If a ray falling from the point of the cathetus b (fig. 14.) on the convex mirror bF , be, together with its reflex IF , continued within the concavity of the mirror, FH will be the incident ray from the point of the cathetus H , and FO its reflex. For $bFE = IFM$; but $bFE = M$

$= M F O$, and $I F M = E F H$; therefore $M F O = E F H$; and, consequently, if $H F$ be taken for the incident ray from the point H , $F O$ will be the reflected ray.

Hence, since the point of the cathetus H is the image of the point h in the convex mirror, but the point h the image of H in the concave; if the image of an object, reflected by a convex speculum, be seen by a reflection made in its concavity, it will appear like the object itself.

And since the image of an infinite cathetus is less in a convex glass than one-fourth of its diameter; a portion of the cathetus, less than a fourth part of the diameter, may appear of any magnitude required in a concave one. A point, therefore, distant from a concave speculum less than one-fourth of the diameter, must appear behind the mirror at any distance, how great soever.

Since the image of any object, how broad soever, is contained in a convex speculum, between the two lines of incidence of its extreme points; if an object be placed between the two lines, at a distance less than one-fourth of its diameter, the breadth of the image, how great soever, may all appear.

Since then the image of an object included between two lines, at a distance less than one-fourth of the diameter, may exceed the just height and breadth of the object; nay, may be made of any magnitude, how big soever; objects placed between the focus and mirror must appear of enormous magnitudes in concave mirrors; the image being so much the greater in the concave mirror, as it is less in the convex.

In a convex mirror, the image of a remote object appears nearer the centre than that of a nearer object: therefore, in a concave mirror, the image of an object remote from the mirror appears at a greater distance than that of a nearer object, provided the distance of the object from the centre be less than a fourth part of the diameter.

In a convex speculum, the image of a remote object is less than that of a near one: therefore, in a concave one, the image of an object placed between the focus and the mirror, is nearer the focus than the speculum.

The image, therefore, of an object receding continually from a concave speculum, becomes continually greater, provided it do not recede beyond the focus, where it becomes confused; and as it approaches, it grows continually less. In a convex speculum, if the sphere, of which it is a segment, be smaller, the image is smaller than in another of a larger sphere: therefore in a concave, if the sphere, of which it is a segment, be smaller, the image will be larger than in another whose sphere is larger: whence concave mirrors, if they be segments of very small spheres, will do the office of microscopes.

7. If an object $A B$ (*fig. 15.*) be placed between a concave mirror and its focus, its image will appear behind the mirror in an inverted situation. Let $A B$ be the length of the object: since the point A is seen in the cathetus $C a$, and the point B in the cathetus $C b$, the higher point is seen in the higher place a , and the lower in the lower b ; or the object appears behind the mirror in an erect situation. But if $A B$ represent the breadth of the object, it appears in the same manner that the part to the right corresponds with the right, and the left to the left, both of the object and image. However, in direct vision the right hand part of an object corresponds to the left of the spectator, and the left to the right; and, therefore, in a concave speculum, the parts to the left hand of an object between the focus and speculum appear to the right, and the right to the left.

8. If an object $A B$ (*fig. 16.*) be placed between the focus and the centre, its image $E F$ will appear inverted, and in the open air, beyond the centre, the eye being placed

beyond the centre. For the rays, by which the point A is reflected, concur in the cathetus $G F$, beyond the centre C in F , and those by which the point B is reflected, concur in the cathetus $D F$, beyond the centre C in E ; therefore the point B radiates on the eye placed beyond $E F$ as from E , and the point A as from F ; consequently B is seen in E , and A in F , and the image of the object is seen beyond the centre in an inverted position. 9. If an object $E F$ be placed beyond the centre C , and the eye likewise beyond the centre, the image will appear inverted in the open air, between the centre and the focus. Hence, the inverted images of objects placed beyond the centre, are reflected by a concave mirror, erect; and may be received on a paper applied between the centre and the focus, especially if the room be dark; if the object $E F$ be farther distant from the centre than the focus, the image will be less than the object; because $A C$ is less than $E C$, and, therefore, $A B < E F$.

On this principle, concave mirrors, especially those which are segments of large spheres, and are capable of reflecting entire objects, exhibit many pleasing phenomena. Thus, if a man flourish his sword against the mirror, another comes out of it, and meets him with the same motions; and the image of his head coming out of the mirror, if he strike with his real sword, the imaginary sword will strike his real head. If he stretch out his hand, another hand will be stretched out of the mirror, and meet it at a great distance in the open air, &c. And on the same principle are constructed catoptric cistulae, which, when looked into, exhibit images much bigger than the chest. See CATOPTRIC CISTULA.

10. The image of a right line, perpendicular to a concave mirror, is a right line; but all oblique or parallel lines are concave. For since every point of a line perpendicular to the speculum is in the cathetus of incidence, its image will of course be a right line. But if $A B$ (*fig. 15.*) be parallel, or oblique to the speculum, and $C F$ be drawn from the centre C perpendicular to $A B$, $C A$ will be greater than $C D$; and, therefore, as $C F = C E$, $F D > A E$; consequently the point D will appear farther behind the speculum than A . Therefore, since c is farther distant from D , than a from A , and b from B , the image $a c b$ will appear concave.

MIRRORS, *Cylindrical, Conical, Parabolical, and Elliptical*, or specula, are those terminated by a surface respectively cylindrical, conical, parabolical, and spheroidal.

To prepare, or make, *cylindrical, conical, parabolical, elliptical, and hyperbolical Mirrors.*—For the *cylindrical and conical* sort, if they are to be of glass, the method of preparing them is the same as that already laid down for convex mirrors.

If of metal, they are to be made after the manner of concave mirrors, only that the clay moulds there described require other wooden ones of the figure of the mirror.

For *elliptical, parabolical, and hyperbolical* mirrors, the mould is to be thus prepared. On a wooden or brazen plane or table, describe the figure of an ellipse $A B$ (*fig. 17.*) a parabola, or an hyperbola, $C D$ (*fig. 18.*) after the manner taught under those heads; which done, cut out the figure from the plane with all the accuracy imaginable.

To the elliptic figure fit an axis, as $E F$, with two fulcra to sustain it, &c. and a handle to move it; lay a quantity of the clay, above described, under it; and turn about the axis by the handle, till the plane $A B$ hath turned, or impressed the elliptical figure exactly upon it.

The axis of the parabolical or hyperbolical figure $C D$, is to be fixed at the vertex E in such a manner as that it may

may always remain erect; this is to be turned about as above, till it hath given its own figure to the clay applied about it. The part of the mould, thus formed, is to be dried, and either smeared over with fat, or sprinkled with brickdust; then a convex mould is to be made, by putting a quantity of the same clay into the cavity thus formed. This latter is called the *male*, as the former the *female* mould. The male mould, being well dried, is to be applied within the female, in such a manner, as only to leave the intended thickness of the mirror between them. The rest as for concave mirrors.

These mirrors are not made without the utmost difficulty; because, if the moulds be ever so just, the figure of the mirror is apt to be damaged in the grinding. See SPECULUM.

MIRRORS, *Phenomena, or Properties of Cylindrical.* 1. The dimensions of objects corresponding lengthwise to the mirror are not much enlarged; but those corresponding breadthwise have their figures altered, and their dimensions lessened so much the more, as they are farther from the mirror; whence arises a very great distortion.

2. If the plane of reflection cut the cylindrical mirror through the axis, the reflection is performed in the same manner as in a plane mirror; if it cut it parallel to the base, the reflection happens in the same manner as in a spherical mirror; if, lastly, it cut it obliquely, or be oblique to its base, the reflection is the same as in an elliptical mirror. Hence, as the plane of reflection never passes through the axis of the mirror, except when the eye and objective line are in the same plane; nor parallel to the base, except when the radiant point and the eye are at the same height, the reflection, in a cylindrical mirror, is usually the same as in an elliptical one.

3. If a hollow cylindrical mirror be opposed directly to the sun, instead of a focus of a point, the rays will be reflected into a lucid line, parallel to its axis, at a distance somewhat less than a fourth part of its diameter.

Hence arises a method of drawing anamorphoses, *i. e.* wild, deformed figures, on a plane, which appear beautiful and well proportioned, when viewed in a cylindrical mirror.

MIRRORS, *as for Elliptic, Parabolic, Conic, and Pyramidal,* we are not much acquainted with their properties: only that in the first, if a ray strike on it from one of its focuses, it is reflected into the other; so that a lighted candle being placed in one, its light will be collected in the other. That the second, inasmuch as all the rays they reflect meet in one point, make the best burning-glasses of all others.

And, lastly, that wild, irregular figures, may be so drawn on a plane, as that, the eye being placed over the axis of the two last, they shall appear beautiful, and well proportioned. (See ANAMORPHOSIS.) For further particulars respecting the theory, materials, construction, and use of mirrors, see GLASS, GRINDING, LENS, MICROSCOPE, SPECULUM, and TELESCOPE.

MIRSERAI, in *Geography*, a town of Persia, in Khorasan; 12 miles W. of Sebzar.

MIRZAGUNGE, a town of Hindoostan, in Bengal; 27 miles S.S.E. of Mahmudpour.

MIRZAPOUR, a town of Hindoostan, in Bengal; 75 miles S.S.E. of Mahmudpour.—Also, a town of Hindoostan, in Bengal: 12 miles S.W. of Kithenagur.—Also, a town of Hindoostan, in Oude; 33 miles N.E. of Kairabad.—Also, a town of Hindoostan, in Allahabad; 41 miles S.E. of Allahabad. N. lat. 25° 10'. E. long. 82° 49'.

MIRZIN, or WOLCIN, a town of Moravia, in the circle of Iglau; 12 miles E. of Iglau.

MIS, a particle prefixed to divers words, particularly

law terms; denoting some default or defect. As, in *misprision*; *misdicere*, to scandalize one; *misdocere*, to teach amiss, &c.

MISA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 43° 43'. E. long. 13° 12'.

MISAGNO, a town of Naples, in the province of Otranto; seven miles S.W. of Brindisi.

MISANDRA, in *Botany*, Juss. 4-5, one of Comberford's fanciful names, the application of which is not very clear to us. It seems to imply that he was displeas'd at meeting every where with a superabundance of the male plants of this kind, in the straits of Magellan, and only once with the females, so that he was long unable to judge of the genus; at least this appears to be the conjecture of Jussieu. See GENERA.

MISANI, in *Geography*, a town in the island of Corsica; six miles W. of Cervione.

MISANTHROPY, *μισανθρωπία*, formed of *μισος*, *hatred*, and *ανθρωπος*, a man, a general dislike or aversion to man, and mankind. In which sense it stands opposed to *philanthropy*, or the love of mankind.

MISAPA, in *Geography*, a river of Mexico, which runs into the gulf of Mexico, N. lat. 18° 12'.

MISARA, a town of Egypt, on the left bank of the Nile; 12 miles S. of Melau.

MISADVENTURE, or MISADVENTURE, *Homicide by Law*. See HOMICIDE.

In the case of misadventure, the law presumes negligence, or at least a want of sufficient caution in him who was so unfortunate as to commit it; who, therefore, is not altogether faultless. The penalty inflicted by our laws is said by Sir Edward Coke to have been anciently no less than death; though others affirm, with greater reason, that it consisted in a forfeiture, as some say, of all the goods and chattels; according to others, of only part of them, by way of fine or wergild: which was probably disposed of, as in France, for pious uses, or for the benefit of the soul of the deceased. However, the delinquent has now, and has had as early as our records will reach, a pardon, and writ of restitution of his goods as a matter of course and right, only paying for suing out the same; and, to prevent this expence, in cases where the death has notoriously happened by misadventure, or in self-defence, the judges will usually permit, if not direct, a general verdict of acquittal. See HOMICIDE.

Stauford distinguishes between *aventure* and *misadventure*. The first he makes to be mere chance: as if a man, being upon or near the water, be taken with some sudden sickness, and so fall in, and be drowned; or into the fire, and be burnt.

Misadventure, according to him, is when a man comes to his death by some outward violence; as the fall of a tree, the running of a cart-wheel, the stroke of a horse, or the like.

MISCANELLO, in *Geography*, a town of Naples, in Basilicata; 26 miles S.E. of Potenza.

MISCARRIAGE, in *Midwifery*, the birth, or exclusion of a fœtus from the womb before it has attained its maturity.

By some writers, the word miscarriage is confined to deliveries, or births happening before the end of the sixth or seventh month, or before the child has acquired so much strength as to give it a chance of living. Children born in the eighth or early in the ninth month, are only said to have come before their time. (See ABORTION, and CONCEPTION.) The failure in an attempt to perform any thing is also called a miscarriage.

MISCELLANÆÆ, in *Botany*, a name given by Linnæus to the 54th of his Natural Orders, and which well expresses the heterogeneous nature of that order, as it stands at the end of his *Genera Plantarum*, where such various genera are brought together, that his leading idea in this assemblage can hardly be traced. They stand under eight heads, as follows.

1. *Refida, Datifca.*
2. *Poterium, Sanguiforba.*
3. *Pistia, Lemna.*
4. *Coriaria*; and *Empetrum* with a mark of doubt.
5. *Achyranthes, Celofia, Amaranthus, Irefine, Gomphrena, Phytolacca*
6. *Nymphæa, Sarracenia.*
7. *Cedrela, Swietenia.*
8. *Telephium.*

In the *Prælectiones in Ord. Nat. Plantarum*, published from the notes of Giseke and Fabricius, p. 594, this catalogue is much diminished, and the 54th order consists of only the first four of the above sections, without any remark or explanation.

The manuscript notes of Linnæus, to his own *Genera Plantarum*, here afford us some assistance. He has there referred the second section of the above list, very justly, to his 35th order, *Sciticeæ*, before *Agrimonia*.

The third section he removes to ord. 15, *Inundata*, which is but a slight improvement.

The fifth goes with great propriety to his *Holeraceæ*, ord. 12th.

The sixth to his *Rhœadææ*, ord. 27th, with a question whether the genera here mentioned be not more akin to *Afarum* and his 11th order, *Sarmentaceæ*; under which last however he has expressed a suspicion that *Arisfölochia, Afurum* and *Cytinus* may rather belong, with *Nymphæa*, to the 27th.

The seventh section he reduces to his *Tribilateæ*, ord. 23d, and *Telephium*, which alone makes the eighth, is removed to the *Holeraceæ*.

MISCELLANÆÆ is also the name of an order of the *Cryptogamia*, according to Schreber, in his *Gen. Pl.* 753. Under it he comprehends *Equisetum, Lycopodium, Porella, Salvinia, Marsilea, Pilularia*, and *Isetes*. These have little affinity, and the order can be considered merely as a receptacle for what could not well be placed elsewhere, as its name seems to imply.

MISCHARON, in *Geography*, a town of Persia, in the province of Irak; 111 miles S.E. of Hamadan.

MISCHIEF, *Malicious*, or *Damage*, in *Law*, is a species of injury to private property, which the law considers as a public crime. This is such as is done, not *animo furandi*, or with an intent of gaining by another's loss; but either out of a spirit of wanton cruelty, or diabolical revenge. Any damage arising from this mischievous disposition, though only a trespass at common law, is now by a multitude of statutes made penal in the highest degree. 22 Hen. VIII. c. 11. 43 Eliz. c. 13. 22 & 23 Car. II. c. 7. 4 & 5 W. & M. c. 23. 1 Ann. stat. 2. c. 9. and 4 Geo. I. c. 12. 12 Ann. stat. 2. c. 18. 1 Geo. I. c. 48. 6 Geo. I. c. 25. 9 Geo. I. c. 22. (See *BLACK AB.*) 6 Geo. II. c. 37. 10 Geo. II. c. 32. 28 Geo. II. c. 19. 6 Geo. III. c. 36. and 48. and 13 Geo. III. c. 33. 9 Geo. III. c. 29. 13 Geo. III. c. 38. See *FELONY*.

MISCHKA, in *Geography*, a river of Russia, in the country of the Cossacks, which runs into the Don, near Verchnei Tchirkovskaja.

MISCHKIN, a town of Russia, in the government of

Jaroslavl; 60 miles W. of Jaroslavl. N. lat. 58° 42'. E. long. 40° 22'.

MISCHNA, or MISINA, from מִשְׁנָה, *iteravit*, a part of the Jewish Talmud.

The Mischna contains the text; and the Gemara, which is the second part of the Talmud, contains the commentaries; so that the Gemara is, as it were, a glossary on the Mischna.

The Mischna consists of various traditions of the Jews, and of explanations of several passages of scripture; these traditions, serving as an explication of the written law, and supplement to it, are said to have been delivered to Moses during the time of his abode on the Mount; which he afterwards communicated to Aaron, Eleazer, and his servant Joshua. By these they were transmitted to the seventy elders, by them to the prophets, who communicated them to the men of the great sanhedrim, from whom the wise men of Jerusalem and Babylon received them. According to Prideaux's account, they passed from Jeremiah to Baruch, from him to Ezra, and from Ezra to the men of the great synagogue, the last of whom was Simon the Just; who delivered them to Antigonus of Socho; and from him they came down in regular succession to Simeon, who took our Saviour in his arms; Gamaliel, at whose feet Paul was educated, and last of all to Rabbi Judah the Holy, who committed them to writing in the Mischna. But Dr. Prideaux rejecting this Jewish fiction, observes, that after the death of Simon the Just, about two hundred and ninety-two years before Christ, the Mischnial doctors arose, who, by their comments and conclusions, added to the number of those traditions, which had been received and allowed by Ezra, and the men of the great synagogue; so that towards the middle of the second century, after Christ, under the empire of Antoninus Pius, it was found necessary to commit these traditions to writing; more especially as their country had considerably suffered under Adrian, and many of their schools had been dissolved, and their learned men cut off; and, therefore, the usual method of preserving their traditions had failed. Rabbi Judah, on this occasion, being rector of the school of Tiberias, and president of the sanhedrim in that place, undertook the work, and compiled it in six books, each consisting of several tracts, which altogether make up the number of sixty-three. (Prid. Connect. vol. ii. p. 468, &c. ed. 9.) This learned author computes that the Mischna was composed about the 150th year of our Lord; but Dr. Lightfoot says, that Rabbi Judah compiled the Mischna about the year of Christ 190, in the latter end of the reign of Commodus; or, as some compute, in the year of Christ 220. Dr. Lardner is of opinion that this work could not have been finished before the year 190, or later, and he thinks that it is placed soon enough at the year 180. (Collect. of Jewish and Heathen Testimonies, &c. vol. i. p. 178.) Others, however, apprehend, that the Mischna was not committed to writing till near the middle of the fifth century, alleging that St. Austin, who died in the year 430, says expressly (Cont. Advers. Leg. and Proph. lib. ii. c. 1.) that the Jewish traditions were not in writing. And yet that it was written before 500 seems evident, because in 548 Justinian interdicted the use of it in the synagogues. Kennicott's State of the Hebrew Text, vol. ii. p. 443.

Thus the book called the Mischna was formed; a book which the Jews have generally received with the greatest veneration. The original has been published, with a Latin translation, by Surenhufius, with notes of his own, and others from the learned Maimonides, &c. in 6 vols. folio, Amsterd. A.D. 1698—1703. See *TALMUD*.

It is written in a much purer style, and is not near so full of dreams and visions, as the Gemara.

MISCIANO, in *Geography*, a town of Naples, in the province of Otranto, 8 miles W.S.W. of Brindis.

MISCO, or MISKO. See MIXCO.

MISCONTINUANCE, in *Law*, the same with discontinuance.

MISCOPIHINS, in *Geography*, a small tribe of Indians who inhabit between lake Michigan and the Mississippi.

MISDEMEANOUR, or MISDEMISSION, in *Law*, an offence, or fault, particularly when in the execution of an office. See CRIME.

High crimes and misdemeanours denote offences of a heinous nature, next to high treason.

MISE, a French term, literally denoting expense, or disbursement: it is used in our law-books in divers acceptations. Sometimes for the profits of lands; sometimes for taxes, or tallages; and sometimes for expenses, or costs: as *pro misis & custodiis*, for colls and charges in the entries of judgments, &c.

Mise more peculiarly denotes an honorary gift, or customary present, with which the people of Wales used to salute every new king and prince of Wales, at their entrance upon the principality.

Anciently, the mise was given in cattle, wine, corn, &c. for the support of the prince's family; but when that dominion was annexed to the English crown, the gift was changed into money. The county of Flint paid two thousand marks, &c. for the mise.

The county of Cheshir also paid a mise or tribute of five thousand marks at the change of every owner of the said earldom, for enjoying the privilege of that palatinate. At Cheshir they have a mise-book, in which every town and village in the county is rated what to pay towards the mise.

Mise is also used in speaking of a writ of right. What in other actions is called an *issue*, in a writ of right is called a *mise* or *me*: so that *to join the mise upon the mere*, is as much as to say, to join issue on the mere right, *i. e.* to join upon this point, whether the tenant or demandant has the more right.

Yet even in a writ of right, if a collateral point be tried, it is there called an *issue*, not a *mise*. See ISSUE.

Mise is also sometimes used corruptly for *meuse*, a messuage or tenement.

In some manors, a *mise* or *meuse* place is taken for such a messuage or tenement as yields the lord an heriot at the death of the tenant.

MISELAR, in *Geography*, an island in the East Indian sea, of an irregular form, 18 miles long and five broad, near the W. coast of Sumatra. N. lat. 1° 28'. E. long. 97° 56'.

MISEN, MISSEN, or MIZEN, in a *Ship*, denotes either the mast, or sail of that name; but at sea, they always mean the sail when the word *mizen* is used.

This is the hindmost of the fixed sails of a ship, extended sometimes by a gaff, and sometimes by a yard, which crosses the mast obliquely; the fore-end reaching always down to the deck, and the after-end being pecked up as high above the middle of the yard, where it is attached to the mast. The figure of the mizen is a trapezium, or parallelogram, one of whose corners is cut off by a diagonal, extended from one of its sides to the opposite corner, which becomes the peck of the mizen. Some great ships require two mizens; in which case that next the main-mast is called the *main-mizen*, and that next the poop the *behaveventure mizen*.

The use of the mizen is, to keep the ship close to a wind; wherefore if a ship is apt to gripe too much, they use no mizen. But it is often used when a ship rides at anchor, to back her a-stern; so that she may not foul her anchor, on the

turning of the tide; and sometimes a ship lies a-try with her mizen only.

MIZEN *mast* is the mast upon which the mizen and its top-sail and stay-sails are supported, besides other sails, which are set occasionally, as the driver, ring-tail, &c. See MAST.

MIZEN, *Change the*, is an order to bring the mizen-yard over to the other side of the mast. *Peek the mizen*, *i. e.* put the mizen right up and down the mast.

MIZEN, *Set the*, at *Sea*, the word of command to fit the mizen-sail right as it should stand. *Spell the mizen*, *i. e.* let go the sheet, and peek it up.

MIZEN-*Ship*, in a *Ship*. See STAY.

MIZEN-Yard. See YARD.

MISENO, CAPE, in *Geography*, a cape on the N. side of the gulf of Naples. N. lat. 45° 48'. E. long. 13° 52'.

MISERE, a river of America, which runs into lake Superior, N. lat. 46° 14'. W. long. 89° 3'.

MISERERE, *have mercy*, the name, and first word of one of the penitential psalms; being that commonly given by the ordinary to such condemned malefactors as are allowed the benefit of the clergy: whence it is also called the *psalm of mercy*.

It is also the first word in the Latin translation of the 51st psalm, and has been elaborately set to music by all the great composers of the Romish church, from Palestrina to Jomelli and Haydn; but no miserere has been so celebrated as that composed by Gregorio Allegri, for the pontifical chapel at Rome, in 1629; which has continued to be solemnly and exquisitely performed there on Wednesday in Passion week, and on Good Friday. See ALLEGRI, JOMELLI, and Burney's Present State of Music in France and Italy.

MISERERE *Mei*, denotes a kind of colic, or disorder of the intestines, in which the excrements, instead of passing off the common way, are often thrown up by the mouth. The *miserere mei* is the same with what we otherwise call *volvulus*, and *iliac passion*.

MISERICORDE, CULTELLUM, in *Ancient Armour*, the name of the dagger, which was the constant companion of the sword, at least from the days of Edward I., and is mentioned in the statute of Winchester. Its appellation of misericorde is derived by Fauchet, the French antiquary, either from its being used to put persons out of their pain, who were irrecoverably wounded, or, from the sight of it causing those knights who were overthrown to cry out for quarter or mercy. After the invention of fire-arms, daggers were screwed into the muzzles of the muskets, to answer the present purpose of the bayonet.

MISERICORDIA, MERCY, in *Law*, an arbitrary amerceiement, or punishment imposed on any person for an offence.

Where the plaintiff or defendant in any action is amerced, the entry is always *ideo in misericordia*.

It is thus called, according to Fitzherbert, because it ought to be but small, and less than the offence, according to the tenor of Magna Charta.

"Multa lenior sic dicta, quod lenissima imponitur misericordia; gravior enim multas lines vocant; atrocissimas, redemptiones." See FINE and REDEMPTION.

Hence, if a man be unreasonably amerced in a court not of record, as a court baron, &c. there is a writ called *moderata misericordia*, directed to the lord, or his bailiff, commanding them to take moderate amerceiements.

MISERICORDIA *communis*, is when a fine is set on the whole county, or hundred.

MISERICORDIA *in cibus & potu*, in our *Old Writers*, is used for any gratuitous portion of meat and drink, given to the religious

ligious in convents beyond their ordinary allowance. (Matt. Paris.) And in some convents they had a slated allowance of these over-commons upon extraordinary days, which were called *miseri cordiæ regulares*.

MISERREPOUR, in *Geography*, a town of Hindooſtan, in Dooab; 15 miles N.W. of Etayah.

MISERY, an iſle between Salem and Cape Ann, in Maſſachuſetts.

MISFEASANCE, in *Law*, a miſdeed or treſpaſs. Whence alſo *miſfeafor*, a treſpaſſer.

MISFORTUNE. See CHANCE.

MISGUM, in *Ichthyology*, the name of a fiſh of the anguilliform kind, but broader and flatter than the eel, and of much the ſame ſize from the head to the tail; it has five black lines, one on the back, two, which are ſomewhat broader, in the middle of the ſides, and two others, which are narrower lower down; theſe are all extended from the head to the tail; the intermediate ſpaces, and the belly, are of a ſomewhat blueiſh-white, dotted with black ſpots; the fins are alſo ſpotted in the ſame manner; the mouth is ſmall and round like that of the lamprey, and is ſurrounded with beards, ſix on the upper jaw, and four on the under; and there are two other very ſlender ones near the noſtrils; the eyes are ſmall; the gills four on a ſide; and beſide the back fin there are four, two near the gills, and two lower on the body. This is a common fiſh about the German ſhores, and is eſteemed a very delicate one at the table; it lays its ſpawn in March, and is in beſt ſeaſon for eating in January and February. It is caught principally in ſtanding and muddy waters; and it is ſaid, that when out of water, it makes a ſort of hiſſing noiſe.

MISHNA. See MISCHNA.

MISIANO, in *Geography*, a town of Naples, in Calabria Ultra; 7 miles N. of Reggio.

MISILMARI, a town of Sicily, in the valley of Mazarà; 6 miles S.S.E. of Palermo.

MISITRA, the ancient *Sparta*, a town of European Turkey, in the Morea, defended by a caſtle on a rock, which is ſaid to be impregnable. The Chriſtians have ſeveral churches, one of which is reckoned the moſt beautiful in the world. The Jews have three ſynagogues, and the Turks have a ſuperb moſque and hoſpital. This town is the ſee of an archbiſhop, and the reſidence of a bey, an aga, and a waywode; and it contains 12,000 inhabitants. In 1770 it was taken by the Ruſſians; 40 miles S.S.W. of Argos. N. lat. 37° 10'. E. long. 22° 25'.

MISKERING, MISKERRING. See ABISHIERING.

MISKOTZ, in *Geography*, a town of Hungary; 30 miles W. of Tokay.

MISLAVA, a town of Hungary; 10 miles E. of Liſſebau.

MISLETOE. See MISTLETOE.

MISLIWECZEK, JOSEPH, in *Biography*, ſon of a miller in Bohemia, not far from Prague, a twin, born in 1737: the brothers reſembled each other ſo much, that their father was frequently uncertain to which of them he was ſpeaking. They were both brought up to the father's trade; but Joſeph in learning muſic at the common reading and writing ſchool, as all Bohemian children do, diſcovered uncommon genius and love for the art. And his father was ſcarcely dead before he quitted the miller's trade, and went to Prague, where he ſtudied muſic under the celebrated organiſt Segert with ſuch ſucceſs, that he ſhortly compoſed ſix ſymphonies, one each month, from January to June. Then, in 1763, he went to Venice, where he had leſſons from Piccette, and afterwards to Parma, where he compoſed his firſt opera, which ſucceeded ſo much, as to procure him a

call to Naples, where the opera of "Belerofonte" ſo eſta- bliſhed his reputation in Italy, that in the next ten years he brought nine operas on the ſtage; among which "Olimpiade," in 1778, was particularly admired, eſpecially the air, "Si circa ſi dice." Soon after the performance of Belerofonte, he went to Venice as a maſter, where he had been before only a ſcholar, and now was as well received as elſewhere. Then he removed to Pavia, and thence to Munich in 1779, and returned to Naples a ſecond time. About 1780, Fortune turned her back upon him: the opera of "Armida," which he ſet for Milan, was performed but once, in which almoſt every thing, except a bravura air for Marcheſi, was *ſſebiata* (hiſſed). Thence he went to Rome, where he had been un- fortunate before, and where he met with new diſgrace in 1781; in which city, after compoſing for different theatres of Italy 30 operas, beſides oratorios, and instrumental muſic of all kinds, he died, in 1782, in mortification and indigent circumſtances.

MISLOWITZ, in *Geography*, a town of Sileſia, in the lordſhip of Pleſz, on the borders of Poland; 32 miles W. of Cracow. N. lat. 50° 13'. E. long. 19° 5'.

MISNIA. See MEISSEN.

MISNOMER, compounded of *mis*, which in compo- ſition ſignifies *amiſs*, and *nomer*, to name, in *Law*, a wrong name, or the uſing of one name for another.

A miſnomer furniſhes one of the principal pleas in abate- ment.

MISOLOGIO, in *Geography*, a town of the Morea, in the paſhawite of Carnia, containing about 5000 in- habitants. It is ſituated on a ſwampy flat, ſcarcely above the level of the ſea. An extenſive ſhallow reaches along the coaſt for many miles, and is paled in for a meir, and kept in repair by the farmers of the fiſhery. This fiſhery was farmed in 1811 by forty perſons, who pay to the vizier Ali Paſhaw upwards of 3500*l.* ſterling. In Miſologio one of the prieſts teaches Greek, and the children, as in other parts of Greece, are taught writing, &c. by the parochial clergy. The inhabitants wear the Albanian dreſs, and though they grievouſly complain of the taxes, they admit the juſtice and vigour of Ali Paſhaw's government. The town has a ſmall fortification about two miles diſtant from the ſhore. The articles exported from Miſologio are ſimilar to thoſe which are uſually ſent from Patras and Lepanto. It has lately begun to ſend wool to Sicily, which wool is low priced, but not ſo inferior in quality as might be ſuppoſed from the rates at which it is ſold.

MISPACH, a town of Bavaria, in the lordſhip of Upper Waldeck; 27 miles S.S.E. of Munich.

MISPRISION, derived from the old French *meſpris*, a *neglect* or *contempt*, in *Law*, ſignifies a neglect or overſight, and is generally uſed to denote all ſuch high offences as are under the degree of capital, but nearly bordering upon them.

Miſpriſions are generally divided into two ſorts: negative, which conſiſt in the concealment of ſomething which ought to be revealed; and poſitive, which conſiſt in the commiſſion of ſomething which ought not to be done.

Miſpriſion of Clerks, is a neglect of clerks, in writing, or keeping records.

By the miſpriſion of clerks, no proceſs ſhall be annulled, or diſcontinued. And juſtices of aſſize ſhall amend the defaults of clerks miſ-ſpelling a ſyllable, or letter, in writing.

Miſpriſion of Felony, which is the concealment of a felony which a man knows, but never aſſented to, is puniſh- able, in a public officer, by ſtat. Weſtm. 1. 3 Ed. 1. c. 9. with imprifonment for a year and a day; in a common per- ſon

for with imprisonment for a less discretionary time; and in both with fine and ransom at the king's pleasure, declared by the judges in his courts of justice. Justices of the Common Pleas have a power to arrest any mercenaries upon persons offending by misprisions, contempts, or neglects, for not doing, or minding, any thing, in or concerning law.

MISPRISION of Treason, is a negligence in not revealing treason, where a person knows it to be committed.

It is enacted by Stat. 1 & 2 Ph. & Mar. c. 10 that a bare concealment of treason shall be only held a misprision; which concealment becomes criminal, if the party apprised of the treason does not, as soon as conveniently may be, reveal it to some judge of assize, or justice of the peace. (1 Hal. P. C. 372.) Besides, the statute 1 Eliz. c. 2. enact, that those who forge foreign coin, not current in this kingdom, their aiders, abettors, and procurers, shall all be guilty of misprision of treason. The punishment of misprision of treason is loss of the profits of lands during life, forfeiture of goods, and imprisonment during life. 1 Hal. P. C. 374.

The misprisions already recited belong to the class of those that are denominated negative. Misprisions, which are merely positive, are generally termed *contempts* or *high misdemeanours*. See **CONTEMPT**.

MISQUE Pocona, in *Geography*, a town of South America, in the viceroyalty of Buenos Ayres, and province of Santa Cruz de la Sierra; 100 miles S.S.W. of Santa Cruz.

MISQUI, a town of Peru; 60 miles N. of La Paz.

MISR *d'Attiké*, a town of Egypt, on the Nile, S. of Cairo, to which it is a kind of suburb.

MISS, a river of Carinthia, which runs into the Drave; five miles E. of Lavamand.

MISSA. See **MASS**.

MISSA *Pape Marcelli*, is the title of a celebrated mass in *Musick*, composed by Palestrina, and said to have prevented music from being banished the church. Concerning this production, it has been related by Antonio Liberati, in his famous letter to Ovidio Perfapeggi, and after him, by Adami, Bernardi, and other musical writers, that the pope and conclave having been offended and scandalized at the light and injudicious manner in which the mass had been long set and performed, determined to banish music in parts entirely from the church; but that Palestrina, at the age of twenty-six, during the short pontificate of Marcellus Cervinus, intreated his holiness to suspend the execution of his design till he had heard a mass, composed in what, according to his ideas, was the true ecclesiastical style. His request being granted, the composition, in six parts, was performed at Easter, 1555, before the pope and college of cardinals; who found it to grave, noble, elegant, learned, and pleasing, that music was restored to favour, and again established in the celebration of sacred rites. This mass was afterwards printed, and dedicated to the successor of Marcellus, pope Paul IV., by whom Palestrina was appointed maestro di cappella to the pontifical chapel.

The friends of choral music will doubtless be curious to have a faithful and minute account of a composition which had sufficient power to preserve their favourite art from disgrace and excommunication; and having before us an accurate score of it, which Signor Santarelli, the pope's maestro di capella, himself procured out of the archives of the Sistine chapel, where it is still performed, we can venture to assert, that it is the most simple of all Palestrina's works: no canon, inverted fugue, or complicated measures, have been attempted throughout the composition; the style is grave, the harmony pure, and by its facility the performer and hearer are equally exempted from trouble.

MISSEAL, *Misatit*, a mass ball, containing the several dances to be used on the several days, feasts, &c.

The Roman missal was first compiled by pope Gelasius, and afterwards reduced into better order by pope Gregory the Great; who called it the *book of sacraments*.

Each diocese, and each order of religious, have their particular missal, accommodated to the festivals of the province, or of the order.

MISSEALAND, in *Geography*, a river of Africa, which rises in Dar Far, and after a course of nearly 500 miles loses itself in the lake of Litré.

MISSEASAGA ISLAND, an island that lies opposite to the mouth of the river Trent in Upper Canada, and at the same distance from the portage at the head of the bay of Quinte.

MISSEASAGA River, a river of Upper Canada, which runs into lake Huron, between le Serpent and the Salmon rivers, on the N. shore. See **MISSASAGUELS**.

MISSEL BIRD, in *Ornithology*, the common English name of the larger species of thrush, called also the *skrite*, and by authors the *Turdus viscivorus major*; which see. It is much larger than any other of the thrush kind; its legs and feet are yellow; its head of a brownish lead colour, and its back, tail, and rump of the same colour, with an admixture of yellow; but in the summer months it a little changes its colour, and becomes more grey, or of the colour of unripe pickled olives; its throat, breast, and belly, are all variegated with black spots; the middle of its belly whitish, and the upper part of its breast, and part of its sides, and the under feathers of its tail, yellowish; its bill is shorter and thicker than that of other thrushes, and of a dusky colour, except the base of the lower mandible, which is yellow. It usually is seen on the top branches of tall oaks, elms, and other high trees, and sings very sweetly, and is the largest bird that has any melody in its note. It begins its song, sitting on the summit of a high tree, very early in the spring; often with the new year, in blowing showery weather, whence it is called in Hampshire the storm-cock; the note of anger or fear is very harsh, between a chatter and shriek. It remains the whole year with us, flies singly, except with its female, and drives all the lesser species of thrushes from it. It is the best of all the kinds for the table.

MISSELTOE. See **MISTLETOE**.

MISSEN-MAST, or **MIZZEN-Mast**. See **MISEN**.

MISSEN-Sail. See **MISEN**.

MISSIGUINIPI RIVER, in *Geography*, a river of Canada, which runs into the Saguenay, N. lat. 48° 22'. W. long. 71° 10'.

MISSILIA, among the Romans, a name given to largesses, thrown among the people on occasion of games and shows, such as small gold or silver coins, sweetmeats, and sometimes animals, as sheep, oxen, deer, &c. which were let loose to be carried off by the people.

The word comes from *mittere*, to throw, or let loose.

MISSIMA, in *Geography*, a town of Japan, in the island of Nippon.

MISSINABE LAKE, a lake of America, in Canada. N. lat. 48° 39' 42". W. long. 84° 2' 42".

MISSINABE House, a station belonging to the Hudson's bay Company, situated on the E. side of Moose river, and eight miles from Missinabe lake.

MISSING WOOD, a phrase used among *Bowlers*. See **BOWLING**.

MISSION, *Missio*, among the Romans, a term used to signify the emperor's sending to rescue a wounded gladiator from his antagonist. The *munerarii*, or persons who exhibited

bited the games, and likewise the people, used to rescue a favourite gladiator. The manner of their signifying this favour, was *pollice presso*, or with the thumb hid in the palm of the hand. However the gladiator was only saved for that time; whereas by the *rudis* he had a free discharge.

MISSION. See EMISSION, MANUMISSION, REMISSION, and TRANSMISSION.

MISSION, in *Theology*, denotes a power or commission to preach the gospel. Jesus Christ gave his disciples their mission in these words, "Go, and teach all nations, &c."

The Romanists reproach the Protestants, that their ministers have no mission; as not being authorized in the exercise of their ministry, either by an uninterrupted succession from the apostles, or by miracles, or by any extraordinary proof of a vocation.

Many among us deny any other mission necessary for the ministry, than the talents necessary to discharge it.

MISSION is also used for an establishment of people zealous for the glory of God, and the salvation of souls; who go and preach the gospel in remote countries and among infidels.

There are missions in the East as well as in the West Indies. Among the Romanists, the religious orders of St. Dominic, St. Francis, St. Augustine, and the Jesuits, have missions in the Levant, America, &c.

The Jesuits have also missions in China and all other parts of the globe, where they have been able to penetrate. The Mendicants abound in missions.

There have been also several Protestant missions, for diffusing the light of Christianity through the benighted regions of Asia and America. Of this kind has been the Danish mission, planned by Frederic IV., in 1706. And the liberality of private benefactors in our own country has been also extended to the support of missionaries among the Indians in America, &c.

MISSION is also the name of a congregation of priests and laymen, instituted by Vincent de Paul, and confirmed, in 1632, by pope Urban VIII., under the title of "Priests of the Congregation of the Mission."

These profess to make it their whole business to assist the poor people in the country; and to this purpose they oblige themselves never to preach, or administer any of the sacraments, in any town where there is an archbishop, bishop, or provincial residing.

The priests of the mission were also intrusted with the direction and government of a female order, called "Virgins of Love, or Daughters of Charity," whose office it was to administer assistance and relief to indigent persons, who were confined to their beds by sickness and infirmity. This order was founded by a noble virgin, whose name was Louise Gras, and received, in the year 1660, the approbation of pope Clement IX.

They are settled in most provinces of France, Italy, Germany, and in Poland. At Paris they have a seminary, which they call the *Foreign Mission*, where youth are bred up, and qualified for missions abroad.

MISSIONARY, an ecclesiastic who devotes himself and his labours to some mission, either for the instruction of the orthodox, the conviction of heretics, or the conversion of infidels.

MISSISSIPPI RIVER, in *Geography*, a river which by its various windings, from its confluence with Beau-bassin at the head of Chignat channel, to its main source, and from thence by a line due E. to the bay of Verte, in the straits of Northumberland, separates the provinces of Nova Scotia and New Brunswick.

MISSISSIPPI, a large river of America, which, toge-

ther with its eastern branches, waters $\frac{1}{3}$ ths of the United States, forms their western boundary, and separates them from Louisiana. It rises in White Bear lake, N. lat. $48^{\circ} 15'$. W. long. $98^{\circ} 30'$, and in its course receives several streams both from the E. and W., the largest of which are the Missouri from the W., and the Illinois, Ohio, and Tennessee from the E. The soil on both sides of this river, and in the vicinity of its tributary streams, is not inferior to any in North America. This river is navigable to St. Anthony's Falls, and, as some say, beyond them. Salt of excellent quality is produced from the salt-springs or licks that are contiguous to it, and on its upper branches are great quantities of coal. An island of considerable size is formed by its mouths in the gulf of Mexico, between 29° and 30° N. lat. and 89° and 90° W. long.

MISSISSIPPI Territory, a district formed of the western part of the state of, and bounded N. by Tennessee, W. by the Mississippi river, S. to W. by Florida, E. by the Appalachicola and Flint rivers. The principal part of this country is inhabited by the Creek, Choctaw, Chickasaw, and Cherokee nations of Indians. It was erected into a territorial government in 1800, and divided into three counties, *viz.* Washington, including 1250 inhabitants, Pickering with 2940, and Adams with 4660. The total number is 8850, of which 3489 are slaves. Natches is the capital. It is watered by many fine rivers, and contains large tracts of the best land in the United States.

MISSISSAGUIS, a tribe of Indians who inhabit the shores of lake Ontario, and one of the most numerous in this part of the country. The men are in general stout, and most excellent hunters and fishers; but less warlike than any of the neighbouring nations. They are of a darker complexion than other Indians; some of them being nearly as black as negroes. Both men and women, particularly the latter, are very dirty and slovenly in their appearance: the rancid grease and fish oil, with which the women daub their hair, necks, and faces, render them in a summer's day extremely offensive. These Indians supply the inhabitants of Kingston, of Niagara, and of the different towns on the lake, with fish and game, the value of which is estimated by bottles of brandy and loaves of bread.

MISSIVE, something sent to another, from the Latin word *mitto*, *I send*.

We say missive letters, or letters missive, meaning letters sent from one to another.

In propriety letters missive are letters of business, but not business of great concern; in contradistinction from letters of gallantry, letters on points of learning, dispatches, &c. See LETTERS.

MISSON, MAXIMILIAN, in *Biography*, a well known French writer, was a counsellor of Paris at the time of the revocation of Nantes, which circumstance obliged him to quit his country and come over to England. In 1687, and the following year, he travelled to Italy with an English gentleman, in the character of governor, and soon after his return he published the fruits of his observations, in a work entitled "Nouveau Voyage d'Italie," in 3 vols. 12mo. These travels were looked upon as a faithful and lively picture of the countries described, but the Catholics were offended at the representations given of the ceremonies and popular superstitions prevalent among them, which they charge with unfaithfulness and exaggeration. Misson wrote likewise "Memoires d'un Voyageur en Angleterre;" and "Le Theatre sacré des Cevennes, ou Recit des Prodiges arrivés dans cette Partie du Languedoc, et des petits Prophètes." He died, at an advanced age, in London, in the year 1721. Moreri.

MISSOURI,

MISSOURI, in *Geography*, a river of North America, in Louisiana, which falls into the Mississippi from the westward, 18 miles below the mouth of the Illinois, and about 116 miles from the Balize, or mouths of the Mississippi, in the gulf of Mexico. Hutchins says that it is navigable 1300 miles, and larger than the Mississippi.

MISSOURIS, the Indians who inhabit the banks of the above river, and who are said to have 1500 warriors.

MIST, a meteor, called also fog. See Fog and METEOROLOGY.

The bluish mist which we sometimes see on our fields and pastures in a morning, though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle. Dr. Winkler gives, in the Philosophical Transactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in form of a blue mist. Wherever this was perceived, the cattle were sure to come home sick: they appeared dull and heavy, and refused their food; and many of them would die in four-and-twenty hours. Upon dissection there were found large and corrupted spleens, sphaclous and corroded tongues; and in some places those people who were not careful of themselves in the management of their cattle, were infected and died as fast themselves. The principal cause of this disease seems to be the exhalation of some unwholesome steams from the earth; and it was observable, that there had been three earthquakes in Italy the year before it happened.

The method of cure which succeeded best, was this: as soon as any beast appeared to be sick, they examined the tongue, and if apthæ or little blisters were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the apthæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally: take of foot, brimstone, gunpowder, and salt, of each equal parts: mix these in as much water as will make a mixture thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day. The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Swisserland, while almost all died in other places.

It was very remarkable that this contagion, on this occasion, seemed to travel slowly but regularly on: it came at the rate of about two German miles in twenty-four hours; this it kept regularly to during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way, but those which were kept within doors at rack and manger, fell ill at the same time, and in the same manner with those in the open fields.

Dr. Slare was of opinion, that it was owing to certain insects, which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air and the beasts, on this occasion. Phil. Trans. N^o 145.

MISTAKE BAY, in *Geography*, a large bay on the west side of the entrance of Davis's Straits, and N. of Hudson's Straits; from which it is separated by a peninsula of the N. main on the W. and Resolution island on the S.

MISTAKEN BAY, a bay on the N.W. coast of Tavai

Poenannoo, so called by Capt. Cook in 1769; 25 miles S.W. of Cascade Point.

MISTAKES Cape, the S. point of the easternmost of the Heron's islands, about three leagues E.N.E. from Cape Horn, at the extremity of South America.

MISTEK, a town of Moravia, in the circle of Prerau; 7 miles E.N.E. of Freyburg.

MISTELPACH, a town of Austria; 18 miles N. of Vienna.

MISTIC, or **MYSTIC**, a short river which falls into the N. side of Boston harbour, by a broad mouth on the E. side of the peninsula of Charlestown. It is navigable for sloops four miles to the town of Medford, and is crossed by two bridges, one at its mouth, and another a mile above it. The Middlesex canal connects this river with the Merrimack.

MISTISSINY, a lake of Canada. N. lat. 50° 40'. W. long 74°.

MISTLETOE, **MISLETOE**, or *Mistletoe*, in *Botany*. See VISCUM.

MISTRETTA, in *Geography*, a town of Sicily, in the valley of Demona; the see of a bishop; 64 miles W. of Messina. N. lat. 38° 55'. E. long. 14° 22'.

MISTY, a town of Asiatic Turkey, in Caramania; 50 miles S. of Yurcup.

MISUSER, in our *Old Writers*, an abuse of any liberty or benefit: as he shall make fine for his misuser. Old. Nat. Br. 149.

By misuser, a charter of a corporation may be forfeited; so also an office, &c.

MISWALDE, in *Geography*, a town of Prussia, in the province of Oberland; 18 miles S. of Elbing.

MISY, in *Natural History*, the name of a fossile substance, used very frequently by the ancients in medicine, and supposed to be one of their now lost medicines, but erroneously; it being still very common in the Turkish dominions, and not unfrequently found in the mines of Cremnitz in Hungary. It is a considerably firm substance, though of an irregular and seemingly not compact texture, and much resembles some of our gaudy marcasites; but that it wants their hardness and their weight, and is not inflammable.

It is at present no where put to any use. The ancients esteemed it of the same nature with the chalcitis, but that it possessed those virtues in a more remiss degree; they had it from Ægypt and Cyprus, and used it externally in hæmorrhages, and some cutaneous eruptions.

MISY, in *Botany, a name given by Theophrastus, and all the old Greek writers, to a kind of truffle or subterranean mushroom, of a very delicate flavour. The truffles of Numidia, and some other parts of Africa, were always esteemed superior to those of any other part of the world. They are called *terfez*, *camaba*, or *kema*, by some later writers, and were brought to Rome, and so greatly esteemed, that no dish was ranked above them. These were called Lybian truffles by the Romans, and they seem to have been the same with the Cyrenean misy of the Greeks. It is to be observed, that the Greeks in general, in early times, were very little acquainted with the affairs of Africa; and all that they had from this part of the world, was said to come from Cyrene, some old cities of their forefathers being there, and keeping up a friendship and traffic with them. The *thyon*, a tree growing plentifully in almost all parts of Africa, and which is the same with the citrus of the Romans, was in this manner attributed to Cyrene, by the same Theophrastus. And thus, when speaking of truffles, he adds, that the Cyrenean misy surpassed all the other kinds in flavour; his words stand at large in Athenæus; and thence Pliny has taken his account,*

account, which he closes in this manner: "The thing which they call misy, in the province of Cyrene, is of this kind; but it is more fleshy and of a finer taste and smell." This is the sense of Pliny, as the text stands in our copies; but it is probable that he translated Theophrastus better than they, at least as we know that what he says is not his own but taken from that author, we have a right to understand it in his way, and that is, that the roots of this Cyrenean misy have a delicate smell resembling that of meat, or flesh newly cut. Pliny, lib. xix. cap. 3.

It is very certain, that this Cyrenean misy of the old Greeks is the same thing with the delicate African truffe or terzez of Leo Africanus, and the moderns; and Pliny had read some of the ancients who were sensible of this, and had taken from them an account that the African truffes are the finest in the world; and yet did not perceive, that these African truffes were the same with the Cyrenean misy, which he immediately after mentions from Theophrastus.

MITCHEL DEAN, in *Geography*. See DEAN, Michel.

MITCHELLA, in *Botany*, named by Linneus in honour of his friend and correspondent Dr. John Mitchell, a physician at Virginia, whose paper, describing thirty new genera of plants, is published in the *Ephemerides Naturæ Curiosorum*, v. 8, 187, preceded by a dissertation on the principles of systematic botany and zoology. This treatise was afterwards published separately at Nuremberg in 1769, about a year after its author's death. Linn. Gen. 55. Schreb. 73. Willd. Sp. Pl. v. 1. 617. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 246. Michaux Boreali-Amer. v. 1. 86. Juss. 208. Lamarck Illustr. t. 63. (Chamædaphne; Mitchl. n. 27.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Aggregata*, Linn. *Rubiacea*, Juss.

Gen. Ch. *Cal.* Perianth superior, erect, four-toothed, permanent. *Cor.* of one petal, funnel-shaped; tube cylindrical; limb four-cleft, spreading, hairy within. *Stam.* Filaments four, thread-shaped, erect, between the segments of the corolla; anthers oblong, acute. *Pist.* Germen twin, inferior, orbiculate, common to two flowers; style thread-shaped, the length of the corolla; stigmas four, oblong. *Peric.* Berry divisible into two parts, globose, with two distinct crowns. *Seeds* four, compressed, callous.

Eff. Ch. Corolla of one petal, superior; two flowers on each germen. Stigmas four. Berry in two parts, with four seeds.

1. *M. repens*. Linn. Sp. Pl. 161. (*Syringa baccifera*; Plek. Amalth. 198. t. 444. f. 2.)—Native of North America, and introduced at Kew in 1761, by Mr. John Bartram, where it flowers in June. *Stem* decumbent and creeping, slender. *Leaves* in pairs, on short stalks, ovate, pointed. *Flowers* terminal, two on each germen, as in several of the genus *Lonicera*.

MITCHELS, among *Builders*, are Purbeck stones, from fifteen inches square to two feet, squared and hewed ready for paving.

MITCHELSTOWN, in *Geography*, a post-town of the county of Cork, Ireland, situated on the river Funcheon. In it is a college, founded by a former earl of Kington, for the support of twelve decayed gentlemen and twelve decayed gentlewomen, who have each 40*l.* per annum, and comfortable apartments; and a chaplain with 100*l.* per annum, with a house. A fine seat of the Kington family adjoins the town. Near this town, at the foot of one of the Gattee mountains, is the cave of Skeheenrinky, which is described by Arthur Young in his Irish Tour, and preferred by him to the famous cave in the Peak of Derbyshire, as it was by lord Kingborough to the Grot d'Ance in Burgundy. Mitchelstown is 102 miles S.W. from Dublin, and about

24 from Cork, on the road from that city to Cashel. Carlisle. Young.

MITCHIGAMAS, a nation of Indians, who with the Piorias, inhabit near the settlements in the Illinois country.

MITE, in *Natural History*, the name of a small animal very well known, and found in old cheese, and in many other bodies, both recent and perishing. See ACARUS.

To the naked eye the mites in cheese appear like moving particles of dust, but the microscope discovers them to be perfect animals, having as regular a figure, and performing all the functions of life as perfectly as creatures that exceed them many times in bulk.

They are crustaceous animals, and are usually transparent; the principal parts of them are the head, the neck, and the body; the head is small in proportion to the body, and has a sharp snout, and a mouth that opens and shuts like a mole's; they have two small eyes, and are extremely quick-sighted; and when you have once touched them with a pin, you will easily perceive how cunningly they avoid a second touch.

They are of different sorts; for some of them have six legs, and others have eight: each leg has six joints surrounded with hairs, and two little claws at the extremity, with which it very nicely takes hold of any thing; the hinder part of the body is plump and bulky, and ends in an oval form, from which there issue out a few exceeding long hairs; other parts of the body and head are also beset with thin and long hairs.

The males and females are easily distinguished in these little animals. The females are oviparous, as the louse and spider, and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are, however, when first hatched, extremely minute; and, in their growing to their full size, they cast their skins several times.

These little creatures may be kept alive many months between two concave glasses, and applied to the microscope at pleasure. They are thus often seen *in coitu*, conjoined tail to tail; and this is performed by an incredible swift motion.

Their eggs, in warm weather, hatch in twelve or fourteen days; but, in winter, they are much longer; these eggs are so small, that a regular computation shews, that ninety millions of them are not so large as a common pigeon's egg. Baker's Microscope, p. 18.

Mites are very voracious animals; they not only prey upon cheese, but upon all sorts of dry flesh, fish, fruits, and feeds; and almost on all things which have some degree of moisture, without ever being wet; and they have often been seen to eat one another. Their manner of eating is by thrusting alternately one jaw forward and the other backward; and in this manner grinding their food; and after they have done feeding, they seem to chew the cud.

There are several lesser distinctions observable in the mites, which are found among different substances. Those in malt-dust and oat-meal are much nimbler than the cheese-mites, and have more and longer hairs. The mites among figs resemble beetles, and have two feelers at the snout, and two very long horns over them; these have only six legs, and are more sluggish than those in malt-dust. Those found among figs have also very long hairs, and those beset at certain distances with other smaller hairs; whence M. Leeuwenhoek conjectures that these longer and larger hairs are jointed at those places where the short ones are found.

There is a sort of wandering mites found wherever there is any thing that they can feed on; these are often found in form of a white dust, and are not suspected to be living creatures.

The mitre is an animal very tenacious of life; it will live months without food; and M. Leeuwenhoek had one which lived eleven weeks on the point of a pin, on which he had fixed it, examining it by his microscope. Leeuwenhoek's Arcan. Nat. tom. iv. p. 368.

MITRE, a small coin, formerly current; equal to about one-third part of a farthing.

MITRE also denotes a small weight used by the miners. It is equal to the twentieth part of a gram troy, and is divided into twenty-four droits, the droit into twenty perots, and the perot into twenty-four blanks.

MITRELLA, in Botany, received its name from Tournefort, in allusion to the shape of the ripe seed-vessel, which, with its two pointed lobes, resembles a little mitre.—Linn. Gen. 123; Schreb. 301. Willd. Sp. Pl. v. 2. 659. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 73. Juss. 309. Tourn. t. 126. Michaux Boreali-Amer. v. 1. 270. Lamarck Illustr. t. 373. Gärtn. t. 44.—Class and order, *Decandria Digynia*. Nat. Ord. *Succulenta*, Linn. *Saxifrageae*. 107.

Gen. Ch. Cal. Perianth inferior, of one leaf, cut half way down into five segments, bell-shaped, permanent. Cor. Petals five, in many capillary segments, inserted into the calyx, twice exceeding it in length. Stam. Filaments ten, awl-shaped, inserted into the calyx, shorter than the corolla; anthers roundish. Pist. Germen superior, roundish, cloven; styles scarcely any; stigmas obtuse. Peric. Capsule ovate, of one cell, divided half way down into two flat, equal valves, recurved at their points. Seeds numerous.

Ess. Ch. Calyx five-cleft, inferior. Petals five, pinnatifid, inserted into the calyx. Capsule of one cell, with two equal valves.

1. *M. diphylla*. Two-leaved Mitella. Linn. Sp. Pl. 580. Lamarck, fig. 1. (*Cortusa americana altera floribus imbricatis fimbriatis*; Menz. Pugill. t. 10.)—Leaves heart-shaped, slightly three-lobed, toothed. Stalk with two opposite leaves.—Native of North America. Easily cultivated in bog earth, in the shade, flowering in April and May. A delicate little perennial herb, about a span high, pale green, somewhat hairy. Leaves heart-shaped, acute, slightly lobed and toothed; the radical ones several, on longish footstalks. Flower-stalk solitary, erect, bearing a pair of sessile, opposite horizontal leaves about the middle, and terminating in a slender, upright, downy, rather viscid cluster, of minute white flowers, remarkable for their elegantly fringed feather-like petals. Capsule sometimes with three valves.

2. *M. cordifolia*. Heart-leaved Mitella. Willd. n. 2. Lamarck, fig. 3.—Leaves heart-shaped, with bristly teeth. Stalk nearly naked.—Supposed by Willdenow, we know not on what foundation, to be a native of the north of Asia. Michaux found it in Canada. This appears to differ from the former in having sharper bristle-pointed teeth to the leaves, and only one very small leaf, with a few scales, on the stalk. Petals in capillary segments. We have seen no specimen.

3. *M. nuda*. Naked-stalked Mitella. Linn. Sp. Pl. 580. Lamarck, fig. 2. (*M. scapo nudo, petalis imbricatis*; Gmel. Sib. v. 4. 175. t. 63.)—Leaves kidney-shaped, wavy, fringed. Stalk naked.—Native of Siberia and North America, in woods. Miller is said to have cultivated this species in 1758, but we have never seen it in the gardens of the present day. It is smaller than the first species, with rounder, strongly bristly, leaves. Stalk three or four inches high, quite naked, bearing four or five flowers, the segments of whose petals are quite capillary.

4. *M. prostrata*. Prostrate Mitella. Michaux. n. 3.—

“Root creeping. Stems prostrate. Leaves alternate, roundish-heart-shaped, sharpish, with slight obtuse lobes.”—Native of the southern limits of Canada. Michaux.

MITRELLA, in Surgery, a feat for suspending the arm. MITGAING, in Geography, a town of Hindoostan, in the circle of Surgooja; 40 miles N. of Surgooja.

MITHRA, Feasts of, in Antiquity, were feasts celebrated among the Romans in honour of Mithra, Mithras, or the sun.

Mithras was an ancient god of the Persians, whom they worshipped, as Plutarch says, according to the laws of Zoroaster, invoking him as the mediator between Oromazes and Arimannus. Mithras was the sun, which was invoked as a divinity; to him they offered sacrifices, and addressed their prayers, and they had priests set apart for service; and they also worshipped fire as an emblem of the sun; but they had neither temples, statues, nor altars. This Mithras was not well known in Europe, until his worship was brought to Rome, which happened, according to Plutarch, in the time of the Piratic war, A. U. C. 687. It is from this epoch, and more especially from the time of the second and third century of the Christian era, that the worship and mysteries of this divinity were celebrated at Rome. That the Romans worshipped Mithras as the sun, is evident from an inscription dated in the third consulate of Trajan, or about the year of Christ 101. This is the dedication of an altar to the sun, under the name of *Mithra, deo Soli invictio Mithra*. This epithet, invincible, is frequently given to the sun upon other monuments, and it denotes that luminary to be the first and lord of all the rest. But the worship of Mithras was not known in Egypt and Syria in the time of Origen, who died about the year of Christ 263: though it was common at Rome for more than a century before this time. The mysteries of Mithras were both impious and abominable, since human victims were offered on this occasion. The barbarous custom of sacrificing men was abolished by Adrian, but restored again by Commodus, as Lampridius informs us. This worship made great progress in succeeding ages. It was not only spread through Italy and Greece; but it appears from Socrates and 8 women, that the Egyptians, and particularly the people of Alexandria, worshipped the same divinity. Mithras was also known in the island of Crete. He was also worshipped by the Gauls, as appears by a figure of this god found at Lyons. The worship of this divinity was not only extensive, but of long duration; for it was not destroyed when the emperors embraced Christianity. At length, this worship was proscribed at Rome in the year 378, by order of Gracchus, prefect of the prætorium. According to M. Freret, the feasts of Mithras were derived from Chaldea, where they had been instituted for celebrating the entrance of the sun into the sign Taurus.

MITHRA is also a name of the sun in the mythology of the Hindoos. See SURYA.

MITHRAX, in Natural History, the name given by Pliny and the ancients, to a gem found in Persia, which, when held up to the sun, shewed many colours. It was probably no other than the opal. Hence the barbarous writers of the middle ages seem to have taken their account of the mithridates.

MITHRIDATE, MITHRIDATIUM, in Pharmacy, an antidote or composition, in form of an electuary; serving either as a remedy, or a preservative against poisons. Mithridate was formerly one of the capital medicines in the apothecaries' shops, being composed of a vast number of drugs; among which are opium, myrrh, agaric, saffron, ginger, cinnamon, spikenard, frankincense, castor, pepper, gentian, &c.

It is accounted a cordial, opiate, sudorific, and alexipharmic. Matthioli says, it is more effectual against poisons than Venice treacle, and much easier to be made.

It takes its name from its inventor, Mithridates, king of Pontus, who is reported to have so fortified his body against poisons, with antidotes and preservatives, that when he had a mind to dispatch himself, he could not find any poison that would take effect.

The receipt of it was found in his cabinet, written with his own hand, and was carried to Rome by Pompey. It was translated into verse by Damocrates, a famous physician, and hence called *Confessio Damocratis*; and was afterwards translated by Galen, from whom we have it. It has undergone considerable alterations since the time of its royal prescriber.

MITHRIDATE Mustard. See TREACLE Mustard.

MITHRIDATE, *Mustard Bastard*, is a species of *iberis*.

MITHRIDATEA, in *Botany*, received its name from Commerçon, we presume in memory of Mithridates, who, from the celebrated hodge-podge, which he is reported to have invented, as a counter-poison, must have been conversant with herbs and their reputed properties at least. We can trace no reason for the application of the name to this particular plant.—Schreb 783. Willd. Sp. Pl. v. 1. 27. (Tambourissa; Sonnerat Ind. Or. v. 2. 237. Ambora; Juss. 401. Lamarck Illustr. t. 784.)—Class and order, *Monardria Monogynia*. Nat. Ord. *Scabride*, Linn. *Urticæ*, Juss.

Gen. Ch. *Common Receptacle* of one leaf, fleshy, bell-shaped, in four large, ovate, spreading segments; the upper surface covered with innumerable, minute, imbedded florets. *Perianth* scarcely any. *Cor.* none. *Stam.* Filament one, very short, erect; anther erect, channelled, embracing the style. *Pist.* Germen oval; style shorter than the stamen; stigma simple. *Peric* none. *Common Receptacle* enlarged, pulpy, turbinate, concave, its segments folded inward, lodging the seeds in its fleshy substance. *Seeds* solitary to each floret, oval.

Obs. Jussieu thinks the flowers are monoecious, the receptacles of the males being most deeply cut, and expanded, those of the females slightly perforated, by a cruciform incision, at the top. This seems to agree with our specimens from Commerçon, but by no means with Sonnerat's description. Possibly the flowers may become monoecious occasionally, by the casual imperfection of their respective organs.

Ess. Ch. *Common receptacle* many-flowered, four-cleft. Calyx none. Corolla none. Seeds solitary, imbedded in the fleshy receptacle.

1. *M. quadrifida*. Ambora, Drum-tree, or Monkey-apple.—Gathered by Sonnerat in Madagascar, as well as in the isles of Bourbon and Mauritius. Commerçon found it in the latter. The wood of this tree is light, white and pithy, as in *Ficus*, to which the genus is most nearly allied. *Leaves* on the young smooth branches, nearly opposite, stalked, elliptical, obtuse, entire, evergreen, very smooth, with a strong mid-rib, sending off numerous transverse veins; their size on young trees is a span in length, and above two inches in breadth; on old ones about one-third as much. *Flowers* in smooth clusters, from the older branches, or the trunk; their partial stalks about an inch long. *Receptacles*, before they expand, ovate, about the size of a filbert, somewhat roughish or scaly at the outside; when open the male ones, as they seem to us, spread about an inch and a half, displaying abundance of thick-set stamens, among which we can discern nothing else. The ripe fruit is two or three inches wide, of a depressed, roundish, unequal form, hollow, its

pulpy substance, in which the seeds are vertically imbedded, as in *Dorstenia*, being about one-third of an inch thick. The pulpy coat, which envelopes the seeds, is said to be orange-coloured, and to be used for a dye, like the American Arnotto, *Bixa Orellana*. Ambora is the Madagascar name of this tree. The affinity of the genus to *Ficus* and *DORSTENIA*, (see those articles,) cannot be overlooked. The foliage however is smooth; but that is the case with some others of this natural order, though indeed with but very few. Jussieu says the tree discharges a milky fluid, which confirms its relationship to *Ficus*; and if monkeys eat the fruit, as one of its names implies, it would certainly not prove poisonous to mankind, though, like many species of *Ficus*, it may be either tasteless or of a disagreeable flavour.

MITHRIDATES, in *Biography*, king of Pontus, surnamed "Eupator," and "The Great," was the son of Mithridates VI., the first king of that country who entered into an alliance with the Romans. At the death of his father, 123 B. C., he succeeded to the crown when he was only about 12 years of age. He was from a very early period of life accustomed to martial exercises, and the sports of the chase, by which he was enured to fatigues. In his mind were imprinted the characters of turbulence, ferocity, and suspicion, by which, particularly the latter, his life was preserved from several attempts made on him by those appointed to be his guardians. His mother had been appointed joint heir of the crown, but he very soon deprived her of power, and kept her in close confinement, in which she ended her days. When arrived at the age of manhood he took his own sister, Laodice, for a wife, which was the common practice of the eastern monarchs of that period. After the birth of a son he made progress through all the neighbouring Asiatic states, with the view of observing their strength and policy. In this journey he spent three years, during which his queen attached herself to one of the lords of the court, and on his return she made an attempt to poison him. He drank the potion, but his constitution was proof against its baneful contents, and the discovery of her infidelity and wicked intentions was the occasion of her death, with that of all her accomplices.

Mithridates now entered upon his career of ambition: he overran the neighbouring kingdom of Paphlagonia, which he at length divided with his ally Nicomedes, the king of Bithynia, totally regardless of the remonstrances of the Romans, who had declared it a free state. He next reduced Galatia, though under the protection of Rome: after this he anxiously wished to make himself master of Cappadocia, then possessed by his brother-in-law, and friend Ariarathes, whom he caused to be privately assassinated, upon which the kingdom was seized by Nicomedes, who married the widow. Mithridates, however, under the pretence of securing the crown for his nephew, drove out Nicomedes, and seated the young prince upon the throne, whom he afterwards stabbed by the most scandalous treachery. The Cappadocian army, who were witnesses of the abominable deed, threw down their weapons, and suffered Mithridates to take possession of all the fortresses in the kingdom. He now placed on the throne a minor son of his own, under the guardianship of Gordius, who had been his wicked instrument in assassinating his brother-in-law. The jealousy of Nicomedes induced him to bring forward a pretended son of Ariarathes, who was sent to Rome to lay his complaints before the senate, and implore its assistance to seat him on the throne of his fathers. Mithridates, apprized of the fact, sent deputies to state to the senate the impollure, and in the conclusion both kings were commanded to relinquish their claims, and the crown of Cappadocia was conferred

ferred upon Ariobarzanes. This was but the commencement of the dispute, and the Roman commanders, according to their usual practice, endeavoured to excite hostilities among the Asiatic kings, that they might have a pretence to interfere in their contests. From the year 90 B. C. open war may be considered as prevailing between the Roman republic and Mithridates, which was extinguished only by the death of the latter. The early successes of Mithridates led him to aspire to the honour of being the instrument of freeing all Asia from the Roman yoke, and at first he seemed to overrun, in an uninterrupted career, all the countries in their alliance and possession, being every where received by the people as their deliverer. His great object now was to ingratiate himself with people of all classes and countries by several popular acts, such as restoring, without ransom, all the Asiatic prisoners, who had fallen into his hands. The free cities of Asia, won over by these specious acts of generosity, opened their gates to him, and took pleasure in demolishing all the monuments erected by the Romans. Mithridates, determined upon irreconcilable enmity to that people, and wishing to involve the Asiatics in the same principles, sent to the magistrates throughout the cities in which any Roman citizens had established themselves, directing, that on a certain day a general massacre should be perpetrated on all of Italian birth or origin, not excepting women and the youngest children. In this horrid massacre it was imagined, that at least 80,000 Roman citizens lost their lives; some accounts have indeed reckoned them at nearly double that number.

By this master stroke of bloody policy, for which his name must for ever be transmitted with infamy, Mithridates made himself master of the whole of Lesser Asia, and proceeded, without remorse or delay, to the conquest of the neighbouring islands, several of which he quickly reduced. At Cos he took possession of a large sum of money, which had been deposited there by the Asiatic Jews, and intended for the temple of Jerusalem. He next made an attempt upon Rhodes but was defeated, and incurred so much personal risque, that he ever afterwards felt an abhorrence of the sea. Archelaus, one of his generals, crossing over to Greece, made himself master of Athens, while his own son Ariarathes conquered Macedonia and Thrace. He was now at the summit of power, and is said to have received the homage of twenty-five different nations. His memory and talent for the acquisition of languages were so great that he could converse with the natives of all of them without the aid of an interpreter.

From this period we may date his decline; Sylla procured of his countrymen the chief command against Mithridates, and sailing to Greece recovered Athens, in the year 86 B. C. He afterwards defeated with great slaughter the troops of Archelaus at Chæronea, and by two other decisive victories he put an end to the war in Greece. Mithridates was pursued from place to place, till at length he was obliged to submit to conditions, at which the greatness of his mind revolted: these conditions were, that he should resign all his conquests, and confine himself within his paternal dominions of Pontus; that he should release all his captives without ransom; pay down a large sum of money; deliver up the greatest part of his fleet; and practise no hostilities against those who had revolted from him and taken part with the Romans. Although the king had acquiesced in these terms, yet it was with the secret determination to break them as soon as he should be sufficiently powerful for the purpose. A new war kindled about the year B. C. 74, in which the success of Mithridates was so great that he recovered the best part of Pontus, which had, in the early part of the

course, been wrested from him, Bithynia, Cappadocia, and Armenia Minor. At length Pompey, invested with great powers, was sent by the Romans to put an end to this long continued war, which he accomplished by destroying, or dispersing all the king's troops, except a body of cavalry with which he forced a passage. Mithridates fled into Armenia, whence he withdrew to Colchis, and thence to Brythia, between the Euxine and Caspian seas. Here he was so completely concealed that it was supposed he was dead, till he emerged from his retreat at the head of a considerable army, and made himself master of several important places. His success was but short-lived, and those even who were willing to submit to his power, had no confidence in his cause, but chose rather to join what they thought was the strongest party. He now adopted the design of marching into Europe, and exciting the Gauls in his cause, which created such discontents in the army, as to lead them to choose Pharnaces, the favourite son of Mithridates, as their king. Having in vain attempted to reveal his son to the principles of duty, he attempted to destroy himself first by poison, and then by the sword, but in both he failed, and was at last dispatched, at his own request, by a Gallic mercenary. This was in the year B. C. 64, when the king had attained to the 71st year of his age. He was one of the most formidable enemies of the Roman republic, and the news of his death was received with the greatest joy and exultation. His body was delivered to Pompey, who, with the magnanimity of a generous enemy, bestowed upon it a most magnificent funeral. Mithridates was learned, and a patron of learning; he was particularly attached to medicine, and an electuary still bears his name. Plutarch. Univer. Hist.

MITHRIDATES, in *Natural History*, the name of a stone found in some parts of Persia, seeming to be the same as the mithridax or mithrax.

MITHRIDAX, the name of a gem described by Solinus, to which he ascribes qualities the same with those given by Pliny to the mithrax; and therefore probably the same stone with it.

MITIUSCHOV, in *Geography*, an island in the Frozen ocean, near the western coast of Nova Zembla, at the entrance of the Metochik Schau. N. lat. 75° 20'. E. long. 55 38'.

MITOC, a lake of Thibet, about 36 miles in circumference. N. lat. 31° 50'. E. long. 93 24'.

MITOMBA, a kingdom of Africa, in the country of Sierra Leona, situated on the banks of the river Sierra Leona, called also Mitomba.

MITRA, in *Botany*. See HELVELLA, MITREOLA, and OPHIORRHIZA.

MITRALIS VALVULA, in *Anatomy*, the valve placed at the opening, by which the left auricle and ventricle communicate. See HEART.

MITRARIA, in *Botany*, so denominated from a slight resemblance to a mitre, in the form of the outer calyx.—Cavan. Ic. v. 6. 57.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personata*, Linn. *Scrophularie*, Juss.

Gen. Ch. Cal. Perianth double, inferior, permanent, each of one leaf: the outer divided on one side nearly to the bottom, on the other but half way down; the segments ovate, concave, of equal lengths: inner about the same length, in five, deep, lanceolate, nearly equal segments. Cor. of one petal, ringent; tubes many times longer than the calyx, round, inflated upward, contracted at the mouth, pervious; limb short, spreading, in two lips; the upper in two parallel lobes; lower in three very deep ones; all ovate and obtuse. Stam. Filaments four, awl-shaped, two rather the longest, all longer than the corolla, inserted into the

bottom of its tube, with the rudiment of a fifth; anthers ovate, two-lobed. *Pist.* Germen superior, ovate; style awl-shaped, rather longer than the stamens; stigma slightly swelling, obtuse. *Peric.* Berry succulent, of one cell. *Seeds* numerous, oblong, polished, imbedded in pulp.

Obs. It is to be presumed that the germen has two cells, though they are obliterated in the ripe fruit. The double calyx distinguishes this genus from *Besleria*.

Ess. Ch. Calyx double; the outer in two lobes; the inner in five. Corolla two-lipped; the lower lip in three equal entire segments: tube inflated. Berry superior, of one cell, with many seeds.

1. *M. coccinea*. Cavan. Ic. t. 579.—The only known species. Gathered by Lewis Née at St. Carlos, in Chili, flowering in February. *Stem* shrubby, climbing; with weak opposite, squarish, slightly downy, jointed, leafy branches. *Leaves* opposite, sometimes three together, (as often happens to the shrubs of that country, witness *Fuchsia*, *Verbena*, and others), on short stalks, ovate, acute, strongly ferrated, about an inch long; green and slightly hairy above; glaucous beneath. *Flowers* on simple axillary stalks about the length of the leaves, usually solitary, sometimes two or three together, drooping, swelling and roughish towards the top. *Calyx* green; the outer one hairy. *Corolla* an inch and half long, of a rich scarlet. *Stamens* and *style* scarlet, with yellow anthers. *Berry* globose, the size of a currant, tipped with the permanent style.

MITRASACME, from *μῆτρα*, a bishop's mitre, and *ακμή*, the summit; Labillardiere says "*ακμή*, the flower," probably by an accidental mistake, or misconception. He invented this name for the plants in question, because the acute summit of the germen separates, as it advances to maturity, into two points, each crowned with half the divided style, and resembles the cloven termination of a mitre. Mr. Brown, though he adopts the name without alteration, observes, that *Mitragyne* would have been better. Labillard. Nov. Holl. v. 1. 36. Brown Prodr. Nov. Holl. v. 1. 452.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Gentianæ*, Juss. Brown. Labillardiere refers it to the *Scrophulariæ* of Jussieu, but certainly erroneously.

Gen. Ch. Cal. Perianth inferior, angular, in four, rarely but two, deep, acute, slightly spreading, permanent segments. *Cor.* of one petal, deciduous; tube angular, short; limb slightly spreading, in four deep, equal segments. *Stam.* Filaments four, awl-shaped, inserted into the tube, equal, usually shorter than the corolla; anthers heart-shaped, incumbent. *Pist.* Germen superior, ovate, acute, shorter than the calyx, cloven at the point; style terminal, thread-shaped, the length of the corolla, soon splitting lengthwise at the base, and finally all the way up; stigma capitate, two-lobed, finally divided. *Peric.* Capsule ovate, pointed, of two valves and two cells, the partitions from the inflexed margins of the valves, its apex splitting into two parts, each crowned with half the style, but still closed by the respective partitions. *Seeds* numerous, small, roundish, affixed to the central receptacles.

Ess. Ch. Calyx angular, four-cleft. Corolla deciduous, four-cleft, regular; its tube angular. Capsule superior, with two cells and many seeds, divided at the top. Style divided at the base. Stigma capitate.

This genus is most akin to *EXACUM*, (see that article,) but sufficiently distinct. Labillardiere describes but one species, Brown nineteen, of which the first sixteen answer most perfectly to the generic characters. We shall describe Mr. Brown's first and fourth species, as well as *M. Labillardiere's*.

M. polymorpha. Br. n. 1.—Umbel partly compound.

Flower-stalk elongated, smooth like the calyx, whose segments are naked at the summit. Leaves linear, somewhat fringed. Stem erect, hairy.—Gathered by Dr. White, as well as Mr. Brown, near Port Jackson, New South Wales. The root seems to be annual. *Stems* several, erect, from three to six inches high, simple, or slightly branched, leafy, round, hairy. *Leaves* opposite, in pairs crossing each other, sessile, three quarters of an inch long, pale, linear, keeled, revolute, entire, obtuse with a small point; more or less fringed towards the base; smooth above; sometimes hairy beneath. *Flower-stalks* terminal, longer than the stem, round, very smooth, simple or divided, terminating in an umbel of two, three, or four flowers, on long slender smooth stalks, one of which stalks often bears a lateral flower also, so that the umbel is then rather a *cyme*. A pair of short leaves accompanies the base of the umbel. The calyx is entirely smooth, pale, with green angles. *Corolla* white or purplish, bearded within, twice as long as the calyx. The flowers and inflorescence are not unlike *Androsace laetea*, Curt. Mag. t. 868, 981, in their general aspect.

M. canescens. Br. n. 4.—Umbel about three-flowered, sessile; its stalks smooth. Segments of the calyx bearded at the tips. Leaves linear, obtuse, hairy on both sides. Stem procumbent, hairy all over; with ascending branches.—Native likewise of Port Jackson. *Root* perennial. *Herb* much like the last but very hairy, and of a darker hue. The umbels, which have at most but three flowers, are accompanied at the base by a pair of short ovate hairy leaves, and stand each at the top of an elongated hairy branch. *Calyx* smooth, except a little bristly tuft at the point of each segment. *Corolla* pale blue or purplish, with somewhat broader rounder segments than the foregoing.

M. pilosa. Labill. Nov. Holl. v. 1. 36 t. 49. Br. n. 15.—Creeping, hairy. Leaves stalked, ovate, fringed. Flower-stalks axillary, solitary, about the length of the leaves. Calyx hispid.—Native of moist places in Van Diemen's land. *Labillardiere*. *Root* perennial, branched. *Herb* hairy, procumbent, branched. *Stem* round, hollow. *Leaves* opposite, rather fleshy, ovate, entire, about half an inch long, tapering at the base into a short footstalk. *Flower-stalks* sometimes shorter, sometimes longer than the leaves, round, simple, single-flowered. *Calyx* hairy all over. *Corolla* finely downy within; its limb short, in four shallow lobes.

All the species are herbaceous, some smooth, some hairy. *Leaves* sometimes all crowded about the root; always simple, undivided and entire.

None of these plants have been raised in Europe.

MITRAVINDA, in *Hindoo Mythology*, one of the eight wives assigned to Krishna.

MITRE, MITRA, from *μῆτρα*, which signifies the same; a pontifical ornament, worn on the head by bishops, and certain abbots, on solemn occasions.

The mitre is a round cap pointed, and cleft at top, with pendants hanging down on the shoulders, and fringed at both ends. The bishop's is only surrounded with a fillet of gold, set with precious stones; the archbishop's issues out of a ducal coronet. These are never used otherwise than on their coats of arms. Abbots wear the mitre turned in profile, and bear the crozier inwards, to shew that they have no spiritual jurisdiction without their own cloisters.

The pope has also granted to some canons of cathedrals the privilege of wearing the mitre. The counts of Lyons are also said to have assisted at church in mitres.

In Germany, several great families bear the mitre for their crest; to shew that they are advocates, or feudatories, of ancient abbeys, or officers of bishops, &c.

The pope has four mitres, which are more or less rich, according to the solemnity of the feast days they are to be worn on. The mitre was originally the women's head dress, as the hat was that of the men. This appears from Remulus in Virgil, who reproaches the Trojans, that they were dressed like women, and wore mitres.

“Et tunice manicas & habent redimicula mitræ.”

The cardinals anciently wore mitres, before the hat, which was first granted them by the council of Lyons, in 1243. Authors make no mention of the mitre as an episcopal ornament, before the year 1000.

MITRE, in *Architecture*, is the workmen's term for an angle that is just 45 degrees, or half a right one.

If the angle be a quarter of a right angle, they call it a half-mitre.

To describe such angles, they have an instrument called the mitre-square; with this they strike mitre-lines on their quarters, or battens; and for dispatch, they have a mitre-box, as they call it, which is made of two pieces of wood, each about an inch thick, one nailed upright on the edge of the other; the upper piece hath the mitre-lines struck upon it, on both sides, and a kerf, to direct the saw in cutting the mitre-joints readily, by only applying the piece into this box.

MITRE is used by the writers of the Irish history for a sort of base money, which was very common there about the year 1270, and for thirty years before, and as many after. There were, besides the mitre, several other pieces called according to the figures impressed upon them, rolaries, lionades, eagles, and by the like names. They were imported from France, and other countries, and were so much below the proper currency of the kingdom, that they were not worth so much as a half-penny each. They were at length decayed in the year 1300, and good coins struck in their place. These were the first Irish coins in which the sceptre was left out. They were struck in the reign of Edward, the son of our Henry III., and are still found among the other antiquities of that country. They have the king's head in a triangle full-faced. The penny, when well preserved, weighs twenty-two grains; the halfpenny ten grains and a half.

MITRE-SILS, in *Canals*, are the angular sils of lock-gates.

MITRED ABBOTS. See ABBOT.

MITREKE, in *Geography*, a town of Arabia, in the province of Oman; 44 miles W. of Haske.

MITREOLA, in *Botany*, a name given by Linnæus, in the first edition of his *Genera Plantarum*, to the *Mitra* of Houkoun, engraved in the nineteenth unpublished plate of that botanist, both names alluding to the resemblance of the minute capsule to a mitre. See OPHIORRHIZA.

MITROVATZ, in *Geography*, a town of Slavonia; 32 miles E.N.E. of Gradisca.

MITTA, in our *Old Writers*, is an ancient Saxon measure. Its quantity is not certainly known; but it is said to be *mensura decem modiorum*, a measure of ten bushels. Doomsday.

Mitta, or *mitcha*, being besides a measure for salt and corn, is used for the place where the cauldrons were put to boil salt. “Chalderias quoque ad sal conficiendum cum propriis sedibus mitche vocantur.”

MITTAMPOUR, in *Geography*, a town of Hindoostan, in Rohilcund; 20 miles S.W. of Bissowla.

MITTAW, the capital of the duchy of Courland, the residence of the duke and of the regency of the country, situated on the river Aa, in that part of the duchy called “Semigallia.” The town is extensive, containing within

its circuit many gardens and vacant spaces. The walls and moats are decayed, and the houses are destitute of elegance; nevertheless it is tolerably well inhabited. It has two Lutheran churches, a beautiful Calvinistic church, and a Popish church. The town school, though the principal in the country, is not flourishing. The palace, built by the late duke, is a pile of buildings, in which are spacious and handsome apartments almost wholly unfurnished. The academy, constituted at a great expence, contained, in May 1785, almost as many professors as students, the former being eight, and the latter twenty; 56 miles W. of Riga. N. lat. 56° 38'. E. long. 23° 10'.

MITTELWALD, or MIEDZIBOR, a town of Silesia, in the principality of Oels; 16 miles N.E. of Oel. N. lat. 51° 23'. E. long. 17° 40'.—Also, a town of Silesia, in the county of Glatz, on the Neisse, near its source, and on the borders of Bohemia; 27 miles S. of Glatz. N. lat. 50° 2'. E. long. 16° 29'.

MITTENDARI, among the Romans, commissioners sent into the provinces by order of the *prefectus pratorii*, or captain of the guards, upon some public account, as to inspect the behaviour and management of provincial governors, and observe whatever was amiss; all which they were to lay before the prefect, who had authority to remedy such abuses.

MITTENDIS *Recordo & Proecessu*. See RECORDO.

MITTENDO *Manuscriptum Pedis Finis*, in *Law*, a writ judicial, directed to the treasurer and chamberlains of the exchequer, to search for and transmit the foot of a fine, acknowledged before justices in eyre, into the common pleas, &c.

MITTENWALD, in *Geography*, a town of Bavaria, in the bishopric of Freysing; 10 miles N.N.W. of Innspruck.

MITTENWALDE, a town of Brandenburg, in the Middle Mark; 22 miles S.E. of Potsdam. N. lat. 52° 15'. E. long. 13° 32'.

MITTER L'ESTATE, and *Mitter le droit*. See RELEASE.

MITTERBURG, in *Geography*, a town of Istria, and capital of a county, containing several churches and a convent; defended by a castle, which is situated on a rock; 30 miles S.E. of Trieste. N. lat. 45° 23'. E. long. 14° 7'.

MITTERSILL, a town of Salzburg, on the Salz- bach; 36 miles S.S.W. of Salzburg.

MITTIMUS, in *Law*, a writ by which records are ordered to be transferred from one court to another; sometimes immediately, as out of the king's bench into the exchequer; and sometimes by a certiorari into the chancery; and from thence, by a mittimus, into another court.

MITTIMUS is also used for a precept in writing, directed by a justice of peace to a gaoler, for the receiving and safe-keeping a felon, or other offender, by him committed to the gaol.

This is a warrant under the hand and seal of the justice, containing the cause of the commitment of the offender.

MITTWEYDA, in *Geography*, a town of Saxony, in the circle of Leipzig; 30 miles W. of Dresden. N. lat. 50° 58'. E. long. 12° 52'.

MITU, or MITU-PORANGU, in *Ornithology*, the name of a Brazilian bird of the pheasant kind, according to Mar- grave, and the generality of those who speak of it; but supposed by Mr. Ray rather to approach to the nature of the peacock or turkey-cock; and in the Linnæan system a species of the *crax*; the *CRAX Alegor*, which see.

MITYLENE, or METELIN, the ancient *Lesbos*, one of

MITYLENE.

the most considerable islands of the Grecian Archipelago, is situated in the vicinity of the coast of Natolia, which it seems to command, and it is placed at an equal distance from the gulf of Smyrna and the channel of Constantinople, not far from the principal islands of the Archipelago. By this position the possession of it is extremely important, more especially as its interior resources render it susceptible of the most flourishing state. But being in the hands of the Turks, the advantages of its situation are lost, and its population, agriculture, and industry are from day to day diminishing and falling into decay. In some parts of the island, said to be 36 miles long and 14 broad, are volcanic mountains and others composed of marble, that extend almost through the island: its mountains are covered with wood, particularly with pines that yield excellent pitch for the use of the dock-yard established near the fourth harbour, and for the careening of the vessels and boats which come to Mitylene for that purpose. On these mountains are also found oaks, the arbutus, the andrachne, the lentisk, the turpentine tree, the myrtle, the agnus castus, a few leguminous shrubs, and several rock-roses, among which is that which yields the ladanum. The "velana" oak is more common on the rising grounds and in the plains than on the mountains. The elm grows in the low and watered places, and the plane tree is chiefly found on the brinks of the rivulets and torrents. The mountains also afford a variety of springs, of which some are medicinal. The vallies of the island are extremely fertile, well watered, and in some degree cultivated, though in this respect they admit of much improvement. The principal towns of this island are Mitylene and Molivo, which see; and its harbours are port Caloni and port Olivier. At the head of port Caloni is a plain two leagues in extent, the principal culture of which consists in corn, cotton, and olive trees; figs, musk and water melons, pumpkins, and various legumes are also gathered here. Here are several villages; but the population is not proportioned to the fertility and extent of the soil adapted to culture. The air in this quarter is insalubrious, and often fatal; so that these villages are inhabited only by poor Greek cultivators: the Turks, who are proprietors of lands, preferring a residence at Mitylene, Molivo, and the other places that are best situated in the island.

Port Caloni lies in the middle of the southern part of the island; it is very extensive and very safe, but little frequented; none but vessels thwarted by the wind, or buffeted by a storm, anchoring here, and not one entering it to take in a cargo, or to unload. The other port, called port Yero or port Olivier, derives its name from the great number of olive trees which are planted in the adjoining plain, and on the declivity of the mountains and hills that surround it. In the eastern part of the harbour, there are a few calcareous hills, which have not been attacked by the fire of volcanoes. Here is found near the sea a copious spring of hot mineral water, much valued by the inhabitants of Mitylene. The captain-pacha has built here a basin capable of containing 10 or 12 persons; he has also repaired the building, which is occupied by the Turk charged to receive all those who wish to make use of these waters; which are nearly two leagues from Mitylene. Port Olivier is one of the safest and most spacious harbours of the Archipelago; it lies at the eastern and southern extremity of the island, and is said to abound with fishes and conchylia, among which are excellent oysters, which are carried to Scio and Smyrna. It is frequented, during the whole year, by boats and vessels that come hither to load with the oil which is made in the environs. Although this island is exposed in winter to sudden gales of wind from the N.E. and the E., which come from the mountains of

Asia, as well as to the N. wind, which reigns over the whole Archipelago, the climate is nevertheless tolerably fine, and the temperature of the air somewhat mild. It seldom freezes in that season; but in summer the heat is rather powerful on the S. coast, and the air is, in general, more unwholesome there than in the other parts of the island. This island is divided into lordships; but as the aga of other countries is obliged to join the land-forces when required at Mitylene, he is subject to a maritime duty, from which he contrives to exempt himself by some pecuniary sacrifices. In Mitylene are reckoned 8000 Greeks paying the karatch, (capitation tax,) from the age of seven to their death; so that the population may be estimated at near 20,000, including the women and children above that age. It is thought that there are nearly as many Turks as Greeks in the island, which contains in all 40,000 inhabitants. The Jews are not sufficiently numerous to be taken into the calculation. According to an ancient custom in this island, the eldest daughter alone inherits the property of the father and mother to the exclusion of the sons and other daughters. This custom has been long respected and religiously followed; but of late the patriarch of Constantinople, the archbishop, and all the clergy of Mitylene have somewhat modified this law, by admitting all the daughters to a partition in a certain proportion. The quantity of oil which is exported from this island in ordinary seasons is estimated at upwards of 50,000 quintals; almost the whole of which is sent to Constantinople. The oil is, in general, but of an indifferent quality, because the inhabitants, not having a sufficient number of mills, are obliged to gather their olives slowly. Italy draws from Mitylene 8000 quintals of "Velanida," a part of which comes from the coast of Asia. Dried figs are an article of exportation of little importance, as well as wool. Cotton, sesamum, silk, ivory, wax, and different species of grain are gathered in a small quantity; but the last are not sufficient for the supply of the inhabitants, who draw a great quantity of wheat and barley from the coast of Asia. They also import oxen, horses, and mules for agriculture and draught, as well as part of the sheep that are killed at the slaughter-house. Wine is now scarce, because a great part of the grapes is employed by the Turks in making confection, and because the Turks are accustomed to convert the other into brandy. The wine of ancient Lesbos has lost its reputation, being sweet and ill-flavoured, as are, in general, all the wines of the Archipelago. Although there are no rivers in this island, a few torrents, supplied by rain waters and springs, serve to furnish sufficient water for consumption and for watering part of the plains, so as to procure for the inhabitants legumes, herbage, and fruits.

In the channel formed by the island of Mitylene and the coast, at the entrance of the Adramyttian gulf, are some small islands, which the Greeks call "Musconisi," and navigators "Myconisses," but formerly they bore the name of "Hecatones." They are said to be fertile in wines and oil. For the ancient state of this island, see LESBOS.

MITYLENE, sometimes called "Castro," or "Metelin," is the chief town of the island above described. It contains 2 or 3000 Greeks, 3 or 4000 Turks, and 30 or 40 Jewish families. The citadel is spacious, provided with cannon in tolerably good condition, and defended by 5 or 600 janizaries, almost all married and settled. Within it are two mosques and a great number of houses occupied by this militia. The modern town extends in a semicircle along the north harbours, on a part of the ground occupied by the ancient city; of the former grandeur of which some remains are still visible. Cicero de Leg. Agr. and Vitruvius, lib. i. c. 6. expatiate on its magnificence. Such was the flourishing

flourishing state of the fine arts in the city of Mitylene, called by Strabo *ἡ μουσικὴ πόλις*, when Marcellus, after the battle of Pharsalia, returned to end his days there in literary ease, that a modern traveller, after the lapse of 17 centuries, could behold nothing but proofs of the splendour to which they had attained. *Tournef. Voy. du Lev. tom. ii. p. 81. See LESBOS.*

The two harbours of Mitylene are separated by a tongue of land, on which was constructed by the Genoese a citadel, which the Turks have preserved. The upper or north harbour is secured from the N.E. wind by a jetty, the origin of which is carried back to ancient Greece. The south harbour is open and faces the S.E.; it is a little less extensive and less deep than the other; none but the boats of the country can anchor in it, while the north harbour can admit small merchant vessels. Men of war and European ships, which commerce attracts to Mitylene, anchor in summer off the south harbour; but they scarcely expose themselves there in winter, because there happen sometimes in that season very impetuous gales from the N.E., which might occasion their destruction, or oblige them to cut their cables, and get under sail with all expedition. There was formerly a canal of communication between these two harbours, which separated the tongue of land just mentioned, and formed of it an island, on which was built part of the town. Time has choked up the canal, but it has not destroyed the jetty, which ran from the little island, and sheltered the north harbour from the worst weather. N. lat. 39 20'. E. long. 26 14'. *Olivier's and Sonnini's Travels. Clarke's Travels, vol. ii.*

MITZLER, LORENZ CHRISTOPH, of Kolof, in *Biography*, born in 1711, a singular character and voluminous publisher on musical subjects. But before he meddled with music, his pretensions were various. He set off a doctor of physic, then got ordained a minister of the Lutheran church, and next assumed the character of a counsellor learned in the law. After trying his hand at these professions, in music he appeared at first a theorist and critic more than a practical musician. In 1740, however, he composed odes, which were mathematical, dry, and dull. These were ridiculed throughout Germany. Mattheson is very jocular on his works; but Mitzler took all for serious panegyric. Among his numerous productions specified by Gerber, (in his continuation of Walther's Musical Lexicon,) many of which have, perhaps, never been read, there is no one which seems to have merited that honour. He died in 1778. If his life was of little use to the world, it must be owned that he diligently tried to render the world useful to himself.

MITZUZ, in *Geography*, a town of Japan, in the island of Nippon; 110 miles W.N.W. of Jedo.

MIXCO, a town of Mexico, in the province of Guatimala; 25 miles E. of Guatimala.

MIXEN, in *Agriculture*, a term applied to a compost dunghill. See COMPOST and MANURE.

MIXING of Mortar. See MORTAR.

MIXIS, *Μίξις*, *Mixture*, in the *Ancient Music*, was one of the parts of Greek melopœia, by which the composer was instructed how to combine intervals properly, and distribute them in different genera and modes, according to the character of the melody proposed. See MELOPŒIA.

MIXO-LYDIAN, the name of one of the modes of ancient music, called also *Hyper-Dorian*; which see. The mixo-lydian mode was the most acute of the seven modes to which Ptolemy had reduced all the modes of the Greek music. (See MODE.) This mode was said to be affecting and passionate, exciting great emotions, and therefore applicable to tragedy. *Aristoxenus* assures us, that it was invented by

Sappho; but *Pittarch* avers, that ancient fables ascribe it to Pytochides. He also says that the Argians fined musicians who first adopted it, and who had introduced into music the use of seven strings; that is, making the seventh string a key-note.

MIXT, or MIXED Body, in *Philosophy*, is that which is compounded of divers elements or principles.

By which *mixt* stands contradistinguished from *simple*, or *elementary*, which is applied to bodies consisting of one principle only.

The schoolmen define a mixt body to be a whole resulting from several ingredients, altered, or new modified, by the mixture. On which principle the several ingredients do not actually exist in the mixt; but they are all changed, so as to conspire to a new body, of a different form from that of any of the ingredients. But the modern philosophers rarely conceive the term in so much strictness. The business of chemistry, we say, is to resolve mixt bodies into their principles, or component parts.

The school philosophers distinguish mixt bodies into perfect and imperfect.

MIXTS, *Perfect*, are the class of organized and animated bodies, where the elements, or ingredients of which they are composed, are changed, or transformed, by a perfect mixture. Such are plants, beasts, and men.

MIXTS, *Imperfect*, are unorganized and inanimate bodies, the forms of which remain still the same as of the ingredients that constitute them. Such are meteors, minerals, metals, &c.

MIXT, in *Chemistry*. See AGGREGATE.

MIXT, or *Mixed Action*, in *Law*. See ACTION.

MIXT Angle, *Fable*. See ANGLE, and FABLE.

MIXT Figure, in *Geometry*, is that which consists partly of right lines, and partly of curve lines.

MIXT Force, *History, Mathematics*. See FORCE, HISTORY, and MATHEMATICS.

MIXT, or *Mixed Larceny*. See LARCENY.

MIXT Mode. See MODE.

MIXT Number, in *Arithmetic*, that which is partly an integer, and partly a fraction: as $4\frac{1}{2}$.

MIXT Obligation. See OBLIGATION.

MIXT Ratio, or *Proportion*, is when the sum of the antecedent and consequent is compared with the difference between the antecedent and consequent: as if $3 : 4 :: 12 : 16$
 $a : b :: c : d$

then $7 : 1 :: 28 : 4$
 $a + b : a - b :: c + d : c - d.$

MIXT Salts, *Stairs, Service*. See SALTS, STAIRS, and SERVICE.

MIXT Tithes, are those of cheese, milk, &c. and of the young of beasts. See TITHE.

MIXTILINEAR ANGLE. See ANGLE.

MIXTION, MIXTIO, or *Mislio*, the act of mixing; or the union and coalition of divers conspicles into one body. The Peripatetics, who hold an alteration essential to mixtion, define it the union of several altered ingredients, or miscibles.

Mixtion makes a considerable operation in the chemical and Galenical pharmacy; where divers powders, species, and other simples, are said to be *mixed*, *misceri*, though without any communication, or transition of the virtues of one into those of another. See COMBINATION and COMPOSITION.

MIXTURE, MESCOLANZA, a connection in the modes of canto-fermo, in chants which go higher or lower than the octave, and modulate into another mode, participating both

both of authentic and plagal. The mixture is only practicable in modes that go in pairs, as the first mode or tone, and the second, the third with the fourth, the plagal with the authentic, and reciprocally.

MIXTURE, the name of a stop in the full organ, repeating the same intervals of the octave in the key of C throughout the scale. See FURNITURE.

MIXTURE, *Mixtura*, or *Mislura*, in a philosophical sense, is an assemblage, or union, of several bodies of different properties, in the same mass.

To determine the ratio of the ingredients of a mixture, is that celebrated problem proposed by Hiero, king of Syracuse, to Archimedes, on occasion of a crown of gold, in which the workman had fraudulently mixed silver; the solution of which was matter of so much transport to that divine mechanic. See *HIERO'S CROWN*.

MIXTURE, in *Matters of Drapery*, denotes the union or blending of several wools of different colours, not yet spun. Hence a mixture, or mixed stuff, is that whole wool and warp are of wools of different colours, dyed and mixed before they were spun. See CLOTH.

MIXTURE, in *Pharmacy*, differs from a julep in this respect, that it receives into its composition not only salts, extracts, and other substances dissoluble in water, but also earths, powders, and such substances as cannot be dissolved.

Mixtures depend upon diffusion and suspension in any liquid of insoluble substances minutely divided; and for this purpose, it is often necessary that the liquid itself should be rendered more dense by the addition of some viscid matter, as mucilage or syrup. Mixtures are sometimes denominated from their medical properties and effects; such as astringent, diuretic, laxative, &c. but most commonly from the name of the principal ingredient used in their composition. The London college includes under the general head of mixtures those medicines which have usually been denominated *emulsions*. See EMULSION.

The principal mixtures are the following:

Mislura ammoniaci, Mixture of gum ammoniac, P. L. is formed by rubbing two drachms of gum ammoniac with half a pint of water gradually poured upon it, until they are perfectly mixed. A similar preparation, under the name of *lac ammoniac*, milk of ammoniac, is ordered by the Dublin college to be made by triturating a drachm of gum ammoniac in eight fluid-ounces of penny-royal water, gradually adding the water until the mixture acquires the appearance of milk, and then straining it through linen. This preparation is beneficially employed as an expectorant in doses of from f. ℥ss to f. ℥j, combined with an equal quantity of almond mixture.

Mislura amygdalæ, Almond mixture, P. L. 1809, *Lac amygdalæ*, P. L. 1787, *Emulsio communis*, P. L. 1745, is prepared by gradually adding a pint of distilled water to two ounces of almond confection, and rubbing them together. A similar mixture, called *emulsio amygdalæ communis*, almond emulsion, in the Edin. disp. is prepared by well beating an ounce of blanched sweet almonds in a stone mortar, gradually adding 2½ lbs. of water, and then straining. The *lac amygdalæ*, almond milk of the Dub. coll. is formed by rubbing 1½ oz. of sweet almonds blanched with ½ oz. of purified sugar, adding gradually 2½ pints of water, and then straining. The *emulsio vinosæ niloticæ*, emulsio arabica, Edin. or emulsion of gum arabic, is made in the same manner as the almond emulsion, 2 oz. of gum arabic being added during the trituration of the almonds. The *Arabic emulsion*, Dub. is prepared by dissolving two drachms of gum arabic in powder in a pint of warm decoction of barley, and when it is almost

cold, pouring it gradually upon half an ounce of blanched sweet almonds beaten to a palle, with the same quantity of purified sugar, triturating at the same time so as to form a milky mixture; and then straining.

The mixtures above described are used as diluents and demulcents in inflammatory fevers, strangury, dysury, and other affections of the urinary organs; but they are principally employed as vehicles for the exhibition of more active remedies. The dose is from f. ℥ij to oʒs frequently repeated.

Mislura affasætidæ, Mixture of affasætida, P. L. 1809, *Lac affasætidæ*, P. L. 1787, is prepared by rubbing two drachms of affasætida with half a pint of water, gradually poured upon it, until they are perfectly mixed. The *lac affasætidæ*, milk of affasætida, Dub. is obtained by triturating a drachm of affasætida with eight fluid-ounces of penny-royal water gradually added until an emulsion is formed. This mixture is chiefly used as an enema in flatulent colic, worms, and convulsions of infants occasioned by irritation of the bowels during dentition. When given by the mouth, the dose may be from f. ℥ss to f. ℥jss often repeated.

Mislura camphoræ, Camphor mixture, P. L. 1809, *Mislura camphorata*, P. L. 1787, *Julepum è camphora*, P. L. 1745, is formed by rubbing half a drachm of camphor with 10 minims of rectified spirit, then adding gradually a pint of water, and straining the liquor. The *mislura camphorata*, Dub., camphorated mixture, is prepared by rubbing a scruple of camphor with 10 drops of rectified spirit of wine, and then with half an ounce of refined sugar, adding a pint of water during the trituration, and straining the mixture through linen. This is an elegant vehicle for more active remedies in low fevers and nervous affections. The dose is from f. ℥j to f. ℥ij, given every three or four hours. The *emulsio camphorata*, Edin., camphorated emulsion, is made of a scruple of camphor, two drachms of sweet almonds blanched, a drachm of refined sugar, and 6 oz. of water, in the same manner as the common almond emulsion. This is given with advantage in typhus and nervous cases in doses of f. ℥ij, every three or four hours. See CAMPHOR.

Mislura cornu ussi, Mixture of burnt hartshorn, P. L. 1809, *Decoctum cornu cervi*, P. L. 1787, *Decoctum album*, P. L. 1745, is prepared in the manner described under *Hart's HORN*.

Mislura cretæ, Chalk mixture, P. L. 1809, *Mislura cretacea*, P. L. 1787, *Julepum è cretæ*, P. L. 1745, is formed by mixing half an ounce of prepared chalk, three drachms of refined sugar, half an ounce (an ounce Dub.) of acacia gum powdered in a pint of water. The *potio carbonatis calcis*, olm, *potio cretacea*, Edin., chalk potion, is made by rubbing together 1 oz. of prepared carbonate of lime (chalk), ½ oz. of refined sugar, 2 oz. of mucilage of gum arabic, then gradually adding 2½ lbs. of water and 2 oz. of spirit of cinnamon, and mixing them.

These preparations of chalk are given in acidity of the primæ viæ, and combined with opium or catechu in diarrhœa. The dose is from f. ℥j to f. ℥ij, given every three or four hours; or after every liquid evacuation.

Mislura ferri composita, Compound mixture of iron, P. L. 1809, is prepared by rubbing together a drachm of powdered myrrh, 25 grains of subcarbonate of potash, and a drachm of refined sugar, and during the trituration adding gradually, first, 7½ oz. of rose-water and half a fluid-ounce of spirit of nutmeg, and lastly, a scruple of sulphate of iron powdered. The mixture should be immediately poured into a proper glass bottle and stopped close. The myrrh requires to be well dried before it can be reduced to powder. This mixture, which is very similar to the celebrated anti-hectic

hectic mixture of Dr. Griffiths, is a compound very commonly directed as an useful tonic, particularly in hysteria and chlorosis, and in phthisis, when no active inflammatory diathesis subsists. The dose is from f. ℥j to f. ℥ij, given two or three times a day.

Mistura guaiaci. Mixture of guaiacum, P. L. 1809, *Lac guaiaci*, P. L. 1787, is made by rubbing 1½ drachm of guaiacum gum-resin with two drachms of refined sugar; then with two fluid-drachms of mucilage of acacia gum, and when they are mixed, pouring on gradually eight fluid-ounces of cinnamon water. This is administered in doses of from f. ℥ss to f. ℥ij, two or three times a day; diluting freely with tepid barley water or gruel for aiding its operation.

Mistura moschi. Musk mixture, P. L. 1809, *Mistura moschata*, P. L. 1787, *Julepum é moscha*, P. L. 1745, is prepared by rubbing a drachm of musk with the same quantity of refined sugar, then with the same quantity of acacia gum powdered, and adding by degrees six fluid-ounces of rose-water. This may be given to the quantity of f. ℥ij every three or four hours in spasmodic affections and the sinking state of typhus. The late Mr. White of Manchester found this mixture combined with ammonia ℥f, spirit of lavender f. ℥i, and spirit of juniper f. ℥j, very useful in sloughing phagedenic ulcers of a syphilitic and strumous nature.

MIZÆEL, in *Geography*, a town of Norway, in the diocese of Drontliem; 44 miles N.E. of Romsdal.

MIZELL, a town of Bohemia, in the circle of Bolef-law; nine miles S.E. of Jung Buntzel.

MIZEN. See MISEX.

MIZEN-HEAD, in *Geography*, supposed to be the Notium of Ptolemy, a cape of the county of Cork, Ireland, being the south-westerly extremity of the island as well as of the county of Cork. N. lat. 51° 23'. W. long. 9° 43'.

MIZEN-HEAD, a cape of Ireland, in the county of Wicklow, on the E. coast between Wicklow-head and Arklow. N. lat. 52° 52'. W. long. 6° 4'.

MIZNEPETH, in the *Jewish Antiquities*, a kind of mitre worn by the high-priest. See CIDARIS.

MIZQUITL, in *Botany*, a name used by some authors for that species of the acacia, or Egyptian thorn, whose unripe fruit affords the inspissated juice, which is the true succus acacie of the shops, and whose gum naturally flowing from the trunk and branches is the true gum arabic.

MIZZY, in *Agriculture*, a term sometimes applied to a bog, or a quagmire.

MLIOWNOWY, in *Geography*, a town of Poland, in the palatinate of Kiev; 40 miles S.W. of Czyrkafy.

MLLAVA, a town of the duchy of Warsaw; 40 miles N.N.E. of Plozk.

MLODE, a town of Poland, in the palatinate of Kiev; eight miles S.E. of Bialacerkiew.

MNAKEH, a town of Arabia, in the province of Yemen; 12 miles W. of Sana.

MNASIUM, in *Botany*, is most probably named by Schreber from some resemblance to the *μνασιον* of Theophrastus, an Egyptian plant, eatable like *papyrus*, and of a very sweet taste. Mart. Schreb. 214. Willd. Sp. Pl. v. 2. 22. Mart. Mill. Dict. v. 3. (*Rapatea*; Aubl. Guian. v. 1. 305. Juss. 44. Lamarek Illustr. t. 226.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Eufata*, Linn. *Junci*, Juss.

Gen. Ch. *Cal.* Spatha of two, ovate valves, terminated by a linear, spreading leaf. Perianth inferior, of one leaf, divided into three, lanceolate, concave, acute, bordered segments. *Cor.* of one petal; tube very short; limb cloven into three, deep, lanceolate, concave, acute seg-

ments. *Stam.* Filaments six, very short, inserted into the tube; anthers long, square, terminated by an ovate, excavated, acute leaflet. *Pyl.* Germen superior, three-lobed, roundish, marked with three streaks; style very long, striated; stigmas three, spirally twisted together. *Peric.* and *Seed* unknown.

Eff. Ch. Spatha of two valves, many-flowered. Calyx three-cleft. Corolla of one petal, three-cleft, with a very short tube. Anthers terminated by a leaflet. Stigmas three, spirally twisted.

1. *M. paludosum* Willd. and Martyn. (*Rapatea paludosa*; Aubl. Guian. t. 118)—Native of woods, marshes, and the banks of rivers in Guiana, flowering in June.—Root perennial, woody, fibrous. Stalks numerous, naked, two feet high, striated, compressed, bordered, gradually broader towards the top, and springing from the bases of the radical leaves. Leaves very long, narrow, acute, smooth, striated, entire; sheathing at the base, and mutually embracing each other; narrower above the sheath. Flower-stalks scaly beneath the base of the calyx. Corolla yellow.

Willdenow observes, that *Mnasia* has greatly the habit of a *Pontederia*, but that it differs materially from that genus in the structure of its flowers.

MNEME-CEPHALICUM BALSAMUM, the name of a famous compound balsam, said to have been purchased from a certain English physician by Charles duke of Burgundy, at the price of 10,000 florins. Some who have been very lavish in its praises have affirmed, that it has a power of preserving in the mind the remembrance of all things that are past; but this kind of praise seems to be extravagant and unfounded; inasmuch, that we think it needless to enumerate the ingredients of which this famous balsam (which we regard as fabulous in the effects ascribed to it) consists. We shall therefore content ourselves with referring to Sennertus' account of it in his Pract. lib. i. cap. 5.

MNEMONIC TABLES. Among the artifices to assist the memory, this is one of great use.

Mnemonic tables exhibit in a regular manner, what is to be remembered of the same subject. And although the sciences ought to be taught in a scientific manner, as much as possible, and that every thing should be so placed as to be intelligible and demonstrable from what has preceded it; yet tables ought not to be rejected, as they are helps to retain the doctrines of which the mind has had sufficient evidence. In such tables the properties of things are to be expressed concisely; illustrations and demonstrations should be left out, as the proposition ought to have been made sufficiently clear and certain, before it is registered in the table. Hence, the contents of such tables ought only to be the definitions, and the propositions relative to the subject. If a subject require a long table, this may be subdivided into smaller; by making first a table of the most general heads, and referring from each of these heads to a separate table; by this means the order and connection of the whole will be preserved. Such tables would produce a local and artificial memory, of great use to the retention and recollection of things. They would greatly facilitate a distinct view of the properties of their subjects, and facilitate recapitulation. Besides, as the expressions used in such tables ought to be very concise, so as just to be sufficient to excite the idea of the object to be remembered, soon after that idea has been acquired; after some time a certain obscurity will be found in perusing the tables, which will give us timely warning that our ideas begin to fade, and that they ought to be renewed. And this may be done without much trouble, if not too long delayed.

MNEMO-

MNEMONICA, formed of *μνημονεύειν*, I retain in memory, denotes the art of memory. Under the article MEMORY we have illustrated the nature and operation of this faculty, and mentioned some of the principal methods, both ancient and modern, which have been invented for aiding the exercise of it. Since that article was printed, we have had an opportunity of perusing a publication, entitled "The Art of Memory, founded upon the principles taught by M. Gregor Von Feinaigle," &c. The author has, with great industry of research, detailed the principal systems of artificial memory, both before and after that of Mr. Grey was announced to the public in his "Memoria Technica," of which we have given a concise account under the article above cited. It sufficiently appears, without any laboured proof, that the principal expedient for assisting the memory is derived from association; and of this expedient Simonides, Cicero, and Quintilian availed themselves in the contrivances which they suggested for this purpose. Having fixed upon certain symbols of the subjects which they wished to recollect, they would transfer these symbols to the different compartments of a house, or public building, or to the different parts of the walls of a city, a public road, or a picture, and when these compartments, &c. presented themselves to view, or occurred in recollection, they would suggest the symbols attached to them, and these symbols would revive the remembrance of the sentences or subjects, or parts of those sentences, to which they appertained: and thus, by means of such compartments and symbols, a whole discourse might be committed to memory, and recollected when occasion required. Upon these principles, as we have reason to believe, was founded the topical memory of the ancients; and from this source, without doubt, are derived all the various systems of local and symbolical memory, that have been practised in more modern times.

Bradwardine seems to have been the first, who in this country made an attempt to form a system of topical memory on the plan of the ancients. (See BRADWARDINE.) The "Ars Memorativa" of Publicius, probably printed before the year 1482, treats of the arrangement of places, and the combination of images, and has been the fountain whence many subsequent writers have derived considerable information. Grataroli, in his "Castel of Memorie," a translation of which by W. Fulwood was published at London in 1562, and Thomas Watson of Oxford, in his MS. entitled "Artificiose Memorix Libellus," dated 1583, preserved in the British Museum, have referred to the ancient plan of dividing houses and walls for the assistance of the memory. J. Baptista Porta, in his "Ars Reminiscendi," printed at Naples in 1602, treats, like the authors already mentioned, of places and images; exchanges figures for symbols; represents letters by symbols, and gives two alphabets, one consisting of letters formed from various objects, and another, in which they are deduced from the different positions of the human body. Schenckel, a native of Bois-le-Duc, in 1547, and the author of "Gazophylacium Artis Memorix," published in 1610, propagated his discoveries in the mnemonic art through the Netherlands, Germany, and France, and they were received with great applause. The performances of this author excited astonishment; he repeated 40 sentences of some length, without any connection, and after merely writing them down and reading them twice, backwards and forwards, and in any order that was desired. Some of his pupils also distinguished themselves in a still more surprising manner. A German translation of Schenckel's work was published by Dr. Klüber, in 1804, under the title of "Compendium der Mnemonik, &c." The treatise of John Willis, entitled "Mnemonica

&c." Lond. 1618, and a translation of which by Sowersby was published at London in 1661, contains many curious particulars. His plan is that of a topical memory; or of a memory to be assisted by some suitable edifice, and its appropriate divisions. The "Ars Memorix localis," published at Leipsic in 1620, and written by one of the professors of the university, merits preference, according to Morhof in his "Polyhistor," to all the treatises on mnemonics for perspicuity and arrangement. Morhof, in his dissertation "De Arte Lulliana" (see Polyhistor, T. t. l. 2. c. 5.) has preserved an elaborate account of Raymund Lully's system of artificial memory, to which he directed his attention at a very early period, and he is supposed to have been the first among the moderns who practised this art. (See the article LULLY.) D'Assigny's "Art of Memory," a third edition of which was published in London in 1706, contains many useful observations on the importance of a retentive memory, and on the mode of aiding the exercise of it; but it closes with some fanciful receipts for "comforting the memory," principally taken from early writers on this subject, and hardly deserving to be rescued from oblivion. Buffier's "Pratique de la Memoire Artificielle, &c." 8vo. Paris, 3 tom. 1719—1723, is intended to facilitate the acquisition of chronology and universal history, and his system is said to be ingenious and simple. Of Grey's "Memoria Technica" we have given a concise account under the article ARTIFICIAL MEMORY; more need not here be said, as this useful manual is in almost every one's possession. Lowe's "Mnemonics delineated in a small Compaſs and easy Method, &c." 8vo. Lond. 1737, is considered by Dr. Watts as a material improvement of Grey's treatise, and accordingly it has been annexed to the eighth and last edition of that work. In Feyjoo's "Cartas Eruditas y Curiosas," 4to. 5 tom. Madrid 1781, there is a dissertation on remedies for the memory, and one on the art of memory. In another essay, the principles of the art are stated to consist in particular places and images, and a sphere or globe is divided into various compartments. In a section of this essay, Feyjoo speaks of remembering certain words by the means of images, and in another section he illustrates the application of the art to poetry. Since the posthumous publication of these essays, the author having died in 1765, after having been with difficulty saved from the horrors of the Inquisition, for the freedom of his censures on the licentiousness of the clergy, and the superstitions of the Romish church, (see FEYJOO,) no mention of the local and symbolical memory occurs until the year 1806, when it was announced in the "Philosophical Magazine," (vol. xxvi. p. 282.) that the study of the science of mnemonica was revived in Germany. In 1807, M. Gregor Von Feinaigle, a native of Baden, visited Paris, and delivered lectures on his "New System of Mnemonics and Methodics."

In 1811, M. Feinaigle visited England; and in June of that year he obtained leave from the managers of the "Royal Institution" to exhibit to the public an experiment of the efficacy of his method "of facilitating and assisting memory."—"Four children, two boys and two girls, all under 14 years of age, had been put under M. Feinaigle's care but two or three days before: he had one of the girls but an hour and a half; and the longest tuition that any of them had received was but four hours and a half.—One of them repeated Goldsmith's Hermit backward and forward, and stated the stanza, the line, and the order of any remarkable word required of him.—One little girl answered to questions in the chronology of the Roman emperors; and another multiplied, without slate or paper, two sums of eight figures by eight, and declared that she had not previously been taught arithmetic.—A boy determined the geographical

cal situation, in degrees and minutes, of 50 different cities; and on a planisphere chalked out on a board, marked down the true situation of places named to him.—Mr. Fincher, of the Institution, also recited the mineralogical tables of Linnæus, the second part of which he had taught himself on M. Feinaigle's system, together with the first part of Briffon's ornithologic system; and he declared, from his own experience, that the principles of M. Feinaigle's art were equally calculated to give facility in the acquisition, and certainty in the retention, of the tables of any other science—a fact which was confirmed by several gentlemen present, who have attended the private courses of the professor."—M. Feinaigle has since that time repeated his exhibitions at Liverpool, in Scotland, and in London, to the astonishment of many persons who attended.

Locality, or the connection of our ideas with places, as we are informed by the anonymous author, whose treatise we have cited, is made the foundation of this system. In this respect, it is analogous to the scheme of mnemonics practised by the ancients, but it is here applied much more extensively and advantageously than it was by them. How far it deserves this commendation, the reader who is desirous of farther information concerning it will be informed by consulting the treatise already quoted; in which, as we conceive, there is a just development of the principles of M. Feinaigle; but the detail is so extensive and so incapable of abridgment, that it would be inconsistent with our limits to enlarge, so as to give any satisfaction to our readers. The general principle of this art is that of dividing walls and houses into different compartments, and annexing numbers to them in a particular order, or words together with the numbers; the recollection of these words being assisted by associating some idea of relation between the objects and their situation. Consonants are also annexed to the figures, which letters are not merely arbitrary, but adapted as nearly as possible to the form of the figures. These letters, and the figures which they are intended to represent, should be impressed strongly on the memory, as the consonants must be converted into words by the introduction of vowels. To each word should be affixed some striking idea; and the objects that are selected, each of which is expressed by a word, must be arranged in different places, beginning with the floor, and proceeding to the first, second, and third wall, &c. Having divided a room into parts, as the floor and walls, subdivided these into places, changed figures into letters, and formed words, we shall by these means be enabled to remember a series of figures or things. For this purpose, it would be advantageous to fix upon some room to which we have been accustomed. If this room should have been hung with pictures, engravings or plans, or ornamented with busts, &c. the remembrance of places, or localities, will be facilitated. The order of things in a room will be familiar to us. The squares or places may be filled with some pictures of our own drawing, and it will be as easy to remember the symbols, or hieroglyphics, as to remember the situation or place of any picture, or article of furniture in a room. By supposing the floor to be constructed of mosaic, instead of being covered with a carpet, we shall have spaces for symbols. The outlines of the symbols are intended to represent, as accurately as possible, the various figures in the two rooms, to which our plan extends, so that they may be permanently fixed in our memory. How these symbols are made applicable to chronology, history, &c. requires a more diffuse detail than our limits will allow. Having already given our opinion of the various artifices that have been devised for aiding the memory, it is needless to enlarge. The reader will perceive that it must

VOL. XXIII.

require time and labour, and no inconsiderable exertion of memory, to derive any advantage from mechanical modes of aiding the exercise of it.

Under the article MEMORY, we have given some examples of extraordinary retentiveness in the use of this faculty. To those already mentioned, we shall here add some others. See AVICENNA, FULLER, JEWEL, and SCALIGER.

Lipsius remembered the whole history of Tacitus, and pledged himself to recite it word by word, or any passage that might be required. Francis Suarez could repeat all St. Augustine's works by heart, alleging particular lines and words, with the volume and page in which they occurred. Magliabecchi had a surprising memory. A gentleman who wished to try it, lent him a MS. which he was going to print, and soon after it was returned, the author came to him with a melancholy aspect, and pretended it was lost. Magliabecchi being requested to recollect as much of it as he could, wrote the whole without missing a word, or making any variation in the spelling. We have mentioned some extraordinary instances of the power of memory possessed by Jedediah Buxton under his article. Without the assistance of pen, ink, chalk, or any other mark, he could multiply five or six figures by as many, or divide as large sums off hand, in less time than the most expert arithmeticians could perform their operations. Being asked how many cubical $\frac{1}{4}$ ths of an inch were contained in a body, whose three sides were 23145789 yards, 5641732 yards, and 54965 yards; after about five hours, in the midst of more than 100 of his fellow labourers, he computed the result; and gave it in a line of 28 figures, without the least hesitation or mistake. He would repeat his answers to difficult questions a month or two after he had solved them. Of his own accord he calculated how much one farthing doubled 140 times would amount to; and the answer was set down from his lips in 39 places of pounds, and an odd 2s. 6d. Being once asked how many barley corns would reach eight miles; he answered, in $1\frac{1}{2}$ minute, 1520640 barley corns. In 13 minutes he computed, that the distance of York from London, being 204 miles, a coach-wheel, whose circumference was six yards, would turn round in that interval 59,840 times. By the strength of his memory he multiplied 39 figures by 39 figures, and had no recourse to pen, ink, or paper.

At the moment of writing this article, the editor is informed of a boy, from Vermont in America, not eight years of age, who performs wonders in extempore calculation. The rapidity and correctness with which he multiplies and divides large numbers, with which he finds all the factors of a composite number, and whether any number proposed be prime or not, and with which he solves a variety of arithmetical questions that are proposed to him, are truly astonishing.

The editor has been favoured by F. Baily, esq. of Gray's Inn, an eminently competent judge of those performances in which this boy excels, with the following account. His name is Zerah Colburn. He was born at Cabut, a town lying at the head of Onion river, in Vermont, America, on the 1st of September 1804. He began to manifest his extraordinary powers in August 1810, when he was not six years of age; though he had derived no other advantage from education beyond what was to be obtained at a small school in a remote part of the country. On the 12th of May 1812 he arrived in this country, and has since exhibited his astonishing performances to a great number of spectators, and before many persons of the first eminence for mathematical and philosophical knowledge.

At a meeting of his friends, which was held for the purpose

pose of concerting the best method of promoting the views of the father, this child undertook, and completely succeeded in, raising the number 8 progressively up to the sixteenth power; and in naming the last result, viz. 281,474,976,710,656, he was right in every figure. He was then tried as to other numbers, consisting of one figure; all of which he raised (by actual multiplication and not by memory) as high as the tenth power, with so much facility and dispatch, that the person appointed to take down the results was obliged to enjoin him not to be so rapid. With respect to numbers consisting of two figures, he would raise some of them to the sixth, seventh, and eighth power; but not always with equal facility: for the larger the products became, the more difficult he found it to proceed. He was asked the square root of 106929; and before the number could be written down, he immediately answered 327. He was then required to name the cube root of 268,336,125; and with equal facility and promptness he replied 645. Various other questions of a similar nature, respecting the roots and powers of very high numbers, were proposed by several of the gentlemen present; to all of which he answered in a similar manner. One of the party requested him to name the factors which produced the number 247483, which he immediately did by mentioning the two numbers 941 and 263; which indeed are the only two numbers that will produce it. Another of them proposed 171395, and he named the following factors as the only ones that would produce it; viz. 5×34279 , 7×24485 , 59×2905 , 83×2065 , 35×4897 , 295×581 , and 413×415 . He was then asked to give the factors of 36083; but he immediately replied that it had none; which in fact was the case, as 36083 is a prime number. Other numbers were indiscriminately proposed to him, and he always succeeded in giving the correct factors, except in the case of prime numbers, which he discovered almost as soon as proposed. One of the gentlemen asked him how many minutes there were in forty-eight years; and before the question could be written down, he replied 25,228,800: and instantly added, that the number of seconds in the same period was 1,513,728,000. Various questions of the like kind were put to him; and to all of them he answered with nearly equal facility and promptitude; so as to astonish every one present, and to excite a desire that so extraordinary a faculty should, if possible, be rendered more extensive and useful.

Being asked to inform the gentlemen present how he was enabled to answer, with such facility and correctness, the questions that were proposed to him, he declared that he did not know how the answers came to his mind. It was observed, however, that the child performed his several operations by some rules known only to himself. The discovery was made in one or two instances, when he had been closely pressed upon that point. In one case he was asked to tell the square of 4395; he at first hesitated, fearful that he should not be able to answer it correctly: but when he applied himself to it, he said it was 19,316,025. On being questioned as to the cause of his hesitation, he replied that he did not like to multiply four figures by four figures: but, said he, "I found out another way; I multiplied 293 by 293, and then multiplied this product twice by the number 15, which produced the same result." On another occasion, his highness the duke of Gloucester asked him the product of 21,734 multiplied by 543: he immediately replied 11,801,562: but, upon some remark being made on the subject, the child said that he had, in his own mind, multiplied 65202 by 181. Now, although in the first instance it must be evident to every mathematician that $4395^2 = (293)^2 \times$

$(15)^2$; and further, that in the second case 543 is equal to 181×3 , and consequently that $21734 \times (181 \times 3) = (21734 \times 3) \times 181$; yet, it is not the less remarkable that this combination should be immediately perceived by the child, and we cannot the less admire his ingenuity in thus seizing instantly the easiest method of solving the question proposed to him.

Amongst a variety of cases of this kind, the following singular instance is particularly worthy of being recorded. He was asked to tell the square of 999999: which, after some little time, he stated to be 999,998,000,001; and he further observed, that he had produced this result by multiplying the square of 37037 by the square of 27. He then, of his own accord, multiplied that product by 49; and said that the result (viz. 48,999,902,000,049) was equal to the square of 6,999,993. He afterwards multiplied this product by 49; and observed that the result (viz. 2,400,995,198,002,401) was equal to the square of 48,999,951. He was again asked to multiply this product by 25; and in naming the result (viz. 60,024,879,950,060,025) he said that it was equal to the square of 244,999,755. These astonishing efforts of his mind require no comment; and sufficiently shew that he possesses a more intimate knowledge of the science of numbers than can be obtained by the ordinary, or even more abstruse rules of arithmetic.

It is well known to mathematicians, that Fermat had asserted that $2^{32} + 1 = 4,294,967,297$ was a prime number; but Euler detected that error, by discovering that it was equal to $6,700,417 \times 641$. The same number was proposed to this child, who (after a lapse of some weeks) found out the factors by the mere operation of his mind: and the method which he took to obtain his object, clearly shewed that he had not derived his information from any other source.

MNEMOSILLA, in *Botany*, a genus of Forskall's, which, according to Jussieu, is the same as *HYPERCOUM*. See that article.

MNEMOSYNE, in *Mythology*, was the daughter of *Cœlus* and *Terra*, according to the theogony of Hesiod; and Jupiter being enamoured of her, made her mother to the nine Muses. To Mnemosyne is ascribed, according to Diodorus Siculus, the art of reasoning, and giving suitable names to every being, so that we can describe them, and converse about them without seeing them. Mnemosyne is generally allowed to have been the first who used helps for the memory, and this is intimated in her name.

MNETHEL, in *Geography*, a town of Persia, in the province of Chusistan; 102 miles E. of Sulter.

MNEVIS, in *Mythology*, the name of a sacred bull, consecrated to the sun, and worshipped by the Egyptians at Heliopolis. The worship of Mnevis gradually disappeared, when Apis became the general deity of the country. From the era in which Cambyles overthrew the magnificent temple of Heliopolis, we may date the downfall of the worship of Mnevis. This Mnevis was, according to Bryant, a compound of Men-nevas, the lunar god Nevas, the same as Noas, or Noah. The name relates to the same person who, in Crete, was styled Minos; and the same also who was represented under the emblem of the Men-taur or Mino-taurus. *Ant. Myth.* vol. ii. p. 416, &c.

MNIARUM, in *Botany*, so called from *μνίαιος*, mossy, in allusion to its habit. *Forst. Gen.* 1. t. 1. *Linn. Suppl.* 18. *Schreb.* 9. *Willd. Sp. Pl.* v. 1. 30. *Mart. Mill. Dict.* v. 3. *Juss.* 441. *Brown Prodr. Nov. Holl.* v. 1. 412. *Labill. Nov. Holl.* v. 1. 8. (*Ditoca*; *Gærtn.* t. 126.)—*Class and order, Monandria Digynia. Nat. Ord. Holeraceæ, Linn. Atriplices, Juss. Chenopodiis affinia, Brown.*

Gen. Ch. *Cal.* Perianth inferior, pitcher-shaped, permanent, cut half way down into four equal, erect, obtuse, rigid segments. *Cor.* none. *Stam.* Filament one, capillary, erect, inserted into the mouth of the calyx, scarcely longer than its segments; anther roundish, furrowed. *Pist.* Germen superior, oval; styles two, thread-shaped, gradually divaricated, the length of the stamens; stigmas simple. *Peric.* none. *Seed* solitary, small, oblong, with a membranous coat, enclosed in the hardened tube of the calyx.

Ess. Ch. Calyx pitcher-shaped, four-cleft. Corolla none. Seed one, enclosed in the tube of the calyx.

Akin to *Scleranthus*, from which it differs in the stamens being, for the most part, solitary; the calyx four-cleft; and the stalks two-flowered, with four bracteas at the summit. The seed in both genera is inverted, the embryo curved round the albumen, the radicle superior. *Brown.*

1. *M. biflorum*. Linn. Suppl. 81. Forst. Prodr. 2. Comm. Goett. v. 9. 19. t. 1. (*M. pedunculatum*; Labill. Nov. Holl. v. 1. 8. t. 2. *Ditoca muscosa*; Gært. v. 2. 196. t. 126. f. 1.)—Stem tufted. Branches very smooth. Leaves finely toothed at the base only, shorter than the fruit-stalks. *Br.*—Native of New Zealand, Terra del Fuego, and Van Diemen's land. The stems compose dense massy tufts, varying in height, with the aspect of a *Minuartia*. Every part of the herb is smooth. Leaves opposite, awl-shaped, united and finely toothed at the base; otherwise entire. *Flower-stalks* axillary, solitary, simple, at first short, but subsequently elongated beyond the leaves; each bearing a pair of minute sessile greenish flowers, accompanied by four little ovate bracteas. The calyx of the fruit is hardened, tumid, ovate, closed about the seed, and crowned with its own little permanent segments.

2. *M. fasciculatum*. Br. n. 2.—“Stems procumbent, branched. Branches minutely downy. Leaves finely toothed throughout. Fruit-stalks scarcely so long as the leaves.”—Gathered by Mr. Brown in Van Diemen's land.

MNIUM, a word adopted by Dillenius from the Greeks, whose *μνιον* is synonymous with Mosses. He therefore chose it for one of his own genera of Mosses, the character of which is to have two different kinds of heads, or fructification; the one powdery and naked, that is, destitute of calyx as well as of capsule; the other of the same capsular nature as in *Bryum* and *Hypnum*. Considering this character as sufficient to distinguish *Mnium* from all other Mosses, he proceeds to inquire into the nature of these different parts of fructification. In his conclusion he mistakes the male for the female, though his error has not commonly been observed, because he terms capsule what he believed to be the anther, but which is indeed the capsule, properly so called. (See DILLENIIUS and MUSCI.) We therefore now resume the language, though we discard the ideas, of this eminent writer.

Dillenius, considering every moss as a *Mnium* in which he met with a powdery head, although he did not detect the capsule, has made eight species; but this principle has widely misled him. His fifth and sixth species are *Jungermannia*, his seventh is the *Blasia pusilla*, previously well defined, as a distinct genus, by Micheli. In the rest of his species, Dillenius is as correct as any person could, at that time, be.

Linnæus, following up the principle he had adopted from Dillenius, referred to *Mnium* every moss, with a terminal fruit-stalk, in which the powdery head of male flowers, supposed by them female, had been observed. As his followers proceeded to look more and more closely into the structure of these minute vegetables, the powdery heads, or stamens, as they were termed when surrounded by leaves, were

discovered in many species, hitherto referred to *Bryum*. Nor is this wonderful, for the discoveries of Hedwig have proved them essential to every moss, they being unquestionably the male flowers. For a long time botanists were perpetually disputing, whether to refer particular species to *Mnium* or *Bryum*, according as they had met with the powdery head or not. Hudson alone has shewn his judgment, in considering the naked or leafless head as proper to the former; by which, except the original blunder respecting two or three *Jungermannia*, he has preserved himself from error. Hedwig has confused the subject by reversing the original characters. His *Bryum* has a round or capitate male flower, or powdery head; his *Mnium* a flat or discoid one. This leads to no natural character. Indeed the difference itself is uncertain, the part in question varying in convexity at different periods of growth. The ablest botanists who have in general followed Hedwig, as Schreber, Swartz, and Roth, well aware of his mistake in this instance, thought to correct it, by uniting the two genera into one, under the name of *Bryum*. Hoffmann, more boldly but less successfully, recurred to the fringe alone, making almost every terminal-fruited moss with a single fringe *Bryum*, with a double one *Mnium*. See FRINGE of Mosses.

The writer of the present article at length proposed to distinguish *Mnium* by the longitudinal furrows of its capsule, which in another double-fringed genus, *Bartramia*, had been found a certain and clear mark of difference. This character keeps the original real *Mnia* of Dillenius together, except the first, which is the *Tetraphis pellucida*; and has the advantage of associating with them most naturally the *Arthropodium* of Hedwig, a genus whose distinction was founded by its author on the axillary, not terminal, male flowers; a character which the slightest attention to mosses will shew to be of no importance, as to generic discrimination. *Mnium* is therefore now defined as follows. Tr. of Linn. Soc. v. 7. 261. Fl. Brit. 1344.

Ess. Ch. Capsule cylindrical, at length furrowed. Outer fringe of sixteen tapering teeth; inner a lacinated membrane. Veil smooth. Flowers terminal.

The furrows are always sixteen, being equal in number to the teeth of the outer fringe, and indeed to the principal segments of the inner one. Six species are defined in the Transactions of the Linnæan Society above quoted.

1. *M. androgynum*. Narrow-leaved Spring-moss. Linn. Sp. Pl. 1574. Sm. Fl. Brit. 1344. Engl. Bot. t. 1238. Hedw. Theor. 149. t. 12. f. 48—50. (*M. perangustum et brevibus foliis*; Dill. Musc. 230. t. 31. f. 1. *Bryum androgynum*; Hedw. Sp. Musc. 178. Turn. Musc. Hib. 11.)—Monoecious. Capsule straight. Lid conical. Leaves imbricated every way, spreading; toothed at the point.—Native of moist shady boggy places throughout Europe, flowering in March. The capsules, which ripen in April or May, are very rare. The stems form dense perennial tufts, and are branched, clothed with bright green, dotted, pellucid, lanceolate, single-ribbed, acute leaves; toothed towards the point; entire and revolute below. *Flowers* terminal; the male in little round stalked heads; female on the same plant, sessile. *Capsule* nearly upright, on a shining red stalk an inch long. *Lid* short, conical, blunt, striated, a little curved.

2. *M. conoideum*. Club-fruited Spring-moss. Sm. Fl. Brit. 1345. Engl. Bot. t. 1239. (*Bryum conoideum*; Dickf. Crypt. fasc. 4. 9. t. 11. f. 2. Turn. Musc. Hib. 112. *Grimmia*? Forsteri; Sm. Fl. Brit. 1196. Engl. Bot. t. 2225. *Bryum Forsteri*; Dickf. Crypt. fasc. 3. 4. t. 7. f. 8.)—Monoecious? Capsule straight, obovate. Lid awl-shaped. Leaves imbricated every way, spreading, entire.—Native of

the trunks of trees in Scotland and Ireland, but rare. Smaller than the former. The *stems* compose small, convex, perennial patches, and are mostly simple, leafy, half an inch high. *Leaves* oblong, entire, pale green, single-ribbed, pointless, dotted just as in the foregoing. *Male flowers* unknown. *Fruit-stalks* solitary, terminal, half an inch high. *Capful* obovate, with a curved lid, of nearly its own length. The more we consider the matter, the less doubt have we respecting the above synonymy.

3. *M. palustre*. Greater Forked Spring-moss. Linn. Sp. Pl. 1574. Sm. Fl. Brit. 1346. Hedw. Sp. Musc. 188. Schmidel. Ic. 218. t. 56. f. 2. (*M. majus*, ramis longioribus bifurcatis; Dill. Musc. 233. t. 31. f. 3, 4. Bryum palustre; Engl. Bot. t. 391. Turn. Musc. Hib. 113.)—Dioecious. *Capful* oblique. Lid conical. Leaves acute; the upper ones curved to one side. Stem erect, forked.—Native of bogs, about mountain rivulets, and in various watery situations throughout Europe; flowering in April and May; fruiting in June and July. The *stems* are three or four inches high. *Leaves* of a light yellowish-green, lanceolate, acute, channelled, single-ribbed, entire; wavy when dry. *Male flowers* like a broad disk, surrounded with radiating leaves; often proliferous, throwing up stalked round heads, like the male flowers of the first species; *female* sessile. *Fruit-stalks* solitary between the new shoots of the season, two or three inches high, wavy, red below. *Capful* curved, with a short conical lid.

4. *M. reclinatum*. Procumbent American Spring-moss. Sm. Tr. of Linn. Soc. v. 7. 262. (*M. ramis brevibus, inordinatè progredientibus*; Dill. Musc. 239. t. 31. f. 8.)—Dioecious. *Capful* nearly erect. Lid conical. Leaves bluntish, rather turned one way. Stem procumbent, much branched.—Gathered by Mitchell in bogs in Virginia. *Dillenius*. Its colour and habit are like the last, but the size only half as great. *Capful* slender, nearly erect. Stem much branched, not forked. *Male flowers* stalked, naked.

5. *M. pendulum*. Pendulous-fruited Spring-moss. Sm. n. 5.—*Capful* pendulous. Lid nearly flat. Leaves awl-shaped, striated, recurved. Stem erect.—Gathered by Mr. Menzies, in New Zealand. *Stems* determinately branched, leafy, clothed with rusty down, like many mosses that grow in clear springs. *Leaves* yellowish, single-ribbed, imbricated every way, but recurved, chiefly toward one side. *Fruit-stalks* red, two inches high. *Capful* cylindrical, or somewhat bell-shaped, chestnut-coloured. Lid flat, with a central knob.

6. *M. arrhenopterum*. Axillary Spring-moss. Sm. n. 6. (*Arrhenopterum heterostichum*; Hedw. Sp. Musc. 198. t. 46. f. 1—9. Bryum heteropterum pellucidum; Dill. Musc. 352. t. 45. f. 11; but indifferent. *B. foliis membranaceis obtusis*; Dill. Musc. 552. t. 35. f. 19; better; both determined by the Dillenian herbarium. Hypnum illecebrum; Linn. Sp. Pl. 1594; excluding the synonym of Dillenius. Fl. Lapp. ed. 2. 329.)—*Capful* inclining. Lid awl-shaped. Leaves elliptical, obtuse. Stem erect. Native of Virginia, Pennsylvania and Lapland.—*Stems* about two inches high, branched. *Leaves* imbricated, pale whitish-green, elliptical, concave, shining, single-ribbed, serrated at the end. *Fruit-stalks* an inch long, straight, rather stout. *Capful* curved, with a beaked red lid.

There appear to be several species still referrible to this genus, which are not as yet any where described.

MO, in *Geography*, a town of Sweden, in Helshingland; six miles W. of Soderhamn.

MOA, an island in the East India sea, about 30 miles long and 10 broad. S. lat. 8° 21'. E. long. 127° 45'.

MOAB, *Land of*, or MOABITIS, so called from Moab one of the incestuous sons of Lot, in *Ancient Geography*, was situated in Arabia Petræa, on the north of Midian, having the river Arnon on the west, which divided it all the way from the tribe of Reuben, the Ishmaelites on the east, and the land of Gilead on the north. Their country was at first inhabited by the gigantic Emims, whom they expelled, making themselves masters of it, and of all its cities, which were both numerous and considerable. Some of these cities, mentioned by Josephus, were on the other side of the Arnon, and therefore not so properly in Moabitis, as in the land of the Amorites, or Reubenites; particularly Heshbon; but they might have been inhabited by the Moabites. The limits of this country, indeed, were continually fluctuating; so that we read of the plains of Moab, called also by Moses the land of Moab; but which had been taken by Sihon, quite as far as the river above mentioned. Mount Nebo is placed by Moses in the land of Moab, though seated on the other side of the Arnon, in the kingdom of Sihon. This river, however, seems to have been the proper northern boundary between these two kingdoms, as Moab seems to have been the southern boundary between Arabia Petræa and Deserta. See MOABITES.

MOAB, in *Geography*, a town of Arabia, in the province of Hadramaut; 83 miles W. of Hadramaut.—Also, a town of Arabia Felix, in the province of Yemen, and residence of the prince, built in 1708, and situated between Damar and Sanaa.

MOAB, or *El-Raba*, a town of Syria; 50 miles S.E. of Jerusalem.

MOABITES, in *Ancient History*, the descendants of Moab, the son of Lot, by his eldest daughter. The posterity of Lot settled in the country bordering on the mountain, where he was born, which some make part of Cœlefyria, while others allege that it belongs to Arabia; and having driven out the old inhabitants, they possessed a small tract called Moabitis, or the land of Moab. (See MOAB.) They were governed by kings, practised circumcision, and employed themselves mostly in pasturage and breeding cattle, which constituted their chief wealth. It is probable that their language was a dialect of the Canaanitish or Hebrew. They had once the knowledge of the true God, and retained it till the time of Moses, even after they had very much corrupted their religion by introducing the worship of false gods. The idols of the Moabites, mentioned in scripture, were Chemosh and Baal-Peor. Some suppose that these were different names of the same idol; but others think that Baal-Peor was Bacchus, and Chemosh seems to have been a different idol. In the practice of their religious rites, they sacrificed both in the open air, on mountains dedicated to that service, and in temples built for their idols in the cities: besides oxen and rams, they offered on extraordinary occasions human victims, according to the Phœnician custom.

The first inhabitants of the country were a gigantic race, called Emims, or Terribles, probably descendants of Ham. These were expelled by the Moabites; but the latter in process of time lost that part of their land which lay to the N. of the river Arnon. When the Israelites, after the death of Othniel, returned again to idolatry, Eglon, king of Moab, was an instrument in punishing them; he invaded Israel and kept the Israelites in subjection eighteen years. Ehud, having secretly put Eglon to death, was obliged to make his escape beyond Jordan; and there he assembled a body of forces, who attacked the Moabites, and slew 10,000 of their best men. By this disaster the power of the Moabites was broken, and the Israelites were freed from the yoke

of that nation. Notwithstanding the protection which the king of Moab afforded to the parents of David and to David himself, when he was persecuted by Saul, as soon as he came to the crown the Moabites entered into a confederacy against him; but in consequence of a signal victory which he obtained over them, many of them were put to the sword, and the rest became his vassals and tributaries. From this time they continued subject to Solomon and Rehoboam, until the revolt of the ten tribes, upon which they became tributaries to the kings of Israel, though they had kings of their own, who were little better than viceroys. After the death of Ahab, Mesha, king of Moab, rebelled against his son Abaziah, but the short reign of this prince not permitting any attempt to reduce him, his brother and successor Jehoram, assisted by Jehoshaphat, king of Judah, and the king of Edom, his tributary, made an expedition for this purpose; the result of which was, the defeat of the Moabites and the desolation of a great part of their country. It was not long before the Moabites, entering into an alliance with the Ammonites, the Edomites of mount Seir, and other neighbouring nations, attempted to revenge the losses they had sustained in this invasion of their country on Jehoshaphat, king of Judah, who had encouraged Jehoram to undertake it. Their attempt proved unsuccessful, and terminated in their total ruin. After this period the Moabites do not seem to have disturbed Israel for many years. On the declension of the kingdom of Israel, they seem to have retaken from the tribes of Reuben and Gad a great part of the land which formerly belonged to them, before the invasion of Sihon; but elated by their success, they behaved with pride and insolence, in consequence of which several of the ancient prophets, and Isaiah in particular, threatened them with utter destruction. After the dreadful discomfiture of the army of Sennacherib, the son of Shalmaneser, the Moabites often revolted from his successors, and were as often reduced, till they were entirely subdued by Nebuchadnezzar; but upon Nebuchadnezzar's departure from Judea and Syria, after his second expedition into these parts, they, with the other neighbouring nations, proposed to Zedekiah to enter into a league against the Chaldeans, to which that prince consented, on the accession of the Egyptians to their confederacy; but this measure, adopted by Zedekiah against the remonstrance of the prophet Jeremiah, became the occasion of his utter ruin; for his new allies deserted him in his distress. From this period history makes little mention of the Moabites, who became subject to the great empires, and at length coalesced as one people with the neighbouring nations which inhabited the deserts of Syria; so that, although Josephus mentions the Moabites as a distinct nation long after, observing that they were subdued by Alexander Jannæus, king of the Jews, and that in his time they were a numerous nation; yet, in the third century after Christ, they had lost their ancient name, and were comprehended under the more general denomination of Arabians. *Anc. Un. Hist.* vol. i.

MOAGANORE, in *Geography*, a town of Hindoostan, in Golconda; 10 miles N.W. of Rachore.

MOAGAS, a cluster of small islands in the Caribbean sea, near the coast of South America, at the entrance of the gulf of Venezuela: they are eight or nine in number, extending from north to south, and but one excepted, low, flat, and covered with trees. The southernmost is the largest.

MOAMAA, a port and good harbour of Nubia, in the Red sea; 15 miles S. of Aidab.

MOANESS, a cape on the N. coast of the island of Shetland. N. lat. $60^{\circ} 44'$. W. long. $1^{\circ} 32'$.

MOANGUNGE, a town of Bengal; 72 miles N.N.W. of Dacca.

MOAR, a town of Hindoostan, in Bahar; 22 miles N.E. of Bahar.

MOAR-LOVRE, in *Agriculture*, a term made use of by some to express a peculiar distemperature of corn, a sort of blight. In this case the earth is said to sink away from the roots of the corn, and to leave the plants standing in a great part above the ground with naked roots; which are too weak to support the stalks: the plants, of course, fall down, and the ears become light. It is a distemper peculiar to corn growing on light and loose lands, which Mr. Tull has mentioned in his *Horse-hoeing Husbandry*. And it is supposed that the best remedy is to bring up mould against the rows, when they are strong enough to bear it, and it is fine and dry; the motion of the stalks with the wind draws in this loose powdery mould, and it spreads equally, settles about the roots, and covers them so as to produce fresh nourishment and support.

MOAT, in *Fortification*, a deep trench dug round a town or fortress to be defended, on the outside of the wall, or rampart. See *Plate VII. Fortif. fig. 1. lit. b, b, b, &c.*

The depth and breadth of a moat often depend on the nature of the soil; according as it is marshy, rocky, or the like. The brink of the moat next the rampart in any fortification is called the *scarp*, and the opposite one the *counter-scarp*. See *DITCH*.

MOAT, Dry, is that which is destitute of water: this ought to be deeper than one which is full of water.

MOAT, Lined, is that whose scarp and counterscarp are cased with a wall of mason's work lying aslope.

MOAT, Flat-bottomed, is that which hath no sloping, its corners being somewhat rounded.

MOAT, Angle of the. See *ANGLE*.

MOATAZALITES, **MOTAZALITES**, or *Separatists*, a religious sect among the Turks, who deny all forms and qualities in the divine Being: or who divest God of his attributes.

There are two opinions among the Turkish divines concerning God. The first admits metaphysical forms, or attributes; as, that God has wisdom, by which he is wise; power, by which he is powerful; eternity, by which he is eternal, &c.

The second allows God to be wise, powerful, eternal; but will not allow any form or quality in God, for fear of admitting a multiplicity.

Those who follow this latter opinion are called *Moatazalites*: they who follow the former, *Sepphalites*.

The Moatazalites also believed that the word of God was created in *subjeeto*, as the schoolmen term it, and to consist of letters and sound; copies thereof being written in books to express or imitate the original; they denied absolute predestination, and affirmed that man is a free agent. They held that if a professor of the same religion be guilty of a grievous sin, and die without repentance, he will be eternally damned, though his punishment will be lighter than that of the infidels. Moreover, they denied all vision of God in paradise by the corporeal eye, and rejected all comparisons or similitudes applied to God. This sect is said to have first invented the scholastic divinity, and is subdivided into no less than twenty inferior sects, which mutually brand one another with infidelity. Of these the most remarkable are the Hodelians, the Jobbaisians, the Hashemians, the Nodhamians, the Hayetians, the Jahedhians, the Mozdarians, the Bacharians, the Thamamians, and the Kadarians. *Sale's Prelim. Disc.* p. 159, &c.

MOATE, or **MOATE GRENOGUE**, in *Geography*, a post-town,

town, or rather village in the county of Westmeath, Ireland. It is 52 miles W. by N. from Dublin, and $7\frac{1}{2}$ from Athlone.

MOAWIYAH, in *Biography*, sixth caliph of the Arabians, was the son of Abu Sofian, a chief of Koreish, and an eminent commander under Mahomet. Moawiyah was appointed secretary to the prophet, an office which he filled for several years, but after the conquest of Syria, he was made governor of the province of Omar, and was continued in that high station by Othman. He obtained great success against the Greek emperors, and, in 654, he conquered the isle of Rhodes, and demolished the famous colossus of the sun. In the following year he became a competitor for the caliphate, but Ali was elected; Moawiyah instantly declared against him, and prevailed upon Amru to join him. He was proclaimed caliph at Mecca and at Medina, and maintained a civil war against Ali, till the assassination of that caliph in 660. Moawiyah was, at the same time, severely wounded by one of the three conspirators who undertook to restore peace among the Mussulmans by the assassination of the two rivals, but he escaped with his life. At first, Hassan, Ali's son, opposed the pretensions of Moawiyah, but soon resigned his power to his opponent, who obtained the caliphate without a rival in 661, being the first prince of the dynasty of the Ommiyans. An insurrection of the Kharegites was one of the first events of his reign, which was quelled by the people of Irak, with the total extermination of the sect. A reconciliation with his illegitimate brother Ziyad, a man of great talents, who had taken the part of Ali, and was made governor of Persia, added great strength to the throne of Moawiyah, who, to gain him, did not scruple to violate the laws of the Koran, by acknowledging him as the blood of the Koreish, though his legal father was a Greek slave. The temper and severity of Ziyad was of great service in suppressing some commotions which threatened to disturb the peace of the empire. In 668, Moawiyah sent his son Yezid with an army to besiege Constantinople, but the undertaking was beyond the Mussulman power, and after spending seven years in a series of repeated summer attacks, attended with a variety of petty events, but signalized by no great action, they relinquished the enterprize. The caliph's arms were more successful in another quarter, and obtained for him the complete possession of Samarcand. Moawiyah fixed his residence at Damascus, and the great object of his latter years was to secure the crown to his son Yezid, who was by no means fitted for the high rank to which he aspired. Moawiyah, after a long struggle with the people, procured the public recognition of Yezid as his own colleague, and presumptive heir to the caliphate. In a very short time after this he expired at Damascus, after a reign of about twenty years, and when he had attained to the age of seventy-five. He was, says his biographer, the most eminent of the Saracen caliphs, and extolled for his capacity, courage, generosity, and clemency. He was the first of the caliphs who wore rich garments, and affected royal splendour. He was a patron of learning, particularly of those who were proficient in poetry. Univer. Hist.

MOBARACGUNGE, in *Geography*, a town of Hindoostan, in Oude; 14 miles W. of Fyzabad.

MOBAS, a town of New Mexico, in the province of Hiaqui; 25 miles S.E. of Riochico.

MOBILE, MOVEABLE, any thing susceptible of motion, or that is disposed to be moved either by itself, or by some other prior mobile, or mover.

MOBILE, *Primum*, in the *Ancient Astronomy*, was a ninth

heaven, or sphere, imagined above those of the planets, and fixed stars.

This was supposed to be the first mover, and to carry all the lower spheres round along with it; by its rapidity communicating to them a motion by which they revolved in twenty-four hours. But the diurnal revolution of the planets is now accounted for, without the assistance of any such *primum mobile*.

MOBILE, *Perpetuum*. See *Perpetual MOTION*.

MOBILE, in *Geography*, a large, navigable river of America, formed by two main branches, the Alabama, and the Tombekbee, in the S.W. part of Georgia, just below a considerable island, the S. point of which is in about N. lat. $31^{\circ} 26'$, and W. long. $87^{\circ} 55'$. Pursuing a S. course into West Florida, the confluent stream enters the gulf of Mexico at Mobile Point in N. lat. $30^{\circ} 17'$, 11 leagues below the town of Mobile. Large vessels cannot approach the town within the distance of seven miles: the breadth of the bay is in general about three or four leagues. Alligators of a large size and in great number bask on the shores, as well as swim in the rivers and lagoons. The course of this river from the N.E. source of the waters of the Alabama to Mobile Point is estimated at about 460 miles. Large boats can navigate 350 miles, and canoes much farther.

MOBILE, a city of West Florida, formerly important and splendid, but now in a state of decline. Its figure is oblong, and it is situated on the W. bank of the river. The bay of Mobile terminates a little to the N.E. of the town in marshes and lagoons, which subject the inhabitants to fevers and agues in the hot season. The town contains several elegant houses, occupied by French, English, Scotch, and Irish. Fort Conde, situated near the bay, towards the lower end of the town, is a regular fortress of brick; and there is a neat square of barracks for the officers and soldiers. Mobile, when possessed by the English, sent yearly to London skins and furs to the value of from 12 to 15,000*l.* sterling. It surrendered to the Spanish forces in 1780.

MOBILE, *Mobiles*, plural, in the *Ancient Greek Music*, the moveable or central sounds of each tetrachord, such as were tuned differently in different genera; whereas the two extremes, or the lowest and highest sound of each genus, were fixed: *soni stantes*. See *TETRACHORD*, *GENUS*, and *SOUND*.

MOBILIA BONA, in the *Civil Law*, are what in common law, &c. we call *moveables*, or *moveable goods*.

MOBILITY, in the *Schools*, &c. an aptitude or facility to be moved.

The hypothesis of the mobility of the earth is the most plausible; and is that universally admitted by the later astronomers. Pope Paul V. appointed commissioners to examine the opinion of Copernicus touching the mobility of the earth. The result of their enquiry was, a prohibition to assert, not that the mobility was possible, but that it was actually true: that is, they allowed the mobility of the earth to be held as an hypothesis, which gives an easy and sensible solution of the phenomena of the heavenly motions; but forbade the mobility of the earth to be maintained as a thesis, or real effective thing; because they conceived it contrary to scripture. See *COPERNICAN System*, and *COPERNICUS*.

MOCAMBO, in *Geography*, a river of Africa, which runs into the Indian sea; 15 miles S. of Mozambique.

MOCANERA, in *Botany*, Just. 318, the name by which the *Visnea Mocanera*, Linn. Suppl. 251, is known in the Canary Islands, and which Jussieu preferred as a generic appellation, because he was informed the person from whom the other was derived, was unworthy of botanical commemoration. We have indeed been assured of this by the late Mr.

Mr. Masson, the discoverer of the shrub, who was very indignant at the name of *Vifnea*. Mr. De Vifne, designed to be honoured by it, was a merchant at Lisbon, who had a choice garden, and took delight in the cultivation of rare and curious plants, in a country where that taste was then in its infancy. So that, though he might not be a scientific botanist, his claim is equal to that of abundance of persons, on whom a similar honour has been, rather too indiscriminately indeed, bestowed. See *VISNEA*, or rather, as Schreber more correctly has it, *VISMEA*.

MOCARA, in *Geography*, a village of Egypt, situated in a chain of mountains, extending across the desert more than 150 miles from E. to W., in the road from Cairo to Siwah, and deriving their name from that of the village; 90 miles W. of Cairo.

MOCARANGA, or *MOCANA*, which has been erroneously called *Mon matapa*, from the title of the monarch, an extensive country of Africa, situated at some distance from the Indian sea, between 15° and 20° S. lat., and 28° and 36° E. long. But within its whole extent other countries are included, almost as far southward as the Cape of Good Hope, and on the N.W. to the confines of Congo; but on the W. and N.W. it is bounded by Monoemugi. The climate is temperate, though the mountains called Lupata, or the spine of the world, forming a great chain from N. to S., are perpetually covered with snow; the air clear and salubrious, and the soil fertile and well watered, so that its pastures feed a great number of cattle, more valued by the inhabitants than their gold. The country affords plenty of rice, millet, and other grain, but no wheat; fruit trees in abundance, and sugar-canes, which grow without culture; its forests swarm with wild beasts and variety of game; and its rivers abound with fish, and also with gold; nevertheless it is but thinly inhabited. Whilst those lands which are watered by the rivers Cuamo or Zambezi, which encircle the kingdom on the N. and W., and Spiritu Sancto, and others that flow into them, are fertile and productive, the inland parts are sandy, dry, and barren; and the occupiers, who are few in number, are under a necessity of fetching from a great distance water for washing their gold-dust, if their cisterns, for want of rain, fail to supply them. This country, though destitute of horses, and other beasts of burden, is overstocked with elephants, many of which are annually destroyed, so that the Portuguese are plentifully supplied with ivory. The riches of this part of Africa are of a large size, and supply grease and oil, which, as the inhabitants conceive, is a sovereign remedy against pains and aches as well as sprains and rigidity of the limbs, when taken inwardly, or applied externally. The natives are black, with woolly hair, they are well formed, robust, and healthy, and more agile and active than those of Quiloa, Mombasa, and Melinda. They are fond of war, which they prefer to traffic; and those of the lower class are habituated to diving; and by this practice, they fetch up from the bottoms of their rivers and lakes the mud that yields gold; and having separated the one from the other, they exchange their gold with the Portuguese for cotton cloths, and other articles of merchandize, which are brought hither from India and Europe. Their food consists of the flesh of oxen and elephants, salted and dried fish, and a variety of fruits; and also of bread made in their cities of rice or millet; and their drink is sour milk and oil of Sesame or Turkey wheat. Persons of superior rank and opulence have strong liquors made of honey, millet, and rice, and also palm-wine, which is held in high estimation. Their dress extends only from the girdle downwards; that of the common people is made of dyed cotton; but persons of quality wear Indian silks, or cotton embroidered with gold, over

which they commonly have a lion's skin, or that of some other wild beast, with the tail hanging behind, and trailing on the ground. The men marry as many wives as they can maintain; but the first is the chief, and her children are the father's heirs, the rest being treated as servants. The king, or emperor, is said to have 1000 wives, all of whom are the daughters of some of his vassal princes; but the title and honour of queen belong exclusively to the first. He neither wears in his own dress nor suffers his subjects to wear any clothes that are manufactured out of his own dominions, under an apprehension that they conceal some charm or poison. The metropolis of this empire is called "Benematapa," or "Banamatapa," and by some writers it is called "Medrogan." It is a spacious city, about 20 miles W. of Sofala. The houses are neat, white-washed within and without, and adorned with beautiful cloths of cotton, finely wrought or dyed. But the greatest ornament of the city is the imperial palace, which is a large and spacious edifice of wood, well flanked with towers, with four avenues, or stately gates, at which a numerous guard is constantly stationed. The emperor's guard is said to consist of women lightly armed. The Portuguese have two fortresses, and another station near the mountains of Fura, which are said to abound in gold. One of the emperor's queens is said to be the protectress of the Portuguese, and another of the Moors. The emperor, by the account of a Dutch commodore who visited this country in 1606, ruled from Mozambique to the Cape of Good Hope. The chief province is in an isle or delta, between two branches of the Cuamo and the Espirito. This isle is about 750 French leagues in circuit, and the chief town was Banamataxa. At that period there were many subject kings, and the emperor had a guard of 200 deys. Among the rivers that roll gold are the Panami, Luanga, and Mangiano. But later accounts of this country, and of other Portuguese settlements on the eastern coast of Africa, are wanting; the Portuguese, probably from motives of interest, are silent.

MOCAUMPOUR, capital of a country of the same name to the N. of the country of Bengal; 40 miles S.S.E. of Catmandu. N. lat. 27° 35'. E. long. 85° 37'.

MOCEFU, a town of Peru, in the diocese of Truxillo; 10 miles S.E. of Lambayeque.

MOCENIGO, ANDREW, in *Biography*, a noble Venetian, flourished in the early part of the sixteenth century, and was employed in the public service of his country, which he managed with success. As an author he wrote in Latin a "History of the War sustained by the Republic of Venice, in consequence of the League of Cambray, from 1500 to 1501, in four Books;" and he composed a poem in Latin verse on the war with Bazajet II., which is lost. Moreri.

MOCHA, a small island in the Pacific ocean, near the coast of Chili. S. lat. 38° 30'.

MOCHA, or *Mokha*, a town of Arabia, in the province of Yemen, situated on a dry and barren spot in that part of the province called Tehama, or the plain country. Its fortifications are the walls which surround it, some towers on the way to Mufa, dignified with the name of castles, and two other castles of the same fort, upon the two arms of the harbour. The greatest of these two castles is called "Kalla Tejar," and the smallest "Kalla Abdurrab," from the names of two saints buried in these places. These are provided with some few pieces of cannon. The houses in the city are built of stone: some of them are handsome; but others, both within and without the walls, are not better than the common huts that are found through all the Tehama.

Tehama. In the environs of this city are abundance of date trees and many agreeable gardens. Mocha was built about four centuries ago, and like many other cities of the Tehama, it owes its origin to a saint, the celebrated scheik Schædeli. This saint was in such reputation, that a multitude of persons from the most distant countries resorted hither to receive his instructions. His hermitage stood on the sea-side, and many huts were built around it for the accommodation of his followers: these formed a village, which by degrees was enlarged into a city. Some other circumstances contributed to give celebrity to its establishment. A ship bound from India to Jidda cast anchor, about 400 years ago, in this latitude. Several of the crew, perceiving huts in the desert, had the curiosity to visit them. The strangers were hospitably received by the scheik, and regaled with coffee, to which he ascribed singular virtues. The Indians, who were unacquainted with the use of coffee, thought that it might be a seasonable remedy to the master of the ship, who was ill. Schædeli assured them, that he should not only be cured by the efficacy of his prayers and of the coffee, but that if they would land their cargo there, they might dispose of it to considerable advantage. Assuming at the same time the air and the tone of a prophet, he told them that a city should one day be built upon that spot, which would become an eminent mart of the Indian trade. The master of the vessel visited the prophet, drank the coffee, and was restored to health. Many Arabs flocked to hear the preaching of the saint, and among them were several merchants, who purchased the whole cargo. The Indians returned home, related their adventure, and induced many of their countrymen to resort to this place. An elegant mosque was raised upon the tomb of the prophet, which stands without the walls of the city. The well that supplies the inhabitants with water, and one of the city gates, bear his name. His descendants are held in honour, and enjoy the title of scheik; the people swear by him; and his name will be remembered as long as Mocha stands. He is not only the patron of Mocha; but all the Mussulmans who drink coffee mention him every morning in their prayers, esteeming him as *their* patron; thanking God that through his mediation mankind were taught the use of coffee, and imploring the favour of heaven on the scheiks, his descendants. Mocha was the last city in Yemen of which the Turks retained possession. It is said that the Arabs did not conquer but buy it. Since the Turks were dispossessed, it has never had another master but the Imam. A Dola, having enriched himself in the government of this city, fortified it, and drew a ditch round it, which is now filled up. He was suspected of aspiring to independence, and was cast into prison. From that time, a Dola has never been continued above three years in this lucrative post. After the monsoon season, the Dola of Mocha is annually obliged to give an account of his administration, and is either confirmed in his employment, or instantly recalled to Sana. Many Jews live here in a separate village, as in the other cities of Yemen. Here are also about 700 Banians, Rajaputs, and other Indians, some of whom are merchants, and others gain a subsistence by the exercise of different mechanic arts. When they have made a small fortune, they return home to India; and on this account are always regarded as strangers. Several nations frequently traded to this port. The Portuguese, who two centuries ago were very powerful on the Arabic gulf, have long since ceased to send ships thither. The Dutch rarely appear here; and the French never in time of war, though they still continue to rent warehouses. The English at present engross, by way of India, almost exclusively, the whole trade of this place, which is conducted for them by a Banian. The trade of Mocha being so considerable, the cus-

oms must afford a large revenue to the Imam. The Turks, Arabs, and Indians, pay eight or ten *per cent.* upon their value; after they have been inspected at the custom-house: all Europeans enjoy the privilege of having their goods inspected in their own warehouses, and of paying only three *per cent.* upon their value. The Indians of late, since the English have become so powerful in Bengal, pay only three *per cent.* but the merchants in Mocha pay likewise five *per cent.* on all Indian goods which they purchase. There is also a tonnage duty, regulated not by the tonnage of the vessel but by the number of its masts. A merchant, however, who lades a large European ship with coffee in this port, receives from the Dola a premium of 400 crowns. The Arabs have scarcely any article for exportation except coffee, and of this the Indians are not very fond. The English ships must return empty to India, if they did not gain considerably by carrying money, with which the Arabian merchants entrust them. When a foreign vessel arrives in the road of Mocha, it must not salute with guns, but only hoist a flag. It is observable, that the trade on the coasts of the Red sea cannot be advantageous to any nation which have not settlements in India. The Arabians make no use of the productions of Europe. There is, indeed, a quantity of iron sold in Arabia, which has in times past been purchased chiefly from the Danes. A stranger cannot be too much on his guard against Mahometan brokers. He will find it advantageous to address himself rather to the Banians, among whom are many considerable merchants, who are very honest men. N. lat. 13° 19'. E. long. 43° 23'.

Mr. Bruce, in his "Travels to discover the Source of the Nile," mentions two other Mochas, besides that which we have above described. The first is in Arabia Deserta, in N. lat. 30 nearly, not far from the bottom of the gulf of Suez. The second is in S. lat. 3°, near Terfish on the coast of Melinda. The meaning of Mocha, he says, is in the Ethiopic *prison*, and it is particularly given to those three places, because in any of them a ship is forced to stay or be detained for months, until the change of the monsoon sets her at liberty to pursue her voyage.

MOCHICAGUI, a town of New-Mexico, in the province of Cinaloa; 60 miles W.N.W. of Cinaloa.

MOCHLIA, from *μοχλος*, a lever, in Surgery, a reduction of bones from an unnatural to a natural position.

MOCHO, or MOCOA Stones. See AGATE and DENDRITIS.

MOCHOW, in Geography, a town of Bohemia, in the circle of Kaurzim; 12 miles W.N.W. of Kaurzim.

MOCK-BIRD, Indian, in Ornithology. See TURDUS *Cyanus*.

Mock-Bird of Guiana. See ORIOLUS *Americanus*.

Mock Lead, in Mineralogy, a name given by the English writers to a sort of fossil, called also *blende* and *galena*.

Mock Nightingale, in Ornithology. See MOTACILLA *Atricapilla*.

Mock Orange, in Botany. See PHILADELPHUS.

Mock Privet. See MOCK PRIVET.

Mock, or running a muck, is a practice that has prevailed time immemorial in Batavia. To run a muck, in the original sense of the word, is to get intoxicated with opium, and then rush into the street, with a drawn weapon, and kill any one that comes in the way, till the party is himself either killed or taken prisoner. If the officer takes one of these *omocks* or *mobaroks* (as they have been called by an easy corruption) alive, he has a considerable reward, and the unhappy wretches are always broken alive on the wheel: but such is the fury of their desperation, that three out of four

are necessarily destroyed, in attempting to secure them. See AMOK.

MOCKELN, in *Geography*, a lake of Sweden, in the province of Smaland; 25 miles S.W. of Wexio.

MOCKERN, a town of the duchy of Magdeburg; 16 miles E. of Magdeburg.

MOCKJACK BAY, a bay of America, on the coast of Virginia, in the Chesapeake. N. lat. 37° 24'. W. long. 76° 23'.

MOCLIN, a town of Spain, in the province of Granada; 12 miles S. of Loja.

MOCO, in *Commerce*, a small silver coin in the West Indies, which in some places is $\frac{1}{4}$ th of the dollar, and in others $\frac{1}{8}$ th.

MOCOA, in *Geography*, a town of South America, in the province of Popayan; 70 miles S.E. of Popayan.—Also, a town of Mexico, in the province of Culiacan, on the river St. Sebastian; 90 miles N.W. of Culiacan.

MOCOCO, or MAUCACO, in *Zoology*. See LEMUR *Catto*.

MOCODAME, in *Geography*, a small island near the S.E. coast of Nova Scotia. N. lat. 45° 4'. W. long. 61° 20'.—Also, a river of Sumatra.

MOCOS, a tribe of the Eboe slaves, brought from the interior of Africa. See EBOES.

MOCO-MOCO, a town of Sumatra, the capital of Anac-Soongey, on the S.W. coast. This country rose from the ruins of Indrapour, and extends on the sea-coast from Mandoota river to that of Ori. A small tax was laid on the people of Anac-Soongey, in satisfaction for the murder of a prince by the raja of Indrapour, which is now paid to the sultan of Moco-Moco. The tax is a foocoo (the 4th part of a dollar), a bamboo of rice, and a fowl, from each village annually. The government of Anac-Soongey is Malay, but a great part of the country dependent upon it is inhabited by the original doosoon or village people. The chiefs are obliged to attend the sultan, and carry their contribution or tax; but his authority is very much limited. The officers next in rank to the sultan are called Mantrié, a corruption, as some have supposed, of Mandarin; 30 miles S.W. of Indrapour. S. lat. 2° 25'. E. long. 101° 12'. Marsden's Sumatra.

Moco-Moco, or *Little Oroonoko*, a river of South America, which runs into the Atlantic, a little S. of Oroonoko.

MOCORITO, a town of Mexico, in the province of Culiacan; 72 miles N.W. of Culiacan.

MOCOS, a collection of small islands in the Indian sea, near the coast of Siam. N. lat. 13° 50'. E. long. 97° 52'.

MODAGHIRY, a town of Hindoostan, in Mysore; 13 miles N. of Venicatighery.

MODAIN, MADAIN, or *el Modain*, a town of the Arabian Irak, on the side of the Tigris, on the site of the ancient Ctesiphon. It is said by Herbelot to have been founded by Sapor and enlarged by Chosroes, who built a palace here that was the most magnificent in all the East. In 637 this place was taken and plundered by Said, the lieutenant of Omar. The riches of which it was despoiled were immense, consisting, in part, of the throne, the crown, the royal standard, and carpet of the ancient Persian kings; 20 miles S. of Bagdad.

MODAL, in *Logic*, &c. a term applied to propositions which include certain conditions and restrictions.

MODAL, in *Music*. The characters for time in the first stages of figurative music or counter-point were called *modal signs* for the moods.

The different modes or moods for ascertaining the *quan-*

tum of each tact, or pulsation of time in music, were the following:

○ ○ 3, for a perfect long, or three breves.

○, a perfect breve, or three semibreves.

○, two imperfect breves, and, in the compositions of Tallis and Bird, sometimes three minims.

○, an imperfect breve, or two semibreves.

Besides these, there were others for a species of jig time, in which semibreves or minims were ternary, and moving in triplets, while the longer notes were binary: C 3, C 2, C 3, &c. Zaccani, *Prat. Mus. lib. ii. cap. 54.* makes the modal signs amount to fourteen.

MODANE, in *Geography*, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of St. Jean de Maurienne; 15 miles E. of it. The place contains 925, and the canton 3267 inhabitants, on a territory of 450 kilometres, in 7 communes.

MODBURY, a market-town and borough, situated in the hundred of Ermington, and county of Devon, England. The town consists chiefly of four streets, running in the direction of the cardinal points, and crossing each other at right angles. It is a borough by prescription, but has lost its right of sending members to parliament, having petitioned to be exempted from that *burthen*, as it was then considered, in the reign of Edward I. The plea of exemption was the poverty of the inhabitants, who were unable to pay their representatives, as was customary at that early period. Modbury is now governed by a portreeve (usually styled mayor), two constables, and several other officers, who are elected annually at a court-leet held at Michaelmas. All persons who possess any freehold within the borough are liable to be chosen; being considered in the light of freemen or free burgesses. Even so late as the commencement of the last century, it appears from the records, that the borough-court here took cognizance of all debts under forty shillings; and in the reign of Charles I. the same records shew that the inhabitants possessed the authority of enrolling deeds in the rolls of the borough. The chief support of this town is its woollen trade, which was formerly much more considerable than at present. A great quantity of yarn was likewise spun here and in the neighbourhood about fifty years ago, at which time a weekly market was held, distinctly to facilitate the sale of that article. This market has long been discontinued, but to preserve the right, the bell still rings for the yarn-market at twelve o'clock. A plush and hat manufactory have also been established of late years. The petty sessions for the hundred are held here. Thursday is the market-day for provisions.

The population of this town, according to the parliamentary returns of 1801, comprised 1813 persons, 832 males, and 981 females, of which number 862 were returned as engaged in trade, and 944 in agriculture.

The church of Modbury is a very spacious and handsome building, surmounted by a lofty spire, of later erection than the rest of the edifice. On the south aisle stands a fine alabaster statue, in armour, supposed to be the effigy of one of the Champernoune family. Besides the established church, there are two other buildings in this town appropriated to divine worship; one belonging to the Presbyterians, and the other to the Anabaptists. Here was formerly an alien priory, dependent on the abbey of St. Peter sur Dive, in Normandy, which seems to have been founded shortly after the conquest. Its religious inmates were monks of the order of St. Benedict. On the dissolution of the alien monasteries, in the reign of Henry VI., this priory was granted to the college at Eaton. The precise site on which it stood is uncertain, but as there are two fields adjoining to the western side

of the church-yard, still called "Priors'-parks," it was most probably situated somewhere near that spot. Indeed, on the opposite side of the road which passes these parks, there appear some remains of an ancient building, which may have formed part of the priory.

The proprietor of the manor here, at a very remote period, was sir James Okestone, or Oxton, from whose family it passed into that of the Champernoues, who possessed a splendid mansion immediately adjoining to the town, only a small portion of which is now standing. Of the grandeur of this seat, and the magnificent manner in which its owner lived, tradition speaks very highly. They are said, in particular, to have kept a fine band of singers and musicians, with whose execution queen Elizabeth was so much delighted, that she requested the loan of them for a month, but being refused by Mr. Champernoune, out of pique found some pretence to sue him at law, and occasion his ruin; he being compelled to sell no less than nineteen manors to support the litigation.

The vicinity of this town is adorned with a number of family seats, some of ancient and others of modern erection. Wimpston, the ancient mansion of the Fortescues, is particularly remarkable as being the house in which the celebrated sir John Fortescue was born. This gentleman raised himself by his talents to the dignity of chief justice and chancellor in the reign of king Henry VI., and wrote a work entitled "De Laudibus Legum Angliæ," which is still held in great repute among legal antiquaries. The other seats of note near Modbury, are Train, Fleet-house, Madridge, Fowlescombe, Stowford, Butterford, Shilston, and Fardel, which last was long in possession of the Raleighs. Polwhele's History, &c. of Devonshire, two vols. folio. Beauties of England and Wales, vol. iv.

MODDAPOUR, a town of Bengal, on the right bank of the Ganges; 27 miles N. of Mahmudpour.

MODDIGONG, a town of Hindoostan, in Goondwana; 10 miles N. of Ramteak.

MODDIGUBA, a town of Hindoostan, in the circar of Gooty; 10 miles W. of Amantpour.

MODE, or MOOD, *Modus*, in *Philosophy*, a manner of being; or a quality or attribute of a substance, or subject, which we conceive as necessarily depending on the subject, and incapable of subsisting without it.

Mr. Locke defines modes to be those ideas (he should have said *things*) which do not imply any supposition of subsisting by themselves, but are considered as mere dependencies, and affections of substances.

Our ideas of things may be reduced to two kinds: the one of things, which we conceive separately, and by themselves, called *substances*; and the other of things which we conceive as existing in others, in such manner as that we cannot allow them existing without them, and these we call *modes* or *accidents*.

It is the characteristic, then, of a true mode, to have such a relation to some subject, as not to be clearly and distinctly conceivable without conceiving the subject, of which it is a mode, at the same time: when, on the other hand, the conception of the subject does not at all infer or require that of the mode.

Thus, what gives us to know that thought is not a mode of extended substance, or matter, is, that extension, and the other properties of matter, may be separated from thought, without ceasing to conceive thought all the while.

We always consider things as clothed with certain modes, except we reflect on them in the abstract, or general; and it is the variety of modes, and the relations, that occasions the great variety of denominations of the same thing.

They are the various modes of matter, *e. g.* that make all the diversity of bodies, or corporeal beings, in nature.

There are various divisions and kinds of modes: as, 1. *essential*, or *accidental*. An *essential* mode, or *attribute*, is that which belongs to the very nature or essence of the subject in which it is; and the subject can never have the same nature without it, as roundness in a bowl, solidity in matter, thinking in a spirit, &c. and this is *primary*, when it is the first or chief thing that constitutes any being in its particular essence or nature, and makes it to be that which it is, and distinguishes it from all other beings, as roundness in a bowl: or *secondary*, which is any other attribute of a thing, that is not of primary consideration, called a *property*; as volubility in a bowl. An *accidental* mode, or *accident*, is such a mode as is not necessary to the being of a thing; for the subject may be without it, and yet remain of the same nature which it had before; or it is that mode, which may be separated from its subject, as blackness or whiteness in a bowl, learning in a man, &c.

2. Modes are *absolute* and *relative*. An *absolute* mode is that which belongs to its subject; without respect to any other beings whatsoever. A *relative* mode is derived from the regard which one being has to others: thus, roundness and smoothness are the *absolute* modes of a bowl; but greatness and smallness are *relative*. See RELATION.

3. Modes are *intrinsic*, or *extrinsic*. The former are conceived to be in the subject or substance; as when we say a globe is round, &c. The latter mode is a manner of being which some substances attain by reason of something that is external or foreign to the subject, and is called external denomination; as the globe lies within two yards of the wall, &c.

4. Modes are also *inherent*, or *adherent*, *i. e.* *proper* or *improper*. *Adherent* modes arise from the joining of some accidental substance to the chief subject, which yet may be separated from it; as when a bowl is wet, &c. *Inherent* modes have a sort of in-being in the substance itself; as the bowl is swift or round, &c.

5. *Action* and *passion*, using the terms in a philosophical sense, are modes which belong to substances; as when a smith with a hammer strikes a piece of iron, the smith and hammer are agents or subjects of action, and the iron is the patient, or subject of passion.

6. Modes may be divided into *natural*, *civil*, *moral*, and *supernatural*, all which pertain to the apostle Paul, who was a little man, a Roman by the privilege of his birth, a man of virtue or honesty, and an inspired apostle.

7. Modes belong either to *body*, or to *spirit*, or to both. Modes of *body* belong only to matter, or corporeal beings; such are *figure*, *rest*, *motion*, &c. These are *primary*, when they belong to bodies considered in themselves, whether there were any man to take notice of them or no, as shape, size, &c.; or *secondary*, which are such ideas as we ascribe to bodies, on account of the various impressions that are made on the senses of men by them, called secondary qualities: such are all colours, sounds, tastes, smells, and all tactile qualities. (See QUALITY.) Modes of *spirit* belong only to minds, such are *knowledge*, *will*, &c. Modes belonging to body and spirit, are called mixt or human modes, because they are found in human nature; such are *sensation*, *imagination*, *passion*, &c. in which there is a concurrence of the operation of animal and intellectual nature.

8. There are also modes of other modes, which, though they subsist in and by the substance, as the original subject of them, are properly and directly attributed to some mode of that substance; thus swiftness and slowness are modes of motion, which is itself the mode of a body.—Watt's Logic, p. i. c. 2. § 3 and 4.

Mr. Locke divides modes into *simple*, and *mixt* or *compound*.

Modes, *Simple*, are combinations of simple ideas of the same kind, or even of the same simple ideas divers times repeated; as a dozen, a score, &c. which are only the ideas of many distinct units put together.

The modifications of any simple idea, Mr. Locke observes, are as perfectly different and distinct ideas in the mind, as those the most remote and inconsistent: thus, *two* is as distinct from *three* as blindness is from heat. With this view that author examines the *simple* modes of space; which are found to be distance, capacity, extension, figure, place, and duration.

The mind has several distinct ideas of *sliding*, *rolling*, *crawling*, *creeping*, &c. which are all but the different modifications of motion. *Swift* and *slow* are two different ideas of motion, the measures of which are made out of the distance of time and space put together.

The like variety we have in sounds; every articulate word is a different modification of sound, as are all notes of different length put together, which makes that complex idea called *time*.

The modes of colours might be also very various; some of which we take notice of as the different degrees, or as they are termed, *shades of the same colour*. But since we seldom make assemblages of colours without taking in figure also, as in painting, &c. those which are taken notice of, do most commonly belong to mixed modes; as, *beauty*, *rain-bow*, &c. All compounded tastes and smells are also modes made up of the simple ideas of those senses.

As to the modes of *thinking*; when the mind turns its view inward upon itself, *thinking* is the first idea that occurs, in which it observes a great variety of modifications; and therefore frames to itself distinct ideas.

Thus the perception annexed to any impression on the body made by an external object, is called *sensation*. Where an idea recurs without the presence of the object, it is called *remembrance*. When sought after by the mind, and brought again in view, it is called *recollection*. When held there long under attentive consideration, it is called *contemplation*. When ideas float in the mind without regard or reflection, it is called in French a *reverie*. When the ideas are taken notice of, and, as it were, registered in the memory, it is *attention*. When the mind fixes its view on any one idea, and considers it on all sides, it is *intention* and *study*.

Of these various modes of thinking, the mind forms as distinct ideas, as it does of white and red, or of a square or a circle.

Modes, *Mixt*, are combinations of simple ideas of several kinds; as in *beauty*, which consists in a certain composition of colour, figure, &c.; *theft*, which is the concealed change of possession of any thing, without consent of the proprietor, &c.

There are three ways by which we get ideas of *mixt* modes:
 1. By experience and observation of things themselves; thus, by seeing two men wrestle, we get the idea of wrestling.
 2. By invention, or voluntary putting together of several simple ideas of our own minds: so he that first invented printing, had an idea of it first in his mind before it ever existed.
 3. By explaining the names of actions we never saw, or notions we cannot see; and by enumerating all those ideas, which go to the making them up: thus, the *mixt* mode which the word *lye* stands for is made up of the simple ideas.
 1. Articulate sounds. 2. Certain ideas in the mind of the speaker. 3. Words, the signs of these ideas. And,
 4. Those signs put together by affirmation, or negation,

otherwise than the ideas they stand for are in the mind of the speaker.

Mixt modes have their unity from an act of the mind, combining those several simple ideas together, and considering them as one complex one: the mark of this union is one name given to that combination.

This gives the reason, why there are words in every language, which cannot be rendered by any one single word of another. For the fashions and customs of one nation make several combinations of ideas familiar to one, which another had never any occasion to make. Such were *οργανισμοι* among the Greeks, and *proscriptio* among the Romans.

This also occasions the constant change of languages; because the change of custom and opinion brings with it new combinations of ideas, which, to avoid long descriptions, have new names annexed to them, and so they become new species of *mixed* modes.

Of all our simple ideas, those which have had most *mixed* modes made out of them, are thinking, and motion (which comprehend in them all action), and power, from whence these actions are conceived to flow.

Of this kind are the modes of actions, distinguished by their causes, means, objects, ends, instruments, time, place, and other circumstances; as also of the powers fitted for those actions. Thus *boldness* is the power to do or speak what we intend, without fear or disorder; and this power of doing any thing when it had been acquired by frequent doing the same thing, is that idea we call *habit*; and when forward and ready, upon every occasion, to break into action, we call it *disposition*: thus *testiness* is a disposition or aptness to be angry. Power being the source of all action, the substances, in which those powers are, when they exert this power, are called *causes*: and the substances thereupon produced, or the simple ideas introduced into any subject, are called *effects*. The efficacy by which the new substance or idea is produced, is called in the subject exerting that power, *action*; and, in the subject in which any simple idea is changed, or produced, *passion*: which efficacy, in intellectual agents, we can conceive to be nothing else but modes of thinking and willing; in corporeal agents nothing else but modifications of motion.

MODE, *Division of a*. See DIVISION.

MODE, in *Grammar*. See MOOD.

MODE, in *Logic*. See MOOD.

MODE is also used for the modification of a proposition; or that which renders it *modal* and *conditional*.

MODE, *Indirect*. See INDIRECT.

MODE, Fr. a key in *Musick*. In plain-chant the modes are numbered.

The ecclesiastical modes are called *authentic*, when the 5th is above the principal, as $\overset{a}{E}$; and *plagal*, when the 4th

is above the principal, and the 5th below its octave, as $\overset{d}{G}$.

See CANTO-FERMO, and TONES of the CHURCH.

MODES of the *Ancient Greek Music*. The ancients differ extremely among themselves in defining their modes; obscure in all parts of their music, upon this subject they are nearly unintelligible. They all agree that a mode is a certain system or constitution of sounds, and it seems as if this constitution was in itself nothing more than an octave filled with all the intermediate sounds according to the genus.

In high antiquity, the Greeks had but three modes, at the distance of a tone from each other, which was natural:

the lowest being called the *Dorian*, the middle the *Phrygian*, and the highest the *Lydian*.

Afterwards, in dividing the tones into semitones, two other modes were obtained, as the *Ionian* and the *Æolian*; the first being inserted between the *Dorian* and the *Phrygian*, the second between the *Phrygian* and the *Lydian*.

In process of time the system being extended above and below, musicians established new modes at both extremities, which took their denomination from the first five, adding the prepositions *hyper*, above, and *hypo*, below. Thus the *Lydian* mode was followed by the *hyper-Dorian*, the *hyper-Ionian*, the *hyper-Phrygian*, the *hyper-Æolian*, and the *hyper-Lydian*, ascending; and after the *Dorian* mode, came the *hypo-Lydian*, the *hypo-Æolian*, the *hypo-Phrygian*, the *hypo-Ionian*, and the *hypo-Dorian*, in ascending. These fifteen modes are all enumerated in *Alypius*. See the plate, where their order and intervals are expressed in Greek characters, and by equivalent notes in the *Guido* scale. But it must be remembered, says *Rouffeu*, that the *hypo-Dorian* was the only mode which was used to its whole extent. In proportion as the others mounted, the upper notes were avoided, in order not to exceed the natural compass of the voice. These observations are necessary for the clearing up some passages in ancient authors, which seem to imply that the lowest modes had the highest notes, which indeed was true, in having in their melodies more notes above the keynote. For want of this knowledge, *Doni* is extremely embarrassed by these apparent contradictions.

Greek theorists differ in the number of modes: while with some they amount to 15, *Aristoxenus*, according to *Euclid*, admitted only 13, suppressing the two highest; the *hyper-Æolian*, and *hyper-Lydian*. But in the work of *Aristoxenus* that is come down to us, he only specifies six, concerning which he relates the different sentiments of the times.

At length, *Ptolemy* reduced the number of these modes to seven; saying that modes were introduced in music in order to vary the melodies by the contrast of grave and acute; for it is evident that they may be multiplied far beyond 15; but these seven suffice to facilitate the transition from one mode to another, by consonant intervals easy to produce.

He therefore includes all the modes in the compass of an octave, of which the *Dorian* mode was the centre; so that the *mixo-Lydian* was a 4th above, and the *hypo-Dorian* a 4th below. The *Phrygian* a 5th above the *hypo-Dorian*; the *hypo-Phrygian*, a 4th below the *Phrygian*: whence it appears, that to count from the *hypo-Dorian*, which is the lowest mode, there was the distance of a tone to the *hypo-Phrygian*; from the *hypo-Phrygian* to the *hypo-Lydian*, another tone; from the *hypo-Lydian* to the *Dorian*, a semitone; from that to the *Phrygian*, a tone; from the *Phrygian* to the *Lydian* still a tone, and from the *Lydian* to the *mixo-Lydian*, a semitone, which extend to a seventh, in the following order:

1	-	F	-	-	Mixo-Lydian.
2	-	E	-	-	Lydian.
3	-	D	-	-	Phrygian.
4	-	C	-	-	Dorian.
5	-	B	-	-	Hypo-Lydian.
6	-	A	-	-	Hypo-Phrygian.
7	-	G	-	-	Hypo-Dorian.

Ptolemy retrenched all the other modes, pretending that these seven occupied all the sounds of the diatonic octave. From these seven modes of *Ptolemy*, with the addition of the *hypo-mixo-Lydian*, it is supposed that *Guido* formed the eight ecclesiastical modes. See *TONES of the CHURCH*.

Such is the clearest notion which we are able to form of the tones or modes of the ancient music; while we consider them as differing from each other only by grave and acute; but still other differences subsisted, which characterized them more particularly: as expression, the kind of poetry to which they were applied, the kind of instrument by which they were accompanied, the rhythm or cadence of the verse, names or *ars* peculiar to certain people from whom the principal modes had their names: as the *Dorian*, *Phrygian*, *Lydian*, *Ionian*, *Æolian*.

There were still other modes, which should rather be called styles or kinds of composition: as the tragic mode, appropriated to the theatre; the nomic, consecrated to *Apollo*, the dithyrambic, to *Bacchus*, &c. See *STYLE* and *MELOPŒIA*.

In our old music, the word *mode*, or *mood*, was applied to measure or time, in order to fix the relative value of all the notes in a movement by a general sign, which was placed after the clef, at first by circles and semi-circles pointed, or without points, according to the numbers 2 and 3, differently combined. It is from these ancient expedients that

we still retain $\overline{\text{C}}$ for common time, and a barred $\overline{\text{C}}$ for a

quicker dual measure. See *MODAL* and *PROLATION*.

These characters, except the two last mentioned, have long been disused; yet it is necessary to understand them, in order to be able to decipher old music.

Thus far the chief of this article is from *Rouffeu*, which includes almost all the knowledge on the subject, that the most laborious and profound commentators of the seven ancient *Greek* writers on music, published by *Meibomius*, ever conjectured, we dare not say discovered, on the subject.

The general opinion concerning the modes of *Ptolemy*, till about the middle of the last century, was such as we have described, till *fr. Haskins Eyles Stiles* formed an ingenious hypothesis concerning them, which was read to the *Royal Society* in 1759, and afterwards published in the *Philosophical Transactions*, vol. li. part ii. for 1760, under this title: "An Explanation of the Modes or Tones in the Ancient Grecian Music." *Sir Francis* in this dissertation endeavours to prove, that the ancients had a double doctrine of the modes, an *harmonic* and a *musical* doctrine. By the *harmonic* doctrine, the modes were all one and the same series of intervals, such as the general system furnishes, only at different pitches; by the *musical*, they consisted of so many different arrangements of intervals, or species of octave. *Sir Francis* regarded the *harmonic* doctrine as only a tuning trick, to produce more readily the different species of octave between the fixed sounds.

He explains this in a diagram, taking his pitch, according to *Ptolemy*, at *hypate meson*, our *E* in the base, and makes all his mutations between that sound and its octave, *nete die zeugmenon*. And this, according to *fr. F. E. Stiles*, is the *diapason* chosen by *Ptolemy*, cap. 2, lib. ii. for the purpose of exhibiting his divisions of the several species.

Diagram of the Species of Diapason in the seven Modes admitted by *Ptolemy*, according to the Doctrine of *Sir Francis Haskins Eyles Stiles*.

Mese

Mixolydian. Key of D minor. Lydian.

Mese C*

Lydian.

Mese B

Dorian.

Mese G*

Hypolydian.

Mese F*

Hypophrygian.

Mese E

Hypodorian.

Sir Francis gives quotations from the ancient Greek writers in confirmation of his doctrine, several of which indeed seem favourable to it; at least they imply a difference on some occasions from the intervals in the natural or great system: this difference he imagines to be expressed by the term *μεταβολη*, *mutatio*.

He very truly asserts, that no transposition of the same melody into a higher or lower key, can have so powerful an effect as a change in the modulation, or succession of intervals; and observes, that modern music has but two considerable changes in the same key; these are from major to minor, and from minor to major. The first seems reserved for pathetic effects.

Sir Fr. Haskins Eyles Stiles falls foul on all his predecessors. After his opinion, we have that of Rousseau, the chief part of whose article in his *Diét. de Mus.* we have translated, and given whatever is most new and useful in former and subsequent articles, and his opinion on the ancient Greek modes and other articles peculiar to the music of the ancients.

Metastasio, in two letters to Saverio Mattei on the Grecian music, has considered it with his usual elegance, candour, and clearness; but he does not treat of the modes in particular, so much as on ancient Greek music in general. We shall therefore reserve our extracts from these two letters, till Greek music and music of the ancients are considered at large. See SYSTEM.

MODECCA, in *Botany*, a genus of the Cucurbitaceous order, figured in Rheede Hort. Malab. v. 8. t. 20-23, and indicated by Jussieu under *Passiflora*, Juss. Gen. 398. A species of the same, from Sierra Leone, flowered many years ago, in lady Amelia Hume's stove, and still exists there. We believe it to be a perfectly well defined genus, and have proposed to call it *Blepharanthus*, on account of the fringed petals, which make its essential character, and to preserve an analogy with its near ally *Trichosanthes*. We have only waited for a more correct knowledge of the

several species, and of some circumstances in the generic character. It is abundantly distinct from *Passiflora*. S.

MODEL, an original, or pattern, proposed for any one to copy or imitate.

St. Paul's church is said to be built after the model of St. Peter's at Rome.

MODEL is particularly used in building for an artificial pattern, made of wood, stone, plaster, or other matter, with all its parts and proportions; in order for the better conducting and executing some great work, and to give an idea of the effect it will have in great.

In all great buildings it is much the surest way to make a model in relievó; and not to trull to a bare design, or draught. There are also models for the building of ships, &c. and for extraordinary stair-cases, &c.

MODEL, in *Painting and Sculpture*, is any thing proposed to be imitated. And

Hence, in the academics, they give the term model to a naked man, disposed in several postures, to give an opportunity to the scholars to design him in various views and attitudes.

The sculptors have little models of clay or wax to assist them in their designs of others that are larger, in marble, &c. and to judge of the attitude and correctness of a figure.

Statuaries likewise give the name model to certain figures of clay or wax, which are but just fashioned, to serve by way of guide for the making of larger, whether of marble or other matter.

MODENA, *Duchy of*, in *Geography*, a principality of Italy, bounded on the N. by the duchy of Mantua, on the E. by the Bolognese, on the S. by the republic of Lucca, and on the W. by the duchy of Parma, and part of Tuscany; about 60 miles in its greatest length, and from 20 to 36 in breadth. The soil resembles that of the duchy of Parma; the agriculture is little superior, the middle-men and metayers impeding industry, though some peasants in the mountains are proprietors of land. The breed of sheep is neglected. The country, however, abounds in corn, excellent wine, and other productions. In some parts is found a kind of alkaline earth, which, being reduced to powder, has been used as an antidote to poisons, fevers, dysenteries, and others disorders. In other parts wells are dug, 40 or 60 feet deep, and on the water a reddish petroleum is seen to float, which abounds most in autumn and spring. These wells are enclosed, and every fortnight oil is skimmed off the surface; and this oil is used for embalming, varnishing, painting, and as an ingredient in some medicinal preparations. Amber is dug out of a soil impregnated with petroleum. This duchy affords a variety of petrifications. In digging wells near Modena, to a certain depth, a particular stratum is found, on penetrating which the water gushes up as from a subterranean lake or river. About 10 miles S. of the capital there is an aperture in the earth called "La Salza," whence, particularly in spring and autumn, ascend, with a very loud noise, smoke, flame, ashes, and stones, attended with a strong smell of sulphur. Carrara, in the S. of this duchy, affords the celebrated marble used in statuary. The chief rivers are the Crostolo, the Secchia, and the Panaro. This duchy is a remnant of the power of the celebrated family of Este, who also possesses the adjacent country of Ferrara, which was seized by the pope in 1598. The remaining territory contains about 320,000 souls, and the city of Modena 30,000; the revenue being 140,000*l.* Since the French revolution, which has produced such changes in the geography, as well as in the general state of Europe, the whole of this duchy forms a part of Italy, and is now divided into

into the departments of the Crostolo, the Panaro, and the Apennines.

MODENA, the capital of the above duchy, and now capital of the department of Panaro, the ducal residence, and a bishop's see, is an ancient, large, tolerably built, fortified town, with a strong citadel, containing a ducal palace, which is large and splendid, and distinguished by a well furnished picture-gallery, a cathedral, many parish churches and convents, and from 25,000 to 30,000 inhabitants. It is situated in a fertile plain; and its streets are, in general, large, straight, and ornamented with porticoes and piazzas. The university was for a long time under the direction of eminent professors; and the magnificent college of Charles Boromeo, is an academy for 70 or 80 young noblemen. In a chamber under the cathedral tower is the curiosity so much talked of by travellers, called "Secchia rapita," which is nothing more than a well-bucket, with iron hoops, hung up by an iron chain, taken in a war from the inhabitants of Bologna, and preserved here as a trivial monument of courage and victory. The house of Este possessed this city ever since the year 1288. On the approach of the French, the duke retired from his dominions, with a large sum of money, to Venice. Upon an armistice, he agreed to pay to the republic 7,500,000 livres in cash, 2,500,000 livres in provisions and military stores, and to give, besides, pictures and other douceurs; 30 miles S. of Mantua. N. lat. 44° 38'. E. long. 10° 56'.

MODENORE, a town of Hindoostan, in the circar of Condapilly; 20 miles N.W. of Masulipatam.

MODÉRATA, MISERICORDIA, in *Law*, a writ that lies for him who is amerced in a court-baron or other court, not of record, for any transgression beyond the quality or quantity of the offence. It is directed to the lord of the court, or his bailiff, commanding them to take a *moderate amercement* of the party. This writ is founded upon Magna Charta.

If a man be amerced in a court-baron on presentment by the jury, where he did not any trespass, he shall not have this writ, unless the amercement be excessive and outrageous; and if the steward of the court, of his own head, will amerce any tenant or other person without cause, the party ought not to sue for this writ of moderata misericordia if he be distrained for that amercement; but he shall have action of trespass. (New Nat. Br. 167.) When the amercement which is set on a person is assessed by his peers, this writ of moderata misericordia doth not lie; for then it is according to the statute 10 Edw. II.

MODERATION, in *Ethics*, is a virtue consisting in the proper government of our appetites, passions, and pursuits, with respect to honours, riches, and pleasures; and in this sense it is synonymous with *temperance*: it is also often used to denote *candour*.

MODERATO, Ital. in *Music*, implies a time neither quick nor slow; much resembling *andante*, but somewhat quicker. See *ANDANTE*.

MODERATOR, in the *Schools*, the person who presides at a dispute, or in a public assembly.

Such a doctor was the moderator, that is, the president, at such a disputation, in such an assembly, &c.

MODERATOR Ring, in *Anatomy*, is used by Valsalva for that ring which the muscles of the eye make round the optic nerve, at the bottom of the orbit. He alleges, that the exterior fibres of these muscles which rise from the nerve, must shorten it when they contract, and when the interior fibres act they must compress it; so that these different fibres of the muscles affect the nervous fluid here very differently.

Valsalva also describes such another ring made round the motory nerves of the eye; but acknowledges, that it is neither so remarkable nor distinct as the former. Med. Eff. Edin. Abr. vol. ii. p. 410.

MODERE', Fr. in *Music*. See *MODERATO*.

MODERN, something new, or of our time. In opposition to what is antique, or *ancient*.

Modern authors, according to Naude, are all those who have written since Boethius: the modern philosophy commences with Galileo: and the modern astronomy with Copernicus.

MODERN Medals are reckoned all those that have been struck within these three hundred years. See *MEDAL*.

MODERN, in *Architecture*, is improperly applied to the present, or Italian manner of building; as being according to the rules of the antique. Nor is the term less abused when attributed to architecture purely Gothic.

Modern architecture, in propriety, is only applicable to that which partakes partly of the antique, retaining somewhat of its delicacy and solidity; and partly of the Gothic, whence it borrows members and ornaments, without proportion or judgment.

MODERN Music, *Musica Moderna*, may be divided into two parts: first, *antiquo moderna*, which is generally a serious sort of music, consisting of many parts; and which has been in use from Guido's time to the beginning of the last century. Secondly, the *modern*, which has been used in the two last centuries: it is very different from the *antiquo moderna*, being brisker, lighter, gayer, and more sprightly.

The characteristics of the first state of counterpoint, or music in parts, were *plain simple harmony*, consisting of common chords, of note against note; then *figurative harmony*, or notes of different lengths, consisting of different figures or characters moving at the same time. After this was found to be possible, the more artificial contrivances were cultivated of fugue and canon, but without air or melody, except in fragments of canto-fermo, and tunes of such popular ballads as were sung in the streets, and upon which most of the early masses in four parts were constructed.

MODERN, or *Modra*, in *Geography*, a town of Hungary; 14 miles N.N.E. of Presburg.

MODESTY, in *Ethics*, is sometimes used to denote humility; and sometimes to express chastity or purity of sentiment and manners. Modesty was deified by the Romans under the name of "Pudicitia;" and at Rome she had two temples, one dedicated to the chastity of the nobles, and the other to that of the populace, and also altars on which sacrifices were offered to her. The origin of the distinction between the chastity of the Patrician ladies, and that of the Plebeians, is thus related by Livy (l. x. c. 25.) Virginia, of a Patrician family, having married a Plebeian named Volumnius, who was, however, afterwards consul, her sister, looking upon this match to be unworthy her name, having joined with the other matrons, would no longer suffer her to partake in the mysteries of the goddesses of Chastity, but drove her out of the temple. Virginia, stung with this affront, got a chapel raised in the long street, the same where was the goddess's temple from which she was excluded, and she dedicated it to the chastity of the Plebeian ladies; where the wives, who were not of the senatorian order, convened from that time to offer sacrifice to that goddess. Chastity was represented under the figure of a woman veiled, or seeming to point her right-hand, or her fore-finger, to her face, to signify that she has no reason to blush.

MODI, in *Geography*, a small island in the gulf of Engia. N. lat. 37° 27'. E. long. 23° 33'.

MODIA.

MODIANORE, a town of Hindoostan, in Myfore; 45 miles E.N.E. of Bangalore.

MODIBOO, a town of Africa, in the kingdom of Bambarra, delightfully situated on the banks of the Joliba or Niger, which is here very broad, and cultivated with many small and verdant islands, all of them stocked with cattle, and crowded with villages; 65 miles N.E. of Segou. N. lat. $14^{\circ} 38'$. W. long. $1^{\circ} 35'$.

MODICA, a town of Sicily, in the valley of Noto; 8 miles W. of Noto. N. lat. $36^{\circ} 51'$. E. long. $14^{\circ} 43'$.

MODIFICATION, in *Philosophy*, that which modifies a thing; that is, gives it this or that manner of being.

Quantity and quality are accidents which modify all bodies.

According to Spinoza's system, all the beings that compose the universe are only so many different modifications of one and the same substance. And the different arrangement and situation of their parts make all the difference between them.

MODIFICATIVE, something that modifies, or gives a thing a certain manner of being.

Father Buffier establishes a new part of speech, which he calls *modificative*. Nouns and verbs, he observes, are susceptible of divers circumstances or modifications; in the phrase, *zealists*, we have a noun and verb without any modification; but in that, *zeal without discretion acts rashly*, the noun and verb are each attended with a modification or circumstance.

The last kind of words, which serve to modify nouns and verbs, since they have no general name in the common grammars, he chooses to call *modificatives*: which include what grammarians commonly call *adverb, conjunction, and preposition*.

MODILLIONS, in *Architecture*, mutules carved into consoles, placed under the fessit or bottom of the drip of the corona in the Corinthian and Roman orders, for supporting the larnier and cyma, or appearing to perform the office of support.

In Grecian architecture, the Ionic order is without modillions in the cornice, and also the Roman examples of the same order, except the temple of Concord at Rome, which has both dentils and modillions.

A singular and curious example of a modillion cornice, but contrary to the principles of architecture, is to be found in the interior cornice of the Tower of the Winds at Athens, where the projecting part is much thicker than the interior part, where the stress seems to lie, and, consequently, gives the idea of weakness.

A singular example of modillions is to be found in the frontispiece of Nero at Rome, where they consist of two plain faces, separated by a small cyma reversa, and crowned with an ovolo and bead.

Another very extraordinary form of modillions is that placed in the frieze of the fourth order of the Coliseum, cut on the outside, or projecting part of a cyma reverse form.

In most examples of the Corinthian and Roman orders, the cornices have both dentils and modillions; but in our opinion, if the two are used together, in good proportion to the other parts, so as to appear distinctly at a reasonable distance, the cornice will be overcharged, both in proportion and weight, to the other principal members of the entablature, or the entablature to the whole order; the one or the other ought, therefore, to be omitted in the same cornice.

In the general disposition of modillions, if each one is conceived to be divided into two equal parts by a vertical plane at right angles to the surface of the frieze, one of the modillions is so disposed, that its dividing vertical surface will be entirely in a plane passing through the axis of the column, and

in the column next the angle of the building there is generally only one modillion between that through which the plane along the axis passes, and the angle of the corner.

The vertical sides of modillions at right angles to the face, are generally finished with volutes of different sizes, and turned on different sides of the same line, the greater being that next to the vertical surface, to which they are attached, and the lesser at the extremity.

The fessits of the modillions, so constructed, follow the under line of the volutes, and the connecting undulated line which joins them. The upper part of each volute is on the same level, and is attached to a moulding of the cyma inverse form, which returns round it, and this moulding is again attached to the corona, which hangs over the modillion.

In some of the Roman buildings the modillions are not placed over the axes of the columns, neither upon those at the extremes, nor over the axes of the intermediate shafts. In the Pantheon, the modillion next each angle of the building has its vertical side, which is opposed to the next modillion nearer to the central plane of the portico, over the axis of the column, and consequently the whole breadth of the modillion on one side of the axis entirely, and on that side next to the angle of the building. In the whole portico are forty-seven modillions, including the one at each extreme; the intervals are, therefore, forty-six in number, and forty-four between the columns that are between their axes. The portico is octo-style, and, consequently, the inter-columns are seven in number: from this it will be found, that if the columns were placed equidistantly, the number of inter-modillions would be 6^2 ths in number. In this temple the corresponding intervals are very irregular. The two extreme ones are, according to Desgodetz, $9' 4\frac{1}{2}''$, and $9' 2\frac{1}{8}''$: the next two, nearer the centre, are $9' 5\frac{1}{8}''$, and $9' 1\frac{1}{8}''$: the next two, still nearer to the centre, are exactly equal, being $9' 5''$ each, and the central intercolumniation is $10' 4\frac{3}{4}''$: so that the modillions appear to be equally divided, without any regard to the axis of the columns. The same irregularity in the disposition of the modillions may be observed in the temple of Concord, and in that of Jupiter the Thunderer. In the three remaining columns of the temple of Jupiter Stator, each column has a modillion placed over its axis, and each inter-column has three modillions regularly disposed: the distance between the lower ends of the shafts are 3 mod. 4 pa. $\frac{1}{2}$, and the columns are in height 20 modules, 6 parts $\frac{1}{2}$ ths.

In the Pantheon, the modillions are placed in the pediment, contrary to the authority of Vitruvius.

MODIŁOWA, in *Geography*, a town of Poland, in Volhynia; 36 miles N.E. of Zytomiers.

MODIN, a village of Palestine, situated on a hill, deserving of notice, on account of the tomb of the Maccabees, and also of a victory obtained by Judas Maccabæus, over Antiochus Eupator; 14 miles E.S.E. of Jaffa.

MODINAGUR, a town of Hindoostan, in Bahar; 25 miles E.N.E. of Hajipour. N. lat. $25^{\circ} 34'$. E. long. $85^{\circ} 51'$.

MODIOLI, in *Natural History*, a name given by some authors to the trochitæ or single joints of the rays of the petrified magellanic star-fish, which, when connected in numbers together, form that fossil called entrochus. Others have also used this word, *modiolus*, to express the compound body, or entrochus itself. Though the general form of the trochitæ be thin and flat, yet they are sometimes found considerably thick; and though the entrochi or compound modiola are usually so many cylinders of equal diameter in all parts, yet there are sometimes found such as are thick in the middle, and thence gradually taper to each end; some

also

also are composed of joints, each of this form; these differ very greatly from the common kind, and instead of consisting of a number of little wheels, are made up of a series of little barrels, joined, as it were, end to end.

MODIOLUS, from *modus*, a measure, in *Surgery*, since it was formerly so constructed, that it would only enter to a certain depth: the crown or saw of the trepan. Anciently it resembled in shape the nave of a wheel.

MODIUM, in *Geography*, a town of Norway, in the province of Aggerhuus; 20 miles W. of Christiania.

MODIUS, in *Antiquity*, a kind of dry measure in use among the Romans for several sorts of grain.

The modius contained thirty-two heminæ, or sixteen sextaries; or $\frac{1}{2}$ of the amphora; amounting to an English peck. See **MEASURE**.

MODIUS, FRANCIS, in *Biography*, a learned critic, was born at Oudenburg, in Flanders, in 1546. The wars of the Low Countries obliged him to retire to Cologne, and he spent the greater part of his life in Germany. Being at Bonne in 1587, he lost all his effects, and was himself dangerously wounded. Towards the close of life, he was presented with a canonry at Aire, where he died in 1597. Modius wrote annotations upon many of the Latin classics, which are mostly to be found in his "Lectiones Nov-antiquæ," which were first printed at Frankfort in 1584, and were reprinted in letters by Gruter, in the fifth volume of his "Thesaurus Criticus." He was author likewise of poems and other pieces. Moreri.

MODO & Forma, in *Law*, a phrase used in processes and pleadings, by which the defendant absolutely denies the thing charged on him by the plaintiff, *modo & forma declarata*, in the manner and form set forth.

The civilians in the like sense say, *negat allegata, prout allegantur, esse vera*.

MODON, in *Geography*, a sea-port town on the S.W. coast of the Morea; with a large and safe harbour. The town is the residence of a pacha, and see of a Greek bishop; 42 miles W.S.W. of Mistra. N. lat. 36° 58'. E. long. 21° 35'.

MODRITZ, a town of Moravia, in the circle of Brunn; five miles S. of Brunn.

MODRSAW, a town of Austrian Poland, in the palatinate of Cracow; 24 miles W. of Cracow.

MÖDRUSCH, a town of Austrian Croatia, the see of a bishop; 24 miles W.N.W. of Sluin.

MODULATION, from *Modulatio*, Lat., in *Music*, is one of the most important terms of a musical dictionary. In the articles **COMPOSITION** and **COUNTERPOINT**, it has been treated after our own ideas and experience; here we shall give our readers the rules laid down by others, not to confute, but to confirm and strengthen our own. And first, we should give Padre Martini's instructions, and those of Dr. Pepusch on the subject, as the most profound contrapuntists of Italy and Germany during the early part of the last century, if these learned theorists had not adhered so religiously to the ecclesiastical modulation of the old masters, founded on the modes or tones of the church, so as to preclude all the modulation of secular music, which has been extended, and in many instances improved, during the last hundred years. We shall, therefore, now chiefly translate and confine ourselves to the article *Modulation* in the dictionary of Rousseau, in which it is amply and clearly treated, according to the practice of the best masters at the time of his writing; that is, 30 or 40 years ago. See works on the same subject by subsequent writers still living, such as Fricke, Bemitzrieder, Kollmann, &c.

But first we must observe, that *to modulate* during the

sixteenth century, implied nothing more than a change of voice from one found to another; but the ingenious citizen of Geneva, more consonant to present practice in music, defines modulation, "the manner of establishing and treating a key;" but adds, that the word, at present, generally implies the art of conducting melody and harmony, successively, into many keys, in a manner agreeable to the ear, and according to rule. If the key is announced by harmony, it is from harmony that the laws of modulation arise.

These laws are easy to conceive, but difficult rigorously to observe. To modulate properly in the same key, we must begin first by running through all the notes of that key in good melody, frequently repeating its essential chords, and strongly marking them. That is, passing from the chord of the 7th to the 5th, or $\frac{1}{2}$ of the 7th to the key-note; but in various ways to avoid monotony. Secondly, to make no closes, nor to repose but upon those two chords, or at most on that of the 4th of the key, called by the French the subdominant, or 5th below the key. Thirdly, never to alter any of the sounds of the principal key by a flat or sharp, which would lead to another key.

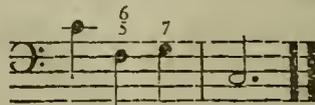

But to pass from one key to another, which is now understood to be the principal business of modulation, analogy must be consulted, with respect to the relation of keys, and the number of chords appertaining to two keys.

Let us begin by a major key, or key with a sharp 3d. Whether we consider the 5th of the key as being more immediately related and connected with it of any found except the octave of the key-note; or whether we regard it as the first found that is heard in the resonance of the key-note, the 5th will always be found the most agreeable interval upon which to establish a modulation the most analogous to that of the key-note.

The 4th of the key, if not a part of the chord of the key-note, the key-note is at least a part of the chord of the 4th. For if CEG form the chord of the key-note, that of the 4th will be F A C; thus C is the bond of union between the two keys. Indeed it is only necessary to change one found of the principal key to form the scale of its 5th above, and 5th below, or 5th and 4th of any major key. In the key of C, an F \sharp or a Bb does the business.

There are two minor chords in the key of C, in which only one note differs from the chord of C, as A c e, and e g B. But the sharp 7th, and other accidents which happen to the chords and melody of these minor keys, changes their character so much, that the double relation between the chords of C and A, and C and E is soon effaced.

As all the sounds of the scale of C are comprised in the chords of the key-note, and its two 5ths,

See plates throughout this article.

the gammut or scale of C, if altered only by one single sharp, furnishes the scale and chords of G, the 5th above C, which shews the great analogy between these two keys, and facilitates the means of passing from one to the other by one alteration only.

The key of the 5th is, therefore, the first which presents itself after the key-note in the order of modulation.

The same simplicity of relative sounds between the key-note and its 5th above is also found to subsist between the key-note and its 5th below, or 4th above.

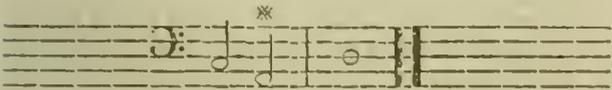

Though the modulating from C to A minor, its 6th, and from C to E minor, its 3d, is only by the change of one note in the chords, the sharp 7th must be heard in one of the chords of these minor keys, to make either A or E a key-note.

These immediate modulations furnish the means of passing to more remote keys by the same rules, and of returning afterwards to the key-note, of which we must never lose sight.

We have four regular modulations from the key of C major; EFGA. To modulate into D, wholly unrelative to C, it must be brought about by means of a consonant movement of the fundamental A with a sharp 3d.

But we must dwell but an instant in this modulation, lest the key of C is forgotten, which itself is altered in going into D. A long period in D would require intermediate modulations to return to C, into which it would be dangerous to wander. No good modulation into B, the sharp 7th of C, can have place, at least immediately, as it has no true 5th, and would lead to a harmony too sudden and remote from that of the principal key. In every modulation, all the parts must change the key at the same instant, to avoid carrying on two modulations at the same time. Huygens, says Rousseau, has well remarked, that the prohibition of two successive 5ths has this rule for its principle; for it is impossible to have many perfect successive 5ths between two parts, without modulating into two unrelative keys. The hexachords are composed of pure harmony to fundamental bases, without modulation. The descending scale in the *règle de Poëve*, modulates into the 5th of the key. But, in fact, only three notes in the base can ascend in one key, diatonically; the 4th note arrives at a new key to the top of the scale, which produces a perpetual modulation by 4ths, from C natural into all the 23 keys.

To modulate on a keyed instrument, is usually done in arpeggio, by preluding extempore, of which the variety, to a man of science, is unbounded. Abel, no lesson-player on the clavichord or harpsichord, possessed this talent to a wonderful degree.

MODULE, in *Architecture*, a certain measure taken at pleasure, for regulating the proportions of columns, and the symmetry or distribution of the whole building.

Architects usually choose the diameter or semidiameter of the bottom of the column for their module; and this they subdivide into parts or minutes.

Vignola divides his module, which is a semidiameter, into twelve parts, for the Tuscan and Doric; and into eighteen, for the other orders.

The module of Palladio, Scamozzi, M. Cambray, Def-Vol. XXIII.

gold-ty, Le Clerc, &c. which is also the semidiameter, is divided into thirty parts, or minutes in all the orders.

Some divide the whole height of the column into 20 parts for the Doric, 22½ for the Ionic, 25 for the Roman, &c. and of one of these parts they make a module, by which to regulate the rest of the building.

There are two ways of determining the measures or proportions of buildings: the first by a fixed standard measure, which is usually the diameter of the lower part of the column, called a module, subdivided into sixty parts, called minutes. In the second there are no minutes, nor any certain and stated division of the module; but it is divided occasionally into as many parts as are judged necessary. Thus the height of the Attic base, which is half the module, is divided either into three, to have the height of the plinth; or into four, for that of the greater torus; or into six, for that of the lesser.

Both these manners have been practised by the ancient as well as the modern architects; but the second, which was that chiefly used among the ancients, is in the opinion of Perrault preferable.

As Vitruvius, in the Doric order, has lessened his module, which, in the other orders, is the diameter of the lower part of the column, and has reduced that great module to a mean one, which is a semidiameter; M. Perrault reduces the module to a third part for the same reason, viz. to determine the several measures without a fraction. For in the Doric order, beside that the height of the base, as in the other orders, is determined by one of these mean modules; the same module gives likewise the heights of the capital, architrave, triglyphs, and metopes. But our little module, taken from the third of the diameter of the lower part of the column, has uses much more extensive; for, by this, the heights of pedestals, of columns, and entablatures, in all orders, are determined without a fraction.

As then the great module or diameter of the column has sixty minutes; and the mean module, or half the diameter, thirty minutes; our little module has twenty. See COLUMN.

MODULER, Fr. in *Music*; to modulate extempore is a research after new effects and new combinations. Learning, hand, and experience are necessary to do credit to the performer, and please and surprize the hearer. And we may add that a prelude, toccata, or voluntary by a great player, seems inspiration, and is worth a hundred pieces committed to paper.

MODULI CAMPANORUM, chimes. See Grassineau, p. 139, a long article on the subject. See CARILLONS.

MODUNDAH, in *Geography*, a town of Bengal; 18 miles N.N.E. of Calcutta.

MODUS DECIMANDI is when a parcel of land, a sum of money, or a yearly pension, belongs to the parson, either by composition or custom, time out of mind, in satisfaction for tithes in kind: or, when there is by custom a particular manner of tithing allowed, different from the general law of taking tithes in kind, which are the actual tenth part of the annual increase.

This is sometimes a pecuniary compensation, as twopence an acre for the tithe of land; sometimes it is a compensation in work and labour, as that the parson shall have only the twelfth cock of hay, and not the tenth, in consideration of the owner's making it for him: sometimes in lieu of a large quantity of crude or imperfect tithe, the parson shall have a less quantity, when arrived to greater maturity, as a couple of fowls instead of tithe eggs, &c. In short, any means by which the general law of tithing is

altered, and a new method of taking tithes is introduced, is called a *modus decimandi*, or special manner of tithing. In order to make a good and sufficient modus the following rules must be observed :

1. It must be certain and invariable. (1 *Keb.* 602.) 2. The thing given, in lieu of tithes, must be beneficial to the parson, and not for the emolument of third persons only. (1 *Roll. Abr.* 649.) 3. It must be something different from the thing compounded for. (1 *Lev.* 179.) 4. One cannot be discharged from payment of one species of tithe, by paying a modus for another. (*Cro. Eliz.* 446. *Salk.* 657.) 5. The recompence must be in its own nature as durable as the tithes discharged by it; *i. e.* an inheritance certain. (2 *P. Wms.* 462.) 6. The modus must not be too large, which in law is called a *rank modus*. (11 *Mod.* 60.) In these cases of prescriptive or customary moduses, the law supposes an original real composition to have been regularly made, which being lost by length of time, the immemorial usage is admitted as evidence to shew that it did once exist, and that from thence such usage was derived. Now time of memory hath been long ascertained by the law, to commence from the reign of Richard I. and any custom may be destroyed by evidence of its non-existence in any part of the long period from his days to the present. *Blackst. Com.* b. ii.

MODYPOUR, in *Geography*, a town of Hindoostan, in Bahar; nine miles S. of Patna.

MODZIEN, a town of Persia, in the province of Mazanderan; 48 miles S.W. of Astarabad.

MOECKARN, a town of the duchy of Magdeburg; 16 miles E. of Magdeburg.

MOEDA. See **MOIDORE**.

MOEN, or **MONA**, in *Geography*, an island of Denmark, in the Baltic, separated from the S. end of the island of Zealand, and from the N.E. coast of Falster, by a narrow sea, about 16 miles in length, and from three to five in breadth; containing one town, *viz.* Stoege or Stege, and several villages. N. lat. 55°. E. long. 12° 20'.

MOEN, or **MÖN**, a river which rises in Westphalia, three miles N.W. of Brilon, passes by Rhuden, &c. and joins the Roer at Nehem.

MOENCHIA, in *Botany*, received its name from Ehrhart in memory of Conrad Moench, a professor of botany at Hesse Cassel, author of the *Flora Hassiaca*. *Ehrh. Beitr. fasc.* 2. 177. This genus consists of only one species, *Sagina erecta*, Linn. Sp. Pl. 185. Sm. Fl. Brit. 200. *Engl. Bot.* t. 609. The only difference in the essential character consists in the structure of the capsule, which splits at the top into eight teeth, instead of separating, more or less perfectly, into four valves, like other *Saginae*. The habit of this elegant little plant must also be allowed to be dissimilar to that of the genus with which it has always been associated. See *SAGINA*.

MOERDA, See **MURDER**.

MÖERHINGIA, in *Botany*, was named by Linnæus in honour of Paul Henry Gerard Mörhing, a German physician, in the duchy of Oldenburg, who was the author of various botanical tracts. His first treatise appeared in 1733, entitled the anatomy of vegetables, in which the apparent structure of leaves, after being macerated in water, is particularly considered.—Mörhing printed a catalogue of his own garden in 1737, and furnished afterwards several papers for the *Ephemeries Naturæ Curiosorum*. He died in 1792, at the advanced age of 82 years. Linn. Gen. 195. Schreb. 264. Willd. Sp. Pl. v. 2. 439. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 416. Juss. 300. La-

marck Illustr. t. 314.—Class and order, *Ocandria Digynia*. Nat. Ord. *Caryophyllei*, Linn. and Juss.

Gen. Ch. *Cal.* Perianth inferior, of four lanceolate, spreading, permanent leaves. *Cor.* Petals four, ovate, undivided, spreading, shorter than the calyx. *Stam.* Filaments eight, capillary; anthers simple. *Pist.* Germen superior, globose; styles two, erect, the length of the stamens; stigmas simple. *Peric.* Capsule roundish, of one cell and four valves. *Seeds* numerous, roundish, convex on one side, angulated on the other.

Ess. Ch. Calyx inferior, of four leaves. Petals four. Capsule of one cell, and four valves.

1. *M. muscosa*. Linn. Sp. Pl. 515. Jacq. Austr. t. 449. (*Alnus saxifraga angustifolia minima montana*; Column. *Ecphr.* p. 1. 292. t. 290.)—Found growing in mossy situations, near trickling rills, on mountains in the south of Europe, flowering throughout the summer. *Root* perennial, thread-shaped and creeping. *Stems* annual, herbaceous, thread-shaped, round, slender, smooth, much branched. *Leaves* opposite, linear, very narrow, smooth, dilated at the base, so as to make the stem somewhat perfoliate. *Flowers* solitary, on long, erect, slender, axillary stalks. *Petals* ovato-linear, obtuse, milk white. *Capsules* yellowish when ripe. *Seeds* eight or ten, kidney-shaped, dark-brown, furnished with a large, white, jagged border to their scar of insertion.

MÖERIS, LAKE, in *Ancient Geography*, a lake of Egypt, concerning the situation and extent, and even the existence of which, authors have differed. It has been represented as the noblest and most wonderful of all the works of the kings of Egypt; and accordingly Herodotus considers it as much superior to the pyramids or labyrinth. As to its situation, Herodotus (lib. ii.) and Strabo (lib. xvii.) mark it out by placing the labyrinth on its borders, and by fixing the towns, which were round it, such as Achanthus to the south, Aphroditopolis towards the east, and Arsinoë to the north: Diodorus Siculus (lib. i.) and Pliny (lib. v.) confirm these authorities, by placing it at 24 leagues from Memphis, between the province of that name and that of Arsinoë. If the lake, like that of Mareotis, had totally disappeared, doubts as to its situation might still have been entertained; but the position marked by the above-mentioned historians leads us to a lake, actually existing, known by the name of *Birket Caroun*, (which see,) more than 50 leagues in circumference. With regard to the extent of this lake, we recur again to the testimonies above cited: Herodotus says, that the circumference of the lake Mœris was 3600 stadia, or 60 schenes, which, says the historian, form the dimensions of the maritime base of Egypt, (75 leagues.) He adds, that it stretches from N. to S. and that its greatest depth is 300 feet. The historian has fixed the measure of the schene in Lower Egypt at four miles, or $1\frac{1}{4}$ league, so that the 60 schenes make 75 leagues. If we compare the measures by Strabo and Diodorus Siculus, we shall find that the base of Egypt was estimated at 75 leagues, and hence it will follow, according to the account of Herodotus, that the lake was in circuit 75 leagues. Some writers, who have taken the usual measure of the stadium at 100 toises, have assigned to this lake a circumference of 150 or even 180 leagues. But as the historian has determined the measure of 3600 stadia to be 60 schenes, or 75 leagues, he must have made use of stadia of 50 toises each. Bossuet, the bishop of Meaux, has vindicated the statement of the largest extent of 180 leagues, which Voltaire has treated with raillery; and M. Rollin, conceiving it to be incredible, adopts the opinion of Pomponius

nus Mela, who says, that this lake is but 20,000 paces, that is, seven or eight French leagues in circumference. Pliny estimates it at 250,000 paces, or about 80 leagues. M. D'Anville, with a view of conciliating the different contending parties, has, in his map of Egypt, marked a great canal, to which he gives the name of the lake Mæris. The depth of 300 feet ascribed to this lake by historians must be exaggerated; but perhaps less so than we may be led to imagine. The bottom which it occupies is a basin, formed by the mountains. It is very low, since the Nile runs into it even by the canal of Tamiéh. Although the mud may have gradually collected in a series of ages, its depth is still very considerable. Two pyramids, says Herodotus, constructed in an island towards the middle of the lake, rise from 300 feet below the water, and are as high out of it. Each of them has on its summit a colossal statue, seated on a throne. Their total elevation, taken from the base, is a stadium of 600 feet; thus marking the measure of the stadium, as he had before, in giving the circumference of the lake, reduced it to 50 toises. These pyramids no longer exist; nor indeed did they exist in the time of Augustus, for they are not mentioned by Strabo. Lake Mæris, says Herodotus, occupies a soil very dry, and delituate of springs. It derives its waters from the Nile, which runs into it during six months; and during the remainder of the year it restores them to the river. During the former period, the fishery produces a talent of silver daily to the royal treasury, and 20 minas only during the latter. According to the natives of the country, a canal is pierced across the mountain, the extended chain of which commands Memphis. This is an outlet by which the superfluous waters are poured into the sands of Libya on the western side. As for the earth that was taken from the lake, the historian was informed, that it had been conveyed to the river, and carried by the current into the sea. According to the account of Strabo, the province of Arsinoë contains the wonderful lake of Mæris, which resembles the sea in its extent, its colour, and its shores. As deep as it is extensive, it receives at the beginning of the inundation the waters which would otherwise cover the harvests and the habitations of men; they are conducted thither by a large canal. When the Nile subsides, they return by two other canals (those of Tamiéh and of Bouch), which, as well as the former, serve for watering the fields, which is naturally performed. At the head of the canals sluices are formed, which are opened at pleasure; whether to introduce or to let off the waters.

At present this lake is only about 50 leagues in circuit; but this diminution by no means proves that Herodotus and Pliny were deceived in their calculations. Considering the revolutions to which Egypt has been subject for a series of 2000 years, it might have undergone still greater changes. The noble design of forming this lake is said to have been conceived by one of the Pharaohs, called Mæris, and he determined to change a part of the country, which was sandy and desert, into an useful lake. After the excavation had been made by the labour of some thousands of men, and at an immense expence, he drew a canal 40 leagues in length, and 300 feet wide, for the purpose of conducting thither a part of the waters of the Nile. This great canal, which still subsists entire, is known under the name of "Bahr Joufeph," Joseph's river. It opens near "Tarout Echerif," and ends at "Birket Caroun." As in several places this canal was cut out of the rock, the labour and expence must have been very great. It was not sufficient to have disengaged Egypt from the excess of the inundation, which in those remote ages remained too long on

the lands, at that time lower than they are in our days, and occasioned its sterility; it was necessary also to render these waters useful to agriculture. This great prince succeeded in doing this by drawing two other canals from the lake to the river. At their opening were formed two sluices, which were kept shut during the increase of the Nile; then the waters conveyed by the canal of Joseph were heaped up in the immense inclosure of lake Mæris, encompassed with dykes and mountains. During the six months that the Nile was on the decline, these sluices were opened, and a surplus of water of about 80 leagues in circumference, and 30 feet higher than the ordinary level of the river, formed a second inundation to be directed at pleasure. One part returned to the Nile, and served for the navigation. The other part branched out into innumerable rivulets, watered the fields, and diffused fertility even to the very sandy hills. This great work supplied the deficiency of water in years of a moderate overflow, by retaining those precious waters, which otherwise would have flowed uselessly to the sea. Its benefits were still more strongly marked in the time of a great inundation. It received that hurtful superfluity of them, which would have prevented the sowing of the earth. Lest this artificial sea should break down the barriers that were opposed to it, and cause frightful devastation in the country, a canal was cut through the mountains, by which the superfluous waters were poured into the sands of Libya. At present this lake has lost almost all its advantages. From the period of nearly 1200 years, since which Egypt has fallen into the hands of barbarous nations, they have either destroyed, or suffered to perish, the chief part of these monuments. The Marcotis is dried up, the canal of Alexandria is no longer navigable, and the Mæris is only 50 leagues in circumference. If the canal of Joseph were cleared out, where the mud is collected to a vast height, if the ancient dykes were re-established, and the sluices of the canals of Tamiéh and of Bouch restored, lake Mæris would still serve the same purposes. It would prevent the devastation, of the too great swellings of the rivers, and supply the deficiency of those which are inadequate. We should see it, as on former occasions, extending itself from Nesle and Arsinoë to the Libyan mountains, and offering to the view of the astonished traveller, a sea formed by the hand of man. Rollin's Anc. Hist. vol. i. Savary's Letters in Egypt, vol. i.

MOERSBERGEN, in *Geography*, a town of Holland, in the department of Utrecht; 10 miles E. of Utrecht.

MÆSIA, called by the Greeks *Myfia*, in *Ancient Geography*, a country of Europe, lay N. of Macedonia and Thrace, and extended from S. to N. as far as the right bank of the Danube. From W. to E. it extended from Pannonia, where the Drinus (Drin), passing to Sirmium and Singidunum (Belgrade), in order to discharge itself into the Danube, served for its boundary: to the W., comprehending the territory called "Pontus-Euxinus," from the promontory called "Hæmi-Extrema," and to the S. as far as the Istropolis. This large extent of country was divided into two distinct territories, partly by the mountains, and partly by the river Cæbrus (Zebris), which discharged itself into the Ister. The part comprehended between the Drinus and the Cæbrus was called "Mæsia Superior," and that which extended from the Cæbrus to the sea was called "Mæsia Inferior;" i. e. Upper and Lower Mæsia. The principal river of Upper Mæsia was the Margus (Morava), formed of two other rivers; and farther to the E. it had the Tinacus (Timak). The principal towns were Singidunum (Belgrade), Viminacium (Mioas), Bonomia (Vidin), and Ratiaria (Artzar). In the interior of the country is

Neiffus (Niffa); besides other places mentioned by Ptolemy. The principal rivers of Lower Mœfia were the Cœscus (Esker), the Osmus (Ofmo), the Utus (Vid), the Iatrus (Jantra), all which rivers ran from S. to N. and emptied themselves into the Danube: the Panyfus ran from W. to E., and discharged itself into the Euxine sea, near Odeffus (Vafna). The principal towns are, upon the Danube, Cœscus (Artzar), Nicopolis (Nicopoli), Duroftom (Drittra or Silhtria), Axopolis (Raffovat), and Trafmi. In the interior country were Sardica or Triaditza, near Sophia, Taurefium, the birth-place of Juftinian, called Juftiniana prima (Dginftendil), Nicopolis ad Hæmum (Ternova), Nicopolis ad Iatrum (Nicopi), and Marianopolis (Marienopoli). Upon the coasts of the Euxine sea, in the part called Scythia, and S. of this part, were Tomi (Temefwar), the place of Ovid's exile, Caria (Kalgri), and Odeffus (Varna).

MOESKIRCH, in *Geography*, a town of Germany, and capital of a lordship, belonging to the princes of Furitenburg; 18 miles N. of Conftance. N. lat. 47° 59'. E. long. 9° 14'.

MOESTLIN, MICHAEL, in *Biography*, a German Lutheran divine, and celebrated mathematician, who flourished in the 17th century, was born at Goppingen, in the duchy of Wirtemberg. He obtained the friendship and patronage of the duke, who sent him to the university of Tubingen, where he was quickly distinguished by his diligence and talents, and took his degrees. After this he embarked in the ministry, was chosen pastor of the town of Tetschen, and discharged the duties of his office to the satisfaction of his flock, and acquired universal respect by his unaffected piety and exemplary manners. He also obtained considerable reputation for profound skill in the mathematics, for which he had a sort of natural turn. On this account he was elected mathematical professor at Heidelberg, where he remained about three years, and then returned to Tubingen. Here he was appointed to the mathematical chair, in which he continued during the remainder of his life. He died in 1650. He is said to have been the first person who explained the cause of the pale light observable on the disk of the moon a little before and after the change. In Italy he delivered an harangue in defence of the Copernican system, and is thought to have influenced Galileo in renouncing the old hypotheses, and in embracing the system which has now obtained a sure footing. He published "Ephemerides," and several other works connected with science. Moreri.

MŒURS, Fr. morals, manners. Rousseau has treated this word as a musical term; and informs us that it constituted a branch of Greek music, under the title of "Hermofmenon," which consisted in knowing how to choose what was most beautiful and proper in each genus, without permitting musicians to give to each object and each character all the forms of which it was susceptible; but obliged them to confine themselves to what was most appropriate to the subject, the occasion, the persons, and the circumstances. The morals consisted further in so arranging and proportioning all the constituent requisites in musical composition, such as the mode, the time, the rhythm, melody, and even the transitions; so that in the entire piece there should be a conformity and agreement which left no disproportion; but that all its several parts should constitute one perfect whole.

To prescribe to what point of perfection an art should be carried, and reduce to rules what is decorous, fitting, and excellent, was a degree of refinement to which the moderns pretend not to have arrived.

MOEY, in *Geography*, a small island in the East Indian sea. S. lat. 5° 50'. E. long. 132° 50'.

MOFFAT, a large village in the county of Dumfries, Scotland, is situated upon the banks of the river Annan, at the distance of fifty miles south-west from Edinburgh, and is distinguished chiefly as the most celebrated watering place in the northern division of our island. It stands upon a considerable eminence, encompassed on the east, west, and north sides by hills of different heights, some of which are inclosed and cultivated, and others laid out as pasture lands. A fine holm, or valley, extends to the south, carrying in its bosom the limpid stream of the Annan. The principal street, declining in the direction of this vale, commands a charming view of it, for the space of several miles. The houses here are for the most part well built, and the streets are kept exceedingly clean and smooth; and from their height and gravelly foundation dry so rapidly, that in an hour after the heaviest rain, the inhabitants may promenade without the smallest inconvenience. There is one capital inn in the village, where the post-office is kept, and several lesser ones, as well as excellent lodging-houses, fit for the reception of the most genteel families. Here are an assembly-room and a bowling-green.

The Moffat Well is situated about a mile and a half from the village, having an excellent carriage road leading to it, and a long room, stables, and other conveniences for the accommodation of the company when they are stationed there. The valuable medicinal properties of this well were first discovered about 160 years ago; since which time it has been constantly held in great estimation. Its waters are powerfully diuretic, and generally allowed to be effectual in the cure of scurvy and scrophula, if the patient's lungs are not injured previously to the use of them. When poured into a glass the water sparkles like champagne, and is so extremely volatile that it cannot be drunk in perfection, unless at the fountain. According to the late Dr. Garnet, who paid considerable attention to this subject, when analysed, it is found to contain of muriat of soda (common salt) 36 grains; sulphuretted hydrogen gas 10 cubic inches; azotic gas 4 ditto; carbonic acid 5 ditto.

At the distance of four miles from Moffat, is another mineral spring, called the Hartfell Spaw, because issuing from a rock of alum-slate in a tremendous ravine, on the side of a mountain of that name. The chief mineral substances of this water are the sulphats of iron and alumina, which give it a powerful tonic quality. It is principally used, therefore, in cases of weakness; but has likewise been found serviceable in tettersous complaints and obstinate old ulcers. This well is honoured with high encomiums by Dr. Johnson. Several ether chalybeate and petrifying springs have been discovered in the country adjacent to this village. One at Evan-bridge is equal in strength to the wells at Harrowgate, but it has hitherto been entirely neglected.

The vicinity of Moffat is no less fruitful in remains of antiquity than in salubrious springs. Part of a Druidical temple is still visible close to the bank of a rivulet which passes out of a small lake, and falls into the water, deriving its name from the village. Near this spot are likewise vestiges of a Roman road; and several stations and encampments of that people. A piece of gold was found a few years ago in a moss adjoining to the road, which is supposed to have formed part of some military ornament. Its outer edge was adorned with a border, in which were the following letters formed by cutting through the interstices, IOV. AVG. VOT. XX. Vestiges of a British encampment may be seen about three miles south-east from the village. On the road between it and the well is a large mound,

of a conical form, with a very deep ditch round it: another of smaller dimensions stands at the distance of a few hundred yards. A mile east from the Roman road are two caves, cut out of free stone rock; they are of a large size, but by whom formed, or for what purpose, it is difficult to conjecture. Many ruins of old towers are visible in this parish, as well as in the adjoining one of Kirkpatrick-juxta; some of which are placed in small enclosures, defended by walls and ditches. Among the more remarkable of the entrenched parks, as they are called, is the park of Achencafs, where the walls measure 15 feet in thickness, and upwards of 20 in height.

According to the parliamentary returns of 1801, the resident population of this parish amounted to 1610 persons, *viz.* 748 males, and 871 females. Sinclair's Statistical Account of Scotland.

MOFFEN ISLAND, in *Geography*, an island in the North sea, N. of Spitzbergen; it is of a round form, about two miles in diameter, with a lake or large pond of water in the middle, and between this lake and the sea the ground is from half a cable's length to a quarter of a mile broad: the whole island, besides this pond, is covered with gravel and small stones, without the least verdure or vegetation of any kind. The navigators of the *Caracas*, who visited this island, saw only one piece of drift wood, about three fathoms long, with a root on it, and as thick as the ship's mizen-mast, which had been thrown up near the high part of the land, and lay upon the declivity towards the pond. They also saw there bears, and a number of wild ducks, geese, and other sea-fowls, with bird's nests all over the island. They found an inscription over the grave of a Dutchman, who was buried there in July 1771. The tide seemed to flow eight or nine feet, and a current was found which carried the ship to the N.W. from the island, but which before carried it to the S.E., at the rate of a mile an hour, towards it. On the W. side is a fine white sandy bottom, from two fathoms, at a ship's length from the beach, to five fathoms, at the distance of half a mile. It is remarked, as surprising, that no notice should be taken of this island by the old navigators; unless it may be supposed that it did not then exist, and that the streams from the great ocean up the W. side of Spitzbergen, and through the Waygat's shoals, meeting here, raised this bank, and occasioned the quantity of ice that generally blocks up the coast in its vicinity. N. lat. $80^{\circ} 5'$. E. long. $12^{\circ} 30'$. Phipps's Voyage towards the North Pole.

MOFHAK, a small town of Arabia, in the province of Yemen, situated on the summit of a steep hill. This town has a dola. The revenue of the town, and of the territory annexed to it, is enjoyed by one of the Imam's sons. Mofhak lies in the route from Sana to Beit el Fakih.

MOGADOR, or Mogodor, called also by the Moors *Suera*, a town of Morocco, in the province of Hea, which received its name from a faint, held here in great veneration, by the name of Sidi Mogodor, whose tomb is to be seen at a small distance to the south of the town. It had formerly a wretched castle, built by the Portuguese, to preserve a communication with their settlements to the south of this coast; and also to protect the entrance of a harbour, formed by a channel between the main land and a small island. The situation appearing favourable for a place of trade, the emperor resolved to found a city here; and the wealthier Moors began to build houses, to gratify the wishes of their sovereign. Foreign merchants were invited to do the same; and with a view of inducing them to comply with the emperor's wishes, large abatements were offered in the custom duties; but promises to this purpose were not very scrupu-

lously observed. This city was begun in 1760, and has since been completely finished. It contains a great number of houses, handsomely and solidly constructed. The streets are all straight lines, and there is no town in the empire in which a regularity of plan is so strictly observed. It is surrounded with walls, and batteries are erected, not only on the sea-side, but towards the land, to defend it from any incursion of the southern Moors. The emperor has brought all the European merchants to settle at Mogodor, and, notwithstanding its distance from Europe, it is the only port on the coast which maintains a continual commercial intercourse with that quarter of the world. This city stands on marshy ground, and so low, that, at spring-tides, it is almost surrounded by the sea. The country about it is a melancholy desert of accumulated sand. The Europeans, however, have the advantage of a more easy communication with the southern provinces, which, by exchanging their productions for the commodities of Europe, render the trade of this place very flourishing. The port of Mogodor is formed by a channel between the main land and an island more than a mile in length. The entrance of this channel is to the north-west, and its outlet to the south. It is sufficiently large for ships of a middling size, but in general it has not sufficient depth; and this disadvantage is daily increased by the accumulation of sand. The number of ships which have been lost in this port in winter, by violent storms from the south-west, sufficiently prove how very dangerous it is in bad weather; 80 miles S.W. of Morocco. N. lat. $31^{\circ} 30'$. W. long. $9^{\circ} 30'$. Chemer.

MOGADOURO, a town of Portugal, in the province of Tras-los-Montes; 22 miles S.W. of Miranda di Duero.

MOGAMI, a town of Japan, in the island of Nippon; 110 miles N. of Jedo.

MOGANOOR, a town of Hindoostan, in Bahar; 11 miles S of Namacul.

MOGARO, an island in the gulf of Venice, near the coast of Friuli. N. lat. $45^{\circ} 47'$. E. long. 31°

MOGATA, a town of Sweden, in East Gothland; 7 miles E. of Soderkioping.

MOGGIO, in *Commeroe*, an Italian corn measure, which at Florence contains 8 facchi, or 24 staja; the stajo being 4 quarti, 16 metadeli, or 32 mezzete: the moggio contains about 16 English bushels. At Leghorn, a moggio contains 2 rubbi, or $7\frac{1}{2}$ facchi; a sacco, 3 staja, or 384 buffoli. A sacco of good wheat weighs about 168 lb. of Leghorn, and contains 3720 French, or 4503 English cubic inches; so that 43 sacs of Leghorn are equal to 90 English bushels. See Tab. XXXI. under the article MEASURE.

MOGGURAH, in *Geography*, a town of Bengal; 8 miles N.W. of Goragot.

MOGHOSTAN, the denomination by which the southern part of the province of Kerman, in Persia, is distinguished.

MOGILEV, a town of Russia, and capital of a government, on the river Dnieper. The town is handsome and commercial, and a place in which the Russians carry on a considerable trade. It was taken from the Russians by the Poles in 1662; and by the division of Poland, in the year 1773, it was ceded to Russia, with its territory, and erected into an archbishopric of the Roman church, with an assistant bishop; 340 miles E.N.E. of Warsaw. N. lat. $53^{\circ} 52'$. E. long. $30^{\circ} 14'$.

MOGILEVSKOE, a government of Russia, bounded on the north by the government of Polotsk, on the north-east by that of Smolensk, on the south-east by that of Novgorod Sieverskoe, on the south by that of Tchernigov, and on the

west

west by Poland; about 176 miles in length, in its widest breadth 120, in the north part 68, and in the south only 24. N. lat. 52° to 55° . E. long. 29° to 33° .

MOGILNICA, or MOULNICZA, a town of the duchy of Warfaw; 36 miles E. of Rawa.

MOGIMERI, a town of Brazil, in the government of St. Paul; 35 miles E. of St. Paul.

MOGLA, or MULLA, a town of Asiatic Turkey, and principal place of a Sangiacat, in Natolia, on the ruins of the Alinda; 100 miles S.E. of Smyrna. N. lat. $37^{\circ} 8'$. E. long. $28^{\circ} 22'$.

MOGLE, a town of Bosnia; 35 miles E. of Banjaluka.

MOGNA, a town of Italy, in the Feltrin.

MOGO, a town of Persia, in Laristan, on the coast of the Persian gulf; 40 miles W. of Lundsje.

MOGONTUEVSKOI, a town of Russia, in the government of Irkutsk, on the borders of China; 60 miles S.S.E. of Dorouinsk.

MOGORIN, in *Botany*, a name given by the Portuguese to an Indian or Chinese flower, growing on a small shrub. It is of a wonderful white colour, and not unlike the *ginseng*, only that it abounds more with leaves, and smells much sweeter; one single flower filling a whole house with its odoriferous effluvia. On this account the Chinese put a high value upon it, and carefully defend the shrub it grows on from the inclemency of the winter, by covering it with vases provided on purpose.

MOGORIUM, a name of barbarous origin, applied by Jussieu, *Gen.* 106, to such of the Linnæan species of *Nyctanthes*, as have a pulpy fruit, the calyx and corolla of such being perfumed to have at least eight divisions; and the real *Nyctanthes*, being agreed to have a dry capsular fruit, besides other marks of distinction. Sir Joseph Banks and Dr. Solander have referred all the above-mentioned species to JASMINUM, (see that article,) in which they have been followed by Vahl and Willdenow. The measure is justified by the variability of number in the parts of these flowers, even on the same individual plant, and the strong generic affinity between them all, independent of number. Such as have naturally a five-cleft flower, very commonly acquire one, two, or three additional segments; and those which have naturally eight, as *J. Sambac*, are liable to have twelve or more, without any obliteration of their organs of impregnation. When the latter takes place, the divisions of the corolla become greatly multiplied, as in other common instances.

MOGRABIANS, MOGARBA, or *Men of the West*, in *Military Language*, a name given to the infantry of the Turks, composed of the peasants of Tunis, Algiers, and Morocco, who have thought proper to seek in Syria and in Egypt that respect which is denied them in their own country. All the accoutrements and baggage of these soldiers are confined to a rusty firelock, a large knife, a leathern bag, a cotton shirt, a pair of drawers, a red cap, and sometimes slippers. Their pay is 5 pialtres (about 10s. 10d.) per month, out of which they are obliged to furnish themselves with arms and clothing. They are maintained at the expence of the pacha, &c.

MOGUAR, in *Geography*, a town of Spain, in the province of Seville, at the mouth of the Tinto; 43 miles W. of Seville. N. lat. $37^{\circ} 12'$. W. long. $6^{\circ} 58'$.

MOGUL EMPIRE, in an extensive sense, denotes that empire of Asia, over which Tamerlane and his immediate successors reigned, and in which India was not included; but in a more restricted sense, it signifies, as custom has in later times appropriated the name, that empire which was

held by the descendants of Tamerlane in Hindooftan and the Deccan. The origin of the Mogul empire is so far remote, that it is difficult to distinguish between fabulous tradition and the records of authentic history. It probably arose from small beginnings, and extended itself by the conquests of ambitious princes. It appears, however, to have been of very limited extent, if indeed it existed at all under this appellation, when Temujin, better known under the name of Jenghiz Khan, or Gengiz Cawn, made his appearance. The birth of this conqueror is referred to the year 1163; and at the time of his father's death, his subjects are said to have amounted to between 30,000 and 40,000 families: but a majority of these revolted, and in the earlier part of his life and reign he was left almost without any subjects. He rose, however, into notice and power, under the protection of Vang Khan, who was sovereign of a considerable number of Tartar tribes, situated to the north of Kitay, or China, and who has been known among Europeans by the name of Prester John. Thus encouraged and aided, he subdued those subjects who had revolted in the year 1201, and was able to keep possession of his throne. It was not long, however, before Vang Khan became jealous of the growing power, and perhaps manifest ambition, of Temujin, whom he had made his general; so that he contrived treacherous measures for destroying a prince, whom he considered as his rival. This disagreement terminated in an open war, which Temujin prosecuted with success. Vang Khan was defeated in a battle, by which he lost 40,000 men; and soon after was ungenerously put to death by the father-in-law of Temujin, to whom he had fled for refuge. The conqueror seized on the dominions of the vanquished Khan, and rapidly extending his marches and victories, reduced all the Mogul tribes in the year 1205. In a diet, held in the spring of the following year, to which all the great lords both of the Moguls and Tartars were summoned, the Mogul empire was confirmed to him and his successors, together with those kingdoms which he had subdued, and he was solemnly proclaimed emperor. During his inauguration, a prophet is said to have appeared in the assembly with a divine message, declaring that from this time Temujin should assume the name of "Jenghiz Khan, or the most great khan of khans;" and at the same time predicting, that his posterity should be khans from one generation to another. Thus established on the throne, and held in the most profound veneration by his subjects, he projected the extension of his dominions by more conquests. He began with the emperor of Hya, the western part of the empire of Kitay, and in 1209 compelled him to become his tributary: and when, in 1210, an acknowledgment of his being tributary to the emperor of Kitay was demanded of him, he resisted the demand, the consequence of which was a war, that terminated in the dissolution of the Kitay empire. In the year 1216 he resolved to carry his arms westward, and, in his progress, defeated an army of 300,000 Tartars, who had revolted; and in 1218 he deputed ambassadors to express his desire of an alliance with Mohammed Karazm (Charasm) Shah, emperor of Gazna or Ghizni. Although the alliance was concluded, it was soon treacherously violated; and this event occasioned a war, which in 1221 accomplished the conquest of the empire of Ghizni, and thus terminated the dynasty of Charasm. Jenghiz Khan, however, left Hindooftan undisturbed. After the reduction of Charasm, some of the Moguls marched into Iran or Persia, where they made extensive conquests; and others invaded Georgia, and the countries lying west of it, committing in their progress the most atrocious enormities. In 1225 Jenghiz Khan returned to Hya, slew the emperor, and destroyed

stroyed the country. But this was the last exploit of this ambitious and savage conqueror, who died in 1227, as he was marching to complete the destruction of the Chinese. At the death of Jenghiz Khan, the Mogul empire extended over a prodigious tract of country; being, as it has been said, more than 1800 leagues in length from east to west, and upwards of 1000 in breadth from north to south. The successors of Jenghiz Khan, urged by an insatiable ambition, pursued the same plan of conquest; so that Oktay was acknowledged emperor after Jenghiz, and had under his immediate government Mogulestan, or the country of the Moguls properly so called, Kitay, and the countries to the east of the Tartarian sea. His brother Jagatay governed under him a great part of the western conquests. The country of the Kipjacks, and others to the east and north-east, north and north-west, were governed by Batu or Patu, the son of Juji, who had fallen in the wars; while Tuli or Tolay, another son of Jenghiz Khan, had possession of Khorasan, Persia, and that part of India which had been conquered. On the east side the Mogul arms prevailed, and subdued not only the empire of Kitay, but the southern part of China. In the year 1254, Magu, or Menkho, the fourth khan of the Moguls, raised a large army, and gave the command of it to his brother Hulaku, or Hulagu, for the purpose of extending his dominions towards the west. With this army, in 1255, he invaded Iran, suppressing the Ismaelians or Assassins; and two years afterwards he advanced to Bagdad, which he captured. Cruelty and devastation marked the footsteps of the Moguls; fire and sword were the implements of their warfare; and it is said, that in Bagdad, and its vicinity, the number of slain amounted to 1,600,000. In the following year he invaded Syria, took possession of Damascus without resistance on the part of the inhabitants, whose lives were therefore spared; and having captured Aleppo by storm, murdered the inhabitants, without sparing even the children in their cradles. These cities, which in the succeeding year revolted, were again taken by the Moguls and plundered, and the inhabitants were either slaughtered without mercy, or carried into slavery. Hulaku died in 1264; and at the time of his decease we may fix the greatest extent of the Mogul empire. It comprehended the whole of the continent of Asia, excepting part of Hindoostan, Siam, Pegu, Cochinchina, and a few of the countries of Lesser Asia, which the Moguls had not attacked. From this period, however, this vast and overgrown empire began to decline. The ambitious khans failed in their attempts upon Japan and Cochinchina, and also upon Hindoostan; and the empire itself was divided into several smaller partitions. The governors of Persia, being of the family of Jenghiz Khan, owned no allegiance to any superior; those of Tartary pursued the same course; the Chinese threw off the yoke: and thus the continent of Asia assumed, in a great degree, the same aspect which it had before Jenghiz Khan began his conquests. At length, in the year 1369, Timur Bek, or Tamerlane, one of the petty princes of this broken empire, having conquered a number of others, was crowned at Balk, with the pompous title of "Sakeb Karan," *i. e.* the emperor of the age and conqueror of the world. He began his reign with the exercise of various cruelties.

In 1370, Timur crossed the Sihon, made war on the Getes, and attacked Charasm. In 1379 he had fully conquered the country of the Getes, as well as Khorasan; and from that time he pursued his conquests, as Jenghiz Khan had done, though with less cruelty. In 1387, he had reduced Armenia, Georgia, and the whole of Persia; the conquest of which last country was completed by the reduction of Ispa-

han; 70,000 of the inhabitants of which city were slaughtered on account of the sedition of some disaffected persons. After the reduction of Persia, Timur turned his arms northward and westward, subduing all the countries as far as the Euphrates. He took the city of Bagdad; reduced Syria; and having ravaged a great part of Russia, returned in 1396 to Persia, where he made a splendid seat for his whole army. After several irruptions which had been made by the Moguls into Hindoostan, after the death of Jenghiz Khan, Timur, who had already extended his empire over all the western Asia and Tartary, turned his arms towards this country in 1398. In the preceding year he had sent his grandson Peer Mahomed to reduce the Panjab and Moultau, and in October crossed the Indus himself; and joining his grandson near Moultau, his army proceeded in different divisions to Delhi, which submitted without what may be properly termed a battle. The massacres and exterminations that succeeded his taking possession of the city, were executed under his immediate direction; and justly entitled him to the appellation of the "destroying prince." Timur staid in Delhi only 15 days; and then appears to have been on his return to the seat of his empire, when, hearing of a fortress in the Doob that had resisted the arms of a former Mogul invader, he marched towards it and took it. From thence he proceeded to the place where the Ganges issues out of the mountains, and where the Hindoos resort at certain seasons, in vast numbers, to pay their adorations to, and to purify themselves in, that sacred stream. His object was the extermination of these inoffensive people; and he partly succeeded. From this place, turning to the N.W., along the foot of mount Sewalick, he continued his massacres, though not without opposition, until he arrived on the frontiers of Cashmere. He spent little more than five months, between the time of his crossing and recrossing the Indus, and in doing this he paid greater attention to the seasons than Alexander had done. Timur, however, may be said rather to over-run than to conquer or subject; for he did not disturb the order of succession in Hindoostan, but left Mahmood on the throne; referring to himself the possession of the Panjab country only; which his successors did not long retain. His views were at this time directed towards the Turkish empire; and this circumstance induced him to neglect India, which did not promise so plentiful a harvest of glory as the other. During his life, which terminated at Samarcand in the year 1405, he was prayed for in the mosques of Hindoostan, and the coin was struck in his name; but this might be more the effect of policy in the usurpers of Mahmood's throne than the act of Timur. On Timur's death his empire fell into great disorder, and was distracted by civil wars, till at length peace was restored by the settlement of Shah Rukh, Timur's son, on the throne. The empire subject to his dominion was much reduced; Chorasam, Khorasan, Candahar, Persia, and part of Hindoostan being the countries of which it consisted. By him his dominions in this reduced state were transmitted to his son Ulug Beg, well known by his astronomical tables. A succession of princes filled up the interval till the death of Abusaid Mirza, a lineal descendant of Timur. From this time we may consider the empire of Timur as dissolved, though his descendants still reigned in Persia and Hindoostan.

The conquest of Hindoostan was effected by Sultan Baber, a descendant of Timur or Tamerlane, and Jenghiz Khan. This prince reigned over a kingdom composed generally of the provinces situated between the Indus and Samarcand. Being dispossessed of the northern part of his dominions by the Uzbeks, he determined to try his fortune in Hindoostan, whose distracted state under Ibrahim II. in 1516, encouraged his hopes

hopes of conquest. His first expedition from Cabul, where he resided, across the Indus, was undertaken in 1518; this was succeeded by four others; and in the fifth (A.D. 1525), he defeated the emperor of Delhi, and put an end to the dynasty of Lodi. He reigned only five years in Hindoostan, chiefly employing himself in the reduction of the eastern provinces. It was in the person of Baber that the line of Tamerlane first mounted the throne of Hindoostan; and it was in that of Acbar, his grandson, that it was established. The conquest of their ancestor, about a century and a half before, had no share in effecting the present settlement. Baber was, in reality, the founder of the Mogul dynasty; and from this event Hindoostan derived the appellation of the "Mogul empire." The princes of the house of Timur have since their first establishment on the throne eagerly pursued the conquest of the Deccan, not considering that this region, which possessed ample resources within itself, and innumerable advantages in point of security from an enemy without, was also situated at such a distance from the capital, as to hold out to its viceroy the temptation of independence whenever a favourable opportunity offered. Perhaps, says major Rennell, if the Deccan had been originally left to itself, the posterity of Timur might still have swayed the sceptre of Hindoostan. In process of time the Mogul empire became merely nominal; and the emperors were regarded as of no political consequence, otherwise than as their names and persons are made use of by different parties to forward their own views. The Mogul empire attained its full measure of extent under the reign of Aurungzebe, see his article. In this empire many parts of it were 1000 miles distant from the seat of government; and accordingly its history is one continued lesson to sovereigns, not to grasp at too much dominion, and to mankind to circumscribe the undertakings of their rulers. Rennell's *Me. moirs*, *Introd.* See DECCAN, DELHI, and HINDOOSTAN. See also MONGOLIS.

MOGULISTAN, or MOGOLISTAN, the country of the Mogul Tartars. In a larger sense, this term comprehends the whole of Tartary, from the Caspian to the North Atlantic; but, in a more restricted sense, to an extensive tract of country between Bucharia and China, north of Thibet. See *MOGUL Empire* and MONGOLIS.

MOGULMARY, a town of Bengal; 18 miles S. of Burdwan.

MOGULPOUR, a town of Hindoostan, in the circar of Schaurunpour; 36 miles S.S.W. of Schaurunpour.

MOGULPURRAH, a town of Hindoostan, in Bahar; 18 miles N.N.W. of Bahar.

MOGULS. See MONGOLIS.

MOGULSERAI, a town of Hindoostan, in Benares; 10 miles S.E. of Benares.—Also, a town of Hindoostan, in the circar of Sirhind; 15 miles N.N.E. of Sirhind.—Also, a town of Hindoostan, in the country of Agra; 24 miles N.N.W. of Kerowly.

MOGURANI, a town of Walachia; 48 miles N. of Bucharest.

MOGWITZ, a town of Silesia, in the principality of Neisse; 6 miles N.N.E. of Ottmucha.

MOGYESZO, a town of Hungary; 12 miles W. of Tokay.

MOHACS, a town of Hungary, on the Danube; 56 miles W. of Zegedin. N. lat. 46° 2'. E. long. 18° 44'.

MOHADAN, AL, a town of Arabia, in the province of Hedsjas; 80 miles E. of Madian.

MOHADY, a town of Hindoostan, in Berar; 31 miles E.N.E. of Nagpour.

MOHAIR, in *Commerce*, the hair of a kind of goat, frequent about Angora in Turkey; the inhabitants of which city are all employed in the manufacture of camblet made of this hair. See CAMELET and CAPRA *Angorensis*.

Some give the name mohair to the camblets or stuffs made of this hair: of these there are two kinds; the one smooth and plain; the other watered like tabbies: the difference between the two only consists in this, that the latter is calendered, the other not. There are also mohairs both plain and watered, whose wool is of wool, cotton, or thread.

MOHAIR-Shell, in *Natural History*. See MOIRE.

MOHANG-LENG, in *Geography*, a town of the kingdom of Laos, so called by the Chinese; *Mohang*, in the language of the country, signifying town. It is of considerable extent, but only enclosed with a palisade; on the west are large forests and several rivers. This city stands on both sides of a river, called Meinam Tai, which, by the Chinese accounts, joins the river of Siam. Fish is rare, but buffalo and venison are common in the markets.

MOHANOO, a town of Hindoostan, in the circar of Chanderee; 33 miles W. of Chanderee.

MOHASSIL, formerly called "Disferdar," an officer at Aleppo, is reckoned the second person of the city in the civil line, and, on the demise of the bashaw, is by the Divan usually appointed Mutulleem, or temporary governor, till orders come from the Porte. He is farmer-general of the land-tax, the customs, and the capitation tax; on which account he is obliged to retain a number of subordinate officers dispersed in the province, and to perform considerable business. He exercises a limited judicial power in matters of revenue, and has a prison in his own palace. The Mohassil's influence is considerable: he lives splendidly, and is much courted by the agas or land-renters, as well as by the merchants. He is, from his office, one of the members of the Divan, or council.

MOHAUN, a town of Hindoostan, in Oude; 15 miles N. of Lucknow.

MOHAWK BAY, a bay in Fredericksburg, Upper Canada, which lies opposite to Mohawk's settlement, and close to the mouth of the river Apannac.

MOHAWK River, a river of New York, which rises to the northward of Fort Stanwix, about eight miles from Black or Sable river, a water of lake Ontario, and runs southwardly 20 miles to the fort, then eastward 110 miles, and after receiving many tributary streams, falls into Hudson's river, by three mouths, opposite to Lonfinburgh and Troy, from seven to ten miles N. of Albany. This fine river is navigable for boats from Schenectady, nearly or quite to its source; and the opening of this navigation by means of the locks and canals round the Little Falls, completed in 1795, is very advantageous to the commerce of the state. A shore of at least 1000 miles in length is thus washed by boatable waters, exclusive of all the great lakes; and many millions of acres of excellent tillage land, rapidly settling, are accommodated with water communications for conveying their produce to market. The intervals on both sides of this river, of various widths, are some of the richest and best lands in the world; and are distributed into farms, which are occupied and cultivated principally by Dutch people, whose agricultural practice admits of great improvement, as they neglect to employ the manure of their barns in the culture of their land. The banks of this river were formerly thickly settled with Indians; and at the period when Albany was first settled, it is said that at Schenectady there were 800 warriors, and that 300 warriors subsisted within a space now occupied by a single farm. About three miles

from its entrance into the Hudson, the river is about 1000 feet wide; the rock over which it pours, as over a mill-dam, extends from S.W. to N.E. almost in a line from one side of the river to the other, and is about 40 feet in perpendicular height, and including the descent above, the fall is as much as 60 or 70 feet. About a mile below the falls is a handsome bridge; and immediately below the bridge the river divides into three branches, which form several large islands.

MOHAWK, or *Cookquago*, a branch of Delaware river, which, after it mingles with the Popachton branch, is called Delaware.

MOHAWK, formerly a town on the S. side of the river of the same name, in Montgomery county, New York, situated in a very fertile country. It was abandoned by the Mohawk Indians in 1780.

MOHAWKS, an Indian nation, acknowledged by the other tribes of the Six Nations to be the true old heads of the confederacy. They were formerly very powerful, and had their habitation on Mohawk river. As they were strongly attached to the Johnson family, a part of them emigrated to Canada with Sir John Johnson as early as the year 1776. About 300 of this nation now reside in Upper Canada.

MOHAWK Settlement is in the bay of Quinti, Upper Canada, W. of Richmond, and comprehended between the river Shannon and Bowen's creek.

MOHAWK Village, on the Grand river, or Ouse, in Upper Canada, is the principal village of the Six Nations, in the tract purchased from the Mississauga nation, by his present majesty, on account of their loyalty and attachment during the late revolution, in which they lost their possessions on the Mohawk river. This tract is 100 miles long, and 12 wide, intersected by Grand river, from its mouth in lake Erie upwards. The village is beautifully situated, has a neat church with a steeple, a school-house, and a council-house; and not far from it a grist and a saw-mill. These buildings have for the most part been erected by government, which pays a miller, schoolmaster, and blacksmith, for their services at the village; and the society for propagating the gospel makes an allowance to a clergyman of the established church for occasional visits to these tribes. The liturgy of the church of England has been translated into the Mohawk language, and printed for the use of the Six Nation Indians. In 1800, this nation, the Seneca and Oneida pagans, revived their custom of sacrificing white dogs to their gods, which had been neglected for 30 years, under a notion that the neglect of this sacrifice had been one cause of their various misfortunes.

MOHAWKS' Corn, in *Botany*, a name given by the Indians to a peculiar sort of the maize, or Indian corn. It is most frequent in the more northerly parts of America. The general time of sowing the maize in Virginia and other places, is in the end of April; but this mohawk kind need not be sown before June, and yet will come well to maturity before the winter. The stalks of this kind are shorter than those of the common sort. The ears also are shorter and grow nearer the ground, and the corn is generally of various colours. Phil. Transf. N^o 142.

MOHAWK. See *Mock*.

MOHAWRY, in *Geography*, a town of Hindoostan, in the circar of Chanderee; 45 miles W. of Chanderee.

MOHEGAN, a place situated between Norwich and New London, in Connecticut, in America; which is the residence of the remaining few of the Mohegan tribe of Indians. A considerable part of this small number removed lately to Oneida, with the late Mr. Occom.

MOHELNO, a town of Moravia, in the circle of Znaym; 24 miles N. of Znaym.

VOL. XXIII.

MOHERNANDO, a town of Spain, in New Castile; 10 miles N. of Guadalajara.

MOHERRY, a town of Hindoostan, in the circar of Cicacole; 20 miles S.W. of Ganjam.

MOHIGONG, a town of Hindoostan, in the circar of Ruttumpour; 16 miles S.E. of Dumdah.

MOHICCONS, a tribe of Indians, whose habitations lie on a branch of the Susquehannah, between Chagocet and Gwegy. Hutchins, some years ago, reckoned them at 100, but Imlay, in 1773, estimates them only at 70 fighting men. They were formerly a confederate tribe of the Delawares.—Also, an Indian tribe, in the N.W. territory, which inhabits near Sandusky, and between the Scioto and Muskingum: their warriors are reckoned to be 60.

MOHILA, one of the Comora islands, in the Indian sea, between the island of Madagascar and the coast of Africa. It has a good road for ships, and it is said to be fertile. It is governed by a sultan, whose children share his authority in different districts of the island, bear the same appellation, and possess the same insignia of state, though they hold their power in subordination to him. The sultan himself never appears in public, without being attended by 20 of the principal persons of the island, and on such occasion his dress is a long robe of striped calico, hanging from his shoulders to his feet, with a turban on his head. The people are also generally clad in the same manner, and are perpetually chewing the areca, or betle nut, like the Indians of the East, whose manners they greatly resemble. S. lat. 12° 30'. E. long. 43° 50'.

MOHILL, a post-town of the county of Leitrim, Ireland; 78 miles W.N.W. from Dublin.

MOHILNA, a town of Poland, in Volhynia; 44 miles N. of Zytomiers.

MOHILOW, a town of Poland, in the palatinate of Braclaw; 60 miles S.W. of Braclaw.

MOHN, called by the Esthenians "Muhoma," which literally signifies the land of boils or sores, an island of the Baltic, separated from the main land by a strait, called the Great Sound, about two Swedish miles over in its broadest part, and near a mile where it is narrowest; the transport being made in summer by large boats, called Prames. Boats of a similar kind pass between Mohn and Oesfel, across the Little Sound, which bears some resemblance to a spacious haven. Mohn lies to the S.W. of Oesfel, forming a parish of itself, with its own church and preacher. Near the middle of the island, on an eminence, stands the church. Many of the boors live here comfortably; and having a little portion of forest, which, and also their hay fields, are inclosed by a wall of stones. As a shelter from storms, to which these seas are subject, some have their houses built in the midst of these little thickets. Not only acorns and bilberries, but also wild nuts and crab apples grow here, of which last the boors make a tolerably well tasted cyder; and in the farms they use them also for swine-wash. The circumference of the whole island measures about 95 versts. The passage over the Great Sound in summer is made with oars in about four hours, but with a sail and fair wind in less than two. To Mohn belong two small islands; one lying towards the N., and quite uninhabited, is merely a hay-field for the boors of Mohn; the other lies nearly between Oesfel and Mohn in the Little Sound, and is occupied by three boors. On Mohn is a large stagnant lake, from which a canal has been made into the sea. Tooke's Russ. Emp. vol. i.

MOHO, a town of Peru, in the diocese of La Paz; 25 miles S.E. of Afungaro.

MOHR, a town of Germany, in the county of Hoya; five miles W. of Hoya.

MOHRAU, a town of Silesia, in the principality of Neisse, near a river of the same name; 28 miles S. of Neisse.

MOHRIA, in *Botany*, a curious genus of ferns, named by Dr. Swartz after his friend Dr. D. M. H. Mohr, of Kiel, the coadjutor of professor Weber, in several excellent botanical publications, particularly respecting the class *Cryptogamia*. In these he has displayed great knowledge and application, though not without some inaccuracy, and rudeness, rather than acrimony, of criticism. Experience, and a naturally good disposition, would gradually have overcome such defects, while his scientific abilities would have rendered the most extensive services to botany, had not an early death disappointed the hopes of his friends.—Swartz. Syn. Fil. 6. 159.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*. Linn. Juss.

Gen. Ch. *Capsules* sessile, distinct, roundish, depressed, concentrically striated, of one cell, bursting by a longitudinal fissure at one side, without any separate ring, situated near the margin of the frond. *Seeds* numerous, roundish, minute. *Involucrum* from the crenate inflexed margin of the lobes.

Ess. Ch. *Capsules* near the margin of the frond, distinct, sessile, concentrically striated, without a ring, bursting longitudinally. *Involucrum* from the crenate inflexed margin.

1. *M. thurifraga*. Incense-fern. Swartz. Syn. Fil. 159. 385. t. 5. (*Polypodium cafferorum*; Linn. Mant. 307. *Adiantum cafferorum*; 447. *Osmunda marginalis*; Lamarck Dict. v. 4. 655. *O. thurifera*; Swartz in Schrad. Journ. for 1800. 105. *Filicula aethiopica*, denticulatis pinnulis, averfa parte, Asplenii ritu, villosa lanugine tectis, pediculo splendente nigro; Pluk. Mant. 77. t. 150. f. 3.)—Gathered by Koenig at the Cape of Good Hope; by Sonnerat, as well as Commerfon, in the isle of Bourbon. The roots consist of many long, branched, blackish, hairy fibres. *Fronde* in dense tufts, near a span high, bipinnate, densely clothed beneath with imbricated, taper-pointed scales, as are also the stalks in some degree. *Leaflets* of the barren fronds roundish or ovate, sharply pinnatifid; those of the fertile fronds, which are considerably taller, ovate, obtuse, deeply and bluntly lobed, their edges, or terminations of the lobes, inflexed over the capsules, which are each the size of the smallest pin's head, ranged in a simple row, at a little distance from the margin of the leaflet. There are generally two capsules under each segment of the leaflet.

The smell of the recent fern is said to resemble that of incense, or gum benzoin: hence the French in the isle of Bourbon term it *la feuille d'encens*.

We cannot trace the error of Dr. Swartz's citation of Lamarck. His misquotation of Plukenet could not, on account of the confused arrangement of this author's book, be, without great care, avoided; but we trust our correction is right.—This genus differs from *Osmunda* in the structure as well as situation of its capsules, and is unquestionably very distinct from that and all others.

MOHRIN, in *Geography*, a town of Brandenburg, in the New Mark; 20 miles N. of Custrin. N. lat. 52° 54'. E. long. 14° 31'.

MOHRUNGEN, a town of Prussia, in the province of Oberland, situated on a lake of the same name, which almost surrounds it; 55 miles S.S.W. of Königsberg. N. lat. 53° 31'. E. long. 19° 51'.

MOHUN, a town of Hindoostan, in the circle of Kitchwara; 10 miles S. of Budawar.—Also, a town of Hindoostan, in Oude; 16 miles N.E. of Cawnpour.

MOHUNGUR, a town of Hindoostan, in the circle of Gohud; 18 miles S.W. of Narwa.

MOHUR, in *Commerce*, a coin in the East Indies. Gold mohurs, sometimes called gold rupees, are struck at the mint of Calcutta, as well as Sica rupees, called silver rupees; 16 of the latter are, by regulation, to pass for one of the former. The value of the gold mohurs has undergone considerable variations at different periods. At present the weight of the mohur is 13.28 massa, or 190,894 grains, and its fineness $23\frac{2}{3}$ carats, containing 189,462 grains of fine gold; and it is, therefore, worth 1*l.* 13*s.* 6½*d.* sterling. At Madras, the mohurs, or gold rupees of Bengal, occasionally pass for four star pagodas. (See PAGODA.) At Bombay, the gold mohur passes in account for 15 rupees. In 1774 the coin, called the gold mohur, or gold rupee, was ordered to be made of the same weight as the silver rupee, and to be equal in fineness to a Venetian sequin; so that the proportion of gold to silver in the Bombay coins was nearly as 15 to 1. Afterwards this proportion ceased; and gold, coined according to the regulation of 1774, exchanged for only 13 times its weight of silver. Accordingly, in order to remedy this, it was settled in 1800, that the mohur should be of the same weight and fineness as the silver rupee; and that it should pass for 15 such rupees.

The following TABLE shews the Assay, Weight, Contents, and Value of the East Indian Mohurs.

	Assay.		Weight.			Contents in pure Gold.	Value in Sterling.		
	car.	gr.	oz.	dwt.	gr.		Grains.	£	s.
Mohur, or gold rupee of Shah Allum, 1770	1	2½	0	7	22¼	186.8	1	13	0¾
Mohur of the same, 1787	1	2¾	0	7	23	188.5	1	13	4½
Half mohur of the same, 1787	1	2½	0	3	23½	94.	0	16	7½
Quarter mohur of the same, 1787	1	2½	0	1	23¾	47.	0	8	3¾
Sicca gold mohur of Bengal, dated 19th June, 1789	1	3½	0	7	23	189.7	1	13	7.
Old Bombay mohur still in circulation	0	3½	0	7	10½	170.	1	10	1
Surat mohur, of the latest coinage	0	0½	0	7	11	165.	1	9	2½
Tippoo's gold rupee	1	2	0	8	20½	181.5	1	12	1¾
Mohur, of the Dutch E. I. Company, 1783	3	3¼	0	10	2	181.5	1	12	1¾
Ditto	4	1	0	9	20	174.5	1	10	10½
Half ditto	3	1¼	0	5	3½	90.2	0	17	0¾

MOHURBUNGE, a province of Hindoostan, S.W. of Bengal.

MOIYLNA, a town of Lithuania, in the palatinate of Minsk; 36 miles S.W. of Minsk.

MOLA, a town of Naples, in Principato Citra; 18 miles S.S.W. of Cangiuro.

MOJABRA, a town of Africa, in Tripoli; 10 miles E. of Augela.

MOJAN, an island in the Baltic, belonging to Sweden. N. lat. 39° 22'. E. long. 18° 45'.

MOJARA, a town of South America, in the province of Tucuman; 18 miles N. of St. Salvador de Jugui.

MOIDENA, a town of Bengal; 20 miles S. of Kishnagar.

MOIDORE, MOEDA, or *Lisbonnia*, in *Commerce*, an old gold coin, struck and formerly current in Portugal.

The moidore and its divisions are reckoned by the *rees*, which see.

The gold pieces coined in Portugal before the year 1722, are now, on account of the signorage and the rise in the price of gold, 20 *per cent.* higher than their original value: thus, the old *dobras*, coined at 20,000 *rees*, are worth 24,000: the *Lisbonnines* or *moidores*, coined at 4000 *rees*, are worth 4800; and the halves and quarters in proportion; but few of these coins are now in circulation. The gold coins struck since 1722, are the *dobra*, of 12,800 *rees*; the *meia dobra*, *Joaneſe*, or Portugal piece, of 6400 *rees*; the half *Joaneſe* of 3200; the *dezeſeis teitooos*, of 1600; the *quartinho*, of 1200; the *oito teitooos*, of 800; the old *crufado*, of 400, now very scarce, and the new *crufado*, of 480 *rees*.

The Assay, &c. of Portugal Coins, will appear in the following TABLE.

	Assay.		Weight.		Contents in pure Gold.	Value in Sterling.			
	car.	gr.	oz.	dat. gr.		Grains.	£	s.	d.
Dobraon of 24000 rees - - - -	Standard		1	14	12	759.	6	15	0

Milrea, coined for the African colonies, 1755	Standard		0	0	19 ¹ / ₂	18.1	0	3	2 ¹ / ₂

The impressions on the gold coins of Portugal are as follows:

The *dobraon*: arms of Portugal, with 20,000 on one side, and five flowers on the other: legend, JOANNES V. D. G. PORT. ET ALG. REX. (John V. by the grace of God king of Portugal and Algarves): reverse a cross, with four M's in the four angles; legend, IN HOC SIGNO VINCES, (by this sign thou shalt conquer). The half *dobraon* bears the same impressions, except that it is marked 10,000.

The *moidore* bears the same impressions as the *dobraon*, except that it is marked 4000, and has four B's in the four angles of the cross; but some of an ancient date bear on the reverse a cross, surrounded by four connected semi-circles, and a whole circle, with the legend ET BRASILIÆ DOMINUS ANNO, &c. (and lord of Brazil, in the year, &c.) The half and quarter *moidores* are marked 2000 and 1000; their impressions are in other respects the same as on the *moidore*.

The *Joaneſe*: head of the reigning sovereign, with name and titles; thus JOANNES V. D. G. PORT. ET ALG. REX; or MARIA I. D. G. PORT. ET ALG. REGINA, (Mary I. queen of Portugal and Algarves); and the pieces coined by the prince regent, since 1804, bear his head, with JOANNES B. G. PORT. ET ALG. P. REGENS (John, prince regent, &c.): reverse, arms of Portugal. The *dobra* or double *Joaneſe*, the half, quarter, and eighth *Joaneſe*, all bear the same impressions.

The *quartinho*: arms of Portugal, with 100, and the

legend, MARIA, D. G. &c.: reverse, a cross, with four flowers, and the legend IN HOC SIGNO VINCES, as before.

The old *crufade*: head of the reigning king; reverse, a crown; legend, JOAN, V. D. G. P. REX, as before.

The new *crufade*: name of the reigning sovereign, over it a crown; and under the name two palms, with 400 at the bottom; reverse the cross and legend, as in the *quartinho*.

The *milrea*: coined for the African colonies,—arms of Portugal, with 1000 on the side, and the name and title as above: reverse, a cross and circles as in the old *moidores*; legend, ET DOMINUS AF. OR. ANNO, &c. that is, "Dominus Africae orientalis" (lord of eastern Africa). Kelly's Un. Cambist.

MOIETY, MEDIETAS, the half of any thing.

MOIGOLSCHAR, in *Geography*, a cape of Russia, on the N.W. coast of Nova Zembla. N. lat. 72° 40'. E. long. 52° 14'.

MOIKA, a river of Russia, which runs from the right of the Fontanka, not far below its departure from the Neva, and runs almost parallel with it, into which it falls to the left of the Great Neva, close above its mouth.

MOILON, is a name given by the French to a kind of stone, that forms the upper crust, and lies round the free stone in most quarries. It is an excellent substance for forming the body of fluxes or soft enamel.

MOIMENTA DE BEIRA, in *Geography*, a town of Portugal, in the province of Beira; 13 miles S.W. of Castel Rodrigo.

MOINE, PETER LE, in *Biography*, was born at Chaumont, in Bassigny, in 1602. He entered into the society of the Jesuits at seventeen, and continued to serve it by his labours and writings till his death, at Paris, in 1671. The principal work for which he is famous as a poet, is "Saint Louis, ou la Couronne reconquise sur les Infidelles," in eighteen books, which, for a time, stood high among the epic poems in the French language. It is said to display a vigorous imagination, and considerable powers of poetical expression. Boileau, being called upon for an opinion of Le Moine, said, "he had too much extravagance for his praise, and too much poetry for his censure." He was a considerable writer in prose, in which his style and manner resemble those of verse. His "Peintures Morales;" "Traité de l'Histoire;" "La Galerie des Femmes fortes," have a considerable merit. Moreri.

MOINE, STEPHEN LE, a very learned French Protestant divine in the 17th century, was born at Caen, in Normandy, in the year 1624. Having laid in a good stock of elementary learning at his native place, he was sent to Sedan, where he went through a course of divinity under the celebrated Du Moulin. From thence he went to Leyden to study the Oriental languages. Upon his return to France in 1650, he was appointed pastor to the church of Gefosse. He afterwards removed to Rouen, where his zeal in maintaining Protestant principles exposed him to the persecution of the Catholics. In 1676 he left France, came over to England, and was honoured with the degree of doctor by the university of Oxford. From hence he passed over to Holland, and obtained the professorship of divinity at Leyden, which he occupied with much reputation during the rest of his life. In the year 1685, he published a collection of curious Greek treatises, relating to ecclesiastical history, preceded by long *prolegomena*; it was entitled "Varia Sacra, seu Sylloge variorum Opusculorum Græcorum ad rem ecclesiasticam spectantium." He was author of many other curious and learned works. He died in 1689, in the 65th year of his age. Moreri.

MOINE, JOHN LE, a French cardinal, who flourished in the 13th and 14th centuries, and founded a college at Paris called after his name, was a native of Cressy, in Ponthieu. He was educated at the university of Paris, where he studied divinity and the canon law, and was admitted to the degree of doctor. After various promotions in the church, he was raised to the purple, either by pope Celestine, or by Boniface VIII. By the last mentioned pontiff he was held in high esteem, and appointed his legate in France, at the time of his contest with Philip the Fair. In this business the cardinal was ready to sacrifice the interests of the sovereign and of his country, that he might gratify the ambition of the court of Rome. He died at Avignon, in 1313. He was author of "A Commentary on the sixth Book of the Decretals," which is said to display the knowledge and abilities of an able and profound canonist. It was printed at Paris in 1536, and at Venice in 1586. Moreri.

MOINE, ABRAHAM LE, a French Protestant divine, who was born towards the close of the 17th century, and became a refugee in England on account of his religion. He officiated as minister to a French church at London, and died in the year 1760. He is known chiefly by "A Treatise on Miracles," which was written in answer to Chubb, and which, on many accounts, was thought well of by the late learned Mr. Hugh Farmer. Subjoined to the treatise on miracles is a postscript, intended to vindicate the authority of the ancient fathers, in answer to what had been advanced by Dr. Middleton in his "Free Enquiry." Le Moine published also "A Sermon in Defence of Sacred History,

in Answer to Lord Bolingbroke," and some other sermons. He also translated into the French language bishop Gibbon's "Pastoral Letters;" "The Trial of the Witnesses of the Resurrection of Jesus;" and "Discourses on the Use and Intent of Prophecy," by bishop Sherlock. These translations are accompanied with curious and interesting dissertations, by the translator. Gen. Biog.

MOINE, in *Geography*, a river of Louisiana, which runs from the N.W. into the Mississippi, in N. lat. 40° 5'. W. long. 91° 54'.

MOINE, La, a bay on the S. coast of Newfoundland; 25 miles E. of Cape Ray.

MOINEAU, in *Fortification*, is a flat bastion, raised before a curtain when it is too long, and the bastions of the angles too remote to be able to defend one another.

Sometimes the moineau is joined to the curtain, and sometimes it is divided from it by a moat. Here musqueteers are placed, to fire each way.

MOINHO DIEGO, in *Geography*, a town of Portugal, in Estramadura; 30 miles N.E. of Lisbon.

MOJOS, a town of South America, and capital of a province, in the viceroyalty of Buenos Ayres; 14 miles N. of St. Salvador de Jujui.

MOIRA, a post-town of the county of Down, Ireland, chiefly inhabited by persons concerned in the linen manufacture, for which the neighbouring country is peculiarly favourable. White lime-stone is abundant in the neighbourhood. Moira gives the title of earl to the Rawdon family. It is 69 miles N. from Dublin.

MOIRA'S Strait, an inlet on the E. coast of the Prince of Wales's Archipelago, in the duke of Clarence's strait. N. lat. of the entrance 54° 58'. E. long. 228° 22'.

MOIRANS, a town of France, in the department of the Jura, and chief place of a canton, in the district of St. Claude. The place contains 1190, and the canton 6855 inhabitants, on a territory of 195 kilometres, in 30 communes.

MOIRE, in *Conchology*, the mohair shell, a name given by the French virtuosi to a peculiar species of *voluta*, which seems of a closely and finely reticulated texture; and resembles on the surface a piece of mohair, or a very close silk-worm's web.

MOISDON LA RIVIERE, in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Chateau-Briant; six miles S. of it. The place contains 1505, and the canton 4958 inhabitants, on a territory of 257½ kilometres, in 5 communes.

MOISIE, a river of Lower Canada, on the N. shore of the St. Lawrence, a little E. of the Seven Islands: it runs into the latter river in N. lat 50° 15'. W. long. 65° 40'.

MOISSAC, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban, situated on the Tarn, near its confluence with the Garonne; 13 miles N.W. of Montauban. The place contains 10,035, and the canton 14,008 inhabitants, on a territory of 162½ kilometres, in six communes. N. lat. 44° 6'. E. long. 1° 10'.

MOISTURE. See HUMIDITY and HYGROMETRY.

The instrument used for determining the degree of moisture in the air is called an hygrometer. Under the article HYGROMETRY, we forgot to introduce an account of a new hygrometer, with which the editor was some years ago favoured by Mr. Coventry, of Southwark, the construction of which is as follows: take two sheets of fine tissue paper, such as is used by hatters and watch makers, and sometimes called lawn-paper, each sheet of which generally weighs about twenty-seven grains. Let the moisture be thoroughly evaporated

evaporated by the fire, without scorching the paper; till after repeated trials it is brought to its driest state: in this state cut each sheet till it weighs exactly twenty-five grains. These sheets, thus prepared, should be kept in a box or drawer, with a quantity of the same paper designed for use; and they will always serve for determining the proper weight of any quantity of paper for other hygrometers. This paper hung in any place, and kept free from dust, and weighed with a nice pair of scales, will serve to exhibit the moisture of the air, by its increase of weight above fifty grains. But to avoid the trouble of weighing, Mr. Coventry prepared an hygrometer of it in the following manner. A (Plate XIV., *Hydraulics*, fig. 2.) represents a pillar supporting the beam B B, to one end of which are suspended fifty grains of paper D, cut round, and threaded on a silk string, with a small glass head between the sheets, for the freer admission of the air: at the other end of the beam is a brass weight E, to counter-balance the weight of the paper and its appendages. At the bottom there is an ivory scale F F, of twelve prime divisions, answering to twelve grains of moisture: each prime division is subdivided into ten parts, making in the whole 120 divisions: on the index C is a sliding weight G, which, with the weight E on the beam, serves to adjust the instrument; so that twelve grains shall make the index just traverse the scale of the twelve divisions. If the air was so dry as to leave no moisture in the paper, the index would then point to 0: if it contained six grains of moisture, the index would point to sixty; if twelve grains were in the paper, it would point to the moist extreme, one hundred and twenty: but the air has never yet been observed so moist, as to make the index point to the moist extreme, nor so dry as to allow its reaching to the driest extreme, even in the hottest part of summer, by nearly twenty divisions: whence it is inferred that there is in the air a greater quantity of moisture in hot weather than is generally imagined. H is an adjusting screw for fixing the stand upright by means of the point of a plummet that hangs behind. This hygrometer, adjusted, may be made to correspond with another, ascertained to the same weight at any distance: by which we might determine the exact difference of the state of the air, with respect to moisture, in inland, and places near the sea-side. The advantages of this hygrometer are the following: as it is made of the thinnest substance that can be procured, it is the soonest affected with dryness or moisture, and exhibits immediately the first change of the weather: it is not acted upon by heat or cold, or any other cause, as most other instruments of this kind are; it has one datum from which to reckon, *viz.* the dry extreme, whence all other degrees of moisture may be nicely estimated. All hygrometers of this sort will act nearly alike, as thermometers or barometers; and may be reduced to a regular standard. Mr. Coventry found by this hygrometer, that in clear frosty weather, the air contains a very considerable degree of moisture: for on Jan. 27, 1776, in the morning, being a very hard frost, the thermometer in the house 24°, and in the open air 17°, the hygrometer stood at ten grains, *i. e.* at the division 100: and on the next morning, when a thaw came on, it stood at 96; which shews that there is as much moisture in the air during the frost, as when we perceive it dissolved in a thaw. He adds, that it is pleasing to observe the constant motion of this hygrometer: for even in constant settled weather, it is always in motion, from moist towards dry, from about eight in the morning till about four in the afternoon: and from dry to moist, from about 4 P.M. to about 8 A.M. In hot gloomy weather, the hygrometer is mostly found to advance with speed towards moist, and shews that the air at such times retains a great

quantity of moisture: and this always forebodes heavy showers. For curious experiments some of these hygrometers are made to traverse the whole scale of division for every grain of moisture that is imbibed by the papers.

MOISTURE, *Radical*. See RADICAL.

MOITTORET, DE BLAINVILLE, ANTHONY, in *Biography*, a French architect and geometrician, was born at a village four leagues from Dijon, in the year 1650. His genius led him to the study of geometry and architecture, in which he became an expert proficient, and settled in business at Rouen. Here he acquired considerable reputation by his skill as an artist, and by his useful and popular elementary writings. He was appointed surveyor and gauger-royal of Rouen, under which office the public breweries of that city were included by a commission from the king. He died at Rouen in 1710, when he was about sixty years of age: he was author of "A Treatise on Gauging, with Instructions for measuring Mason's Work, &c." which went through several editions during the author's life, and after his death it was republished with improvements at Rouen, in 1714, under the care of M. Hacquet, with the title of "Blainville's New Elements of Geometry." He also published "A Treatise on the extensive Commerce of France, for the Information of Tradefmen," which was reprinted after his death, in 1728, with considerable additions, in two volumes: he is author, likewise, of abridgments "On the Art of Levelling;" "On Spherics," &c. which were favourably received by the public, and became very popular.

MOIVRE, ABRAHAM DE. See DE MOIVRE.

MOKA, in *Geography*, a town of Hindoostan, in Golconda; 28 miles S. of Adoni.

MOKAMO, a town of Hindoostan, in Bahar; 40 miles N.E. of Rangur.

MOKATTAM, a mountain of Egypt, near Cairo; which see.

MOKEIA IBN AMER, a town of Arabia, in the province of Yemen; 22 miles N.N.E. of Chamir.

MOKERAMPOUR, a town of Bengal, 12 miles from Midnapour.

MOKESSET, a town of the Arabian Irak, on the Tigris; 116 miles N.W. of Bassora.

MOKEYA, a name given by the Arabs to those coffee-houses which stand in the open country, and are intended, like our inns, for the accommodation of travellers. They are mere huts, and are scarcely furnished with a "ferir," or long leat of straw ropes; nor do they afford any refreshment but "kischer," a hot infusion of coffee-beans. This drink is served out in coarse earthen cups; but persons of distinction always carry porcelain cups in their baggage. Fresh water is distributed *gratis*. The master of the coffee-house lives commonly in some neighbouring village, whence he comes every day to wait for passengers. We may here observe that a "mansale" is a house in which travellers are received and entertained *gratis*, if they content themselves with such treatment as is usual in the country; they are all lodged in a common apartment, which is furnished with a "ferir," and are served with "kischer," hot millet bread, camels' milk, and butter. Niebuhr.

MOKLAFF, in *Geography*, a town of Arabia, in the province of Yemen, the residence of a sbeick; 30 miles S.E. of Loheia.

MOKLIA, or MUCHLI, a town of European Turkey, in the Morea; 16 miles S.S.W. of Argos.

MOKNAN, or MOHANAN, a town of Egypt, on the W. side of the Nile, near which, according to Dr. Pocock and M. d'Anville, was the site of the ancient Memphis; 5 miles S. of Gizeh. See MEMPHIS.

MOKO,

MOKO, a town and district of Africa, in the country of Calabar.

MOKOKF, in *Botany*, Kämpf. Amœn. 873. t. 774, a Japanese tree, with very fragrant but short-lived blossoms, the *Cleyera japonica* of Thunb. Jap. 224. This proves of the same genus with the Linnæan *Ternstroemia*, and the *Taoniabo* of Aublet. (See *TERNSTROEMIA*.) Some discordance between the descriptions of Kämpfer and Thunberg, which puzzled Jussieu, arose from a degree of inaccuracy in Thunberg's description of the corolla, which is really monopetalous, like that of *Camellia*.

MOKOMOE, in *Geography*, a town of Bengal; 37 miles N.E. of Ramgur.

MOKONTPOUR, a town of Hindoostan, in Oude; 14 miles S. of Canouge.

MOKRETZ, a town of European Turkey, in Bulgaria; 44 miles S.S.E. of Viddin.

MOKSCHAK, a town of Russia, in the government of Penza, near the source of the river Mokschia; 36 miles W.N.W. of Penza. N. lat. 58° 40'. E. long. 44° 50'.

MOKUI, a town of Mingrelia; 20 miles N.E. of Isgaur.

MOL, Fr. an epithet which Aristoxenus and Ptolemy give to a kind of diatonic genus, and a species of the chromatic. See *GENUS*.

For modern music the word *mol* is only used in compositions where B♭ occurs, or B*mol*, in opposition to B*quarre*, or B*quadro*, which formerly was called B*dur*, or B*durum*. Zarlino, however, calls the diatonic mol a kind of diatonic genus. See *DIATONIC*.

MOLA, PIETRO FRANCESCO, in *Biography*, was a celebrated painter, born at Lugano in 1609. He was a disciple of Cesari d'Arpino, but did not follow the principles of that master long, having too good a taste not to improve by an abode which he enjoyed for some time at Venice, where he carefully studied the works of Titian. Mola possessed considerable skill in historical painting; but his forte lay in landscape; the heroic style of which he fought from Titian; but, like him, he often weakened the interest of his pictures by the introduction of figures upon so considerable a scale as to excite a doubt which is principal, the actors or the scene. His peculiar excellence lay in the richness of his colour and the freedom and fulness of his touch; together with the grandeur of composition which he exhibited in his landscapes, frequently not unworthy of Titian himself. There is a picture by him in the gallery of the Louvre in Paris, which for sublimity almost vies with the St. Peter Martyr; and for colour, is quite equal to it. The subject of this picture is St. Bruno's Vision in the Desert.

The genuine pictures of this master are rarely to be met with in this country, though there is plenty of those which bear his name, and perhaps were executed by his brother Giovanni Battista Mola; whose works bear more resemblance to Albani than those of Francesco. He died in 1665, at the age of 56.

MOLA, or *Mola di Gæta*, in *Geography*, a town of Naples, in the province of Lavora, situated near the sea. It has a custom-house and a garrison, which is relieved every week from Gæta. It was anciently a Roman colony, but after the defeat of the Samnites it became a prefecture, and thus continued till it was ranked among the military colonies of Italy by the triumvirs Octavius, Antonius, and Lepidus. Under the emperors it became considerable; but it was at length ransacked and destroyed by the Saracens in 956, and its bishopric transferred to Gæta. It is situated on the ancient Appian way; and it was from this place that Cicero endeavoured to make his escape into Greece. (See *CICERO*.)

The city of Formiæ stood on or near this spot. Between Mola and Gæta the road is rendered agreeable by the number of orange-trees which are planted in the adjoining fields; three miles N.E. of Gæta. N. lat. 41° 18'. E. long. 13° 29'.

MOLA di Bari, a town of Naples, in the province of Bari, on the coast of the Adriatic; 20 miles E. of Bari.

MOLA, in *Physiology*. See *MOLE*.

MOLA, in *Ichthyology*, a species of *Tetrodon*; which see. — Also, a species of *Diodon*; which see.

MOLA, in *Anatomy*, a bone of the knee, called also *patella*, *rotula*, &c.

MOLANAGUR, in *Geography*, a town of Hindoostan, in Bahar; 21 miles E.S.E. of Saferam. N. lat. 24° 50'. E. long. 84° 32'.

MOLANDS, a town of Norway; 12 miles N.N.E. of Christiansand.

MOLANUS, JOHN, in *Biography*, was born at Lisse, in Flanders, in the year 1533. As his parents were originally of Louvain, whither they returned with him while he was very young, and also on account of his having spent the greatest part of his life in this city, the surname of *Louvainensis* is generally given to him. He was educated at Louvain, where, having sedulously applied himself to the study of divinity, he was admitted in the year 1570 to the degree of doctor of divinity, and for some years filled the chair of professor of that faculty with great reputation. He was nominated censor of books by the pope and the king of Spain, as well as canon of the church of St. Peter at Louvain. He died in 1585, at the age of fifty-two. He was author of a great number of works which were in high estimation at the time when they were written, but are now scarcely ever enquired for. He was concerned, with other members of the university, in publishing the Antwerp edition of the works of St. Augustine in the year 1577, and the notes at the end of the Latin bible of the divines of Louvain, published also at Antwerp in 1580. Moreri.

MOLANUS, GERARD-WALTER, a Lutheran divine and professor in the seventeenth and eighteenth centuries, was born at Hamelen, in the duchy of Brunswick-Lüneberg, in the year 1633. In 1660, he was elected professor of mathematics, and in 1672 he became professor of divinity in the *Gymnasium* of Rintelen, in the duchy of Schaumburg. He obtained other instances of preferment, and took precedence in the states of Calenberg, and was president of the consistory of Hanover. He died in 1722, at the age of eighty-nine. He had collected a valuable cabinet of medals, and an excellent library, of which he made a good use. As an author his most important work was published first in the German language, in the year 1697, and afterwards repeatedly reprinted in Latin, under the title of "*Lipfanographia, seu Thesaurus Reliquiarum Electoralis Brunsvico-Luneburgicus*." He was author also of "*Epistola ad Dominum Joachimum Meyerum quâ exponit cogitationes suas de numero aureo Posthumi ab eo edito. &c.*" Moreri.

MOLAPARA, in *Geography*, a town of Bengal; 30 miles W. of Dacca.

MOLARES, in *Anatomy*, the grinding teeth. In the old arrangement, the five posterior teeth on each side of the jaw are so called. At present the two front and smaller of these are called bicuspides, and the term molares is applied exclusively to the three posterior ones. See the description of the teeth in the article *CRANIUM*.

MOLARIS Glandula, one of the mucous glands of the mouth, placed near the back grinding teeth.

MOLARES, in the *Natural History of the Ancients*, the name for

for the compound mineral bodies we now call pyrites, and marcasites.

MOLASSES. See **MOLASSES.**

MOLBEITZKOL, in *Geography*, a town of Russia, in the government of Novgorod; 24 mile S.E. of Tichvin.

MOLCHINA, a town of Russia, in the government of Tobolsk; 60 miles S.E. of Narim.

MOLCZAR, a town of Lithuania, in the palatinate of Novogrodek; 16 miles S. of Novogrodek.

MOLD, or **MOULD,** a market-town in the hundred of Mold, Flintshire, North Wales, is pleasantly situated in a small but fertile plain, surrounded by lofty and rugged hills. It consists chiefly of one long and very spacious street, and, according to the parliamentary returns of 1801, contains a population of 4235 persons. The market is held on Saturday every week, and there are four fairs during the year. The assizes for the county of Flint are holden in this town. On the north side of it rises a large mount called Bally-hill, said to be partly natural and partly artificial, the summit of which was formerly crowned by a Norman castle, probably erected by Eulace de Cruer in the reign of William Rufus. This fortress seems to have been a place of great strength, as the sides of the mount are not only very arduous of ascent, but are defended by a deep foss and ramparts. History records that it stood several sieges without being compelled to surrender, till at last it was stormed by the Welsh forces under the command of prince Owen Gwynedd, in the time of Henry I. Subsequent to this period it suffered many vicissitudes, and was completely demolished during the desperate contests maintained against England by the celebrated Owen Glyndwr. Wynne, in his History of Wales, informs us, however, that it was soon rebuilt, and thereafter once more levelled with the ground by Griffith a Gwynwyn, about the year 1267, since which time it does not appear to have been restored. The view from the scite of this castle, though circumscribed, is extremely beautiful. The church here is a very handsome edifice in the pointed style, consisting of a nave and two side aisles, with a tower at the west end. In the interior are several monuments. The living is a vicarage in the patronage of the bishop of St. Asaph. A considerable cotton-thread manufactory is carried on here. The vicinity of Mold is decorated by several mansions, some of ancient and some of modern erection, the seats of independent gentlemen, who generally reside on their estates. Of these the most conspicuous are Leeswood, Tower, Rhual, and Nerquis-hall. Immediately adjoining to Rhual is Maes-y-Garmon, or the field of Germanus, so called from its having been the scene of a most decisive victory achieved by the British Christians under the missionary bishops, Germanus and Lupus, over the Pagan Picts and Scots, in the year 448. A pyramidal stone, erected on the spot in 1736, by Nathaniel Griffith, the then proprietor of Rhual, bears a Latin inscription commemorative of the event. The hills which inclose the vale in which Mold is situated abound with rich lead mines some of which are wrought with signal advantage both to the proprietors and contractors. On Moel-y-Famma, the highest point of these hills, a monument has been lately erected by subscription, as a memorial of the event of our most gracious sovereign having reigned for the unusual period of fifty years. Beauties of England and Wales, vol. xvii. from Wynne's History of Wales.

MOLD. See **MOULD.**

MOLDAU, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 21 miles N.W. of Leitmeritz.

MOLDAVIA, a province of European Turkey, bounded N. and N.E. by Poland, from which it is separated by the

Dniester, E. by Bessarabia, S. by Walachia, and W. by Transylvania; situated at about 190 miles in its greatest length from N. to S., and somewhat less in breadth from E. to W. It is crossed from N. to S. by the river Pruth. Some lands in this province are very fertile, but a considerable part of the eastern division consists chiefly of deserts, and is uncultivated; and on the western side it is very mountainous. The Pruth and the Siret are its principal rivers. Its inhabitants are of Walachian extraction, and their religious profession is that of the Greek church; but they are intermixed by Mahometans, Russians, Poles, Rascians, and Armenians. About the close of the twelfth century a colony of Walachians from Transylvania settled in this country. They migrated under the conduct of a person named Bogdan, who established their government both civil and ecclesiastical; and who obtained, with a view to the latter, an archbishop and other ecclesiastics from the patriarch of Constantinople. As he was the first prince, and founded the chief towns, the country was denominated Bogdania. The prince or waywode of this province is styled hospodar, and is the vassal of the Ottoman Porte, to whom he pays a yearly tribute. Moldavia is divided into Upper and Lower. Upper Moldavia extends almost to Jassy, and its boundaries are the river Dneister on the E., on the N. that river and Poland, and on the W. Transylvania. Moldavia on the W. borders on the mountains of Transylvania; its southern boundary is the Danube; Bessarabia bounds it on the S.E., and on the E. it is bounded by the Dneister. Its capital is Jassy.

MOLDAVICA, in *Botany*, Tourn. Inst. 184. t. 85: Moldavian Balm. (See **DRACOCEPHALUM.**) Tournefort associates with it also the *Dracocephalum canariense* of Linnaeus.

MOLDAVITZA, in *Geography*, a town of European Turkey, in Moldavia; 40 miles W. of Suezava.

MOLE, THOMAS, in *Biography*, a learned English Protestant dissenting minister, of whom little is known but from his works. He is supposed to have received his academical education under Mr. Jones of Tewkesbury, by whom bishop Butler, and archbishop Secker, were also inducted into the knowledge of the sciences and theology. He was probably first settled as minister at Uxbridge, in Middlesex, in 1725, from which place he removed in 1728 to Rotherhithe; and about the year 1743, he quitted Rotherhithe for Hackney, where he lived some years, and then returned to Uxbridge, or its neighbourhood, to spend the remainder of his life. The latter part of his days he employed in writing, in the Latin language, a life of the celebrated Laurentius Valla, including the religious and literary history of his time: The MS. of this work was sold at a common auction with his other books, and has probably been long since consumed as waste paper. Mr. Mole died near Uxbridge about the year 1780, at a very advanced age. He was the author of several single sermons and tracts, that do much credit to his talents as a writer and controversialist. Dr. Kippis ranks him, in point of learning, with Lardner, Benfon, and Chandler; and Dr. Lardner has shewn his respect for Mr. Mole's critical skill, by incorporating with his own some very ingenious observations that he received from him, on the case of the demoniac who resided among the tombs on the coast of Gadara. Gen. Biog.

MOLE, in *Agriculture*, is a small well known subterraneous animal, which often does great mischief in the fields, by loosening the earth, raising hills, and destroying the roots of corn, grass, and other productions of the vegetable kind.

In respect to the natural history of the mole, as connected with

with the art of husbandry, it has been observed by M. Aurnagnac, that it lives under ground. Its health is liable to be injured by too free access of the air: yet that it sometimes leaves one subterraneous habitation and passes on the surface in search of a better. It lives on the roots of plants, on insects, and on worms. Hence it is commonly found in lands of soft fertile soil. It never fixes its abode in miry, nor in gravelly grounds. If surprised in its subterraneous recesses by water, it springs in great haste to the surface. And that in winter, and during rain, it betakes itself to the upper grounds, which are the least humid, and the least liable to be inundated. But in spring, the mole comes down from its winter residence to the meadows, where it finds a soft mould capable of being easily penetrated, and containing plenty of roots. And after suffering long drought, it flies to ditches, to the brink of the first stream, or to shelter under hedges. In the months of February, March, April, and May, the female produces its young; bringing commonly four or five at a birth. These animals prepare beforehand, for this occasion, an arched recess under ground in a situation somewhat elevated, and generally under cover of a bush or hedge. To the number of four or five mole-hills may be observed very near to the upper side of this recess. It cannot live without being at work. Being obliged to search under ground for its food, it forms there long tunnels or subterraneous passages, named in French *boyaux*. These tunnels are usually parallel to the surface of the earth, and vary in depth according to the changes of seasons, from four to six inches. And as the moles are almost equally afraid of cold and of heat, they make their passages the deepest, and work at the greatest distance under the surface, in summer and in winter. They are extremely timid when they perceive themselves to be in danger. They then penetrate by a perpendicular opening, to the depth of a foot and a half below the level of their ordinary residence. And in forming their passages they throw back the mould, which they remove towards the surface. It is thus the mole-hills are raised. Upon every new change of place a mole raises three, four, six, or even nine of these hills, according to its age. Consequently, all the mole-hills formed by any one mole, communicate by subterraneous passages with one another. When with any instrument, a tunnel or passage, recently formed by a mole is opened, the mole will, in a few minutes, come to close up the aperture, in order to secure herself from danger, and from the access of the external air. It constructs, for this purpose, over the aperture, an arch of loose mould, having, externally, the appearance of an oblong mole-hill, and mending up the tunnel much in the same manner in which a plumber might mend a leaden pipe, by clumsily applying, on the outside, a piece of lead to cover any hole in it. And should this new mole-hill likewise be broken down, the mole will again return to repair it. These two capital facts constitute the fundamental principles of the art of the mole-catcher. The mole works in all seasons; because it cannot otherwise have subsistence. That it sleeps, as some naturalists have affirmed, all winter, is not true. It is, however, languid in this season; working now much less than in summer. It is about the beginning of spring, that the mole sets to work with the greatest activity, and raises the greatest number of mole-hills. It is then obliged to find food for its young; as spring is its season for parturition. The ground is now more easily wrought than at other times. The animal, too, in itself becomes more vigorous, by the diminution of the cold, and the return of the genial temperature of spring. These are the causes of its increased activity in toil. The male is much stronger than the female, and raises a greater number

of mole-hills, and those larger. The female works less than the male, throws up fewer mole-hills, and those smaller. And the young moles form only long covered ways at the surface; the mould raised over which is scarcely sufficient to hide them. When they begin to make mole-hills, these are small, without any regular shape, and arranged zig-zag. The hours of working, for moles, are at sun-rise, at the hour of nine in the morning, at noon, at three in the afternoon, and at sun-set. But it is at sun-rise, and at sun-setting, that they ply their work with the greatest briskness. And in times of drought, they do not throw up mole-hills, except at sun-setting. In winter their moments of working are when the earth is somewhat heated by gleams of sun-shine. The sense of seeing is exceedingly obtuse in the moles; but its hearing is exquisitely delicate and acute.

MOLE-Catcher, a term applied to a person whose business is principally the catching and destruction of moles. See *MOLE*.

MOLE-Catching, the art of catching and clearing land of moles. It is stated in regard to the principles of destroying these animals, that it is difficult to take moles unless when they are at work. That the most favourable time for the mole-catcher is in the beginning of spring. And that it is in the meadows they should be, in this season, the most earnestly attacked. They are to be attacked at sun-rise, at the hour of nine in the morning, at noon, at three in the afternoon, or at sun-set. That it is better to commence an attack upon them at sun-rise, than at any other time in the day. And that the next most convenient hour is nine in the morning; because, if all the moles which are wished to be destroyed cannot be then taken, the operations may be renewed at those other hours in the day at which these animals are known to resume their work. In watching for a single mole, care must be taken to make no noise, and especially not to stamp nor beat upon the ground. One may, at any time, force a mole to come above ground, by pouring a sufficient quantity of water into its subterraneous recesses. And should a person happen to be near a mole-hill, when the mole happens to betray its presence by stirring the mould; let him then, with his hoe, break into the tunnelled passage between that and the next mole-hill; and let him, with a little earth, close up the passage at the aperture made with his hoe. The mole is now imprisoned between the mole-hill, and the place where its passage is broken into, and stopped up. If the earth of a mole-hill be freshed and newly raised, you may conclude that there is a mole within it. The same thing may be inferred of any number of fresh mole-hills within small distances of one another. Yet, however fresh the earth of any mole-hill, if there be in its centre a perpendicular hole of about two inches diameter; you may be sure that the mole is not within, but has left his residence in search of a better. And when you find an assemblage of mole-hills together, of which the earth is quite fresh; then, upon removing them all with the hoe, and laying open the passages communicating among them, you cannot fail to find the mole that works within. This labour might prove too tedious and troublesome. But it will become very simple, if the mole can be confined between two points not remote from each other. Nothing more will then remain to be done, but to open with the hoe the intermediate passage between these two points. And a mole may be reduced to confinement between two such points, by making a few slight openings in the length of the tunnelled passage, in which you desire to confine her. These openings interrupt her course; for she will not pass, till she shall have first repaired them. But when you break into the tunnelled passage of a mole, close the passage slightly

with

MOLE-CATCHING.

with a little loose earth at both ends of the hole you have made.

It may be noticed, that in the practice of mole-catching on these principles, "the only instrument absolutely necessary to the mole-catcher is a hoe. But that it will be convenient that he have likewise at hand, a few pieces of straw, a few bits of paper, and a picher of water.

And thus prepared, "the first thing a mole-catcher should do on a farm or estate which he goes to free from moles, is to examine how those moles may be so confined, that he shall be able to attack them all at once; for by thus attacking them, he will the soonest accomplish his whole task."

In the plate of *Agriculture (Moles)*, a representation is given of a meadow covered with mole-hills, as at *figs. 1, 2, 3, 4, 5, 6, 7*, which are taken from the work of a late French writer. And by surveying this meadow as a mole-catcher, he perceives a detached mole-hill, as *fig. 1*; and perceiving the earth composing it to be fresh, or newly thrown up, he concludes, then, that there is a mole beneath. The mole-hill is large; he thence knows the mole within it to be a male. And with respect to the two mole-hills, *fig. 2*, they are at no great distance one from another; of course he knows them to be the work of a single mole. They appear fresh; and he concludes the mole to be still busy within. They are small; he, on this account, supposes it to be a female that has made them.

And the three mole-hills, *fig. 3*, are near to one another; and, consequently, the work of a single mole. They are fresh; he of course knows the mole to be now at work within. They are large; and have therefore been thrown up by a male. The six mole-hills, *fig. 4*, are not distant from one another; they must have been all thrown up by one mole. They are fresh; the mole is still at work. They are small; and, therefore, raised by a female. The zig-zag covered ways, or imperfect mole-hills, as at *fig. 5*, are fresh; a young mole is beneath.

But the five mole-hills, as at *fig. 6*, are dry; they have been deserted. And the seven mole-hills at *fig. 7*, are yet fresh; but one of them, shown at *M*, has a perpendicular hole opening at the top. The mole by which it was thrown up is hence known to be but just gone. By these observations he knows that there are in this meadow two male moles, two females, and a young one. And it is of consequence to know whether the moles be males or females; young or old. The males work quicker than the females; and are, therefore, to be more narrowly watched. The young ones, raising but a very little mould to cover them, as they move along at the surface, go also very quick; and should therefore be kept constantly in view, after they have once been discovered.

It may be observed, that in the operations for destroying them in the first case, as where a mole makes but one mole-hill, *fig. 1*, the mole-catcher removes this mole-hill with the hoe; and ascertains whether it has communication with any of the mole-hills adjacent. For this last purpose, he hems, or makes a slight noise, at the aperture or mouth of the internal passage from the demolished mole-hill. He at the same time applies his ear to listen what ensues within. If the mole-hill be without any communication with any other; the mole being nigh is frightened by the noise; he hears it stir; and it cannot escape him. With his hoe he lays open the tunneled passage *ab*; and at *b* he finds the mole. But the creature, aware of its danger, may possibly have had time to descend deeper into the earth, by the perpendicular passage *bc*; he has then two methods for taking her; he either digs to *c*, and there finds his prey; or he pours in water at *b*, and the mole comes out of herself. On the

other hand, if upon hemming he could not hear her stir; he concludes that this mole-hill communicates with others near it; and he proceeds in the following manner.

This is the second case, as that where a mole has thrown up two mole-hills *A, B*, *fig. 2*, he now makes an opening *de*, more than nine inches long, in the direction of the tunnel which runs between the two mole-hills. With a little earth he closes the two ends *d, e*, of the tunnel. Within a few seconds, the mole, disagreeably affected by the air, and fearful of danger, comes to repair the breach, and is discovered by its working at *d*, or *e*. If it come to *d*, he knows that he shall find it between that point and the mole-hill *A*. And when it comes to *e*, he is sure of finding it between *e* and the mole-hill *B*. In either instance, he proceeds as was indicated in the first case; and lays open either that part of the tunnel which terminates at the mole-hill, or that which ends at *B*.

But in the third case, where the mole has thrown up three hillocks, *C, D, E*, *fig. 3*, he now makes the four apertures *f, g, h, i*. The mole will be soon discovered by its stirring the mould at *f*, at *g*, at *h*, or at *i*. If it work at *f*, it is confined between that point and the hillock *C*. If it be perceived to work at *i*, it is confined between the point *i*, and the hillock *E*. And if it work at *g*, or *h*, it is in the space between these two points.

And in these three suppositions, he operates as in the first case, by laying open that part of the passage within which the mole is confined. If the mole be shut up between *g* and *h*; and he does not choose to take the trouble of laying all that space open; he then removes the mole-hill *D*, and makes a third cut like the others. He watches for the working of the mole; and he then knows by the side this appears on, whether he shall find the animal between the third cut and the point *g*, or between that third cut and the point *h*.

Also in the fourth case, where a mole has made four or more mole-hills, *fig. 4*, he takes, for example, the six mole-hills *F, G, H, I, K, L*. He makes the cut *kl*. If the mole come to work at *k*, it is confined between that point and the mole-hill *F*. If, on the contrary, she come to *l*, she is confined between *l* and the mole-hill *L*. In either of these suppositions, he makes from *K* to *F*, or from *l* to *L*, the same means of operation as in the third case; that is, he proceeds just as if there were but three mole-hills.

But a different mode of operating in the second, third, and fourth cases, is this; he supposes, that when he has made the cut *de*, *fig. 2*, the mole comes to work at *d*, and he observes it the moment it comes there. He knows that it must travel along *de*, to repair the breach in its tunnel by an arch of earth, which it must raise from the bottom of the place laid open. If he remain there, without making a noise, he shall see it come to work. Then, to take this mole, he has only to put the end of his hoe behind it, before it comes to the point *e*. The earth which he had before put at the aperture, *d*, will hinder it to advance; the end of the hoe will prevent it from retiring; and he shall easily take it, by removing with his fingers that small portion of loose earth with which it is covered. Is it possible, even without an aperture, to know the moment a mole comes to work at it? Nothing more is, for this end, necessary, than to place there a chip of straw, bearing a bit of paper at its upper end. This small standard will be subverted, or at least shaken by the very first movement the mole shall make at the place where it stands. The shaking, or fall of the chip of straw, calls the mole-catcher to watch and take the animal within.

Also in the fifth case, where the mole comes not to work

MOLE-CATCHING.

at the cuts made first by the mole-catcher, he supposes, that if, after making the aperture *kl*, he finds that the mole continues to work at the mole-hill *L*; he is now sure that it is between the point *l* and the mole-hill *L*, and his subsequent operations are the same as in the third case; that is, he must act as if there were but three mole-hills *L*, *K*, *L*.

In order to know whether a mole shall come during his absence to work under a mole-hill, he softly flattens the mole-hill with his foot; and if, on his return, he perceives a small eminence to have been raised on the level, he can then have no doubt but the mole has been working there.

However, in the sixth case, there is a different manner of operating from cases second, third, fourth, and fifth, where a person happens to be near a mole-hill at the moment when the mole breathes or blows at it. Should he be beside the mole-hill *L*, *fig. 4*, at the moment when the mole comes to work there; he does not use the uncertain method of the gardeners, who remove the mole-hill with the spade; but he cuts at *mn*, the tunnel communicating between the mole-hill and the next one *K*. This is a certain means of confining the mole between the mole-hill and the point *mn*. When the mole is thus inclosed, he proceeds, as in the first case, and lays open the space within which it is confined.

And in the seventh case, as when several fresh mole-hills are found near to some other mole-hills, old and dry, as *figs. 4* and *6*, which is more troublesome than any other of the mole-catcher, it is doubtful whether the fresh mole-hills do or do not communicate by tunnels with the old and dry ones. It is necessary to begin by making cuts between the old and the new hillocks, that the mole, when attacked in the new, may not be able to escape to the old. One may then proceed, according to circumstances, as in the foregoing cases. When this happens to be the case, too many cuts cannot be made, unless a person is anxious to spare the surface of the ground. It is good, for instance, as in *figs. 4* and *6*, to make a cut in the direction from *H* to *N*, and another in the direction from *H* to *O*; as there may be a tunnel in either, or tunnels in both of these directions.

But on this, it is observed, that "if one were constantly to watch a single mole, and not to proceed against any other, till after the first were taken; only a very few could be destroyed in one day. But when a farm is surveyed to discover the moles, all the fresh hillocks should be greatly flattened with the foot, and all the necessary cuts made,—as of these too many cannot be made, unless a person is afraid of breaking the surface too much. Set up little standards of straw with paper streamers. Then pass about from one mole-hill to another, and proceed as directed above. If you thus proceed against several moles at once, you must exercise great vigilance; otherwise, while you are busy with one mole, others may make a good passage across the cuts; and then you will have to begin with them anew. A mole will be longer in repairing and crossing one of the cuts, if a lump of hardened earth is put at the bottom. This precaution should be always taken." This is considered by *M. Dralet*, the translator of the above, as "of all the means hitherto employed for the extermination of moles, the easiest and the surest."

In the sixth volume of the *Agricultural Magazine*, a writer, however, proposes a more simple, easy, and effectual practice, and which is less troublesome and expensive. It is the invention of a common labourer, who clears nearly one half of the county of Glamorgan. His contrivance is composed entirely of oak, deal, or elm wood, but the first is the best, and common nails, and may be made by any carpenter or wheel-wright, and set to work by any common labourer. This is shewn at *fig. 8*, in the plate. *A* and *B*

are two boards of oak, forming the sides of the trap, eighteen inches long, five inches wide, and half an inch thick. *C*, the bottom of the trap, more fully explained in *fig. 9*. *E*, a piece of oak board, five inches long, two inches wide, half an inch thick, nailed on the top edges of the boards *A* and *B*, both to strengthen the trap and to keep the sides at a proper distance. *A* (*fig. 9*) is the trap with its bottom upwards. *C*, *C*, two pieces of oak board, five inches wide, four inches and a half long, half an inch thick. *D*, an aperture, nine inches long, four inches wide, made to receive the fall of the trap. *L*, a hole for a common clout-nail (forming the pivot of the fall) to turn in. And at *fig. 10* is *D*, the fall of the trap, nine inches long from *F* to *H*, three quarters of an inch thick (the distance from *F* to *G* two inches and a half, or three inches), from *G* to *H* half an inch thick and four inches wide. *G* shews the hole for the clout-nail forming the pivot. *M*, the dotted lines, shews the manner in which the upper part of the fall *D* must be bevelled, to prevent its falling both ways. At *fig. 11* is seen "the mole-pot, the uses of which will be more fully explained afterwards, composed of four pieces of oak board, each five inches wide at the top, nine inches wide at the bottom, twelve inches long, one inch thick, or thereabouts, having two ears, as at *K*, *K*, with a hole in each large enough to carry a piece of small rope or spun-yarn." And at *fig. 12* is shewn a mole-trap set in the side of a ditch.

In the view of finding the runs or tunnels, "the farmer or his servant must carefully examine the ditches of each field, in order to discover where the moles have made their main tracks; which having once found, and the trap set thereon, he may rest assured that every one passing through it will be inevitably destroyed; neither are their runs at all difficult to be found, as the only thing necessary to observe is, whereabouts they have broken out most on that part of the field the nearest to the ditch, in the side of which he must then make an opening with a small common spade, opposite to the nearest place where they are observed to work most, in order to open the run. Should the first endeavour to strike upon it prove unsuccessful, he will not fail to find it by searching thereabouts, either a little higher or lower. In common fields and uninclosed lands a different method must be pursued; and as, of course, there are no ditches, the higher grounds and banks will be the certain and proper place to search for their runs, which having once found, the workman must proceed in the following manner: First, a hole must be cut out the length of the trap, as represented in *fig. 12*, in such a manner that when it is inserted, the run may enter each of its ends, as shewn by the dotted lines; and also a hole or well of such a size that the mole-pot may be easily suspended therein. Secondly, a small clout-nail, of which he should take several in his pocket; or should he have forgotten to do so, a thorn out of the hedge must be thrust into the hole *n*, *fig. 9*, which also communicates with the hole *n*, *fig. 10*, and will effectually prevent the fall from acting. Thirdly, a small handful of fine earth, like that usually thrown up by moles whilst working, and which may be taken from one of their heaps, must be scattered all over the bottom of the trap so as to cover it, as well as both ends communicating with the run. Fourthly, a turf, something longer and wider than the trap, must be cut off the head-land, both to serve as a cover to it, as is seen at *PPPP*, (*fig. 12*), and as a certain mark by which it may be found with the greatest ease: and lastly, two pieces of spun-yarn must be fastened, one to each ear of the mole-pot *11*, *fig. 4*, by which it must be tied on the trap in such a manner, that any weight put upon the fall *D* at *11* may be thrown to the bottom; the carpenter having previously taken care that the weight

MOLE-CATCHING.

weight of the fall from F to G shall more than counter-balance that from G to H, so that no sooner shall a mole be thrown into the pot than it will spontaneously resume its former situation, and be on a level with the rest of the bottom."

After "the trap with the fall has been fastened up by the clout-nail at *n*, the fine earth thrown over the bottom, the turf covered over the top, and the mole-pot properly suspended, by being tied over the whole; nothing further will be required to be done to it for three or four days, (for the moles must be allowed to pass freely along it for that time, as it will induce them to use their run without fear, and be the means of taking them with the greater certainty). The workman must now carefully examine his trap, and on gently hitting up the turf will plainly perceive their marks, (taking care, however, not to leave any opening for the light to enter), and pulling out the clout-nail at *n*, the trap will then be fit for working, and the fall will throw them into the mole-pot, out of which it is impossible for them ever to escape." And farther, "should the farmer have strictly followed the above instructions, and notwithstanding the moles still continue to work about his land, he may be certain they have forsaken the run on which he has set his trap, and he must therefore search for their new one." It is concluded that "the advantages arising from using traps of the above construction are, that the materials are to be procured every where; they can be made by any common mechanic at a very small expence, (the wood being used rough as it comes from the saw,) are very durable if made of oak; are not liable to get out of repair, and if they should, can be mended most probably by a labourer; they catch the whole year, and do not require looking after more than three or four times in that period, and that will comparatively require so short a time, that a workman may with ease look over all the traps on a very large farm; and supposing the fields to lie contiguous to each other, one trap for each ten acres would, on an average, be fully sufficient."

It is stated, by the first writer noticed above, that mole-traps are either simple or complex. The simple mole-trap is a hollow cylinder of wood, white-iron, or pottery, thirteen or fourteen inches long, and in diameter a little larger than the tunnels of the mole. This cylinder is closed at one end, and has at the other a sucker or valve pressing against an exterior-edging. When the mole comes to the extremity covered by the sucker or valve, she presses this back in order to continue her progress through the cylinder, and can return no more. Two of the traps may be united so as to form a double trap, having a valve at each end. By this the mole may be taken as she enters, whatever side she approach. It is added, that "the most remarkable of the complex traps used in Normandy, is a small piece of board fixed in the ground by four iron pins with cross points extending from them; and on these points the mole transfixes itself. It is very seldom that those succeed who make use of these and other mole-traps: for they do not use the fit means to entice the creature to the snare. That method is, nevertheless, very simple. Nothing more is necessary than to make a few holes by which the air may enter the tunnel of the mole, and give her notice of the injury done to her work. It will be easy to him who has read the preceding information and directions, to employ such mole-traps, in certain cases, with infallible success. He supposes, for instance, the two mole-hills A, B, (*fig. 2.*) and makes the aperture *dc*. If the mole stir the earth at *d*, he there presents the valve of either the simple or the double mole-trap; and he is sure of taking it. If, on the contrary, it presents it-

self at *e*, he must there use the trap. He acts in the same way in every one of the cases mentioned above. It may be easily believed, that there are some of those cases in which it will be convenient to use mole-traps. They are exceedingly useful when the mole-hills happen to be at considerable distances one from another, as in the end of winter. But, in the time of drought, and when the weather is very cold, the hillocks are so very near to one another, that the traps can be of little use.

But the common method of destroying moles is, however, by traps, made in the following manner: take a small board, about three inches and a half broad and five inches long; on one side thereof raise two small round hoops or arches, one at each end, like the two hoops or bails of a carrier's waggon, capacious enough for a mole to creep through easily: in the middle of the board make a hole about the bigness of a goose-quill, and have in readiness to put into it a flick about two inches and a half long, fitted at one end to the hole and a little forked at the other. Cut also a hazel or other stick, about a yard or a yard and a half long, which will rise with pretty strong elasticity when it is stuck into the ground; and to the end of this stick fasten a very strong noose of string or horse-hair, made so as to slip easily. Have likewise in readiness four small hooked sticks; then go to the furrow or passage of the mole, and after you have opened it fit in the little board with the hended hoops downward, so that when the mole passes that way it may go directly through the two semicircular hoops. But before you fix the board in this manner, put the hair string through the hole in the middle of it; place the noose in a circular form, so as to make it answer to the two hoops; put the small stick before mentioned gently into the hole in the middle of the board, so as just to stop the knot of the hair string, without entering so far as absolutely to tighten it. Then fasten the board down with four hooked sticks, and cover it with earth. When the mole, passing in its furrow, comes into this trap, it will displace the small stick that hangs perpendicularly downward, the knot will then be drawn through the hole, and the noose instantly straightened by the rising of the end of the hazel stick to which it is fastened, will catch the mole round the neck or body and hold it fast.

MOLES, Fumigating of. This is a mode adopted in order "to suffocate the mole in its retreat, for which some advise to take a small nut-shell, or any little vase, solid and of small capacity, and in it to burn cedar root, or wax and sulphur, with a portion of straw, then to stop up every hole by which the smoke might issue out. The success of these methods is very uncertain, and indeed none at all in the hands of any person not well acquainted with the artifices and haunts of the mole. Sometimes all the mole-hills in a garden or a meadow, whether fresh or dry, communicate by many different passages with one another, as has been shewn. In this case all these mole-hills must be pressed down and closed up. But in doing this you will yourself preserve the mole from the threatened suffocation. Suppose, for instance, that the mole which made the hillocks (*fig. 4.*) is to be suffocated, and that you put the combustible matters in at H. If the mole be at I or L, the smoke will be hindered from penetrating beyond I, by your shutting up the passage there; and your precaution to ensure the death of the mole will prove the very means of its escape. It is only by cuts in the passages that fumigation can be made effectual. To suffocate the mole of the hillocks (*fig. 4.*), make the breach *lk*: close up its extremities; put in your combustible matters between *k* and F, and between *l* and L, after leveling the hillocks L, F. But you must first ascertain whether the

mole-hill, H, (*fig. 4.*) has any communication with those of *fig. 6*, and if it has, cut off that communication by other breaches," in the manner already described.

There are some other modes proposed for the destruction of this animal, but they are much less certain than those which have been just detailed.

MOLES, Poisoning of. It may be noticed, that for this purpose there are several recipes; some propose to throw into their retreats nuts, which have been pierced on one side and boiled in a strong lixivium. Others boil such nuts in water, with a handful of hemlock, and use them as above. In some countries people take the root of white hellebore, with the bark of dog's colewort pulverized and sifted; mix this with barley-meal: steep the mixture in wine and milk; cut it in small pieces, then throw it into the mole-hills. In other countries it is usual to take the green of a leek, or to put arsenic on the white, and bury this in the freshest mole-hill that can be discovered. These poisons, it is observed, are in general used injudiciously. The mole rarely seeks its food at the surface where its hillocks are placed. It pushes back the earth, as it works, to the extremity of its tunnel. That earth raises the layer next above it; and by the continual repetition of this process, the mole-hill is at last formed. The mole, while undisturbed, keeps always within its tunnel; and it is into the tunnel, therefore, that the poisoned bait ought always to be cast, instead of being left in the hillock. In order to destroy the mole which formed the mole-hills A, B, (*fig. 2.*) make a cut, *d e*, in the tunnel which communicates between them. Put the poisoned bait then into it, at either *d* or *e*, or even between them. The animal will come of course to repair the breach, will find the substance, eat it, and be destroyed.

MOLE-Hill, a term applied to a small mouldy heap of earth, thrown up by the mole on grass or other lands. It has been observed by a late writer, that "in the more rich and fertile soils, hills of this sort are frequently thrown up in great numbers, from their abounding more with the food of the subterraneous animals that produce them. Meadows are often extensively and seriously injured by them, on account of their depth of soft humid soil. Moles usually reside, destroy, and render useless the grass, not only of the very spot where the hills are raised, but likewise to some extent immediately around them, as well as impeding the free course of the scythe: for these reasons, the extermination of moles becomes an object of great consequence to grass husbandry. In the early spring months, when such hills are in a tolerably dry and powdery state, no time should be lost in spreading them out, and dispersing them, in as even and regular a manner as possible, over the surface of the sward that adjoins them; as, when they remain long without being sealed, they do considerable injury to the grass plants underneath them, by blanching and rendering them tender. This business may be very conveniently performed by a common iron-toothed garden rake. But it is invariably the best method never to suffer the animals to remain in the land, but to procure an expert mole-catcher to destroy them, and thus wholly prevent the hills being thrown up." As soon as the hills have been dispersed over the land in the manner directed above, the operator should be careful in raking up all the small stones, that may have been thrown out with the mould; as when left upon the ground, especially where it is to be mown, they prove a very disagreeable impediment to the scythe. But before this is done, it is beneficial to make use of a bush-harrow.

MOLE-Plough, an implement intended for the purpose of draining land, by forming a sort of pipe in it.

This plough was long ago invented by Mr. Adam Scott, and as since improved, and made use of in the midland counties, is an implement which, in suitable soils and situations, as in parks, pleasure-grounds, and where much regard is had to the surface-appearance of the land, may be of considerable benefit in forming temporary drains. It makes a drain, without opening the surface any more than merely for the passage of a thin coulter, the mark of which soon disappears. This instrument is chiefly employed in such grass-lands as have a declination of surface, and where there are not many obstructions to contend with: but it may be used in other kinds of land, as on turnip grounds that are too wet for the sheep to feed them off, or where, on account of the wetness, the seed cannot be put into the earth. With this plough the drains should be made at the distance of ten or fifteen feet, in straight lines, and also contrived so as to discharge themselves into one large open furrow, or grip, at the bottom of the field. As it requires great strength to draw this implement, it can only be used where a good team is kept. It is suggested by an intelligent farmer, that in deep clayey soils it may be highly useful; but that, where there are beds of gravel or sand intervening, it cannot be employed with advantage. And it has been found useful in thin peaty soils.

This sort of plough is represented at *fig. 1*, in *Plate Agriculture (Ploughs)*, in which *a* is the beam; *b*, the coulter; and *c*, the cone which forms the drain. It has been lately improved, so as to require much less force of draught, by having wheels placed before, and a roller behind. But a greater and more important improvement has been made on this tool by Mr. Lumbert. Mr. A. Young states, that "in a communication from his son, inserted in the 36th volume of the *Annals of Agriculture*, mention is made of this plough having been greatly altered by Mr. Lumbert of Rislington Wick, near Stow, on the Wolds of Gloucestershire, who worked it by eight men turning windlasses. This he takes to be the first public notice of any such invention. Thomas Estcourt, esq. M. P. for Cricklade, and a member of the Board of Agriculture, had, since that period, several times mentioned the same object to him. In March 1804, he had the goodness to inform him, that the plough was then working at Cricklade; and, upon his expressing a wish to see it, obligingly proposed to write to Mr. Wells, surgeon at Cricklade, informing him of his intention, and requesting his writing to Mr. Lumbert, the inventor, to desire his presence at the same time. These necessary previous steps being taken, he arrived at Cricklade, March 21st, and had the satisfaction to find that the plough was then at work within a mile of the town, whither he repaired with Mr. Wells and Mr. Lumbert. The field in which the machine was working belongs to Mr. Champenoun of Cricklade; the soil a very rich surface loam upon a clay bottom, which made it wet, and demanded the operation of draining. The state of the surface (though grass) was such as would have been very materially injured, by so many horses as must have been necessary to draw the mole at the depth he found it working, which was from 17 to 18 inches. Eight women work it: and in respect to the labour exerted, it is sufficient to note that Mr. Lumbert contracts for the work at three halfpence per perch, lug, or rod, of $5\frac{1}{2}$ yards; his foreman contracting with him for doing it at three farthings, the machine being found by the master, the man paying himself and the women out of that sum. The plough does, according to soil and circumstances, from 150 to 200 perches a-day: 300 have been done. At 200, three farthings a perch are 12s. 6d. per diem; the eight women at 8d. are 5s. 4d., leaving

ing 7s. 2d for the foreman's pay, and the reparation of the chain, the chief object in the repairs, as it breaks often, and wants the addition of a false link whenever that accident happens. He timed the motion of the plough for some rods, and found the average five yards in a minute. At this speed, 490 perches would be done in nine hours; but the time of moving the windlafs, frame, and anchor, is a large deduction, though he should have conceived not sufficient to reduce the performance to 200 perches. He could not but much admire the efficacy of the anchor and *scorts*, in quickly fixing and preserving the steadiness of the machinery, in resilience of so great a force as is necessary to move the mole deep buried in clay."

And it is added, that "the present construction of the machine was the result of many experiments, in making them under divers variations. Mr. Lumbert speaks of two circumstances particularly, which cost him much attention and many trials: the line of traction, and the due elevation of the beam. He has not comprehended why the beam should be elevated (other circumstances remaining the same); why any elevation further than parallel to the horizon should be necessary, the parts connected forming one piece in either case. This question, which is intimately connected with the structure of all wheel-ploughs, and is found under great variations, from the elevated beam of the Norfolk plough to the very depressed position of the beam of the Hertford one, deserves more attention than it has commonly met with. The line of surface being 1 : 2, and the tendency of the share into the ground 1 : 3, should the elevation of the beam be proportioned as 1 : 4? The line of traction, in Mr. Lumbert's plough, being to a little above 1, suppose his mole working at 5, he seems to have proportioned the elevation of his beam somewhat to the same angle above ground at 6, that is, at 22½ degrees. He found it necessary that the line of traction should cut the centre of the front roller, but not drawing by it. If a line be drawn from the horse's shoulder, while drawing, to the heel of the Norfolk plough, he has often found, when the ploughs are said to go well, that such line passes by the centre of the wheels; but the Norfolk plough is truly a wheel machine, the draught being to the carriage, and not to the plough itself: whereas Mr. Lumbert draws from the heel of his beam. The line of traction, however, in Mr. Lumbert's machine, is always varying: the angle is very acute, when the women begin to turn; but necessarily becomes less and less so, till the mole arrives at the windlafs frame. The elevation of his beam throws a great weight on it, by counteracting the tendency of the mole into the ground. Quære, if this line of traction be not to the centre of the compound resistance? If so, it explains the reason for his greater ease of draught; but it does not explain why he should not have availed himself of high wheels in front, instead of a low roller, converting his machine into a true wheel-plough, and drawing from the carriage; the chain from the plough heel being fixed to the carriage, as that from the coulter (or near it) is in the common wheel-plough."

The same writer farther states, that "Mr. Lumbert has made this great improvement of the mole-plough about seven or eight years, and the success attending it has been considerable. Mr. Poulton of Cricklade and Mr. Wells have used it, as well as Mr. Champernoun. Mr. Coxé at Water Eaton has drained, as he was informed, some hundreds of acres with it. Many have used it at Perton; nor had Mr. Adams heard of any failures. All known here have been on clay; but they have heard of its answering on less stiff bottoms. The drains ran well after three years."

It is added, that "Mr. Lumbert, in their examination

of the machine, desired him to observe that the bottom of the mole was not at all bright, there being no wear there, while the upper parts were worn quite bright; and from this circumstance he concludes, that any attention to keep frosts out of the slit made by the coulter and standard is unnecessary. He conceives that the force of pressure, and consequent plashing, is all on the upper side of the pipe, inasmuch that he is firmly persuaded that the operation is chiefly at the bottom of the pipe, where the soil is left porous, on comparison with the top of it: and he is so much of this opinion, that he conceives the water, which runs down by the slit, is more likely to be conducted over the pipe than to get into it." Mr. Young states, that "he merely reports his remarks without a comment."

It is hinted, that "the improver goes to any part of the kingdom with his machine for drawing of 1½d. per rod; but if to a distance, must have insured work, in the proportion of 200 rods for every mile he travels going out. At any considerable distance, this amounts to so large a quantity, that, in many cases, it would be advisable for several neighbours to join for providing sufficient employment. He sells the tool complete at 50 guineas, having a patent. He can go 24 inches deep; and he has, on his own farm, drains that have stood well seven years. When the ditch of a field is not in such a direction as suits for the conveyance of the water from the pipes made by the mole, or other circumstances render it necessary to have a bottom main drain to take the water, his mode of making these *clay-drains*, as he calls them, is by digging to a certain depth with common spades; and at the bottom of the trench so opened he takes a spit, with a narrow spade that has a cutting edge. This tool opens a trench, which just receives a jointed wooden frame, with a chain at the end, by which it is drawn on by the application of a lever. This frame, fitting the space left by the narrow spade, is covered with clay, rammed close and firmly to it, being first wetted, that it may slide from this clay vault when drawn on by the lever: and from much experience he finds these drains perfectly safe and durable. Over the rammed clay mould, enough to fill to the surface is thrown in."

The writer also mentions, that in discoursing "with him on other applications of the power he exerts in drawing the mole, he informed him that Mr. Barker of Fairford has a water, that was so choked up with mud and weeds, that a duck could scarcely swim in it. He applied the windlafs, frame, and chain, to drag out all; and with such success, that no other method would have cleansed the water at so cheap a rate: some drag, scraper, or other contrivance, must of course be necessary for taking and retaining the mud," &c. And Mr. Young supposes, that "a very useful application of this power would be to the purpose of drawing turnips or cabbages from off wet land, which, by common carting, is attended with so much mischief. He has seen temporary sheds roughly erected, on the borders of turnip-fields in Suffolk, for stall-feeding beasts: the addition of the windlafs, to draw the turnips to such sheds, would be extremely important. Another application of this force, well deserving attention, is, for drawing the machine which he has seen in the maritime part of Essex, wherewith cross-roads are levelled. Where ruts are deep, and combs and quarters high, with other inequalities, this tool, a sort of harrow, might be very cheaply used for effectually smoothing the whole, and improving the roads at a very small expense." And as "much the most economical system in which the thrashing-mill can be applied is, that of a circular iron rail-way, whereon to draw the stacks to the mill, as he has fully explained in the 33d volume of the Annals: in-
stead

Head of the application of the power of the wind or horses to draw the flacks, the windlafs and anchor of the mole-plough might be moft cheaply applied. Another application of this power which he fhall mention is, for the draught of ploughs and other machines, when comparatively tried: the force exerted would be more regular and ftady than that of horses, or even oxen; and the only attention particularly demanded would be to keep the chain parallel to the furrow, and at the right diftance from it."

But Mr. Young fuggells, that "in the operation of hollow draining itfelf, a moft important defideratum yet remains, and that is the drawing a plough that fhall cut an open trench, for filling up with ftraw, wood, or ftone. Two fuch ploughs have been invented: Mr. Arbuthnot's, a plate and explanation of which are to be feen in his "Eastern Tour;" and Mr. Makin's, which is kept in the Society's repository in the Adelphi buildings. The trampling of fo many horses as thefe ploughs required, was the great objection to their ufe. This ferious evil is done away in the windlafs fcheme; and he cannot but recommend to Mr. Lumbert's attention the improvement of one of thefe ploughs, or the invention of another, for executing thefe drains by means of his windlafs. He ftates, that "in all forts of hollow draining, Mr. Lumbert is decidedly of opinion that the cuts fhould be in the direktion of, and with the flope of the land: not diagonally acrofs it, which is the common praftice. In the latter method, the drains operate but on one fide: cutting off the courfe of the water, as it defcends, it drains the land only below the cuts; but if made with the flope, they operate equally on either fide; and as he fupposes the veins or pores of the foil, which conduct the water to act in every direktion, provided the water itfelf is taken away, his cuts in the direktion of the flope receive it laterally from every portion of the land between the drains, the defcent from which to the bottom of the drain is greater than the angle of the defcent of the natural furface of the field. It would not be eafy to bring this opinion to the teft of exaët experiment; but a very ingenious farmer in Suffolk, Mr. Simpson of Witnefhams, near Ipfwich, has the fame conviction, and has drained fome hundreds of acres very fuccefsfully upon this plan."

But the nature, ufe, and application of this implement may, however, be better underftood from fig. 2, in *Plate Agriculture (Ploughs)*, in which,

1. The beam.
2. The mole, to which fegments for lengthening it fcrew on at 3.
4. The roller at heel, on which it preffes.
5. The chain, 50 to 60 yards long, which winds on to the two cylinders, 7, 7.
6. A pulley, around which the chain, 5, plays.
- 8, 8, 8. Windlaffes turned each by two women.
9. Stays, which entering the ground, affift in keeping the machine ftady.
10. The anchor.

And the proportion and refpective angles of all the parts may be meafured by the feale which is given in the plate. See **PLOUGH**.

MOLE-Traps, the name of fuch traps as are contrived for the purpofe of taking and deftroying moles. They are of feveral different kinds. See *MOLE-Catching*.

MOLE, *Mola*, or *Mola Carneæ*, in *Physiology*, a mif-ftapen mafs of hard flefh, fometimes generated in the wombs of women, inftead of a fœtus; called alfo a *false conception*. It is, however, a very rare produktion; what is called a mole by women being generally found on examination to be nothing more than coagulated blood. The following ap-

proaches neareft to what the ancients conceived to be a mole, of any thing that has occurred to the writer of this article. A woman, about twenty-feven years of age, was delivered of a female fœtus, and its placenta, in which nothing uncommon was obferved; and although the uterus remained of an unufual fize, yet the pains not recommencing, there was no fufpicion entertained but that its bulk was occafioned by coagulated blood. On the third day the pains became violent, and this monfter was born. Its ftape was fpherical, but fomewhat flattened. It meafured in its largeft diameter eight inches, and weighed about eighteen ounces. It received its nourifhment by an umbilical cord, to which was attached a portion of membranes, and although no placenta was found, it is probable it had a fmall one, and that it was inclofed in its own involucreum. It was completely covered with a cuticula, and a little above the part where the navel-fting terminated, there was a hairy fealp covering a bony prominence, fomewhat refembling the arch of the cranium. On diffection it was found to be plentifully fupplied with blood-veffels, proceeding from the navel-fting, and branching through every part of it. It had a fmall brain, and nerves paffing from thence through the foramina of the bones; but no refemblance of any thoracic or abdominal viscera. The reft of its bulk was made up of fat. This was inferted, with the plate of the external appearance of the object, in the feventy-firft volume of the *Philofophical Tranfactions*.

MOLE, *Moles*, a mafive work formed of large ftones laid in the fea by means of coffer-dams, extended either in a right line, or an arch of a circle, before a port; which it ferves to clofe; to defend the veffels in it from the impetuofity of the waves, and to prevent the paffage of fhips without leave.

Thus we fay the mole of the harbour of Meffina, &c.

MOLE is fometimes alfo ufed to fignify the harbour itfelf.

MOLE, *Moles*, among the Romans, was alfo ufed for a kind of maufoleum, built in manner of a round tower on a fquare bafe, infultate, encompassed with columns, and covered with a dome.

The mole of the emperor Adrian, now the caftle of St. Angelo, was the greateft, and moft ftately of all the moles. It was crowned with a brazen pine-apple, in which was a golden urn containing the afhes of the emperor.

MOLE, in *Zoology*. See **TALPA**, and the article **MOLE**, *supra*.

MOLE-Cricket, *Grylotalpa*, in *Entomology*. See **GRYLIUS**.

MOLECULE, **MOLECULA**, in *Physics*, a little mafs or portion of any body.

The air, by refpiration, infinuating itfelf into the veins and arteries, endeavours by its elaftic power to divide and break the molecules of the blood, which on their part refift fuch divifion.

MOLEEAH, in *Geography*, a town of Bengal; 54 miles W.N.W. of Midnapour.

MOLENE, a fmall ifland in the Englifh channel, near the W. coaft of France; fix miles S.E. of Ufhant. N. lat. 48° 24'. W. long. 4 52'.

MOLENES, a fmall ifland in the Englifh channel, near the coaft of France; 13 miles W. of the ifland of Bas. N. lat. 48° 47'. E. long. 3° 33'.

MOLENPURG, a town of Auftria; 16 miles S.W. of Crems.

MOLES CARNEÆ, in *Anatomy*, a name given by Vefalius, and others, to a mufcle called by Winflow, Albinus, and others, the *complexus*. Spigelius calls it the *carneæ moles trigenino adjuncta*.

MOLES Carneæ labia formans, a name given by Fallopius

to the muscle called by *Albinus orbicularis oris*, and by *Cowper confriator labiorum*.

MOLESTANDO. See *Nos Mollands*.

MOLESWORTH, *ROMNEY*, in *Biography*, viscount Moleworth of Ireland, descended from an ancient English family, was born at Dublin in 1656. Having received the elements of a good education, he was sent to complete his studies at Dublin college. He married, at an early age, the sister of the earl of Bellmont. When the prince of Orange came to England in 1688, Mr. Moleworth rendered himself conspicuous as a friend to liberty and the Protestant religion, for which he was afterwards attainted and his estate sequestered by king James's Irish parliament. The success of the Popish king, even in Ireland, was very short lived, and Mr. Moleworth was immediately noticed by king William, who raised him to the rank of privy-counsellor. In 1692 he was sent out envoy-extraordinary to the court of Denmark, where he resided three years. He had not, however, been very long in his situation before he found reason to be disgusted with the manners and habits of that newly enslaved country, and his eagerness to infill upon privileges which he conceived were his due in the high character of ambassador, gave offence, and he was forbidden to enter the court. Without the ceremony of taking leave, he withdrew to Flanders, on pretence of business, and thence returned to England, where he set about writing "An Account of Denmark." This work, written probably in resentment for the ill treatment he had met with, gave such an unfavourable account of the government and nation, that it was noticed by prince George of Denmark, consort to the princess Anne, afterwards queen of England, and a memorial was presented to king William, by the Danish envoy, complaining of the insult. It was undoubtedly one of the publications of that period which was most hostile to arbitrary power, and which exposed with the greatest freedom the arts by which public liberty was overthrown. Dr. King was employed to answer this work, in the performance of which, being furnished with facts by the Danish resident, he was enabled to detect some mistakes and misrepresentations: the book was however well received, and was translated into several foreign languages. For the author it procured the esteem and friendship of lord Shaftesbury, in unison with whose political principles he always acted. Mr. Moleworth was continued a member of the privy council till the latter part of the reign of queen Anne, when he was removed on account of a complaint from the clergy in convocation, to whose increasing influence he was always inimical. On the accession of George I. he was taken again into favour, and in 1716 was called to the house of lords in Ireland, by the title of viscount Moleworth. After this he spent his time chiefly in a literary retirement, connected with and much esteemed by several men of learning and liberal principles, among whom were Locke, Molyneux, and Toland. To the latter he was a warm friend and benefactor, though his own circumstances were narrow. Lord Moleworth died in 1725, at his seat near Dublin, in the sixty-ninth year of his age. Besides the work already referred to, he wrote an address to the house of commons for the encouragement of agriculture; and to his pen were ascribed several temporary publications in favour of the English constitution, and the general principles of liberty. One of his daughters, Mary, the wife of George Monk, esq. at her death, in 1715, left a collection of poems, which her father published, and dedicated to the princess of Wales, afterwards queen Caroline. *Biog. Britan.*

MOLEVETO, in *Geography*, a town of the island of Ceylon.

MOLFETTA, a town of Naples, in the province of Bari, on the coast of the Adriatic, the see of a bishop; eight miles E.S.E. of Trani. N. lat. 41 18'. E. long. 16 39'.

MOLIERE, *JOHN-BAPTIST POUQUÉLIN DE*, in *Biography*, the most celebrated of modern writers in comedy, was born at Paris in 1620. His father, who was valet de chambre upholsterer to the king, and kept a broker's shop, designed to bring him up to his own employment, and gave him a conformable education. The youth, without any advantages of education beyond those of mere reading and writing, imbibed a taste for literature, and was sent to the Jesuits college as a day-scholar. His assiduity was soon observed; he became connected with Chapelain and Bernier, with whom he attended lectures in philosophy, under Gassendi. His father, with increasing years, became very infirm, and the business of the royal household was devolved on the son, and he attended Louis XIII. to Narbonne in 1641. On his return to Paris he resolved to devote himself to theatrical employments. He connected himself with a company of young persons, who acted in the suburbs of St. Germain, and assuming the name of Moliere, composed several little pieces of the comic kind, and performed his part on the stage. At length he joined La Bejart, a provincial actress, and they formed a company, which, in 1653, represented at Lyons his first regular comedy in verse, "L'Étourdi." This was followed by "Le Dépit Amoureux," and "Les Précieuses ridicules," exhibited at Beziers, where Moliere was favourably received by the prince of Conti, who was chief of the states of Languedoc. He next visited Grenoble and Rouen, and from the latter came to Paris, under the protection of Gallon, duke of Orleans, who introduced him to Lewis XIV. He soon obtained permission to open a theatre in the metropolis, which was first in the old Louvre, and afterwards in the Palais Royal, and in the year 1665 he was placed in the service of the king, with a pension. He rose in reputation as a writer by the new pieces which he presented to the public, and became more and more perfect as he advanced in experience and observation. At mature age he married the daughter of the actress Bejart, who also followed the same profession, and he is said to have incurred very deservedly the same sort of ridicule as that which he bestows plentifully upon the poor husbands in his comedies. In friendship he was more lappy, and he numbered among his intimates not only men of wit, but some of the greatest persons about the court. He died in consequence of his exertions in acting a principal part in his play, "Le Malade Imaginaire." He was labouring under a slight pulmonary complaint, and was strongly urged to postpone the representation: "What," says he, "will become of so many poor people who depend on it for the very means of subsistence. I should reproach myself for having neglected a single day to supply them with that of which they stand in need." He exerted himself with unusual spirit, and his efforts brought on the rupture of a blood-vessel, by which he was suffocated. This event happened in February, 1653, when he was only in the fifty-third year of his age. By almost the general consent of Europe, he is placed at the head of that genuine comedy, which has for its subject the ridiculous in character and manners; and it is agreed that no one ever united more pleasantry in dialogue and incident, with more good sense and penetration in selecting just objects for comic satire. He is also regarded as the great reformer of the French theatre in respect to comedy, as Corneille was in respect to tragedy. His more serious compositions, and those written in verse, are by his countrymen esteemed his master-pieces, especially:

especially the "Misanthrope" and the "Tartuffe." The latter, touching upon religious hypocrisy, excited a great clamour against him from the pretended devotees, who had interest to procure a prohibition of its second representation from the parliament. This temporary attack has not prevented the "Tartuffe" from retaining its place as one of the great ornaments of the French stage. Moliere had always a large portion of the philosophy of good sense, and rarely failed to discern the weak part of what he chose for the topic of his farcasm. He had also a just sense of propriety in the conduct of life, and in serious humour he is always the friend of honour and integrity. His own character was, in many respects, estimable. He was kind, obliging, and generous. Nevertheless, after his death, the archbishop of Paris, Harlai, a man of loose morals, without, probably, half the good qualities of the actor, but desirous of pleasing the rigorists of the Roman church, refused him Christian burial, and the king's authority was requisite to procure him private interment in a chapel belonging to the church of St. Eustace. The bigotry of the mob, whom the priests had kept ignorant to make them engines in their own cause, impeded even this obscure ceremonial, and they could not be dispersed till money was given them for the purpose. "Such," says an able biographer, "was the treatment of a man who was an honour to his country, and who will ever rank among the principal ornaments of the age in which he lived! No one was more impressed by a sense of his merit than the great Conde, who, in reply to a wretched rhymist, that had brought him an epitaph on Moliere, "Would to heaven he had presented me with thine!" He is honoured with memorials by Boileau, Voltaire, and the king, who being asked to name the first writer that had appeared in his reign, named Moliere, without the smallest hesitation. His style in prose is perfectly natural and easy: in verse he has been accounted incorrect and careless. As an actor he excelled only in comedy: his voice was feeble and indistinct, but his strong features, animated by intelligence, rendered him the perfect representative of the characters, in his own pieces, which he took upon himself. His works have been a thousand times reprinted: the best edition is said to be that of Bret, at Paris, in six volumes, with commentaries. Moreri.

MOLIERES, JOSEPH-PRIVAL DE, a celebrated French priest and mathematician, who flourished in the eighteenth century, was born at Tarascon, in the county of Foix, in the year 1677. Owing to a tender and delicate constitution, he chose for himself a life of study, and became, in a short time, famous for his learning on divers topics, but particularly in the several branches of belles lettres and mathematics. His elder brother, who had obtained considerable rank in the army, having been slain in battle in 1695, M. Moliere's parents were desirous that he should settle in the world, but his love of study rendered their persuasions ineffectual. That he might put an end to all importunity on this head, he entered at once into the church, and was ordained priest in the year 1701. He afterwards entered in the congregation of the oratory, and taught the classics and philosophy with great success in several of their seminaries. Some years after this, having read and greatly admired the works of father Malebranche, he was anxious to become acquainted with their author; and for that purpose quitted the oratory and repaired to Paris. Here he attached himself closely to that philosopher, and during his stay in the metropolis, he presented several memoirs to the Academy of Sciences, and in 1721 he was admitted into it as an adjunct to the mechanical class. Two years afterwards he obtained the professorship of the College-royal, and in 1729 rose to the

rank of associate in the Academy of Sciences. He had already published a work, entitled "Mathematical Lessons, &c.," in which the principles of algebra and arithmetical calculations are methodically laid down, and the theorems explained and demonstrated. After this, which was well received, he published four volumes of "Lectures on Natural Philosophy, containing the Elements of Physics determined solely by the Laws of Mechanics, &c." This was said to be a very whimsical performance, in which he endeavoured to unite the system of Descartes with the principles of Newton, and he attempted to rectify the ideas of the French, by the experiments of the English philosopher. In 1741 he published the first part of his "Elements of Geometry," intended as an introduction to his physical lectures. He was a very irritable man, which led him frequently into passions, of which one was the cause of his death in 1742. In other respects he was reckoned a very amiable character, but was apt to be so absent, or absorbed in his studies, as to appear almost wholly insensible to surrounding objects. His infirmity in this respect became known, and he was accordingly made the subject of depredations. A shoe-black, once finding him profoundly absorbed in a reverie, contrived to steal the silver buckles from his shoes, replacing them with iron ones. At another time, while at his studies, a villain broke into the room in which he was sitting, and demanded his money; Moliere, without rising from his studies, or giving any alarm, coolly shewed him where it was, requesting him, as a great favour, that he would not derange his papers. Moreri.

MOLIERES, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 10 miles N. of it. The place contains 2493, and the canton 6870 inhabitants, on a territory of 132½ kilometres, in seven communes.

MOLIETTA, a town of Naples, in Bari; eight miles E.S.E. of Trani.

MOLILLA, a town of Hindoostan, in Bednore; 10 miles E. of Bednore.

MOLIN, a town of Persia, in Khorasan; 16 miles N.W. of Zeuzan.

MOLINA, in *Biography*. See MOLINISTS.

MOLINA, in *Geography*, a small town of Spain, in the province of Murcia, pleasantly situated on the borders of a valley, which is watered by the Sagara. It is surrounded by considerable plantations of all kinds of trees, and fertile rich gardens, embellished with oranges, lemons, olives, pomegranates, and palms. The streets are large, straight, airy, and pleasant: the number of inhabitants is about 3000. The parish church is a handsome structure, but deformed by bad paintings; eight miles N. of Murcia.

MOLINA, a town of Spain, and capital of a lordship in New Castile, situated on a river of the same name, which runs into the Tagus, 15 miles S.W. of it; 100 miles N.E. of Madrid. N. lat. 41° 8'. W. long. 2° 1'.

MOLINA, in *Botany*, Lamarck Dict. v. 4. 227. Cavan. Monadelph. 435. t. 263, so called by the writer last mentioned, in honour of John Ignatius Molina, author of a natural and civil history of Chili, from which Jussieu has adopted several genera, with most uncouth names. See GÆRTNERA.

MOLINÆA, so denominated by Commerçon, according to Jussieu, in memory of Johannes Molinæus (Jean des Moulins,) to whose assistance Dalechamp had recourse in the composition of his laborious work, after John Bauhin had been driven away from Lyons by the bigotry of the Papists; his learning and excellent character having made him too conspicuous there for a Protestant, like his father at Paris.

(See

(See *BATHUS*.) Commerson, it seems, intended at the same time to commemorate his friend Desmoulins, author of an arrangement of the plants about Clugni, published in Durande's *Flore de Bourgogne*—Juss. 248. Willd. Sp. Pl. v. 3. 329. Lamarck Illustr. t. 305. (Trigonis; Jacq. Amer. 102? Juss. 248?)—Class and order, *Ostrandria Monogynia*. Nat. Ord. *Tribilata*, Lim. *Sapindi*, Juss. See *CUPANIA*, to which *Molina* and *Trigonis* are there referred by our excellent predecessor, the Rev. Mr. Wood, on the authority of Mr. Dryander, or rather of Lamarck. From an examination of Commerson's specimens, we have no doubt of the propriety of this measure. We find an evident style in *Molina*, though perhaps it may not be protruded till after impregnation; but this removes one of Willdenow's objections. As to the *arillus*, or tunic of the seed, Lamarck's plate, fig. i, seems to indicate one, though not perhaps so remarkable as that in Plumier's Nov. Gen. t. 19. *Cupania*, being the oldest name and unexceptionable, is necessarily preferred to the above.

MOLINE', in *Heraldry*. A cross moliné is that which turns round both ways at all extremities, though not so wide or sharp as that said to be anchored.

MOLINET, CLAUDE DU, in *Biography*, a learned French ecclesiastic and antiquary in the seventeenth century, was born at Chalons, in Champagne, in the year 1620. Having been instructed in the rudiments of learning at his native place, he was sent to Paris to go through his course of philosophy. Here he entered among the canons-regular of St. Genevieve of the order of St. Augustine, and afterwards became attorney-general of that congregation. He might have been raised to higher dignities, but his love of study and retirement induced him to decline them. Medals and antiquities of various kinds were his favourite subjects of pursuit, and having been attached to them from almost his earliest years, he had collected a considerable cabinet, which he annexed to the library of St. Genevieve, together with other rarities and curiosities. He was employed by Lewis XIV. to arrange his cabinet of medals, and augment their numbers, as well as to purchase agates and other precious stones, of which father Molinet was reckoned an excellent judge. He added more than 800 medals to the royal collection, and was amply and nobly remunerated by his sovereign's liberality, of which the library at St. Genevieve supplied abundant evidence; for the improvement of that institution was the prime object to which all the fruits of his labours were devoted. He died in 1687, at the age of sixty-seven. He is known as an author by learned notes to an edition of the letters of Stephen, bishop of Tournay; "Historia Summorum Pontificum a Martino V. ad Innocentium XI. per eorum Numismata;" "The Cabinet of the Library of St. Genevieve;" "Reflections on the Origin of Secular Canons, and on the Antiquity of Canons-Regular;" and other works which display much learning, and will afford gratification to antiquarians. Moreri.

MOLINEUX'S HARBOUR, in *Geography*, a bay on the S.E. coast of Tavai-Poenamoo, the southern island of New Zealand. S. lat. 46° 24'. W. long. 189° 50'.

MOLINISTS, in *Ecclesiastical History*, a sect in the Romish church who followed the doctrine and sentiments of the Jesuit Molina, relating to sufficient and efficacious grace. Lewis Molina, after whose name this sect was called, was a Spanish Jesuit, and professor of divinity in the university of Eborac, in Portugal. In the year 1588, he published a book, to shew that the operations of divine grace were entirely consistent with the freedom of human will; and he introduced a new kind of hypothesis to remove the difficulties attending the doctrines of predestination and liberty, and to

reconcile the jarring opinions of Augustinians, Thomists, Semi-Pelagians, and other contentious divines. Molina affirmed, that the decree of predestination to eternal glory was founded upon a previous knowledge and consideration of the merits of the elect; that the grace from whose operation these merits are derived, is not efficacious by its own intrinsic power only, but also by the consent of our own will, and because it is administered in those circumstances, in which the Deity, by that branch of his knowledge, which is called *scientia media*, foresees that it will be efficacious. The kind of prescience, denominated in the schools *scientia media*, is that foreknowledge of future contingents, that arises from an acquaintance with the nature and faculties of rational beings, of the circumstances in which they shall be placed, of the objects that shall be presented to them, and of the influence which these circumstances and objects must have on their actions.

The great antagonists of the Molinists were the Jansenists.

MOLINO, in *Geography*, a town of Naples, in Abruzzo Ultra; 13 miles S.S.E. of Aquila.

MOLINOS, in *Biography*. See *QUIETISTS*.

MOLINOSISTS, in *Ecclesiastical History*, a sect among the Romanists, who adhere to the doctrines of Molinos. These are the same with what are otherwise called Quietists.

MOLISE, in *Geography*, a city of Naples, which, though not the capital, gives name to the county or district to which it belongs; 48 miles N.N.E. from Naples. N. lat. 41° 39'. E. long. 14° 25'.

MOLISE, County of, a province of Naples, having N. Abruzzo Citra, E. Capitanata, S. Lavora, and W. those which were denominated the states of the church. Of all the provinces of Naples, this is the smallest, being about 30 miles long, and 24 wide. It is fertile in corn, wine, and saffron, and affords plenty of game and silk. The capital is Campo-basso.

MOLIVO, a sea-port town on the N.W. coast of the island of Metelin, or Mitylene, built on rocks of basalt, precisely on the spot formerly occupied by Methymna: it is commanded by a castle almost in ruins: its population may be estimated at 2 or 3000 inhabitants, as well Turks as Greeks; its territory is formed of a plain of moderate extent, very fertile, and surrounded by volcanic mountains: its productions consist principally of oil, corn, and barley; it furnishes a little wine and various fruits; and also cotton and several kitchen-garden plants; 20 miles N.N.W. of Castro.

MOLL, a town of France, in the department of the Two Nethes, and chief place of a canton, in the district of Turnhout; 10 miles from Harenthals. The place contains 3694, and the canton 15,679 inhabitants, on a territory of 265 kilometres, in five communes.

MOLLARU, a town of Hindoostan, in the circar of Rajamundry; 45 miles N.E. of Rajamundry.

MOLLE, in *Botany*, Clus. Exot. 322. Tourn. Inst. 661, a barbarous name, of Peruvian origin. See *SCHINUS*.

MOLLE, in *Geography*, a town of Norway, in the province of Drontheim. N. lat. 62° 48'. E. long. 7° 36'.

MOLLE, in *Ichthyology*, the name of a small species of whiting, common in the Mediterranean, and in the markets of Rome, Venice, &c. and called by authors the *afellus omnium minium*, and the *merlangus*. It is a species of *Gadus*; which see.

MOLLE, Ital., *Mol*, Fr., *Mollis*, Lat. In the primitive scale of Guido, the sound B, when flat in the hexachord of F, was called *B melle*, sweet, soft, compared with B in the

hexachord of G, when it was called *B-durum*, harsh, and *B-quadro*, square, from the form of the *B*, which was made like a Gothic *B*, or rather *b* for half; a character still retained by the Germans for *B* natural. In solmifation, *B-durum* implies more than *B ♯*, and *B molle*, *B b*.

MOLLER, HENRY, in *Biography*, a learned German Lutheran divine in the sixteenth century, was born at Hamburg in the year 1530. He officiated some time as pastor to a church in the landgraviate of Hesse with great reputation, and was honoured with the degree of doctor of divinity. He was much celebrated for his skill in biblical literature, and he particularly excelled in the knowledge of the Hebrew and Chaldee languages. During fourteen years he filled the chair of professor of the Greek and the Oriental languages in the university of Wirtemberg, of which he was probably deprived for refusing submission to the famous "Form of Concord." He died at Hamburg in 1589, in the sixtieth year of his age. He was author of "Commentaries" on the book of Psalms, and the prophecy of Isaiah. He was likewise known as a poet. Moreri.

MOLLERUSA, in *Geography*, a town of Spain, in Catalonia; 10 miles E.N.E. of Lerida.

MOLLIDON, a town of Hindooistan, on the Doob; 18 miles N.N.W. of Etaya.

MOLLIENS-VIDAME, a town of France, in the department of the Somme, and chief place of a canton, in the district of Amiens. The place contains 836, and the canton 12,456 inhabitants, on a territory of 232½ kilometres, in 29 communes.

MOLLINARI, SIMONE, in *Biography*, was maestro di capella del Duomo at Genoa, and published, in 1605, "Concerti Ecclesiastici," as they are called; but these, which are in Dr. Aldrich's Collection of Music in Christ-church, Oxon, were only masses and motets, accompanied by instruments, which, about this time, became very common in Italy.

MOLLIS PORTIO. See PORTIO.

MOLLITIES OSSIUM. This curious and extraordinary disease may be defined to be a morbid softness and flexibility of the bones, arising from a deficiency of the phosphat of lime in their structure. Whether their firmness and stability are lost, in consequence of this matter being too abundantly absorbed, or of its not being duly and sufficiently secreted, is a question which we cannot undertake to resolve. Some writers treat of the mollities ossium with rickets; but although it is true, that, in both these diseases, the bones lose their natural solidity and proper shape, it appears to us that the two affections deserve a marked distinction, inasmuch as rachitis is an affection peculiar to childhood, and the bones only change their shape gradually; whereas the mollities ossium has frequently been observed to afflict adults, and occasion such a softness of the bones, that, in the extreme stage of the disease, they may be at once bent in any direction whatsoever.

The following case, drawn up by Mr. Gooch, will serve to impress the reader with an idea of the disorder: "Mary Hayes, of Stoke-Holy-Crofs, near Norwich, in Norfolk, was born January 11, 1718, had never been married, and always lived a regular, temperate life. Her father was unhealthy, but it is not known to what disease he was subject; her mother was healthy, and she herself was always looked upon as a strong healthy girl, till about fifteen years of age, when she fell into the green sickness, and took various medicines to no purpose. She had no other complaints till October, 1748, when she was seized with pains, universally attended with feverish symptoms; and thus she continued some weeks, after which the pain was chiefly confined to her legs and thighs, but not increased by external pressure.

"She broke her leg in June, 1749, as she was walking from her bed to her chair, without falling down, and heard the bones snap. The fracture was properly treated by one of the ablest surgeons, and due regard had to her indisposition. No callus was generated; but in a few months the bones grew flexible, from the knee to the ankle. Those of the other leg and thigh were visibly affected soon afterwards, in the like manner; and both legs and thighs then became œdematous, and subject to be excoriated, discharging a thin yellow ichor. About this time," says Mr. Gooch, "I first saw her with the surgeon who had the care of her.

"The winter after breaking her leg she had symptoms of the scurvy, and bled much at the gums.

"Many eminent physicians prescribed for her, but without any effect, unless the regularity of her menstruation, for the last eighteen months, be ascribed to chalybeate medicines, which were part of their prescriptions; though the same kind of medicines were formerly prescribed, and long continued, without having that effect, even when she was in a condition to take exercise.

"About a year before her death she was removed to the parish she belonged to, where I had an opportunity of visiting her often, and observing the progress of her disease. She told me she had found but little alteration of her complaints in general, for some time past, and thought her appetite and digestion rather mended. She breathed with difficulty, and her thorax appeared so much straightened, as necessarily impeded the expansion of the lungs. Her spine was much distorted, and any motion of the vertebræ of the loins excited extreme pain. Her legs and thighs being quite useless, she was confined to her bed in a sitting posture. The bones she rested upon, having lost their solidity, were much spread, and the ends of her fingers and thumbs, by frequent efforts to raise herself, were become very broad, with a curvature of their phalanges. *She now measured but four feet, though before this disease she was five feet and a half high, and well shaped.*

"From this time," says Mr. Gooch, "I observed the flexibility of her bones became gradually more general, and the difficulty of breathing increased, with a wasting of her flesh. For the last four months of her life she had a total suppression of the menstrual discharge, and a great tendency in her legs to mortify, which had long been anasarcaous, and excoriated almost all over. She retained her senses perfectly to the last, and but a few minutes before she died, talked concerning her miserable condition and approaching end, in a very rational and composed manner, with her nurse, who perceived no signs of the change which was just at hand; then reclined her head, and expired instantly without a groan.

"Two days after her death, which happened on Feb. 6, 1753, her limbs being first well stretched out, she was measured, and found wanting, in her natural stature, two feet and two inches! I opened the abdomen and thorax, removing the sternum entirely, with some portion of the ribs, in order to gain at once a full view of those cavities, and to observe how the viscera contained in them had obstructed each other in their respective functions, as well as to inspect the state of them. The heart and lungs were found, but flaccid, and much confined in their motion, to which the enormous size of the liver contributed in some measure, extending quite across the abdomen, and bearing hard against the diaphragm, &c. The lungs did not adhere to the pleura, nor was the liver scirrhus; it was faulty only in its bulk. The mesentery was found, except one large scirrhus gland in it. The spleen was extremely small. Nothing else was found observable in these cavities.

"All her bones, except her teeth, were more or less affected, and scarcely any would resist the knife. Those of the head, thorax, spine, and pelvis, were nearly of the same degree of softness. Those of the lower extremities were much more dissolved than those of the upper, or of any other part. They were changed into a *parenchymous* substance, like soft dark-coloured liver, without the least offensive smell. I cut through the whole length, without turning the edge of the knife, and found less resistance than firm muscular flesh would have made, meeting only here and there with bony laminæ, as thin as any egg-shell.

"Those bones were most dissolved, which, in their natural state, are most compact, and contain most marrow in their cavities, &c."

Mr. Gooch further acquaints us, that the periosteum was rather thicker than ordinary; the cartilages thinner, but no where in a state of dissolution like the bones. He shewed specimens of the dissolved bones to sir John Pringle, in London, and then sent them to Dr. Hunter, who occasionally exhibited them in his anatomical lectures.

Mr. Gooch also sent some of the same substance to an ingenious chemist, desiring him to analyse it; the latter "could discover neither acid nor alkali prevailing in it; but that it contained near seven-eighths of an oleaginous substance, with a small portion of earth."

July 1753, Mr. Gooch saw a similar case to this in a woman, aged twenty-five, in the workhouse at Norwich, under the care of Mr. Swift, an ingenious man, and a very able surgeon. In this example, the ribs, having become exceedingly soft, "fell (to use Mr. Gooch's words) with the sternum flat upon the lungs," and obstructed respiration to such a degree, that when this gentleman saw her, she lay panting for life. In the other case, of which the narrative is given above, the ribs and sternum turned outwards, and the respiration was not quite so much obstructed.

Cases of the mollities ossium are recorded in the Philosophical Transactions; Mém. de l'Acad. Royale des Sciences; Act. Hafniens; German. Ephem. Forestus and Saviard have also detailed cases of the same disease; and a most remarkable example was published by Morand, at Paris, in 1752.

The causes of this singular disorder have hitherto baffled investigation. In the famous case of Madame Supiot, the patient had been in the habit of eating an extraordinary quantity of salt, and this circumstance was immediately suspected as the cause of the disease; yet, in other cases, the immoderate use of salt could not fall into suspicion, and Madame Supiot herself certainly continued to grow worse and worse, long after she had relinquished the custom of taking so much salt with her victuals. We are, therefore, justified in concluding that the eating of this substance had nothing to do with the production of the disease. Were salt capable of having this effect, sailors and others, who live so much on salted provisions, ought frequently to be afflicted with mollities ossium; yet this does not appear to be the fact.

With regard to the treatment, it does not appear that any successful method has been discovered. The deficiency of the phosphat of lime in the structure of the affected bones, has led to the suggestion of exhibiting this substance as a medicine. This may easily be done; but how to make the fecerning arteries deposit it in the bones is a more baffling consideration. We know of no cases, in short, exemplifying the efficacy of this plan, though it is both rational and free from danger.

Madder, from its known property of tinging the bones red, has been supposed to have a particular action on the

osseous system; but, says Boyer, it is now well ascertained, that it has no greater effect in rickets (which is a disease at all events analogous to mollities) than any other bitter plant. *Malad. des Os*, tom. ii.

MOLLUGO, in *Botany*, a name in Pliny, book xxvi. chap. 10, which he indicates as belonging to a plant rough both in foliage and flavour. Linnæus retains it for a genus of a smooth and tender habit, to which, if derived from *mollis*, it would be most suitable.—Linn. Gen. 42. Schreb. 58. Willd. Sp. Pl. v. 1. 491. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 184. Juss. 300. Lamarck Illustr. t. 52. Michaux Boreali-Amer. v. 1. 77. Gærtn. t. 130.—Class and order, *Triandria Trigynia*. Nat. Ord. *Caryophyllea*, Linn. Juss.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, slightly spreading, permanent leaves, internally coloured. *Cor.* none. *Stam.* Filaments three, bristle-shaped, shorter than the calyx, approaching the pistil; anthers vertical, oblong, cloven at the base. *Pist.* Germen superior, ovate, with three furrows; styles three, very short; stigmas obtuse. *Peric.* Capsule ovate, corrugated, of three membranous pellucid valves, and three cells; the partitions from the middle of each valve. *Seeds* numerous, roundish-kidney-shaped, polished.

Ess. Ch. Calyx of five leaves. Corolla none. Capsule of three cells and three valves. Seeds numerous.

1. *M. oppositifolia*. Opposite-leaved Mollugo. Linn. Sp. Pl. 131. (*M.* n. 53; Linn. Zeyl. 21. Jeonpala; Herm. Zeyl. 4. *Alfinc spergulae facie Bengalensis, foliis angustis ad genicula binis, flosculis autem plurimis ad caulem radiatis, semine minutissimo fulvo*; Pluk. Phyt. t. 75. f. 6.)—Leaves opposite, lanceolate. Branches alternate. Flower-stalks lateral, several together, single-flowered. Native of Ceylon. Linnæus describes it as "an annual herb, with long, diffuse, smooth, alternate branches. Leaves opposite, lanceolate, smooth, running down into footstalks. Flower-stalks several, axillary, equal, capillary, single-flowered. Calyx of five leaves."—Plukenet's figure, quoted at the suggestion of Burmann, answers pretty well to this description; and though it has the aspect of an *Hedyotis*, the inferior calyx, proper to *Mollugo*, is sufficiently indicated. According to Hermann this herb is eaten in salads by the vulgar.

2. *M. striata*. Close-leaved Mollugo. Linn. Sp. Pl. 131. Burm. Ind. 31. t. 5. f. 3. (*Alfinc multifolia floribunda glabra, ex sinu Bengalensi, foliis subrotundis, flore majore*; Pluk. Almagest. 21. t. 257. f. 2.)—Leaves about four together, lanceolate. Flowers in panicle clusters, drooping. Stem erect, angular.—Native of Java and Bengal. Root fibrous, annual. Stems several, from two to twelve inches high, erect, slender, angular, smooth, bent at the lower joints, leafy. Leaves three, four, or more, at each joint, lanceolate, entire, smooth, of a pale glaucous green, tapering at the base into a sort of footstalk; in starved plants broader and shorter. *Stipulas* in pairs, small, membranous, roundish. Flowers very small, whitish, in long, slender, almost capillary, smooth clusters, collected into slight panicles; the partial stalks bent downward. Capsule roundish, very thin and membranous. Seeds almost black.

3. *M. hirta*. Hairy Mollugo. Thunb. Prodr. 24.—Decumbent. Leaves four together, obovate, hairy. Native of the Cape of Good Hope. Annual. Of this we have no further knowledge.

4. *M. pentaphylla*. Five-leaved Mollugo. Linn. Sp. Pl. 131. (*Alfinc ramosa procumbens quadrifolia, ad radicem polyphylla*; Burm. Zeyl. 13. t. 8. f. 1.)—Leaves obovate; those of the stem four or five at a joint. Panicles cymose, somewhat racemose.—Native of various parts of the East Indies. This differs from *M. striata* in having numerous

Stems spreading circularly, nearly prostrate, and obovate *leaves*. The *flowers* are twice as large, with a tawny hue, at least when dried, and compose more dense, level-topped, forked or cymose *panicles*, whose branches are scarcely racemose, and by no means elongated.

5. *M. nudicaulis*. Naked-leaved Mollugo. (*Alfne foliis ad radicem politis*; Burm. Zeyl. 14. t. 8. f. 2.)—Leaves obovate, all radical. Stems panicled, forked, naked. Flowers four-cleft. Native of Ceylon; *Burmah*; of Sierra Leone; *Afzelius*. Linnæus confounded this with the last, not perceiving that Burmann had figured two very different plants in his *tab.* 8, without numbering them; and he cites t. 8. f. 1, 2. This by an error of the press is become 12, which Willdenow copies. Burmann refers to a wrong synonym in Sloane, but he describes the present species very well, as having all the *leaves* at the root, with very long, radical, *flower-stalks*, and four-cleft *flowers*, all which circumstances distinguish it from the last.

6. *M. Spergula*. Spurrey Mollugo. Linn. Sp. Pl. 131. Burm. Ind. 31. t. 5. f. 4. (*Pharnaceum Mollugo*; Linn. Mant. 561. Willd. Sp. Pl. v. 1. 1508; but not Linn. Sp. Pl. 389, which is well figured in Herm. Lugd.-Bat. t. 21, and from which it appears, by his Mant. 562, Linnæus meant to distinguish the present species, intending probably to have called it *P. Spergula*, *P. Mollugo* being an error of the pen in p. 561.)—Leaves obovate, rough-edged, four or five together. Branches alternate, hairy at one side. Stalks axillary, single-flowered.—Native of the East Indies. *Stems* procumbent, alternately branched, leafy, round, smooth, except a hairy lateral line. *Leaves* four or five at each joint, obovate, spreading, from two lines to half an inch long, rough or toothed at the edge; on short, often woolly, *foot-stalks*. *Flower-stalks* axillary, solitary to each leaf, simple, single-flowered, the length of the leaf. Linnæus describes minute, linear, cloven *petals*, and five barren filaments, alternate with the five fertile ones, all which is hostile to the character of *Mollugo*; and removes this species to *Pharnaceum* at least, if not elsewhere. We merely describe it here to correct the above errors, and as being what he really meant for *M. Spergula*.

7. *M. verticillata*. Whorled Mollugo. Linn. Sp. Pl. 131. Willd. n. 5. (*M. Spergula*; Linn. Syst. Nat. ed. 10. v. 2. 881. *Alfne spergula mariana, latiori folio, floribus ad nodos, pediculis curtis circa caulem insidentibus, calyculis elegantè punctatis*; Pluk. Mant. 9. t. 332. f. 4. *A. erecta pentaphylla, flore albo*; Burm. Zeyl. 13. t. 7. *A. procumbens, gallii facie*; Ehret. Pict. t. 6. f. 3.)—Leaves whorled, spatulate, unequal. Branches alternate, smooth. Flower-stalks shorter than the leaves, single-flowered.—Native of Virginia. Cultivated in the English gardens in 1748, when Ehret delineated it. This species is a hardy annual, flowering from June to August. The *stems* are prostrate, smooth, much branched, and widely spreading. *Leaves* obovate, acute, entire, smooth, tapering into a footstalk; their length from half to one and a half inch. *Flower-stalks* several together, lateral, not axillary, capillary, deflexed, much shorter than the leaves. *Seeds* very prominent through the capsule, marked with dorsal furrows.

The botanical history of this genus is so confused, that though we have cleared it up in some degree, with the necessary assistance of the Linnæan herbarium, we are by no means certain that nothing more remains to be done. The species require to be confronted throughout with those of *Pharnaceum*, a genus scarcely differing but in number of itaments, the most trivial of all possible characters in this tribe. See PHARNACEUM. S.

MOLLUSCA, in *Natural History*, the name of the se-

cond order of the Linnæan class of Vermes; and it includes animals that are naked; and furnished with tentacula or arms: for the most part they are inhabitants of the sea; and by their phosphorescent quality illuminate the dark abyss of the waters. (See LUMINOUS Animals.) This order, which comprises simple animals furnished with limbs, is separated into distinct divisions, classed according to the situation of the mouth, and the structure of the body; thus:

In division A the mouth is placed *above*; this division includes the following genera:

Aëtinia,	Mammaria,
Afcidia,	Pedicellaria,
Clava,	Salpa.
Dagylia,	

In division B the mouth is placed *before*; and in this are the

Derris	and	Pterotrachea.
--------	-----	---------------

In division C the mouth is placed *before*; and the body has a lateral perforation. In this there are four genera, *viz.* the

Doris,	Limax,
Laplytia,	Tethys.

In division D the mouth is *before*; but the body is furnished with feelers on the fore-part. There are two genera only, *viz.*

Ictothuria	Terebella.
------------	------------

In division E the mouth is *before*; and the body furnished with arms. Of these there are seven genera, *viz.*

Clio,	Scyllæa,
Lernæa,	Sepia,
Lobaria,	Triton.
Onchidium,	

In division F the mouth is *before*; and the body furnished with peduncles or feet. In this there are the following five genera:

Amphitrite,	Nereis,
Aphrodite,	Spio.
Nais,	

In the last division G, the mouth is placed *beneath*; and generally central. There are five genera in this, *viz.*

Asterias,	Medusa,
Echinus,	Physophora.
Lucernaria,	

See VERMES.

MOLLUSCUM, in *Medicine*, an appellation applied by Dr. Willan to a singular cutaneous disease, of which there are not many cases recorded. It consists of numerous soft tubercles, containing an atheromatous matter, which are of various sizes, from that of a vetch to that of a pigeon's egg, and of different forms, some being sessile, and some attached by a neck. It is not uncommon to meet with one or two of these mollusca; but the singularity above alluded to is, that they sometimes grow all over the surface of the body, and that without any disorder of the general habit. They have no tendency to ulceration or suppuration, but continue permanent through life, having apparently no natural termination. The knife or ligature might be employed for the removal of those which are attached by a peduncle; but the great number of these, independently of those which are sessile, deters from the attempt.

MOLMAN, in our *Old Writers*, a man subject to do service. It is applied to the servants in a monastery.

MOLMA-

MOLMASECA, in *Geography*, a town of Spain, in the province of Leon; 20 miles W. of Astorga.

MOLMUTIN, or **MOLMUTIAN LAWS**, the laws of Dunwallo Molmutius XVI. king of the Britons, who is said to have begun his reign four hundred and forty years before the incarnation.

He was the first who published any laws in this land; and they continued famous therein till the time of William the Conqueror.

MOLNPA'TTY, in *Geography*, a town of the island of Ceylon; 18 miles N.W. of Trincomalee.

MOLOCH, in *Mythology*, the chief and peculiar deity of the Ammonites, who are said, by Vossius and others, to have worshipped the sun under this appellation, and to have sacrificed their children to him. In the scripture it is frequently asserted that the "Ammonites passed their seed through fire unto Moloch." As to the meaning of this expression there is a considerable disagreement among ancient and modern authors. The Jewish writers very generally maintain, that the children were merely carried or led between two fires, by way of purification; whereas the Christian writers have been of opinion, that they actually burnt their children by way of sacrifice to this grim idol. Near Jerusalem there was a place in which this horrid custom was observed; it was called the valley of the sons of Hinnom, so named, as it is said, from the shrieks of the children that were sacrificed; and also Topheth, from a Hebrew word "toph," signifying a drum or tabret, which they used, among other instruments, to drown the dreadful outcries of the unhappy victims. The Canaanites in general were, in the days of Moses, become incorrigible idolaters, and they are accused of offering human sacrifices to Moloch. See the passage above cited from Levit. xviii. 21. From them this detestable worship was transmitted to their descendants the Phœnicians; and as the Carthaginians were a colony that came from Phœnicia, the first gods of Carthage were the same as those who were adored at Tyre and Sidon. The latter people are known to have worshipped Saturn, and Saturn was the same with Moloch, to whom they sacrificed their children. Moloch was represented among the Ammonites under the monstrous figure of a man and a calf. About the feet of the statue were constructed several furnaces, into which they threw the children whom they offered up to that god, and their cries were drowned, as we have already observed, by drums and other musical instruments. Who this Moloch was, has been a subject of various conjectures. Some say that he was the same as Priapus; others assert that he was the sun; but the most common opinion has been, that he was the same with Saturn; and as Saturn is thought to have been Abraham, it has been concluded that the worship of Moloch was formed upon the imperfect accounts which the pagans had collected concerning that ancient patriarch; and that all the circumstances of the sacrifices offered to Moloch were expressive of Abraham's adventures.

MOLOCHATH, in *Ancient Geography*. See **MULUCHA**.

MOLOCHI, in *Geography*, a town of Naples, in Calabria Ultra; three miles N.E. of Oppido.

MOLOCHITES, in *Natural History*. See **MALACHITES**.

MOLODIVE, in *Geography*, a town of the island of Ceylon, on a tongue of land separated by a narrow channel from the E. coast; 46 miles N. of Trincomalee.

MOLOGA, a town of Russia, in the government of Jaroslavl, at the union of the river Mologa with the Volga; 65 miles N.W. of Jaroslavl. N. lat. 58°. E. long. 38° 22'.

MOLOPS, a word used by some medical writers to express the purple spots which appear upon the skin in malignant fevers.

MOLOS, in *Geography*, a town of Arabia, in the province of Yemen; 16 miles N.N.E. of Jerim.

MOLOSSES, **MOLASSE**, or *Melassé*, that gross, yet fluid matter remaining of sugar, after refining, and which no boiling will bring to a consistence more solid than that of syrup; hence also called *syrup of sugar*.

In the manufacture of sugar in the West Indies, the molasses, not improperly called the treacle of sugar, is obtained by the following process. The curing-house, which is a large airy building, is provided with a capacious molasses cistern, the sides of which are sloped and lined with tarras or boards. Over this cistern there is a frame of massy joist work without boarding. On the joists of this frame empty hogsheds without headings are ranged. In the bottoms of these hogsheds eight or ten holes are bored, through each of which the stalk of a plantain leaf is thrust, six or eight inches below the joists, and which is long enough to stand upright above the top of the hoghead. Into these hogsheds, the mass from the cooler is put, which is called *potting*; and the molasses drains through the spongy stalk and drops into the cistern, from which it is occasionally taken for distillation. For other particulars, see the article **SUGAR**; and particularly the method of *claying* sugar.

The term *molasses* has been used to denote the sediment of one kind of sugar called *chypre*, or brown sugar, which is the refuse of other sugars not to be whitened, or reduced into loaves. (See **SUGAR**.) Molasses have been much used in Holland among poor people, for the preparation of tobacco, and also instead of sugar.

MOLOSSES, Artificial. There has been found a method of making molasses from apples, without the addition of sugar. The apple that succeeds best in this operation is the summer-sweeting of a middle size, pleasant to the taste, and so full of juice, that seven bushels will yield a barrel of cyder. The manner of making it is this: the apples are to be ground and pressed, then the juice is to be boiled in a large copper till three quarters of it be evaporated; this will be done with a moderate fire in about six hours, with the quantity of juice above mentioned; by this time it will be of the consistence and taste as well as the colour of molasses.

This new molasses serves to all the purposes of the common kind, and is of great use in preserving cyder. Two quarts of it put into a barrel of racked cyder, will preserve it, and give it an agreeable colour.

The invention of this kind of molasses was owing to Mr. Chandler, of Woodstock, in New England, who living at a distance from the sea, and where the common molasses was very dear and scarce, provided this for the supply of his own family, and soon made the practice general among the people of the neighbourhood. It is to be observed, that this sort of apple, the sweeting, is of great use in making cyder, one of the very best kinds we know being made of it. The people in New England also feed their hogs with the fallings of their orchards of these apples; and the consequence of this is, that their pork is the finest in the world. Phil. Trans N^o 374. p. 230.

MOLOSSES Spirit, a very clean and pure spirit, much used in England, and made from molasses or common treacle dissolved in water, and fermented in the same manner as malt or the common malt-spirit. If some particular art is not used in the making of this, it will not prove so vinous as the malt-spirit, but more flat and less pungent and acid, though otherwise much cleaner tasted, as its essential oil is of a less nauseous flavour. Whence if good fresh wine leys, abounding

in tartar, be duly fermented in the solution made thin for that purpose, the spirit will by that means become much more vinous and brisk, and approach more to the nature of the foreign spirits.

After the first distilling of molosses spirits from the wash into low wines, it is to be rectified, and in the succeeding rectifications proper additions are to be made. Alkaline salts, so common in the rectifying of the malt-spirits, must be avoided in this case, as not at all suiting this spirit, and the neutral ones only must be used, such as sandiver, common decrepitated salt, sal enixum Paracelsi, and the like; but upon the whole nothing so considerable is to be expected from these salts, as from a careful rectification in balneo Mariae, without any other admixture; by this alone repeated two or three times with fresh water each time, the spirit will at once be made fit for the nicest uses.

Where the molosses spirit is brought to the common proof-strength, if it be found not to have enough of the viscosity in it, it will be very proper to add to it some good spiritus nitri dulcis; and if the spirit be clean worked, it may by this addition alone be made to pass on ordinary judgments for French brandy.

When newly distilled, this spirit, like all others, is colourless, and limpid as water; but our distillers always give it the same sort of yellow tinge, which the foreign spirits are found to obtain from the casks in which they are sent over. They have many ways of giving this colour extempore; but the two most in use are, either by an extract of oak-wood, or by burnt sugar.

Molosses spirit being occasionally dearer than that of malt, it is frequently met with basely adulterated with a mixture of that spirit, and indeed seldom is to be bought without some dash of it. Many have a way of mixing malt in the fermenting liquor; by this the yield of the whole is greatly increased, and the maker may assure the buyer that the spirit is pure as it ran from the worm.

England is the principal place where this spirit is made at this time: it was at one time prepared in great quantities in France, especially on the river Loire; but it has been forbidden there under a severe penalty. In Holland also they have it not, on account of the high duty laid upon treacle in favour of their own sugar-bakers.

We meet with very little of molosses spirit reduced to the strength of alcohol or spirit of wine, though, when rectified to this state in a proper manner, it is very little inferior to the real alcohol of wine, the name of which is so well known among us, though the thing itself is perhaps never seen here. All that we call spirit of wine being no other than malt spirit reduced to an imperfect alcohol, or a spirit almost totally inflammable.

Great quantities of molosses spirit are used in the adulterating of brandy, rum, and arrack; and great quantities are used alone in the making of cherry-brandy and other drams by infusion, in all which many prefer it even to the foreign spirits.

In most of the nice cases in our compound distillery, the molosses spirit supplies the place of a pure and clean malt-spirit, which we have not yet the way of producing in the large way to advantage. Our cinnamon, citron, and other fine cordial waters, are made with it; for the malt spirit would give these a very disagreeable flavour.

There is also another use to which this spirit serves extremely well, and in which even a foreign spirit that has any remarkable flavour will not do so well; this is the making of the extemporaneous wine, which some people are so fond of. See *Extemporaneous WINE*.

It gives a yellow stain to the hands, or other substances

dipped into it: and may therefore be of use in dyeing. It is possible also, that the vinegar-makers may find use for it in their way; but the most advantageous of all its uses is to the distiller himself, a quantity of it added to new treacle intended for fermentation will be of great use in the process, and increase very considerably the quantity of spirit; but the proportion in regard to the new matter must not be too great. Shaw's Essay on Distillery.

For the method of extracting spirits from molosses in the West Indies, see the article RUM.

MOLOSSIS, in *Ancient Geography*, an inland province of the ancient kingdom of Epirus; which, according to Scylax, was only 40 stadia, or furlongs, in compass. It derived its name from Molossus, the son of Pyrrhus and Andromache, and contained the following cities, viz. Dodona, (which see,) Passaron, Tecmon, Phylace, and Horreum. See EPIRUS.

MOLOSSUS, in the *Greek and Latin Poetry*, a foot consisting of three long syllables, as *audiri, constabant, virtutem*. It takes its name either from a dance in use among the people called Molossi, or Epirotæ; or from the temple of Jupiter Molossus, where odes were sung in which this foot had a great share; or else because the march of the Molossi, when they went to the combat, was composed of these feet, or had their cadence. The same foot was also called among the ancients, *Vertumnus, extensipes, hippius, & canius*. Dion. iii. p. 475.

MOLRAUZEPOLLAM, in *Geography*, a town of Hindoostan, in the Carnatic; 10 miles N.W. of Madras.

MÖLSEN, or *Hohen MÖLSEN*, a town of Saxony, in Thuringia; 28 miles N.E. of Weimar. N. lat. 51° 10'. E. long. 12° 5'.

MOLSHEIM, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Strasburg; 10 miles W.S.W. of Strasburg. The place contains 2534, and the canton 16,072 inhabitants, on a territory of 167½ kilometres, in 18 communes. N. lat. 48° 32'. E. long. 7 34'.

MOLTA, or MOLTURA, a duty or toll paid by vassals to the lord for grinding their corn at his mill.

MOLTCHANA PIATSKIA, in *Geography*, a town of Russia, in the government of Tobolsk, on the Oby; 80 miles S.S.E. of Narim.

MOLTCHANOVKA, a town of Russia, in the government of Tobolsk, on the Oby; 92 miles S.S.E. of Narim.

MOLTEN GREASE, in the *Manege*. See GREASE.

MOLTER, in *Rural Economy*, the toll taken at a mill. See MOULTER.

MOLTIFAO, in *Geography*, a town of Corsica; 15 miles N. of Corte.

MOLTING, or MOULTING, the falling off or change of hair, feathers, skins, horns, or other parts of animals, happening in some annually, in others only at certain stages of their life. See MOULTING.

The generality of beasts molt in the spring.

The molting of a hawk is called *mewing*.

The molting of a deer is the quitting of his horns in February or March.

The molting of a serpent is putting off his skin. See EXUVIÆ.

MOLTON, SOUTH, in *Geography*, an ancient market and borough town in the hundred of the same name, and county of Devon, England, is situated on an eminence near the western banks of the river Moule, at the distance of 29 miles from Exeter, and 182 from London. Previously to the Norman conquest

conquest it formed part of the royal demesnes. It then came into the possession of private persons; and in the reign of Richard II. reverted to the crown. It was afterwards purchased by the burgessea; and the civil government is now vested in a mayor, eighteen capital burgessea, a recorder, town clerk, and two serjeants at mace. The town was represented in parliament in the thirtieth year of Edward I.; but no return has been made since that period. It is also remarkable for having been constituted an episcopal see, by an act passed the twenty-sixth of Henry VIII.; but it does not appear that any bishop was ordained. The parish church is a spacious structure, and contains several monuments. The guildhall is a convenient fabric; and the market place is extensive and well built. The number of houses was, in the year 1801, returned to parliament as 572, occupied by 2753 persons: of these many derive employment from the manufacture of ferges, shalloons, and felts; and in obtaining lime from the various kilns in the neighbourhood. Provision is made for the education of the children of the more respectable natives, by a well-regulated free-school, founded in 1614, and of those of an inferior class by a charity-school: in the former the late judge Buller acquired the rudiments of that extensive legal knowledge, by which he afterwards became so distinguished. The town has the privilege of six annual fairs, and a weekly market on Saturday.

South Molton was the birth-place of the late Rev. Samuel Badoock, who acquired considerable literary reputation by his critiques on the authenticity of Chatterton's poems, and on other publications. He died in 1788, aged 41.

Between the towns of South Molton and Chumleigh, the Roman station Termolus is supposed to have been situated. It has been conjectured to have been near the junction of the rivers Taw and Mole; but antiquaries have not been able to identify the precise spot. The vicinity affords many remnants of Roman antiquity. Beauties of England and Wales, vol. iv.

MOLUCCA BALM, in *Botany*. See MOLUCCELLA.

MOLUCCA Bean. See BEAN.

MOLUCCA Nuts. See GUILANDINA and BEAN.

MOLUCCA Islands, in *Geography*, islands in the East Indian sea, first discovered by the Portuguese in the year 1510. Strictly speaking, this appellation comprehends only the five following islands, viz. Ternat, Tidore, Motir, Makian, and Bakian or Batchian; but since the kings of the Moluccas have possessed territory in Gilolo, and other adjacent isles, and as the term *Molucca* islands is considered as synonymous with that of *Spice* islands, the appellation has been extended. (See *Spice Islands*.) The Moluccas, properly so called, having been discovered by the Portuguese, afforded to the Spaniards an inducement to make their first circumnavigation under the conduct of Magellan, a Portuguese commander. These two nations for some time contested the right of possessing these islands, till at length they were surrendered to the Portuguese, and from them they were wrested in 1607 by the Dutch. The opulent commerce in these seas was also claimed by the English; and in 1619 a treaty was signed, which declared the Moluccas, as well as Amboyna and Banda, common to both, so that the English were to have $\frac{1}{3}$ d of the produce and the Dutch $\frac{2}{3}$ ds: whilst each of these powers contributed its respective proportion for defending the islands from invaders. But a most atrocious plot was soon framed and carried into execution by the Dutch for rendering themselves independent of all competitors. As each of the islands will be described under its proper appellation, we shall not enlarge here.

MOLUCCELLA, in *Botany*, called *Molucca* by Tournefort, because it was supposed to grow in the Molucca

islands. The name, as Linnæus has altered it, may be tolerated, but it is none of his best.—Linn. Gen. 266. Schreb. 392. Willd. Sp. Pl. v. 3. 128 Mart. Mill. Dict. v. 3. Sm. Prod. Fl. Græc. v. 1. 415 Ait. Hort. Kew. ed. 2. v. 3. 410. Juss. 115. Lamarck Illustr. t. 510. Cærtn. t. 66. (Molucca; Tournef. t. 88.)—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, very large, turbinate, gradually terminating in a very wide, bell-shaped, toothed or spinous, incurved, permanent limb. Cor. of one petal, ringent, smaller than the calyx; tube and throat short; upper lip erect, concave, undivided; lower cleft into three segments, of which the middle one is most prominent and emarginate. Stam. Filaments four, under the upper lip, two of them shorter; anthers simple. Pist. Germen superior, four-cleft; style in size and situation like the filament; stigma cleft. Peris. Capsule none. Fruit top-shaped, truncated, in the bottom of the open calyx. Seeds four, convex on one side, angulated on the other, broader upwards, truncated.

Obs. *M. spinosa* has the calyx with seven long spines; *M. lævis* has five small ones; and the calyx of *M. frutescens* is furnished with twelve spreading spines. In some species the calyx is longer than the corolla, in others shorter.

Ess. Ch. Calyx bell-shaped, dilated, much wider than the corolla, spinous.

1. *M. spinosa*. Linn. Sp. Pl. 821. Fl. Græc. t. 567, unpublished. (Molucca spinosa; Ger. em. 691.)—Upper lip of the calyx lanceolate, with a very long point; lower rounded, with seven spines. Leaves on stalks, ovate, palmate and cut.—A native of the Levant, and gathered by Dr. Sibthorp on mount Parnassus. It flowers in July and August.—Root annual. Stem about four feet high, erect, smooth, square, purplish, branched at the bottom. Leaves opposite, on longish stalks, strongly veined, smooth, dark green, palmate and cut. Flowers ten or twelve in a whorl, remarkable for the large pyramidal, upper tooth of their calyx, and the many radiating spines of the lower border. Corolla white, its upper lip hairy; palate streaked with purple.

2. *M. lævis*. Linn. Sp. Pl. 821. Fl. Græc. t. 566, unpublished. (Melissa Molucca lævis; Ger. em. 691.)—Calyx bell-shaped, slightly five-toothed; teeth equal, minutely spinous. Leaves on longish stalks, roundish or ovate, toothed.—Native of Syria, and found by Dr. Sibthorp between Smyrna and Bursa. Time of flowering like the last. Root annual. Stems about three feet high, branched, smooth, square, variegated with purple. Branches opposite, smooth. Leaves on long stalks, roundish, deeply notched or toothed, smooth, light green. Flowers axillary, about six in a whorl, the numerous whorls crowded together into a long spike, conspicuous for the rounded, reticulated calyxes which become tawny by age. Corolla white with a lilac tinge, shorter than the calyx.

3. *M. tuberosa*. Willd. n. 3. Pallas. It. v. 3. app. n. 101. t. T.—Calyx funnel-shaped, five-toothed; teeth equal, pointed. Stem-leaves nearly sessile, oblong wedge-shaped, toothed.—Native of muddy places, on hills in the south of Tartary, flowering in May and fruiting in July.—Root perennial, large, composed of two or three ovate knobs, occasionally simple, like a radish, and somewhat bitter. Stem erect, branched, jointed, divaricated, square, smooth, hairy at the joints. Radical-leaves on long rough stalks, ovate, deeply notched; those of the stem almost sessile, wedge-shaped, veined, nearly smooth. Flowers about three or four

four in a whorl, forming a loose spike. *Corolla* bright yellow, twice as long as the calyx.

4. *M. persica*. Willd. n. 4. Burm. Ind. 128. t. 38. f. 2.—Calyx funnel-shaped, five-toothed. Leaves sessile, wedge-shaped, serrated and spinous.—A native of Persia. Willdenow says that Linnæus confounded this species very erroneously with the following, *M. frutescens*, with which however it by no means agrees, except in habit. *Stem* simple, erect, very smooth, hoary, jointed, furnished with simple, long, unequal spines at each joint, generally from five to twelve in number. *Leaves* wedge-shaped, entire at the base, serrated at the end; the serratures terminating in downy spines. *Flowers* in dense whorls. Spinous teeth of the calyx minute. *Corolla* twice the length of the calyx. From Burmann's figure.

5. *M. frutescens*. Linn. Sp. Pl. 821. Fl. Græc. t. 563, unpublished. Allion. Pedem. n. 122. t. 2. f. 2.—Calyx funnel-shaped, five-toothed; teeth spinous. Leaves on short stalks, elliptical, obtuse, slightly five-toothed.—Found by Sherard in Italy, and by Dr. Sibthorp in the isle of Cyprus. *Stem* shrubby, much branched, round or nearly so, with downy branches. Spines at each joint four, awl-shaped, recurved. *Leaves* ovate, downy, on short stalks. *Flowers* axillary, solitary, their stalks about as long as the leaf-stalks. *Calyx* tubular, with five, broad, spinous teeth, nearly equal. *Corolla* scarcely exceeding the calyx, white, with purple streaks on the lower lip. We have separated the last species, which grows in Persia, from this, although professor Martyn is of opinion that they are the same plant; comparison, however, of Dr. Sibthorp's drawing with Burmann's figure shews them to be sufficiently distinct.

6. *M. grandiflora*. Willd. n. 6. (*M. diacanthophylla*; Pallas. Nov. Act. Petrop. v. 10. 380. t. 11.—"Calyx funnel-shaped, five-cleft, its segments pointed. Leaves sessile, in three, deep, cut segments."—Native of Tartary. We have seen neither specimen nor figure of this. Willdenow describes the *corolla* as longer than the *calyx*, its upper lip hairy and cloven.

MOLUCCELLA, in *Gardening*, comprehends plants of the herbaceous annual exotic kind, of which the species cultivated are; the smooth Molucca balm (*M. lævis*); and the prickly Molucca balm (*M. spinosa*).

Method of Culture.—These plants may be increased by sowing the seeds in the early autumn on a mild hot-bed, or in pots plunged into it, and when the plants have attained a little growth be planted in small pots, and placed under a hot-bed frame in winter, where they may have free air in mild weather by taking off the glasses, being carefully covered in frosty weather, keeping them pretty dry, otherwise they are apt to rot. In the spring the plants may be turned out of the pots, with the earth about their roots, and planted in a warm border, defended from strong winds, giving them a little water to settle the earth to their roots; after which they require no other care but to be kept clean from weeds, and be supported with stakes as there may be occasion.

These plants afford ornament and variety in the borders among other tender annual kinds.

MOLUCHES, in *Geography*, a tribe of Patagonians inhabiting the western part of the country. The dead among them are buried in square pits, in a sitting posture, with their weapons and drinking utensils; and an old matron annually opens the grave to cleanse and clothe the skeletons. Around are those of the slain horses, supported with props. The language of the Moluches is more copious and elegant than could have been expected, the verbs having three numbers, and as many tenses as the Greek. See **PATAGONIA**.

MOLUTA ARMA. See **ARMA**.

MOLWITZ, in *Geography*, a town of Silesia, in the principality of Brieg; three miles from Brieg.

MOLY, in *Botany*. See **ALLIUM**.

This plant is supposed to have been wild rue, whose root is black, and the flower white, whence Ovid (*Met.* l. 14.) says:

"Pacifer huic dederat florem Cyllenius album,
Moly vocant superi, nigra radice tenetur."

According to Homer, Mercury gave this plant to Ulysses, by which he had evaded Circe's charms, the meaning of which is said to be, that he was thus taught to recover himself from his remissness, and to give counsel to his companions to quit so dangerous an abode. This plant, so difficult to be found, according to Homer, is the prudence which Ulysses exerted in extricating his soldiers from the seat of voluptuousness; and it may be supposed that all the transformations which Homer, Ovid, and the other poets say this princess wrought, were rather the effects of her charms and beauty than of her magic, though Horace (*1 Epist.* 2. 23.) leads us to understand, that they were the potions which she administered that produced these wonderful effects.

MOLYBDÆNA, **LEADWORT**, a name given by some authors to the great toothwort, or dentillaria of Rondeletius. See **TOOTHWORT**.

MOLYBDENUM, in *Chemistry*, a simple oxydable body and a metal. It is obtained from a blueish-black substance, which, till the experiments of Scheele, was confounded with plumbago. Like the latter substance, it has considerable lustre, feels as if it were greasy, and soils the fingers, but not to the same degree with plumbago.

Scheele found this substance to consist of sulphur and a white powder, which possessed acid properties, and which he denominated the *acid of molybdæna*.

Bergman was the first who suspected this acid to be the oxyd of a metal. He accordingly requested Hielm in the year 1782 to make some experiments with a view to determine this fact. This experimentalist mixed the acid of this metal with linseed oil into the form of paste. This was exposed in a close crucible, lined with charcoal, to a very strong heat. By this means he succeeded in reducing the metal.

In order to obtain it in greater purity, he first roasted the ore to expel the sulphur, which reduced it to the state of powder. This powder being made very fine, he next dissolved it in ammonia, filtered the solution, and then evaporated it to dryness. By boiling this residuum with nitric acid he obtained a white powder, which was the molybdic acid. This being mixed with oil, and treated as before, afforded the metal in small grains.

This metal is so very infusible, that it has hitherto not been obtained but in small granulated bits. On this account we know very little of its physical properties. Its metallic nature, however, has been clearly made out, by the additional labours of Pelletier, Heyer, and others.

It is said to be of a greyish-white colour, possessing metallic lustre. Its specific gravity is supposed to be about seven.

We are indebted to Mr. Hatchett for some experiments upon the oxyds of this metal. He found it capable of four stages of oxydation; namely, the black, the blue, and the green oxyds, besides the white, which is the acid. These different oxyds, it appears, have been obtained by abstracting oxygen from the acid. The black is procured by heating the acid in contact with carbon, and the blue by a longer continuation of the same process. The latter is also obtained

tained by immersing a plate of tin into a solution of the acid.

The acid is obtained by distilling nitric acid two or three times from any of the oxyds of this metal. The proportions of oxygen in molybdenum have not been ascertained, and till then we cannot, with much certainty, rely upon the number of its oxyds.

Molybdenum combines with sulphur. Indeed its native ore is a sulphuret. It is singular that we have no accurate analysis of the native sulphuret, as it might lead to some knowledge of its other compounds. It readily combines with sulphur, and forms a substance similar to the native sulphuret.

If the acid be heated with sulphur in a close vessel, such as a retort, part of the sulphur combines with the oxygen and forms sulphurous acid; the remainder combines either with a lesser oxyd, or with the metal forming a sulphuret. Molybdenum combines with phosphorus, but the compound has not been examined.

Helm, who first reduced this metal, has succeeded in alloying it with many of the other metals. He combined it with gold, platinum, silver, copper, iron, tin, nickel, zinc, lead, and some others. None of these alloys, however, appear to be important, they are almost all of them brittle.

MOLYBDIA, in *Natural History*, the name of a genus of crystals. The word is derived from the Greek *μολυβδος*, lead; and expresses crystals altered in their figure by particles of that metal. The crystals of this genus are of a cubic form, or composed of six sides, at right angles, like a dye. Of this genus there are three known species.

MOLYBDIC ACID, in *Chemistry*. This substance, to which we have already alluded, is arranged among the rest of the acids. Scheele, as has appeared under the account of the metal, was the discoverer of this acid. We are indebted for additional facts relative to this substance, to Hatchett and Bucholz. It may be prepared by boiling nitro-muriatic acid upon the sulphuret for some time; or, by distilling this acid repeatedly from it, a white powder will be formed, mixed with sulphuric acid. This latter, being washed away, will leave the molybdic acid tolerably pure. Another method has been given by Bucholz. He directs the ore to be reduced to fine powder, and roasted at a red heat, gradually lowering the temperature, and stirring it frequently, to keep the powder from adhering. This powder is of a grey colour, and contains a considerable portion of the acid oxyd. This is digested with soda or ammonia, which takes up the molybdic acid. It is remarkable, that molybdats of potash and soda are colourless. May not the colour above-mentioned arise from abstraction of oxygen? For these facts we are indebted to Mr. Hatchett.

This acid forms insoluble salts with many of the metals. Hence it precipitates mercury, copper, lead, &c. from their solutions.

Tin filings change this acid into the blue oxyd, by abstracting some of its oxygen.

Bucholz has attempted the analysis of this acid. He digested 100 grains of molybdenum with nitric acid, till the whole was converted into molybdic acid, which weighed 140 grains. He, therefore, concluded that the acid consists of 100 of the metals, and 40 of oxygen, which gives in the 100, 67.1 of metal, and 32.9 oxygen. If the acid be the fourth oxyd of molybdenum, we may form some idea of the other oxyds, and the rest of the compounds of molybdenum. If we take the acid at 33 *per cent.* of oxygen, and

put the weight of the atom of molybdenum equal x , then

$$\frac{x}{4 \times 7} = \frac{67}{33}, \text{ and } x = 57 \text{ nearly.}$$

Hence for the protoxyd $\frac{57 + 7}{14} = \frac{100}{11}$, or 11 *per cent.*

nearly. The second oxyd $\frac{57 + 2 \times 7}{14} = \frac{100}{20}$, or nearly 20

per cent. From these data, the third will contain 27 *per cent.* of oxygen. From the same reasoning, taking the atom of sulphur at 13, the first sulphuret will contain from 18 to 19 *per cent.* of sulphur.

MOLYBDOMANTIA, *Μολυβδομαντία*, in *Antiquity*, a species of divination, by observing the motions, figures, &c. of melted lead.

MOLYN, PETER, in *Biography*. See TEMPESTA.

MOLYNEUX, WILLIAM, an excellent mathematician and astronomer, was born at Dublin in the year 1656. As his constitution was naturally very tender, he was not sent to school, but instructed in the elementary parts of learning by a private tutor at home. At the age of fifteen he was entered at Trinity college, in his native city, where he distinguished himself for the vigour of his abilities, and the exemplariness of his manners; and having made a remarkable progress in academical learning, he was admitted to the degree of B. A. From Dublin college he went to London, and was entered a student of the Middle Temple in 1675. Here he spent three years, and obtained as much law as was necessary for a gentleman who did not intend to follow it as a profession. The bent of his genius led him to devote much of his time to mathematical and philosophical pursuits, and he returned to his native country in 1678, where he married, and continued to prosecute such branches of natural and experimental philosophy as were most agreeable to his taste. Being much attached to the principles of astronomy, he began, in 1681, to make observations, and commenced a literary correspondence with Mr. Flamsteed, the astronomer-royal of London. Shortly after this, he projected the design of establishing a Philosophical Society in Dublin, in imitation of the Royal Society, that had been but a few years established in London under the auspices of the king. Sir William Petty accepted the office of president, and our author was appointed the first secretary. The meetings of the society were held weekly, and by means of them Mr. Molyneux's scientific reputation became widely extended, and procured him the esteem of persons of the highest rank, and, among others, of the duke of Ormond, then lord-lieutenant of Ireland, to whose influence he was chiefly indebted for his appointment, jointly with sir William Robinson, to the offices of surveyor-general of the king's buildings and works, and chief engineer. In 1685, he was elected fellow of the Royal Society at London, and in the same year, for the purpose of improving himself in the art of engineering, he obtained an appointment to view the most considerable fortresses in Flanders. In the course of his tour he was introduced to Cassini, and the other celebrated astronomers, in the places through which he passed. Upon his return, in 1686, he published his "*Sciothericum Telescopium, or A new Contrivance of adapting a Telescope to an horizontal Dial, for observing the Moment of Time by Day or Night.*" In 1687, when sir Isaac Newton's "*Principia*" first appeared, he expressed his astonishment at such an effort of human intellect, at the same time modestly doubting if he should be able to comprehend all its parts. He was, per-

haps, one of the first who was anxious to apply the principles, discovered in the book, to the practical purposes of religion: "One observation," says he, "is truly to be wondered at, and that is, the *sesquialtera ratio* between the periods and distances of the planets, and that not only among the primary erratics, but even among the lesser sets of dancers.—It is, in my opinion, an amazing thought to consider how universally this great law runs through the whole frame of nature, and agrees to bodies at such vast distances, and that seem to have no tie or respect to each other. It is to me, beyond exception, the strongest argument that can be drawn from the frame of the universe, for the proof of a God, to see one law so fixed and inviolable among those vast and distant *Chori*, who certainly could not therefore be put into this posture and motion by chance, but by an omnipotent intelligent Being." In 1688, owing to the confusion that existed at that period, the Philosophical Society of Dublin was broken up and dispersed; after Mr. Molyneux had distinguished himself by the communication of several papers upon curious subjects, some of which were sent to the Royal Society at London, and printed in their Transactions. During the following year, he, in common with a number of other Protestants, withdrew from the disturbances in Ireland into England. Mr. Molyneux, after a short residence in the metropolis, settled with his family at Chester, where he employed himself in arranging and correcting the materials which he had before prepared for his Dioptrics. The work was published in 1692, under the title of "Dioptrica Nova, A Treatise on Dioptrics, in Two Parts, &c." He gave it the title *Nova*, because it was almost entirely new, very little being taken from other writers, and because it was the first book that had appeared in English upon the subject. It contains several generally useful propositions for practice, demonstrated in a clear and easy manner, and the history of the discoveries made by several optical instruments. In the preface, the author notices the "Essay on the Human Understanding," which, he says, "has rectified more received mistakes, and delivered more profound truths, established upon experience and observation, for the direction of man's mind in the prosecution of knowledge, than are to be met with in all the volumes of the ancients." This compliment proved introductory to an acquaintance between the two philosophers, and a mutual correspondence was carried on by them as long as Mr. Molyneux lived, to whom, it is believed, many improvements in the second edition of Mr. Locke's work are to be attributed. When tranquillity was restored to Ireland, Mr. Molyneux returned, and was elected one of the representatives for the city of Dublin, in the parliament that was convened in 1692. In the following parliament, in 1695, he was chosen representative for the university, and held that seat during the remainder of his life. He was likewise nominated by the lord-lieutenant one of the commissioners of the forfeited estates, with a salary of 500*l. per annum*; but he declined the office, considering it to be an invidious employment. He was a zealous friend to the linen manufactory, and was at all times an open and avowed advocate for the freedom and independence of his country, and in this character he published "The Case of Ireland, stated in relation to its being bound by Acts of Parliament made in England," which is said to contain the substance of all that can be advanced on this very interesting subject, written with great clearness and strength of reasoning. The book was drawn up with great caution; nevertheless, a complaint was preferred against it to the house of commons, who thought proper to address his majesty on

the occasion, asserting the dependency and subordination of Ireland to the kingdom of England. Mr. Molyneux, previously to the publication, had asked the opinion of Mr. Locke concerning the fundamental principle upon which his argument was founded; but this excellent man, instead of answering the letter of his friend, urged him to come to England, that they might talk over the subject together. To this he assented, and spent five of the happiest weeks in his life with Mr. Locke. When they separated, it was with an intention to renew the meeting in the following spring; but ere that arrived, death had deprived the world of Mr. Molyneux, who died in October, 1698, in the forty-third year of his age. He wrote several papers, that are inserted in the Philosophical Transactions, from vol. xiv. to xxix. Many of his letters are preserved in the collection of "Familiar Letters between Mr. Locke and several of his Friends." Biog. Brit.

MOLYNEUX, SAMUEL, the only descendant of the preceding, was born at Chester in the year 1689. He was educated according to the plan laid down by the friend of his father, Mr. Locke. The progress of the child was very rapid, so that he knew more at the age of six or seven, than most children do at double that age. On the death of his father, the care of his education devolved upon an uncle, Dr. Thomas Molyneux, an eminent physician at Dublin, and a friend also of Mr. Locke, who executed the trust reposed on him with honour and fidelity. The young man, improving all the advantages bestowed upon him, became one of the most polished and accomplished gentlemen of his age, and was appointed secretary to the prince of Wales, afterwards king George II. As he was possessed of an ample fortune, he pursued, with great ardour, the sciences of astronomy and optics, and projected many schemes for their advancement. He applied himself to find out a convenient method of manufacturing specula for sir Isaac Newton's reflecting telescope, in which his chief design was to reduce the method of making these instruments to a sort of certainty, in order that the difficulty in constructing them, and the danger of miscarrying, might no longer discourage any workman from attempting to make them for public sale. With the assistance of Mr. Bradley, the Savilian professor of astronomy at Oxford, he succeeded so well, that the whole process, being communicated to a skilful optician, the construction of these telescopes was, afterwards, executed with great readiness and dispatch. His zeal for the improvement of his favourite sciences, induced Mr. Molyneux not only to collect and consider what had been written and practised by others, but also to procure a complete apparatus for the purpose of making new experiments. In the midst of these avocations, which were honourable to him as a philosopher, he was appointed one of the lords commissioners of the admiralty, by which means he became so involved in public affairs, that he had no leisure to promote the interests of philosophy and science. He accordingly gave all his papers to Dr. Robert Smith, professor of astronomy at Cambridge, whom he invited to make use of his house and instruments, in order to finish what he had left incomplete. By the death of Mr. Molyneux, which happened soon after this, the professor was precluded from the benefit of this invitation: he, however, supplied what was unfinished by our ingenious author from Huygens and others, and published the whole in his "Complete Treatise on Optics." Mr. Molyneux married lady Elizabeth, sister to the earl of Essex, but had no children. Biog. Brit.

MOLZA, FRANCISCO MARIA, a distinguished character among the Italian literati, was born in 1489, at Modena.

From

From a very early age he was conspicuous for the readiness and avidity with which he imbibed classical literature: to his knowledge of the Greek and Roman languages, he added that of Hebrew. At the age of sixteen, he was sent to Rome to pursue his studies, but unfortunately he met with bad company, and entered upon a licentious course, which influenced the fortunes of the remainder of his life. To reclaim him, he was married to a Modeste young lady of noble descent, when he had scarcely attained to man's estate, with whom he lived till she had borne him four children. In 1576, he returned to Rome, where he spent almost all the remainder of his life. Study and pleasure seem alternately to have occupied all his thoughts. Among the many objects of his transitory attachments, is mentioned Furnia, a Roman courtesan, of whom he was so much enamoured, that it has been said he assumed the surname of Furnius on her account; but as his own mother's family name was De Forni, he probably derived the additional appellation from that. By these amours, he did serious injury to his reputation, and was once brought into the most imminent danger from the hand of an assassin; and he finally contracted a disease, the consequence of illicit connections, which brought him, as it has thousands, and tens of thousands of the votaries to pleasure, to a miserable end. From the year 1529 to 1535, Molza was at Rome in the court of cardinal Ippolito de Medici; after whose death, and the elevation of Paul to the papedom, he removed to that of cardinal Farnese. The profligacy of his conduct was no obstacle to an intimacy with many men of letters, such as Bembo, Sadoleto, Colocci, &c., and he was regarded as one of the principal ornaments of the literary academies then flourishing in that capital. His compositions were chiefly poems both in Italian and Latin, and on topics of all kinds, moral and serious, sportive and amorous, in all which he excelled. His elegies are excellent imitations of Tibullus. He was reckoned a powerful orator, and his epistles are graceful and elegant. He died, as we have already hinted, under the most excruciating sufferings, in 1544. Of his works, many were published separately, but no edition of the whole collectively appeared till that of Bergamo, in 1749, to which an account of his life is prefixed by Serassi.

MOLZA, TARQUINIA, daughter of Camillo, the eldest son of the subject of the foregoing article, was born at Modena in 1542. She was instructed in the classics, in Hebrew, and in the belles lettres, and made great progress in every thing which she undertook: she became an adept in some of the abstruse branches of science, and was a proficient in music; but with all these, she was distinguished by the graces and amiable qualities of her sex. She was married, in 1560, to Paul Porrino, but never had any children; and after his death, in 1578, she passed her life in literary retirement at Modena, where she died in 1617. She distinguished herself by her writings, consisting of Latin and Italian poems, and translations from Plato, and other classics. Her remains were printed in the Bergamo edition of her grandfather's works. This lady was the subject of numerous eulogies from contemporary writers; but the most extraordinary honour that she received, was that of being presented with the citizenship of Rome, by the senate and people of that city, in a patent reciting her singular merits, and conferring upon her the title of *Unica*. The honour is extended to the whole noble family of Molza.

MOM, in *Geography*, a town of Arabia, in the province of Hedysas; 5 miles N. of Mecca.

MOMAPANE LAKE, a lake of Canada; 160 miles N. of Quebec. N. lat. 49° 40'. W. long. 71°.

MOMARACKPOUR, a town of Hindoostan, in Bahar;

21 miles N.W. of Chupra. N. lat. 25° 59'. E. long. 84° 38'.—Also, a town of Hindoostan, in Allahabad; 30 miles N. of Gazyppour.

MOMBACA, or MOMBAZA, a kingdom of Africa, near the coast of the Indian sea, south of Melinda, of unknown extent. The soil is very fertile, and produces rice, millet, and other grain, fruit-trees, and vegetables of various kinds; great numbers of cattle and of poultry are bred in this country; and it abounds with excellent springs of fresh water. The climate is temperate, and the air is healthy. The capital, formerly on a peninsula, has been insulated by cutting a canal across the isthmus. The houses are stone, cemented with mortar, and covered with paintings and other ornaments; the streets, though narrow, are straight, and the houses are contiguous, and terraced on the tops. The city is defended by a citadel, which served the Portuguese for a place of retreat, from which, however, they were expelled by an Arabian scheid in 1631; but they regained their possessions in 1729. Before the city is a commodious bay, being both spacious and affording deep water. From this port a considerable commerce is carried on with the neighbouring countries. The inhabitants are various in their complexion; but their dress is after the Arabian fashion. They differ also with regard to religion, as Christians, Mahometans and idolaters, are intermixed; but they are said to be more civil and hospitable to strangers than any others on the same coast. S. lat. 3° 30'.

MOMBEIRA, a river of Africa, in Benguela, which runs into the Atlantic, S. lat. 15° 15'.

MOMBEL, a town of France, in the department of Mont Blanc; 10 miles W.N.W. of Chambéry.

MOMBELTRAN, a town of Spain, in Old Castile; 27 miles S.S.W. of Avila.

MOMBRIZO, BONINI, in *Biography*, an Italian man of letters in the 15th century, was born at Milan, and became professor of eloquence in that city. He was author of several works, which were well received, and among others some Latin poems, particularly one "On the Sufferings of Jesus Christ." His chief performance is entitled "Sanctuarium, five acta vitæ Sanctorum," in two volumes. For this, it is generally admitted, that ecclesiastical historians are under great obligations to him, as he has drawn from obscurity many important and valuable facts, which, without his researches, would have been lost to the world. Of this work, subsequent writers have availed themselves; but a perfect copy of it is now exceedingly rare, and greatly sought for by curious collectors. Moreri.

MOMDSONA, in *Geography*, a town of Thibet; 9 miles S. of Lassa.

MOMEGASTRO, a town of Spain, in Aragon; 12 miles E. of Balbastro.

MOMELSDORF, a town of the duchy of Wurzburg; 9 miles N.W. of Ebern.

MOMENT, in *Time*, the most minute and indivisible part of duration; or what we otherwise call an *instant*.

A moment ought not to be conceived as the least part of time, but as a termination or limit of time. Maclaurin's *Fluxions*, vol. i. p. 245.

MOMENTS, in the new doctrine of infinites, denote the infinitely small parts of quantity.

Moments are the same with what we otherwise call *infinitesimals*, and *differences*; being the momentary increments, or decrements of quantity, considered as in a continual flux. Moments are the generative principles of magnitude: they have no determined magnitude of their own; but are only inceptive of it.

Hence, as it is the same thing, if, in lieu of these moments,

the velocities of their increases and decreases be made use of, or the finite quantities proportionable to such velocities; the method of proceeding, which considers the motions, changes, or fluxions of quantities, is denominated, by sir Isaac Newton, the method of fluxions.

Leibnitz, and most foreigners, considering these infinitely small parts, or infinitesimals, as the differences of two quantities; and thereby endeavouring to find the differences of quantities, *i. e.* some moments, or quantities infinitely small, which being taken an infinite number of times, shall equal given quantities; call these moments, *differences*; and the method of procedure the *differential calculus*. See *CALCULUS Differentialis*.

MOMENT, *Momentum*, in *Mechanics*, is the same with *impetus*; or the quantity of motion in a moving body. See **FORCE**.

MOMENTUM is sometimes also used simply for the motion itself. Moment is frequently defined by the *vis insta*, or the power by which moving bodies continually change place. In comparing the motion of bodies, the ratio of their momenta is always compounded of the quantity of matter, and the celerity of the moving body; so that the moment of any such body may be considered as a rectangle under the quantity of matter, and the celerity.

And since it is certain, that all equal rectangles have their sides reciprocally proportionable; therefore, if the moments of any moving bodies be equal, the quantity of matter in one to that of the other, will be reciprocally as the celerity of the latter to the celerity of the former; and, on the contrary, if the quantities of matter be reciprocally proportionable to the celerities, the moments or quantities in each will be equal.

The moment, also, of any moving body may be considered as the aggregate or sum of all the moments of the parts of that body; and, therefore, where the magnitudes and number of particles are the same, and where they are moved with the same celerity, there will be the same moments of the wholes.

MOMENTARY MOTION. See **QUANTITY**.

MOMFLOT, in *Geography*. See **MONFALOUT**.

MOMORDICA, in *Botany*, a name of whose derivation we find no satisfactory account. Linnæus deduces it from *mordeo*, to bite, because, he says, "the seeds seem to have been bitten." But this applies rather to the pulpy fruit, which, in the original species, cracks and flies asunder irregularly, so as to have that appearance. The name was first given to this plant by Castor Durante, and appears to be Italian, having originally belonged to some sort of *Geranium*.—Linn. Gen. 506. Schreb. 662. Willd. Sp. Pl. v. 4. 601. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 380. Juss. 395. Tourn. t. 29, 30. Lamarck Illustr. t. 794. Gærtn. t. 88.—Class and order, *Monocœcia Syngenesia*; or rather *Monocœcia Polyadelphia*; see Sm. Intr. to Botany, 478. Nat. Ord. *Cucurbitaceæ*, Linn. Juss.

Gen. Ch. Male. *Cal.* Perianth of one leaf, concave, in five lanceolate spreading segments. *Cor.* in five deep divisions, united to the calyx, but larger and more spreading, veiny and rugose. *Stam.* Filaments three, awl-shaped, short; anthers on two of the filaments double, or cloven, with two appendages at each side; on the third filament simple, with appendages on one side only, and consisting of a compressed body, with a pollen-bearing line once reflexed.

Female on the same plant. *Cal.* Perianth like that of the male, superior, deciduous. *Cor.* as in the male. *Stam.* Filaments three, very short, without anthers. *Pist.* Germen inferior, large; style one, cylindrical, columnar, three-cleft; stigmas three, tumid, oblong, directed outwards.

Peric. Berry spongy, oblong, separating elastically, of three cells, with soft, membranous, distant partitions. *Seeds* several, compressed.

Ess. Ch. Male, Calyx five-cleft. Corolla deeply five-cleft. Filaments three.

Female, Calyx five-cleft. Corolla deeply five-cleft. Style three-cleft. Berry separating elastically.

1. *M. Balsamina*. Common. or Male, Balsam-apple. Linn. Sp. Pl. 1433. Lamarck Dict. v. 4. 237. Zorn Pl. Med. t. 45. (*Balsamina mas*; Ger. em. 362. *B. mas*, fructu puniceo, and *Momordica fructu lutco-rubefcente*; Besl. Eyst. autumn. ord. 1. t. 4. f. 2, 3)—Fruit roundish-ovate, pointed, angulated and tubercular. Bractea heart-shaped, toothed, above the middle of the flower-stalk. Leaves smooth, five-lobed, palmate, deeply toothed.—Native of the East Indies. A very tender annual in our gardens, kept occasionally for curiosity merely, notwithstanding its reputed vulnerary or balsamic virtues, from whence the specific name arose. The ripe fruit, infused in olive oil, said to possess a tonic and healing quality, is now out of use. The stems are long, weak, slender, smooth, leafy, supported by long, simple, spiral, capillary tendrils, opposite to each leaf-stalk. Leaves alternate, stalked, about two inches wide, of a bright shining green, naked, finely dotted, cut half way down into five, scarcely seven, broad, spreading lobes, with broad, sharp capillary-pointed teeth. Flowers large, yellow, on axillary, solitary, simple stalks, twice the length of the leaf-stalks, and bearing at the top a rounded bract. Fruit about two inches long and one broad, orange-coloured, or almost scarlet, splitting at one side when ripe, and discharging its seeds with some force through the cleft, by means of the elasticity of its coat.

2. *M. Charantia*. Hairy Balsam-apple. Linn. Sp. Pl. 1433. I. Mill. Illustr. t. 83. (*Balsamina cucumerina indica*, fructu majore flovescente; Comm. Hort. v. 1. 103. t. 54. *Amara indica*; Rumph. Amb. book 10. 410. t. 151.)—Fruit oblong, taper-pointed, angulated and tubercular. Bractea heart-shaped, entire, below the middle of the flower-stalk. Leaves seven-lobed, palmate, bluntly toothed, somewhat hairy.—Native of the East Indies. Cultivated by Miller in 1731. It differs from the former in having a much longer fruit, more pointed at each end; leaves usually more deeply palmate, with broader more shallow teeth, their veins very hairy beneath; flower-stalks elongated, rather hairy, bearing their bractea, which is entire, in their lower part.

3. *M. muricata*. Muricated Balsam apple. Willd. n. 3. (*M. Charantia* ß; Linn. Sp. Pl. 1433. Lamarck Dict. v. 4. 239. *M. zeylanica*; Mill. Dict. ed. 8. n. 3. Pavel; Rheede Malab. v. 8. 18. t. 10.)—"Fruit oblong, muricated, taper-pointed. Bractea heart-shaped, nearly entire, below the middle of the flower-stalk. Leaves seven lobed, palmate, toothed, pointed."—Native of the East Indies. The leaves of this are nearly smooth, less deeply lobed and toothed, with taper points. Fruit only an inch and half long, not furrowed, but beset with numerous sharp prominent points.

4. *M. senegalensis*. African Balsam-apple. Lamarck Dict. v. 4. 239. Willd. n. 4.—"Fruit ovate, acute, tubercular. Bractea heart shaped, entire, near the base of the flower-stalk. Leaves seven-lobed, deeply palmate, somewhat toothed, and rather hairy.—Gathered by M. Rouffillon in Senegal. Lamarck. More hairy or downy than *M. Charantia*, the leaves smaller, more deeply lobed; flower-stalks generally longer; fruit shorter, being oval, and not above an inch long, warty; flowers small. Lamarck.

5. *M. operculata*. Covered Balsam apple. Linn. Sp. Pl. 1433. Ait. Hort. Kew. ed. 1. v. 3. 499. Willd. n. 5. (*M. ame-*

MOMORDICA.

(*M. americana*, fructu reticulato sicc; Comm. Rar. 22. t. 32.)—Fruit elliptical, angular, sharply tuberculated, with a beaked lid. Leaves five lobed, toothed.—Native of the West Indies. Sent to Kew, in 1787, by Mr. Alex. Anderson. It is annual like the rest, and flowers from June to September in the stove. The leaves are finely downy, with five shallow spreading lobes. Tendrils divided. Fruit ovate, or obovate, an inch and half long, its angles armed with pointed tubercles, its top a taper deciduous lid, leaving a small orifice, through which the seeds escape, the rest of the fruit when old becoming dry and reticulated.

6. *M. Luffa*. Egyptian Balsam-apple. Linn. Sp. Pl. 1433. (*Cucumis aegyptius reticulatus*, seu *Luffa arabum*; Vessing. Ægypt. 48. t. 50, 51. Petola; Rumph. Amb. book 10. 405. t. 147.)—Fruit oblong, somewhat cylindrical, furrowed, smooth; reticulated within. Male flowers corymbose. Bractea heart-shaped entire, at the base of each partial stalk. Leaves rough, five-lobed, toothed.—Native of the East Indies. Cultivated near Cairo by the Arabs, (who call it *Luffa*.) rather, as it appears, for curiosity than use, the fruit not being eatable. This has the herbage more like some sort of Melon than the rest of the species. The leaves are rough with minute tubercles. Tendrils many-cleft. Male flowers numerous, pale yellow with orange streaks, in a downy corymbus, with small smooth bracteas. At the bottom of their long common stalk stands a solitary stalked female flower, whose long germen is clothed with dense down. The stamens are truly polyadelphous, with large sinuous anthers. Fruit a span long, swelling upwards, smooth, displaying, when the skin is removed, a most elegant reticulated structure, in which the seeds are lodged.—*Luffa sativa*, Cav. Ic. v. 1. 7. t. 9, 10, is evidently nearly allied to this plant, but its stamens are said to be all separate. The angles of the fruit moreover seem to be sharper, and its coat thicker, opening by a lid, as in the last. The tendrils and inflorescence agree with *M. Luffa*, but, as Cavanilles observes, the two plants require to be compared in a living state, especially their stamens. See LUFFA.

7. *M. cylindrica*. Cylindrical Balsam-apple. Linn. Sp. Pl. 1433. Willd. n. 7.—Fruit cylindrical, very long. Bractea heart-shaped, entire, at the base of the flower-stalk. Leaves heart-shaped, angular, toothed.—Native of Ceylon and China. Of this we find no figure. The Linnæan specimen has an angular stem. Tendrils simple, very long. Leaves heart-shaped, finely toothed, rough, angular rather than lobed, on rough stalks. Flowers small, with very hairy stalks and calyx. Fruit, according to Linnæus, a foot long, rather hairy. Seeds black. Flowers yellow.—This seems by Willdenow to be cultivated in Germany, but we have it not.

8. *M. trifoliata*. Three-leaved Balsam-apple. Linn. Sp. Pl. 1434. Willd. n. 8. (*Poppya sylvestris*; Rumph. Amb. book 9. 414 t. 152. f. 2.)—Fruit ovate, prickly. Leaves ternate, toothed.—Native of the East Indies. Distinguished by its ternate leaves, which are smooth on the upper side; the leaflets all equally stalked. Fruit red, the size and shape of a hen's egg, rough with small prickly protuberances.

9. *M. pedata*. Pedate Balsam-apple. Linn. Sp. Pl. 1434. (*M. fructu striato lævi*, vulgò Caigua; Feuill. Peruv. v. 1. 754. t. 41.)—Fruit ovate, striated. Leaves pedate, serrated.—Native of Peru. We have never seen this but in the garden of the Marquis Hippolito Durazzo, at Genoa, in 1787. Feuillée says the Peruvians eat the fruit in their soups, its cooling qualities being peculiarly welcome in that hot climate. The leaves are dark green, rough with callous tubercles, and remarkable for being pedate; their lobes are

pinnatifid, rather than serrated, in our specimens. Flowers small, greenish-yellow; the male ones umbellate; female solitary, at the base of their common stalk. Calyx with long, narrow, acute segments. Germen rough. Fruit, according to Feuillée, about four inches long, greenish-white, spongy, with a sharpish taste. He represents the tendrils as of two or three branches; in our's they are simple. Thus, with the deeply cut leaves, and their callous roughness, not mentioned in his prolix description, makes us fully believe our's may be a distinct species. There is no specimen in the herbarium of Linnæus, as he merely copied Feuillée.

10. *M. lanata*. Woolly Balsam-apple. Thunb. Prodr. 13. Willd. n. 10.—“Leaves ternate, pinnatifid, rough. Fruit woolly.”—Native of the Cape of Good Hope.

11. *M. echinata*. Bristly Balsam-apple. Muhlenb. MSS. Willd. n. 11. (*Sicyos lobata*; Michaux. Boreal-Amer. v. 2. 217.)—Fruit with four seeds, roundish, beset with long bristles. Leaves heart-shaped, roughish, with five sharp angular lobes, obscurely toothed.—Native of Pennsylvania, towards the river Ohio. We have specimens from the Rev. Dr. Muhlenberg. The stem is deeply furrowed, smooth. Tendrils long, divided, not many-cleft. Leaves on long stalks, opposite to each tendril, of a pentagonal figure, with five divaricated, pointed, distantly toothed lobes; heart-shaped at the base, where there is also a small additional lobe, or dilatation, at each side. Both surfaces of the leaves are rough with extremely minute prickles, especially on the ribs and veins, in our specimens, though Michaux and Willdenow describe them as smooth. Flowers small; the males very numerous, in axillary downy panicles, from two to six inches long; females solitary, stalked, at the base of the stalk of the panicle. Germen globose, beset with long weak prickles. Fruit roundish, the size of a gooseberry, likewise prickly, with only four seeds.

12. *M. dioica*. Dioecious Balsam-apple. Roxb. in Willd. n. 12.—“Fruit elliptical, mucicated. Flowers dioecious. Leaves heart-shaped, pointed, toothed.”—Native of the East Indies.—Stem angular, climbing. Leaves heart-shaped, undivided, pointed, toothed, smooth on both sides, two inches long. Tendrils simple. Flowers dioecious; the female ones axillary, solitary. Fruit the size of the first species, elliptical, very thickly beset with sharp tubercles. Willdenow.

13. *M. spicata*. Spiked Balsam-apple. Linn. MSS.—Leaves heart-shaped, slightly three-lobed, wavy, rough. Male flowers in long loose spikes, with fan-shaped, rough, toothed bracteas; female axillary solitary. Germen elliptical, rough.—Of this we find a specimen in the herbarium of the younger Linnæus, under the above name, but without any indication of its native country. The stem is furrowed, slightly prickly. Tendrils, as far as we can judge, simple. Leaves on long rough stalks, opposite to the tendrils, heart-shaped, with three or five slight angular lobes, wavy, rough with minute callous tubercles, the veins hispid. Male flowers in lax, simple, solitary, axillary, long-stalked spikes, each flower accompanied by a large, sessile, fan-shaped, rough bractea, toothed at the summit; female solitary, on a short axillary stalk; its germen elliptical, furrowed, hispid; calyx with a very long tube.—The male inflorescence marks this as a very distinct species, that seems not to be any where described.

14. *M. Elaterium*. Squinting Balsam-apple or Squinting Cucumber. Linn. Sp. Pl. 1434. Bulliard t. 81. (*Cucumis sylvestris*; Camer. Epir. 946. *C. affinis*; Gerem. 912.)—Fruit elliptical, hispid, elastic at the base. Leaves heart-shaped, wavy, rough. Tendrils none.—Native of waste ground in the south of Europe. It is a hardy annual,

annual, now and then allowed a place in curious gardens for the sake of its fruit, which, to the surprise of those who touch it unawares, starts from its stalk with a violent spring, squirting out the seeds by the orifice. The *herb* is a rank, spreading, rough and hairy, rather glaucous, weed, with round thick branches, destitute of tendrils. *Flowers* dull yellow; the males but few together in an axillary cluster, accompanied at the bottom by one female blossom. *Fruit* pendulous, elliptical, blunt at each end, about two inches long, green, rough with innumerable small bristles, of a thick coriaceous texture, without valves.—The extract of this fruit, known by the name of ELATERIUM, (see that article,) is a violent and dangerous purge.

MOMORDICA, in *Gardening*, contains plants of the annual trailing and perennial kinds, of which the species cultivated are, the common momordica, or male balsam apple (*M. balsamina*); the hairy momordica (*M. charantia*); the Egyptian momordica (*M. luffa*); and the elastic momordica (*M. elaterium*).

Method of Culture.—All these plants may be increased by sowing the seeds of the first three sorts upon a moderate hot-bed, in the early spring months, as about March; and when the plants have had a little growth, let them be pricked out into another hot-bed, fresh air being given in fine weather, and water occasionally; or they may be let remain in the first hot-bed till they have acquired sufficient growth, and have four or five leaves, when they should be removed into the hot-bed where they are to remain, one or two plants being put into each light, due shade and water being given till fresh rooted. They afterwards demand the same management as the cucumber kind, the branches being suffered to extend themselves in the same manner. When thus managed, and properly treated, in respect to air and water, they produce fruit and ripe seeds in the latter end of summer, when it must be immediately gathered, to prevent its being dispersed. The plants may likewise be set in pots, and placed in the hot-house, their vines or stems being supported by sticks, in which mode they have a much better appearance and effect.

The fourth sort may be sown or suffered to scatter, where the plants are to remain, or on beds of fine mould in the autumn, the plants being afterwards thinned out, or removed into rows in an open situation, three or four feet apart, and as many distant in them, requiring only the further culture of being kept clean from weeds. Where the soil is dry, they often continue three or four years.

All the sorts afford ornament, the first three sorts in the stove, and the last in the open borders. The fruit of the last also affords a medicinal substance by inspissation.

MOMORDICA, *Stinking*. See BRYONIA.

MOMOT, in *Ornithology*. See RAMPHASTOS *Momota*, and MOMOTUS.

MOMOT *Pheasant* of Latham. See PHASIANUS *Motmot*.

MOMOTUS, in *Natural History*, a genus of birds of the order PICÆ, of which there is but a single species: the generic character is, bill strong, slightly curved, serrate at the edges; nostrils feathered; tail wedged; feet gressorial.

Species.

BRASILIENSIS, or Brazilian Momot. Green; front blueish-green; hind-head violet; crown black. This bird, remarkable for the beauty of its plumage, is a native of South America, and seems to be chiefly found in Brasil, whence it derives its name. It was first described by Hernandez, in his History of Mexico; who says, "It is the size of a dove, and has scarlet eyes, with a black pupil; a crooked blackish bill, almost three inches long, sharp-

pointed, with the lower mandible shortest, and the upper serrated; the head is blue like that of the peacock; the legs and feet brown, and the rest of the bird green; and what is extraordinary, is, that the tail has one quill longer than the rest, and feathered only at the end." This description was regarded by Ray as very inaccurate, and in his edition of Willoughby's Ornithology, he says, "This is, I dare say, more strange than true, for the tails of all birds, I ever yet saw, have their feathers growing by pairs, that is, two of a sort, on each side." Edwards, about half a century ago, described it as a species of Roller, and named it the "Saw-billed Roller." According to this naturalist, "It is short-legged in proportion, and not long-winged; the bill is pretty straight, moderately bending downwards at the point, toothed on the edges like a saw; the upper mandible dusky, the lower flesh-coloured towards its basis; the nostrils are covered with small black feathers, and some black bristles pointing forward round the upper mandible; the upper part and the sides of the bill are encompassed with black, from which run black lines through the eyes, and broader black lists, mixed with a little blue, from the corners of the mouth down the sides of the neck; the top of the head is of an ultramarine blue, though next the bill inclining to sea-green; in the middle of this blue space, on the crown of the head, is a black spot; it has also a spot of black feathers, edged with blue, on the fore part of the neck, a little below the throat; otherwise the whole underside, from the bill to the covert-feathers beneath the tail, is of an olive or greenish buff colour." Other naturalists have given descriptions rather different. Linnæus considered it as a species of the Ramphastos, or Toucan genus, and denominated it "RAMPHASTOS *Momota*;" but Dr. Latham instituted for it a separate genus, the structure of the feet forbidding it to be associated with the Toucans, which have scansorial or climbing feet, having the toes placed two forwards and two backwards, as the parrot genus. Edwards had noticed as a great singularity in this bird, that the two long tail-feathers seem as if they were stripped of their webs on each side for an inch space, a little within their tips; but Latham says, "That though the tail, in many specimens, exhibited the very remarkable particularity described by Edwards, yet in its truly natural, or perfectly complete state, the two middle feathers are entirely webbed throughout their whole length." The momotus is nearly equal in size to a magpie, measuring about eighteen inches in length. It is said to be a bird of solitary habits, frequenting thick woods, and is seen singly. It makes its nest on the ground, sometimes in the deserted hole of an armadillo, or other quadruped; it is composed of dry grass and stalks, and it lays commonly two eggs.

In Gmelin's last edition of Linnæus, there is a variety mentioned, and described as variegated with green, tawny, blue, and cinereous. The body above olive green, beneath rusty; head large; crown blue, black in the middle; bill black, scarcely two inches long; the legs are black, and the claws hooked.

This bird feeds on insects and raw flesh, the fragments of which it macerates in water; when taken it strikes violently with the bill; the voice is harsh, weak, and tremulous. Shaw, Latham. Gmelin's edit. of Linnæus.

MOMPOX, or *Santa Cruz de Mompox*, in *Geography*, a town of South America, in the province of Carthagena, on the left bank of the Magdalena; 110 miles S. S. E. of Carthagena. Mompox, which is a very commercial port, has a royal custom-house, and a handsome quay of considerable height, as the river rises regularly 12 or 13 feet in the beginning of December. N. lat. 9° 19'. W. long. 74° 11'.

MOMUS, in *Mythology*, was, according to Hesiod, the son

son of Night and Sleep, and was supposed both by the Greeks and Romans to be the god of buffoonery and jests. Satirical to excess, he made even the gods, and Jupiter himself, the objects of his most pungent raillery. None of the ancients have exhibited him in his true and lively colours more appropriately than Lucian. Momus is said to have derived his name from the free and bold manner in which he censured the vices and defects of others; *Momus* in Greek implying censure. It was he who found fault with the gods, because, in the formation of man, they had not made a little hole or window in his breast, that one might have seen into his heart what were his thoughts: though Vitruvius ascribes this reflection to Socrates.

MONA, in *Geography*, or LA GUENON, a small island in the West Indies, between Hispaniola and Porto Rico. N. lat. 18° 10'. W. long. 68° 28'.

MONA, in *Ancient Geography*, an island of Great Britain, now called Anglesea, the ancient seat of the Druids; which was first attempted by Suetonius Paulinus, and afterwards reduced by Agricola. In the British tongue it was called Môn, and when conquered by the English, Anglesey, that is, English island. See ANGLESEY.

MONACHUS, in *Zoology*, a species of *Phoca*; which see.

MONACHUS, in *Ornithology*, a species of *Falco*; which see.

MONACO, in *Geography*, was, before the French revolution, a small principality of Italy, situated on the coast of the Mediterranean, between the county of Nice and the Genoese territory, and about four or five Italian miles in circuit. The chief line of the Grimaldi, who had governed this principality for 800 years successively, failed in 1731; but the eldest daughter of Antony Grimaldi, having been, in 1715, declared heiress of the principality, was married to Francis Leonorus, count de Torrigny; and the fruit of this marriage was Honoratus Camillus Leonorus, who adopted the name and arms of Grimaldi. Monaco is now united to France.

MONACO, a town of France, and principal place of a district, in the department of the Maritime Alps, late capital of the principality above-mentioned, and the residence of the duke. It is a small town, with narrow streets, situated on a rock near the sea: it is fortified and has a garrison and a good harbour, and possesses a right of compelling all ships that pass by to put in and pay toll; 6 miles N.E. of Nice. The place contains 1130, and the canton 3730 inhabitants, on a territory of 37½ kilometres, in 4 communes. N. lat. 43° 43'. E. long. 7° 22'.

MONACONDA, a town of Hindoostan, in Tellingana; 8 miles W.S.W. of Warangole.

MONAD, in the *Philosophy* of Leibnitz, is a simple substance without parts. The existence of monads must be admitted, since without these no compound or aggregate of simple substances could exist. These simple substances are properly called monads, because, as unity is the fountain and origin of numbers, and comprehends all their powers, so simple substances are the matter of, which all corporeal masses are formed. Since monads have no parts, they have neither extension, figure, nor divisibility. They are the true atoms of nature, and elements of things, incapable of destruction, except by the power of God. Each monad differs from every other; for it is impossible that any two things should be found in nature perfectly alike. Monads have an internal principle of variation, by which they are continually varying in a certain manner; and hence arises a plurality of properties and relations. This perpetually varying state, which involves and represents multitude in unity, is perception, which is not, however, to be confounded with consciousness. The

action of the eternal principle of monads, by which a transition is made from one perception to another, may be called appetite. The perception and appetite of monads are not to be explained mechanically by figure and motion, because they are affectations of a simple substance without parts. In monads, therefore, nothing is found but perception and appetite; and in this respect all monads may be said to partake of the nature of soul; although that term is more properly applied to those living beings, which have distinct perception united with memory. The present state of monads arises from the past, and perception from perception, as motion from motion. Monads are, in a state of perception, similar to that of a mind in a stupor, which has a perpetual succession of minute and indistinct perceptions. God alone, says Leibnitz, is primitive unity, or simple original substance, from whom are produced all created or derived monads. These owe their existence to the effusion of the rays of divinity, limited in their effects by the finite capacity of the creatures who receive them. Creatures have not proceeded necessarily from the divine essence, but have been created, according to the plan of the divine understanding, by the energy of the divine will and power; and their continued preservation is a continual creation.

Monads have universally an influence on each other, and are reciprocally active and passive. They are active, in proportion as their perceptions are distinct; passive, as they are confused. In simple substances, the influence of one monad upon another is not mechanical, but ideal, and is not effected without the intervention of the Deity, who directs them according to the ideas of his own intellect. From the universal influence of all creatures upon each individual, and of each upon all, it follows, that every simple substance receives an impression or image of all the rest, and becomes, as it were, a perpetual living mirror of the universe. As the same city viewed from different places appears different, and is optically multiplied; so it happens, that in consequence of the infinite multitude of simple substances in nature, pictures of the universe are multiplied without end; according to the different points of sight of different monads. By these means, all possible variety, and, consequently, all possible perfection, is produced in the universe. Since there is in nature a universal *plenum*, the motion of any body or composition of monads must affect every other body by means of intervening bodies; and every present motion will have a necessary connection with every other future motion; whence he who sees all things can read in the present whatever will happen in any future time or distant place. Although each created monad reflects the whole universe, that monad which is the animating principle of any body, affects that body more distinctly than all others. As the whole body reflects the whole universe by the connection of all matter *in pleno*, so also the soul reflects the whole universe, while it reflects that organized body, by which it is in a peculiar manner perceived, and with which it seems a living animal. Since matter is not only infinitely divisible, but is actually divided without limit, every portion of matter may be conceived to be a world of living creatures; and every part of a living body to be itself full of all other living bodies. All bodies are like rivers, perpetually flowing; some parts entering, and others passing away. The soul changes its body, not instantaneously, but by degrees, so that, strictly speaking, there is no such thing as death, or a state in which the soul is separated from the body. In conception, no new animal is produced; but a pre-existing animal is disposed to a transformation, by which it passes into another species. In death, though the machine in part perishes, the animal itself remains indestructible.

From this concise statement of Leibnitz's system, as it respects monads, it will be easily perceived, that his monads approach nearer to the permanent intelligent natures, called by Pythagoras numbers, and by Plato ideas, than to the solid and indivisible atoms of Epicurus. Brucker's *Philos.* by Enfield, vol. ii. See *LEIBNITZIAN Philosophy*.

MONADELPHIA, in *Botany*, from *μονος*, one, and *αδελφος*, a brother, the 16th class of the Linnæan artificial, or sexual, system, consisting of plants whose filaments are united into one parcel, or set. This union is more or less complete. In the Mallow tribe, the combined filaments make a long tube, crowned at its summit by the anthers, which, from its resemblance to a column, has obtained the name of *columniferæ* for such flowers. In the Geranium family the union is much more slight; while in some genera, as *Oxalis*, it is but partial, or confined to certain species only. The late professor Cavanilles, of Madrid, undertook an illustration of the class *Monadelphia*, in several quarto dissertations, with plates, which make all together two rather thick volumes. In this work he has referred to the class in question a vast number of genera, never before suspected to belong to it, and which unquestionably want its true character. This character consists in an actual union, or immediate coalescence, of the filaments themselves into one body; whereas many of the plants considered by Cavanilles as monadelphous, are so merely through the medium of a tubular nectary, or of some other body, which is no part of the stamens. This is totally inadmissible, for we might just as well refer to this class, every plant whose filaments are connected by insertion into a corolla, or calyx, of one piece.

The class *Monadelphia* is not in itself a natural one, though it embraces some tribes that are natural combinations, as the *Columniferæ* and *Gerania*. Its orders are distinguished by the number of stamens, easily determined at their upper part, bearing the anthers, where they are always, for a considerable distance, separate and distinct. These orders are eight, *Triandria*, *Pentandria*, *Heptandria*, *Octandria*, *Decandria*, *Endecandria*, *Dodecandria*, and *Polyandria*; of which the last, comprising the *Columniferæ*, and some other noble plants, is the most numerous and important.

MONADELPHIA is also the name of an order of the 21st and 22d classes (*Monoccia* and *Dioccia*) of the Linnæan system, founded on the same character as the class so denominated. This order in the 21st class is chiefly formed of the Fir, or coniferous, tribe, and of some of the natural order of *Euphorbiæ* of Jussieu; in the 22d also it contains some of the allies of the Fir, with a very few genera besides. Professor Willdenow has removed the Gourd or Cucurbit tribe to the *Monoccia Monadelphia*, justly perceiving that they were inaccurately referred to *Monadelphia Syngenesia* by Linnæus; an order which, as far as is hitherto known, has no existence in nature. Their anthers in fact are quite distinct, their filaments only being more or less combined. But this combination is not into one set, except perhaps in *Sicyos* and *Seebium*. The rest of this tribe are by no means monadelphous, but polyadelphous, their five stamens being united by their filaments into three sets. See **MOMORDICA**.

MONADNOCK, GREAT, in *Geography*, a mountain of America, in Cheshire county, New Hampshire, between the towns of Jeffrey and Dublin. The foot of the hill is 1395 feet, and its summit 3254 feet, above the level of the sea. Its base is five miles in diameter from N. to S., and three from E. to W. On the sides are some appearances of subterraneous fires.

MONADNOCK, Upper Great, a high mountain in Canaan, in the N.E. corner of the state of Vermont.

MONAGHAN, a county of Ireland, in the province of Ulster. It is rather of an oblong form, having its greatest extent from north to south, and being very narrow, except in one part, where it stretches between the counties of Fermanagh and Cavan, which form its western boundary. On the north it runs into the county of Tyrone in an angular direction, being separated from it on the north-east by the river Blackwater. The county of Armagh lies on the east of it, that of Louth on the south-east, and that of Meath on the south. The length of this county is 30 miles (38 English) from north to south; its greatest breadth is 19 miles (24 English), but in most parts it does not exceed 10. and is not always so much. The area is 179,600 Irish plantation equal to 288,500 English acres; and in square miles 280 Irish or 450 English. This is the statement of Dr. Beaufort and Sir Charles Coote. Mr. Wakefield, for what reason he does not state, says the area is 509 English miles. The whole is divided into 21 parishes, of which 20 had churches when Dr. Beaufort published, all in the diocese of Clogher. The population is stated by Dr. Beaufort at 118,000 for 21,523 houses; but the general increase since the publication of his work is sufficient ground for considering it too low an estimate.

Monaghan has a large proportion of bog, and a great number of small lakes, which, together with its being exposed to the north-westerly winds, render it very damp, though it is far from being unwholesome. On the north-west the Slieb-Baught mountains divide it from Tyrone; and on the east the Fews mountains are the boundary. In most parts of the county the surface is hilly, but no part is inaccessible to the plough. The turf bogs, supplying abundance of fuel, are of great value, and have been reckoned one cause of its great population, in which it is inferior to no county in Ireland, Dublin and Armagh alone excepted. The soil is in general deep clay, which is particularly favourable for flax, and this is the principal crop. In 1809 three thousand two hundred acres were sown with flax, a greater number in proportion to the extent than in any county except Armagh. Potatoes and oats are successfully cultivated, but there is very little wheat; and the small farms into which the land is divided do not answer for grazing or dairy husbandry. The lower classes are sensible of the value of vegetables, which are raised very abundantly in their little gardens; and with similar encouragement to that given by lord Hardwicke on his estate in Cambridgeshire, these gardens would contribute in a still greater degree to the comfort of the proprietors. The linen manufacture is the great object of the people, and is productive of its usual happy effects, though it is not favourable to improved agriculture. The Slieb-Baught mountains, which extend into this county from Tyrone, form an uninterrupted ridge of high land, the highest part of which is called Cairnmore. These have, in general, neither a fruitful soil, nor any natural beauties to recommend them, being an uninteresting waste, and almost always wet and moory. There are parts, however, which have beds of the richest limestone, and abundance of marble, particularly on the eastern side of Cairnmore. This mountain is famous for its millstone quarry. Those most valued consist of a red and very hard grit or sandstone, the grain of which is close. There is also a soft whitish sandstone, which is more easily procured, but which soon wastes away. In this neighbourhood is also a fine kind of potters' clay, which is carried to the pottery at Dundalk, and is used in making the best thin glazed ware. Indications of coal have also been observed here, and in other parts of the county. Crieve, which is south of the town of Ballibay, is the highest ground in Monaghan. The stone here is of a very hard

hard quality, of a colour between blue and dark green, and is found to answer very well for building. It is called *rubinstone*, and seems to be a kind of greenstone. Crieve abounds with lead ore of the richest quality. On the summit of this mountain is a lake covering about fifty acres, which is very deep, and is principally supplied from springs. This lake serves as a reservoir for supplying a number of bleach-mills, fourteen of them being worked by the stream flowing from it. The consequence of these establishments has been the reclaiming of a considerable part of the mountain, notwithstanding the badness of the soil; so that what was regarded a few years ago as a waste with nothing to recommend it, has, in consequence of the application of a stream of water to the prevailing manufacture, become a most thriving and valuable district. It has been already mentioned, that Monaghan abounds with small lakes which might be turned to the supply of a canal extending through it from lough Neagh to lough Erne, which seems to be practicable without very great expence, should the improvement of the country render it desirable. The number of these lakes is 184, of which 30 are considerable sheets of water. Lough Barrac, near Castle Blayney, and the lake of Kilerow at Coote Hill, principally deserve notice for their extent and beauty. The rivers are numerous, but inconsiderable. Of Monaghan, the county town, an account will be given in the next article. Clones, Carrickmacross, Castle Blayney, and Ballibay, have been noticed in preceding volumes under their respective heads. As none of them are boroughs since the Union, Monaghan is represented in parliament by only two members, who are, according to Mr. Wakefield, returned by no individual prevailing interest.

In the history of Ireland we do not find any matter of moment relating to this county until the reign of James I., when 500,000 acres in Ulster were escheated to the crown under the charge of the proprietors being disaffected to the king's government, which forfeiture included almost the whole of Monaghan. A great part of these lands was soon after assigned to British adventurers, mostly Scotch; but considerable estates were left, according to sir John Davis's statement, to several of the name of M'Mahon, which had been the prevailing family in it. These were probably forfeited at a subsequent period, as the name of M'Mahon does not occur in the list of the present proprietors given by sir Charles Coote. "The rent rolls of large estates," says the writer last named, "will be found from near 20,000*l.* to 1,000*l.* per annum, and a very considerable part is held in grants from 20*l.* to 500*l.* per annum. The large estates are in no instance resided on by the immediate proprietors, but the lesser ones are almost uniformly otherwise, and are held in grants from the crown, since the Scotch colony was introduced here; and also a considerable share of these lands comprehended gifts to Cromwell's soldiers, many of whose posterity now enjoy so small a tract, as does not yield above 20*l.* annual income. I suppose taking the large farms in Monaghan they would not average 25 acres; nor could the small ones, which are far more numerous, average six acres, so that ten may be the mean rate of the whole county." "The largest estates," according to Mr. Wakefield, "exhibit the most wretched cultivation; fields without hedge-rows, and enclosed only by earthen banks or dykes; land running to waste, which, with great truth, may be compared to its inhabitants, that is, losing its strength for want of proper nourishment, and existing in a state of the utmost poverty." It would be easy to enlarge upon the evils arising from non-resident landlords, rack-rents paid to middle men, and a consequent wretched system of agriculture; but to do so in this place would not be likely to contribute to amendment, and the re-

VOL. XXIII.

marks would not belong to this more than to many other counties. Beaufort's Memoir. Sir C. Coote's Statistical Survey. Wakefield's Account of Ireland.

MONAGHAN, a market and post-town of Ireland, and the shire-town of the county of Monaghan, described in the preceding article. Before the Union it was a borough, but is not now represented. It is 62 miles N.N.W. from Dublin. N. lat. 54 16'. W. long. 6 49'.

MONAH, a town of Hindoostan, in Baramaul; eight miles N. of Namacul.

MONALIAN, a township of America, in York county, Pennsylvania.

MONAINCHA, in *Ecclesiastical Antiquities*, the name of a celebrated old monastery in Ireland, which belonged to the Culdees, and is mentioned by Cambrensis. It is situated in the bog of Monela, in the county of Tipperary; three miles S.E. from Roscrea. Archdall. Ledwich.

MONAMBASCHAGATT, a town of Africa, on the river Camarones.

MONANDRIA, in *Botany*, from *μνος*, one, and *ανδρ*, a man, the first class of the Linnæan sexual, or artificial, system, characterized by having one stamen only, in the same flower with the pistil. It consists of two orders, distinguished by the number of their styles, or sessile stigmas; like all the orders of the first 13 classes of this system. Some few species of *Valeriana*, a naturally triandrous genus, are monandrous.

The character of this class is in general easy and obvious, but a difference of opinion exists among botanists, concerning some genera which Linnæus has referred to it. These are of the natural order of *Scitamineæ*, in several of which order the two lobes of the anther are separated by the breadth of the filament, which is in them unusually great. But that these two lobes do really constitute one anther only, is evident from other genera of the same natural order, in which, the filament being but of the ordinary slender dimensions, the two lobes are brought closely together. There are other instances of a similar distance between the two lobes of an anther, as in *Berberis*.

MONANDRIA is likewise the name of an order of the class *Gynandria*, as well as of the *Monœcia* and *Diœcia*. Respecting the two last, every body is agreed, but the first has been established since the time of Linnæus, and consists of all the known *Orchideæ*, except *Cypripedium*, which that great botanist considered as having two anthers, but which prove, on a correct investigation, and especially by the analogy of the *Scitamineæ*, to have really but one. See ORCHIDEÆ and SCITAMINEÆ.

Some species of *Salix*, considered as monandrous, are perhaps more truly monadelphous, their anther being certainly double, and their filaments two, united into one from the bottom to the very summit. In other species this union is but partial, and these are universally deemed monadelphous.

MONANTHUEIL, HENRY DE, in *Biography*, or, when latinized, *Monantholius*, a French physician and mathematician, was born of a noble family, possessed of an estate of the same name, in the Vermandois, about the year 1536. His birth place was Rheims; but he received his education in the college of Presla, at Paris, under the direction of the celebrated Ramus, whose doctrines he afterwards defended. He then transferred his studies to the college royal, where he applied with ardour both to mathematics and medicine, and received the degree of doctor in the latter science. He held the office of dean of the faculty of medicine for two successive years, 1578 and 1579. His mathematical acquirements had obtained for him the appointment of professor in 1576,

which he fulfilled with so much distinction, as to gain the honour of numbering among his auditors the celebrated James Augustus de Thou, the learned Peter de Lamoignon, and other eminent characters. He continued to perform the duties of this professorship with undiminished zeal and reputation, for a period of thirty years; while at the same time he did not neglect those of his medical office. He was extremely active in maintaining the privileges of the faculty, and successfully exposed the impositions of a noted empiric of his day, named La Riviere, who was exiled from Paris by an arrêt of parliament. He was on terms of intimate friendship with William du Vair, keeper of the seals; and was the Musæus, on whom that gentleman bestowed so high an eulogium in his discourse "On Constancy." He was distinguished by his steady loyalty during the trouble of the league, and pronounced the first public panegyric on king Henry IV., when his majesty obtained the possession of Paris from the hands of that faction. He died in the year 1606, highly respected for every quality that could adorn the man and the scholar. He was author of the following works: "Liber de Angulo Contactus, adversus Jacobum Peletarium," 1581;—"Oratio, quale esse deberet Collegium Professorum Regionum," 1595;—"Ludus Jatro-mathematicus, Musis factus," 1597;—"Commentarii in Librum Aristotelis de Mechanicis," with the Greek text, and a new Latin version, 1599;—"De Puncto, primo Geometriæ principio, Liber," 1600;—"Problematis omnium quæ à 1200 annis inventa sunt nobilissimi Demonstratio," 1600. And he left in an unfinished state a large mathematical work, entitled "Hepatecon Mathematicum," on which he had been long occupied. Gen. Biog. Eloy Dict. Hist.

MONARCHICI, in *Church History*, heretics towards the end of the second century, who allowed but one person in the godhead, and maintained that the father, the creator of all things, had united himself to the human nature of Christ; whence they were called Monarchians; and they also taught that the father was crucified; on this account they were denominated Patripassians.

MONARCHY, *μοναρχία*, a large state governed by one; or a state where the supreme power is lodged in the hands of a single person.

The word comes from the Greek *μοναρχος*, one who governs alone; formed of *μονος*, solus, and *αρχη*, imperium, government.

Of the three forms of government, *viz.* democracy, aristocracy, and monarchy, the last is the most powerful, all the sinews of government being knit together, and united in the hand of the prince; but then there is imminent danger of his employing that strength to improvident or oppressive purposes. As a democracy is the best calculated to direct the end of a law, and an aristocracy to invent the means by which that end shall be obtained, a monarchy is most fit for carrying those means into execution.

Honour, says Montesquieu, which aspires to preferments and distinguishing titles, is the prevailing principle in monarchies; this sets all the parts of the body politic in motion; by its very action it connects them, and thus each individual advances the public good, while he only thinks of promoting his own particular interest; this principle gives life, not only to the whole body politic, but to the laws, and even to the virtues themselves. This principle is altogether unknown in despotic governments; of which fear is the principle.

As honour is the principle of a monarchical government, systems of education and of legislation should be formed and conducted with a constant regard to this principle. The nobility should be rendered respectable and hereditary,

and their lands should have privileges annexed to them as well as their persons. The laws should also favour all kinds of commerce, consistent with the constitution of the government, that the subjects may be able, without ruining themselves, to satisfy the continual cravings of the prince and his court. Some fixed regulation should also be established; that the manner of collecting the taxes may not be more burdensome than the taxes themselves.

Monarchy has a great advantage over a despotic government. As it naturally requires there should be several orders belonging to the constitution under the prince, the state is more fixed, the constitution more steady, and the person of him that governs more secure. We may also add, that as people who live under a good government, are happier than those who, without rule or leaders, wander about the forests; so monarchs who live under the fundamental laws of their country, are far happier than despotic princes, who have nothing to regulate either their own, or their subjects' hearts. In monarchies, where honour alone predominates, the prince's rewards would consist only of marks of distinction, if the distinctions established by honour were not annexed to a luxury which is necessarily attended with wants; the prince therefore is obliged to confer honours that lead to wealth; and it is a general rule, that great rewards, in monarchies and republics, are a sign of their decline; because they are a proof of their principles being corrupted, and that the idea of honour has no longer the same force in monarchy, nor the title of citizen the same force in a republic. The very worst Roman emperors were those who were most profuse in their largesses, *viz.* Caligula, Claudius, Nero, Otho, Vitellius, Commodus, Heliogabalus, and Caracalla. The best, such as Augustus, Vespasian, Antoninus Pius, Marcus Aurelius, and Pertinax, were economicals. Under good emperors the state resumed its principles; all other treasures were supplied by that of honour. In a republic presents are odious, because virtue does not need them. In monarchies honour is a much stronger incentive than presents. But in a despotic government, where there is neither honour nor virtue, people cannot be determined to act but through hopes of the conveniences of life. In monarchical governments, Montesquieu is of opinion, that the laws ought not to oblige a subject to accept of a public employment; nor should a subject be obliged to accept of a post in the army inferior to what he held before, because honour, true or false, will never bear with what it calls degrading itself; nor should civil and military employments be conferred on the same person; nor is venality of public employments improper, as he thinks, in monarchies. He adds, that in monarchies there should be no censors, because being founded on honour, it is in the nature of honour to have the whole universe for a censor. In monarchies, the administration of justice, which decides not only in regard to life and property, but likewise to honour, demands very scrupulous inquiries. In monarchies, it is a great inconvenience for the ministers of the prince to be judges. Our author thinks, that luxury is extremely proper for monarchies, and that under this government there ought to be no sumptuary laws. Republics, he says, end with luxury, and monarchies with poverty. As democracies are destroyed when the people despoil the senate, magistrates, and judges of their functions; so monarchies are corrupted when the prince insensibly deprives societies of their prerogatives, or cities of their privileges. In the first case the multitude usurp a despotic power; in the second it is usurped by a single person. Monarchy is destroyed, when a prince thinks he shews a greater exertion of power in changing, than in conforming to the uses of things; when he deprives some of

MONARCHY.

his subjects of their hereditary employments, to bestow them arbitrarily upon others, and when he is fonder of being guided by his fancy than by his judgment. It is destroyed, when the prince, directing every thing to himself, calls the state to his capital, the capital to his court, and the court to his own person. Monarchy is destroyed, in fine, when the prince mistakes his authority, his situation, and the love of his people; and when he is not fully persuaded, that a monarch ought to think himself secure, as a despotic prince ought to think himself in danger. *Montesq. Sp. of Laws, vol. i. passim.*

The most ancient monarchy was that of the Assyrians, which was founded soon after the deluge, in the year 259 B.C. We usually reckon four grand or universal monarchies; the Assyrian, Persian, Grecian, and Roman; though St. Augustine makes them but two, *viz.* those of Babylon and Rome. Belus is placed at the head of the series of Assyrian kings who reigned at Babylon, and is by profane authors esteemed the founder of it, and by some the same whom the scriptures call Nimrod. The principal Assyrian kings after Belus were Nimus, who built Nineveh, and removed the seat of empire to it; Semiramis, who, disguising her sex, took possession of the kingdom instead of her son, and was killed and succeeded by her son Ninyas; and Sardanapalus, the last of the Assyrian monarchs, and more effeminate than a woman. With him terminated the ancient monarchy of Assyria, in the year 820 B.C. After his death, the Assyrian empire was split into three separate kingdoms; *viz.* the Median, Assyrian, and Babylonian. The first king or prefect of the Median kingdom was Arbaces; and this kingdom lasted till the time of Assyages, who was subdued and divelled of his kingdom by Cyrus. The first king of the new Assyrian kingdom was Phul, who began his reign in the year 777 B.C., and this kingdom was united to that of Babylon under Assaradinus, 680 B.C. The Babylonian kingdom commenced under Nabonassar, 747 B.C., and after being united to that of Assyria, was again separated, 667 B.C., Saosduchinus being its first king, and Nimus II. king of Assyria. These monarchies continued separate until the year 606 B.C., when Assyria was united to Media. The Babylonian kingdom terminated by the conquest of Cyrus, 538 B.C. In the time of Cyrus, there arose a new and second monarchy, called the Persian; which stood upwards of two hundred years, from Cyrus, whose reign began 559 B.C., to Darius Codomannus, who was conquered by Alexander, 331 B.C., and the empire translated to the Greeks. The first monarch was Cyrus, founder of the empire; the second Cambyfes, the son of Cyrus. 3. Smerdis. 4. Darius, the son of Hytaspes, who began his reign 521 B.C. 5. Xerxes, who succeeded Darius, 485 B.C. 6. Artaxerxes Longimanus, who commenced his reign 464 B.C. 7. Xerxes II., who began his reign 425 B.C. 8. Ochus, or Darius, called Nothus, 424 B.C. 9. Artaxerxes Mnemon, 404 B.C. 10. Artaxerxes Ochus, 358 B.C. 11. Arses, 337 B.C. 12. Darius Codomannus, 335 B.C., who was defeated by Alexander the Great, and deprived of his kingdom and life about 331 B.C.; and the dominion of Persia after his death was translated to the Greeks. The third monarchy was the Grecian. As Alexander when he died did not declare who should succeed him, there started up as many kings as there were commanders. At first they governed the provinces, that were divided among them, under the title of viceroys; but when the family of Alexander the Great was extinct, they took upon them the name of kings. Hence, in process of time, the whole empire of Alexander produced four distinct kingdoms; *viz.* 1. The Macedonian, the kings

of which, after Alexander, were Philip, called Arrideus, 323 B.C., Cassander, 316 B.C., Antipater and Alexander, 298 B.C., Demetrius Poliorcetes, 294 B.C., Pyrrhus, 287 B.C., Lysimachus, 286 B.C., Ptolemy, called Cerannus, 280 B.C., Meleager, 279 B.C., Antipater the Etesian, 278 B.C., Antigonus Gonatas, 277 B.C., Demetrius, 243 B.C., Antigonus Dofon, 232 B.C., Philip, 221 B.C., and Perseus, 179 B.C., under whom the Macedonian kingdom was reduced to the form of a Roman province. 2. The Asiatic kingdom, which, upon the death of Alexander, fell to Antigonus, 311 B.C., comprehending that country now called Natolia, together with some other regions, beyond Mount Taurus. From this kingdom proceeded three lesser ones; *viz.* that of Pergamus, whose first king was Philetaerus the Eunuch, 283 B.C., and whose last king, Attalus, called Philometor, in the year 132 B.C., appointed the Roman people to be his heir: Pontus, reduced by the Romans into the form of a province, when they had subdued the last king, Mithridates; and the Syrian. 3. The Syrian, to which that of Babylon was united, of whose twenty-two kings the most celebrated were Seleucus Nicator, founder of the kingdom, 312 B.C., Antiochus Deus, 261 B.C., Antiochus the Great, 223 B.C., Antiochus Epiphanes, 175 B.C., Tigranes, 83 B.C., and Antiochus Asiaticus, 69 B.C., who was conquered by the Romans under Pompey; and Syria was reduced into the form of a Roman province, 65 B.C. 4. The Egyptian, which was formed by the Greeks in Egypt, and flourished near two hundred and forty years under twelve kings; the principal of whom were Ptolemy Lagus, its founder, 323 B.C., Ptolemy Philadelphus, 284 B.C. founder of the Alexandrian library; and queen Cleopatra, who was overcome by Augustus; in consequence of which Egypt was added to the dominion of the Romans, 30 B.C. The fourth monarchy was the Roman, which lasted two hundred and forty-four years, from the building of the city, until the time when the royal power was abrogated. The kings of Rome were Romulus its founder, Numa Pompilius, Tullus Hostilius, Ancus Martius, Tarquinius Priscus, Servius Tullius, and Tarquin the Proud, who was banished, and with whom terminated the regal power. *Holberg's Introd. to Univ. Hist. by Dr. Sharp, p. 85, &c.*

There seems, in reality, no necessity to make the Medes, Persians, and Greeks, succeed to the whole power of the Assyrians, to multiply the number of the monarchies: it was the same empire still, and the several changes that happened in it, did not constitute different monarchies. Thus the Roman empire was successively governed by princes of different nations, yet without any new monarchy being formed thereby. Rome, therefore, may be said to have immediately succeeded Babylon in the empire of the world. See EMPIRE.

Of monarchies some are *absolute* and *despotic*, where the will of the monarch is uncontrollable, as Denmark, &c.; others are *limited*, where the prince's authority is restrained by laws, and part of the supreme power lodged in other hands; as in England. See GOVERNMENT.

Some monarchies, again, are *hereditary*, where the succession devolves immediately from father to son; and others are *elective*, where, on the death of the monarch, his successor is appointed by election.

According to Hobbes, monarchy, as well as aristocracy, derives all its authority from the people, who transfer all their right, *v. gr.* the supreme power, by a plurality of suffrages, &c. to some one person called a monarch; so that whatever the people could have done before this translation, may be now rightfully done by him to whom

the translation is made. This done, the people are no longer to be looked upon as a body, but a dissolved multitude; because they were only one by virtue of the supreme power, which they have now transferred to another.

Nor can the monarch, according to this author, oblige himself by any covenants, to any person, for the authority he has received; because he receives the power from the people, which, as soon as that is done, ceases to be a body; and the body ceasing, the obligation to the body ceases of course. The people, therefore, are obliged to pay obedience to the monarch, by virtue of those covenants, whereby they mutually oblige themselves to what the people, as a body, enjoin to be done.

He argues, farther, that as a monarch cannot be obliged by any covenants; so neither can he do any injury to his subjects; an injury being nothing else but a breach of covenant; and where there is no covenant, there can be no breach of one. De Cive, c. 8. See HOBBIISM.

Fifth-MONARCHY Men, in the *Ecclesiastical History of England*, were a set of wrong-headed, and turbulent enthusiasts who rose in the time of Cromwell, and who expected Christ's sudden appearance upon earth to establish a new kingdom: and, acting in consequence of this illusion, aimed at the subversion of all human government. Burnet's Hist. of his Own Times, vol. i. p. 67.

MONARDA, in *Botany*, named in honour of Nicholas Monardes, a Spanish physician and botanist who lived at Seville towards the close of the sixteenth century, and who published various treatises relating to the natural productions, and especially to the *Materia Medica*, of the new world.—Linn. Gen. 16. Schreb. 22. Willd. Sp. Pl. v. 1. 124. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 50. Vahl. Enum. v. 1. 217. Michaux. Boreal-Amer. v. 1. 16. Juss. 111. Lamarck Illustr. t. 19. Gærtn. t. 66.—Class and order, *Diandria Monogynia*. Nat. Ord. *Verticillatae*, Linn. *Labiatae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, cylindrical, striated, permanent, with a five-toothed, equal mouth. *Cor.* unequal; tube cylindrical, longer than the calyx; limb ringent: upper lip straight, narrow, linear, undivided; lower reflexed, broader, cloven into three segments, of which the middle one is longer, narrower, and emarginate; its sides obtuse. *Stam.* Filaments two, bristle-shaped, as long as the upper lip, by which they are embraced; anthers compressed, truncated at the top, convex and straight at the lower part. *Pist.* Germen superior, four-cleft; style thread-shaped, parallel to the stamens; stigma cloven, acute. *Peric.* none. *Seeds* four, roundish, lying at the bottom of the calyx.

Obs. *M. didyma* has four stamens, two of which are abortive.

Eff. Ch. Corolla unequal, its upper lip linear, and inclosing the filament. Seeds four.

1. *M. fistulosa*. Purple or Crimson Canada Monarda. Linn. Sp. Pl. 32. J. Miller. Illustr. t. 3. (*M. fistulosa*, var.; Curt. Mag. t. 145.)—Leaves oblong-lanceolate, pointed, hairy, flat. Stems obtusely angular.—Native of Canada as well as other parts of North America, cultivated by Mr. John Tradescant in 1656. It flowers from June to August.—*Root* perennial, strongly fibrous and spreading. *Stems* nearly three feet high, obtusely angular, hairy, branched at the upper part. *Leaves* opposite, on short stalks, broad at the base, but sharply pointed at the end, hairy and toothed. *Flowers* in one or two terminal, dense whorls, of a beautiful deep crimson colour.—The whole herb is remarkable for its fragrance as well as beauty, and is not

unfrequently cultivated in our gardens. The variety figured by Curtis, and quoted above, is larger and more showy than the original species, its blossoms far surpassing that in size and brilliancy of colour. The floral leaves also are richly tinted with lilac or purple.—Upon comparing Curtis's figure with the Linnæan Herbarium, it appears that this variety of *fistulosa* is what Linnæus has called *M. mollis* in the third volume of the *Amanitates Academicae*, p. 399.—It may be propagated by parting its roots.

2. *M. oblongata*. Long-leaved Monarda. Willd. n. 2. Ait. Hort. Kew. ed. 2. v. 1. 51.—Leaves oblong-lanceolate, rounded and somewhat contracted at the base, hairy, flat.—Native of North America, and cultivated in 1761, by Mr. James Gordon. It flowers from July to September.—There is no figure of this species, but, from a specimen in Dr. Smith's herbarium, we find that it chiefly differs from the preceding in having its *leaves* more oblong, and more attenuated, though not actually tapering, at the base; they are also more hairy on the under side. The *calyx* is shorter and more hairy at the margin. The *flowers* also are smaller.

3. *M. didyma*. Scarlet Monarda, or Oswego-Tea. Linn. Sp. Pl. 33. Curt. Mag. t. 546. (*M. coccinea*; Michaux. Boreal-Amer. v. 1. 16.)—Leaves ovate, smooth. Whorls of flowers capitate, with two imperfect, additional stamens. Stem acutely angular.—Native of hills on the mountains of North America; introduced into this country by Peter Collinson, before 1752. It flowers from June to August.—*Root* perennial. *Stems* about two feet high, squarish, acutely angular, branched so as to become bushy towards the top. *Leaves* opposite, on short stalks, toothed and fringed at the edge, when bruised, emitting a grateful, refreshing smell, which, independently of the beauty of the plant, would entitle it to a place in every garden. *Flowers* much like those of *M. fistulosa* in habit, but larger, and of a rich scarlet hue; most of them furnished with two additional abortive stamens, whence the specific name.—This increases greatly by throwing out radical shoots, which may be transplanted.

4. *M. rugosa*. White Monarda. Willd. n. 4. Ait. Hort. Kew. ed. 2. v. 1. 51.—Leaves ovato-lanceolate, heart-shaped, smooth, rugose.—Native of North America; cultivated in 1761, by Mr. James Gordon; flowering from July to September.—This species is adopted by Vahl and Martyn from Aiton, but as we are unacquainted with any specimen or figure, we can only give professor Willdenow's description, who says that it is very nearly allied to the following species, *M. clinopodia*, but that its *leaves* are longer, smoother, and somewhat rugose like those of many species of *Salvia*. The *flowers* also are white.

5. *M. clinopodia*. Wild Basil-leaved Monarda. Linn. Sp. Pl. 32.—Leaves ovato-lanceolate, smooth, rounded and unequal at the base.—Native of Virginia; cultivated by Mr. William Malcolm in 1771. It flowers in July.—*Root* creeping. *Stems* about two feet high, square, rather acutely angular, branched. *Leaves* opposite, remarkably smooth, attenuated, remotely serrated; the floral ones narrower, and coloured at the base. *Flowers* capitate, terminal, of a pale colour.—The specific name originated from a striking resemblance in the leaves to those of *Clinopodium incanum*, and was originally written by Linnæus, on the specimen in his herbarium, *clinopodifolia*.

6. *M. punctata*. Spotted Monarda. Linn. Sp. Pl. 32. Andr. Repof. t. 546. Sm. Insects of Georgia, t. 24. (*M. lutea*; Michaux Boreal-Amer. v. 1. 16.)—Flowers in whorls. Corolla spotted. Bractæas large and coloured.—Native of North America; cultivated here in 1714, by Mr. Thomas Fairchild.

Yairchild.—*Root* biennial. *Stems* erect, nearly two feet high, branched, jointed. *Leaves* in stalks, lance-late, in clusters at each joint, serrated from the middle to the end, smooth, veined. *Flowers* axillary, in dense whorls, yellow, spotted with purple, accompanied by very handsome, crimson bracteas. Michaux has changed the specific name to *lutea*, because he observes, the corolla in every species of *Monarda* is spotted. We cannot however accede to this change, as in our present plant, the spots on the corolla are so infinitely more apparent than in any other, as to render the name sufficiently descriptive.

7. *M. allophylla*. Variegated-leaved *Monarda*. Vahl. Enum. v. 1. 219. Michaux. Boreal-Amer. v. 1. 16.—Leaves oblong, serrated. Calyx bearded at the border. Flowers capitate, terminal.—Found by Michaux in North America, from whom and Vahl all that we know of it is collected. The former says, that the shape, serratures, and pubescence of its leaves are so various as to induce a supposition that its varieties may constitute different species. *Flowers* flesh-coloured.

8. *M. ciliata*. Virginian ciliated *Monarda*. Linn. Sp. Pl. 33. (*Chnopodium angustifolium non ramosum, flore caeruleo: labio trifido, atripurpureis maculis ornato; Pluk. Alm. t. 164. f. 3.*)—Leaves oblong or oval, gradually pointed. Flowers capitate, whorled. Bracteas ciliated.—Native of Virginia and Carolina. Introduced at Kew by Mr. Francis Masson in 1798. It flowers in July.—*Root* creeping. *Stems* a foot or more in height, distantly jointed, hairy, especially at the upper part. *Lower leaves* on stalks, roundish, an inch long, notched; upper ones sessile, narrower. *Flowers* capitate, in whorls, large, blue, elegantly marked, with dark purple spots. The habit and appearance of this species are different to all the rest, and it has the smell of Mint.

MONARDA, in *Gardening*, contains plants of the fibrous-rooted, herbaceous, showery, biennial, and perennial kinds, of which the species cultivated are: the purple monarda (*M. fistulosa*); the long-leaved monarda (*M. oblongata*); the scarlet monarda, or Oswego tea (*M. didyma*); the white monarda (*M. rugosa*); and the spotted monarda (*M. punctata*).

Method of Culture.—All these plants may be increased by parting the roots, and some of them by slips and cuttings as well as seeds. But as the first sort does not increase fast by the roots, the seeds may be sown in the autumn on a bed of good earth, and in the following summer the plants be removed into nursery rows half a foot apart, in a rather shady situation, and in the beginning of the following autumn set out where they are to remain and flower. They succeed best in a soft loamy soil not too much exposed.

The roots should be divided either in the autumn or very early spring, but the former is the better season, being afterwards either planted out in rows till they are strong, or, when strong, at once where they are to remain. And strong slips or cuttings of the branches may be taken off in the beginning of summer, and planted out in a shady border, due shade and water being given till well rooted, when in the autumn they may be removed to where they are to remain.

The third species succeeds best in a light soil in an eastern aspect.

These plants all afford ornament in the borders and clumps of pleasure-grounds, &c.

MONARDES, NICHOLAS, in *Biography*, a Spanish physician, was born at Seville in the early part of the sixteenth century. He received his education at the university of Alcalá de Henarez, and settled in the practice of his pro-

fession in his native city. Little is recorded respecting his life, which terminated at the same place in the year 1578. He was considerably distinguished, however, by his writings, the first of which related to a controverted question, and was entitled, "De secunda vena in Pleuritudine inter Græcos et Arabes concordia," Hispal. 1539. His next was a tract, "De Rosa et partibus ejus; de succi Rosarum temperatura, &c."—But his reputation was chiefly extended by his work, in the Spanish language, concerning the medicinal substances imported from the new world, entitled, "Dos Libros de las cosas que se traen de las Indias Occidentales, que sirven al uso de Medicina," Sevilla 1565. It was reprinted in 1569 and 1580, and to the latter edition a third book was added. Charles l'Ecluse, or Clusius, translated this work into Latin, with the title of "Simplicium Medicamentorum ex novo orbe delatorum, quorum in Medicina usus est, Historia," Antw. 1574, and improved it by his annotations, and by the addition of figures. This work was also translated into Italian and French. The botanist will seek in vain for accuracy in his descriptions, but the work was useful, by exciting the public attention to medicines heretofore little known. Monardes also published three works in Spanish, which were translated into Latin by l'Ecluse, with the title of "Nicolai Monardi Libri tres, magna Medicinæ secreta et varia Experimenta continentes," Lugd. 1601. The first of these relates to the lapis bezoardicus; the second, to the use and properties of steel, which he was the first after Rhazes to recommend as a deobstruent, according to Dr. Freind; and the third, to the efficacy of snow. His name is perpetuated by the botanical genus *Monarda*, in the class diandria of Linnæus. Eloy Dict. Hist. Gen. Biog.

MONAS, in *Natural History*, a genus of insects of the order Infusoria. The generic character is, worm invisible to the naked eye, most simple, pellucid, resembling a point. This genus includes five species, of which three are found in our own country. Mr. Adams describes five other species.

Species.

* *ATOMUS*. Whitish, with a variable point. The animalcule itself appears as a white point, which, when highly magnified, is egg-shaped: the smaller end is generally marked with a black point, of which the situation is sometimes varied, and found at the other end. Sometimes there are two black points seen crossing the middle of the body. Mr. Adams says it was found in sea-water that had been kept the whole winter; it was not fetid, but no other species of animalcule could be discovered in the same water.

PUNCTUM. A solid opaque black point. The animalcule of this species are very minute points, solid, opaque, and black, round and long. They are dispersed in the infusion, and move with a slow wavering motion, and were found in a fetid infusion of pears.

* *MICA*. This is transparent, or rather semi-transparent, like talc, with an oval moveable circle in the middle. It may be discovered sometimes in very pure waters with the third lens of a single microscope: when the magnifying power is increased, it appears nearly spherical, or oval, as it seems able to assume either of these forms at pleasure. There is a considerable variety in its motions: it often turns round for a long time in the same place. An appearance has been exhibited like two kidneys in the middle of the body, and the little animal is beautifully encompassed with a kind of halo, arising, most probably, from invisible and vibrating fibrillæ.

* *LENS*. This, as its name imports, is transparent, with frequently

frequently a greenish margin. It is nearly of a round figure, and so pellucid, that it is not possible to discover the least vertige of intestines. The animalcula of this species are frequently seen collected together, forming a kind of vesicular or membranaceous mass. The motions of the *lens* are in general rapid, and Mr. Adams says that two united together may frequently be seen swimming among the rest; while in this situation they have been mistaken by observers for a different species, but it is the same generating another by division. It is found in almost all kinds of water; also in infusions of animal and vegetable substances, myriads are said to be contained in a single drop.

TERMO. A most minute simple gelatinous point. Of this Mr. Adams observes, "Among the various animalcula which are discovered by the microscope, this is the most minute and the most simple; a small jelly-like point, eluding the powers of the compound microscope, and being but imperfectly seen by the single; these and some others of the *Monas* kind are so delicate and slender, that it is no wonder they often escape the sight of many who have examined infusions with attention; in a full light they totally disappear, their thin and transparent forms blending as it were with the water in which they swim. Small drops of infused water are often so full of these, that it is not easy to discover the least empty space, so that the water itself appears changed into another substance less transparent, but consisting of innumerable globular points, thickly sown together; which, though full of life, seem only a kind of inflated bladder. In this a motion may be perceived, something similar to that which is observed when the sun's rays shine on the water, the animalcula being violently agitated, or in commotion like a hive of bees."

Such are the species described in Gmelin's edition of Linnæus. Mr. Adams has mentioned five others as follow:

OCCELLUS. Transparent like tale, with a point in the middle. The margin is black; it moves irregularly; is found in ditches covered with conserva, and frequently with the "*Cyclidium milium*."

TRANQUILLA. Egg-shaped, transparent, with a black margin. The animalcula of this species seem to be animated points, and nearly fixed to one spot, where they have a fluctuating and reeling motion; they are frequently surrounded with a halo, like the *mica*, but differ in their figure, being sometimes spherical, and sometimes quadrangular. They are found in urine kept some time. This fluid is, after it has remained any length of time in the vessel, covered with a dark coloured pellicle, in which the little animals exist. In most cases a single drop of urine is fatal to animalcula, but the discovery of these prove that there are beings of a peculiar kind appropriated to and flourishing in it.

LANELLULA. Flat and transparent. Found chiefly in sea-water. Its colour is whitish, twice as long as it is broad, transparent, with a dark margin, the motion is vacillatory; it often appears as if it were double.

PULVISGULUS. Transparent, with a green margin. The animalcula of this species appear, when properly magnified, like spherical pellucid grains of different sizes; the circumference is green, and a green bent line passes through the middle of some of them, supposed to indicate that they are separating into two distinct animalcula. They rove about with a wavering motion, and are found early in the spring in marshy grounds.

UVA. Transparent and gregarious. The animalcula of this species, when collected in a heap, have a rotatory motion. The smaller particles separate from the larger, dividing, sometimes, into as many portions as there are constituent par-

ticles in the group, when separated they revolve with incredible swiftness. "To try," says Mr. Adams, "whether this group of animalcula was collected together by mere chance, or whether it was their natural state, the following experiment was made. A single corpuscle was taken the moment it was separated from the rest, and placed in a glass by itself; it soon increased in size, and when it had attained nearly the same bulk as the group from which it was separated, the surface began to assume a wrinkled appearance, which gradually changed till it became exactly similar to the parent group." The same process was again tried, and with similar success. It is found in a variety of infusions.

MONASABA, in *Geography*, a town of Hindoostan, in Oude; 25 miles E. of Mahomdy.

MONASERAI, a town of Hindoostan, in the circle of Sumbulpour; 10 miles S.E. of Sumbulpour.

MONASIO, a town of Italy, in the department of the Lario; 15 miles N. of Como.

MONASTEER, a town of Africa, built by the Arabs, on a peninsula, which advances into the sea; 50 miles S.E. of Tunis.

MONASTER, a town of Russian Poland, in the palatinate of Kiev; 40 miles E. of Bialacerkiev.

MONASTEREVEN, a post-town of Ireland, in the county of Kildare and province of Leinster. It is situated on the river Barrow, and the Athy branch of the grand canal passes very near it. It has a flourishing trade, and a considerable population. There was an abbey here, which after the suppression came into the Moore family. It still wears the venerable appearance, and retains the name of an abbey, and under the appellation of Moore abbey is the seat of the marquis of Drogheda. Monastereven is 30 miles S.W. from Dublin, and 10 N.W. from Maryborough.

MONASTERII PROVISOIR. See PROVISOIR.

MONASTEROLO, in *Geography*, a town of France, in the department of the Stura; three miles N.W. of Savigliano.

MONASTERY, a convent, or house built for the reception of religious; whether it be abbey, priory, nunnery, or the like.

MONASTERY is only properly applied to the houses of monks, mendicant friars, and nuns. The rest are more properly called *religious houses*.

For the origin of monasteries, see **MONASTIC** and **MONK**. The houses belonging to the several religious orders, which obtained in England and Wales, were cathedrals, colleges, abbeys, priories, preceptories, commanderies, hospitals, friaries, hermitages, chantries, and free chapels. These were under the direction and management of several officers. The dissolution of houses of this kind began so early as the year 1312, when the Templars were suppressed; and in 1323, their lands, churches, advowsons, and liberties, here in England, were given by 17 Edw. II. stat. 3. to the priory and brethren of the hospital of St. John of Jerusalem. In the years 1390, 1437, 1441, 1459, 1497, 1505, 1508, and 1515, several other houses were dissolved, and their revenues settled on different colleges in Oxford and Cambridge. Soon after the last period, cardinal Wolsey, by licence of the king and pope, obtained a dissolution of above thirty religious houses, for the founding and endowing his colleges at Oxford and Ipswich. About the same time a bull was granted by the same pope to cardinal Wolsey to suppress monasteries, where there were not above six monks, to the

value

MONASTERY.

value of eight thousand ducats a year, for endowing Windfor, and King's college in Cambridge; and two other bulls were granted to cardinals Wolsey and Caspiens, where there were less than twelve monks, and to annex them to the greater monasteries; and another bull to the same cardinals to enquire about abbeys, to be suppressed, in order to be made cathedrals. Although nothing appears to have been done in consequence of these bulls, the motive which induced Wolsey, and many others, to suppress these houses, was the desire of promoting learning; and archbishop Cramer engaged in it with a view of carrying on the Reformation. There were other causes that concurred to bring on their ruin: many of the religious were loose and vicious; the monks were generally thought to be, in their hearts, attached to the pope's supremacy; their revenues were not employed according to the intent of the donors; many cheats in images, feigned miracles, and counterfeit relics, had been discovered, which brought the monks into disgrace; the Observant friars had opposed the king's divorce from queen Catherine; and these circumstances operated, in concurrence with the king's want of a large supply, and the people's desire to save their money, to forward a motion in parliament, that, in order to support the king's state, and supply his wants, all the religious houses might be conferred upon the crown, which were not able to spend above 200*l.* a-year; and an act was passed for that purpose, 27 Hen. VIII. c. 28.

By this act about 380 houses were dissolved, and a revenue of 30 or 32,000*l.* a-year came to the crown; besides about 100,000*l.* in plate and jewels. The suppression of these houses occasioned great discontent, and at length an open rebellion; when this was appeased, the king resolved to suppress the rest of the monasteries, and appointed a new visitation; which caused the greater abbeys to be surrendered apace; and it was enacted by 31 Hen. VIII. c. 13. that all monasteries, &c. which have been surrendered since the fourth of February, in the twenty-seventh year of his majesty's reign, and which hereafter shall be surrendered, shall be vested in the king. The knights of St. John of Jerusalem were also suppressed by the 32 Hen. VIII. c. 24. The suppression of these greater houses by these two acts, produced a revenue to the king of above 100,000*l.* a-year, besides a large sum in plate and jewels. The last act of dissolution in this king's reign was the act of 37 Hen. VIII. c. 4. for dissolving colleges, free chapels, chantries, &c. which act was farther enforced by 1 Edw. VI. c. 14. By this act were suppressed 92 colleges, 110 hospitals, and 2374 chantries and free chapels. The number of houses and places suppressed from first to last, so far as any calculations appear to have been made, seems to be as follows:

Of lesser monasteries, of which we have the valuation	374
Of greater monasteries	186
Belonging to the hospitallers	48
Colleges	90
Hospitals	110
Chantries and free chapels	2374
Total	3182

Besides the friars' houses, and those suppressed by Wolsey, and many small houses, of which we have no particular account.

The sum total of the clear yearly revenue of the several houses at the time of their dissolution, of which we have any account, seems to be as follows:

	£	s.	d.
Of the greater monasteries	104,919	13	3½
Of all those of the lesser monasteries, of which we have the valuation	29,572	1	10½
Knights hospitallers head house in London	2,385	12	8
We have the valuation of only 28 of their houses in the country	3,026	9	5
Friars' houses, of which we have the valuation	751	2	0½
Total	140,784	19	3½

If proper allowances are made for the lesser monasteries, and houses not included in this estimate, and for the plate, &c. which came into the hands of the king by the dissolution, and for the value of money at that time, which was at least six times as much as at present; and we also consider that the estimate of the lands was generally supposed to be much under the real worth, we must conclude their whole revenues to have been immense.

It doth not appear that any computation hath been made of the number of persons contained in the religious houses.

Those of the lesser monasteries dissolved by 27 Hen. VIII. were reckoned at about	10,000
If we suppose the colleges and hospitals to have contained a proportionable number, these will make about	5,347
If we reckon the number in the greater monasteries, according to the proportion of their revenues, they will be about 35,000; but as probably they had larger allowances in proportion to their number than those of the lesser monasteries, if we abate upon that account 5000, they will then be	30,000
One for each chantry and free chapel	2,374
Total	47,721

But as there were probably more than one person to officiate in several of the free chapels, and there were other houses which are not included within this calculation, perhaps they may be computed in one general estimate at about 50,000. As there were pensions paid to almost all those of the greater monasteries, the king did not immediately come into the full enjoyment of their whole revenues: however, by means of what he did receive, he founded six new bishoprics, viz. those of Westminster, (which was changed by queen Elizabeth into a deanery, with twelve prebends and a school,) Peterborough, Chester, Gloucester, Bristol, and Oxford. And in eight other sees he founded deaneries and chapters, by converting the priors and monks into deans and prebendaries, viz. Canterbury, Winchester, Durham, Worcester, Rochester, Norwich, Ely, and Carlisle. He founded also the colleges of Christ-church in Oxford, and Trinity in Cambridge, and finished King's college chapel there. He likewise founded professorships of divinity, law, physic, and of the Hebrew and Greek tongues, in both the said universities. He gave the house of Grey Friars, and St. Bartholomew's hospital, to the city of London; and a perpetual pension to the poor knights of Windfor; and laid out great sums in building and fortifying many ports in the channel. It is observable, upon the whole, that the dissolution of their houses was an act, not of the church, but of the state; in the period preceding the Reformation, by a king and parliament.

ment of the Roman Catholic communion, in all points except the king's supremacy; to which the pope himself, by his bulls and licences, had led the way.

Although none, in this enlightened period, can approve either the original establishment or continued subsistence of monasteries; yet the destruction of them was felt and lamented, for a considerable time, as a great evil. One inconvenience that attended their dissolution was the loss of many valuable books, which their several libraries contained: for during the dark ages, religious houses were the repositories of literature and science. Besides, they were schools of education and learning; for every convent had one person or more appointed for this purpose; and all the neighbours that desired it might have their children taught grammar and church music there, without any expence. In the nunneries also young females were taught to work and read; and not only people of the lower rank, but most of the noblemen's and gentlemen's daughters were instructed in those places. All the monasteries were also in effect great hospitals, and were most of them obliged to relieve many poor people every day. They were likewise houses of entertainment for all travellers. And the nobility and gentry provided not only for their old servants in these houses, by corrodies, but for their younger children, and impoverished friends, by making them first monks and nuns, and in time priors and prioresses, abbots and abbeesses. On the other hand, they were very injurious to the secular and parochial clergy, by taking on themselves many prebends and benefices, by getting many churches appropriated to them, and pensions out of many others; and by the exemptions they got from the episcopal jurisdiction, and from the payment of tithes. Nor were they less injurious to the nation in general, by depriving the public of so many hands, which might have been very serviceable to it in trade and other employments; by greatly diminishing the number of people, in consequence of the institution of celibacy; and by their houses or churches being sanctuaries for almost all sorts of offenders. And if the superstition had continued, and the zeal of establishing religious institutions had exerted itself with equal vigour to the present age, we should ere this have been a nation of monks and friars, or probably have become a prey to some foreign invader. We say nothing now of the acts of moral turpitude, which were committed in these abodes of celibacy and indolence; which, however they might have been exaggerated, were without doubt flagrant and atrocious. See Tanner's *Notitia Monastica*; and for an abstract, Burn's *Eccl. Law*, art. *Monasteries*.

MONASTIC, something belonging to monks, or the monkish life.

The monastic profession is a kind of civil death, which in all worldly matters has the same effect with the natural death.

The council of Trent, &c. fix sixteen years for the age at which a person may be admitted into the monastical state.

St. Anthony is the person who, in the fourth century, first instituted the monastic life; as St. Pachomius, in the same century, is said to have first set on foot the cœnobitic life, *i. e.* regular communities of religious.

In a short time the deserts of Egypt became inhabited with a set of solitaries, who took upon them the monastic profession. (See *ANCHORET*, *HERMIT*, &c.) St. Basil carried the monkish humour into the East, where he composed a rule, which afterwards obtained through a great part of the West.

In the eleventh century, the monastic discipline was grown

very remiss. St. Odo first began to retrieve it in the monastery of Cluny: that monastery, by the conditions of its erection, was put under the immediate protection of the holy see, with a prohibition to all powers, both secular and ecclesiastical, to disturb the monks in the possession of their effects, or the election of their abbot. In virtue hereof, they pleaded an exemption from the jurisdiction of the bishop, and extended this privilege to all the houses dependent on Cluny. This made the first congregation of several houses under one chief immediately subject to the pope, so as to constitute one body, or, as they now call it, one *religious order*. Till then, each monastery was independent, and subject to the bishop. See **MONK**.

MONASTIER, in *Geography*, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy; 9 miles S.S.E. of Le Puy. The place contains 1766, and the canton 8255 inhabitants, on a territory of 197½ kilometres, in 9 communes.

MONASTIRSKA, a town of Russia, in the government of Tobolsk, on the Mura. N. lat. 57° 4'. E. long. 99° 24'.

MONATOO, a town of Bengal, in the province of Palamow, where is a passage across mountains to Koonda; 23 miles N.N.E. of Palamow.

MONAZZO, a town of Naples, in the province of Otranto; 14 miles S.E. of Tarento.

MONBACHIO, a town of Naples, in Principato Ultra; 15 miles E. of Conza.

MONBIN, or **MOMBIN**, in *Botany*, the French and Spanish name of a West Indian fruit, called by the English Hog Plum, *Spondias lutea*, Linn. Sp. Pl. 614; Monbin arbor foliis fraxini, fructu luteo racemoso; Plum. Nov. Gen. 44. t. 22. Madam Merian, who gives an excellent representation of this plant in her tab. 13. describes the fruit as of an astringent quality, but causing perspiration, which is of the same yellow colour as itself. See **SPONDIAS**.

MONBLANC, in *Geography, a town of Spain, in Catalonia, on the river Francoli; 17 miles N. of Taragon.*

MONBODDO, **LORD**, in *Biography*, so called according to the courtesy of the Scottish bar, and on this account he is more generally known by that title, than by his name of James Burnet, was born about the year 1714. He was educated at one of the Scotch universities, and paid a great attention to classical studies: but as soon as he had determined on the law as the future profession of his life, he passed through the ordinary course of juridical studies, and was, in the year 1737, admitted a member of the faculty of advocates at Edinburgh. His application to literary and juridical studies was almost incessant, and he acquired a high reputation for legal knowledge, as well as for an extensive acquaintance with the Grecian language and literature. In the year 1767 he obtained a judge's seat on the bench of the court of session, and performed with credit and honour the duties of that high office; inasmuch that it is recorded, that no sentence passed by him was ever reversed by the house of peers. In the course of his literary studies, he was led to attempt the composition of a work, that might raise his name to distinction among men of letters, the main object of which is to prove the superior wisdom of the ancients, compared with that of the moderns. The first volume of his intended work, entitled "The Origin and Progress of Language," was given to the public in 1773, which was followed, at different periods, by five other volumes. With the philosophical history of language was involved necessarily that of civilization and knowledge; and what the author wrote on these subjects was perused by critics

critics with sentiments of mingled respect, derision, and indignation. His lordship had, however, many advocates, whose zeal, to say the least, was in every respect equal to their knowledge and learning. Those who were partial to modern literature, says a biographer of lord Monboddo, on account of their ignorance of, and inability to enter into that of antiquity; or who, though not unacquainted with the more popular of the ancient authors, were, however, strangers to the deeper mysteries of Greek erudition, condemned lord Monboddo's work with bitter and contemptuous censure. The Scotch literati generally held the labours of their countryman in much disesteem; but in England its reception was more favourable to the author's expectations. Here were found some critics of universally acknowledged talents and profound learning, who, while they smiled at many of his strange notions and hypotheses, were willing to applaud him for the service he had done to the interests of learning. In the late Mr. Harris, the author of *Philosophical Grammar*, and other erudite works, he found an admirer and literary friend, who was exceedingly delighted to meet with a person that had cultivated those studies with an ardour equal to what he had himself bestowed on them, and who almost worshipped the excellence of the ancient Greeks, as far surpassing all other excellence. While lord Monboddo was proceeding in his publication of this work, he commenced the composition of a larger undertaking, with the express view of unfolding and vindicating the principles of Grecian philosophy. This work, entitled "*Ancient Metaphysics*," consisted of five volumes, quarto, of which the first was published in 1779, and the last appeared after the author's death. In this he vainly attempts to revive the absurd principles of the Aristotelian philosophy, and treats modern systems, not excepting that of the immortal Newton, with a sort of ridicule and contempt, that only exposed himself to well merited derision, or to the more worthy emotions of pity and compassion. Lord Monboddo's private life was spent in the practice of all the social virtues, and in the enjoyment of much domestic happiness. He married an amiable lady, by whom he had a son and two daughters; but of these joys in the cup of life, he was quickly bereaved by the loss of his son and wife,—afflictions which cut deep to the heart: but like a true philosopher, when he found sorrow of no avail, he roused himself to exertion, and called forth his Christian principles, which, in the midst of calamity, led him to trust and hope in him who gave, and who has a right to take away.

He was now offered, in addition to his place as judge in the supreme civil court in Scotland, a seat in the court of judicary, the supreme criminal court, on which he would have done the highest honour, compared with some of the men who have since sat there, and who will be everlastingly remembered for their sentences in the years 1793, 1794, &c. Though the salary of this office would have produced a convenient increase of his income, he was satisfied with his present emoluments, and refused to accept what had been offered, lest his business should too much detach him from his favourite studies. His patrimonial estate did not amount to more than a clear income of 300*l. per annum*, yet he would never raise his rents, supposing that he was by this means serving his tenants; an idea unquestionably founded in error. We have known many instances, in which land has been vastly improved, and tenants enriched, by demanding of them a rise in their rents, corresponding to the increased demands of the times. The error of lord Monboddo was, however, very venial: it originated from the best and most humane motives. He shewed, indeed, at no time a parti-

cular solicitude for any great improvement of his lands: his main object was, that the persons who lived on them should be amply supported by the produce. The vacation of the court of session afforded him leisure to retire every year, in the spring and autumn, to the country, where he was accustomed to dress in a style of simplicity, as if he had been only a plain farmer, and to live among the people upon his estate with all the kind familiarity and attention of a father among his children. In this state he had a visit from Dr. Samuel Johnson; and though, probably, no two persons could differ more than these, yet lord Monboddo was too hospitable to enter into any contentious discussions with a stranger in his own house. His lordship frequently visited London, during his vacations; to which city he was allured by the great number of men of profound erudition, whose conversation he had an opportunity of enjoying there. In all his journeys he was accustomed to ride on horseback, attended by a single servant. On his return from the last visit, which he made purposely to take leave of his friends, he was taken ill on the road, and would probably never have reached home, had not a friend overtaken him, and prevailed on him to travel the remainder of the way in his carriage. His lordship died in June 1799, in the 85th year of his age. Although rigidly temperate in his habits, he delighted much in the convivial society of his friends; and among these he could number all the most eminent characters in Scotland for virtue, literature, and real elegance of conversation. Of his various excellencies we have heard much from a noble lady, now herself no more, who never ceased to cherish his memory with respect and honour.

MONBRUN, in *Geography*, a town of Africa, in the kingdom of Hoval; 15 miles S.W. of Gourbel.

MONBUEY, a town of Spain, in the province of Leon; 30 miles S.W. of Astorga.

MONCADA, a town of Spain, in Catalonia; 8 miles N. of Barcelona.—Also, a town of Spain, in Valencia; 7 miles N.W. of Valencia. This town is now reduced to a village: it has a parish church, a convent of Dominicans, and a population of about 1000 inhabitants.

MONCALIER, a town of France, in the department of the Po, on an eminence near the river, containing two churches, several convents, and a royal palace; 4 miles S. of Turin.

MONCALVO, a town of Istria; 7 miles S. of Rovigno.—Also, a town of France, in the department of Marengo; 9 miles N. of Asti.

MONCAON, a small but fortified town of Portugal, in the province of Entre Duero e Minho, on the Minho; 25 miles N. of Braga. N. lat. 42°. E. long. 8° 10'.

MONÇARAS, a town of Portugal, in Alentejo, on the Guadiana, containing more than 1500 inhabitants; 25 miles E. of Evora.

MONCAYO, a town of Spain, in Aragon; 11 miles W. of Borja.

MONCHABOO, a town of the Birman empire, which was formerly its capital; 52 miles N. of Ava. N. lat. 22° 34'. E. long. 97° 40'.

MONCLAR, a town of France, in the department of the Lot, and chief place of a canton, in the district of Montauban; 10 miles E.S.E. of it. The place contains 1776, and the canton 5267 inhabitants, on a territory of 150 kilometres, in 8 communes. N. lat. 43° 58'. E. long. 1° 40'.—Also, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve-d'Agen; 7 miles west from it. The place

contains 2061, and the canton 8462 inhabitants, on a territory of 150 kilometres, in 10 communes.

MONCON, a town, with a castle, of Spain, in Aragon, on the river Cinca; 25 miles N.W. of Lerida.

MONCONTOUR, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Loudun; 7 miles S.S.W. of Loudun. The place contains 819, and the canton 7173 inhabitants, on a territory of 212½ kilometres, in 18 communes. N. lat. 46° 53'. E. long. 0° 4'.—Also, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brienc; 10 miles S.S.E. of St. Brienc. The place contains 1685, and the canton 14,380 inhabitants, on a territory of 215 kilometres, in 11 communes.

MONCONYS, BALTHASAR DE, in *Biography*, a writer of travels, was born at Lyons, and received the early part of his education in the Jesuits' college of that city. The plague, which in 1628 desolated many countries, at this period, forced him to quit his native place; and he went to Spain, where he completed his studies at the university of Salamanca. He attached himself to mathematics, chemistry, and astrology; and in Portugal, which he visited, he gained considerable reputation by his facility in forming horoscopes. From Portugal he travelled into the East, for the purpose of increasing his knowledge in the occult sciences, as they were falsely called, and tracing the remains of the philosophy of Hermes Trismegistus, and Zoroaster. Discovering, perhaps, the vanity of the pursuit, he returned to France, and devoted himself to mathematical and physical studies, which engaged him in correspondence with most of the learned men of his time. He died at Lyons in 1665; soon after which his travels were published, in three volumes, quarto: they are said to contain many rare and very curious observations. Moreri.

MONCOORAH, in *Geography*, an island in the mouth of the Ganges, about twelve miles long, and three broad. N. lat. 22° 10'. E. long. 91° 10'.

MONCOQ, a town of France, in the department of the Lot, and chief place of a canton, in the district of Cahors; 12 miles S.W. of Cahors. The place contains 1970, and the canton 10,804 inhabitants, on a territory of 205 kilometres, in 16 communes. N. lat. 44° 20'. E. long. 1° 17'.

MONCRIF, FRANCIS-AUGUSTIN PARADIS DE, in *Biography*, a French poet and polite writer, was born of a family in middle life, at Paris, in 1687. Though intended for a business suited to his rank in society, he devoted himself to literature, hoping to obtain the patronage of some person of consequence. One of his earliest compositions was an "Ode on the Death of Louis-le-Grand," by which he expected to conciliate the favour of the regent. But he did not excel in lyrics, and is chiefly distinguished by small theatrical pieces, complimentary verses, madrigals, and ballads, which the French call *romances*. He was an actor as well as a writer, read with grace, and acted in a very agreeable way in the dramatic interludes then in vogue, and thus rendered himself acceptable to the most cultivated societies; at the same time, by his discretion and good humour, avoided every thing that might give offence. He obtained the posts of private secretary to the count of Clermont, and reader to the queen, and was admitted to many honours in the court of Lewis XV. He did not live wholly to himself, but was liberal to his poor relations, zealous in the service of his friends, and grateful for past favours; an instance of which last quality he gave, in his request to be allowed to

follow into his retreat the count d'Argenson, who was exiled in 1757. Moncrif lived enjoying perfect health till a very short time before his death, which took place in 1770, when he had attained the age of 83. As an author, his principal productions are "Essai sur la Nécessité et sur les Moyens de plaire," which is a very instructive work on the art of becoming agreeable in society; "Les Abderites," a comedy; "Poesies diverses;" some dissertations; and several little dramatic pieces of the opera kind. His "Histoire des Chats" was a trifle of the sportive kind. His works have been published collectively in four volumes.

MONDA, or MUNDA, in *Geography*, a town of Spain, in Grenada, near which Cæsar gained a victory over the sons of Pompey; 23 miles W. of Malaga.

MONDAGELE, a town on the east coast of Ceylon; 28 miles S. of Trincooli.

MONDAHU, a river of Brazil, which runs into the Atlantic, S. lat. 3° 10'. W. long. 40° 46'.

MONDARA, a town of Nubia; 40 miles S.W. of Dekin.

MONDAY, PLOUGH. See PLOUGH.

MONDAY Bay, in *Geography*, a bay on the coast of Terra del Fuego, in the straits of Magellan, affording good anchorage in 20 fathoms; 15 miles S.E. of Cape Upright.

MONDEGO, a river of Portugal, which rises near Guarda, in the province of Beira, and discharges itself into the Atlantic, 12 miles S.W. of Montemor e Velho.

MONDEJAR, a town of Spain, in New Castile; 25 miles E. of Madrid.

MONDELLO, a town of Sicily, in the valley of Mazara; 8 miles N. of Palermo.

MONDIM, a town of Portugal, in the province of Beira; 10 miles S.S.E. of Lamego.

MONDINO, or in Latin MUNDINUS, in *Biography*, a physician deservedly celebrated in the dark ages, was born at Milan, according to Freind, and flourished early in the 14th century. He held the professorship of medicine at Bologna in the year 1316, and enjoyed an extensive reputation throughout Italy, then the great seat of science, for his medical skill. His principal claim to distinction, however, rests upon his zeal and success in the cultivation of anatomy, of which art he must be deemed the restorer, having been the first among the moderns who dissected human bodies. He was the author of a work, entitled "Anatomia omnium humani Corporis interiorum Membrorum," first printed at Pavia in 1478, and afterwards frequently republished, with various commentaries. It is a methodical treatise, very copious upon the subject of the viscera, in the description of which he introduced many original observations, but passes lightly over the subject of the nerves and blood-vessels. It abounds, however, with a multitude of errors, resulting from his attachment to the opinions of Galen and Avicenna, and is marked by the rudeness and inaccuracy of the times. Nevertheless, it conferred a real benefit on the infant science, and acquired such a high character for authority in Italy, that the statutes of Padua, and some other medical schools of Italy, prohibited the use of every other work, as a textbook for the students of anatomy: and it continued in this general estimation for nearly two centuries. Mundinus died at Bologna in 1325, or 1326, and was buried in the church of St. Vital. Freind's Hist. of Med. Eloy Dict. Hist.

MONDONEDO, in *Geography*, a town of Spain, in Galicia, 25 leagues N.E. of St. Jago, and at a similar distance W. of Oviedo, is surrounded by mountains; situated at the bottom of a hill, at the entrance of a fertile and pleasant valley, and in the midst of several springs and brooks, and separated by

the two rivers Sigto and Ruzos from its suburbs. It is the see of a bishop, suffragan of Compostella, and has seven churches, including the cathedral and convents, one chapter of canons, one seminary, one oratory, and two hospitals. The town, which is tolerably large, is encompassed by walls, and has five gates and two bridges. The houses are tolerably built, of good stone; the streets are rather narrow, but regular; the grand square is watered by a fountain, and many other fountains cool and cleanse the streets. The air is very salubrious. The population consists of 5600 persons. The place is defended by the castle of Castro Oro. The river Mino rises at a little distance north of this town.

MONDASEDO, *Sierra de*, a mountain of Galicia of great extent, occupying the whole extremity of the north-east of Galicia, towards the Asturian boundary to the east, and proceeding to the north as far as Cabo Ortegal, and to the west as far as the Atlantic ocean.

MONDONVILLE, JOHNS JOSEPH CASSANEA DE, in *Biography*, born at Narbonne in 1711, owes his reputation and his fortune to incessant diligence and toil, a great passion for his art, and a regular conduct. He at first acquired his reputation by the violin: he was the rival of the famous Guignon, who was at the head of his art. They executed together at the Concert Spirituel, and varied with great taste numerous favourite airs in duo, to the infinite satisfaction of the public. He is celebrated by the famous Le Cat of Roan, for producing the *sons harmoniques* upon his violin, of which art he seems to have been the first who distinguished himself.

He composed sonatas for the harpsichord, with an accompaniment *obligato* for the violin, which at one time were in high favour all over Europe. After this, motets for a single voice, accompanied by difficult lessons on the harpsichord, which gained him the place of master of the chapel royal. He directed the Concert Spirituel during many years with great reputation, and likewise composed several pieces for the opera, which had great success.

M. Laborde, from whom this article is extracted, has recorded his private character in a way that does his memory more honour, perhaps, than his compositions; which, though in great favour in these days at Paris, were always too much cast in a French mould to be equally admired elsewhere. His melody was national, but his accompaniments were spirited and ingenious. He died in 1772, at 61.

MONDOVI, in *Geography*, a town of France, in the department of the Stura, late capital of a small province in Piedmont, to which it gave name; situated at the foot of the Apennines, on a mountain near the river Ebro. It was erected into a bishopric by pope Urban VI. in 1388, under the archbishopric of Turin. Besides the cathedral, it has five parish churches, an university, twelve convents, and about 10,000 inhabitants. It was taken by the French, after a splendid victory, in 1796; 30 miles S. of Turin. N. lat. 44° 24'. E. long. 7° 56'.

MONDRAGON, a town of Spain, in the district of Guipuscoa, in the province of Biscay, near which are medicinal springs, and a mine of excellent iron; 24 miles S.S.W. of St. Sebastian.

MONDRAGONE, a town of Naples, in Lavora, near the sea-coast, celebrated on account of its medicinal baths; 13 miles N.W. of Capua.

MONDUKOLSKOI, a town of Russia, in the government of Irkutsk, on the borders of China. N. lat. 50° 8'. E. long. 103° 24'.

MONEAH, a town of Hindoostan, in Bahar, on the right bank of the Ganges; 17 miles W. of Patna.

MONÉBA, a town of Africa, in Calbari, on the Camaroon. N. lat. 3° 40'.

MONEDA, a town of Sweden, in the province of Smolnd; 14 miles N.W. of Wexio.

MONEDULLA, JACKDAW, in *Ornithology*, a species of *Coccyz*; which see.—Also, a species of *Crotophaga*. See *CYPTOMYGA Ani*.

MONÉER, in *Geography*, a town of Hindoostan, in Bahar; 23 miles N.W. of Saferam.

MONÉGAL, a town of Hindoostan, in Golconda; 33 miles S. of Combanet.

MONÉGLIA, a town of the Ligurian republic; seven miles W. of Brugnato.

MONÉINS, a town of France, in the department of the Lower Pyrenees, and chief place of a canton, in the district of Oleron; 9 miles W. of Pau. The place contains 5550, and the canton 11,004 inhabitants, on a territory of 157½ kilometres, in 7 communes.

MONEMERION, ΜΟΝΕΜΑΙΩΝ, among the ancient Romans, a show, according to some, wherein none but tame bealls were exposed to view.

Others will have it to be a show of one day's continuance.

MONESTIER, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Briançon; 13 miles N.W. of Gap. The place contains 2708, and the canton 4736 inhabitants, on a territory of 212½ kilometres, in three communes.

MONESTIEN-DE-CLERMONT, a town of France, in the department of the Here, and chief place of a canton, in the district of Grenoble; 16 miles S. of Grenoble. The place contains 509, and the canton 4258 inhabitants, on a territory of 355 kilometres, in 10 communes.

MONESTIES, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 9 miles N. of Alby. The place contains 1210, and the canton 8101 inhabitants, on a territory of 250 kilometres, in 18 communes.

MONETA, or JUNO MONETA, in *Mythology*, the goddess of money, who had a temple at Rome, is represented upon medals with the instruments of coinage, the hammer, the anvil, the pincers and the die, with the Latin word "moneta." Others say, that this name is formed from *monco*, I warn or advise, because a little before the Gauls besieged Rome, she had warned the people to buy a sow big with young, an etymology that is supported by the authority of Cicero: "Junonem appellatam monetam, a moneo videlicet verbo, denominatam." See MONEY.

MONETÆ PES. See PES.

MONETAGIUM, MONETAGE, or *Mintage*, the right or privilege of coining money.

MONETALES TRIUMVIRI. See TRIUMVIRI.

MONETARIUS, or MONEYER, a name which antiquaries and medallists give to those who struck the ancient coins or monies.

Many of the old Roman, &c. coins have the name of the monetarius, either written at length, or at least the initial letters of it. See MEDAL.

MONETIA, in *Botany*, received its name from L'Heritier, in compliment to the celebrated J. B. de Monet, Chevalier de Lamarck; see LAMARCKIA.—L'Herit. Stirp. Nov. I. t. I. Schreb. 81. App. 813. Willd. Sp. Pl. v. 1. 669. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 264. (Azima; Lamarck Dict. v. 1. 343. Illustr. t. 807. Juss. 425.)—Clas and order, *Tetrandria Monogynia*, L'Herit. (*Dissecta Tetrandria*, Schreb. 813.) Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, swelling, permanent, cloven into four, lanceolate, acute, reflexed segments, two of which are deeper than the rest. *Cor.* Petals four, linear, acute, recurved, longer than the calyx. *Stam.* Filaments four, erect, inserted into the receptacle, almost as long as the corolla; anthers ovate, incumbent. *Pist.* Germen superior, nearly square, terminating in a thickish, conical style, shorter than the stamens; stigma acute. *Peric.* Berry? juiceless, globular, with a little point, surrounded by the calyx, of two cells? *Seeds* solitary, flat on one side, convex on the other.

Obs. The flowers are occasionally trifold or bifid.

Ess. Ch. Calyx inferior, four-cleft. Corolla of four petals. Berry? of two cells. Seeds solitary.

1. *M. barlerioides*. Four-spined Monetia. L'Herit. Stirp. Nov. t. 1. Willd. Thunb. Prodr. 28. (*Azima tetracantha*; Lamarck Dict. v. 1. 343. *Lycium indicum spinis quaternis ad foliorum singulorum exortum*; Seb. Thef. v. 1. 21. t. 13. f. 1.)—Spines four. Leaves smooth on both sides. Native of India, and the Cape of Good Hope. It flowers in the stove about August or September. This is a middling-sized spinous shrub, resembling *Barleria hystrix* in habit. *Root* perennial, woody, branched, cracked, with the taste of liquorice. *Stem* erect, full of chinks, ash-coloured. *Branches* opposite, diffuse, dense; the smaller ones prickly, deflexed, square, green at first, afterwards greyish. *Shoots* green, naturally downy, but becoming smooth by culture. *Prickles* four together, crossing each other horizontally, awl-shaped, sharp-pointed, withering at the tip, with one internal streak, about half as long as the leaves. *Leaves* opposite, on very short stalks, spreading, ovate, pointed, entire, ribbed. *Flowers* axillary, on the young shoots, about three in a cluster, sometimes solitary, sessile and herbaceous. *Braçtes* two-leaved, opposite, adhering to the flowers laterally, very narrow, acute, changing into prickles.

2. *M. diacantha*. Two-spined Monetia. Willd. (*Azima diacantha*; Lamarck Dict. v. 1. 343. *Amaranthoides indicum verticillatum parietariæ hirsutis foliis, spinosum*; Pluk. Alm. t. 133. f. 3. Tsjerou-Kára; Rheed. Hort. Malab. v. 5. 73. t. 37.)—Spines two. Leaves downy beneath. Native of India.—This is an evergreen shrub, rising to the height of six feet, with a thickish stem, and numerous ash-coloured branches, which are very spinous. *Leaves* two or three together, almost sessile, roundish-oblong, thick, close; dark green, smooth and shining above, paler and hairy beneath. *Flowers* axillary, at the base of the spines, small and greenish. The whole herb has a bitter flavour.

Mr. Dryander, in his remarks on Professor Gmelin's edition of the *Système Naturel*, Linn. Trans. v. 2. 221, observes "that *Azima nova* he supposes is meant for *Azima tetracantha* of Lamarck. *A. diacantha* being only taken from Plukenet's figure, is consequently doubtful."—We have however retained it after the example of Willdenow, relying upon the accuracy of Rheede's description and figure.—Kanden-Kára; Rheed. Hort. Malab. v. 5. 71. t. 36, seems undoubtedly of this genus, and perhaps merely a variety of *diacantha*.

Schreber, on revising this genus, has removed it from *Tetrandria* to *Dioecia*, a measure, of which we do not see the propriety, both organs being present in all the flowers, though, as it appears, each is occasionally defective.

MONETOU ISLANDS, in *Geography*, two islands in lake Michigan. N. lat. 44° 50'. W. long. 85° 28'.

MONEY, in *Commerce*, is a general term for coin, paper, or any other measure of value, or representative of property, that passes current from hand to hand as a circulating medium. See BANK, CASH, CIRCULATION, COIN, CURRENCY,

EXCHANGE, PAPER Money, and POLITICAL Economy. For an accurate definition of money, see the next article.

The origin of money seems to have been coeval with the first regulations of civil society, or at least it is too remote to be traced by any authentic history. The invention of this common measure, or standard, according to which all other things should be estimated, is ascribed by some persons, on the authority of Josephus, to Cain; although the first information that has been transmitted concerning it, originates with the patriarch Abraham, who paid 400 shekels for a burying place. The Greeks refer the invention of money to Hermodice, wife of king Midas; and the Latins to Janus. Barter, that is the exchange of one commodity for another, was the ordinary mode of traffic in the earlier periods of the world: thus we find in Homer, that Glaucus's golden armour was valued at 100 oxen, and Diomedes's armour at 10. This method, which still obtains among savage nations, must have been found extremely inconvenient in the early ages of commerce, and hence the necessity of adopting some commodity of general utility and demand as a measure of value. This necessity and its expedient are well explained by Aristotle in his Politics (book i. chap. 6.) "All useful things," says the philosopher, "could not, without great difficulty, be transported from place to place, it was resolved, by common consent, that in bartering commodities, they should reciprocally give and receive some substance, which, being in its nature applicable to the purposes of life, might, at the same time, be easily carried about."

The substance which has been adopted as a circulating medium, or measure of value, has been various in different ages and countries. In Italy it was originally cattle, if we may judge from the Latin word *pecunia*, money, which is said to be derived from *pecus*, a herd or flock. Thus Scaliger says, "à pecu formatur pecunius, unde pecunia: sub-intelligatur res vel quid simile, et sicut veterum divitiarum consistebant in copia pecudis, ita moneta pecudis effigie primùm notata fuit. Et apud Athenienses nummi figurâ boum signati fuerunt." Pliny says, that money was called *pecunia*, because their first coin was stamped with the figure of a cow. The Latin word *moneta* for money is however probably more modern than *pecunia*, and is said to be derived from *moneo*, to advise or mark, that is, to shew by some mark the weight and fineness of the metal of which coins were composed. Thus, according to Isidorus, "Moneta ita appellatur, quia monet nê qua fraus in pondere vel metallo fiat." In favour of this etymology, Suidas observes, that when the Romans were in want of money, Juno admonished them to practise justice, and then there would be no want of money; and when they had found the good effect of this counsel, she was surnamed Juno Moneta, and money was coined in her temple. In process of time, money was made a goddess, and enshrined by the name of *Dea Pecunia*, under the figure of a woman holding a balance in one hand, and a cornucopia in the other.

In all nations where commerce has made any considerable progress, the precious metals, either in coins or ingots, or their representative value in paper, have been adopted as money. Other substances, however, are still used for this purpose in different countries, especially for the common or inferior purposes of trade, as cowries or small shells in India, and salt bricks, and beads, in Abyssinia. See COIN, and the sequel of this article.

As we have already given an account of the progress and present state of metallic monies under the article COIN, and of monies of exchange under the head EXCHANGE, it remains here to explain what is to be understood by monies of

MONEY.

of account, and to state their names in different countries, and also their value compared with sterling.

Money is distinguished into real and imaginary. By real money is understood coin, or any other circulating medium, and by imaginary, or ideal money, a nominal sum, which is not represented by any piece or coin, but which is used in keeping accounts, as the pound sterling, the livre Tournois, &c.

Imaginary monies have had their origin, for the most part, in real coins, or in weights. These units, which were originally adopted as measures of value, have been always continued under the same denomination, notwithstanding the fluctuations which may have taken place in the prices of metals, or of merchandize. There are, however, imaginary monies which have not thus originated, but have been contrived for the purpose of simplifying accounts, as the centimes of France, and the cents in America. It should, however, be observed, that all monies of account are not imaginary, nor are they, in all places, the monies of exchange, but they are most generally so.

In order to understand the monies of account in the following table, some preliminary explanations may be necessary.

Monies are distinguished in different countries by particular denominations, as *specie effective*, *currency*, *banco*, *giro*, *moneta di cambio*, *cash*, *valuta*, &c.

Specie and *effective* generally mean coin, but in Germany the word *specie* is applied to the rix-dollar and its divisions, as coined after the rate of the empire.

Currency mostly signifies the common or current money of a place, which, in Holland, is called *casfe*, in Venice *moneta piccola*, and in other parts of Italy *moneta lunga*; but in some parts of Germany, and particularly in Augsbourg, *currency* means money of account, and it has the same meaning in America and the West Indies, where it derives its name from a paper currency which has been long depreciated and discontinued.

Banco is the money which is placed in banks of deposit,

and which is not drawn out, but transferred from one person to another, in the payment of debts and contracts.

Giro, in most parts of Germany, means money of exchange, which in Italy is called *moneta di cambio*.

Cash generally means real money, but in Hanover the term is applied to a certain superior kind of money used for large payments, as distinguished from another sort, used in inferior departments of business, called, *old value*. The word *cash* is likewise applied to a small coin in China, and in some parts of India beyond the Ganges.

The word *valuta* or *valcur*, is applied in most parts of the continent of Europe to the prices or rates at which different kinds of monies are reckoned in commercial transactions.

The difference of one sort of money compared with another is mostly reckoned at so much *per cent.* When a better sort is given for a worse, the premium or per centage is called *agio*. But when the difference or per centage is considered with regard to the inferior sort of money, it is called *discount*. *Discount* is likewise a term applied to an allowance of so much *per cent. per annum* for the payment of money before it becomes due, and this discount differs from the former as *agio* differs from *interest*.

Interest is an allowance of so much *per cent. per annum* for the use of money, and is therefore an addition to the principal, but *agio* adds nothing to the capital, being only the actual difference in value. In the same manner discount between different sorts of monies, and discount for prompt payment differ; in the former case there is no loss nor diminution, but in the latter there is a deduction from the principal. See AGIO, INTEREST, and DISCOUNT.

The following table, which we extract, by permission, from the Universal Cambist, will shew the value of the principal monies of account of the chief trading places, in sterling, according to the mint regulations of those countries compared with the mint laws of England; and though most of the monies are imaginary, yet, as they represent certain sums of coined money, their value is thence easily known.

TABLE of Monies of Account, containing the Value of the Monies of Account of different Places (expressed in Pence and Decimals of Pence), according to the Mint Price both of Gold and Silver in England; that is, 3*l.* 17*s.* 10½*d.* per Oz. for Gold, and 5*s.* 2*d.* per Oz. for Silver.

From the above table the Intrinsic Par of exchange may be computed where the monies of account and of exchange are the same; but for a more systematic and comprehensive statement of the par, both according to assays and mint regulations; see EXCHANGE.

We shall here subjoin some additions to the historical part of the present article, as well as to that of COIN and COINAGE, to which the reader is referred.

Among the ancient Britons, iron rings, or, as some say, iron plates, or tin plates and rings, were used for money. Among the Lacedæmonians, iron bars were quenched with vinegar, thus intending that they should not serve for any other use. Seneca observes, that there was anciently stamped money of leather, *corium forma publica impressum*; and the same thing was put in practice by Frederic II. at the siege of Milan; to say nothing of an old tradition among

MONEY.

among ourselves, that, in the confused time of the barons wars, the like was done in England. In 1360, king John of France, who agreed to pay our Edward III. for the ransom of his person 3,000,000 of gold crowns, was reduced to the necessity of paying for the necessaries of his household in leather money, in the middle of which there was a little nail of silver. The Hollanders, we know, coined great quantities of pasteboard in the year 1574. Numa Pompilius made money of wood and leather; nor does it appear that the Romans were much acquainted with the art of striking money in metal during the time of their kings. There is reason to believe, that both gold and silver money were very early in use in Egypt and Asia, and thence soon afterwards introduced into Carthage and Greece. From Greece it was brought to Rome, and thence gradually westward into all the Roman provinces.

The first shape, says Mr. Pinkerton, in which money appeared, was that of pieces of metal without any stated form or impression, but merely regulated to a certain weight; for *weight* was the grand standard of ancient coinage, so that all large sums were paid in weight even down to the Saxon period of England. With us weight is now applied to each particular piece, and that only in gold: whereas, with the ancients, weight was applied to the sum total; to silver as well as gold; nay, in some instances, to brass. In Greece large sums were referred to so many "Mnæ," or "Minæ," and also to the larger denomination of so many "Talents." (See MINA and TALENT.) As in Greece the first estimation of money was merely by weight, this was likewise the case in Rome. Silver was the metal first used in Grecian coinage, but copper in the Roman; the former metal having been long unknown to the Romans. The first valuation of Roman money was by the "libra gravis æris," or pound of heavy brass; and when by the progress of their conquests they obtained silver and gold, these were regulated in the same manner. The common Roman pound, yet used at Rome, consisted of 12 ounces of 458 grains each, equal to our ounce avoirdupois; but the money ounce seems to have had only 420 troy grains, and the pound 5040. This was the standard of copper; and when silver came to be coined, seven denarii went to the ounce, as in Greece eight drachms: the gold was regulated by the scriptulum, scrupulum, scruple, or third part of a denarius, and by the larger weights just mentioned. (See DENARIUS, ÆS, and SESTERTIUS.) Money in old Rome, when rising to a high sum, was estimated not by the talent, a term unknown to the Romans, but by the hundred weight of brass, called "Pondus" by way of eminence. See SESTERTIUM.

As to the origin of the Roman coinage we may observe, that the states adjoining to Latium, and from which most probably the form of the first Roman coinage was derived, were, on the N. and W. the Etruscans; and upon the S. and E., at a great distance, the Grecian colonies in Magna Græcia and Sicily. To the Etruscans Mr. Pinkerton ascribes the origin of the Roman coinage, and not to the Grecian colonies, or to the Sicilians. (See LIBRA.) The first Roman coinage, according to Pliny and other respectable authors, took place in the reign of Servius Tullus in the year 460 B.C., or according to the common calculation 550 years B.C. The coinage of Tullus seems to have been confined to the As, Æs, or piece of brass only. (See As.) The largest imperial brass coin was a piece of the value of two-pence English, called "Sestertius;" which see. Before the time of the first Cæsar, as Mr. Pinkerton thinks, yellow brass began to be used in

the Roman coinage, and this was always considered as double in value to the Cyprian, or copper. From Augustus downward, the large brass were all of the yellow sort, and not one of them copper. The largest of those that are called the middle size were likewise all of yellow brass; and that of the next size, which is the As, weighing the half ounce, is universally copper. The orichalcum, or what we term brass, was by the ancients held in far superior esteem to copper, or the "Æs Cyprium." It is observed, that all the large brass coins were of yellow metal, and the middle brass yellow, or red; but the former were always of the finest workmanship. The rust, with which time covers them, has confounded them together, and our putting little more value on brass than on copper hath confirmed the deceit, whereas the ancients put double the value on brass that they put on copper; but the large brass should not be taken for copper, because they sometimes have now a copper hue: before the person who examines can decide, he must always scrape the side of the metal; and he will thus learn that the ancient coinages of brass and of copper were kept as distinct as those of gold and silver. (See SESTERTIUS.) Under Valerian and Gallienus, there appeared a new coinage of copper mixed with silver. Coins of this sort are just the size of the denarius; and, indeed, they are the "denarii," or "philippeï ærei." See DENARIUS and FOLLIS. For an account of the silver coinage of Rome; see DENARIUS.

The gold coinage of Rome took place, according to Pliny, sixty-two years after silver, that is, in the 547th year of the city, by vulgar account, or 204 B.C. At that time the scruple, which even now remains, passed for 20 sesterces. Afterwards it was thought proper to coin 40 pieces out of the pound of gold; and by degrees this weight was diminished to 45 in the pound. See SCRUPLE.

The aureus, or common gold coin, in the first coinage was worth 30 silver denarii, equal to 1*l.* sterling; gold being to silver as 17½ to 1. It thus continued till Sylla's time, when it weighed no less than 166 grains at an average, or 30 in the pound of gold. About the year of Rome 675, 77 years B.C., the aureus fell to the rate of 40 to the pound, and passed for 20 denarii. In the reign of Claudius the aureus went for 100 sesterterti, or 25 silver denarii; at which rate it remained. The aureus fell by degrees to 45 in the pound, or about 110 grains of medial weight each, and continued of this standard till the time of Elagabalus, when it fell to about 92 grains at an average, or near 55 in the pound. Under Philip aurei of two or three sizes appear, of a rude fabric, and having a head of Rome on one side, and various reverses; and this practice of making different sizes of gold coins continued, so that under Valerian I., Gallienus, and his successors, five or six sizes occur. That the aureus went for 25 silver denarii down to Alexander Severus is clear, but the value of these different sizes does not appear. Supposing that standard to remain till the time of Constantine I. the double aureus will have borne 50 silver denarii, and the aureus 25. The "triens" must have had eight silver denarii, and two denarii ærei; the double triens twice as much. The denarius was not then worth above 1*4s.* English. Under Aurelian and his successor Probus, the aureus was of 100 grains; and there were also halves of about 50 grains, and double aurei, upwards of 200 grains, of very fine workmanship. Down to Constantine I. the aureus stood at between 80 and 70 grains. This prince, without altering the size of the coin, introduced, instead of the aureus, the solidus of 6 in the ounce of gold, and to pass for 14 of his

new silver coins, called *Milliarenses*, and 25 *denarii* as before; gold being to silver about 13 to 1. The *solidus*, or chief gold coin, continued of the same standard to the close of the Byzantine empire; for gold was common in Constantinople, while silver became more and more scarce. The *solidus* was worth 12*l.* sterling. See *SOLIDUS*.

In the first gold coinage at Rome, the *aureus* was divided into four inferior parts; the *semissis*, or half, of 60 *sestertii*; the *tertius*, or third, of 40; the fourth, of 30; and the sixth, or *sextupulum*, of 20. But soon after all these subdivisions were discontinued, except the *semissis*, or half; which occurs in the consular times, and in those of some emperors, but is extremely scarce, so that few of them must have been struck. Some have supposed, without sufficient authority, that the Romans called the gold *semissis* a *denarius aureus*. *Denarius* was used, as our penny, for a coin. The common *aureus* was called *denarius aureus* very naturally, because it was of the same size with the silver *denarius*. See *AUREUS*.

With regard to the materials of English money, see *COIN*.

As for the *impression* of money, the Jews, though they detested images, yet stamped on the one side of their shekel, the golden pot which had the manna; and on the other, Aaron's rod; the Dardans, two cocks fighting; Alexander, as is held by some, his horse Bucephalus; though this may be doubted of, because the horse is found as frequently on the coins of several of the kings of Macedonia, his predecessors, as his. The Athenians stamped their coins with an owl, or an *ex*; whence the proverb on bribed lawyers, *bor in lingua*; the people of *Ægina* with a tortoise; whence that other saying, *Virtutem & sapientiam vincunt testudines*. As to the Romans, the monetarii sometimes impressed the images of men that had been eminent in their families, on their coins; but no living man's head was ever stamped on the Roman coin till after the fall of the commonwealth; after that time they bore the emperor's head on one side; and, from this time, the practice of stamping the prince's image on coins has obtained among all civilized nations, the Turks and other Mahometans excepted; who, in detestation of images, inscribe only the prince's name, with the year of the transmigration of their prophet.

For an account of the impression of British money, see *COIN*.

As to the *figure* of money, it is either round, as in England; multangular, or irregular, as in Spain; square, as in some parts of the Indies; or nearly globular, as in most of the rest.

After the arrival of the Romans in this island, the Britons imitated them, coining both gold and silver with the images of their kings stamped on them; when the Romans had subdued the kings of the Britons, they also suppressed their coins, and brought in their own, which were current here from the time of Claudius to that of Valentinian the Younger, this being about the space of five hundred years.

Mr. Camden observes, that the most ancient English coin he had known, was that of Ethelbert, king of Kent, the first Christian king in the island; in whose time all money accounts began to pass by the names of pounds, shillings, pence, and mancus.

The penny seems borrowed from the Latin *pecunia*, or rather from *pendo*, on account of its just weight, which, till Edward III.'s reign, contained as much silver as about three-pence of our money: these were coarsely stamped with the king's image on one side, and either the mint mas-

ter's name, or the city's where it was coined, on the other: five of these pence made their scilling, probably so called from *scillingus*, which the Romans used for the fourth part of an ounce; forty of these scillings made their pound, and four hundred of these pounds were a legacy, or a portion for a king's daughter; as appears by the last will of king Alfred.

By these names they translated all sums of money in their old English testament; talents by *pence*; Judas's thirty pieces of silver by *thirty scillings*; tribute-money, by *penning*; and the mite by *scorthing*.

But it must be observed they had no other real money, but pence only; the rest being imaginary monies, *i. e.* names of numbers, or weights: thirty of these pence made a mancus, which some take to be the same with a mark; mancus, as appears by an old MS., was *quinta pars uncie*. These mancus, or mancusæ, were reckoned both in gold and silver; for in the year 680, we read, that Ina, king of the West Saxons, obliged the Kentish men to buy their peace at the price of thirty thousand mancus of gold. In the notes on king Canute's laws, we find this distinction, that *mancusæ* was as much as a mark of silver; and *manca*, a square piece of gold, valued at thirty-pence. See *MANCUS*.

The Danes introduced a way of reckoning money by ores, *per oras*, mentioned in Domesday book; but whether they were a distinct coin, or a certain sum, does not plainly appear: this, however, may be gathered from the abbey-book of Burton, that twenty ores were equivalent to two marks.

They had also a gold coin called *byzantine*, or *bezant*, as being coined at Constantinople, then called *Byzantium*; the value of which coin is not only now lost, but was so entirely forgotten, even in the time of king Edward III. that, whereas the bishop of Norwich was fined a byzantine of gold, to be paid the abbot of St. Edmundsbury, for infringing his liberty (as it had been enacted by parliament in the time of the Conqueror), no man, then living, could tell how much it was; so that it was referred to the king to rate how much he should pay; which is the more unaccountable, because, but a hundred years before, two hundred thousand bezants were exacted by the sultan, for the ransom of St. Lewis, of France; which were then valued at one hundred thousand livres.

Though the coining of money be a special prerogative of the king, yet the ancient Saxon princes communicated it to their subjects; insomuch, that in every good town there was, at least, one mint, but at London eight; at Canterbury four for the king, two for the archbishop, one for the abbot at Winchester, six at Rochester, at Hastings two, &c.

The Norman kings continued the same custom of coining only pence, with the prince's image on one side, and on the other the name of the city where it was coined, with a cross so deeply impressed that it might be easily parted, and broken into two halves, which, so broken, they call *half-pence*, or into four parts, which they called *farthings*, or *farthings*.

In the time of king John, money coined in the east parts of Germany came in special request in England, on account of its purity, and was called *easterling money*, as all the inhabitants of those parts were called *Easterlings*; and, shortly after, some of those people, skilled in coining, were sent for hither, to bring the coin to perfection; which, ever since, has been called *sterling*, from *easterling*.

King Edward I. who first adjusted the measure of an ell by the length of his arm, herein imitating Charles the Great, was the first, also, who established a certain standard for the coin, which is expressed to this effect by Gre-

MONEY.

gory Rockley, mayor of London, and mint-master. "A pound of money containeth twelve ounces: in a pound there ought to be eleven ounces, two easterlings, and one farthing, the rest alloy: the said pound ought to weigh twenty shillings and three-pence in account and weight; the ounce ought to weigh twenty-pence, and a penny twenty-four grains and a half. Note, that eleven ounces two-pence sterling ought to be of pure silver, called *leaf-silver*; and the minter must add, of other weight, seventeen-pence half-penny farthing, if the silver be so pure."

About the year 1320, the states of Europe first began to coin gold; and, among the rest, our king Edward III.

The first pieces he coined were called *Florences*, as being coined by Florentines; afterwards he coined nobles; then rose nobles, current at six shillings and eight-pence; half-nobles, called *halfpennies*, at three shillings and four-pence, of gold; and quarters at twenty-pence, called *farthings of gold*. The succeeding kings coined rose-nobles, and double rose-nobles, great sovereigns, and half Henry nobles, angels, and shillings.

King James I. coined units, double crowns, Britain crowns; then crowns, half-crowns, &c. On this subject, see *MEDALS*.

TABLES of Gold and Silver, composed from the Authority of Mr. Lowndes, who inspected the original Indentures, and from Bishop Fleetwood.

Queen Anne	<p>I do not find any alteration in the standard of the gold or silver down to the present time. 22 carats fine and 2 alloy are the lb. of gold, and 11 oz. 2 dwt. fine, and 18 dwt. alloy, the standard lb. of silver; and the division of the pound of gold continues the same; that is to say, into 44½ guineas, and the silver into the usual number of crowns, &c. But the guineas have varied in the nominal value several times, rising up to xxxs. and declining to xxs., the present current value; but never have been reduced again to their intended level of xxs., nor indeed ought, when compared with the Portugal pieces of 3l. 12s., 1l. 16s., the guinea appears to be better worth xxs.</p>								
George I.									
George II.									
								15 21	

		To the lb. Troy.	
Portugal	£ 3 12	- 13	£ 46 16 0
English guineas	1 1	- 44½	46 14 6
			0 1 6
And the Portuguese standard worse ⅓ grain			0 2 6
Total worse lb. troy by standard and tale			0 4 0

wherein the Portugal is much more defective than the English coins, may be very good reasons for their being refused in payments in any of the receipts of the public revenue; but answer very well the purpose of those who benefit by the irregularity, in trading with the heavier, and passing off the lighter by tale; and which, if they can turn into guineas or heavy silver, make another gain.

How our standard is proportioned to that of other countries, and thence what the true par of exchange is between us, see COIN.

MONEY.

A TABLE exhibiting the Standard, Weight, Value, and comparative View of English Gold Money from King William I., A.D. 1066, to King George III. A.D. 1764.

Years of the kings' and queens' reigns, or the dates of the several mint indentures.	Standard of the gold at each period.	Value or number of pounds, &c. the lb. troy of stand. gold has been coined into.			Value or number of pounds, &c. the oz. troy has been coined into.			Value of 20 shillings of coined gold at each period of our present money.			Proportion of the same 20 shillings to our present 20 shillings.	Proportion between the current value of the lb. troy of standard silver and standard gold.	Proportion of fine silver to fine gold at each period.

For tables containing the principal gold and silver coins of all nations: the first table shewing the fineness of those of gold, compared with the English standard of 22 carats, with their weight, and contents in pure gold, and their value, according to the mint price of gold in England, *i. e.* 3*l.* 17*s.* 10 $\frac{1}{2}$ *d.* per ounce, standard; and the second table ex-

hibiting the fineness of all silver coins, compared with the English standard of 11 oz. 2 dwts., their weight and contents in pure silver, with their value according to the mint price of silver in England, *i. e.* 5*s.* 2*d.* per ounce, standard; we refer to the valuable publication of Dr. Kelly, entitled "Universal Cambist."

The king, by proclamation, may at any time prohibit all his subjects, not exceeding one year, to lend or advance money to any foreign prince or state, without licence under the great or privy seal; and if any person knowingly offend in the premises, he shall forfeit treble the value of the money lent, &c. two-thirds to the king, and the other to the informer; but persons may deal in foreign stocks, or be interested in any bank abroad, established before issuing his majesty's proclamation. Stat. 3 Geo. II. cap. 5.

MONEY, taking the term in its most comprehensive sense, may be defined to mean any commodity that can be employed for the purpose of facilitating the interchange of what men possess for what they desire.

In the science of political economy, discussion is much retarded and perplexed, by the loose and ambiguous meaning of the terms employed, and by the want of introductory and preparatory axioms: the terms used in this science have, in the common concerns and language of life, acquired certain meanings so firmly, that it is difficult to shake them loose and forget them, when we come to employ them in it. The consequence is, that the reader, not aware that words, the meaning of which is familiar to him, are to be taken, in the discussion on which the author has entered, in a new and peculiar sense, is startled and thrown back into doubt and confusion, when, after having followed the train of reasoning for some time, and admitted its justness and force, he finds that he and the author have throughout it been affixing very different meanings to the same terms. The same perplexing consequences result from the want of introductory and preparatory axioms: perhaps every science would be benefited as well as mathematics, though not to such a degree, if the terms to be employed were previously defined, and the positions to be taken for granted were previously laid down. It is certain that thus the way would be cleared at the commencement, and this every person conversant with subjects which require a long and intricate train of reasoning knows to be of the utmost importance towards the attainment of the truth.

These observations are introduced to apologize for, or rather to warrant the time that may be occupied in pursuing the justness and accuracy of the definition given of money, and in pointing out the erroneous and defective character of some other definitions, before entering on the subject itself.

Hume, in his Essay on Money, has defined it to be "the instrument which men have agreed upon to facilitate the exchange of one commodity for another." At first sight it may seem that this definition of Hume, and that which stands at the head of this article, are precisely the same; they, no doubt, are very similar; and if precision and fullness were not absolutely indispensable in all definitions, and if political economy, as has been already remarked, did not more than most other sciences, require this fullness and precision, Mr. Hume's definition must have been adopted as sufficiently accurate. But on examining it we shall find, that, taking it strictly (and a definition, if it will not bear to be taken strictly, loses its essential character and its whole utility), it does not comprehend money, when employed to interchange labour and skill for commodities. In all cases where one commodity is exchanged for another commodity, and an instrument is employed for the purpose of facilitating that exchange, that instrument, according to Mr. Hume's definition, is money; but if we adhere strictly to his definition, the facilitating of no exchange except of one commodity for another is effected by money; or rather, Mr. Hume's definition does not comprehend any other kind of exchange, except that of one commodity for another, and here he does not comprehend all the uses of money, or employs the term

commodity in a sense not generally known and admitted: in either case it is objectionable; in the first, because there are instances of interchange which it does not comprehend, and in the second case, because it employs a term in a meaning not known and acknowledged.

After all, however, Mr. Hume's definition of money approaches much nearer the truth than those which are commonly given. According to some, money may be defined to be the standard of value. Here another source of error and confusion opens to our view: in all scientific discussions, metaphorical language, or terms borrowed from other subjects, if not employed with great caution and judgment, are very prejudicial: they either leave no distinct idea when transformed from their appropriate subjects, or more frequently carry with them more of their original meaning and force than the subject to which they are applied will admit of. If we examine the phrase standard of value, without at present enquiring how far it is a proper definition of money, we shall find that it gives no distinct idea: the word standard is here employed in a meaning perfectly different from that which is given to it, in subjects where it is a common and appropriate term. If we were to talk of the standard of weight, of height, or of fineness, we should be immediately struck with the expression as conveying no meaning, as, in fact, nonsense: it is well known what a standard weight, height, or fineness are; they mean a weight, height, or fineness fixed by law or custom. Standard of value, therefore, as applied to money, cannot define it, because, if examined, it will be found to convey no meaning: and if the terms be altered, and "standard value" used in their stead, though these words convey a meaning, it is a meaning which cannot be applied to them, if employed as a definition of money. Money cannot be said to be the standard value of commodities: if the price of any commodity were fixed by law, suppose, for instance, that the price of a bushel of wheat were fixed at one guinea, then this coin, this description of money might be said to be the standard value of a bushel of wheat; but in no point of view can money, generally speaking, be said to be the standard value of commodities; and we have shewn that the expression standard of value has no meaning.

It perhaps may be thought that more time has been occupied in pointing out the absurdity of this definition than was necessary; but in political economy, as much is to be done by removing error, as by establishing truth: when error is completely removed, so that the way is clear and open, common sense will do much in this branch of science.

The next definition of money is much more plausible: those who are aware, either of the absurdity, or who suspect the incorrectness of the former definition, maintain that money is the measure of value. In our remarks on that definition which made money the standard of value, it was not deemed necessary to investigate the proper meaning of the word *value*, because the remarks that were offered on the other term were deemed amply sufficient to set it aside. But on examining this definition, both the terms must be scrutinized.

Smith, in his Wealth of Nations, has observed that every commodity has two sorts of value, a value in use and a value in exchange; but in political economy the term *value* can have only one meaning. Political economy relates only to a state of society, where a division of labour exists; where, of course, each man has more of the commodities his labour and skill have produced than he has occasion for, and consequently wishes to exchange them for commodities produced by the labour and skill of others. Where no division of labour exists; where there is, consequently, no interchange of com-
commo-

commodities; there is, strictly speaking, no wealth, no value; there is no room, no occasion for the science of political economy. Whether, in treating of other subjects, *value* should or can be used in a sense different from that which is given it in political economy, as a science relating to the interchange of commodities, is a question foreign to the present discussion. In political economy, and under the circumstances of society, which political economy supposes and refers to, *value* ought only to be employed in one sense. What that sense is a little reflection will teach us.

In the state of society we are supposing commodities are interchanged: before this can take place, the quantities or weights of each commodity that are to be given for any other commodity, must be fixed; and that particular weight or quantity of any given commodity, which can be obtained for a certain weight or quantity of another commodity, may, strictly speaking, be said to be the value of this second commodity; it avails or has power to obtain the former commodity. But this expression may be reciprocally used: if, for instance a bushel of wheat is exchanged for 30lb. of meat, the value of the bushel of wheat may be said to be 30lb. of meat, and the value of 30lb. of meat to be a bushel of wheat. Value, therefore, is a term which, in political economy, has, properly speaking, only one meaning, because this science relates solely to a state of society, where interchange of commodities takes place: and this meaning of the word value, referring to the interchange of commodities, implies that where any two commodities are interchanged, each can procure a certain portion of the other.

Let us now revert to the definition of money under consideration: according to it, money is the measure of value. The expression, at first sight, seems sufficiently precise and clear, whatever opinion may be formed of its propriety and justness as a definition of money. But a closer inspection and examination of it will probably convince us that it is not so precise and clear as at first sight in seems to be. When we talk of a yard as a measure of length, we have precise and clear ideas affixed to our expression: we mean, that if such a table is a yard long, we can immediately not only figure to ourselves its length, but compare it with other objects which possess length. How will this apply to money defined and considered as the measure of value? Whoever knows what a yard is, immediately and clearly knows what is meant by a yard of cloth; but he who equally well knows what an ounce of gold, or a guinea is, by no means, therefore, certainly knows what quantity of corn, or any other commodity, this ounce of gold or guinea will measure. Indeed the very application of the term *measure*, as applied to value, when thus brought forward in a particular case, and not used generally and loosely, must strike us as improper, and contrary to analogy. We have seen what is the meaning of the term *value*; it expresses the quantity of any particular commodity which can be procured in exchange for another commodity:—in order to do as much justice as possible to the definition of money, under consideration, let us take money as one of the commodities, and corn as another; we shall still perceive that the definition is incorrect. How can money be said to measure the value of corn? It has been observed, that value is a reciprocal expression; that is, it can be equally well applied to either of the two commodities, which are interchanged for each other: if money, therefore, may be defined to be the measure of the value of any commodity, of corn for instance; corn, with equal propriety, may be defined to be the measure of the value of money. But in neither case can the definition be used; for nothing changeable in value, that is, which at one

time will command a greater or less quantity of any commodity than at another time, can measure value.

It may, perhaps, be urged, that if the term were changed, and if money were defined to be the expression of the value of commodities, the objection would be removed: there is some weight and propriety in this remark: value must have reference to two commodities: it must express how much of any particular commodity can be obtained for another commodity; and as money is used as that commodity, for which all others are directly given in exchange, the value of all others would naturally be expressed with reference to money. But still this would be a very incomplete definition of money; and when we come to enquire how money (according to the definition given at the head of this article) facilitates the interchange of what men possess for what they desire, we shall find that this definition includes the former.

Let us now inquire what qualities money must possess, in order that it may answer the purpose pointed out in the definition; *viz.* that of facilitating the interchange of what men possess for what they desire. Money, it has been said, being the measure of value, must have value, on the same principle and for the same reason, that whatever measures length must have length. It may be true that money must have value; but not for the reason (if reason it can be called) here alleged. This mode of reasoning affords another instance of the bad effects of borrowing illustrations and proofs in political economy from other subjects. At first sight, the conclusion that money, being the measure of value, must have value, appears to follow necessarily from the facts brought forward in support of it; though those facts are merely analogous, and not belonging to the subject to be proved; but it requires only a little time for reflection, it merely requires that the judgment should have time to withdraw itself from the influence of powerful but irrelevant associations, in order to perceive that there is no force in the remark, that because what measures length possesses length, therefore what measures value (allowing the expression) should possess value.

There is, in fact, not the least occasion for bringing in this analogy to prove that money, in its character of money, must possess value: that is implied in the very meaning of the term; nothing can facilitate the interchange of commodities; nothing can be exchanged itself for any other commodity which does not possess value. But a much more important and difficult question remains to be noticed, discussed, and solved. Is it essential to the character and uses of money that the commodity of which it is formed should possess value, independent of its application as such? Another question arises out of this, or rather is involved in it. Can the value of any commodity, when used as money, be greater than it possessed when not applied to this purpose?

In order that these intricate and important questions may be considered with due deliberation, on sufficient data, and in regular order, it will be proper to call in the aid both of speculative reasoning, and of what we know to be fact. Our acquaintance with the history of nations, at that period when they first began to perceive the necessity of adopting some instrument of barter, is so very imperfect, that we are not supplied with a detail of the different methods they pursued previous to the adoption of the metals for that purpose: it is easy to imagine, however, how they would proceed: and by the help of what we actually know to have been the case, and of what we may fairly conclude to have been the intermediate steps, where history is silent, we may gain the point we have in view; *viz.* an answer to the questions, whether it is essential to the character and uses of money,

that the commodity of which it is formed should possess value, independent of its application as such; and whether the value of any commodity, when used as money, is greater than it possessed when not applied to this purpose. All history coincides in informing us that the commodities first used as money possessed value prior to, and independently of, their being invested with this character. Cattle appear to have been used for this purpose at as early a period of history as we can trace back; and when the metals were first employed, those kinds were chosen which were in regular use and demand, and which, consequently, possessed value. Indeed it is natural to suppose, that if a person could not, in exchange for the produce of his labour, procure directly what he wanted, he would dispose of it only for such a commodity as he knew was in general demand, and which, therefore, he could be at no loss to dispose of. Unless we can imagine that men would barter their commodities for what they neither needed at the moment, nor what, at some future period, would procure them what they needed, this must have been the case. Let us suppose that a person, in this state of society, had more corn than his own wants required; and that another person stood in need of this corn, but had only some commodity to offer in exchange for it, which the first person did not then require: if this commodity were of such a nature, as the first person were likely soon to require, or if it were such as he knew was in demand, and would, therefore, be the certain means of obtaining him any other commodity which he might wish for, he would have no objection to exchange his corn for it. But it is evident, that in both these cases the exchange is that of commodities that are valuable; *i. e.* each of which avails to purchase or procure some other useful and desirable commodity. In the latter case, where the exchange of the corn was made for a commodity which was to be employed again in exchange, that commodity, in fact, was money: it answers exactly to the definition of money, it facilitates the exchange of commodities: the person who possessed the corn, wished, for instance, to exchange it for meat; but the person who was disposed to take his corn, and to whom, at that period, we could suppose he could alone dispose of it, had no meat; he, therefore, offered him some other commodity, and if this commodity would avail, either by direct or indirect exchange, to procure meat, the person possessing the corn would not hesitate to part with the one for the other. But it is plain, that unless this commodity would avail to obtain, either directly or indirectly, the meat which he needed (or whatever else it might be), the person could not part with his corn. Money, therefore, or that commodity which is employed for the purpose of facilitating the exchange of what men possess for what they desire, must possess value, at least when first used in that character.

It still, however, remains to be inquired, whether a commodity used as money, and, as such, possessed of value, when first employed for that purpose, may not retain its character and power of money, when deprived of its property of value. As the metals are now used for money, let us suppose that gold and silver were to lose all value, independently of their character as money; that there was no demand for them as articles of luxury or use:—would they still be as valuable as money? It would, at first sight, appear certain, that as they had derived their power as money solely from their being valuable commodities, when they were stripped of their value, they would at the same time be necessarily stripped of their character of money. But this may be doubted, both from what we know of the human mind, and from what actually takes place. Men, having been

so long accustomed to receive gold and silver in exchange for their commodities; and having so long ceased to revert to, or consider on every occasion of parting with their commodities for these metals, that they were receiving something in exchange intrinsically valuable; *i. e.* valuable independently of its character of money; would, by the mere force of habit and association, and by the confidence which they had produced, continue to receive gold and silver, even after their intrinsic value had ceased; *i. e.* after they had lost that property which at first had made them pass as money. This we see partly to be the case: men do not hesitate to receive coin that is much worn; or, in other words, they exchange their commodities for coin, after it has lost part of its value; and the habit and association are much more likely to be broken, by a diminution in the size, or an alteration in the appearance of the coin, while the value of what is actually received remains the same, than by receiving coin in exactly the same state as usual, only that the metal of which it is made has lost its intrinsic value.

We may therefore infer, on this part of the subject, that no commodity can be employed at first as money, unless it possess value; that any circumstance which affects this value, will, for a very considerable time, affect the character and credit of the commodity as money; but that, in process of time, the consideration of the intrinsic value of the commodity loses much of its force, and it is taken as money without reference to this intrinsic value.

In one respect, however, the value of money would fall, if the commodity of which it were formed lost its intrinsic value; *i. e.* if it no longer were in demand for any other purpose but that of money. Let us suppose that the demand for gold and silver, except for the purpose of money, suddenly ceased: the natural and immediate consequence would be, that what was before used for articles of luxury, &c. would be coined into money; and the quantity of money being thus increased, its value would necessarily fall. The other question that was started, *viz.* can the value of any commodity, when used as money, be greater than it possessed, when not applied to this purpose; has, in a great measure, been solved in the observations already made. In all cases where worn coin is taken, this is, in fact, the case. It may, indeed, be urged, that worn coin, only of the inferior metals, is received at its original value; that gold coin is not so received; and that in the instances where silver coin, when worn, is received at its original value, it is only so received as part of the gold coin. But as there can be no doubt of the fact, that the value of twenty-one worn shillings, when compared with the value of a guinea, is much less than the value of that quantity of silver which would form twenty-one mint shillings, when compared with a guinea, the inference is indubitable, that in all cases where worn silver coin is received either for commodities, or for gold coin at its original value, the value of silver used as money is greater than its value as a simple commodity.

The inference which has been drawn, however, from this circumstance is by no means correct;—that money does not derive its character from the intrinsic value of the commodity of which it is formed, nor from the general confidence resulting from the knowledge of that value, and the consequent willing, and habitual acceptance of it in exchange for all commodities; but from authority. Those who are of this opinion, contend that the stamp on the coin gains it a ready circulation, not because it proves its legal weight and purity, but because it is the sign of the authority of government; that in receiving money no regard is paid to the material of

which it is formed, nor to the value of that material, but solely to the authority which issued it. If this were true, the same authority could make stamped leather pass as current as stamped gold and silver. But this opinion is grounded entirely on a misconception of the nature of money, and of the manner in which any given commodity is invested with that character; it also confounds two things quite distinct and unconnected. There can be no doubt that government, or any body of men, who receive a large portion of the wealth of the community, could give a partial circulation to any kind of money, independently of its intrinsic value, by declaring their readiness to receive it in payment of their demands. In Scotland, and in the provincial districts of England, where local bank notes are common, confidence and circulation are often given to them in a great degree, by the declaration of the agents of government, that they will receive them in payment of the different taxes; but this is not authority: this mode of giving circulation to any kind of money is merely an illustration of the doctrine that has been laid down in this article; that the reason why any commodity, when originally employed as money, should possess intrinsic value, is, that thus it will be readily and generally received; but if this ready and general acceptance can be given any other way, the purpose is effectually answered. In a rude state of society, the only mode of ensuring this was, to offer some commodity in general use and demand; and therefore when a person parted with the produce of his labour, if he could not get for it what he wanted, he selected, and kept by him, some commodity which would always ensure the obtaining of the object of his wishes either directly or indirectly. In a more advanced state of society, confidence would effect the same object; but there is a great difference between authority and confidence; there is a great difference between commanding that any commodity should be received as money, and declaring that it will be received as such. The former mode, we know from history, has always failed of success, whenever the command was not supported by the intrinsic value of the commodity ordered to pass as money. The latter mode, if the declaration came from those through whose hands a great portion of the money of the country must pass, will give credit and circulation as money to any commodity, nearly with as much facility and certainty; though not to such an extent, as if the commodity possessed intrinsic value equal to that at which it was issued as money.

Money, then, or any commodity which can be employed for the purpose of facilitating the interchange of what men possess, for what they desire, must, in the first instance, have possessed intrinsic value: if this intrinsic value were lessened, before its character and use, as money, had become so firmly fixed, as to have superseded or effaced, in commercial transactions, all reference to its intrinsic value, then the value of it, as money, would fall in proportion as its intrinsic value were lessened. But this would not be the case, at least so certainly, and in such exact proportion, if the lessening of the intrinsic value took place in a country of great commerce and confidence, in a gradual manner, and by no means that were calculated to create alarm or distrust.

The next topic, in point of order and importance, connected with the consideration of the principles of money, is suggested, and will be best explained by a passage in the essay "Of Money" by Hume, already referred to. "It was a shrewd observation of Anacharsis the Scythian, who had never seen money in his own country, that gold and silver seemed to him of no use to the Greeks, but to assist them in enumeration and arithmetic." In this sentiment of Anacharsis, we may perceive the germ of the opinions of those

authors, who maintain either what they call the doctrine of an abstract currency, or that money is but counters wherewith to reckon the different commodities that are mutually exchanged in the concerns of life; and it is also worthy of remark, that the mode in which the use of money is supplied in London and all commercial cities, where observation and experience have suggested expedients for it, is exactly that which Anacharsis supposes to have been the only mode, in which gold and silver were of use to the Greeks. Our modern merchants, in many of their transactions, merely set off the value of one commodity against the value of another; this they indeed do by rating the value in their books by pounds, shillings, and pence, but real money is not used in the transaction. But to return to the consideration of the more immediate and relevant topic suggested by the remark of Anacharsis. If gold and silver were of no use, but to assist in numeration and arithmetic, as he directly maintained; and as those who regard it only as counters, virtually maintain; or if the real currency of a country could be only an abstract currency; then the value of this money or currency could not vary, except by a variation in the supply of commodities; for, confining ourselves at present to the doctrine which represents money only as counters, it is evident that they must always bear the same proportion to the commodities (provided, as before remarked, that the supply of commodities did not vary) which they served to rate or estimate, in the same manner as if all exchanges of commodities were effected by the mode adopted in London for many of them, the only circumstance which could make any difference in the value at which they were respectively rated in the books of the merchants, would be a variation in the supply; for if money were only counters, and of no use but to assist in numeration and arithmetic, there would be no motive to increase the quantity of it, and consequently any variation between the supply of it and of commodities, must arise from a greater or less supply of the latter. The inference, that any difference in the value of money, or the command it possesses over commodities, must arise from a variation in the supply of the latter, follows more directly and necessarily from the doctrine of an abstract currency. It is, however, so very difficult to conceive of such a currency, and therefore to reason upon it, that very few observations may suffice. Those who maintain it seem to confound two things; the name and denomination, and the power of the currency; and to infer, because the former may be considered as something abstract, therefore the latter is so also; that because the former remains the same, therefore there is no change in the latter. If, however, by abstract currency, they mean money of account, (and that seems the only clear meaning that can be affixed to the terms,) then the observation just made holds perfectly good; that if there were no other money but money of account, or abstract currency, any variation in the power or value of this, when compared with commodities, must proceed from a change in the supply of the commodities; for it is impossible that mere abstract currency, or money of account, not having actual existence, can vary.

But money is of some other use than merely to assist in numeration and arithmetic; and this leads us to the consideration of it, not merely in the character of a commodity which can facilitate the interchange of what men possess for what they desire—though that is the essential character of it; but as the source of industry, skill, and enterprize, and consequently of real wealth. Mr. Hume, remarking on the observation of Anacharsis, says, "It is indeed evident that money is nothing but the representation of labour and commodities, and serves only as a method of rating and estimating

them. Where coin is in greater plenty, as a greater quantity of it is required to represent the same quantity of goods; it can have no effect either good or bad, taking a nation within itself, any more than it would make an alteration in a merchant's books; if, instead of the Arabian method of notation, which requires few characters, he should make use of the Roman, which requires a great many. Nay the greater quantity of money, like the Roman characters, is rather inconvenient, and requires greater trouble both to keep and transport it; it is not however perfectly correct to say, that, taking a nation within itself, a greater plenty of coin can have no effect, either good or bad; and indeed Mr. Hume afterwards points out some effects both good and bad, which a greater supply of coin produces. One effect, however, he does not advert to, which is of so injurious a nature, that if it were not generally, and in a great degree counterbalanced by the beneficial consequences of this greater supply, it would render it a most serious evil. If, where coin is in greater plenty, a greater quantity of it is required to represent the same quantity of goods; then the power of all those who possess only money, over those goods, must be diminished. We must therefore look to the other consequences of a greater supply of money.

These Mr. Hume has detailed, but the order and manner in which he supposes them to flow, is by no means correct, or warranted by facts. As this is a most important and interesting topic, it will be necessary to quote his observations, before we proceed to point out their error.

"Though the high price of commodities be a necessary consequence of the increase of gold and silver, yet it follows not immediately upon that increase, but some time is required before the money circulates through the whole state, and makes its effect be felt on all ranks of people. At first no alteration is perceived; by degrees the price rises, first of one commodity, then of another, till the whole at last reaches a just proportion with the new quantity of specie which is in the kingdom. In my opinion it is only in this interval or intermediate situation between the acquisition of money and rise of prices, that the increasing quantity of gold and silver is favourable to industry. When any quantity of money is imported into a nation, it is not at first dispersed into many hands, but is confined to the coffers of a few persons, who immediately seek to employ it to advantage. Here are a set of manufacturers or merchants, we shall suppose, who have received returns of gold or silver for goods which they sent to Cadiz. They are thereby enabled to employ more workmen than formerly, who never dream of demanding higher wages, but are glad of employment from such good paymasters. If workmen become scarce, the manufacturer gives higher wages, but at first requires an increase of labour; and this is willingly submitted to by the artisan, who can now eat and drink better, to compensate his additional toil and fatigue. He carries his money to market, where he finds every thing at the same price as formerly, but returns with greater quantity and of better kinds, for the use of his family. The farmer and gardener, finding that all their commodities are taken off, apply themselves with alacrity to the raising more, and at the same time can afford to take better and more clothes from their tradesmen, whose price is the same as formerly, and their industry only whetted by so much new gain. It is easy to trace the money in its progress through the whole commonwealth, where we shall find that it must first quicken the diligence of every individual, before it increases the price of labour."

Now there are three positions maintained in this illustrative reasoning, the first of which may, or may not, be true, according to circumstances; the other two cannot be true

under any circumstance. It is assumed that the price of labour will not be increased, in the first instance, by an increase in the quantity of money, because a greater number of workmen will be employed; and of course the number of workmen thus increased, bearing the same proportion to the increased money, that they formerly did, no addition will be made to the price of labour; this, however, cannot be the case, unless we suppose that before the increased quantity of money gave employment to these workmen, they were entirely unemployed; for if they were previously employed, the greater demand for them, occasioned by the increase of money, must undoubtedly and necessarily raise the price of labour. Again, Mr. Hume supposes that the workmen who have thus gained employment, find every thing in the market at the same price as formerly, though an increased demand for the commodities sold there is necessarily occasioned by the increased money these workmen carry to market. If the price of commodities in the market is not increased immediately on the increase of demand for them, when, or how, can it be raised? not afterwards, for, as Mr. Hume justly observes, the farmer and gardener apply themselves with alacrity to raising an additional supply; and if the price was not raised, when there was only the usual supply, and a more than usual demand, it must fail when the supply is raised proportionally to the demand. The same remarks may be applied to the third position laid down by Mr. Hume, *viz.* that the farmer and gardener, though they go to their tradesmen with more money in their pockets, and can therefore afford to buy better, and more clothes than formerly, yet get them at the old prices.

In fact, the process by which an increase of money in any country promotes industry and raises prices, varies according to circumstances: if the increased supply is brought in by those who lay out money principally or entirely in consumption, the process goes on in one mode; if the increased supply is brought in by those who lay out money principally for the purposes of production, the process goes on in another way. In the first instance, the persons into whose possession the increase of money has come, naturally lay it out according to their fancies and habits, either in obtaining a larger quantity of those commodities which they formerly bought, or in the purchase of other commodities which their inferior means hitherto prevented them from obtaining: in either case there is a greater demand in the market while the supply is the same. If, for instance, the increased money comes into the possession of labouring men, they either lay it out in getting more bread for themselves and families; or if they previously had enough of that, but could not procure meat, the increased money is laid out in the purchase of meat. In the one case there is a greater demand for bread, in the other for meat; while the supply is the same: a rise in price must therefore take place. The next step in the process is that the bakers or butchers, finding a greater demand for their articles, and obtaining consequently a higher price for them, are induced to increase the supply: here then we may suppose the increased money and the bread or meat to have balanced each other. But we must look a little farther; the baker or the butcher, in the first instance, obtaining a higher price for their commodities, and subsequently selling a greater quantity, and thus increasing their profits, are enabled, in their turn, to do what the labouring men did when they obtained more money. They can afford to spend more; (for at present, all the cases we suppose are those of men who lay out their increased money in consumption, not in production); the articles on which they spend their increased profits must in their turn experience a rise of price, which will produce a greater supply. It is needless to pur-

MONEY.

the operations of this additional supply of money any further, or to point out how it will be gradually spread over the community, always in some degree affecting the prices of those commodities to the purchase of which it is applied. It may, however, be further remarked, that there are many disturbing forces, which may prevent the consequences now enumerated from following certainly, and in the order laid down, from an increased supply of money; and that the rise of price is seldom or never proportioned exactly to the increased demand; while, on the other hand, a supply equal to the increased demand seldom brings the prices down to their former level.

Let us now suppose that the increased quantity of money is in the possession of those who will expend it in productions; so no individual case will render the subject more clear, and enable us to trace the consequences more directly and minutely. A cotton manufacturer, for instance, has his capital doubled, and determines to apply this increase of fortune solely to the extension of his trade: of course he must employ more men to work for him, and more of the raw material. Unless we can imagine that there were quite unemployed the additional number of men that he would need, his demand for more workmen must raise the price of labour; and even on the supposition that there were a sufficient number of unemployed workmen, still, if we reflect a little, we must be convinced that the price of labour will be raised, even in this case; for these unemployed workmen, being of course anxious to procure employment, may be considered as a supply greater than the demand in the market; of course this circumstance must have a considerable effect in lowering the price of labour; but when the cotton manufacturer hires them, he in fact increases the demand for workmen, and therefore must raise the price. So that the effect is not altered in its nature, though it is in degree, whether we suppose the cotton manufacturer to go into the market for workmen, where all are already engaged, or where there are a sufficient number to be found unemployed: in the former case, the price of labour would rise much higher than it would in the latter case; for we are to reflect that the lowering of the price of labour or of any commodity is effected, not only by those who want it not being so numerous, or not being so able and willing to purchase it at the former price, but also, in nearly an equal degree, by those who have it to dispose of, on their perceiving the demand diminished, offering it at a lower rate, each being anxious, under these circumstances, to get rid of the article he has in the market.

The first effect, then, of the increased capital of the cotton manufacturer is to raise the price of labour: it is unnecessary to point out again how the increased wages which the labourer obtains will operate on the price of commodities, and subsequently on their supply; this has already been done. But besides a rise in the price of labour, the increased capital of the manufacturer, being partly expended on cotton, and partly also on the buildings and machinery necessary to manufacture this additional quantity of cotton, its effects on these must also be apparent, at first in the rise of price, and afterwards in the greater supply. On the other hand, the supply of cotton goods in the market being increased, while the demand remains the same, the price of them must fall: here then we may perceive an essential difference between the effects of an increased supply of money, accordingly as it comes into the hands of those who lay it out in consumption, or into the hands of those who lay it out in production. In the latter case, the immediate effect is a rise in price, the indirect and subsequent is a greater supply, stimulated by this rise in price; but this greater supply

may not be more than sufficient to meet the greater demand; in the former case, although a rise in the price of labour, and of those articles necessary for the manufacture is occasioned, which is also met by a greater supply; yet, besides these effects corresponding to the effects in the latter instance, there is a greater supply of cotton goods in the market; so that whatever opinion may be formed respecting the consequences (as they affect the national prosperity) of an increased supply of money in the hands of those who expend it in consumption, there seems to be no reason for doubting that the consequences are beneficial, when the increased supply is expended on production.

But it will be proper to look more closely into the effects of a greater quantity of money, in order to perceive in what case it is beneficial to a nation, and by what means it is beneficial; and in what cases it is prejudicial to a nation, and by what means it is so.

When the effect of a greater supply of money is to stimulate industry, so as to bring a greater quantity of commodities into the market, then there can be no doubt that it is beneficial to a nation. At first sight it may appear of little moment, whether there is a greater quantity of commodities produced or not, if the price of them is not diminished: but the real wealth and prosperity of a nation does not consist in there being few commodities produced, though they are sold at ever so cheap a rate; it consists in the abundant supply, provided there is a demand for that supply, whatever be the price of them; for an abundant supply and a proportional demand proves that all classes of the community have full employment; that they are exerting their skill and industry, and that this skill and industry are well paid. Now there is no motive which will stimulate men so powerfully and generally to the exertion of additional skill and industry, as the prospect of greater gain; and the prospect of greater gain cannot be held out, unless there is a greater demand for their goods, and a consequent higher price given for them; this, it is evident, cannot be the case, unless the quantity of money in the nation be increased. It may, indeed, be alleged, that a greater demand for any particular commodity may be created by the abstraction of demand for some other commodity; but in this case it is evident, that what is gained to the nation in one case, is lost in the other; for those who produce the latter commodity will suffer from the diminution of demand, as much as those who produce the former commodity will be benefited by an increase of demand. The case supposed, therefore, must be that of a greater demand for any particular description of commodities, without any variation in the demand for any other commodity; and this case cannot exist, unless there be a greater quantity of money in the nation.

This illustration of the effects of an increased quantity of money has proceeded on the supposition that they were confined within the nation where the increase took place: but it may be proper to examine what will be the effects on the commercial transactions of this nation with other nations: these effects will be similar to those which are known to proceed from great capital; *i. e.* the ability to purchase the raw materials of manufacture cheaper, by taking them in greater quantities, and for ready money, and to sell the manufactured article cheaper, both from the circumstance of the raw materials having been bought cheaper, and from the increase of capital, and consequently of trade, enabling the manufacturer to be satisfied with less proportional profits. It is evident, however, that all these beneficial consequences depend on one important circumstance; that the increased quantity of money, on whatever it is expended, though it at first raises the price, yet soon afterwards, by stimulating indus-

MONEY.

dustry, brings in such an additional supply, as fully answers the increased demand. In this case alone money, when it flows with greater abundance than formerly into a nation, is beneficial to it.

A greater abundance of money will be prejudicial to a nation, either when it flows in too rapidly or irregularly; or when the nation, previously to this additional supply of money, had exerted its industry and skill to the utmost. As this latter case is a very improbable one, we shall confine our observations principally to the former.

When a greater quantity of money flows in very rapidly, the industry of the nation cannot keep pace with it; prices are suddenly raised very high; and though the same effect follows in some degree, even in this case, which we have seen to be the natural consequence of a greater quantity of money, a greater demand, and a rise in the price of commodities, *viz.* that a greater supply is produced by the stimulus given to industry; yet, industry must have some time in which to exert itself, and it also has its limits. Besides, it by no means follows, that the increased demand for any commodity, is in the exact proportion of the increased quantity of money brought into market for the purchase of that commodity; so that if the increased supply of it be regulated by the increased quantity of money, independently of any regard to what is the actual amount of the increased demand, the consequence will be that a larger quantity of the commodity will be brought into the market, than can find vent there, at least at a fair price. Now this circumstance is most likely to happen, where a greater abundance of money flows in very rapidly; the immediate consequence is that there is a strong competition, and the price of the commodity is forced up much higher than would have been the case, if the flow of money into the market had been gradual and progressive.

The same evil results from the circumstance of a greater abundance of money flowing in irregularly; partly in the mode just detailed, and partly in another manner. Nothing renders the production of any commodity so certain and steady, and consequently nothing benefits a nation so large, and those whose labour gives birth to it, so much as a regular and known demand for it: but if at one time there is a large supply of money in the market, and at another time the supply is comparatively small, the manufacturer does not know how to regulate his labour, and as it is safer and more prudent to err on the side of a deficient supply, the market is most likely to suffer in this respect.

We may therefore conclude that where a greater abundance of money flows into a nation slowly, gradually, and regularly, the nation will be benefited by it: industry and skill will proceed in their natural course, by advances likewise slow, gradual, and regular; and the ground which they thus secure, they will keep certainly and firmly. The wealth of the nation resting on a firm foundation, will not be apt to be shaken or diminished. But, on the other hand, where the influx of wealth is sudden, rapid, or irregular, it will certainly tend much more to raise the prices than to increase the supply of commodities; and even that increased supply, as far as it does take place, will not be constant or regular.

The other case, in which a greater abundance of money was stated to be prejudicial to a nation, was that, where, previously to this additional supply, the nation had exerted its industry and skill to the utmost. This, it was added, was a very improbable case; yet it certainly existed in Holland some time before the French revolution destroyed the commerce of that country. Money was there so abundant, that it could scarcely be employed in any manner, so as to produce

a small profit. In this country, therefore, under these circumstances, it is evident that a greater abundance must have been prejudicial; the only effect it could have would have been that of still farther depressing the profits of those who either had money to lend, or who employed it themselves.

Let us now look at the effects on the property of a nation, which would be produced by diminishing the quantity of its money; and, in order that we may perceive and trace these effects more clearly, let us suppose a particular case. Let us suppose that the quantity of money brought into the market for the purchase of meat was diminished: the immediate result would be, that each butcher, anxious to dispose of his meat, would offer it below the usual price; or, if we can suppose that they all persisted in seeking, and actually obtained the usual price, then, in this case, part of the meat must remain unsold. In either case, the butchers would carry home less money than usual, and of course would be able to spend less on the commodities they were in the habit of buying; the vendors of those commodities, in their turn, would either be obliged to dispose of them all at reduced prices, or there would remain unsold a part of them. This would happen if the money withdrawn were what was usually laid out in articles of consumption; but if it were what were usually laid out on labour, and for the manufacture of commodities, it is plain that the price of labour would fall, and the supply of manufactured articles would be diminished. In process of time, no doubt all things would accommodate themselves to this diminished supply of money; but in the mean while industry would be checked, and the real strength and prosperity of the nation would be affected.

It is a curious and difficult question to solve, whether, under any circumstances of the diminution of money, the supply of commodities would still remain the same, so that, in fact, the only consequence would be that all things would be cheaper; in the same manner, that the only consequence of an increased supply of money may, under certain circumstances be, that the price of commodities is raised; or whether, as on the latter supposition, the consequence may be, either that the price is raised, or that industry being stimulated, the supply of commodities is increased in a proportion equal to the increase of money; so, on the former supposition, of a diminution of money, the consequences may be either a diminution of price, or a proportional diminution of supply. One thing, however, is certain, that as it is scarcely possible for money to flow into a nation in greater abundance than formerly, without stimulating the industry of the nation, whatever may be its permanent effects on the price of commodities; so it is scarcely possible for money to be taken away from a nation, without checking its industry, whatever may be the effects of this measure on price.

Dr. Smith justly observes, that it is impossible to determine what is the proportion which the circulating money of any country bears to the whole value of the annual produce circulated by means of it; but though it is impossible to determine this, yet one rule for approximating towards the truth is laid down, which, as it seems to proceed on an erroneous idea of the nature of money, deserves some notice in a discussion on the principles of that commodity. It has been said, that the quantity of money required to conduct the commerce of any nation, must be directly as the amount of that commerce, and as the rapidity with which the money circulates; it is this latter division of the rule for estimating the necessary quantity of money, that requires some notice, as proceeding on an erroneous idea of it. Whenever any commodity employed as money ceases to circulate, it ceases to be money; it is only money, strictly and properly speaking, while it circulates; and in the intervals of its circulation,

ulation, be they long or short, it suffers a temporary loss of that character, because it is not then performing the office of money. A thousand guineas locked up in the chest of a miser, or by any other means kept unemployed, can with no more propriety be called money than a thousand ounces of plate, or a thousand medals of gold in the same situation. The phrase rapidity of circulation, therefore, ought to be set aside, as conveying an erroneous idea. To put this in a stronger and clearer point of view; let us suppose that the circulating medium of any country consists of a million guineas; and that there are coined at the mint an additional hundred thousand: while these continue in the mint, it could not with any propriety be said, that the circulating medium was increased one-tenth; nor could this be said, if, as soon as they were issued from the mint, they were locked up, and not brought into circulation. Let us now suppose, that the circulating medium consists of 1,100,000*l.*, but that one-eleventh of this, or 100,000*l.*, are constantly unemployed: they, strictly speaking, could not be said to constitute any part of the money of the nation; nor, if they were thrown into regular and constant circulation, could it be said that the rapidity of the circulation was increased, any more than it could be said with propriety that the circulation was increased by the additional supply of one hundred thousand guineas from the mint, or from the chest in which they had been locked up. It makes no real difference in the circulating medium of a country, whether the same hundred thousand guineas are constantly locked up, or when a sum to that amount, the guineas constituting it continually changing, is constantly unemployed: the circulating medium in both cases would be actually increased, if that sum were added to the money of the country; *i. e.* if it were brought into constant use; in neither case could it properly be said that the rapidity of circulation was increased.

An erroneous idea, founded on a similar misconception of the real nature of money, is very generally entertained respecting the cause of a high or low rate of interest. That the rate of interest should be low when money is plentiful in a country; and that, on the other hand, it should be high when money is scarce, are supposed to be the natural, obvious, and necessary consequences of these circumstances respectively. Now, as in the case of coin unemployed, it has not the character, and cannot fulfil the offices of money; so in the case of money not brought into competition with any given commodity, it cannot affect the price of that commodity. There is as little reason to suppose that an increased quantity of money would directly and necessarily raise the price of meat, if it were all expended in the purchase of bread, as to imagine that this increased supply, merely because it flows into a nation, should lower the rate of interest: the rate of interest, like the price of all commodities, must depend on the proportion between the supply and demand: if the increased quantity of money is employed to enlarge the supply of money to be lent out at interest, while the demand continues the same, then the rate of interest will be lowered; but if it is employed for any other purpose, then it can have no effect on the rate of interest. Such are the leading and most important topics connected with the discussion of the *principles* of money, to which alone this article has been confined. An attempt has been made to illustrate these principles, in the first place, by pointing out the real nature of money, or the qualities necessary in any commodity which is to be employed for the purpose of facilitating the interchange of what men possess for what they desire; in the second place, by pointing out the modes in which money operates in the interchange of commodities; and in the third place, by detailing and explaining the effects produced

on the prosperity of a nation, by an increase or diminution in the supply of money. Some collateral and incidental topics have also been touched upon, all tending to the same object, *viz.* that of illustrating the nature of money, and the mode of its operations.

It has been thought proper to abstain from introducing any discussion respecting the different kinds of money that have been, or are, generally employed, or respecting the questions to which this branch of the subject would naturally give rise; as whether, if metallic money is employed, one metal alone should be the standard and legal tender, and the others should be permitted to circulate along with it, according to their market price; or whether the proportions should be fixed by law: the discussion of this point will fall under the head of *SILVER*. What are the advantages and disadvantages of a metallic and paper currency; and the various important questions connected with this branch of the subject of money; these will fall under the head *PAPER Currency*: and what circumstances affect the proportional value of the currency of one country, as compared with that of other countries; these will be considered under the head *PAR of Exchange*. In the course of the present article, the nature of value has been slightly touched upon; this will be more fully and particularly treated of under its proper head; and some further illustration of the nature and operations of money, will occur under the articles *PRICE, STOCK or Capital, and WEALTH*, which could not so properly find a place in this article.

In noticing the authors that treat on the *principles* of money, it is scarcely necessary to mention Smith, in his *Wealth of Nations*; on this, as on most of the fundamental topics of political economy, this author is perspicuous and satisfactory, though he does not always exhaust the subject on which he treats.

On the *principles* of money, much perhaps may be gained from his incidental illustrations, and from the general principle that pervades his works, and lies at the foundation of his system, than from what he directly advances on the subject. Hume, in his essay "Of Money," has thrown out only some very luminous ideas, which, though not always exactly correct, as we have endeavoured to prove, yet almost unavoidably, in the mind of an attentive reader, give rise, not merely to the perception of the error which they contain, but also to such a train of reflections as still further illustrate the subject. Indeed it is the singular merit of this author in his essays, that he guides and stimulates his readers to reflection. Sir James Stewart, in his *Enquiry into the Principles of Political Economy*, has entered pretty fully into the subject of money in the 28th chapter of his 2d book: there is a very striking and essential difference between the works of this author and that of Smith in his *Wealth of Nations*. Throughout the whole work of Stewart, there is that want of methodical and luminous arrangement, that obscurity and unsatisfactoriness in reasoning, and that clashing and contradictoriness of opinion, which must exist, where there are no clear and well grounded general principles established and pursued. His chapter on money, however, contains many valuable and sound doctrines; pushed in some instances too far, as where he endeavours to prove that an increase of money in a nation cannot affect the prices; the opinion that it necessarily, uniformly, and permanently must raise the prices, is no doubt erroneous; but if the illustrations in this article are correct, the contrary opinion, that it cannot produce this effect, is also erroneous. The controversy which took place towards the close of the 17th century respecting the state of the currency, and that which took place a few years ago, gave rise to many pamphlets, some of which treat directly and entirely

on the principles of money, and others of them only incidentally; these are, of course, of various merit, and will not add much that is satisfactory and solid to what may be gathered from Smith, Hume, and Stewart.

MONEY, *Falsæ*, or *Basæ*, is either struck by an unqualified person, and of unfatutable metals; or that which has lost of its weight, either by being clipped on the corners, or filed on the edges: or, lastly, by having some of its surface eaten off; if gold, by aqua regia: if silver, by aqua fortis.

Another kind of base money is that made of pieces of iron, copper, or other metal, covered on each side with a thin plate or leaf of gold or silver, neatly soldered and joined round the edges, and struck, like other coin, with figures, legends, &c. only to be distinguished from them by the bulk and weight, and sound.

MONEY-BILLS, in *Parliamentary Language*, comprehend all bills, by which money is directed to be raised upon the subject, for any purpose or in any shape whatsoever; either for the exigencies of government, and collected from the kingdom in general, as the land-tax: or for private benefit, and collected in any particular district, as by turnpikes, parish-rates, and the like. With respect to these bills, the commons are so reasonably jealous of their privilege of framing new taxes for the subject, that they will not suffer the other house to exert any other power but that of rejecting: they will not permit the least alteration or amendment to be made by the lords to the mode of taxing the people by bills of this nature.

MONEY, *Cert.* See **CERT-MONEY**.

MONEY, *Chimney*, *Madning*, *Poll*, *Press*, *Prestation*, *Salvage*, *Ship*, and *Trophy*. See the several articles.

MONEY-WORT, in *Botany*. See **NUMMULARIA**.

MONEYERS, **MONEYORS**, or *Moniers*, officers of the mint, who work and coin gold and silver money; and answer all the warte and charges.

MONEYERS is sometimes also used for hawkers; or those who make a trade of turning and returning money.

MONEYGALL, in *Geography*, a small post-town of Ireland, in the King's county. It is 69 miles S.W. from Dublin, and 10 S.W. from Roserea.

MONEYMORE, a small post-town of the county of Londonderry, province of Ulster, Ireland, in the southern part of the county. It is 83 miles N. from Dublin, and two miles from Cookitown.

MONFALCO, a town of Spain, in Catalonia; 5 miles N.E. of Cervera.

MONFALCONE, a town of Italy, capital of a small principality of the same name, seated on the coast of the Adriatic, and containing about 1200 inhabitants; the whole territory comprehends 20 villages, and about 4600 inhabitants; 15 miles N.W. of Trieste. N. lat. 45° 53'. E. long. 13° 30'.

MONFALOUT, or **MONFLOT**. See **MANFALOUT**.

MONFIA, an island in the Indian sea, near the coast of Africa, governed by a king, tributary to the Portuguese; about 60 miles in circumference. S. lat. 7° 30'.

MONFORT-L'AMAURY, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles. The place contains 2400, and the canton 15,809 inhabitants, on a territory of 212½ kilometres, in 28 communes.

MONFORTE, or **MONTFORT**, a town of Portugal, in the province of Tras-los-Montes; 33 miles W. of Bragança.—Also, a town of Spain, in Valencia; 13 miles W.N.W. of Alicante.—Also, a town of Portugal, in the province of Alentejo; 12 miles S. of Portalegre. N. lat. 38° 56'. W. long. 7° 12'.—Also, a town of Portugal, in Beira; 15

miles S.E. of Castell Branco. N. lat. 39° 38'. W. long. 6° 58'.—Also, a town of Sicily, in the valley of Demona; 10 miles W.S.W. of Messina.

MONFORTE de Lamos, a town of Spain, in Galicia; 15 miles N.N.E. of Orense.

MONGAELLI, a sea-port of Madagascar, on the W coast. S. lat. 13° 55'.

MONGAGUBA, a river of Brazil, which runs into the Atlantic, S. lat. 9° 20'. W. long. 34° 56'.

MONGALLO, or **GALLO**, a kingdom of Africa, N. of Mocaranga; having a capital of the same name, on a river called Mongallo, which runs into the Indian ocean, S. lat. 10° 5'. E. long. 39° 14'.

MONGALORE, a town of Hindoostan, in the Carnatic; 15 miles W. of Gingee.

MONGAN, a town of Chinese Tartary. N. lat. 41° 46'. E. long. 123° 54'.

MONGANORE, a town of Hindoostan, in Golconda; 12 miles W.N.W. of Rachore.

MONGAS, a country of Africa, S. of Sofala, furnishing a great quantity of gold, particularly at Massapa and Maninas, and the mountain of Ophir, whence, as some have supposed, Solomon derived his treasures. The Portuguese are settled at Massapa, under the government of Mozambique.

MONGASABA, a town of Hindoostan, in Oude; 28 miles N. of Kairabad.

MONGAULT, **NICHOLAS-HUBERT DE**, in *Biography*, a man of letters, who was born at Paris in 1674, entered, at an early age, into the congregation of the Fathers of the Oratory, and was sent to study philosophy at Mans. The system then taught in the schools was that of Aristotle, which, as Mongault could not comprehend, he did not scruple to reject, and adopted that of Descartes in its stead, the principles of which he openly maintained in public exhibitions. His want of health obliged him to retire, in 1699, to the college of Burgundy, at Paris, where he finished a translation of Herodian, which was published in the following year. In a few months afterwards, he published the first volume of a translation of the "Letters of Cicero to Atticus," and almost immediately after, Colbert, archbishop of Toulouse, gave him apartments in his palace. In a short time the superintendent Foucault, who wished for the conversation and services of a man of learning, prevailed upon Mongault to reside with him, and obtained for him admission into the Academy of Inscriptions and Belles Lettres. In 1710, the duke of Orleans appointed him tutor to his son, the duke of Chartres: in this situation he is celebrated by Duclou, in his Memoirs of the Regency, as "a man of parts and erudition; a theologian, who thought freely on the subjects of religion;" but whether he thought his pupil incapable of enlightened principles, or that princes should themselves be subjected to the most powerful restraints, he certainly endeavoured to impress on the mind of the young prince a system of religion which had a tendency to excite the greatest degree of terror. The result was, as might have been expected, that after his father's death, the youth went into all the austerities of monkish devotion, in which he continued till his death. The abbé's services were, however, so well received by the family, that he obtained, through their means, several church benefices and civil places. For many years of his life he was subject to melancholy, but when free from this complaint, his conversation was lively and instructive. He died in 1746: besides his translation of Cicero's letters, in six volumes, he published two dissertations in the Memoirs of the Academy of Inscriptions. He was admitted into the French academy in 1718. Moreri.

MONGELIA, in *Geography*, a small island in the Persian gulf, near Cape Barilitan. N. lat. 27° 37'.

MONGER, a little sea vessel which fishermen use.

When a word ends with *monger*, it signifies *merchant*; from the Saxon *manger*, *v. v. mercator*.

MONGERAH, in *Geography*, a town of Hindoostan, in Oude; 55 miles N.W. of Manickpour.

MONGHIR, a town and fortress of Hindoostan, in Bahar, on the S. coast of the Ganges; 40 miles E. of Bahar. N. lat. 25° 25'. E. long. 86° 36'.

MONG-HOA, a city of China, of the first rank, in the province of Yun-nan, to which no district belongs; it is surrounded with high mountains, which abound with the animals that yield musk. N. lat. 25° 18'. E. long. 100° 4'.

MONGIA, or MUGIA, a sea-port town of Spain, in Galicia, near the sea-coast; 35 miles W.N.W. of Compostella.

MONGIARDIA, a town of the Ligurian republic; 23 miles N. of Genoa.

MONGLEE, a town of Hindoostan, in Dowlatabad; 28 miles S. of Renapour.

MONGLEGOARRY, a town of Hindoostan, in the circle of Guntoor; 12 miles E. of Guntoor.

MONGLETORE, a town of Hindoostan, in Goiconda; 30 miles S.W. of Rachore.

MONGOL, one of the small Philippine islands, N.E. of Mabate. N. lat. 12° 14'. E. long. 123° 55'.

MONGOLBONG, one of the smaller Philippine islands, E. of Mabate. N. lat. 12° 10'. E. long. 124°.

MONGOLES, MONGULS, or *Moguls*, a people of ancient origin, and of widely extended dominions in the north-western parts of Asia; whose conquests, as far as history can trace them, might be confined to oblivion, if they had not produced in successive ages signal revolutions in the state of governments and of mankind. It is not easy to separate them from the people called Tartars, or to ascertain their first rise, and their early progress towards that vast empire which they ultimately acquired. Both the Moguls and Tartars are said to have been the descendants of Japhet, the eldest son of Noah. The progeny of Magog, Melchec, and Tubal, as many learned men have maintained, planted both the Scythians, and consequently the country of the ancient Moguls and Tartars. The Tartars claim priority of origin, and pretend to be descended from Turk, the eldest son of Japhet, whom they call Japhis. From their ancient ancestor they derive the name of Turks, which they seem to have retained till the time of Jenghiz Khan. This name was succeeded by that of Tartars or Tatars; and this appellation was afterwards changed by some of their tribes into that of Monguls or Moguls, which appellation prevailed till the dominion of the people, thus denominated, over the southern provinces of Asia expired, when the former name was again resumed. The immediate successor of Turk was his son Taanak, who contributed to enrich and aggrandize the nation over which he presided; and the government descended in this line, from which Timur Beg at a future period is said to have sprung. One of these princes, called Alanza Khan, having twin sons, *viz.* Tatar and Mogul, or more properly Mung'l, divided his dominions between them, not long before his decease. From Tatar Khan, the Tatars or Tartars derived their name, as the Moguls deduce theirs from Mogul or Mung'l Khan. The latter prince, the first monarch of the Moguls, was of a very melancholy disposition, which circumstance gave occasion to his name; *Mung*, in the Tartarian language, signifying *melancholy*. At his death he left four sons, from the eldest of whom, in a direct

line, descended the famous Jenghiz Khan. Kara Khan, the eldest of these sons, ascended the throne upon the decease of his father; and the Tartars say, that in his time the true religion was banished out of the world, and idolatry substituted in its place. His son and successor, Ogus Khan, is said to have worshipped the true God; and issued an order, that every one in his dominions should embrace the true religion. Ogus Khan was a valiant and victorious prince, and subdued by his arms the people of Kitay or Kathay, and those of other nations. Ogus Khan, who extended his conquests through a long reign, as the Tartars say, of 116 years, was held in high veneration over a great part of the East, and regarded as the greatest hero, except Jenghiz Khan, that ever lived in the eastern parts of the world, by the Turks and Tartars of all denominations. The Ottomans, or Ottoman Turks, so called in contradistinction to the Turkish or Tartarian tribes settled in Great and Little Tartary, from him assume the name of Oguzians; and pretend that the Othman or Ottoman family is descended in a direct line from Ogus Khan. The Tartar historians blend many fictions with their account of the Tartarian and Mogul princes, so that at this distance of time, and without the assistance of collateral records, it is impossible to distinguish between the true and the fabulous relations which their history contains. Although they are mistaken in their chronology, as is the case particularly with Abu'l Ghazi Bahadur, whose Tartarian MS. containing the genealogical history of the Turks, Tartars, and Moguls, was brought into Europe by M. Von Strahlenberg, by him translated into the German tongue, and afterwards into French, and published at Leyden in 1726, who refer Ogus Khan to the ninth generation from Noah; it nevertheless appears, that this prince was at the head of a powerful nation in the East, from which the present Tartars sprung, and rendered himself famous by his conquests. Some have supposed, that this Ogus Khan was the same with the Madyes of Herodotus, and, therefore, that the conquests of this prince terminated in the reduction of the Upper Asia, and that he put an end to his expeditions about the year 631 B.C.

Dismissing the ancient history of the Mongoles or Moguls, between whom and the Tartars many contentions subsisted for several successive ages, we shall confine our account of them, in the sequel of this article, to a later period. In the 9th century these nations appeared roaming about the northern side of China and Corea; in the west, or Modern Mongolia, the Mong-u, afterwards called Monk-kos and Mongoles; further to the east, the Kitanes; and lastly, beyond Corea, as far as the eastern ocean, the Niudsches or Kin, who, generally speaking, are the same people with the Tunguses, and the Mandschu or Manchew, the present sovereigns of China. These three people, gradually increasing, became at length powerful nations; though at first they were weak and inconsiderable. In the 10th century, the Kitanes first subdued the two other nations, and then the northern provinces of China. The Niudsches, however, soon rebelled, and being called to their assistance by the Chinese, gained the ascendancy over them, as well as the Kitanes. Upon this, a part of the latter retreated westwards, and took possession of the Lesser Bucbaria, where they have since borne the name of Karakitans, or Karakitayans. In the mean time the Niudsches ruled over the north of China, and the Mongoley as far as the eastern ocean. The Mongoles were divided into several hordes, who, notwithstanding the supremacy of the Niudsches, had their own khans. It was one of these petty princes, Temudschin or Temulin, who, under the name of Tschinghis-khan, or Jenghiz-khan, became the founder of a new monarchy, and

and one of the most memorable ravagers of the world. He was only thirteen years old, on the death of his father in 1176, when he became sovereign of 40,000 families. His career lasted twenty years; during which time he desolated the countries and subjected the people from the Mongolee and from China to the further Asia, and in Europe quite up to the shores of the Dnieper. In the first three years of his warfare, he subdued the Naimans, Kirghises, and the other Tartarian hordes. He received the voluntary submission of the Igures, a polished nation, who communicated the art of writing to the Mongoles, from whom afterwards the Mandchu received it. About the same time he pressed forward into the north-western parts of China, and made the king of Tangut his vassal. Soon after he turned his arms against the Niudsches, proceeding in his conquests, murder, and rapine, as far as the capital of Irking, forced it to surrender, and found in it the wise Ilidschutzay, a truly great and noble-minded man, whom he made his first officer of state; and who not only rescued several millions of persons from their impending fate, who would otherwise have fallen victims to the savage Mongoles, but who may be also justly said to have created the Mongolian state, by polishing the manners of that people, and, as far as he was able, disseminating among them the arts and sciences. While the Mongolian army was fighting against the Niudsches, in 1217, the flames of war broke out with increasing fury on the western side of the Mongolian empire, which, in process of time, communicated to all the countries round, and the Mongoles advanced to nether Asia, and thence again to Europe. Having defeated Keschluk, king of the Naimanes, and caused the country to submit, Tschinghis hastened to meet the sultan of Khovarefm, who had caused his ambassador to be slain, and who was his mightiest and most dangerous adversary, and obliged him to submit. In 1220, Khovarefm, the capital, was captured, and on this occasion the number of the killed amounted to upwards of 100,000 persons, and every Mongolian warrior received to his own share twenty-four slaves. About the same time all the countries and nations round, as far as the Oxus, submitted to his arms. Tschinghis now dispatched an army across that river, took Khorasan, and drove the new khovarefmian sultan to India. Another army was engaged in China against the Niudsches; a third was making conquests in Kaptschak, on the N. side of the Caspian; and a fourth, which had reduced the countries on the S. side of that sea, was now advancing against the Kaptschaks. In 1223, the Polovtzes, a branch of the Kaptschaks, and Russians lost the great battle on the Kalka, and were pursued as far as the Dnieper by the Mongoles; who, without proceeding farther into Russia, returned, laden with their booty, by Kaptschak to Bucharia, to join Tschinghis. In this year Tschinghis convoked a general diet, in which was settled the form of government to be adopted by the conquering countries. His intended progress to India was resisted by the army; and, therefore, after an absence of seven years he returned, in 1225, to Mongolee; but in the following year he was obliged to undertake a campaign against the rebellious Tangut. The Mongoles penetrated across the great sandy desert into that country, and were every where victorious; the royal race was exterminated, and the inhabitants were slaughtered in such shocking multitudes, that scarcely one in fifty was spared. After this conquest, and when Tschinghis was meditating the destruction of the empire of the Niudsches in China, death, in 1227, terminated all his projects. Oktay, the son and successor of Tschinghis, put an end to the empire of the Niudsches in China, and reduced the whole northern China to his authority; he then

made war upon the kings of Corea, and determined, with an army of more than a million and a half of men, to overrun the world from one end of one hemisphere to the other. With 600,000 of his troops he marched in person against the dynasty of Song in southern China; while the main body of his army, under the command of his son Kayuk and his nephews Baaty and Menku, proceeded to the west. In their progress they subdued the Tcherkasses and Avkhases, penetrated the Baschkirey, into Kazan and Bulgaria, and finally came to Moscow. Fourteen Russian towns were burnt in one month, February 1238. Baaty proceeded toward Novgorod, and ordered all the inhabitants in his passage to be massacred: but suddenly changing the direction of his march, he hastened to the regions of the Polovtzes and Bulgarians on the Volga. After a desperate resistance of ten weeks, Kief surrendered (1240), and received a Mongolian viceroy. All Russia, except Novgorod, was now tributary to the Mongoles, who every where appointed viceroys, without expelling the Russian princes. Baaty khan, with two great armies, ravaged Poland, Silesia, and Moravia; marched in person into Hungary, pillaged and murdered wherever he went, both here and in Slavonia, Bosnia, Servia, and Bulgaria. While the Mongoles were committing such horrors in Europe, and prosecuting the war against the Coreans and the southern Chinese, they overran likewise, with their numerous hosts, the hither Asia. A force was sent through Tscherkassia, or Circassia, to make an incursion upon Armenia; and the Mongoles penetrated into the regions of Arbela, marched through Nineveh, approached Bagdad, conquered Erzerum, ravaged and subjugated several cities and districts of the Lesser Asia, and in 1242 made the sultan of Iconium their vassal. In the following year they pursued their inroads into Syria, and came to Aleppo. The death of Oktay saved Asia for a time, and Europe for ever. After an interregnum of four years, the succeeding grand khan Kayuk made formidable preparations for war in Europe, but death defeated his projects. His successor Menku abolished the caliphate, and subjected the sultan of Iconium and Asia Minor, as far as the straits of Constantinople, to the Mongolian authority. Menku was succeeded in 1259 by Koblay. The distance of the paramount sovereign from the other Mongolian states, which extended from the eastern ocean as far as the Dnieper and the Mediterranean sea, accelerated by discord and ambition the dissolution of this enormous monarchy, which now separated into the following extensive states, viz. China, Iran or Persia, as far as the hither Asia, Dschagatay or Tchagatay, so called after its founder, Kaptschak, and Turan; which see respectively. The next ambitious conqueror, or cruel destroyer, as we may call him, that occurs to our notice in the history of the Mongoles, is Timur or Tamerlane, who was prince of Kesch, near Samarcand, about the time when the Mongoles were entirely expelled from China. His dominion took its rise in Grand Bucharia, a part of the ancient Dichagatay. Having succeeded in the reduction of that empire, he received, in 1369, the homage of the grandees, and the title of the sovereign of the world. Of his expeditions and conquests we have given some account under the article *MOGUL Empire*, and referring to his biographical article, we shall here only say that just as he was preparing to restore the dominion of the Mongoles in China, he was removed by death. His successors lost, one after another, all the countries which Tamerlane had left them, Bukharay and Khorasan excepted; and even these the last khan Baber, in 1498, was obliged to abandon, who, however, from being an outcast and a fugitive, became the founder of the state of Grand Mongolia,

Mongolia in Hindoostan. With the fall of the Great Mongolian empire of the Tschinghis began also the epocha of their decline: the dissolution into smaller states, which parted again into smaller still, and were then reduced to subjection, at length brought about a division into stems and hordes, and, consequently, a complete retrogradation from the state of civilization to the condition of raw uncultivated man. It appears that many centuries ago the Mongoles were divided into two leading nations, whose partition might probably be owing either to national circumstances, or to a natural separation by mountains, and afterwards kept up by the separate interests of their princes, or from a national enmity occasioned by perpetual dissensions. These two nations were brought to a union into one common state by the great Tschinghis; but on the destruction of the monarchy which he had erected, they were separated again by the ancient feuds, and have ever since, to their mutual ruin, been engaged in almost perpetual hostilities. The Mongoles, properly so called, compose the one, and the Doerben-Oirat the other of these nations. Doerben-Oirat means the quadruple alliance, and is the common appellation of four principal races, viz. the Oeloet, Kho-it, Tummüt, and Barga-Burat. The Oeloet constitute that branch, which in Western Asia and in Europe is known under the name of *Kalmucks*, which see: the second shoot, Kho-it, is almost extinct, if we except some remains among the Soongares and Mongoles: of the Tummüt, even the place of their present abode is not certainly known; and the fourth stem, Barga-Burat, which probably, at the time of the troubles excited by Tschinghis, took up its residence in the mountains about the Baikal, has, with all its branches, ever since the conquest of Siberia, been under the Russian sovereignty. The Mongoles comprehend the remainder of that people who were driven out of China in the 14th century by the dynasty of Ming, and are at present for the most part under the Mandshur sovereigns of that empire; though a small portion of them own the Russian sceptre. Since the demolition of the Soongarian authority, and the restoration of peace in the Mongoley, they have inhabited the spacious region between Siberia and proper China, from the eastern ocean to the Soongarey; and at present there is scarcely any discernible difference between the yellow Mongoles, living from remote ages under the Chinese protection, and the former Tschinghis or Kalkas-Mongoles. See *KALKAS*.

When Siberia was conquered by the Russians at the beginning of the 17th century, the Mongoles were still a numerous and free people, governed by their own khans, under whose sovereignty were also several Siberian nations. At first they submitted to the Russian arms; soon afterwards they regained their liberty, and even granted support to several nations of Siberia in their resistance to that power. In their intestine wars with the Kalmucks, they were generally conquerors, with the loss, however, of one race after the other. Their frequent and bloody wars with China were still more unfortunate in their issue, as their perpetual feuds finally terminated in a complete subjugation. At present they are not in a condition to liberate themselves from the yoke; though they have preserved their paternal seat, and ostensibly live under the government of their own hereditary princes. The Mongoles, who now form a part of the inhabitants of the Russian empire, withdrew themselves in the 17th century from the Chinese dominions, and put themselves under the Russian supremacy; but this secession was restrained by a border treaty entered into in the 18th century between Russia and China, the former stipulating not to give admittance any more to Mongolian runaways. The Russian Mon-

gols inhabit the regions about the Selenga in the Irkutsk district of the government of Irkutsk, their dwelling place extending from the 121 to the 125th degree of longitude, and between the 50th and 53d degree of north latitude. They consist of seven stems, and these of 20 families or "amaks," which, by the enumeration of the year 1766, comprised, besides 219 baptized, 6918 males.

The vast country of the Mongoles or Moguls is bounded on the N. by Siberia, on the E. by Eastern Chinese Tartary, on the S. by the great wall and Leaotong, and on the W. by Independent Tartary. It was partly from these dry deserts that those conquerors issued, who made all Asia tremble. The Mogulation is subdivided into a multitude of others, who all speak the same language, called the Mogul language, comprehending several dialects understood by one another. These have neither towns, villages, nor houses; they form themselves into wandering herds, and live under plain tents, which they transport from one place to another, according to the temperature of the different seasons, or the wants of their flocks; they pass the summer on the banks of rivers, and the winter at the foot of some mountain, or little hill, which shelters them from the sharp north wind. Each of these tribes has its respective limits, nor can they go beyond them without being thought to commit an act of hostility. They are naturally clownish, and dirty in their dress, as well as in their tents, where they live amidst the dung of their flocks, which, when dried, they burn as fuel. Enemies to labour, they satisfy themselves with the food supplied by their flocks rather than take the trouble of cultivating the earth; they neglect agriculture more from pride, alleging that "the grass was for beasts, and beasts for man." The men hunt the numerous beasts, and game, that roam through their vast wilds; the women tan leather, dig the culinary roots, prepare the winter provisions dried or salted, and distil the koumiss, or spirit of mares' milk. In summer they live only on milk, using, without distinction, that of the cow, mare, ewe, goat, and camel. Their ordinary drink is an infusion of coarse tea in warm water; with which they mix cream, milk, or butter, according to their circumstances. Before they distil their four milk, those of better condition mix with it some of the flesh of their sheep, which, as well as the milk, has been left to ferment. This liquor is strong and nourishing; and their most voluptuous orgies consist in getting drunk with it. Mead and brandy are now great favourites with them. The Moguls are rather short in stature, with flat visage, small oblique eyes, thick lips, and a short chin, with a scanty beard. Their ears are large and prominent, the hair black, and the complexion of a reddish or yellowish-brown; but that of the women is clear, and of a healthy white and red. They have surprising quickness of sight, and apprehension. In their disposition they are free, open, and sincere; they are docile, hospitable, beneficent, active, and voluptuous. Industry is a virtue, entirely female; and though great, it is accompanied with perpetual cheerfulness. They pride themselves chiefly on their dexterity in handling the bow and arrow, mounting on horseback, and hunting wild beasts. Polygamy is allowed, though they commonly content themselves with one wife; marriages are celebrated at an early age, and the bride brings a dower in cattle or sheep. Their tents are circular, in form of the frustum of a cone, and covered with a large piece of white or grey felt. A round hole in the top gives passage to the smoke, which rises from a fire made in the middle of the tent. These tents, which they have been accustomed to prefer to the Chinese houses, are cold in winter, and insupportably warm, and noxiously damp, in summer.

The tents of the nobles are hung with silk, and the floor covered with Persian carpets. The household utensils are numerous; and in the superior tents are vessels of pewter, silver, and porcelain. Their dress consists of a flat yellow bonnet, which covers the head that is shaven, except one lock, wide trowsers, a vest of light stuff with narrow sleeves, and a girdle, which supports the sabre, knife, and implements for smoking tobacco. The outer vestment is of cloth, or skin, with wide sleeves, and linen is wound about the feet, over which are drawn buskins of leather, generally black or yellow. Shirts are unknown. The dress of the women is the same, but instead of the outer garment they wear a gown without sleeves. The skins, which they use for clothing, are generally those of sheep; the wool side being inmost, and the skin on the outside. They are well acquainted with the method of preparing and whitening these skins. But these skins, however carefully prepared, exhale a strong and disagreeable smell, on which account they are called by the Chinese "Tfao-tatse," stinking Tartars. The hair of the females is long, and plaited in tresses.

When pasturage begins to fail, all the tribes strike their tents, generally from ten to fifteen times in the year, proceeding in the summer to the northern, and in the winter to the southern wilds. The herds, men, women, and children, form a regular procession; and are followed by the girls, singing with harmony and spirit. The amusements of these jovial wanderers consist in running-races on horseback, in which even the girls excel; archery, wrestling, pantomime, dances, and the songs of the young women, generally accompanied by the lute, viol, and pipe; the themes of their ditties being tales of gigantic chivalry, and amorous adventures and sentiments; but the melody is harsh and dismal. Cards are not unknown, but the favourite game is chess. The bodies of the princes and chief men are burned with many solemnities; and the tombs are sometimes walled, and ornamented with high poles and fantastic drapery. They are unacquainted with the use of money, and trade only by barter. Such, also, with some shades of difference, are the manners of the Tartars and Mandchurs. In the Mogul language there are many books written in the various countries to which their wide conquests extended.

The religion of the Mogul Tartars is confined to the worship of Fo. For their "Lamas" they entertain the most superstitious veneration; though these are clownish, ignorant, and licentious priests, yet to them they attribute the power of calling down hail or rain; and to them they give the most valuable of their effects in return for prayers, which they go about reciting from tent to tent. These people are very devout, and continually wear hanging at their necks a kind of chaplet, over which they say their prayers.

All the Moguls are governed by khans, or particular princes independent one of the other, but all subject to the emperor of China, whom they consider as the grand khan of the Tartars. When the Manchews subdued China, they conferred on the most powerful of the Mogul princes the titles of "vang," "peilé," "peizé," and "cong," which correspond to our titles of king, duke, count, and marquiss; each of them had a revenue assigned him, but far inferior to the appointments of the Manchew lords at Peking. The emperor settled the limits of their respective territories, and appointed the laws, according to which they are at present governed. These tributary khans have not the power of condemning their subjects to death, nor of depriving them of their possessions: the two cases of death and confiscation being reserved for the supreme tribunal

established at Pe-king for the affairs of the Moguls, to which every individual may appeal from the sentence of his prince, who is obliged to appear in person whenever he is cited.

All the Mogul nations, under the Chinese government, of which we have given an account in the closing paragraph of this article, are divided into four principal tribes, which are the Moguls, properly so called, the Kalkas, Ortous, and Tartars of Kokonor. The country of the Moguls, according to the map of Chinese Tartary, taken from the Memoirs of the Jesuits, extends more than 300 leagues from E. to W., and 200 from N. to S.; it is inclosed between the country of the Ortous, the great wall, Eastern Tartary, and the country of the Kalkas; these people compose 49 "ki," or standards; every standard comprehending an indeterminate number of companies, each of which consists of 150 heads of families; and each company may be reckoned to contain 1000 individuals. Besides these 49 standards, there are five others, under the immediate government of the emperor of China, and commanded by officers whom he sends thither.

The best cultivated canton of all the Mogul territories is the district of "Cartching," near the great wall, where the emperor every year hunts, and where he has caused to be built several pleasure-houses, the principal of which is "Geho." The extensive domains in this district, belonging to the emperor, are let out to farmers, and the number of cattle kept by them is immense. It has been said that they reckoned there 190,000 sheep, distributed into 225 flocks, and almost as many oxen and cows, divided into herds, each of which contained 100. The number of stallions there is more considerable. These riches in farms, studs and flocks make greater impression on the minds of the Tartar and Mogul princes, and render them much more sensible of the majesty of the emperor, than all the magnificence of his court at Pe-king. Anc. Un. Hist. vol. xviii. Tooke's Russia, vol. i. Grofier's China, vol. i. See *MOGUL Empire*, and *TARTARY*.

MONGON, a town of Peru, situated on its coast, in the fourth Pacific ocean; 10 leagues N. of the harbour of Guarmey, and four leagues from Bermajo island: it is known at sea by a high mountain just over it, which is seen at a greater distance than any others on this part of the coast.

MONGON, *Cape*, lies on the S. side of the island of St. Domingo.

MONGOOSE, or MONGOOZ, in *Zoology*, is a species of *lemur* in the Linnæan system, the woolly maucauco of Pennant, and by some called the Macassar fox. See *LEMUR Mongoz*.

MONGOPUNGOLE, in *Geography*, a town of Hindoostan, in the circar of Meywar; 36 miles E. of Cheitore.

MONGOU KIAMEN, a post of Chinese Tartary. N. lat. 44° 46'. E. long. 125° 28'.

MONGUILLEM, a town of France, in the department of the Gers; nine miles N.W. of Nogaro. N. lat. 43° 52'. W. long. 0° 7'.

MONGUIPATANE, a town of Hindoostan, in the circar of Aurungabad; 24 miles S. of Aurungabad.

MONGULCOTE, a town of Hindoostan, in Bengal; 18 miles N. of Burdwan.

MONGULHAUT, a town of Hindoostan, in Bengal; 16 miles N. of Rungpour.

MONGUMMA, a town of Hindoostan, in Beggiland; 15 miles N.E. of Rewah.

MONHEGAN, or MENHEGAN, a small island in the Atlantic

Atlantic ocean; 12 miles S.E. of Pemaquid Point, in the county of Lincoln and state of Maine.

MONHEIM, a town of the duchy of Berg, on the Rhine; nine miles S.S.E. of Dusseldorf.—Also, a town of Bavaria, in the principality of Neuburg; 18 miles W.N.W. of Neuburg. N. lat. 48° 47'. E. long. 10° 46'.

MONI, a small island in the gulf of Bengia.

MONIAGUR, a town of Hindoostan, in Concan; 48 miles N. of Bancout.

MONIAN, a town of Bengal; 20 miles S. of Calcutta.

MONIEH, one of the smaller Hebrides. N. lat. 57° 28'. W. long. 7° 36'.

MONJES, a cluster of small islands in the Spanish main, near the coast of South America. N. lat. 12°. W. long. 70° 40'.

MONIGLIA, GIO. ANDREA, of Florence, in *Biography*, member of the academy della Crusca; a physician by profession, was author of a great number of poems for music. He may be regarded, says M. Laborde, as one of the first who began to reform the abuses of the age; but this was only in his dramatic works, they were all printed at Florence, and dedicated to the grand duke, in 1698. He was established in the service of his court, which, by very expensive efforts, seems to have delighted in the exhibition of whatever the wild imagination of poets could invent. His works were brought on the different stages of Italy from 1657 to about 1680.

MONIKEDAM, or MONIKENDAM, in *Geography*, a sea-port town of Holland, on the river Monick, on the borders of the Zuyder see, with a small port; nine miles N.E. of Amsterdam. N. lat. 52° 29'. E. long. 4° 52'.

MONILIA, in *Botany*, from *monile*, a necklace, alluding to the beaded appearance of the threads, which are supposed to be the seat of the fructification. Perf. Syn. Fung. 691. Obf. Mycol. fasc. 2. t. 4. f. 8, 9. (*Aspergillus*; Mich. Gen. 212. t. 91.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. Stalked or dispersed, fibrous. Threads beaded or jointed.

Perfoon defines 12 species of this minute, but curious genus. They are confounded by common observers, under the general idea of *Mucor*, or Mould, being found on various putrifying vegetable substances; sometimes on the dung of animals. The author just mentioned disposes them in three sections, of which we shall cite an example or two.

Section 1. *Stalked; the threads collected into a round head.*

M. glauca. Perf. n. 4. (*Aspergillus capitatus*, capitulo glauco, seminibus rotundis; Mich. Gen. 212. t. 91. f. 1. *Mucor glaucus*; Linn. Sp. Pl. 1656. Fl. Dan. t. 777. f. 2.)—Tufted, of a glaucous grey.—Common on rotten apples, peaches, melons, &c. It forms tender greyish-white patches, of no determinate figure. When examined with a microscope, each minute individual proves to be a globose *head of threads*, radiating in every direction, and supported by a long slender *stalk*. The texture is so tender and evanescent, that the plant cannot be preserved.

M. penicillatus. Perf. n. 7. Obf. Mycol. fasc. 2. 35. t. 4. f. 8, 9.—Clustered, lemon-coloured, permanent. Stalk downy. Threads even.—Found by Perfoon on the dung of mice, but very rarely. The texture is durable. *Stalks* rigid, shorter than the former, their height scarcely exceeding the diameter of the *head*. The *threads* are smooth, not beaded, forming an exception to the generic character, so that Perfoon justly doubts, whether this little plant be properly referred to *Monilia*. It can hardly however be reduced to any other known genus.

Section 2. *Caulifert; threads straight, digitate.*

M. digitata Perf. n. 9. (*Aspergillus albus tenuissimus*, graminis dactylodis facie, seminibus rotundis; Mich. Gen. 215. t. 91. f. 3. *Mucor crustaceus*; Linn. Sp. Pl. 1656, with an erroneous quotation of Mich. h's letter-press. *M. penicillatus*; Bull. v. 1. 107. t. 504. f. 11.)—Glaucous. Stalk simple. Threads finger-like.—Very common on all kinds of fermenting or corruptible substances, composing greyish uneven tufts, of an extremely delicate and minute structure. The beaded *threads* stand four or five together, radiating, at the top of each common *stalk*. The latter is said by Bulliard to be sometimes branched.

Section 3. *Dispersed, stemless; threads irregularly scattered, moully.*

M. antennata. Perf. n. 12. (*Dematium antenniforme*; Hoffm. Germ. Crypt. 1. 13 f. 4. *Aspergillus cæspitosus*, ex obscuro nigricans, seminibus ovatis; Mich. Gen. 213. t. 91. t. 62.)—Dispersed, black. Joints of the threads ovate.—Common in autumn on the trunks of trees, or on pales, which it renders black in patches. In summer it is said by Perfoon to be, in a young state, tender, more scattered, and almost of an olive colour.

Such minute productions as this, must necessarily be liable to confusion. Those who study *Conseruus*, and look no further, would consider the present as of that genus; Lichenographists might suppose it a *Collema*, destitute of fructification, or more probably a *Lepraria*, consisting of nothing else. The patient observers of these intricate works of creation do great service in collecting them together, even under a confined or partial view of the subject, for the use of those who can consider it on a larger scale; because every body cannot be so laboriously intent on every department of nature.

MONILIFERA, Vaillant's name for the *Osteospermum* of Linnaeus, alluding to the globose form and hard substance of its seeds, which are extremely singular in the class *Syngenesia*. See OSTEOSPERMUM.

MONIMASCA, in *Geography*, a town of Africa, in Cacongo, on the right bank of the Zaire. S. lat. 5° 55'. E. long. 12° 50'.

MONJOUL, a town of Hindoostan, in Bahar; 45 miles E. of Hajypour. N. lat. 25° 34'. E. long. 86° 18'.

MONISTROL DE LOIRE, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Yssengeaux; 19 miles N.E. of Le Puy. The place contains 3913, and the canton 10,453 inhabitants, on a territory of 192½ kilometres, in five communes. N. lat. 45° 17'. E. long. 4° 13'.

MONITORY LETTERS, are letters of warning and admonition, sent from an ecclesiastical judge upon information of scandals and abuses within the cognizance of his court.

MONITOU ISLANDS, in *Geography*. See MONETOU.

MONJUIEH. See MONT-JOUY.

MONJUR, a town of Asiatic Turkey, in Caramania; 20 miles S. of Kirshehr.

MONIY, a river of Brazil, which runs into the bay of Maranhao. S. lat. 2° 40'. W. long. 45° 29'.

MONK, GEORGE, in *Biography* duke of Alpermarle, was son of sir Thomas Monk, and born in 1608. He received his education chiefly from the care of his maternal grandfather sir George Smith, with whom he resided. His father was in reduced circumstances, and having subjected himself to an arrest for debt, the son, indignant at the sheriff's officer who came to serve the process, assaulted and caged him without mercy. To avoid the consequence of this outrage, he entered at the age of seventeen as a volunteer, under

his relation sir Richard Greenville, then about to embark on an expedition against the Spaniards. In this and a following enterprize the success was trifling, and in 1629 he went to serve in the Low Countries, first under lord Oxford, and then under lord Goring, the latter of whom advanced him to the rank of captain. During the following ten years he was present at various sieges and battles, and laid in a stock of professional knowledge, which qualified him for a higher command. He returned home at the commencement of the civil wars, and was engaged in behalf of the king, but he appears, in a short time, to have fallen under suspicion of being inclined to the cause of parliament, and orders had been actually issued to arrest him on his arrival, and his regiment was taken away. He was permitted to go on his parole to Oxford, where he completely justified himself to the king, and was raised to the rank of major-general in the Irish brigade, then employed under lord Byron, in the siege of Nantwich. He was soon made prisoner, and his whole brigade, by Fairfax, and being sent to the Tower of London, was kept in confinement till November 1646. He amused himself, during his leisure, by composing "Observations on military and political Affairs," which he sent in manuscript to lord Liffel, by whose direction they were published after his death. Through the interest of this nobleman, Monk was liberated, on condition of taking the covenant; he went to Ireland, where he was appointed commander-in-chief for the parliament in the north of Ireland, and obliged O'Neal, who was at the head of a rebellion of the natives, to raise the siege of Londonderry. The superiority of the royalists, another party at that time in Ireland, and the unwillingness of the Scotch troops to act with those of the parliament, so embarrassed him, that he found it necessary to make a treaty with O'Neal, and to put Dundalk into the hands of the king's troops, after which he returned to England. The parliament was indignant at this termination, and passed a vote of disapprobation of the treaty with O'Neal, but at the same time so far acquitted Monk, that it was resolved his conduct should not be enquired into. Monk probably never forgave this proceeding, though he soon after accepted a command in Scotland under Cromwell, who formed a regiment for him, and made him lieutenant-general of artillery. He performed several important services for the government, and when Cromwell left Scotland in pursuit of Charles II., Monk was left to command in that country at the head of 7000 men. In this station he acted with vigour and success: besieged and took Stirling castle, whence he sent all the records of the kingdom to London. He stormed Dundee, and, in imitation of Cromwell in Ireland, put the governor, and all the men in arms, to the sword. This example of savage severity deterred other places from resistance, and he became master of the whole country, with the exception of some of the inaccessible parts of the Highlands. His health declined, and in 1652 he was obliged to go to Bath, but on his recovery he returned to Scotland, as one of the commissioners for its union with the English commonwealth.

The Dutch war, in the mean time, broke out, and in 1653 Monk was transferred to the sea-service. "He was now," says Dr. Campbell, in his Lives of the Admirals, "nearly forty-five years of age, which seemed a little of the latest to bring a man into a new scene of life, yet it must be remembered, that he was bred in a maritime country, and had served at sea in his youth; so that the preferment was not absolutely out of his way; or if it was, he soon made it appear that he could easily accommodate himself to any service that might be beneficial to his country." In June 1653 he engaged, with the fleet, of which he had the command,

the Dutch fleet: and being on board the *Resolution* with admiral Deane, who in the very beginning of the action was killed by a chain-shot, a new invention ascribed to De Witte, Monk with great presence of mind threw his own cloak over the dead body, and having taken two or three turns on the deck, and encouraged the men to do their duty, ordered it to be removed into his cabin. The contest lasted two days, and at length terminated in a complete victory obtained by the English. Soon after Van Tromp had fitted out another fleet, with which, on the 29th of July, he engaged the English under Monk. The Dutch admiral was killed in the action, and a most decisive victory accrued to the English, testified by the capture or destruction of more than thirty ships, and the moment the result was known the States General were obliged to send their ministers here to conclude a peace upon any terms that could be obtained. At an entertainment subsequent to the thanksgiving for this victory, Cromwell, now protector, with his own hand put a gold chain around the neck of his successful admiral. After this he was employed again in Scotland, and conducted the government with which he was entrusted, so as to conciliate the personal good-will of the nation, however disaffected in their hearts, to the rule to which they were forced to submit. His former attachment to the royal cause excited some distrust of him on the part of Cromwell, and some hopes of him in the royalists, but he was very cautious, and took care to give no ground of suspicion by his actions. By his letters, and by his conduct, there seems now no doubt that he was steadily and strongly attached to Cromwell, to whom he not only communicated all that he could discover of the king's intelligence with others, but sent him also a copy of the letter, written by king Charles II. to himself, which for a considerable time was considered as a proof of Monk's early affection for the king's service, a supposition that is now clearly and absolutely overturned. Cromwell, however, was suspicious of him to the last, and but a short time before his death he wrote the general, or admiral, a long letter, concluding with the following postscript, "which," says the discerning Campbell, "I conceive affords us a better picture of Oliver than is any where to be met with, and which is no less singular, drawn by his own hand:"

P.S. "There be that tell me, that there is a certain cunning fellow in Scotland, called GEORGE MONK, who is said to lie in wait there to introduce CHARLES STUART. I pray you use your diligence to apprehend him, and send him up to me."

Immediately on the death of Oliver, Monk proclaimed Richard, from whom he received a very kind letter, which among other things said, "that his father had directed him to be governed chiefly by his advice." To this, Monk returned a prudent answer, but did not commit himself: he foresaw that Richard would not be able long to maintain his authority, and was unquestionably preparing to act according to circumstances. But whatever were his private views, no politician could have kept them more closely concealed. His relation and early patron, sir John Greenville, sent the general's brother to him in Scotland, with a letter from the king, soliciting his support; but though he received his brother with kindness, he sent him back with no confidential communication on the subject. Lambert, his principal rival, was at this period possessed of the chief influence over the army in England. By direction of the Committee of Safety, who now held the reins of government, he marched northwards with the view of overawing Monk. The latter, to gain time, dispatched commissioners to London to treat of an accommodation, and in the mean while the parliament re-

sumed

tained its authority. Monk set out on his journey to the metropolis: his character was to highly estimated, that he received addresses on all sides requesting that he would use his influence, and exert his powers, in settling a legal and equitable government. On his arrival he took his quarters in Westminster, affecting a perfect and unlimited obedience to the existing parliament, and even caused some of their orders to be executed which revolted against his own mind. At length he complained of the odious service forced upon him, and required the House, in a peremptory manner, to issue writs for assembling a new and a free parliament. This was the death warrant to the long, or rump parliament, and the general rejoicings that were made on the occasion sufficiently proved the odium which that assembly had incurred with the nation. Every thing now manifestly tended to the restoration of monarchy, and yet Monk still maintained the appearance of attachment to republican principles, and allowed, at least openly, no channel of communication between him and the king. At length the general unboasted himself to a person by the name of Morrice, a relation and intimate friend, and through his means sir John Greenville was admitted to a conference with the general, and entrusted with a verbal message to the king, consisting of assurances of fidelity, and advice for his conduct. Thus was the restoration begun, prosecuted, and perfected by Monk, who assisted, on the 8th of May, 1660, at the proclamation of Charles II. in the capital. On the landing of the king at Dover, he was met by the general, who was hailed by Charles and his brother with all the distinction justly due to one who had been so instrumental in the great event. It was unquestionably regarded as an additional benefit conferred on the sovereign, though perfectly unjustifiable on the part of Monk, that he discouraged and opposed all all those limitations of the royal power and prerogative which some of the best and most judicious friends to political liberty had proposed, and insisted that his restoration should be unconditional. His rewards, as was natural, soon followed, and they were as ample as a subject could expect. His titles, preferments, and fortune he received as favours from the king, all which he might, perhaps, have received in another way, as a very large party in the country would have gladly made him Oliver's successor, but as Campbell expresses it, "Monk generously despised a diadem to which he had no right, and with equal greatness of mind, refused to make any terms with him to whom it belonged, chusing to leave the king's power, and the people's freedom, to be discussed in the only assembly that could have a right to meddle with them." He was created a knight of the Garter, was admitted into the privy-council, made master of the horse, gentleman of the bed-chamber, first commissioner of the treasury, and created duke of Albermarle, with the grant of a landed estate of 7000*l.* per annum. His vast elevation he bore with the modesty and discretion that seemed to be inherent in his disposition. He sat as one of the commissioners for the trial of the regicides, an office which, it is hoped, he undertook with a view of moderating the ferocity of others connected with him, in the same commission. As for Monk, he conducted himself with at least the appearance of humanity in every case, except in the production of private letters from the marquis of Argyle on the trial of that nobleman, and for this he has been justly censured. The question respecting the production of these letters, to the prejudice of the marquis of Argyle, has been lately discussed with much eagerness. Mr. Fox, in his posthumous historical work, has no doubt of the fact, and he speaks of Monk, with that indignation which he was always known to feel for baseness and hypocrisy. He says, "All depended

upon the army, and that army had fallen into the hands of one, than whom a baser could not have been found in its lowest ranks. Personal courage appears to have been Monk's only virtue; reserve and dissimulation made up the whole stock of his wisdom." Mr. Rose endeavours to vindicate the character of the general, but his arguments are feeble, and his reasoning inconclusive. Mr. Serjeant Heywood, in his "Vindication of Mr. Fox's Historical Work," relates very fully and clearly the arguments, for believing that Monk was guilty of the charge imputed to him with respect to the unfortunate marquis. He proves, in the most satisfactory manner, that it is highly probable Monk did receive letters from Argyle which might affect his life, and then offers strong reasons to shew that he most likely produced them to the parliament, which was sitting in judgment on the marquis. Of Monk, the learned serjeant says, "though not guilty of the precise crime for which they [the regicides] were to be tried, he had waded to his dukedom through bloodshed, duplicity, and crimes." And he further adds, "he probably became the restorer of monarchy, only because he was disappointed in the hope of succeeding to the protectorate, on the abdication of Richard. He had recently acted with some of those who were brought before him for trial, and his crimes deserved the same punishment which he unblushingly concurred in inflicting upon theirs." On this subject we refer our readers for more ample information to Heywood's "Vindication," and to the Monthly Review, vols. lix. and lxxix. p. 366, 367.

Monk joined the lord chancellor Hyde in the constitutional measure of disbanding the army, with an exception in favour of his own regiment: and he was chiefly instrumental in the suppression of the insurrection of the Fifth-monarchy men. At the breaking out of the Dutch war in 1664, he exerted all his powers in refitting and manning the fleet, and was appointed joint-admiral of the fleet with prince Rupert. The two commanders put to sea in April 1666, and fell in with the Dutch under the younger Tromp and De Ruyter. By the duke's advice prince Rupert took a division of the fleet to oppose that of the French, which was coming to the aid of the Dutch. The English was now much inferior in number to their enemy, but the duke of Albermarle did not hesitate to begin the attack on the 1st of June, and a most bloody engagement ensued, which lasted four days. On the first three, the English, much inferior to the enemy, were obliged to make a retreating fight, the duke himself closing the rear, with the full resolution of blowing up his ship rather than be taken. On the fourth, the return of prince Rupert enabled the English to face about, and a fresh action ensued, at the end of which they retired to their harbours, having been on the whole the principal sufferers. A new combat, by the same commanders on both sides, on the 25th of July, ended to the disadvantage of the Dutch; after which the duke of Albermarle came home and struck his flag. The daring enterprize of the Dutch in 1667, who sailed up the Thames, and burnt some ships at Chatham, called forth the exertions of this veteran once more, who exposed himself to danger in their defence. At this time he was much out of health, being affected with symptoms of dropsy, which put a period to his life, in January 1670, in the 62^d year of his age. His remains were deposited, with great funeral pomp, in Henry VIIIth's chapel, in Westminster Abbey. Biog. Brit. Hume's Hist. Stockdale's edition of Campbell's Lives of the Admirals, vol. ii.

MONK, anciently denoted a person who retired from the world to give himself up wholly to God, and to live in solitude and abstinence.

The word is derived from the Latin *monachus*, and that from the Greek *μοναχος*, *solitary*, of *μονος*, *solus*, *alone*; because the ancient monks lived in solitude, as the true monks still do.

Such were the hermits and anachorets, who withdrew into deserts, and lived remote from all commerce of mankind.

Some writers, as father Helyot, (Dissert. Prelim.) trace the origin of monks up as early as the time of the Therapeutæ; and maintain, that there had been an uninterrupted succession of monks from the Therapeutæ to St. Anthony. Others, on the contrary, are contented with going back as far as St. Paul the Hermit.

The original of monks seems to have been this. The persecutions which attended the first ages of the gospel, forced some Christians to retire from the world, and live in deserts and places most private and unfrequented, in hopes of finding that peace and comfort among beasts, which were denied them among men. And this being the case of some very extraordinary persons, their example gave so much reputation to retirement, that the practice was continued when the reason of its commencement ceased. After the empire became Christian, instances of this kind were numerous, and those, whose security had obliged them to live separately and apart, became afterwards united into societies. We may also add, that the mystic theology, which gained ground towards the close of the third century, contributed to produce the same effect, and to drive men into solitude for the purpose of enthusiastic devotion.

In this kingdom many persons might seek this kind of refuge, during the persecution of Diocletian about the year 303, and in those perilous and afflictive times, when the Romans oppressed the Britons, and when their situation was rendered more distressing by the invasion of the Scots from Ireland, the Picts and Attacots from the north, and the Saxons and Franks from the east and south.

The monks, at least the ancient ones, were distinguished into *solitaries*, *cœnobites*, and *sarabaites*.

The *solitary* are those who live alone, in places remote from all towns and habitations of men, as do still some of the hermits.

The *cœnobites* are those who live in community with several others in the same house, and under the same superiors.

The *sarabaites* were strolling monks, having no fixed rule or residence.

The houses of monks again were of two kinds, *viz.* *monasteries*, and *lauræ*. See MONASTERY, and LAURA.

Those we call monks now-a-days are *cœnobites*, who live together in a convent or monastery, who make vows of living according to a certain rule established by the founder, and who wear a habit which distinguishes their order.

Those that are endowed, or have a fixed revenue, are most properly called monks, *monachi*; as the Chartreux, Benedictines, Bernardines, &c. The Mendicants, or those that beg, as the Capuchins and Franciscans, are more properly called *religious*, and *friars*; though the names are frequently confounded.

The first monks were those of St. Anthony; who, towards the year 305, formed them into a regular body, engaged them to live in society with each other, and prescribed to them fixed rules for the direction of their conduct. These regulations, which Anthony made in Egypt, were soon introduced into Palestine and Syria by his disciple Hilarion. Almost about the same time, Aones, or Eugenius, with their companions Gaddanas and Azyzas, instituted the monastic order in Mesopotamia, and the adjacent countries; and their example was followed with such rapid success, that, in a short time, the whole East was

filled with a lazy set of mortals, who, abandoning all human connexions, advantages, pleasures, and concerns, wore out a languishing and miserable life amidst the hardships of want, and various kinds of suffering, in order to arrive at a more close and rapturous communication with God and angels. From the East this gloomy institution passed into the West, and first into Italy and its neighbouring islands; though it is uncertain who transplanted it thither. St. Martin, the celebrated bishop of Tours, erected the first monasteries in Gaul, and recommended this religious solitude with such power and efficacy, both by his instructions and his example, that his funeral is said to have been attended by no less than 2000 monks. From hence, the monastic discipline extended, gradually, its progress through the other provinces and countries of Europe. There was, however, a great difference in point of austerity between the western and oriental monks; for the former could never be brought to bear the severe rules to which the latter voluntarily submitted; and the reason of this difference may be partly derived from the nature of the respective climates in which they dwell. The European countries do not so much abound with delirious fanatics, and with persons of a morose and austere complexion, as those arid regions that lie towards the burning east; nor are our bodies capable of supporting that rigid and abstermious method of living, which is familiar and easy to those who are placed under a glowing firmament, and who breathe in a sultry and scorching atmosphere. It was, therefore, the name, more than the thing itself, that was transported into the European countries; though this name was indeed accompanied with a certain resemblance or distant imitation of the monastic life instituted by Anthony and others in the East. There were besides the monks of St. Basil, called in the East, *Calogeri*, from *καλος* *γερων*, *good old man*, and those of St. Jerome, the hermits of St. Augustine, and afterwards those of St. Benedict and St. Bernard, at length came those of St. Francis and St. Dominic, with a legion of others; all which see under their proper heads, BENE-DICTINES, &c.

Towards the close of the fifth century, the monks, who had formerly lived only for themselves in solitary retreats, and had never thought of assuming any rank among the sacerdotal order, were now gradually distinguished from the populace, and endowed with such opulence and honourable privileges, that they found themselves in a condition to claim an eminent station among the supports and pillars of the Christian community. The fame of their piety and sanctity was so great, that bishops and presbyters were often chosen out of their order; and the passion of erecting edifices and convents, in which the monks and holy virgins might serve God, in the most commodious manner, was at this time carried beyond all bounds. However, their licentiousness, even in this century, was become a proverb; and they are said to have excited the most dreadful tumults and seditions in various places. The monastic orders were at first under the immediate jurisdiction of the bishops, from which they were exempted by the Roman pontiff, about the end of the seventh century; and the monks, in return, devoted themselves wholly to advance the interests, and to maintain the dignity of the bishop of Rome. This immunity which they obtained was a fruitful source of licentiousness and disorder, and occasioned the greatest part of the vices with which they were afterwards so justly charged. In the eighth century the monastic discipline was extremely relaxed both in the eastern and western provinces, and all efforts to restore it were ineffectual. Nevertheless, this kind of institution was in the highest esteem, and nothing could

equal the veneration that was paid, about the close of the ninth century, to such as devoted themselves to the sacred gloom and indolence of a convent. This veneration induced several kings and emperors to call them to their courts, and to employ them in civil affairs of the greatest moment. Their reformation was attempted by Lewis the Meek, but the effect was of short duration. In the eleventh century they were exempted by the popes from the authority of their sovereigns, and new orders of monks were continually established; inasmuch that in the council of Lateran, that was held in the year 1215, a decree was passed, by the advice of Innocent III. to prevent any new monastic institution, and several were entirely suppressed. In the fifteenth and sixteenth centuries, it appears from the testimonies of the best writers, that the monks were generally lazy, illiterate, profligate, and licentious epicureans, whose views in life were confined to opulence, idleness, and pleasure. However, the reformation had a manifest influence in restraining their excesses, and rendering them more circumspect and cautious in their external conduct.

Monks are distinguished by the colour of their habits into *black, white, grey*, &c. Among the monks, some are called *monks of the choir*, others *professed monks*, and others *lay monks*; which last are destined for the service of the convent, and have neither clericate nor literature.

MONKS, *Cloistered*, are those who actually reside in the house; in opposition to *extra monks*, who have benefices depending on the monastery.

Monks are also distinguished into *reformed*, whom the civil and ecclesiastical authority have made matters of ancient convents, and put in their power to retrieve the ancient discipline, which had been relaxed; and *ancient*, who remain in the convent, to live in it according to its establishment at the time when they made their vows, without obliging themselves to any new reform.

Anciently, the monks were all lay-men, and were only distinguished from the rest of the people by a particular habit, and an extraordinary devotion. Not only the monks were prohibited the priesthood, but even priests were expressly prohibited from becoming monks, as appears from the letters of St. Gregory. Pope Symiacus was the first who called them to the clericate, on occasion of some great scarcity of priests, that the church was then supposed to labour under: and since that time the priesthood has been usually united to the monastic profession.

MONKS, *Professed*. See PROFESSED.

MONKS, *Proprietary*. See PROPRIETARY.

MONK *Fish*, called also *Angel-fish*, in *Ichthyology*, a species of *squalus*. See SQUALUS *Squatina*.

MONK'S *Hood*, a name given to several species of aconite, or wolf's-bane. See ACONITUM.

MONK'S *Rhubarb*. See RHUBARB, and RUMEX.

MONK'S *Seam*, among *Sailors*, is, when the selvages of sails are laid a little over one another, and sewed on both sides.

MONKAH, in *Geography*, a town of Bengal; eight miles S. of Palamow.

MONKEARY, a town of Bengal; 20 miles S.S.E. of Palamow.

MONKEDOO, a town on the W. coast of Borneo. S. lat. 2° 40'. E. long. 109° 51'.

MONKEY, in *Zoology*, a name given by way of distinction to those apes which have tails; the others, or those without tails, being more properly called *apes*.

The same distinction holds in Latin, the tailed ones being called *papiones* or *baboons*, when they have short tails; *cercopithecus*, when their tails are longer; and those without tails *simia*. See CERCOPITHECUS and SIMIA.

MONKEY of the *West Indies*. See GUARIBA, and SIMIA *Heulzebb*.

MONKEY, *Green*. See CALLITHRICHUS, and SIMIA *Sabaot*.

MONKEY, in *Ship-Building*, a machine for driving bolts where more force is required than the common method, by a mallet. It is composed of a long pig of iron traversing in a groove, or in a frame, with handles, with a groove on the underside, and slides upon a ridge of iron fixed in a bed. The whole is fixed to centre the bolt to be driven, and then the monkey is forcibly drawn, to strike the bolt, by ropes and pulleys.

It also denotes the stand for the pinion and winch-handle, which draw the lock-paddles in a canal, &c. *Plate V. Canals*, fig. 38 and 39, k, l.

MONKEY-*Boat*, a name sometimes applied to a long narrow sort of boat.

MONKEY-*Blocks*, in *Ship-Building*. See BLOCKS.

MONKEY'S *Bread*, in *Gardening*. See DANONIA.

MONKEY-*Flower*, the common name of a flower plant. See MIMULUS.

MONKEY-*Island*, in *Geography*, a small island in Currituck sound, near the coast of North Carolina. N. lat. 36° 22'. W. long. 76° 4'.

MONKEY-*Key*, a small island in the bay of Honduras, near the coast of Mexico. N. lat. 16° 25'. W. long. 89° 35'.

MONKEY-*Point*. See PUNTA *Chica*.

MON-KIEU-TCHIN-HOTUN, a town of Corea. N. lat. 43° 1'. E. long. 129° 50'.

MONKTON, a post-town of America, in Addison county, Vermont, E. of Ferrisburg; containing 1080 inhabitants.—Also, a township of Annapolis county, in Nova Scotia, inhabited by Acadians, and a few families from New England; it consists chiefly of wood-land and salt-marsh, and contains about 60 families.

MONLIRAS, a town of the island of Cuba; 45 miles E. of Bayamo.

MONMOUTH, a large maritime county of New Jersey, in the United States, of a triangular shape; 80 miles in length, and from 25 to 40 in breadth; it is divided into six townships, and contains 19,872 inhabitants, including 1633 slaves. The face of the country is generally level, with few high lands, the most noted of which are Navesink and Centre-hill. The soil is for the most part sandy; but other parts are fertile. At the mouth of Navesink river there is a curious cave, now in a ruined state, 30 feet long, and 15 wide, containing three arched apartments.

MONMOUTH, or *Freehold*, a post-town and capital of the fore-mentioned county, situated 22 miles N.E. by E. of Allentown, 34 E. of Trenton, and 64 N.E. by E. of Philadelphia. It contains a court-house, gaol, and a few compact dwelling houses, with a Presbyterian and Baptist meeting-house.

MONMOUTH, a post-town of Lincoln county, on the E. side of Androscoggin river; 49 miles N. of Portland, containing 701 inhabitants.

MONMOUTH, *Capo*, lies on the E. side of the straits of Magellan.

MONMOUTH-*Island*, one of the four islands of Royal Reach, in the straits of Magellan, and the second from the westward.

MONMOUTH-*Island*, one of the Bashee islands in the East Indian sea.

MONMOUTH, a market-town and borough in the hundred of Scenfreth and county of Monmouth, England,

MONMOUTH.

land, stands on a narrow peninsula, formed by the confluence of the rivers Monnow and Wye. It is a town of great antiquity, and according to Horsley (in his *Britannia Romana*) was the *Blestium* of Antoninus. No Roman remains, however, have been found here to corroborate this opinion, which, though probable, is chiefly founded on the fact of the coincidence of distances between that and the connecting stations, northward and southward, with the actual distances between those and the present site of Monmouth. The castle at this place is mentioned in ancient records as being one of the strong holds garrisoned by the early Saxons, to secure their conquests of the country between the Severn and the Wye; and to curb the depredatory incursions of the Welsh. Very little, however, besides this bare fact, is known concerning this fortress, till the era of the Norman conquest, when it appears, from a passage in *Domesday* book, to have belonged to the king. William, the son of William Fitz-Baderon, to whom four "carucates of land in the castle of Monmouth, part of the royal demesne, were given in custody" about this time, took the surname of *de Monmouth*, from the place, which continued in the possession of his descendants till the reign of Henry III., when John *de Monmouth* became the proprietor. During the reign of that monarch, which is recorded to have been one continued scene of civil strife, this fortress was occasionally besieged and occupied by both parties; and was ultimately resigned, together with the honour, to prince Edward and his heirs for ever, in consideration of certain lands granted for life. The prince soon afterwards surrendered it to the king, who bestowed it on his younger son Edmund, earl of Lancaster, from whom it descended to John of Gaunt, king of Castile and duke of Lancaster, who, as well as his son, Henry of Bolingbroke, (afterwards Henry IV.) made it their favourite residence. Henry V., the celebrated hero of Agincourt, was born in one of the rooms of Monmouth castle in the year 1387, and seems also to have passed his infancy here. This castle subsequently became the property of Henry VI. as part of the duchy of Lancaster, which had descended to him by inheritance. Upon his dethronement and attainder, it fell to Edward IV., who granted it to William, lord Herbert, whom he created earl of Pembroke; but having once more reverted to the crown, Henry VII. possessed it by the same right that he ascended the throne. Since that period, the castle has become private property, but at what date its alienation from the duchy took place is not ascertained. Previously, however, to the close of the 17th century, we find it in the possession of Henry, the first duke of Beaufort, and it is now the property of his illustrious descendant, the present duke.

Under the auspices of its lords, Monmouth early became a privileged place, and particularly enjoyed many immunities as forming a parcel of the duchy of Lancaster. The earliest charter, however, which appears in the archives, is dated in the year 1549, and was granted by the monarch then reigning "to the burgesses of his burgh and town of Monmouth, in the marches of Wales, and within his duchy of Lancaster." This deed confirms various franchises and privileges bestowed upon the inhabitants by Henry VIII.; and in addition confers the power of electing a mayor and two bailiffs. Since that time therefore Monmouth has been governed by officers under that denomination, who are assisted by a common council, composed of eighteen members.

The situation of this town is extremely pleasant and highly picturesque: it stands near the extremity of an expanded vale, surrounded by gentle hills and swelling eminences, either covered to their summits with rich woods, or

laid out in fields of corn and pasture. It is a place of considerable extent, and contains many respectable buildings, but has only one principal street, which leads from the bridge over the Monnow, to the market place. In this street stands the town-hall, an edifice of modern erection, built upon pillars, which form a handsome colonnade. A statue of Henry V. is placed in a niche over the front entrance. The other streets are mostly narrow. One of them leads from the market place to St. Mary's church. That edifice formerly belonged to an alien priory for black monks of the Benedictine order, an institution which was founded in the time of Henry I. by Wilhenoc, grandson of Fitz-Baderon and third lord of Monmouth. Only a few vestiges of the monastery can now be discovered a little to the north of the church, which, with the exception of the tower and spire, is entirely a new building. The church of St. Thomas, now subordinate to St. Mary's, is an ancient structure. Coxe, in his historical tour through this county, says, "that the simplicity of its form, the circular shape of the door-ways, and of the arch separating the nave from the chancel, and the style of their ornaments, which bear a Saxon character, seem to indicate that it was built before the conquest." Some authors even suggest, that there is a probability of the more ancient parts being of British origin. It is certainly, for Wales, a most curious specimen of early architecture; and in no mean degree deserves the attention of the antiquary, particularly the semi-circular arch of the northern door-way.

The county gaol is a new massive edifice, well adapted to its purpose; the apartments are airy; and much attention is paid to the health and morals of the prisoners. This building stands at one extremity of the town, on the banks of the Monnow. Here is a free school founded by William Jones in the reign of James I.; also an alms-house for 20 poor people, established and endowed by the same individual.

The remains of walls, lines of circumvallation, curtains, bastions, and other works of defence, clearly shew that this town must have been, at one time, a strongly fortified place, and from its situation, there is little doubt but it might easily be made so again. On those sides which were unprotected by the river, it has been evidently environed by strong walls, and a deep fosse capable of being filled with water. It had four gates, only one of which is now standing. The suburb of St. Thomas was defended in the same manner as the town, with which it communicated, as now, by a stone bridge with balustrade-towers on each side thrown over the Monnow. There are two other bridges in the immediate vicinity of the town, the Wye-bridge and Tibb's-bridge; the former of which is constructed of stone, and the latter of wood.

The ruins of the castle of Monmouth, the ancient residence of its powerful lords, are discovered occupying the ridge of an eminence situated between the market place and the river Monnow. From a view of these it is evident, that this fortress has been the work of several and even distant periods. Some portions of them bespeak a Saxon if not a Roman origin, while others are of a date posterior to the reign of Henry III. The massive structure of part of the walls is particularly remarkable, being from six to ten feet thick, and are composed of pebbles and liquidated cement, so closely compacted as not to yield in hardness to stone itself. The chamber, in which king Henry was born, is wholly demolished, but some of the beams, which supported the flooring, still remain visible. Adjoining to it is a large apartment, which probably formed the baronial hall, and was afterwards used for the county assizes till about the middle

middle of the last century. A handsome domestic edifice, constructed of stone, stands in the middle of this vast pile of ruins. From the date over the principal door it appears to have been built in 1673, for the occasional residence of the Beaufort family. Two hospitals, founded here by John de Monmouth about the year 1240, are now entirely levelled with the ground.

The manufactures of Monmouth, at the present period, are trifling; so that the inhabitants are chiefly supported by the navigation of the river Wye, the trade with Hereford and Bristol, the supply of the neighbouring district with various kinds of shop-goods, and the number of persons of independent fortune, who reside either constantly or occasionally in the town, or its vicinity. The paring and cleansing of bark brought from the forests of the Upper Wye, for the purpose of exportation, constitutes, during the season, the employment of a number of men, women, and children among the lower ranks. But though fallen in respect of its manufacturing importance now, Monmouth seems to have carried on a very considerable trade some centuries ago.

Monmouth caps are celebrated by Shakspeare in his play of Henry V.; "If your majesties is remembered of it, the Welshmen did goot service in a garden, where leeks did grow, wearing leeks in their Monmouth caps." Fuller likewise praises them highly, by calling them the most "ancient, general, warm, and profitable coverings of men's heads in this island." The old ballad of the caps, printed in "The Antidote against Melancholy," says,

"The soldiers that the Monmouth wear,
On cattles' tops their ensigns rear."

Monmouth has sent one member to parliament since the reign of Henry VIII. The right of election is in the burgessees inhabitants, in conjunction with the burgessees inhabitants of the towns of Newport and Usk, as decided by the house of commons on a petition of right in 1680. According to the parliamentary returns of 1801, the population of this town then amounted to 3345 persons, but Mr. Coxe, in his "Historical Tour," fixes it at about 2600 souls.

The vicinity of this town displays much beautiful and interesting scenery. The views from the high conical hill, called the Kymin, are particularly fine, extensive, and diversified. A walk leads to the summit of this hill, which terminates in a level plain crowned with a wood, through which six vistas have been cut. Each of these exhibits in fine perspective a rich, grand, and varied prospect, of an expansive tract of country. In the centre of the wood, a pavilion, intended for a naval monument, has been lately erected by subscription. It is a circular edifice, consisting of two stories, and built in the form of an embattled tower. The frieze round it is ornamented with medallions of the most eminent British admirals, accompanied with emblematical and appropriate devices. The view from the summit of this pavilion is perhaps the finest and most extensive in England, embracing a circumference of nearly 300 miles, and including within its range all the materials of sublime and beautiful scenery.

Troy-house, the ancient seat of the family of Herbert, and afterwards of that of Somerset, is situated about a mile from the town on the banks of the Trothy, from which river its name is corruptly derived. Of the original edifice few traces can now be discovered, except an old gate-way with a pointed arch. The present mansion was built under the direction of the celebrated Inigo Jones, but though

well proportioned and commodious, it possesses no features of peculiar beauty. This place was formerly much famed for its excellent and luxuriant gardens, particularly in the time of Charles I when they were the property of sir Thomas Somerset, brother to the marquis of Worcester. Two miles west from hence is a Treowen, the seat of the Jones family, but now converted into a farm-house. In the parish of Lanvihangel Tavanbarch, at the distance of three miles to the north, stand the remains of Grace-Dieu abbey, which was founded by John of Monmouth in the year 1229. In the parish of Landeilo Cressney appear the magnificent ruins of White Castle, anciently called Landeilo castle, or Castell-Gwin. This fortress, at the time of the conquest, formed part of the possessions of Brian-Fitz-count, earl of Hereford, from whom it came, first to the Cantalopes, and afterwards to the Braoses. Coxe's Historical Tour through Monmouthshire, 4to. 1801. Beauties of England and Wales, vol. x.

MONMOUTHSHIRE, one of the western counties of England, is bounded on the south-east by the Severn sea or Bristol channel; on the west by Glamorganshire and part of Brecknockshire; on the north by part of the latter county, and that of Hereford; and on the east by Gloucestershire. It extends about 33 miles in length, and 20 in breadth, and comprises, according to the latest surveys, an area of 550 square miles, or 352,000 acres. By the returns made to parliament in 1801, it contained 9365 houses, and a population of 45,582 inhabitants. The whole county is now divided into six hundreds: Scenfreth, Abergavenny, Wentloog, Caldecot, Usk, and Raglan; and comprehends 127 parishes, and seven towns. The latter are Monmouth, Caerleon, Chepstow, Usk, Abergavenny, Newport, and Pontypool. All the parishes, with respect to ecclesiastical jurisdiction, are included in the province of Canterbury, and also in the diocese of Landaff, with the exception of six, viz. Welsh-Bicknor, Dixon, and St. Mary's being in the diocese of Hereford; and Oldcastle, Llanthoay, and Cwmyoy, belong to St. David's.

At the period of the Roman invasion Monmouthshire formed part of the territory inhabited by the Silures, who, besides this district, possessed the counties of Glamorgan, Brecknock, Radnor, Hereford, and such parts of Gloucestershire as lay between the Severn, the Teme, and the Towy. On the division of Britain into provinces by the Romans, this county was included in Britannia Secunda. From the period at which these illustrious conquerors left our island, till the establishment of the Saxon heptarchy, the history of Monmouthshire, in common with that of almost every portion of Britain, is uncertain and contradictory. In the legends of these times, however, it makes a most conspicuous figure. Many of the heroic exploits of Uther Pendragon, and of the celebrated Arthur, are said to have taken place within its boundaries. Caerleon was long the capital of the British dominions, and is frequently described by the bards as equalling Rome in splendour and magnificence. After the full establishment of the Saxon power in England, this county seems to have formed a petty principality of itself, under the name of Gwent, whose princes were sometimes bold enough to aspire at independence, but who, for the most part, paid tribute to the princes of South Wales. The invincible courage which had marked their character at a more remote period, still continued in full force during this era, and opposed a most effectual barrier to the attempts of the Saxon monarchs to subjugate the principality. Canute, the Dane, entered Gwent with a powerful army, in the year 1034, but though he defeated Rytherch-ap-Jestin, prince

MONMOUTHSHIRE.

of South Wales, he was unable to hold possession of the country. It was not, indeed, till the reign of Edward the Confessor, that the Gwentians could be regarded as conquered, when Harold, having penetrated into the heart of Wales, forced the inhabitants to swear fealty to the crown of England, and retained military possession of this county, in order the more effectually to secure the advantages he had gained. The Norman invasion, however, was the signal to all the Welsh tribes for renewing the war, and throwing off the yoke which had been thus imposed. In order again to reduce them, the conqueror, too politic to weaken his own army in such a warfare as Wales presented, encouraged his powerful barons to make incursions into that country at their own expence, and with their own retainers, and, as a reward, granted them the privilege of holding the lands they conquered in capite. Monmouthshire was accordingly overrun in this way after a long and bloody struggle for its independence; but the conquerors having built numerous castles and fortresses in order to overawe the inhabitants, soon began, in their turn, to arrogate to themselves an independent authority. Continual disputes took place betwixt them, with respect to the extent and boundaries of their lands, which not unfrequently terminated in open hostility to each other, and even to the crown of England. The power possessed by these barons marchers, within the limits of their property, was little inferior to that of a prince. They held courts and administered justice at will to their tenants and dependants, in all questions both civil and criminal. This system of jurisprudence, perhaps the most wretched and deplorable that could possibly be adopted, continued in this county, as well as in the other marches of Wales, till the reign of Henry VIII., when the government of the lords marchers was abolished, and Monmouthshire was detached from the principality, and included among the counties of England. The statute, however, authorising this change, does not seem to have been immediately acted upon, for we find Monmouth regarded as a Welsh county so late as the reign of Charles II., when it first began "to be reckoned an English county, because the judges kept the assizes here on the Oxford circuit." From this circumstance it is difficult to fix, precisely, the period at which Monmouthshire might be strictly considered as an English county: probably, however, not before the jurisdiction of the supreme "court of lords marchers," usually held at Ludlow, was finally abolished in the first year of William and Mary.

The general aspect of Monmouthshire presents to the eye a continual recurrence of hill and dale, wood and water, corn fields and meadows; "the sublime of wildly magnificent, and the beauty of mild and cultivated scenery combine to delight the traveller at every turn he makes in this uncommonly diversified district." Nor is the air less favourable to health, than the face of the country is interesting to the view. Except on the more elevated ridges, which are no doubt cold and bleak, it is, for the most part, mild and temperate. It is a remarkable circumstance, that the fogs here, during winter, shift periodically; so that it is no uncommon thing to see the hills enveloped several days with a thick fog, while the valley beneath has the splendour of a genial sun: but on a sudden these effects are entirely reversed; the fog descends into the valley, and the mountains are, in their turn, left open to the rays of heaven. Monmouthshire abounds with rivers, of which the principal are the Severn, the Wye, the Usk, the Rumney, the Monnow, or Mynwy, and the Ebwy. The Wye is particularly remarkable for the beauty and variety of its scenery, exhibiting a continued series of enchanting views, which have

been amply descanted on by Gilpin, Ireland, Warner, and many other tourists; and latterly by Bloomfield, in a poem expressly devoted to the subject. (See WYE.) The Usk likewise displays many charming scenes, and when swelled by mountain torrents spreads itself out into expansive lakes, and occasionally inundates the adjacent country. This river is navigable for barges up to Tredonnoe-bridge. There is only one canal in this county, which was begun in 1792, and finished in 1798. It enters Monmouthshire from Brecknockshire, and divides it nearly into two equal parts, passing in its course close to the towns of Abergavenny and Pontypool, and falls into the estuary of the Usk at a short distance below Newport. About a mile above that town, a branch strikes off to Cramlin-bridge, near Llanhiddel, where it terminates. Still further to facilitate the conveyance of the more weighty articles which this county produces, rail-roads have been formed in different parts of it. One, which connects the iron-works at Blaenavon with the canal at Pontnewydd, is particularly remarkable. It only extends five miles and a quarter in length, and rises no less than 610 feet. The roads in Monmouthshire, with the exception of those from New-Passage to Newport, Caerdiff, and Usk, and thence to Abergavenny, were, till lately, proverbially bad; and though improved, are capable of still further amendment.

Monmouthshire, considered in an agricultural point of view, may be properly divided into three districts. The first, comprising the southern part of the county, consists, almost entirely, of moor, or marsh lands, with a portion of meadow-grounds. The second division, which takes in the eastern line of the county, is particularly fertile. The third division forms the western and most hilly part of the county. The kinds of corn generally raised are wheat, barley, and oats, with a very small proportion of peas and beans. These are, of course, principally produced in the eastern division, the other two being much more pastoral, or grazing, than farming districts. The cattle reared are oxen, sheep, and mules. The first are principally bred in the northern parts, and fed in the southern. These generally grow to a large size, are extremely docile, and well fitted for the labours of the field. The sheep are naturally of an inferior kind, but the flock has been greatly improved of late years, by various crosses with the Cotswold, Southdown and Dorset breeds. Mules are very abundant here, and are a peculiarly fine race, strong in the bone, and of exquisite symmetry, running from fourteen to sixteen hands high, and are so valuable as to sell for thirty or forty pounds each. The breed is constantly kept up to its pristine standard of excellence by the importation of stallion asses from Spain. But whether this traffic should be encouraged is extremely doubtful, considering the superior qualifications of the horse, the breeding of which animal is, in consequence, almost wholly neglected in this county. Indeed the Monmouthshire horses are by far the most miserable race of their species in our island, neither adapted for the saddle, nor useful for agricultural purposes.

Monmouthshire was formerly celebrated for its manufacture of stockings and knit caps, but that trade almost entirely disappeared soon after the establishment of the iron works in the reign of queen Elizabeth. Since that period the iron business, though in different degrees at different times, has constituted the chief employment of the manufacturing classes in the county. This branch of trade has of late years increased to a prodigious extent, so that Monmouthshire will, in all probability, soon take the precedence, as an iron district, of every other county in Great Britain.

At

At Pontypool and at Usk there are still considerable manufactories of japanned goods, generally distinguished by the name of Pontypool ware, because first invented in that town, but this trade has suffered much from the competition of Birmingham, joined to the unfavourable state of our foreign relations. The commerce of Monmouthshire, which is very considerable, is almost entirely confined to the towns of Chepstow and Usk: under these respective names the reader will find the different articles of export mentioned. See Newport and Usk.

Monmouthshire, to the antiquary, is particularly interesting: Caerwent was first the capital of the Silurian dominions, and afterwards a Roman station. The other stations of that people in this district were Isea-Silurum at Caerleon, Gabannum at Abergavenny, Burrium at Usk, and Blestium at Monmouth; but some antiquaries place the two last at Oldcastle and at Caerphilly. To trace the direction of the Roman roads, particularly of the Julia Strata, in their passage through this country, is a subject of much difficulty. This has arisen chiefly from the disagreement of antiquaries with respect to the point at which the legionary troops usually crossed the Severn, which some have fixed at Amesbury, and others at Oldbury, Aull, New Passage, Hebury, and Portishead. The Julia Strata is most distinctly visible in the vicinity of Caerwent, running in the direction of Penhow. A few traces of it can likewise be discovered near Caerleon and Newport, but its course between these towns is wholly uncertain. Mr. Evans, however, conjectured that it proceeded along the right bank of the Usk, leaving Malpas church on the west, and Crindahouse on the east, and passed to the site of St. Woolo's church, on the hill north of Newport, where is a large encampment, and a tumulus, now nearly destroyed, which Mr. Harris regarded as an *arx speculatoria*. Of the roads which struck off from the Julia Strata, one led from Isea-Silurum to Burrium, where dividing into two ramifications, one proceeded to Gobannium and the other to Blestium. Another has evidently run in a south-westward direction, from Abergavenny to Neath, or to some station in Gloucestershire. This road is called by the natives *Sarn-bir*, or the long paved causeway, and in the neighbourhood of Bydewelly still remains almost entire. Besides these, various other marks of Roman civilization have been discovered in this county at different periods, consisting of aqueducts, baths, tessellated pavements, columns, statues, bas-relievs, sudatories, hypocausts, altars, votive and sepulchral stones, sarcophagi, urns, medals, coins, fibulae, &c. Numerous encampments of different forms and sizes are likewise distributed over this county, some of them no doubt originally British, and afterwards altered by the Romans, Saxons, or Danes, and others of them originally Roman, and altered in the same way by the warriors of a later period. A few seem to be Saxon or Danish entirely. Castles and other places of more permanent defence, are no less frequent here than encampments. Several of these have claims to very high antiquity, but the precise period of their erection is unknown. The most distinguished among them are the castles of Caerleon, Usk, and Scenfreth, which are said to be of British origin. The rest are no doubt of a much later date, and most probably not earlier than the period of the Norman conquest. Some of the churches in this county are very ancient, as appears from the style of their architecture, the circular arch, and the crenellated and billeted moulding for which they are so conspicuous, being characteristic of the Saxon and early Norman eras. The custom of whitewashing these edifices is unhap-

pily too much practised here, and destroys the venerable appearance which they would otherwise display. The disgusting and highly injurious practice of burying in churches is likewise extremely prevalent in Monmouthshire.

In concluding this article, it may be remarked, that though Monmouthshire is an English county, the inhabitants more generally speak the Welsh than the English language, particularly in the north-western and south-western districts. Their manners and customs bear a very strong resemblance in every respect to those of the principality. They display the same antipathy to the language and manners of the English, and an attachment to their own ancient practices. Catholics are very numerous in this county, and not only they, but the Protestants also, retain many vestiges of Romish superstition. Thus the custom of begging bread for the souls of the departed, still continues to be practised, on All-Souls' day, among the lower orders. A very interesting and satisfactory account of the antiquities, scenery, &c. of this county, will be found in Cox's "Historical Tour in Monmouthshire," 4to.

MONNEROU, a small island in the channel of Tartary, between the island of Saghalien, and the continent. N. lat. 46° 20'. E. long. 142° 21'.

MONNIER, PETER LE, in *Biography*, an eminent professor of philosophy, was born at Vire, in Normandy, about the year 1685. By his talents he became professor in the college of Harcourt, at Paris, and was elected a member of the Royal Academy of Sciences. He died Nov. 27, 1767. He was author of "Cursus Philosophicus," in six volumes 12mo, which was made a text-book in many of the French colleges. Monnier contributed also a variety of papers, that form a part of the "Memoirs" of the academy of which he was a member. He left behind him two sons, inheritors of his abilities, and both of them admitted to seats in the Academy of Sciences, of whom the eldest is the subject of the following article; the youngest, Lewis William, was made physician to the king at St. Germain-en Laye. Du Fresnoy.

MONNIER, PETER-CHARLES LE, a celebrated French astronomer, was born at Paris in 1715. From a very early period of his life he devoted himself to the study of astronomy, and is said to have made very accurate observations when he was only sixteen years old. At the age of twenty he had the high honour of being nominated a member of the Royal Academy of Sciences at Paris. At this period he accompanied Maupertuis in his expedition to Lapland for the purpose of measuring a degree of latitude. In 1748 he went to Scotland, to join lord Macclesfield in observing an annular eclipse of the sun, and he was the first astronomer who had the satisfaction to measure the diameter of the moon on the sun's disk. The king of France, Lewis XV., was much attached to astronomy, and patronized those who successfully pursued that science; and it is said he not only respected, but honoured and even loved Le Monnier. "I have seen the king," says Lalande, "come out of his cabinet, and look around for Le Monnier, and when his younger brother was presented to him, on his appointment to the office of first physician, his majesty was pleased to wish him the merit and reputation of his brother the astronomer." Monnier was always with the king when he observed the remarkable celestial phenomena. Thus they were together to witness the two transits of Venus, in the year 1761 and 1769. While these important observations were making, at which the celebrated La Condamine was present, the king was particularly careful not to disturb, by the smallest motion, the astronomers in their occupation. It is so de-

scribed by the astronomer himself, in his dissertation on the subject; "His majesty," says he, "perceiving that we judged the last contacts to be of the greatest importance, a most profound silence, at that moment, reigned around us." In the year 1750, Le Monnier was directed to draw a meridian-line at the royal chateau of Bellevue, where the king was accustomed to make his observations. On this occasion Lewis presented him with fifteen thousand livres, which the astronomer expended in instruments, with which he afterwards made his best and most important observations. The king had already presented him with a beautiful house at Paris, where he resided till the revolution, and pursued his astronomical labours. Le Monnier was incessant in his application to his favourite science, and apparently unwearied in those observations which tended to perfect it. Le Monnier was the preceptor of Lalande, and was worthy of such a scholar, as the scholar was of his instructor. Le Monnier forefaw in young Lalande, when he was but sixteen years old, the acute, learned, and indefatigable astronomer. When Lalande was sent to Berlin in 1742, to make observations for the purpose of determining the parallaxes of the moon, Le Monnier lent him his five feet mural quadrant. Le Monnier died at Lizieux, in Normandy, on the second of April 1799, at the advanced age of eighty-four years. He was ardent in his friendships, but his hatred was implacable. Lalande once displeased him, and he could never after regain his favour, but his pupil's gratitude and respect for him were always the same, and were, on every occasion, publicly declared. In 1797, Lalande wrote an eulogium on Le Monnier for the "Connoissance des Temps," in the language of gratitude, resulting from sentiments of profound veneration and esteem for the venerable astronomer, but Le Monnier refused to read it. This great man left behind him a number of valuable MSS. with some good observations. He had by him a series of lunar observations, and a multitude of observations of the stars, which he had announced as early as the year 1741, but he refused to publish them, nor could the most earnest entreaties of those whom he most esteemed, lead him to alter his intentions. Annual Register 1799. See LE MONNIER.

MONNIERIA, in *Botany*, so named by Læfſing and Linnæus, in honour of M. le Monnier, first physician to the French king Louis XV., who accompanied Cassini through the southern provinces of France, in the summer of 1739, and subjoined an account of their natural history, particularly their more curious plants, to the geometrical remarks of that astronomer. M. le Monnier was greatly instrumental in promoting the introduction of hardy exotics into France. He had a choice garden at Versailles, where the writer of this visited him in 1786, and a very extensive and valuable herbarium. Of the time of his death we have no information. Another genus had been previously dedicated to this able botanist, by Bernard de Jussieu; but this was reduced by Linnæus, and subsequent writers, to *Gratiola*. Mr. R. Brown has however re-established it, under the appellation of *HERPESTIS*; see that article, and *GRATIOLA*.—Læfſ. It. 197. Linn. Gen. 363. Schreb. 480. Willd. Sp. Pl. v. 3. 856. Mart. Mill. Dict. v. 3. Juss. 421. Lamarck Dict. v. 4. 261. Illustr. t. 596.—Class and order, *Diadelphia Pentandria*. Nat. Ord. uncertain; suspected by Jussieu and Lamarck to be near the *Borraginææ*, (*Asperifolia* of Linnæus,) or possibly akin to *Spigelia*. We perceive strong indications of the *Euphorbiæ* in some of its characters, however discordant others may appear.

Gen. Ch. *Cal.* Perianth inferior, in five deep, unequal, permanent segments; the upper one longest, linear, incurved

over the flower; the lateral one on the outer side lanceolate, half as long, the rest still shorter and obtuse. *Cor.* of one petal, shorter than the upper segment of the calyx, ringent; tube cylindrical, narrowest in the middle, curved; upper lip ovate, obtuse, undivided; lower in four equal, parallel, straight, oblong, obtuse, deep segments. Nectary an ovate scale, at the base of the germen, within the lower filament. *Stam.* Filaments two, dilated, membranous; the uppermost concave, cloven at the extremity; the lowermost flat, three-cleft; anthers on the upper filament two, combined, hairy within, embracing the stigma; on the lower three, very minute, cylindrical, probably sterile. *Pist.* Germen superior, roundish, five-angled, five-lobed; style solitary, thread-shaped; stigma capitate, oblong, flattened within, orbicular, sharp-edged. *Peric.* Capsules five, ovate, short, compressed, of one cell, divided half way down into two valves. *Seeds* solitary, ovate, tubercular, filling the capsule, straighter and blunter at their inner margin, each enclosed in a tunic, of two smooth elastic valves.

1. *M. trifolia*. Linn. Sp. Pl. 986. Aubl. Guian. v. 2. 730. t. 293.—Gathered by Læfſing at Cumana in South America; by Aublet in the meadows and cultivated land of Cayenne and Guiana. A specimen, sent by Mr. Alex. Anderson, from the Dutch settlements in the last-mentioned country, was given us by sir Joseph Banks, there being none in the Linæan herbarium. The *root* is annual and fibrous. *Stem* about a foot high, repeatedly forked, leafy, round; the upper part rough with minute hairs, curved upward. *Leaves* ternate, on hairy stalks, the lower ones opposite, the rest usually alternate; leaflets nearly equal, above an inch long, ovate, entire, pale green, hairy, especially the edges and ribs, thickly besprinkled on both sides with small resinous dots; the middle one slightly stalked. *Flowers* in terminal, solitary, cloven, divaricated, simple clusters, rather than spikes, with a solitary flower between, at the base. *Calyx* hairy. *Corolla* white. The *leaves*, though they have been dried 20 years, retain an acrid or burning flavour, without any fragrancý.—The natural affinity of this rare plant has puzzled the greatest botanists. We venture to hunt its relationship to the *Euphorbiæ*, rather as a conjecture than otherwise. The *capsules* are pale, dotted like the leaves. *Seeds* dark grey, almost black, rough with prominent points. S.

MONNOYE, BERNARD DE LA, in *Biography*, was born at Dijon in the year 1641. He was brought up to the bar, but his taste and eagerness for polite literature gave him disgust for legal pursuits. He contented himself therefore with a very trifling office, the duties of which gave him an opportunity to employ much time in his favourite studies. He acquired an accurate knowledge of the Greek, Latin, Spanish, and Italian languages, and attained considerable excellence in the composition of French poetry. In 1671, he obtained a prize of the French academy for a poem entitled "Le Duel aboli." Several of his other pieces, written in praise of Lewis XIV., obtained similar honours. He was free from ambition, and notwithstanding the celebrity which he had acquired, he preferred living in his native province to a residence in the capital. He passed his time in an easy state of independence, till the fatal system of Law reduced him, with thousands, to absolute poverty. (See LAW.) In this situation his merit was not overlooked; his distress was alleviated by a pension from the duke of Villeroi, and he lived to the advanced age of eighty-eight. He was extremely conversant with literature in all its branches, and was accounted the oracle of bibliographers of his time. The works by which he is principally known are "Poesies Francoises,"

coises," and "Nouvelles Poésies," which consist of miscellaneous pieces of different degrees of merit. There are annexed to them Latin poems and small pieces which may be ranked with fables, epigrams, and tales, written with elegance and true classical simplicity, but many of them have a licentious tendency. The Latin poems were also published by the abbé d'Olivet, together with those of Huet, Massin, and Fraugier; "Noels Bourguignons," a set of Christmas carols in the Burgundian dialect, much applauded for their humour, but on account of the grossness of some of them, they were condemned by the Sorbonne. Monnoye was author also of "Remarques sur le Menajiana avec une Dissertation sur le Livre De tribus Impostoribus;" "Remarques sur les Bibliothèques de du Verdier et de la Croix-du-Maine." He was editor of "Recueil des Pièces choisies." His own works have been printed in three vols. 8vo. Moreri.

MONOCASY, in *Geography*, a river of America, in Maryland, which, after a S.S.W. course, discharges itself into the Patowmè, about 50 miles above Georgetown.

MONOCEROS, **UNICORN**, in *Astronomy*, a southern constellation formed by Hevelius, containing in his catalogue, nineteen stars, and in the *Britannic Catalogue* thirty-one. See **CONSTELLATION**.

MONOCEROS, in *Ichthyology*, a species of *monodon*; which see.—Also, a species of *Balistes*, with the fin of the head uniradiated, and the caudal rays carinated. This is the *Balistes unicornu* of Bloch, with 51 rays in the anal fin, the *Caprifiscus longus*. &c. of Klein, and the *Acaramucn* of Marcgrave and Willoughby. There is a variety of this, or a distinct genus of *Balistes*, denominated *Scriptus β*, the unicorn fish of Bahama, described in Catesby's *Carolina*. It is found in the sea that washes the coasts of Asia and South America; its colour is varied with cinereous and brown; the first is somewhat more than a foot in length; the second is three feet long; they feed on young crocodiles, and the latter is held to be poisonous.

MONOCEROS, a name which has been given to several animals, among which are, the *unicorn*, generally supposed to be a fabulous animal, but the existence of which, in the interior of Africa, is insisted upon by several writers. A Mahometan African prince is said to have sent two of them to Mecca in the year 1799; an insect called *Meloë monoceros* by Linnæus, and *Noctoxus monoceros* by Fabricius. See the preceding article.

MONOCHORD, a musical instrument with which to try the variety and proportion of musical sounds.

The monochord, according to Boethius, is an instrument invented by Pythagoras, for measuring geometrically, or by lines, the quantities and proportions of sounds.

The ancient monochord was composed of a rule divided and subdivided into divers parts, on which there was a string pretty well stretched upon two bridges, at each extremity. In the middle between both was a moveable bridge, called *magas*, by means of which, in applying it to the different divisions of the line, the sounds were found to be in the same proportion to one another, as the divisions of the line cut by the bridge were.

The monochord is also called the *harmonical canon*, or *canonical rule*; because serving to measure the degrees of gravity, and acuteness of sounds. Ptolemy examines his harmonical intervals by the monochord.

There are also monochords with divers strings, and a multitude of fixed bridges; but the use of all these may be supplied by one single moveable bridge; by only shifting it under a new chord or string, which is placed in the middle, and re-

presents the entire sound, or open note, answering to all the divisions on the other bridges.

When the chord was divided into equal parts, so that the terms were as 1 and 1, they called them unisons; if they were as 2 to 1, octaves, or diapasons; when they were as 8 to 2, fifths, or diapentes; if they were as 4 to 3, they called them fourths, or diatessarons; if the terms were as 5 to 4, diton, or a greater third; if as 6 to 5, demi-diton, or a lesser third; lastly, if as 24 to 25, demi-diton, or diesis.

The monochord, being thus divided, was probably what they call a system, of which there were many kinds, according to the different divisions of the monochord.

Dr Wallis has taught the division of the monochord in the *Philosophical Transactions*; but that instrument is now disused, the modern music not requiring such division.

Censorinus informs us that Apollo found the monochord in the sound of the string of his sister Diana's bow; and it seems at least probable, that the first stringed instrument was a monochord, and that that single string was the string of a bow.

Aristides Quintilianus says that the monochord was recommended by Pythagoras on his death-bed as the musical investigator, the criterion of truth. It appears to have been in constant use among the ancients, as the only means of forming the ear to the accurate perception, and the voice to the true intonation of those minute and difficult intervals which were then practised in melody.

MONOCHORD, *Μονοχορδον*, formed of *μονος*, *solus*, *single*, and *χορδον*, *chord*, is also used for any musical instrument, consisting of only one chord or string.

The monochord, called also the *vielle*, and vulgarly the *burdy-gurdy*, has frets which are raised by the action of the fingers on a row of keys; and instead of a bow, the string is made to vibrate by the motion of a wooden wheel: there is also a second string serving as a drone, producing always the same sound: this is furnished with a bridge loosely fixed, which strikes continually against the sounding board, and produces a peculiar nasal effect. The trumpet marine, or trumpet Marigni, was a string of the same kind, which was lightly touched at proper points, so as to produce harmonic notes only: it was impelled by a bow. The Æolian harp is also an instrument, which, when agitated by the wind, affords a very smooth and delicate tone, frequently changing from one to another of the harmonics of the string, according as the force of the wind varies, and as it acts more or less unequally on different parts of the string. See **ÆOLUS'S Harp**.

MONOCHROMA, *Μονοχρωμα*, compounded of *μονος*, *single*, and *χρωμα*, *colour*, a picture all of one colour.

MONOCOLI, *Μονοκολοι*, a kind of fabulous men, who, as the Arabians give out, inhabit the country of Segir, in Arabia Felix; and are but half formed.

The word is Greek, compounded of *μονος*, *one*, and *κολον*, *a member*.

MONOCOTYLEDONES, in *Botany*, from *μονος*, *one*, and *κοτυληδων*, *a cotyledon*, or *feminal leaf*, one of three great tribes or assemblages of plants, into which the whole vegetable kingdom is divided, by botanists who study a natural system of arrangement, the other two being the **ACOTYLEDONES** and **DICOTYLEDONES**; see those articles, especially the latter. Some plants indeed have been esteemed polycotyledonous, as Flax, and the Fir tribe. But these are so very few, and agree so perfectly in their nature and physiology with the *Dicotyledones*, that they are best comprehended under the same

same denomination. The only vegetables for which we should be disposed to establish a class of *Polycotyledones*, are the Ferns and Mosses, hitherto referred, by Jussieu and his followers, to the *Acotyledones*, but physiologists are not agreed on the subject of the germination of these plants. (See *FILICES* and *MUSCI*). A still greater difficulty exists as to a distinction between the *Monocotyledones* and the *Acotyledones*, to which we have already sufficiently adverted; see *COTYLEDONES* and *GERMINATION*. We shall therefore here consider those two supposed families as but one, for which the denomination of *Acotyledones* would be the most proper of the two, the other term having originated in an old opinion, that what is now known to be the *albumen* of the plants in question, (and was observed in palms and grasses, which make a part of the number,) was really a simple cotyledon.

But although we consider the above two families as but one, as far as concerns the presence, or rather absence, of a cotyledon, we mean not to say the *Fungi*, *Algae*, and *Hepaticæ*, which make the first three orders of Jussieu's *Acotyledones*, have any considerable affinity to those of his orders which he refers to *Monocotyledones*. On the contrary, they are, as well as the *Filices* and *Musci*, his 4th and 5th orders, so very distinct, that no system which combines them all together can be called natural. As to his remaining order of *Acotyledones*, the *Naiades*, they are too heterogeneous for us to decide upon with any certainty; but their natural affinity to the *Monocotyledones* of Jussieu, and their dissimilitude to his *Acotyledones*, are equally obvious. In the following remarks therefore we wish to be understood as speaking of those natural orders which the great French botanist comprehends under his division of *Monocotyledones*, though we consider them as not having properly any cotyledon at all. There are sixteen in number, *Aroideæ*, *Typhæ*, *Cyperoideæ*, *Gramineæ*, *Palmeæ*, *Asparagi*, *Junci*, *Lilia*, *Bromeliæ*, *Aphodeli*, *Narcissi*, *Iridæ*, *Musæ*, *Canna*, *Orchideæ*, and *Hydrocharidæ*. Under the last however Jussieu, by mistake, comprehends some dicotyledonous plants.

The plants in question are remarkable for a great simplicity or plainness of structure. Their leaves are for the most part alternate, simple, with simple parallel ribs. The number three prevails in the parts of fructification instead of five, which belongs to the *dicotyledones*. Their germination is lateral; their interior substance peculiarly soft and cellular. It is a favourite hypothesis of Jussieu that these flowers have no corolla, the gorgeous integument of the liliaceous plants being considered by him as a coloured calyx. His arguments in support of this opinion only prove the great simplicity, and want of decided distinction, in their several parts. Thus, the petal of a tulip is alike liable to become half leaf, or half stamen. The outside of petals of lilies, however richly they may be adorned within, in many instances approaches to the colour and texture of a calyx; while in *Pancreatium* and *Narcissus*, there is a superabundance, or doubling as it were, of the more delicate part of the flower, so that these genera, far from wanting a corolla, appear to have two.

The internal structure of the *Monocotyledones*, as explained by the learned Desfontaines and Mirbel, is extremely peculiar, and differs very essentially from that of other plants. They have no proper bark and wood, augmented gradually by concentric layers. (See *CORTEX*, and *CIRCULATION of the Sap*). Their cuticle indeed is like that of the *Dicotyledones*, generally speaking; except that in some it abounds with a starchy secretion, in no small quantity, nor is that secretion always confined to the cuticle; witness the order of

grasses. Their woody substance is deposited round their numerous longitudinal tubes, as so many centres, such tubes uniting here and there, composing a sort of network, which gives firmness and tenacity to the body of the plant. Indeed the deposition of wood, though not in concentric layers, is regular, according to some determinate arrangement in each family, and in several acquires a great degree of density and hardness. The peculiar secretions of this tribe are very frequently of a saccharine nature; and scarcely ever of a mucilaginous, never, we believe, of a resinous kind. In their constitutions, some of them are very tender with regard to cold, others, in every respect nearly, the most hardy of plants; all are generally of rather rapid growth, though some very long-lived. Their roots are very generally perennial, to which there is scarcely an exception, besides what occur in the natural order of grasses. In consideration of the order last mentioned, the *Monocotyledones* deserve to be considered as the most important of all plants for the support of mankind.

MONOCULUS, in *Entomology*, a genus of insects of the order Aptera, of which the generic character is as follows: legs from four to eight, formed for swimming, and very long; body covered with a crust or shell divided into segments; some have four, some two antennæ, and some are without any; it has *one* or *two* eyes, notwithstanding its name *monoculus*; when there are two eyes they approximate and are fixed in the shell; there are four feelers, in continual motion when swimming; the hind ones are very small, and hook-shaped.

There are sixty-eight species, separated into eight divisions, named according to the first eight letters in the alphabet. These are found chiefly in Europe, a few in India, commonly in muddy ditches, frequently in sea-waters, often parasitic on fuci, conservæ, ulvæ, and other aquatic plants. Many inhabit our own ditches or sea-coasts.

Of all the monocoli by far the greater part are very small water insects, requiring the assistance of the microscope for the investigation of their particular organs; some, however, as we shall see, are so large as to require no very minute inspection, and one species is of a size so gigantic that it is generally considered as the largest of the whole crustaceous tribe. This is the polyphemus, and will be found in the division G.

The insects in division A have a single eye and crustaceous body.

Species.

OCULUS. In this species there are no antennæ, but two feelers, which are long and branched; the tail is inflected. The insects of this species are found in the pools and stagnant waters in many parts of Europe; they swim in swarms upon their back; each insect has a large black eye, which appears to occupy the whole of the head.

* **QUADRICORNIS**. The antennæ in this species are four; the tail is straight and bifid, the divisions are branched. It is described in Donovan's English Insects. It is found in different parts of Europe, and in the stagnant waters of this country. The body is sometimes greyish or greenish, smooth or covered with hair; it has eight legs that are hairy; the female possesses an oval bag, containing the eggs on each side the tail. This is a very minute insect, it derives its specific name from its four horns, and is well known, being very common in almost every stagnant water, and sometimes makes its appearance in that of pumps and wells, and is accordingly observable frequently in water brought to table.

MONOCULUS.

Its size is not greatly superior to that of the common mite.

MISURUS. Here the antennæ are two and linear; the tail ending in two bristles. This insect is found at the banks of ditches, generally among duck-weed, and at first sight is thought to resemble the *Lepisma saccharina*. The number of legs is ten, which are long and hairy; the tail ends in two papillæ.

CARULUS. Antennæ two, linear; body bluish, with a straight two-lobed tail. It inhabits Germany in muddy ditches. The head, the tail, and antennæ are red; the eyes black; abdomen green; legs eight.

* **RIBENS.** Antennæ two, linear; body reddish, with a straight forked tail. Found in ditches and rivulets, and is common through the whole year; it has eight legs.

VACINULATUS. In this the antennæ are two, linear and white; tail curved forked. It inhabits Germany, in ditches.

LONGICORNIS. Antennæ two, linear and very long; tail bifid. It inhabits the sea round Finmark. The tail ends in two bristles.

CAPTIVUS. Antennæ two, linear; head covered with a dilated shield; tail straight cleft. This is found in Germany. It has six legs; and the tail has six joints.

MINUTICORNIS. In this the antennæ are two, short and linear; the tail is cleft and ending in two bristles. It is sometimes though not often found in sea-water. The feelers are about half as long as the antennæ.

CLAVIGER. The antennæ two, subclavate, rigid; tail bifid. It inhabits, though very rarely, the rivers of Germany, and glides slowly along, alternately on its back, sides, and belly, and sometimes it will raise itself upright. The body above is white, and red beneath; the tail is without joints, and the legs are eight.

CRASSICORNIS. The antennæ two, dilated and short; tail bicuspitate. Sometimes found in marshy places. The body is in five segments; the antennæ branched at the base.

CURVICORNIS. Antennæ two, which are minute and straight, with three hairs at the tip; the body is inarticulate; the hands unarmed; the tail forked.

CHELIFER. Antennæ two, short and recurved; body inarticulate; hands chelate; tail forked. Found in sea-water.

BREVICORNIS. Antennæ two, those of the male hooked; the tail is set with very short bristles. It inhabits sea-marshes, and resembles the quadricornis. The antennæ of the female are forked at the tip.

The insects in division B have a single eye and bivalve shell; the antennæ are branched.

Species.

* **PULEX.** Tail inflected; shell mucronate behind. This insect derives its specific name, *pulex* or *water-flea*, on account of its peculiar starting or springing motion; it is almost an universal inhabitant of stagnant waters, appearing sometimes in such vast swarms as to cause an apparent discolouration of the water. It is an insect of a highly singular and elegant appearance, exhibiting, when magnified, a beautiful distribution of internal organs. It is generally about $\frac{1}{16}$ th of an inch in length, but sometimes considerably larger. It is of an oval shape, somewhat truncated in front, and sharply pointed behind; the body is inclosed in a bivalve transparent shell, which, when examined by the microscope, appears finely reticulated. The eyes of these animals are of a sin-

gular construction, they are large in proportion to the insect, and placed very near each other, and appear to consist of many separate globules of a black colour, united under a common film. In the female insect the ovarium is generally very conspicuous, filling the greater part of the space between the shells; the ova are very large in proportion to the size of the animal, and the young are hatched before their exclusion from the parent. This animal is said to possess, in an inferior degree, the surprising property of the genus *aphis*, viz. that of producing a series of already impregnated descendants.

LONGISPINUS. Tail inflected; shell ferrulate before and prickly behind. Found in fresh water. The shell is ovate, white, and pellucid, ending behind in a strong spine ferrate each side, and half as long as the shell; it has eight legs.

QUADRANGULA. The tail is inflected; shell quadrangular unarmed. Found in stagnant pools; the body is sometimes red, and it has six legs.

SIMUS. Tail inflected; shell oval unarmed; found in marshes; the shell is pellucid and yellowish.

RECTIROSTRIS. Tail inflected; hind head with two projecting horns: inhabits marshes. The shell is oval pellucid, with gaping valves, and ciliate on the fore-margin; the tail two long bristles; legs six to eight.

CURVIROSTRIS. Tail inflected; the front has two inflected horns. It is found in pools; the shell is hairy on the fore-margins; front has two pendent horns; the tail ends in two hooks; it has eight legs.

* **MUCRONATUS.** Tail inflected; shell ovate, beneath inflected, and prickly behind. It is found in marshes. Swims on its back on the surface of the water. The shell has four black dorsal streaks; it has twelve legs.

CRYSTALLINUS. Tail inflected; oblong crystalline; head with two short horns at the tip. Found in fresh water. The body is white pellucid, with twelve hairy legs.

PEDICULUS. The tail of this species is inflected. It inhabits fresh water.

SETIFER. The tail is straight; shells with long tufts of hair at the angles of the valves. It inhabits stagnant pools. The shell is oblong, pellucid, and crystalline; the antennæ have three branches; the legs, which are eight or more, are very hairy; and the tail is divided at tip.

The insects in division C have a single eye and bivalve shell; the antennæ are simple.

Species.

VIRIDIS. Shell ovate, downy, green; the fore-legs falcate, and ferrate within. It is found in sea-water on fuci and conservæ.

* **LUTEUS.** Shell ovate, gibbous, glabrous, pale yellow. Found on fuci.

* **FLAVIDUS.** Shell oblong, glabrous, pale yellow. It is found frequently on the *Fluitra lineata*. The shell is pellucid; fore-legs round.

GIBBOSUS. Shell ovate, hispid, and gibbous each side. Found on ulvæ. The shell is ovate, pale, and bristly.

COARCTATUS. Shell ovate, glabrous, and contracted in the middle. It inhabits fuci. The shell is of a greenish hue, with a black eye.

The insects in division D have a single eye and bivalve shell; antennæ tufted at the tip.

Species.

DETECTUS. Shell oblong, white, pellucid; tail with two

MONOCULUS.

two bristles. Inhabits ditches. It has four legs, the fore ones are recurved; hind-ones reflected.

STRIGATUS. Shell kidney-shaped, brown, with three white bands. Found in muddy ruts. The shell is glabrous; the antennæ have eleven bristles.

ORNATUS. The shell of this species is ovate, situate beneath, on the fore-part, and variegated with white, green, and fulvous.

PILOSUS. The shell is ovate, brown, ciliate before and behind. This species is found in the nectaries of the *Utricularia minor*. The shell is smooth, glabrous, and opaque.

CANDIDUS. Shell ovate, snow-white, immaculate. It is found in marshes. Shell obtuse before and behind.

LÆVIS. Shell ovate, glabrous, greenish. Inhabits ditches. The shell is obtuse and opaque; tail ending in a spine.

VIDUA. Shell ovate, white, with three black bands. Found in muddy water. In this species two of the bands are in the middle, and one on the fore-margin. The valves are gibbous and whitish.

TELEMUS. Shell sub-globular, three-toothed behind with a truncate lip on the fore-part. It is found at Algira, and is pellucid. Some naturalists imagine that it does not belong to this genus.

LENTICULARIS. Shell compressed and lentiform. Found in Finland.

* **CONCHACEUS.** Shell ovate, downy. Found in stagnant water. This is an English insect, and has been described and figured by Mr. Donovan. The body is green, opaque, with yellowish legs; its abdomen nearly two-lobed, and fulvous, with a black circle in the middle: it contracts itself within the shell, and swims on the belly.

FASCIATUS. The shell is oblong, whitish, with a green band. Found in stagnant water, and resembles a grain of barley. The green band is placed in the middle behind the eye.

MONACHUS. Shell glabrous, yellow, edged with black; the shell is opaque, truncate before, and rounded behind.

CRASSUS. Shell oblong, gibbous, yellowish, with an oblique, abbreviated, fulvous band. It inhabits fenny places.

Insects in division E with a single eye and univalve shells, and two antennæ.

* **SATYRUS.** Shell ovate, pellucid, and emarginate behind; antennæ obtuse. This species is noticed by Baker and Adams on the microscope. The shell is flat and membranaceous; fore-legs with a double shank; tail truncate, and cleft in the middle.

SILENUS. Shell is ovate, opaque, and sub-marginate behind; last joint of the antennæ subulate. It is found in ditches filled with the leaves of trees. The shell is sometimes yellowish.

MÆNUS. Shell oval; antennæ horizontally extended; body truncate at the base. Inhabits sea-water. Swims on its back; shell with a convex fulvous back.

FAUNUS. Shell ovate, pellucid, and emarginate behind; last joint of the antennæ subulate. Found in ditches among duck-weed. Shell gibbous; antennæ bent back.

BACCHUS. The shell is ovate, emarginate behind, and ending in two bristles. It inhabits rivers. The antennæ are stretched forwards.

THYAS. The shell of this species is dilated, linear; the antennæ are incumbent. Found in stinking sea-water. The fore-legs are branched.

BRACTEATUS. The shell is globular, and unarmed; it

has six legs. Is found in fresh water. The antennæ are obtuse; shell very pellucid.

* **SALTATORIUS.** Shell oval-oblong, and bristly behind. This is described by Baker and Adams. The shell is pellucid, and terminated by bristles.

Insects in division F have their shells univalve, and two eyes placed beneath.

CHARON. Shell pellucid, and four legs. Found in ditches. The eyes are spherical, remote, deep black, with four capillary circles round them.

* **DELPHINUS.** Shell gibbous; eight legs. Inhabits rivers. It is described by Baker on the microscope.

ARMIGER. This species has six legs.

Insects in division G have their shells bivalve; two eyes placed on the back.

Species.

POLYPHEMUS. Shell orbicular; the future lunate, and toothed behind; tail subulate, and very long. This species is commonly distinguished by the title of molucca, or king-crab. Specimens have sometimes been seen two feet in length, exclusive of the tail. It is a native of the Indian ocean, and is generally found in pairs. The colour of the whole animal is of a yellowish-brown; the shell is very convex, rounded in front, and lunated behind, where it joins the lower part of the body. The shell, which is of a crustaceous nature, is marked on each side into several spiny incisions. It has seven legs on each side, which are situated beneath the concavity of the large or round part of the shell, and are each terminated by a double claw; the branchiæ, or respiratory organs, are disposed in the form of several flat, rounded, imbricated lamellæ, on each side the lower part of the body; the tail, which is straight, triangular, and of the same crustaceous nature with the rest of the shell, is equal in length to the whole body, and gradually tapers to a sharp point. The eyes in this species are distant from each other, of a semi-lunar form, and the surface is divided into a great number of minute conical convexities: this part is, however, regarded as constituting the cornea, or exterior covering of the eye, the organs themselves being placed on a pedicle, beneath each of the semi-lunar corneæ. A writer in the *Philosophical Transactions*, speaking of this insect, says, "the eyes, instead of being approximated, as is required in the Linnæan generic character, are extremely distant from each other, being situated towards the sides of the shell. The whole structure of the animal is very remarkable, and particularly his eyes, which are between the fourth and last pair of claws on each side, reckoning from his mouth, and excluding the small pair there placed, are inserted the rudiments of another pair, or a claw broken off on each side, at the second joint or elbow: on these extremities are the eyes, like those of the horns of snails, but under the covert of a thick and opaque shell, nature in that place hath wonderfully contrived a transparent lantern, through which the light is conveyed.

CYCLOPS. Shell convex, with three lines of raised spines; tail very long, and unarmed. It is about one-third the size of the polyphemus, and is found in India. Shell lunate before, with three raised dorsal lines, and two acute teeth, finely serrate behind, with a raised line in the middle, in which are three teeth.

* **APUS.** Shell oblong, truncate, and serrate behind; tail ending in two bristles. It is found in stagnant water. This is the largest of the European monoculi. It is a rare species in this country, having been only observed in a few particular situations. In its general shape it is considerably allied

allied to the large exotic species above-described, but the form of the body is more lengthened. The branchiæ, or respiratory organs, are large, and distributed into numerous imbricated rows on the under part of the body; beneath the front is a pair of jointed trisid arms, extending on each side to a considerable distance; the eyes are placed near each other in front of the shell; the tail is terminated by a pair of long forks, or setaceous processes; the colour of the whole insect is of a pale greenish-brown above, and reddish beneath. An account has been given in the 40th vol. of the Phil. Trans. that this species has been seen in numbers in a pond at Bexley, in Kent. It is also added, that the same pond, having been perfectly dried, and being suddenly filled, during a heavy thunder-storm, swarms of the same animals were again observed in it within the space of forty-eight hours after.

* **PISCINUS.** Shell heart-shaped and flat; body short; tail bifid, and composed of one thin flap. It is a native of European seas. Found on flounders, cod-fish, salmon, &c. adhering on the outside between the scales, running swiftly, with its tail elevated, both on the fish and on the water. Shell pellucid, with yellowish marks; abdomen very short, with a long bifid tail.

PENNIGERUS. Shell hemispherical, with a linear future; tail feathered. Inhabits fresh water.

SALMONEUS. Shell oblong; tail imbricate, and four-leaved. It is found, as its name denotes, sticking to the salmon, between the scales.

Insects of division H have bivalve shells, two eyes, and capillary antennæ.

Species.

BRACHYURUS. Shell globular; tail deflected; four antennæ. It is found in marshes. The shell is pellucid, reddish-brown when young, and green as it grows older, with a white eye on the fore-part, and a black one behind; legs are twenty to twenty-four.

* **SPHERICUS.** Shell globular; tail inflected; two antennæ. This species is found among the duck-weed in stagnant water. It is a native of Europe, and found frequently in this country. It is very minute; the shell is reddish; it has two antennæ; twelve legs; and the tail is furnished with a small hook at the extremity, and concave beneath; the ovaria are green.

QUADRANGULARIS. Shell quadrangular, hence its specific name; tail inflected; antennæ two; legs in number are from twelve to sixteen, besides numerous smaller ones; the tail is armed with two minute spines at the tip.

LAMELLATUS. Shell ventricose; tail inflected lamellate; antennæ two. Found in stagnant water. The shell is convex; eyes are green; legs capillary; the tail has a broad ferrate lamina beneath, and two spines at the tip.

TRIGONELLUS. Shell gibbous before; tail inflected, ferrate; four antennæ. Found in ditches. The shell is ciliate, with a sharp proboscis; antennæ with three bristles at the tip; ovaries black.

TRUNCATUS. Shell ovate, and toothed behind; tail inflected, ferrate; four antennæ. Inhabits stagnant waters. Shell oblique, striated, ciliate before, and ferrate behind; the tail is broadish, and ending in a claw.

LONGIROSTRIS. Shell roundish; tail inflected; shell prickly on the fore-part. It inhabits rivulets. The proboscis is longer than the head, curved, and subulate.

MACHOURUS. Shell oblong; tail straight; antennæ four. It is found in lakes. The shell is pellucid, whitish; legs eight; nail lanceolate.

SOON. Shell ovate; tail projecting, curved; antennæ two. Found in almost all kinds of waters. The shell is pellucid, without stria, teeth, or fringe. It has four legs, and the tail is bicuspidate at the tip.

MONOCULUS, or *Monophthalmus*, (from $\mu\omicron\varsigma$, single, and *oculus*, or $\sigma\upsilon\mu\mu\alpha$, an eye,) a bandage in Surgery, formerly much more employed than at present. It consisted of a roller, ten or twelve feet in length, and about three inches in breadth. It was first fixed on the occiput, about a foot of the bandage being left hanging down. It was then carried obliquely round the head, over the forehead, to the occiput again. After being applied thrice round the head in this oblique direction, the remainder of the bandage was expended in more horizontal turns. The end, hanging down behind, was lastly brought over the vertex to the forehead, and the whole was secured with pins. The chief use of the monocusus was to retain dressings and application on diseases about the eye. The old surgeons had also a double monocusus; but it scarcely merits description, as it is now seldom or never made use of.

MONODON, in *Ichthyology*, a genus of fishes of the order Cete. The generic character is: two teeth in the upper jaw, extending straight forwards, long, spiral; spiracle on the fore and upper part of the head. Dr. Shaw has altered the generic character, by using the singular, *tooth* projecting, instead of *two teeth*, because though he admits there are sometimes two teeth, yet as the animal is generally found with one only, and because the generic name *monodon* is derived from that very circumstance, the alteration seems necessary. According to Gmelin there is but one species, *viz.* the *monoceros*, but Dr. Shaw mentions two species. We shall describe them both:

Species.

MONOCEROS, or *Narwal*, is a native of the northern seas, where it is sometimes seen of more than twenty feet in length from the mouth to the tail. It is at once distinguishable from every other kind of whale, by its very long, horn-like tooth, which is perfectly straight, of a white or yellowish-white colour, spirally wreathed throughout its whole length, and gradually tapers to a sharp point. It measures from six to nine or ten feet in length, and proceeds from a socket on one side of the upper jaw, having a large cavity at its base or root, running through the greater part of the whole length. In young ones, and sometimes in those that are full grown, there are two teeth, but in general the narwal is found with a single tooth, the socket of the other being closed, or at most but obscurely visible, and now and then the appearance of a second tooth in an extremely small state, or just beginning to emerge, is perceptible, as if intended by nature to supply the place of the other, if broken or cast. The head of the narwal is short, and convex above, the mouth is small; the spiracle or breathing-hole is duplicated within; the tongue is long; the pectoral fins are small. The general form of the animal is rather long than thick in proportion to its size. The colour, when young, is nearly black, but the belly is lighter. As, however, it advances in age, it becomes marbled, or variegated with black and white on the back and sides, while the belly is nearly white. The skin is smooth, and there is a considerable depth of oil or blubber beneath it. It is chiefly found in the northern parts of Davis's straits, and its food is supposed to consist of small flat fish, as well as of actiniaz, medusæ, and other marine animals. It is commonly seen in the small open or unfrozen spots towards the coasts of the northern seas. To such places the narwals resort in multitudes, for

the conveniency of breathing, and because they are sure to find, near the shores, a due supply of food: they are taken by means of harpoons, and the flesh is eaten by the Greenlanders, raw, boiled, and dried; the intestines and oil are also used as a food; the tendons make good thread, and the teeth serve the purpose of hunting horns, as well as that of building tents and houses. A throne made for the Danish monarchs is said to be still preserved in the castle of Rosenborg, composed entirely of narwals' teeth, which were formerly considered as more valuable than gold.

SPURIUS. This, if it be a distinct species of the monodon, has a pinnated back, and two small teeth in the upper jaw.

It is described by Fabricius, in his *Fauna Groenlandica*, as a species most allied to the narwal, but not perhaps, strictly speaking, of the same genus; it has no teeth in the mouth, but from the extremity of the upper mandible project two minute, conic, obtuse teeth, a little curved at the tips, weak, and not above an inch long; the body is elongated, cylindrical, black. Besides the pectoral fins and horizontal tail, there is also a minute dorsal fin. Its flesh and oil are considered as purgative; it is among the rarest of whales, and inhabits the main ocean, seldom coming to the shore. It has a spiracle like other whales. It is very seldom taken alive, but found dead on the shores.

MONODY, MONODIA, compounded of *μονος, solus*, and *ᾠδή, a song*, in the *Ancient Poetry*, a kind of mournful song or ditty, sung by a person alone, to utter his grief.

MONODY, in *Music*, a song for a single voice, in opposition to what the ancients called chorodies, or music executed by a chorus.

MONOECIA, in *Botany*, from *μονος, one*, and *οἶκος, a house*, the 21st class of the artificial system of Linnæus, consisting of such plants as have barren, or male, flowers on the same individual with fertile, or female, ones; whereas in the 22d class such flowers grow upon distinct individuals of the same species. (See **DIOECIA.**) How far these classes are natural or not, we have explained under that article.

The orders of *Monoechia* in Linnæus are eleven, distinguished upon the same principles as those of *Dioecia*. 1. *Monandria* is exemplified by *Aegopicon* and *Zannichellia*, permanently monoecious genera, as having a different structure in the accessory parts of their male and female flowers. 2. *Diandria* is scarcely tenable, one of its two genera, *Anguria*, having no such difference of structure, and the other, *Lemna*, having certainly the stamens and pistil in the same flower, except by accidental or partial imperfection. 3. *Triandria* contains *Carex*, *Sparganium*, &c., with some plants of the order of *Tricocca*, or *Euphorbia*, all properly placed here. 4. *Tetrandria* consists of the *Littorella*, *Betula*, *Buxus*, *Urtica* and others. 5. *Pentandria* embraces a remarkable tribe, closely allied, for the most part, to the Syngenesious, or compound, class; but their anthers are separate, and in some of them, as *Xanthium* and *Nepbelium*, the female flowers have no resemblance to that class, nor to their own males. 6. *Hexandria* consists chiefly of a very few grasses. 7. *Heptandria* depends only on *Guettarda*, much better placed in *Pentandria Monogynia*. (See **GUETTARDA** and **MATTHIOLA.**) 8. *Polyandria*, (having eight or more stamens,) is best illustrated by the important genera *Fagus*, *Quercus*, *Juglans*, &c. whose male flowers are, in most cases, amentaceous. 9. *Monadelphia* has the no less important genus *Pinus*, with some of the *Euphorbia*. 10. *Syngenesia* consists of the Gourd or Cucumber tribe; but it is difficult to account for their being placed here, their anthers being in no manner combined. On the contrary, their filaments are more or less united, inasmuch that Willdenow removes them to the 9th order, *Monadelphia*.

This does not seem correct with respect to any of the tribe; and in those we have examined the filaments are united, more or less completely, into three sets, so as strictly to constitute an order of *Monoechia Polyadelphia*, which should take place of this 10th Linnæan order. (See **MONORDICA.**) 11. *Gynandria*, composed of *Andrachne* and *Agyneia*, does not appear to exist in nature at all, these genera belonging more properly to the 9th order, *Monadelphia*, where some of their allies already find a place.

We cannot too often protest against the abolition of the monoecious and dioecious classes, whether we consider them in the light of natural or commodious arrangements, although some plants may have been improperly referred to them.

MONOEMUGI, or **NIMAAMA,** in *Geography*, a kingdom of Africa, having, as it is said, great extent, and reaching northward to Abyssinia; bounded on the E. by the kingdoms of Mongallo, Mozambique, and other small states along the coast of the Indian sea; on the S. by Mocaranga, and on the W. by Congo and Angola; but its real limits have not been ascertained. The sovereign, however, is represented as a rich and powerful prince, and has subdued most of the surrounding and adjacent kingdoms. To this sovereign belong many rich gold, silver, and copper mines, which enable him to carry on commerce with Abyssinia and other countries, as well as with some of the eastern coasts, with whom he is under a necessity of exchanging the precious metals for Indian and European commodities, as he has no port of his own in either the eastern or western sea. Elephants being numerous supply vast quantities of ivory for this trade, and afford to the emperor considerable profit, as well as benefit to his subjects. M. de Lisse, in his Atlas, divides this kingdom into the five following provinces or sovereignties: viz. the Maracates, the Mossagueras, the kingdom of the Bengas, of Maity, and of Maravi; and this last M. d'Anville places on the southernmost border of the lake of that name.

MONOGAMIA, in *Botany*, from *μονος* and *γαμος, a simple marriage*, the sixth order of the class *Syngenesia* in the Linnæan system, as left by its author, destined to admit such genera as have their anthers combined, the flowers being simple. Such were supposed to be *Lobelia*, *Viola*, *Impatiens*, *Jasione*, among British plants, and the exotic *Scripium*, *Strumpfia*, and *Corymbium*, to which might be added *Calicera*, Cavan. Ic. t. 358, and *Barreria* of Schreber. But the union of the anthers is found by no means universal throughout all the species of these genera, at least of the two first, which are very natural genera; and on the other hand this union occurs here and there among the species of others no less natural, as *Gentiana*. In short, the character in question proves of no avail in simple flowers; nor is there any natural affinity, between the above British genera at least, and the most natural class of compound flowers with combined anthers, the true *Syngenesia*. *Scripium* and *Corymbium* cause no difficulty; for they are in every respect genuine Syngenesious plants, and though the florets are solitary in each partial calyx, the flowers are aggregate, or collected in a common calyx; so that they readily go to the 5th order of *Syngenesia*, termed *Polygemia-segregata*, and serve but to strengthen and confirm that most natural class. The order *Monogamia* is now therefore generally abolished, certainly with great advantage. The plants which composed it are removed to *Pentandria Monogynia*, where most of them meet with many natural allies. *Calicera* of Cavanilles appears to be referrible to *Syngenesia Polygemia-segregata*. The affinity of *Strumpfia* is doubtful. *Barreria*, Aublet's *Poraguiba*, is considered by Jussieu as akin to his *Berberides*.

MONO-

MONOGAMY, compounded of *monos*, *solus*, and *γυνή*, *marriage*, the state or condition of those who have only married once, or are restrained to a single wife. See **POLYGAMY**.

MONOGASTRIC, in *Anatomy*, a name given by Vicentini, and some of the French writers, to one of the muscles of the ear, called by Cowper the *internus auris*, and more properly by Albini, the *tensor tympani*.

MONOGRAM, **MONOGRAMMIS**, a cipher, or character, composed of one or more letters interwoven; being a kind of abbreviation of a name; anciently much used as a badge, seal, arms, &c.

Among medallists, a monogram is the name of a prince, city, or the like, of which the characters are, as it were, woven together, and the limb of one character applies to three or four others; so that in the small space of one or two characters a whole name is comprehended.

Under the eastern empire, it is usual to find **MIK**, which are the monogram of Maria, Jesus, Constantine.

The use of monograms is of an ancient standing, as appears from Plutarch, and from some Greek medals of the time of Philip of Macedon, Alexander his son, &c. The Roman *Imperium* bore the monogram of Jesus Christ, consisting of two letters, a **P** placed perpendicularly through the middle of an **X**, *e. gr.* , as we find it in several medals of the time of Constantine, those being the two first letters of the word *Χριστός*, *Christ*.

Kings formerly marked their coins with their monograms: of this we have instances in Charlemagne's coins. That prince also used the monogram for his signature. Eginhard gives us this reason for it, *viz.* that Charlemagne could not write; and that, having attempted in vain to learn in his grown age, he was reduced to the necessity of signing with a monogram.

The ancients also used monograms as notes, or abbreviations of inscriptions; for the understanding of which we have express treatises of Valerius Probus, Sert. Ursatus, &c.

MONOGRAPHI, in *Botany*, authors who have written express treatises on only one plant; as Douglas on the Guernsey lily, &c.

MONOGYNIA, from *μνος*, *one*, and *γυνή*, *a female*, is the name of such orders in the first thirteen classes of the Linnæan system, as have a single style, or sessile stigma, in each flower. A single style however is by no means confined to these classes, being universal in the 14th and 15th as well as in the 17th and 19th, all very extensive and natural classes of the same system, and it occurs here and there amongst the others; though in none of these instances does it give a denomination to any order, or section. See **DIGYNIA**.

MONOK, in *Geography*, a town of Hungary; 12 miles W.N.W. of Tokay.

MONOKA, a river of Maryland, which runs into the Chesapeake. N. lat. 38° 10'. W. long. 76° 53'.

MONOLOGUE, Fr. an opera tune by one actor alone, who only speaks or rather sings to himself. In declamation it is a soliloque. "It is in monologues (say the French) that all the powers of music are displayed; the performer giving way to all the ardour of his genius, unrestrained in the length of his air or recitative by the presence of an interlocutor." The accompanied recitatives of the Italians, which produce such great effects, are always monologues.

MONOMACHIA, *Μονομαχία*, from *μνος*, *solus*, and *μαχη*, *combat*, a duel, or single combat of man against man.

Monomachia was anciently allowed by law, for the trial

or proof of crimes. It was even permitted in pecuniary causes, as appears by ancient records. It is now forbidden both by the civil and canon laws. See **COMBAT**.

Alciat has written a treatise "De Monomachia."

MONOMERES, a word used by the ancients as a one, but more frequently joined with the word *phorbæa*, to express one sort of the handle used to confine the head, by those who played on the ancient pipe. This consisted only of one straight and one transverse piece; and the latter came fully over the mouth, and closed it up, except that a hole was cut in it to receive the mouth piece of the pipe. The *diemeræ* consisted of several pieces, and only tied up the lower lip.

MONOMIAL, in *Algebra*, a root or quantity that has but one name; or consists but of one part or member. Such are *ab*, *aab*, *aaabb*. See **QUANTITY**, **BINOMIAL**, **TRINOMIAL**, **ROOT**, &c.

Monomials may be either rational, or irrational.

MONOMIES CASTLE, in *Geography*, a fort of America, on the river Winnebago. N. lat. 44° 18'. W. long. 87° 34'.

MONOMIES River, a river of North America, from which is derived the name of a tribe of Indians, and which runs into that part of lake Michigan, called "Green bay," N. lat. 44° 46'. W. long. 87° 27'.

MONOMONIL, a town of N. America, on the W. side of Green bay. N. lat. 44° 32'. W. long. 87° 28'.

MONOMOTAPA. See **MOCARANGA**.

MONONGAHELA RIVER, a branch of the Ohio, 400 yards wide at its junction with the Alleghany at Pittsburg; navigable with batteaux and barges beyond Redstone creek, and still farther with lighter craft. It rises at the foot of the Laurel mountain in Virginia, passes into Pennsylvania, separates Fayette and Westmoreland from Washington county, and then joining the Alleghany river at Pittsburg, forms the Ohio.

MONONGALIA, a county in the N.W. part of Virginia, about 40 miles long and 30 broad; containing 8540 inhabitants.

MONOPAGIA, a word used by some *medical* writers, for that species of head-ache which affects only one point, or small part of the head.

MONOPETALOUS, in *Botany*, a flower whose *corolla* consists of but one piece, or petal, as in the Primrose. A monopetalous corolla is almost universally tubular. Very rarely the tube is slit, from top to bottom, at one side, as in *Goodenia* and *Sevolvæ*. There are indeed a few monopetalous flowers which seem to be so from a partial defect, as *Amorpha*, the only petal of whose corolla is the standard (*vexillum*), the wings and keel being wanting, though the form of every part of the fructification, as well as the habit of the shrub, indicates its strictly papilionaceous nature. Another genus, *Rittera* of Schreber, (*Possira* of Aublet and Jussieu) which is also of the leguminous kind, though not papilionaceous, has a single lateral petal, of a broad roundish figure, with a very short claw. (See **RITTERA**.) The distinction between a monopetalous and polypetalous corolla, is the most absolute of all, in the systems of those who arrange plants by this part; and is indeed less liable to variation than even the absence or presence of the corolla itself. See **COROLLA** and **CLASSIFICATION**.

MONOPHAGI, *Μονοφαγίαι*, in *Antiquity*, a designation given to those who celebrated the Ægeian festival, because they feasted or eat together without the assistance of their servants; none but the denizens of that island being allowed to be present.

MONOPHYSITES, from *μονος, solus*, and *φύσις, natura*, in *Ecclesiastical History*, a general name given to all those sectaries in the Levant, who only own one nature in Jesus Christ; and maintain, that the divine and human natures of Christ were so united, as to form only one nature, yet without any change, confusion, or mixture of the two natures. See **EUTYCHIANS**.

The Monophysites, however, properly so called, are the followers of Severus, a learned monk of Palestine, who was created patriarch of Antioch in 513, and Petrus Fullensis, whence they were called "Severians."

The Monophysites were encouraged by the emperor Anastasius, but depressed by Justin and succeeding emperors. However, this sect was restored by the eloquence, activity, and diligence of Jacob Baradæus, an obscure monk, inasmuch, that when he died bishop of Edessa, A.D. 578, he left it in a most flourishing state in Syria, Mesopotamia, Armenia, Egypt, Nubia, Abyssinia, and other countries. The laborious efforts of Jacob were seconded in Egypt, and the adjacent countries, by Theodosius, bishop of Alexandria, and he became so famous, that all the Monophysites of the East considered him as their second parent and founder, and are to this day called Jacobites, in honour of their new chief. The Monophysites are divided into two sects or parties; the one African, the other Asiatic: at the head of the latter is the patriarch of Antioch, who resides, for the most part, in the monastery of St. Ananias, near the city of Merdin, his episcopal seat; and also at Amida, Aleppo, and other Syrian cities: the former are under the jurisdiction of the patriarch of Alexandria, who generally resides at Grand Cairo, and are subdivided into Copts and Abyssinians. From the fifteenth century downwards, all the patriarchs of the Monophysites have taken the name of Ignatius, in order to shew that they are the lineal successors of Ignatius, who was bishop of Antioch in the first century, and consequently the lawful patriarchs of Antioch. In the 17th century, a small body of the Monophysites in Asia, abandoned, for some time, the doctrines and institutions of their ancestors, and embraced the communion of Rome: but the African Monophysites, notwithstanding that poverty and ignorance which exposed them to the seductions of sophistry and gain, stood firm in their principles, and made an obstinate resistance to the promises, presents, and attempts employed by the papal missionaries, to bring them under the Roman yoke: and in the 18th century, those of Asia and Africa have persisted in their refusal to enter into the communion of the Roman church, notwithstanding the earnest intreaties and alluring offers, that have been made from time to time by the pope's legates, to conquer their inflexible constancy. The Monophysites propagate their doctrine in Asia with zeal and assiduity, and have not long ago gained over to their communion a part of the Nestorians, who inhabit the maritime coasts of India. Mosheim's *Eccl. Hist.*

MONOPIN HILL, in *Geography*, a hill on the island of Banca, which forms the N.E. point of the entrance of the Straits. S. lat. 2° 3'. E. long. 105° 18'. The difference of longitude between the island Lusepara, which lies in the S. entrance of the Straits of Banca, and Monopin hill, which forms one side of the entrance from the north, is 55'. See *Straits of BANCA*.

MONOPOLI, a town of Naples, in the province of Bari, on the coast of the Adriatic sea; the see of a bishop; containing six churches and nine convents; 144 miles E. of Naples. N. lat. 41° 8'. E. long. 17° 19'.

MONOPOLY, strictly speaking, in the language of the law, is very similar to engrossing: the latter is the act of

buying up corn and other provisions, for the purpose of selling them again; the former is the same offence, extended to other branches of trade: both are supposed to be done for the purpose of gaining the entire command of the market, and by this means raising the prices of the commodities engrossed or monopolised.

Monopoly is also a term applied to a "licence or privilege allowed by the king, for the sole buying, selling, making, working and using of any thing whatsoever, whereby the subject is restrained from that liberty of manufacturing or trading which he had before." These licences and privileges, in all despotic governments, have been made use of to favour and enrich individuals; or, by the sale of them; to contribute to the wants of the sovereigns: and even in freer governments, ignorant of the real mode of promoting industry and enriching the people, licences and privileges of this kind have been too frequently granted on the erroneous idea, that their commerce would be fostered and protected in its infancy. In this kingdom, during the reigns of Elizabeth and James I. monopolies were carried to a most vexatious and destructive extent; so that many branches of trade and manufacture were absolutely closed, except to those who had obtained licences to engage in them, and the great body of consumers were inadequately supplied with bad articles at an exorbitant rate. These evils at last became so oppressive and glaring, that by the 21st James I. c. 3. all such monopolies were declared to be contrary to law and void (except patents to the authors of new and useful inventions, for a term not exceeding fourteen years). By the same statutes, monopolists are liable to be punished by treble damages and double costs, if they disturb any persons engaged in a trade to which they claim the privilege of monopoly. This statute evidently refers only to those cases where a monopoly licence is claimed, and endeavoured to be acted upon, so as to disturb the trade of those engaged in the same line.

The engrossing or monopoly of corn and provisions is an offence at common law, and is described by statute 5 and 6 Edw. VI. c. 14.; by this statute, the penalty is the forfeiture of the goods or their value, and two months imprisonment for the first offence; double value, and six months imprisonment for the second; and for the third, the offender to forfeit all his goods, to be set in the pillory, and imprisoned at the king's pleasure.

Monopoly, as a subject in political economy, may be considered under three points of view. In the first place, the practicability of the alleged crime of getting into one's possession, or buying up, all, or such a quantity of, any commodity as will give the command of the market, and consequently of the price. In the second place, the monopoly, which by patent is given for a term of years, to the authors of new and useful inventions: the propriety and policy of this kind of monopoly afford ample room for discussion; of course, if this kind of monopoly were to be set aside, some other mode of rewarding the authors of new inventions, less objectionable, must be suggested: this kind of monopoly will be considered under the article **PATENT**. In the third place, that species of monopoly, wherein a government grants either to a body of men, which secures them any particular trade; or to the nation at large, by which the colonial trade is not suffered to be touched by any foreign nation. This last species of monopoly, or the monopoly of the colonial trade, will be considered under the article **NAVIGATION Act**: at present, therefore, we shall confine our observations to the alleged crime of engrossing or monopolizing any commodity, for the purpose of commanding the market, and raising the price; and to that monopoly which

which a government grants to any particular body of men, by which they alone can carry on the trade which is the object of the monopoly

Smith's opinion respecting engrossing and forefalling is well known: the popular fear respecting them he compares to the popular terrors and suspicions of witchcraft, and he concludes by observing, that the law which should restore entire freedom to the inland trade of corn would probably prove as effectual to put an end to the popular fears of engrossing and forefalling; as the law which put an end to all prosecutions for witchcraft, destroyed the fear and suspicion of it, by taking away the great cause which encouraged and supported them.

Indeed, when we consider the numerous and great obstacles and difficulties which must lie in the way of every person who attempts to get into his possession the whole, or the greater part of any commodity; the immense capital, or credit which he must possess; the confidence he must place on the integrity of his agents, and the reliance he must have on their skill and judgment; the effect on the price of the commodity, which his attempts to monopolize it must necessarily produce; and the great probability that he will be compelled to desist from his undertaking, long before he has brought it to a close, from an erroneous calculation of his means: it will appear evident that it cannot be the interest of any man to risque his capital in such an absurd and impracticable undertaking. If there should be persons so blind to their own interests as to begin the attempt, their punishment may safely be left to flow from their own measures, as, long before they can materially, or even in a trifling degree, injure the public, they will either open their eyes to their own folly, or be incapacitated by their own ruin from proceeding in their enterprise.

But though monopoly, strictly speaking, appears thus impracticable, yet there is no doubt that the price of commodities may be partially and temporarily affected by the quantity of capital possessed by those who have them for sale. It is well known that if the farmer, for instance, be straightened for money, he will be compelled to bring his grain to market early in the season, in a much larger proportion than if his capital were sufficient to enable him to pay his rent, and carry on his agricultural labour, without having recourse to this measure: if, on the other hand, his capital is such, that he has no occasion for the money the early sale of his corn would produce, he will bring it to market only in those quantities, and at those seasons, which he thinks will conduce most to his own interest. At first sight it might seem as if the public would be most benefited by farmers of the former description; but a very little reflection will convince us, that the temporary reduction in the price of corn, occasioned by their want of adequate capital, will be much more than balanced, in a national point of view, by the unequal distribution of it through the year, to which this will give rise, as well as by the want of economy in the use of it, which the forced and unauthorized reduction of it will produce.

It may then safely be inferred that the attempt to monopolize any commodity is so absurd, and so contrary to the most narrow and obscure views of self-interest, that no law is necessary to prevent or punish it; and that, with respect to the supposed effect of capital, in raising the price of commodities, in many points of view capital, by enlarging the quantity produced, and giving rise to competition, must have the opposite effect; while an inadequate capital must narrow and thwart the industry and operations of the possessor, and even at the time that it compels him to dispose

of his produce, is injurious, not only to himself, but to the nation at large.

In a monopoly of the colony trade, no particular body of men in the nation are favoured: the monopoly regards the whole nation as contradistinguished from foreigners: but in the monopoly of any trade granted by government to a particular body of men, the privilege is granted at the expense, and to the loss of the rest of the nation. This is the first and most striking evil, but there are others not inferior in magnitude and extent. Not only is a large portion of the nation excluded from the means of increasing their industry and consequently their wealth; but they are compelled to purchase the articles of the monopoly trade at the monopoly price, and to sell such articles as they manufacture for that trade, at the price which the holders of the exclusive privilege may choose to give. Nothing supplies a market so regularly, or so cheaply, or with goods of such good quality, as open and fair competition; nothing, on the contrary, renders the supply so irregular, or the goods so high priced, or of such inferior quality, as monopoly. For these and various other subordinate reasons, therefore, a monopoly trade must be injurious to the nation at large; and it not unfrequently happens that it is conducted with such negligence, ignorance, and extravagance, as not to be beneficial to those who possess it. Under certain circumstances, when there was little spirit of enterprise, when individual capital was small, and combined with these circumstances, in cases where the risque was great, where great length of time was necessary to establish the trade, and where the returns, at first, were slow and trifling, it might have been wise and politic to grant exclusive privileges of trade; but certainly it cannot be wise and politic to grant or to continue them, under circumstances of an opposite description.

MONOPS, in *Natural History*, a name given by Ælian, and some other of the old Greek writers, to the bonasus. The name *monopus* was given this animal, according to Aristotle, by the people of the country where the creature was most frequent, and therefore is not to be attempted on any Greek etymology. Some of the Greeks have called the same creature *monopos*, and some *bsinthos*.

MONOPTERE, *Μονοπτερος*, a kind of temple among the ancients, round, and without walls; having its dome supported by columns.

MONOPTOTE, *Μονοπτοτον*, in *Grammar*, a noun, which has only one case; as *inficis*.

MONOPTRAL TEMPLE, in *Architecture*, an edifice, consisting of a circular colonnade supporting a dome. The monoptral temple is open, or without any inclosing wall, and consequently without a cell, as in other temples.

MONOPYRENEOUS FRUITS, in *Botany*, are such as only contain one kernel or seed.

MONORCHIS, the specific name of an *Ophrys* in Linnæus, Sm. Fl. Brit. 936. Engl. Bot. t. 71, which remains in the same genus in Dr. Swartz's new arrangement of this tribe. It is so called from having but one apparent globular-bulb, or rather knob, to the root; the other being formed at the end of a longish shoot, about, or after, the time of flowering, so as commonly to escape observation.

MONORCHIS. Beside the common signification of this word as the name of a plant, physicians have also used it to express a man who has but one testicle.

MONORHYMÆ, from *μονος*, *solus*, and *ῥυμη*, *rhyne*, a poetical composition, all the verses of which end with the same rhyme.

Monorhymes are said to have been invented by the old French poet Leonin, who addressed some Latin verses of

this kind to pope Alexander III., whence they are also called *Leomne verses*.

MONOS, in *Geography*, a river of Guinea, which runs into the Atlantic, 15 miles S. of Tombi.

MONOSPERM-ALTHÆA, in *Botany*, a name contrived by Inard for the *Waltheria* of Linnæus, and intended to express a plant of the Marsh-mallow kind, with a single seed. See *WALTHERIA*.

MONOSTICH, MONOSTICHON, an epigram, or poetical piece, consisting of one single verse.

MONOSYLLABLE, MONOSYLLABUM, a word of a single syllable; or, that consists of one or more letters which are pronounced together.

The French language abounds in monosyllables more than any other. This renders it the more perplexing to foreigners, and yet the beauty of the language seems to consist in it. One of the best and smoothest lines in Malherbe consists of twelve monosyllables: speaking of Calista, he says, "Et moi je ne voi rien quand je ne la voi pas." In this the genius of the English tongue differs very much from the French, an uninterrupted series of monosyllables in the former having always an ill effect. This Mr. Pope both intimates and exemplifies in the same verse. "And ten low words oft creep in one dull line." Pasquier cites an elegy of forty-two verses, consisting wholly of monosyllables.

MONOTHELITES, compounded of *μονος*, *single*, and *θελημα*, *will*, of *θελω*, *volō*, *I will*, in *Ecclesiastical History*, an ancient sect, which sprung out of the Eutychians and Monophysites; thus called, as only allowing of one will in Jesus Christ.

The opinion of the Monothelites had its rise in 630, and had the emperor Heraclius for an adherent, who, by publishing an edict in favour of it, hoped thus to restore peace and concord both in church and state: it was the same with that of the Acephalous Severians.

They allowed of two wills in Christ, considered with regard to the two natures; but reduced them to one, by reason of the union of the two natures; thinking it absurd there should be two free wills in one and the same person. See *ECITHESIS* and *TYPE*.

They were condemned by the sixth general council, in 680, as being supposed to destroy the perfection of the humanity of Jesus Christ, depriving it of will and operation. Mosheim gives the following account of the state of this subtle controversy; the grounds of which are not, indeed, easily understood and explained. 1. The Monothelites declared, that they had no connection with the Eutychians and Monophysites; but maintained, in opposition to both these sects, that in Christ there were two distinct natures, which were so united, though without the least mixture or confusion, as to form by their union only one person. 2. They acknowledged, that the soul of Christ was endowed with a will, or faculty of volition, which is still retained, after its union with the divine nature. For they taught, that Christ was not only perfect God, but also perfect man; whence it followed, that his soul was endowed with the faculty of volition. 3. They denied that this faculty of volition in the soul of Christ was absolutely inactive; maintaining, on the contrary, that it co-operated with the divine will. 4. They, therefore, in effect, attributed to our Lord two wills, and these, moreover, operating and active. 5. They, however, affirmed, that, in a certain sense, only one will and one manner of operation were in Christ. Their sentiments were afterwards embraced by the Maronites.

MONOTOCA, in *Botany*, from *μονος*, *one*, and *τοκος*;

a fetus, or *conception*, because the germen has, from the first, the rudiments of but one seed, by which this genus is distinguished from others of its natural order. Brown. Prodr. Nov. Holl. v. 1. 546.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Epacridee*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of five equal, erect, concave, permanent leaves, with a pair of smaller ones at the base, which are sometimes deciduous. *Cor.* of one petal, funnel-shaped, twice the length of the calyx; its limb in five equal, spreading, smooth, beaked segments; throat naked and pervious. Nectary a lobed cup-shaped gland, surrounding the base of the germen. *Stam.* Filaments five, thread-shaped, equal, inserted into the tube of the corolla, shorter than its limb; anthers oblong, incumbent. *Pist.* Germen superior, roundish; style columnar, short; stigma obtuse. *Peric.* Drupa oval, pulpy. *Nut* solitary, oval, of one cell. *Seed* solitary.

Eff. Ch. Outer calyx of two leaves. Corolla five-cleft, funnel-shaped, naked at the mouth and border. Germen single-seeded. Drupa pulpy.

A New Holland genus of shrubs, or small trees, separated by Mr. Brown from the *Styphelia* of preceding authors, on account of the above characters. The leaves are feathered, simple. Spikes axillary, rarely terminal, of few flowers, which are small, white, often becoming dioecious, by a partial defect in their organs of impregnation.

Section 1. *Outer calyx deciduous. Small trees, with dioecious flowers.*

1. *M. elliptica.* (*Styphelia elliptica*; Sm. Bot. of New Holl. 49.)—Clusters erect, either nearly terminal and aggregate, or axillary and solitary. Leaves elliptic-oblong, four times as long as broad.—Sent by Dr. J. White, in 1793, from the neighbourhood of Port Jackson, New South Wales, where it was also gathered by Mr. Brown. The branches are variously divided, round, leafy, downy when young. Leaves numerous, scarcely an inch long, obovate or elliptic-lanceolate, entire, tipped with a spinous point; dark glaucous green and smooth above; pale, convex, with somewhat radiating, but nearly parallel, ribs beneath. Footstalks broad and short. Clusters about the length of the leaves, their stalks angular and downy. Bractees solitary, concave, at the base of each partial stalk. Flowers scarcely a line in length. The outer calyx is permanent in our specimens.

2. *M. albens.* Br. n. 2.—Clusters erect, solitary, either terminal or axillary. Leaves oblong-linear, acute, spinous-pointed, white beneath.—Native of Port Jackson. Like the former, but the leaves are longer, narrower, and paler, more tapering at the point, their edges appearing minutely crenate under a microscope.

3. *M. lineata.* Br. n. 3. (*Styphelia glauca*; Labill. Nov. Holl. v. 1. 45. t. 61.)—Spikes axillary, very short, drooping, stalked. Leaves elliptic-oblong, acute, spinous-pointed, nearly flat.—Native of Van Diemen's land, where it was gathered by both the above authors. The shape of the leaves is most like the first species, but the very short, axillary, stalked, obtuse spikes (not clusters), which Mr. Brown says are drooping, though the French author represents them erect, distinguish the present plant. The germen is, erroneously it seems, drawn with five cells in Labillardiere's plate.

Section 2. *Outer calyx permanent. Shrubs, with both organs of the flower perfect.*

4. *M. scoparia.* (*Styphelia scoparia*; Sm. Bot. of New Holl. 48.)—Spikes axillary, very short, nearly sessile, drooping, of few flowers. Leaves linear-oblong, somewhat revolute.

revolute. Stem erect.—Native of Port Jackson, New South Wales. The stem is very bushy, branched in a determinate manner, smooth throughout. Leaves numerous, about half an inch long, narrow, but somewhat elliptical, entire, spinous-tipped, the edges reflexed. Flowers small, three or four, in a little, recurved, minutely bracteated, spike.

5. *M. empetrifolia*. Br. n. 5.—"Spikes axillary, drooping, of two or three flowers. Leaves oblong-oval, pointed, divaricated; convex above; striated and whitish beneath. Stem prostrate."—Gathered by Mr. Brown in Van Diemen's land. Of this we have no specimen.

MONOTONIA, MONOTONY, in Rhetoric, a want of variation, or inflexion of the voice; or a fault in pronunciation, where a long series of words is delivered with one unvaried tone. This is one of the principal faults of our English orators.

Dr. Blair observes, that monotony is the great fault into which writers are apt to fall, who are fond of harmonious arrangement; and to have only one tune, or measure, is not much better than having none at all. A very vulgar ear will enable a writer to catch some one melody, and to form the run of his sentences according to it; which soon proves disgusting. But a just and correct ear is requisite for varying and diversifying the melody; and hence we so seldom meet with authors, who are remarkably happy in this respect.

In pronunciation, care should be taken to guard against monotony. It is justly observed by a good writer on this subject, that for an orator always to use the same tone or degree of his voice, and to expect to answer all his views by it, would be much the same thing, as if a physician should propose to cure all distempers by one medicine. From hence it is evident, that though various inflections and tones of the voice are requisite to make it harmonious and pleasing to the ear, yet the degree of it should differ according to the nature of the subject, and design of the speaker. And as a perfect monotony is always unpleasant, so it can never be necessary in any discourse. Lect. on Rhet., &c. vol. i. Ward's Orat., vol. ii. See PERIOD, PRONUNCIATION, SENTENCE, and VOICE.

Monotonia is opposed to chanting or singing in speaking.

MONOTONOUS, MONOTONY, used figuratively in music, except in speaking of drums, implies dull, psalmodic strains, always in the same style or key.

MONOTRIGLYPH, in Architecture, denotes the space of one triglyph, between two pilasters or two columns.

MONOTROPA, in Botany, received that appellation from Linnæus, in exchange for *Hypopitys*, though the alteration seems, in our humble opinion, by no means for the better. The word is formed from *μονος*, one, and *τροπον*, to regard or consider, alluding to the regard paid by its author to the single terminal flower, for the determination of the class and genus, in preference to the lateral ones, according to a favourite principle assumed by himself, and exemplified in this genus, *Ruta*, *Adoxa*, *Chrysofplenium*, and others. He appears in the *Philosophia Botanica*, p. 186, to have lost sight of this original idea, classing the name in question with those deduced from the soil, stumbling, as it were, between *solum* and *solus*; an error rather to be lamented than censured, when we reflect that this immortal book was dictated hastily from a sick bed. (See LINNÆUS.) We must nevertheless still contend, that the name previously bestowed on this plant by Bauhin and Dillenius, from *υπο*, under, and *τροπος*, a fir-tree, alluding to its perhaps invariable station, was liable to no exception. Linn. Gen. 214. Schreb. 291. Willd. Sp. Pl. v. 2. 573. Mart. Mill. Dict. v. 3. Sm.

Fl. Brit. 440. Juss. 430. Michaux Boreali-Amer. v. 1. 266. (*Hypopitys* Dill. Gen. 134. t. 7.)—Class and order, *Dicandria Monogynia*. Nat. Ord. doubtful, Linn. Juss. The latter observes, that it is "a genus by itself, akin to no other." Its habit is that of *Cytinus*, whatever difficulty there may be in bringing them together by technical characters. The want of green in the colour of such parasitical plants is remarked by Linnæus, in Fl. Suec. 135, though the discovery has lately been attributed to one of his pupils.

Gen. Ch. Cal. none, unless the five outer petals be considered as a coloured calyx. Cor. Petals ten, inferior, oblong, erect, parallel, serrated at the extremity, deciduous; the five outermost, or alternate, ones gibbous at the base, concave, and bearing honey, at the inside. Stam. Filaments ten, awl-shaped, erect, simple; anthers simple, two-lobed. Pist. Germen superior, roundish, pointed; style cylindrical, the length of the filaments; stigma capitate, obtuse. Peric. Capsule ovate, with five angles, obtuse, of five valves. Seeds numerous, chaffy.

Obs. This description is taken from the terminal flower, according to the rule in *Phil. Bot.* sect. 178. The lateral flowers, in such species as have any, lose one-fifth, in the number of every part of the fructification.

Ess. Ch. Calyx none. Petals ten; the five outermost concave and honey-bearing at their base. Capsule superior, of five valves.

1. *M. Hypopitys*. Yellow Bird's-nest. Linn. Sp. Pl. 555. Engl. Bot. t. 69. Fl. Dan. t. 232. Ehrh. Phytoph. 44. (*Orobanche hypopitys lutea*; Mentz. Pugill. t. 3. Morif. sect. 12. t. 16. f. 13.)—Flowers spiked, externally smooth, as well as their bractæas; the lateral ones octandrous.—Native of fir woods in Europe and North America, growing parasitically on the roots of those trees, and flowering in July. Dillenius says, on the authority of Mr. Manningham, that it grows also in beech woods. Michaux asserts the American plant to be but half the size of the European. With us it is nearly a span high. The whole herb succulent, of a pale straw-colour, turning brownish when arrived at maturity, and then acquiring a fragrant smell, like that of primrose flowers, though generally compared to their roots. The stem is simple, thick, round, clothed with scattered ovate scales, rather than leaves, and terminating in a spike of several flowers, at first drooping, finally erect. Each flower is accompanied by a bractæa, exactly resembling the scales of the stem, rather shorter than the flower, which, with its very short partial stalk, is nearly an inch long. Sometimes the filaments, and inner side of the petals, are hairy. Willdenow says there is a variety with upright flowers, which is occasionally single-flowered. We have sometimes found the lateral blossoms with only six petals and stamens.

2. *M. lanuginosa*. Downy Bird's-nest. Michaux n. 2.—Flowers spiked, all over downy, as well as their bractæas.—Sent from North America, by Kalm, to Linnæus, who confounded it with the former. Michaux gathered the same in the woods of North Carolina. He justly describes it as having the habit of the foregoing, but smaller in all its parts, varying with a drooping or upright spike, the flowers turned all one way. The scales of the stem are rather pointed. The stem, scales, petals, and every other part of the flowers, are clothed with fine, soft, dense hairs, peculiar to this species. The specimen of the former in the Linnæan herbarium, as well as one we have from France, has indeed scattered hairs on the filaments, as well as on the inner side of the petals, near the edge. Whether these indicate a specific distinction,

distinction, we have not materials to decide, but we have seen them in no British specimen.

3. *M. uniflora*. Drooping Single-flowered Bird's-nest. Linn. Sp. Pl. 555. Michaux n. 3. (Orobanche virginiana, flore pentapetalo cernuo; Pluk. Phyt. t. 209. f. 7.)—Stem single-flowered. Scales bluntish. Flower pendulous.—Native of Maryland, Virginia, and Canada; Linn.; of shady woods in South Carolina; Michaux. Root a dense congeries of entangled fibres. Stem about six inches high, seldom quite straight in any part, angular, smooth. Scales obovate, bluntish, smooth, scattered, not numerous. Flower terminal, solitary, perfectly pendulous, the upper part of the stem, for about an inch, being curved into an arch. Corolla bell-shaped, the size of the first species, or bigger. Stamens ten, hairy. Plukenet's figure is very good.

4. *M. Morifoniana*. Upright Single-flowered Bird's-nest. Michaux n. 4. (Orobanche monanthos virginiana, flore majore; Morif. sect. 12. t. 16. f. 5.)—Stem single-flowered, straight. Scales lanceolate. Flower erect.—Native of the shady woods of Carolina. Michaux. A specimen, sent by Kalm from North America, is confounded in the Linnæan herbarium with the last. The stem of the present species is nearly twice the height of *M. uniflora*, perfectly straight, except its taper base, which is slightly flexuose. Scales larger, more lanceolate and acute, especially the upper ones. Flower always perfectly erect, about the size of the last, or rather bigger, with ten petals, and as many hairy stamens.

Morison's figure, with which Linnæus finds fault, supposing it done for the foregoing, expresses this species sufficiently well. Michaux has first distinguished the two, and, as it appears to us, very justly. He describes the scales as more distant in the present, which is not the case in the only specimen we have seen, any more than in Morison's plate. The stem, in five specimens of the *uniflora* before us, is also the most slender of the two; Michaux terms it thick, as well as shorter than the other.

No successful attempt, as far as we have heard, was ever made to cultivate any of this genus; yet as gardeners now succeed with several of the *Orchidææ*, at one time thought quite as unmanageable, we know not why they should despair, even of these parasitical plants. Rotten stumps of fir, placed so as to receive their minute seeds, and then removed into a fit situation, might possibly attain the desired end. S.

MONOU, in *Geography*, a country of Africa, north of the Grain coast.

MONOVAC, a town of Spain, in the province of Valencia; 21 miles W. of Alicant.

MONOULLAH, a town of Bengal; 12 miles N.W. of Goragot.

MON-PADRE, a town of the island of Margareta.

MONPARA, a river on the west coast of the island of Borneo, which runs into the sea, N. lat. $0^{\circ} 36'$. E. long. $109^{\circ} 33'$.

MONPAZIER, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Bergerac; 18 miles S.W. of Sarlat. The place contains 1028, and the canton 4691 inhabitants, on a territory of 245 kilometres, in 14 communes. N. lat. $44^{\circ} 40'$. E. long. $0^{\circ} 59'$.

MONPON, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Ribérac. The place contains 1500, and the canton 5615

inhabitants, on a territory of $247\frac{1}{2}$ kilometres, in 10 communes.

MONQUEGNA, a jurisdiction of South America, in the diocese of Arequipa; about 40 leagues S. of the city of Arequipa, and 16 from the coast of the South sea. This jurisdiction extends at least 40 leagues in length, in an agreeable climate, adorned with large vineyards, from the produce of which great quantities of wine and brandy are made, which constitute its whole commerce. They supply all the provinces bordering on the Cordilleras, as far as Potosi, by land carriage; while they are exported by sea to Callao, where they are greatly valued. Here are also papas and olives. The principal town, which bears the same name, is inhabited by Spaniards, among whom are several noble and opulent families. S. lat. $17^{\circ} 24'$. W. long. $70^{\circ} 56'$.

MONREAL, a town of Spain, in Aragon; 23 miles W. of Calataud.—Also, a town of Spain, in Navarre; 8 miles S.E. of Pamplona.

MONREALE, a town of Sicily, in the valley of Mazara, situated on a lofty hill; 3 miles W.S.W. of Palermo.

MONRO, ALEXANDER, M.D., in *Biography*, an eminent anatomist, and the father of the medical school of Edinburgh, was descended both by his paternal and maternal parents from distinguished families in the north of Scotland. He was born in London, in September 1697, where his father, then a surgeon in the army of king William in Flanders, resided upon leave of absence in the winter. On quitting the army, Mr. Monro settled in Edinburgh; and perceiving early indications of talent in Alexander, his only child, he took great interest in superintending his education. After having given him the best instruction which Edinburgh then afforded, he sent him to London, where he attended the anatomical courses of Cheselden, and was extremely assiduous in dissections: he made numerous anatomical preparations, which he sent home; and, while here, even laid the foundation of his most important work on the bones, a sketch of which he read before a society of young physicians and surgeons, of which he had been elected a member. From London, Alexander went to Paris, where he pursued the same object; and in the autumn of 1718, repaired to Leyden, with the view of profiting by the tuition of the great Boerhaave, who conceived a high opinion of his talents and industry, and wrote a favourable account of him to his friends. On his return to Edinburgh, in the autumn of 1719, he was appointed professor and demonstrator of anatomy to the company of surgeons, the joint demonstrators having spontaneously resigned in his favour. Soon after accepting this appointment, he began also to give public lectures on anatomy, illustrating them by the preparations which he had made when abroad; and at the same time Dr. Alston, then a young man, united with him in the plan, and began a course of lectures on the materia medica and botany. These were the first public courses that had ever been given at Edinburgh, and may be regarded as the opening of that medical school, which has since extended its fame, not only throughout Europe, but over the new world. Mr. Monro suggested this plan; and by the following circumstance, probably, contributed to lead his son into a mode of lecturing, which subsequently carried him to excellence. Without the young teacher's knowledge, he invited the president and fellows of the College of Physicians, and the whole company of surgeons, to honour the first day's lecture with their presence. This unexpected company threw the doctor into such confusion, that he forgot the words of the discourse, which he had written and committed to memory.

Having

Having left his papers at home, he was at a loss for a little time what to do: but, with much presence of mind, he immediately began to draw some of the anatomical preparations, in order to gain time for recollection; and very soon resolved not to attempt to repeat the discourse which he had prepared, but to express himself in such language as should occur to him from the subject, which he was confident that he understood. The experiment succeeded: he delivered himself well, and gained great applause as a good and ready speaker. Thus discovering his own strength, he resolved henceforth never to recite any written discourse in teaching, and acquired a free and elegant style of delivering lectures.

In the same year, 1720, a regular series of medical instruction was instituted at Edinburgh, through the interest of Dr. Monro's father: these two lectureships were put upon the university establishment, to which were soon after added those of Drs. Sinclair, Rutherford, Innes, and Plummer. This system of medical education was, however, incomplete, without affording some opportunity to the students of witnessing the progress and treatment of diseases, as well as of hearing lectures. A proposal was, therefore, made to erect and endow an hospital by subscription; and Dr. Monro published a pamphlet, explaining the advantages of such an institution. The royal infirmary was speedily raised, endowed, and established by charter; and the institution of clinical lectures, which were commenced by Dr. Monro on the surgical cases, and afterwards by Dr. Rutherford, in 1748, on the medical cases, completed that admirable system of instruction, upon which the reputation and usefulness of the medical school of Edinburgh have been subsequently founded.

None of the new professors contributed so much to the celebrity of this school as Dr. Monro, who was indefatigable in the labours of his office, and in the cultivation of his art, and soon made himself known to the professional world by a variety of ingenious and valuable publications. During a period of nearly forty years he continued, without any interruption, to deliver a course of lectures, extending from the end of October to the beginning of May: and so great was the reputation which he acquired, both for himself and the university, that students flocked to him from the most distant corners of the kingdom.

His first and principal publication was his "Osteology, or Treatise on the Anatomy of the Bones," which appeared in 1726, and was intended for the use of his pupils; but it became a very popular work among the faculty in general: for he had the satisfaction of seeing it pass through eight editions during his life, and it was translated into most of the languages of Europe. The French edition, in folio, published by Mr. Sue, demonstrator of sculpture to the Royal Academy of Paris, was adorned with most elegant and masterly figures. To the later editions of this work he subjoined a concise *neurology*, or description of the nerves, and a very accurate account of the lacteal system and thoracic duct.

Dr. Monro was also the father and active supporter of a society, which was established by the professors and other practitioners of the town, for the purpose of collecting and publishing papers on professional subjects, and to which the public is indebted for six volumes of "Medical Essays and Observations by a Society at Edinburgh," the first of which appeared in 1732. Dr. Monro was the secretary of this society; and after the publication of the first volume, when the members of the society became remiss in their attendance, the whole labour of collection and publication was carried

on by himself; "inasmuch that after this," says his biographer, "scarcely any other member ever saw a paper of the five last volumes, except that they were the authors of, till printed copies were sent them by the bookseller." Of this collection, many of the most valuable papers were written by Dr. Monro, on anatomical, physiological, and practical subjects: the most elaborate of these is an "Essay on the Nutrition of the Fœtus," in three dissertations. Haller, speaking of these volumes as highly valuable to the profession, adds, "Monrousibi riminet."

After the conclusion of this publication, the society was revived, at the suggestion of the celebrated mathematical professor, Colin Maclaurin, and was extended to the admission of literary and philosophical topics. Dr. Monro again took an active part in its proceedings, as one of its vice-presidents, especially after the death of Maclaurin, when two volumes of its memoirs, entitled "Essays Physical and Literary," were published, and some materials for a third collected, to which Dr. Monro contributed several useful papers. The third was not published during his life. His last publication was an "Account of the Success of Inoculation in Scotland," written originally as an answer to some inquiries addressed to him from the committee of the faculty of physicians at Paris, appointed to investigate the merits of the practice. It was afterwards published at the request of some of his friends, and contributed to extend the practice in Scotland. Besides the works which he published, he left several MSS. written at different times, of which the following are the principal; *viz.* A History of Anatomical Writers;—An *Encheiridion Anatomica*;—Heads of many of his Lectures; A Treatise on Comparative Anatomy;—A Treatise on Wounds and Tumours;—and, An Oration de Cuticula. This last, as well as the short tract on comparative anatomy, has been printed in an edition of his whole works, in one volume, quarto, published by his son, Dr. Alexander Monro, at Edinburgh, in 1781. This tract had been published surreptitiously, in 1744, from notes taken at his lectures; but is here given in a more correct form.

In the year 1759, Dr. Monro resigned his anatomical chair, which he had so long occupied with the highest reputation, to his son, just mentioned; but he still continued to lecture as one of the clinical professors on the cases in the infirmary. His life was also a scene of continued activity in other affairs, as long as his health permitted. For he was not only a member, but a most assiduous attendant, of many societies and institutions for promoting literature, arts, sciences, and manufactures in Scotland; he was also a director of the bank of Scotland, a justice of the peace, a commissioner of high roads, &c. and was punctual in the discharge of all his duties. His character in private life was as amiable and exemplary as it was useful in public. To the literary honours, which he attained at home, were added those of a fellow of the Royal Society of London, and an honorary member of the Royal Academy of Surgery, at Paris.

Dr. Monro was a man of middle stature, muscular, and possessed of great strength and activity; but was subject for many years to a spitting of blood on catching the least cold, and through his life to frequent inflammatory fevers. After an attack of the influenza, in 1762, he was afflicted with symptoms of a disease of a painful and tedious nature, which continued ever after, until it terminated his existence. This was a fungous ulcer of the bladder and rectum, the distress of which he bore with great fortitude and resignation, and died with perfect calmness, on the 10th of July, 1767, at the age of seventy.

Two of his sons became distinguished physicians. Dr. Alexander, his successor, filled the anatomical chair with great credit to himself and to the university, for upwards of forty years, and became known throughout Europe by his valuable publications; especially by his Treatise on the Lymphatics, in 1770;—On the Anatomy of Fishes, 1785;—On the Nerves, 1783;—On the Bursa Mucoſæ, 1788; and three treatises on the Brain, the Eye, and the Ear, in 1797. Advancing in years, and wishing to relieve himself from the fatigues of the professorship, he associated with himself, in 1801, his son, the third Alexander Monro, who now, 1812, continues to carry on the business of that chair with considerable zeal and credit, while the respected veteran spends his age in repose.

Dr. Donald Monro, the other son of the first Alexander, settled as a physician in London, and attained considerable eminence. He became known as the author of an Essay on the Dropsy, in 1765;—On the Diseases of Military Hospitals, 1764;—On Mineral Waters, 1771;—On preserving the Health of Soldiers; and some other works, and died in the year 1802. See Life of Dr. Monro, prefixed to his works. Gen. B.og.

MONROE, in *Geography*, a county of Virginia, taken from Green Briar, on the south side; 320 miles from Washington.

MONROYO, a town of Spain, in Aragon, on the frontiers of Catalonia and Valencia; 20 miles S. of Alcaniz.

MONS VENERIS, in *Anatomy*, the elevation of the integuments over the pubes in the female subject. See GENERATION.

MONS, in *Geography*, a town of France, and principal place of a district, in the department of Jemmappe, or Gemmappe, of which it is the capital, so called from its situation on a hill. The river Trouide, which runs through it, joins the Hainne in its fauxbourg. Its castle, which was demolished in 1618, is said to have been built by Julius Cæsar, and Quintus Cicero, brother to the celebrated orator, was besieged in this place, and relieved by Cæsar, 50 years B.C. The town is large, the streets are broad, and the great market-place, which is very spacious, contains the town-house, which is a fine old building, with a steeple erected by the states in 1716, the palace of the government, and that of the council of the province. These three palaces are adorned with sculpture and painting. The great church is a fine building, the side altar and chapel being wholly constructed of fine marble: here is a marble tomb, finely embellished; and the statues, among which are the four cardinal virtues, and the resurrection, are in high estimation. Mons is a place of good trade for various articles, particularly woollen stuffs, which are manufactured here in large quantities. The magistracy is composed of a chief, ten scheidins, two pensioners, three greffiers, &c. This town has frequently suffered by the calamities of war. In 1746 its fortifications were demolished by the French; and in this state it was restored to the emperor by the peace of Aix-la-Chapelle. After the battle of Jemmappe, it was summoned by Dumourier, and surrendered the next morning. It contains 18,291 inhabitants, in 2 cantons; the north canton including 13,381, on a territory of 37½ kilometres, in 5 communes; and the south containing 14,252, on a territory of 45 kilometres, in 8 communes. N. lat. 50° 27' 10". E. long. 3 37' 15".

MONSEFU, a town of Peru, in the bishopric of Truxillo; 12 miles S. of Lambayeque.

MONSEIGNEUR, compounded of *mon*, *my*, and *ſeigneur*, *lord*, in the plural messeigneurs, a title of honour and respect used by the French in writing to persons of superior rank or quality.

Dukes, peers, archbishops, bishops, and presidents *a la mortier*, are complimented with the title of messeigneur.

In the petitions presented to the sovereign courts, they use the term messeigneurs.

MONSEIGNEUR, absolutely used, was a title formerly restrained to the dauphin of France.

This custom was unknown till the times of Louis XIV., till then the dauphin was styled *monſieur le dauphin*.

MONSIEUR, a compound of *mon*, *my*, and *ſieur*, *ſir*, in the plural messieurs, a term or title of civility, used by the French, in speaking to their equals, or those a little below them; answering to Mr. or Sir, among the English.

The superscription of all letters begin *A monsieur*, *monsieur* such a one.

The use of the word monsieur was formerly more extensive than at present: they applied it to people who lived many ages before them. Thus monsieur St. Augustine, monsieur St. Ambrose; and the vulgar still say, monsieur St. Paul, monsieur St. Jaques, &c. The Romans, during the flourishing time of their liberty, were unacquainted with that term of parade and flattery, which they afterwards made use of in the word *dominus*. In speaking or writing to each other, they only gave each other their proper names; which practice lasted even after Cæsar had brought the republic under his command: but after the Roman emperors were once well seated on the throne, the courtiers and minions, who by flattery sought to procure favours from them, studied new honours. Suetonius observes, that a comedian on the theatre having called Augustus *dominus*, *lord*; the spectators all stared at him; so that the emperor forbade, for the future, the title to be attributed to him. Caligula was the first who expressly commanded himself to be called *dominus*. Martial, entirely devoted to tyranny, calls Domitian *dominum deumque nostrum*. In time, the title was also applied to the people; and of *dominus*, at length was formed *dom*.

MONSIEUR, absolutely used, is a title or quality formerly appropriated to the second son of France, or the king's brother.

In a letter of Philip De Valois, that prince, speaking of his predecessor, calls him *monsieur le roy*, monsieur the king.

MONSIGNI, M. DE, in *Biography*, formerly maitre d'hotel to the duke of Orleans, father of l'Egalité, was one of the creators of the French comic opera, for which, between the years 1759 and 1777, he composed eleven or twelve different dramas, which, we believe, were all successful; particularly "Le Cadé Dupé; on ne s'avise jamais de tout;" "Le Roi et le Fermier;" "Rose et Colas, &c."

This kind of drama was established at the theatre de la Foire, in 1754, upon the idea of the Italian burletta, in all things except the recitative, the dialogue in the French opera comique being spoken, and incidentally mixed with airs. This ingenious and pleasing composer's name of Monsigni seems Italian; but his style of melody is neither Italian nor French, but a mixture of both. Nothing could be more pleasing and amusing than these dramas to the natives of all Europe, not great critics in singing; for it must be owned, that they were all well written, well set, and well acted; and in the principal man's part, when performed by the admirable Caillot, well sung. Duni, Philidor, and Monsigni, were the patriarchs of the comic musical dramas, and Gretry the king David.

MONSOL,

MONSOL, in *Geography*, a town of Africa, in the kingdom of Anziko, and residence of the micocco or king. S. lat. 1°. E. long. 3° 50'.

MONSON, Sir WILLIAM, in *Biography*, a naval commander, and a writer upon naval subjects, was born about the year 1569, and was sent, at an early age, to Balliol college, Oxford, where he remained about two years. Being desirous of engaging in the sea-service, to which, probably, his parents objected, he entered, without their knowledge, on board a small vessel, fitted out to cruise against the Spaniards. After some years' active service, he accompanied the earl of Cumberland in two expeditions, in the second of which he was taken by the Spaniards, and was detained a prisoner two years. As soon as he was liberated, in 1593, he attached himself again to the earl's service, in which he made two more voyages. In 1596, he was captain of a ship in the earl of Essex's expedition to Cadiz, and in the next year in that to the Azores. After the accession of king James, he was appointed, in 1604, admiral of the narrow seas, an office which he sustained twelve years with credit to his own well earned reputation, and honour to the British flag, by protecting the trade and fisheries from all encroachments. His zeal against the pretensions of the Dutch, and his endeavours to promote an enquiry into the state of the navy, against the will of the earl of Nottingham, lord high admiral, involved him in troubles, and occasioned his committal to the Tower, in 1616; but upon examination into his conduct he was discharged. He was consulted on the duke of Buckingham's expedition against Algiers, Cadiz, and the isle of Rhé, all which he disapproved, and his opinion was fully justified by their want of success. To his country his opposition was unavailing, and to him it was unfortunate, having been kept out of employ for several years; but in 1635 he was appointed vice-admiral. After this he withdrew to a life of privacy, and employed himself in finishing his "Naval Tracts." He died in February, 1642-3, leaving a high reputation as a brave, prudent, and upright commander. He had not the good fortune to perform any very splendid services, yet his zeal for the improvement of the navy of his country merits an honourable mention. His Naval Tracts contain plans and projects for the advancement of the interests of trade and navigation. They are inserted in the third volume of Churchill's Collection of Voyages. Biog. Brit. Campbell's Lives of the Admirals, Stockdale's edition.

MONSON, in *Geography*, a township of Hampshire county, Massachusetts, E. of Brimfield.

MONSONIA, in *Botany*, is designed to commemorate the late lady Ann Monson, a lady of distinguished talents, as well as of eminent botanical taste and knowledge, who by a long residence in the East Indies, had great opportunities of cultivating the study of plants, as well as insects. We trust we shall betray no inviolable secret, in recording that it was to this excellent lady the late Mr. Lee alluded, in the preface to his Introduction to Botany, first published in 1760, where he says he was enjoined not to acknowledge his obligations to those who had kindly helped him in his undertaking. A most elegant East Indian *Illecebrum* was first chosen by Koenig, if we mistake not, to bear the name of *Monsonia*, which remains as its specific appellation; and a more distinct genus, of greater splendour, has been selected for the purpose. Some have thought this but too near to *Geranium*.—Linn. Mant. 14. Schreb. 459. Willd. Sp. Pl. v. 3. 717. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 100. Juss. 269. Lamarek Illustr. t. 638. Cavan. Dill. 179. —Class and order, *Polyadelphia Dodcandria*. Nat. Ord. *Gruinales*, Linn. *Gerania*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, awned, equal, permanent leaves. *Cor.* Petals five, obovate, abruptly toothed, and jagged, longer than the calyx, inserted into the short annular receptacle, or nectary. *Stam.* Filaments fifteen, united into five sets, three in each set, all inserted into the nectary; anthers oblong. *Pist.* Germen superior, pentagonal, short; style awl-shaped; stigmas five, oblong, spreading. *Peric.* Capsules five, aggregate, cartilaginous, oblong, lateral, separating at their inside, each attached upwards to a very long, spiral, elastic awn. *Seeds* solitary, lateral, oblong, somewhat cylindrical.

Ess. Ch. Calyx of five leaves. Petals five, abrupt, toothed. Stamens in five sets, united by a common base. Style five-cleft. Fruit beaked, of five aggregate capsules, with long spiral awns.

1. *M. speciosa*. Large-flowered Monsonia. Linn. Mant. 105. Curt. Mag. t. 73. Cavan. Diss. 179. t. 74. f. 1.—Leaves quinate; leaflets bipinnatifid.—Native of the Cape of Good Hope, like the whole genus. It was sent to Kew in 1774, by Mr. Masson, and decorates the green-house magnificently in spring. *Root* perennial. *Stems* sometimes very short. *Leaves* numerous, mostly radical, on long stalks, and composed of five radiating hairy leaflets, doubly pinnatifid; their segments linear-lanceolate, bluntish, decurrent. *Flowers* two or three inches broad, with deeply cut petals, variegated with shades of rose-colour, ribbed, the eye purple and white; each on a long, bent, simple stalk, with a whorl of lanceolate bractees at its joint. *Calyx-leaves* membranous at the edge, downy upward. Beak of the fruit three inches long, its awns hairy at the inside.

2. *M. lobata*. Broad-leaved Monsonia. Dryand. in Ait. Hort. Kew. ed. 1. v. 3. 100. Willd. n. 3. (*M. filia*; Linn. Suppl. 341. Cavan. Diss. 180. t. 74. f. 2. Andr. Repof. t. 276.)—Leaves heart-shaped, deeply lobed, toothed.—Differs from the last in having the leaves lobed, not compound, though they are sometimes so deeply cut as almost to approach the former. In the flowers there is scarcely a permanent distinction. The petals of the present species are usually greenish at the back, white, with a tinge of red, above. It is much to be suspected that these are but varieties of each other.

3. *M. ovata*. Undulated Monsonia. Willd. n. 4. Cavan. Diss. 193. t. 113. f. 1. (*M. emarginata*; L'Herit. Geran. t. 41. *Geranium emarginatum*; Linn. Suppl. 306.)—Leaves ovate-oblong, toothed, plaited; somewhat heart-shaped at the base.—Sent from the Cape to Kew garden, in 1774, by Mr. Masson, with both the former. This is more caulescent than those, but more slender, and only a biennial. The leaves are nearly ovate, about an inch long. Flowers pale yellow, about an inch in diameter. Beak of the fruit two inches in length. The branches, flower-stalks, and calyx are clothed with very long spreading hairs.

4. *M. spinosa*. Thorny Monsonia. Willd. n. 5. L'Herit. Geran. t. 42.—Leaves elliptical, pointed, entire. Foot-stalks permanent, hardening into thorns.—Stem shrubby, branched, beset with thorns, which are the hardened foot-stalks of former leaves. Flowers larger than in the last.

M. tenuifolia, Willdenow's first species, is our *Grielum tenuifolium*. See GRIELUM.

MONSONIA, in *Gardening*, contains plants of the herbaceous under-shrubby biennial and perennial kinds, for the green-house, of which the species cultivated are, the fine-leaved monsonia (*M. speciosa*); the broad-leaved monsonia (*M. lobata*); the undulated monsonia (*M. ovata*.)

Method of Culture.—The first sort, as it rarely if ever ripens seeds in this climate, must be increased by cuttings of

the root, which should be planted in pots of good mould, and plunged in a tan hot-bed, watering them occasionally, when in a little time buds appear on the tops of the cuttings which are left out of the ground. They should be treated as hardy green-house plants, or be afterwards removed into separate pots, and sheltered under a good garden-frame in the winter season. And the second sort may be best raised in the same manner.

But the third sort should be raised from seeds, which must be sown in the early spring, in pots of light earth, and plunged in a mild hot-bed. When the plants are come up, they should be removed into other pots separately and be managed as the other kinds.

These afford variety among other potted plants.

MONSOON, a regular or periodical wind in the East Indies, blowing constantly the same way, during six months of the year, and the contrary way the remaining six.

In the Indian ocean, the winds are partly *general*, and blow all the year round the same way, as in the Ethiopic ocean; and partly *periodical*, *i. e.* half the year blow one way, and the other half year on the opposite points: and those points and times of shifting differ in different

parts of this ocean. These latter are what we call monsoons.

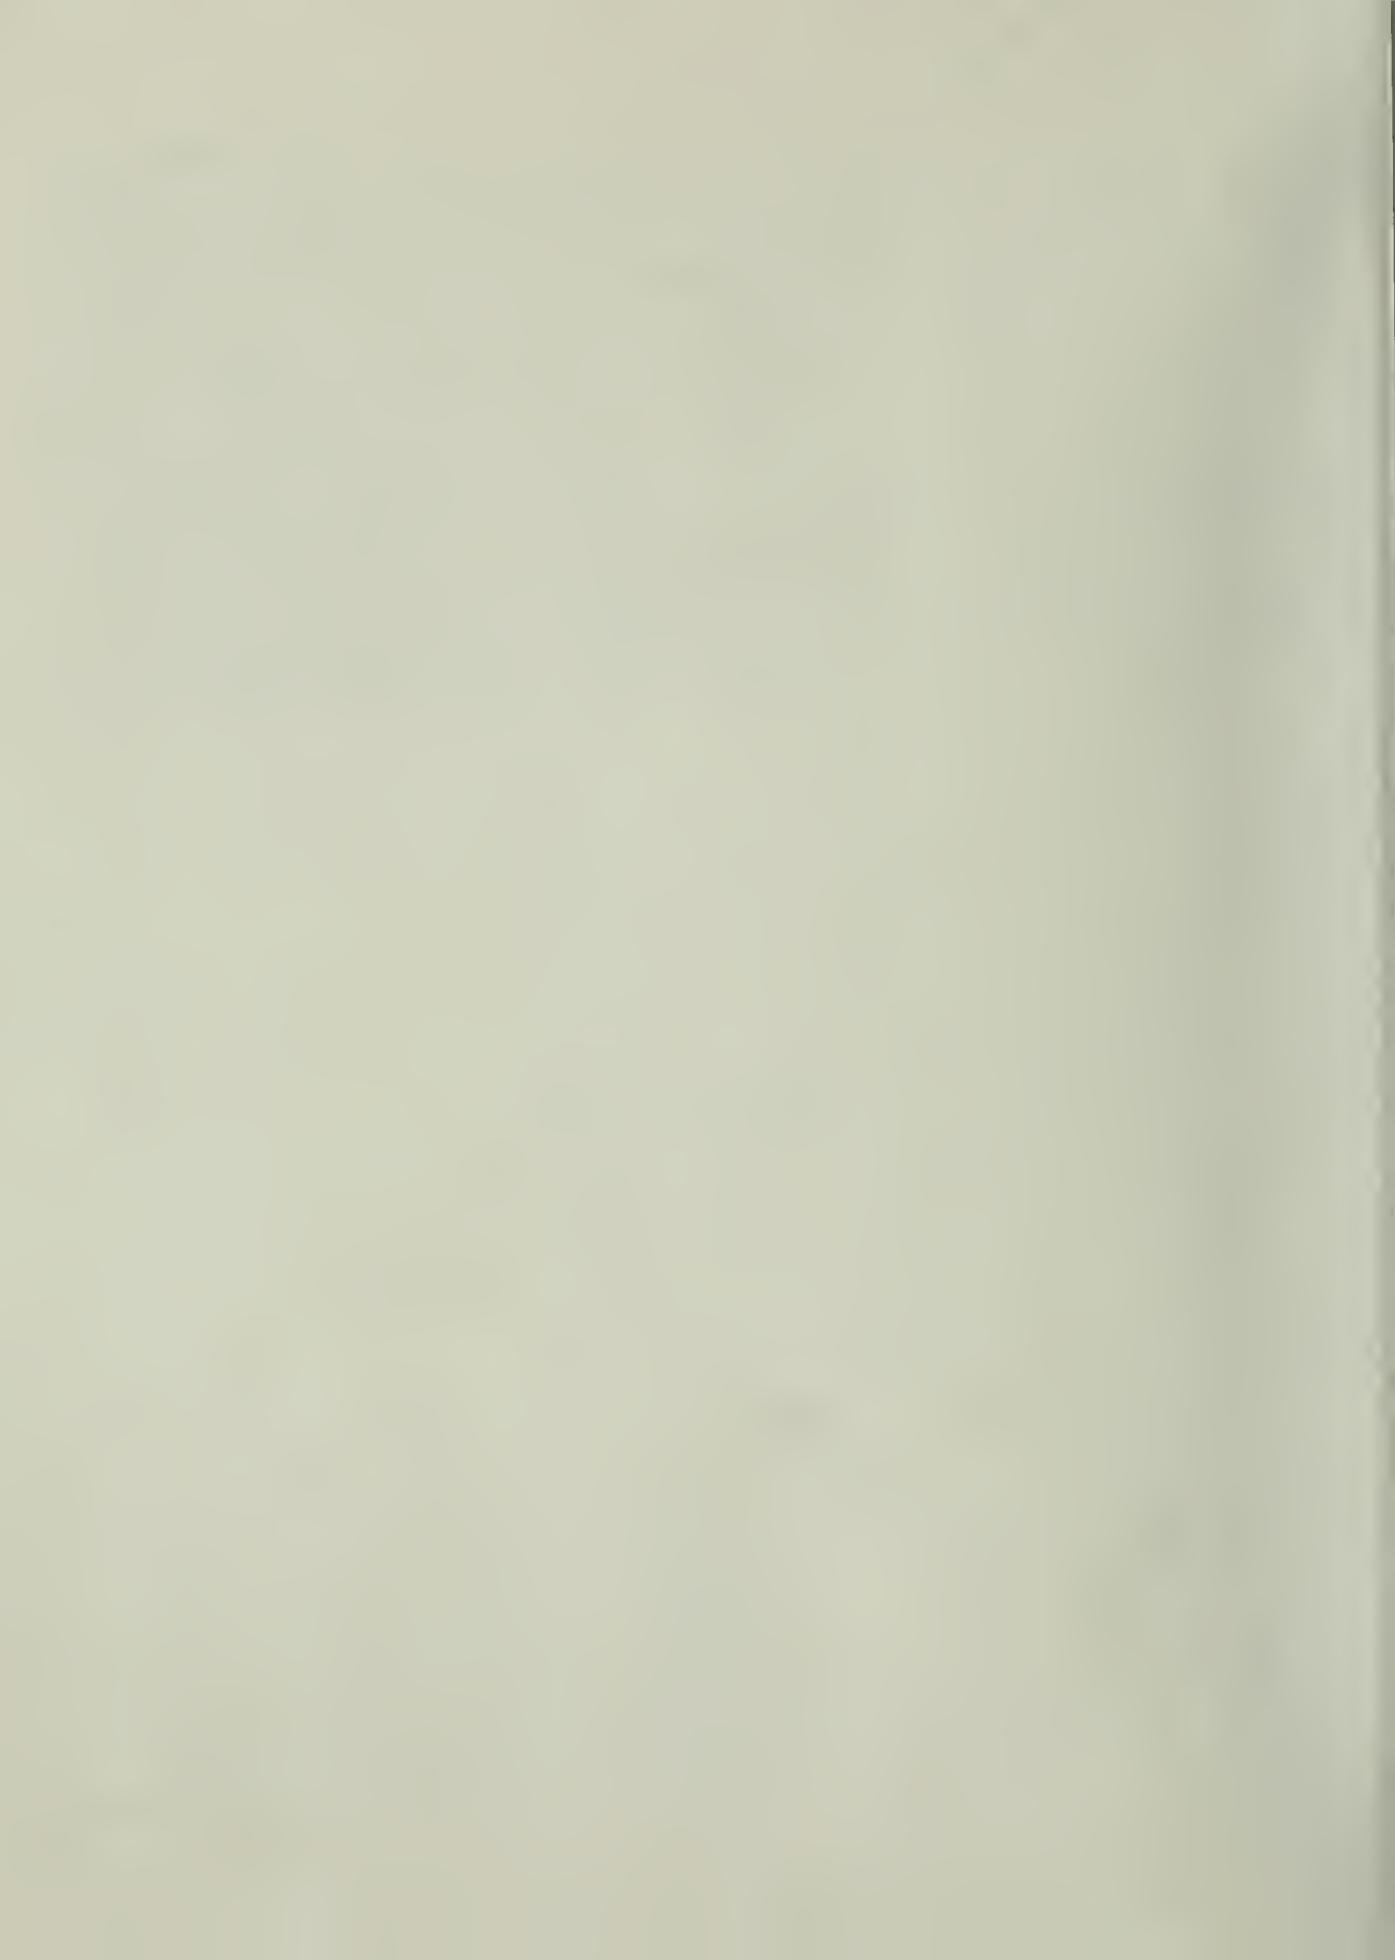

The shifting of these monsoons is not all at once: and in some places the time of the change is attended with calms, in others with variable winds, and particularly those of China, at ceasing to be westerly, are very subject to be tempestuous: and such is their violence, that they seem to be of the nature of the West India hurricanes, and render the navigation of those seas very unsafe at that time of the year. These tempests the seamen call the *breaking up of the monsoons*.

Monsoons, then, are a species of what we otherwise call *trade-winds*.

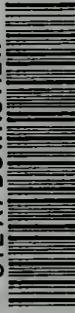

They take the denomination monsoon from an ancient pilot, who first crossed the Indian sea by means of it. Though others derive the name from a Portuguese word signifying *motion*, or change of wind, and sea.

Lucretius and Apollonius make mention of annual winds which arise every year, *etesa flabria*, which seem to be the same with what in the East Indies we now call monsoons. For the physical cause of these winds, see METEOROLOGY and WIND.
