MATTHEW.

MATTHEW, or *Gospel of St. Matthew*, a canonical book of the New Testament. The writer of this gospel, an apostle and evangelist, surnamed Levi, and son of Alphaeus, was, before his conversion to Christianity, a publican, or toll-gatherer under the Romans. He was a native of Galilee, but of what city in that country, or of what tribe of the people of Israel, we are not informed. Jesus found him at the receipt of custom, and called him to be witness of his words and works, thus conferring upon him the honourable office of an apostle. From this time he continued with Christ; and after his ascension, he was at Jerusalem, and partook of the gift of the Holy Ghost, with the other apostles. With them he bore testimony to the resurrection of Jesus; and, as we may reasonably suppose, preached for some time at Jerusalem, and in various parts of Judea, confirming his doctrine with miracles, which God enabled him to perform in the name of Jesus. Socrates, in the fifth century, says, that when the apostles went abroad to preach to the Gentiles, Thomas took Parthia for his lot, Matthew Ethiopia, and Bartholomew India; and it is now a common opinion, that Matthew died a martyr in Ethiopia, in a city called Naddabar, or Naddever; but the mode of his death is not ascertained. Others speak of his preaching and dying in Parthia or Persia; but we may infer from the diversity of these accounts, that none of them are well founded. Heraclion, a learned Valentinian, in the second century, whom Clement of Alexandria has cited, reckons Matthew among those apostles who did not die by martyrdom; nor does Clement contradict him. Chrysostom, though he mentions him with peculiar commendation, and speaks of his "coming from the presence of the council rejoicing," (see Acts, v. 41.) says nothing of his martyrdom. Hence we may infer, that there was not any tradition about it among Christians at that time, or that it was not much regarded.

VOL. XXIII.

St. Matthew is said by many to have written his gospel in Judea, at the request of the Jewish believers, when they were likely to be dispersed by persecution; and it is thought by some, as Baronius, Grotius, Vossius, Jones, Wetstein, &c. that he began it in the year 41, eight years after Christ's ascension. But according to others, as Basnage, Dr. Lardner, &c. who follow the testimony of Irenæus, this gospel was written in the time of Nero, about thirty years after our Saviour's ascension, or about the year 63; 64, or 65 of the vulgar epoch. At the year 64, or about that period, the gospel had been propagated in many Gentile countries, the times were troublesome in Judea, and the war was coming on: several of the apostles were dead, others of them, who survived, were going abroad, and many of the Jewish believers were about to seek shelter elsewhere: now, says Dr. Lardner, was a proper time to write a history of Christ, and of his miracles. Moreover in this gospel are recorded divers plain predictions of the miseries and desolations of Jerusalem, and the overthrow of the temple and the Jewish state, besides many other figurative intimations of the same things in many of our Lord's discourses and parables; which could not be well published to all the world in writing till about this time. The suitableness of St. Matthew's gospel to the state of the Christian religion, and of the Jewish people, about the year 64 or 65, leads to that time. And however unwillingly, from private apprehensions and prejudices, we may admit the thought of protracting so long the writing of the history of our Lord's ministry; the circumstances of things, says Lardner, will constrain us to acquiesce in this season as the most likely. Cave thought that it was written about the 15th year after our Saviour's ascension, in the year 48. It was written, according to the testimony of most of the ancients, as Papias, A. D. 116, Irenæus in 178, Origen in 230, Eusebius in 315, Athanasius, Cyril of Jerusalem,

B

Jerusalem,

Jerusalem, Epiphanius, Gregory Nazianzen, Jerome, Chrysostom, &c. in the Hebrew or Syro-Chaldaic language, which was then common in Judea; but the Greek version of it, which now passes for the original, is said to be as old as the apostolical times. However, many learned moderns, as Fabricius, Erasmus, Lightfoot, Calvin, Le Clerc, Beaufobre, Whitby, &c. are of opinion, that this gospel was first written in Greek, which was much used at that time throughout the whole Roman empire, and particularly in Judea: and it is alleged that Papias, who first advanced the contrary opinion, was a weak and credulous man. Jones, Bafnage, Lardner, Jortin, &c. are of this opinion. Dr. Lardner observes on this point, that if St. Matthew did not write till about thirty years after our Lord's ascension, which he thinks most probable, he would use the Greek language; but if he wrote his gospel within the space of eight years after Christ's ascension, it is most likely that he wrote in the Hebrew. He adds, farther, that there was very early a Greek gospel of St. Matthew, cited or referred to by Clement of Rome, Ignatius, Polycarp, Justin Martyr, and others, none of whom intimate that they made use of a translation: that many of the ancients do not seem to have fully believed that Matthew wrote in Hebrew, because they have shewn very little regard to the Hebrew edition of it: that there are not in our Greek gospel of St. Matthew any marks of a translation: that there is no where any probable account who translated this gospel into Greek; and besides, as the Greek gospel was translated into Hebrew in very early days of Christianity, many not examining it particularly, nor indeed being able to do it, for want of understanding the language, might imagine, that it was first written in Hebrew. Hence, according to Dr. Lardner, sprung the opinion, that Matthew published his gospel at Jerusalem, or in Judea, for the Jewish believers, and at their request, before he went abroad to other people: whereas he apprehends, that this gospel, as well as the others, were written and intended for believers of all nations; and that the Nazarene gospel was St. Matthew's gospel, translated from Greek, with the addition of some other things, taken from the other gospels, and from tradition. Allowing the date of this gospel already assigned, he cannot conceive the reason why Matthew should write in Hebrew any more than any of the other evangelists; for it may be reckoned highly probable, or even certain, that he understood Greek, before he was called by Christ to be an apostle. Whilst a publican, he would have frequent occasions both to write and speak Greek, and could not discharge his office, without understanding that language.

According to the testimony of Irenæus, all the Jewish believers in general received the gospel of St. Matthew entire, with the genealogy at the beginning: for Irenæus says expressly that Matthew "strove by all means to give to the Jews full satisfaction, that Christ was of the seed of David: wherefore he began with his genealogy." The first chapter of this gospel is quoted by Justin Martyr (A. D. 140) in his First Apology; by Tertullian (A. D. 200), who says that Matthew, "for no other reason than that we might be informed of the origin of Christ according to the flesh, began in this manner:"—"The book of the generation of Jesus Christ, the son of David, the son of Abraham." Novatus (A. D. 251) several times quotes the first chapter of this gospel. The second chapter is referred to by Ignatius (A. D. 107), and by Hegesippus (A. D. 173), whence we are led to conclude, that this part of St. Matthew's gospel was owned by this Hebrew Christian. Epiphanius, however, informs us, that the gospel of the Ebionites begins thus: "It came to pass in the days of Herod, the king of Judea,

that John came baptizing with the baptism of repentance in the river Jordan," which is the beginning of the third chapter of St. Matthew, a little altered: and he says expressly, that this gospel called according to Matthew, is "defective and corrupted." It is nevertheless plain from a passage in Hegesippus, that he received the history in the second chapter of St. Matthew; so that, as Lardner suggests, he used our Greek gospel. Or, if he used only the Hebrew edition of St. Matthew's gospel, this history must have been in it in his time. The first and second chapters of this gospel are referred to in the Sibylline oracles, a work of the second century, according to Lardner: and the second chapter is alluded to by Victorinus (A. D. 290.) Cerinthus, an early heretic, who is supposed to have lived in or near the age of the apostles, made use of the beginning of St. Matthew's gospel, and from thence endeavoured to prove, that Jesus was descended in a natural way from Joseph and Mary. These chapters, however, are of doubtful authenticity, and have been rejected by several ancient and modern writers; and the candid reader must allow that they are liable to various objections. The external testimony against them is strong; and their contents present us with difficulties that are not easily solved. It has been alleged, that though the ancients, with one consent, affirm that the gospel by St. Matthew was originally published in Hebrew or Syro-Chaldaic, some of them represent the copies of it as not having the two first chapters; and this circumstance, it is said, affords a strong presumption against their authenticity. Whether this Syro-Chaldaic or Hebrew gospel be the original copy or not, such a copy certainly existed at a very early period; and its authority must be allowed to have considerable weight in deciding this question; especially when it is considered that we have no certain references or allusions to these chapters till the days of Celsus the Epicurean, about the year 150, or later, and of Irenæus, about 178. As to this Hebrew copy, the reception of it by the Ebionites, and perhaps also by the Nazarenes, yields a strong argument in favour of its authority. Epiphanius says, that the Nazarene gospel was *πληρῆστατον*, i. e. most entire, but that the Ebionite gospel was *οὐκ ἔσω πληρῆστατον*, i. e. not altogether entire. The former, it is thought by some, was the true original copy of St. Matthew; and the latter might be, in some degree, corrupted. Irenæus, Eusebius, and Epiphanius say, that the gospel received by the Nazarenes and Ebionites was the gospel of Matthew altered in some particulars, according to their different sentiments. Dr. Lardner adopts this opinion. Dr. Mills thinks, that the Nazarenes and Ebionites had the truest copy of St. Matthew's Hebrew gospel. That this Hebrew gospel was the original of St. Matthew, and that he wrote his gospel in Hebrew, is maintained by Papias, A. D. 116, the disciple and companion of Polycarp; Irenæus, A. D. 148; Tatian, A. D. 172; Hegesippus, A. D. 173; Origen, A. D. 230; Eusebius, A. D. 315; Pantænus, A. D. 192; Cyril of Jerusalem, Epiphanius, Gregory Nazianzen, Jerome, Augustin, Chrysostom, Isidore of Seville, Theophylact, and several other orthodox writers. Nor was this fact questioned, it has been said, till of late; for Erasmus was one of the first, who, in opposition to all antiquity, asserted that Matthew wrote in Greek; and he has been followed by many ingenious moderns; such are cardinal Cajetan, Oecolampadius, Flaccius Illyricus, Calvin, Vossius, and other foreigners, and Dr. Lightfoot, Dr. Whitby, Mr. Jer. Jones, Dr. Lardner, and other English divines.

Those who allow that there was a Syro-Chaldaic gospel of St. Matthew extant in very early times, and that the Nazarenes and Ebionites believed and declared it to be the original

original of St. Matthew, are nevertheless of opinion, that this gospel was originally written in Greek. To this purpose they allege, that the present Greek copy has no mark of a translation; that the Greek was the most proper language, because it was the most universal; and that St. Matthew, who was a publican before he became an apostle, must have been acquainted with it; that if our present copy of St. Matthew's gospel be only a translation, it must be of very doubtful and precarious authority, and that it must appear to be very strange and surprising that this Syro-Chaldaic gospel should be so soon lost, if it had been the work of an apostle. But to return from this digression to the question concerning the genuineness of the two first chapters: it has been urged that these chapters were not referred to for a considerable time after St. Matthew's gospel was publicly known. It is not certain that they are referred to by any of those who are usually called the apostolical fathers, though these fathers frequently refer to other parts of the gospel. Under this class we may comprehend Barnabas, A.D. 71; Clement of Rome, A.D. 96; Hermas, A.D. 100; Polycarp, A.D. 108. Irenæus, without doubt, acknowledged both the chapters as the genuine production of St. Matthew; so do also Clement of Alexandria, A.D. 194, and Tertullian, A.D. 200; and as we descend to later periods, allusions to them more frequently occur. The first and second chapters of St. Matthew's gospel are inserted in the Syriac version of the New Testament, and this may be considered as a strong argument in favour of their authenticity. The arguments from external testimony against their authenticity may be summed up in the following epitome: we have undoubted evidence that these two chapters were wanting in some very ancient copies of this gospel, which were used by the first Christians; the Ebionites certainly omitted these chapters, and we know that the genealogy was omitted by other Christians, nor have we any reason to think that they were inserted in the Hebrew or Syro-Chaldaic copy, which all the fathers jointly affirm to have been the original of St. Matthew: it is not probable that they would have been expunged, if they had been genuine, because there was but one point, *viz.* our Saviour's birth of a virgin, by which they seemed to oppose the notions of some particular sects of Christians, and that those sects might have overcome the difficulty in a much safer way, by either reasoning, as Cerinthus actually did, from the genealogy, that Jesus was the son of Joseph and Mary; or by receiving St. Mark's gospel, and rejecting St. Matthew's altogether. The collateral arguments against the authenticity of these chapters, deduced from their contents, are such as follow: it has been agreed by many writers, that St. Mark, in most places, agrees with the method and order of both St. Matthew and St. Luke, and so doth also St. John, after a short introduction concerning the Logos. St. Mark begins his gospel at what we call the third chapter of St. Matthew; that is, at the time when John came baptizing in the wilderness. As it is most probable that St. Luke was the first who published a gospel, and as he had given the genealogy, and a full account of the birth, &c. of Christ, there was no necessity for those who came after him to repeat the same things, as they were not particularly important to the virtue and happiness of man, the great end which our Saviour and his disciples had in view. Besides, St. Luke's account of the birth of Jesus, and of all the events which followed it, till Joseph and Mary carried him home to Nazareth, which he has fully detailed, is totally different from that which is found in the first and second chapters of St. Matthew's gospel. No coincidence occurs, except in Christ's being born at Bethlehem of a virgin, and in his dwelling at Nazareth. Hence it is inferred, that

the absolute silence of St. Luke, respecting many remarkable events supposed to be related by St. Matthew, yields a strong negative argument against the authenticity of these two chapters. There is also in the contents of these chapters something peculiar both in the sentiments and language, such as does not occur in other parts of the New Testament, chap. i. 20. ii. 12, 13, 19, 22. The appearance of a star in the east, directing the wise men to the new-born Messiah, in Judea, &c., it has been said, more the air of an eastern invention than of a real history. In chap. i. v. 3. a circumstance is mentioned that is scarcely credible, *viz.* that "when Herod the king had heard these things, he was troubled, and all Jerusalem with him." Another peculiarity in these chapters is the behaviour of the Magi to the child Jesus; "they fell down and worshipped him," chap. ii. 11. Moreover, Dr. Wall observes, that the account of the genealogy in St. Matthew is the most difficult to reconcile with St. Luke, or with itself, of any place in the gospel: he adds that there are more difficulties in these two chapters than in the whole Bible besides. There are also in these two first chapters several prophecies of the Old Testament, said to be fulfilled, but which cannot easily be made to correspond with the events by which they are declared to be accomplished. (See chap. i. 22, 23. chap. ii. 6. compared with Micah. v. 2.) The slaughter of the infants at Bethlehem, though a very remarkable fact, is not mentioned by any writer but by the supposed St. Matthew in this second chapter, and by those who quote from him. To this is annexed a prophecy, cited from Jerem. xxxi. 15, &c. supposed to relate to a totally different subject. The passage cited from Hosea, xi. 1. does not seem to have the most distant reference to the Messiah. (See ACCOMMODATION.) The flight from Bethlehem seems to have been impracticable; and from Nazareth it was altogether unnecessary, because the slaughter of the infants did not extend so far.

In order to account for the interpolation of these two chapters, without impugning the authenticity of the whole gospel, those who dispute their genuineness, and maintain that the difficulties which they furnish cannot be obviated by the records of history and the aid of criticism, recur to one or other of the following hypotheses. They take for granted that the gospel was originally written in the Syro-Chaldaic language; and that when it was translated into Greek, the body of Christians had little acquaintance with the language of the original, and therefore left the translator at liberty to add, or, if he had been so disposed, to take away what he pleased, without much danger of detection. If the translator was a believing Jew, it is possible that he might think a few prophecies, cited from the Old Testament, by way of accommodation, would have considerable influence upon some of his unbelieving brethren abroad, who, having never seen the original, would naturally think that the Greek copy was, in every respect, a faithful translation of that original. Or, this interpolation might have happened without the least design. These chapters might originally be a kind of introduction to the gospel of St. Matthew, drawn up by the translator of it into Greek, and never intended by him to be considered as a part of it. When the Greek copy of the gospel was spread abroad, those who were unacquainted with the original would naturally think, that, as it was called the gospel by St. Matthew, it contained nothing but the authentic writing of that apostle; and accordingly, it might be received as such in the countries out of Judea. When Origen, Jerome, &c. perceived that these chapters were wanting in the Ebionite gospel, there was nothing unnatural in their supposing, that they were left out with design, because the Ebionites, &c. were then considered

sidered as heretics, and, of consequence, capable of any fraud or imposture. The Greek copy of St. Matthew soon gained reputation, because it was used by the generality of Christians, whereas the Syro-Chaldaic copy was used by only a few poor Jewish converts in Palestine; and these, reputed enemies to the true faith. Hence the former copy would be deemed of much greater reputation than the latter. Upon the whole it should be observed, that no doctrine, or fact in Christianity, will be affected by the omission of the first and second chapters of St. Matthew; for as to the genealogy, birth, &c. of Christ, we have, in St. Luke's gospel, a full and consistent account of them; whereas these chapters contain scarcely any thing that is not difficult and liable to objections. We do not, however, think the difficulties incapable of solution, nor the objections altogether unanswerable. Professor Michaelis, in his "Introductory Lectures, &c." states, that if these chapters had been wanting in St. Matthew's original text, they ought not to be immediately rejected as an interpolation; for they may have been a separate writing of St. Matthew, designed by him to give an account of the childhood of Christ, to which he prefixed the title *Βιβλος γενεσιαις*, and to prevent its being lost as a separate composition, the translator, as it related to the same subject, might join it to the gospel of St. Matthew. The professor acknowledges the difficulties that occur in these two chapters, but he thinks it unwarrantable to reject them on that account. See Williams's Free Enquiry, &c. first published in 1771, and republished with additions in 1789. Michaelis's Introduction to the New Testament, by Marsh, vol. iii. part 1.

MATTHEW of Westminster, in *Biography*, an ancient English chronicler, and Benedictine monk of the abbey of Westminster, flourished in the fourteenth century: he compiled a chronicle in Latin, commencing from the creation, and proceeding down to the year 1307, which was entitled "Flores Historiarum," hence its author was named "Florilegus." This work related almost entirely to English history, and is freely transcribed from Matthew Paris and others. The writer is applauded for veracity and accuracy, but bishop Nicolson holds him up as a mere compiler, without any great degree of judgment. The "Flores Historiarum," &c. was published at London in 1567, and again at Frankfort in 1601. It is divided into three books, 1. From the creation to the birth of Christ; 2. From that period to the Norman Conquest; and 3. From thence to the beginning of Edward II.'s reign. A period of seventy years was added by other hands. Gen. Bing.

MATTHEW, *St.*, in *Geography*, an island in the Atlantic ocean, discovered in 1516 by the Portuguese, who have a settlement on the island. S. lat. $1^{\circ} 45'$. W. long. $13'$.—Also, an island in the Indian sea, near the coast of Siam. N. lat. $9^{\circ} 35'$. E. long. $97^{\circ} 52'$.—Also, a river of Lower Siam, which runs into the East Indian sea, N. lat. $10^{\circ} 5'$.

MATTHEW'S Bay, *St.*, a bay in the gulf of Mexico, W. of the gulf of Campeachy.—Also, a bay called *Mattheo* bay, on the coast of Peru, in the North Pacific ocean; six leagues to the N.E. by E. from Point Galera, and five or six leagues S.S.W. from the river St. Jago, with anchorage all the way.

MATTHEW'S, *St.*, *Day*, is a festival observed on the 21st of September.

MATTHEW'S Shoals, *St.*, in *Geography*, two rocky islets surrounded with shoals, in the East Indian sea. S. lat. $5^{\circ} 14'$. E. long. $124^{\circ} 54'$.

MATTHEWS, a county of Virginia, 18 miles long and six broad, bounded W. by Gloucester, N. by Middlesex,

E. by the Chesapeake, and S. by Mobjack bay; 193 miles from Washington.

MATTHIAS, *St.*, in *Scripture History*, an apostle, who was chosen in the room of Judas. He was qualified for the office to which he was appointed, by having been a constant attendant on our blessed Lord during the course of his ministry, and was probably one of the 70 disciples. He preached in Judea and part of Ethiopia, and suffered martyrdom. The traditions, and also the gospel of Matthias, are spurious. See GOSPEL.

MATTHIAS'S Day, *St.*, a festival of the Christian church, observed on the 24th of February.

MATTHIAS, in *Biography*, emperor of Germany, son of the emperor Maximilian II. was born in 1557. When he was twenty years of age, he was invited by the revolted states of the Low Countries to take upon himself the government of those provinces, which he accepted, appointing the prince of Orange to act as his lieutenant. His power was very circumscribed, and served only to give a sort of reputation to the revolvers as their nominal head; and in 1581, through the jealousy of the house of Austria, he was honourably dismissed. In 1594, he was appointed general of the army which his brother Rodolph II., emperor of Germany, sent against the Turks. In this service he was very successful, and so well ingratiated himself with the Hungarians, that they conferred upon him the most distinguished honours, and in 1607 elected him their king, on condition that he should confirm all their privileges, and allow the Protestants the free exercise of their religion. After this he was proclaimed king of Bohemia, in prejudice to his own brother Rodolph, and was crowned at Prague in the year 1611: he had, previously to this, obliged his brother to yield him the possession of the archduchy of Austria: and on the death of Rodolph, in 1612, Matthias was elected to succeed him. Such was the rapid elevation of this prince; but soon after he succeeded to the empire, a diet was convoked at Ratisbon, at which the Protestants agreed to present a memorial to the emperor, complaining of his privy-council for interfering in various matters relative to religion, over which they, by right, had no jurisdiction, and making several demands for the purpose of securing to them an equal administration of justice. An evasive answer was given, and the Protestants declined giving supplies of men and money to the empire till their grievances were redressed. The Catholics, on the other hand, recriminated on the Protestants, and, during their contests, the Turks made an irruption into Transylvania. After a variety of fortune, in which Bethlem Gabor took a distinguished part, peace was made in 1615, by which the grand seignor restored to the house of Austria all the places in Hungary that had been conquered by his arms, and re-instated the owners of all lands that had been alienated. Matthias now resolved to curb his Protestant subjects; and took measures accordingly. The Protestants were, however, enabled to procure a convocation of the states, and sent deputies to renew their remonstrances before the council. These, being roused by the ill treatment which they experienced, could not restrain their passions, and actually threw several of the members of the council out of the window; but fortunately no lives were lost on the occasion. The count de la Tour, who was the principal actor in this business, foreseeing its probable consequences, persuaded the Protestants to take up arms in their own defence. Matthias saw he had carried matters too far, and endeavoured to reclaim them by gentle means; but they returned bold remonstrances to his declarations, and accused his prime minister, Klesel, cardinal and archbishop of Vienna, of promoting the persecutions that they

they had sustained. The Protestants of Silesia were equally discontented, and made an alliance with the Bohemians, who were now in a state of actual rebellion. This was the commencement of that thirty years war which desolated Germany, and was productive of so many great and disastrous events. Matthias was obliged to banish his ministers, and the war between the Protestants and Catholics began with various success, but in the end Bohemia remained in the power of the Protestants. Matthias died in 1619, at the age of sixty three, after a reign of seven years as emperor. He left no legitimate issue, and recommended moderation to his successor Ferdinand. Univer. Hist.

MATTHIAS CORVINUS, king of Hungary, son of the celebrated Hunyadi, was a prisoner at his father's death, together with his elder brother Ladislaus, on account of the share which the latter had in the assassination of the count de Gilles, for which he was afterwards executed. Matthias was detained in custody at Vienna, whence he was removed by a counterfeit order to Bohemia. He was still held in confinement at Prague, but upon the death of Ladislaus the Posthumous, in 1458, he was elected king of Hungary, being then about the age of eighteen. From his very early youth he had manifested a martial spirit, and had excelled in warlike exercises. He could not obtain his liberation from the hands of the governor Podzebraski, till he had paid a large ransom and married his daughter. The emperor Frederic, having got possession of the ancient crown of Hungary, refused to deliver it up, and Matthias found himself obliged to go to war for its recovery, which at length he procured by a treaty. He then marched into Bosnia, and recovered Jayeza, the capital, from the Turks, which sultan Mohomet afterwards vainly attempted to reconquer. In 1468, he made a truce with the Turks, and being at peace in his own dominions, he was induced, as well from motives of ambition, as by the persuasions of the pope, to accept the crown of Bohemia offered him by the pontiff, on condition of extirpating the heresy of the Hussites in that country. Against this harmless people, and his father-in-law, the king of Bohemia elect, he carried on a sanguinary war, which was terminated by a treaty, securing to him the crown after the death of Podzebraski. Two years afterwards, that event took place, but the Bohemians elected Uladislav, son of the king of Poland. Matthias, enraged at this proceeding, marched an army into the country, in order to compel the people to acknowledge him for their sovereign; he was however shortly recalled by a rebellion in Hungary, led on by Casimir, second son of the king of Poland, to whom the crown had been offered. Matthias stopped his progress, and, in his turn, became the aggressor. War was continued till 1475, when, by a treaty, the king of Poland kept Lusatia, and the part of Silesia bordering on Bohemia, and Matthias retained the rest of Silesia and Moravia. While engaged in these contests, the Turks were making great progress in the frontiers of Christendom: Matthias, as soon as he had leisure, turned his arms against them, and having, in a measure, attained his object, he attacked the emperor Frederic III., with whom he had a quarrel in 1478. After ravaging Austria, and laying siege to Vienna, he consented to withdraw his troops, on being paid the expences of the war, and receiving the investiture of Bohemia from the emperor, who was to renounce his title of king of Hungary. The payment being refused, and the title still retained, Matthias invaded Lower Austria, of which, together with Vienna, he made himself the complete master in 1487. He died in that city in 1490, about the fiftieth year of his age, leaving no issue but a natural son. Matthias was reckoned one of the most splendid monarchs

of his age; a man of great enterprize, and of fine military talents, liberal and magnificent, an encourager of learning and the fine arts: he was himself acquainted with a variety of languages, and was lively and pleasant in conversation. He was, however, ambitious, and so violent in his temper, as sometimes to surpass, in his resentment, the boundaries of justice and humanity, though he was at no time destitute of the generosity and magnanimity that characterize a great prince. Univer. Hist.

MATTHIAS, *St.*, in *Geography*, an island in the East Indian sea, about 90 miles in circumference. St. lat. 1 50. E. long. 144 30.

MATTHIEU, PETER, in *Biography*, was born at Pontreux, in France, of a family in humble life. He studied among the Jesuits, became principal of the college of Verdun, and was afterwards an advocate at Lyons. He attached himself to the study of the belles lettres, but was particularly partial to history, to which he chiefly devoted himself when he took up his residence at Paris. He had an intention of writing the history of Alexander, prince of Parma, but was not permitted to stay long enough in the country to accomplish his design. He was introduced to Henry IV. by the president Jeanrin, and at the death of Du Haillon was made historiographer of France. He was assiduous in collecting memoirs of every kind, relative to the times in which he lived, as well as the earlier periods of French history. He was continued in his office by Lewis XIII., and accompanied that king in his wars against the Hugonots. He died at Toulouse in 1621. His works are not reckoned among those of the first rank, but they are esteemed exceedingly useful for elucidating the periods which he treats; among these are the following; "L'Histoire des Choses memorables arrivées sous le Regne de Henri le Grand;" "Histoire de la Mort déplorable de Henri le Grand;" "Histoire de St. Louis et Louis XI.;" "Histoire de France sous François I., Henri II., François II., Charles IX., Henri III. et IV., et Louis XIII." This last was a posthumous work, and published by his son, who continued the history of Lewis XIII. to 1621. He was author of some moral verses, entitled "Quatrains sur la Vie et la Mort;" and the tragedy "La Guisarde." Moreri.

MATTHIOLA, in *Botany*, is a genus of Plumier's, named by him after Peter Andrew Matthioli, the most popular commentator on Dioscorides; see the following article. Linn. Gen. 566. Schreb. 131. Willd. Sp. Pl. v. 1. 998. Mart. Mill. Dict. v. 3. Juss. 206. Plum. Gen. 16. t. 6.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. (according to Linnæus) *Cal.* Perianth cylindrical, entire, erect, short, permanent. *Cor.* of one petal, very long, its slender tube gradually terminating in an undivided limb, waved at the margin. *Stam.* Filaments five, awl-shaped, shorter than the corolla; anthers simple. *Pist.* Germen globose, inferior; style thread-shaped, the length of the corolla; stigma thickish, blunt. *Peric.* Drupa globose, of one cell, crowned with the calyx. *Sed.* Nut globose, with a globose kernel.

Ess. Ch. Corolla tubular, superior, undivided. Calyx entire. Drupa with a globose nut.

1. *M. scabra*. Rough Matthiola. Linn. Sp. Pl. 1661. (*M. folio aspero subrotundo, fructu nigricante*; Plum. Ic. 166. t. 173. f. 2. *Rategal, arbore indiano*; Zann. It. 167. t. 75. f. 1, 2? *Guettarda scabra*; Vent. Choix de Pl. 1. t. 1.)—Gathered by Plumier in the West Indies. Ventenat says, it is a native of the Caribbee islands.

This has always been a very obscure plant. Plumier represents

presents it as a *shrub*, with scattered, obovate, entire, very rough *leaves*, the *flowers* somewhat cymose, with pinnated *bractæas*. This last character however is erroneous, as well as the same author's figure and description of the *flower*, from whence Linnæus took his generic characters. Reichard and Swartz have long ago suspected the *Matthiola* to be a *Guettarda*, and Ventenat has at length reduced it to that genus, in the new work, left unfinished at his death, entitled *Choix de Plantes*. He saw the plant in flower in the gardens at Paris, and appears to have had no doubt of its being the same as Plumier's. See GUETTARDA; to the species of which this should now be added, by the name of

G. scabra. Leaves obovate, pointed, rough; rugged above; veiny beneath. Flowers with six stamens.—The stem is as thick as that of an apple-tree, with numerous, horizontal, widely spreading branches, whose subdivisions are opposite, round, rough, with short grey hairs, and leafy at the extremity. Leaves opposite (not scattered), on short thick stalks, accompanied by a pair of awl-shaped *sipulas*. They are three inches long and above an inch broad, rough like the foliage of a fig, obovate, or somewhat elliptical, slightly wavy; dark green above; downy and whitish beneath. Flower-stalks axillary, shorter than the leaves, divided at the top into two spreading dense spikes of white, silky, short-lived, highly scented flowers, much resembling a jasmine. The *bractæas* are lanceolate and crowded, so that Plumier's figure, though not very inaccurate, easily misled Linnæus. The limb of the *corolla* is divided into six oval horizontal segments, one-third the length of its tube. *Drupa* as big as a cherry, black and bitter, its nut of from four to six cells.—This seems to be what Lamarck has figured in his t. 154. f. 3. He, like Ventenat, has properly preferred the name *Guettarda*, to the more ancient one of *Matthiola*, because of the number of species already known under the former appellation, which it would be inconvenient to call *Matthiole*. So the old *Genipa* of Plumier is rightly sunk in the modern but better known *Gardenia*. The synonym of Zannoni, quoted by Linnæus with hesitation, ought surely to be excluded. See GUETTARDA and GARDENIA.

MATTHIOLUS, or MATTIOLI, PETER ANDREW, in *Biography*, an eminent physician, and medical botanist, was born at Sienna, in Tuscany, in the year 1501, where his father practised the same profession. His early education was received at Venice; and thence he was sent to the university of Padua, for the purpose of studying the law; for which, however, he conceived an antipathy, and turned his attention to medicine. His studies were prematurely interrupted by the death of his father; but his conduct had acquired for him the good opinion of the professors, who gave him the degree of doctor before his departure from the university. He returned to Sienna, where he speedily succeeded in finding ample employment. He appears, however, to have quitted his native place subsequently, and to have gone to Rome; whence he removed, in 1527, to the court of cardinal Bernardo Clesio, prince bishop of Trent, who held him in great estimation. He resided 14 years in the valley of Anania, in the district of Trent, where he acquired the respect and affection of the inhabitants to such a degree, that on his departure, men, women, and children accompanied him on his way, calling him their father and benefactor. He next settled as public physician at Gorizia, where a singular proof of the esteem in which he was held was likewise given; when a fire having consumed all his furniture, the people flocked to him the next day, with presents of goods and money, that made him richer than before, and the magistrates advanced him a

year's salary. After a residence of twelve years at Gorizia, he accepted an invitation from Ferdinand, king of the Romans, to take the office of physician to his son, the archduke Ferdinand. He was greatly honoured at the imperial court, and in 1562 was created aulic-counsellor to the emperor Ferdinand. Afterwards Maximilian II. prevailed upon his brother to part with him, and made him his first physician. Finding, however, the weight of age pressing upon him, Matthiolus took leave of the court, and retired to a life of repose at Trent, where he soon after died of the plague, in the year 1577.

He left several works, of which the following are the titles: "Dialogus de Morbi Gallici curatione," printed in the collection of Luifinus. "Apologia versus Amatium Lusitanum," Venice, 1558. "Epistolæ Medicinalium, Libri V." Prague, 1561. "Disputatio adversus viginti Problemata Melchioris Gulandi," Ven. 1563. "Opuscula de Simplicium Medicamentorum Facultatibus secundum genera et loca," ibid. 1569; which is a compendium of vegetable materia medica. His *Epistolæ* also relate chiefly to the virtues of plants, and their mode of exhibition.

The great work, however, by which this physician acquired his fame and honour, was his commentary on the writings of Dioscorides. His first Commentaries in illustration of this ancient botanist, were printed at Venice in 1548, in the Italian language, with the title of "Il Dioscoride, con li suoi discorsi, aggiuntovi il sesto libro de gli antidoti contra tutti i veneni." It was soon twice reprinted. He afterwards published it in the Latin language, and with the addition of small cuts, in 1554, with the title of "Commentarii in sex Libros P. Dioscoridis, adjectis quamplurimis plantarum et animalium imaginibus." Numerous editions, in Latin, enlarged and improved, were afterwards given; and the work was also many times reprinted in Italian, and in French and German translations by different persons. The best edition is that of Venice, 1565, folio, with large plates. Haller remarks, when speaking of the value of this work, that while the author was deeply versed in the study of the Arabians and their followers, he too much neglected the original sources, and the examination of plants. He was, therefore, frequently imposed upon by his correspondents, and sometimes even gave fictitious representations of plants, drawn merely from the descriptions of the ancients. He did not, however, altogether neglect the examination of plants; for he discovered several in Bohemia, and the district about Gorizia, the medicinal properties of which he made the subject of experiments on malefactors. He certainly contributed much to lay the foundation of botanical science; but, as Eloy remarks, the multitude of editions and versions of his work evinces the penury of the age in botanical books. An edition of all his works was published by Caspar Bauhin, with the addition of more than three hundred figures, at Basle, in 1598, folio, which was reprinted in 1674.

Matthiolus was twice married, and left several children: one of his sons was physician to the elector of Saxony. Gen. Biog. Eloy. Haller. Bibl. Botan.

MATTIA, in *Geography*, a river of Albania, which runs into the Adriatic, S. of Alessio.

MATTIACI, in *Ancient Geography*, a people who, according to Tacitus, resembled the Batavi in their habits and manners, and who had a common origin with them. They were alike valiant, but less firm in combat. They were taken under the protection of the Romans, and are supposed to have inhabited the country now called Zealand.

MATTIACUM, a town of Germany, placed by Ptolemy between Budoris and Artaunum; supposed to be Marburg in Hesse.

MATTIG, in *Geography*, a river of Bavaria, which runs into the Inn, near Braunau.

MATTIGAY, a town of Hindoostan, in Mysore, on the Cavery, opposite to Allumbaddy.

MATTIGKOFEN, a town of Bavaria; nine miles S. of Braunau.

MATTINATELLO, a town of Naples, in Capitanata; seven miles E. of Monte St. Angelo.

MATTINS, from the Italian, *mattina*, or the French, *matin*, morning, the first part in the daily service of the Romish church.

Mattins are sometimes held early in the morning, sometimes at midnight, and sometimes the evening before; and infirm people, even in monasteries, are dispensed from attending mattins.

MATTKEM, in *Ornithology*, a common name in Germany for the *Matkultzel*.

MATTO-GROSSO, in *Geography*. See MATO-GROSSO.

MATTS, on board a *Ship*, a kind of broad, thick clouts wove out of spun-yarn, or of a variety of strands, or separate parts of a small rope, or of a number of rope-yarns, twilled into foxes; and used to preserve the main and fore-yards from galling against the masts at the ties, and at the gunnel of the loof. They also serve to keep the clew of the sail from galling there; as also to save the clews of the fore-sail from doing so at the beak-head and bolt-sprit. The longest and strongest sort of these matts are called panches.

MATT-SEE, in *Geography*, a lake in the archbishopric of Salzburg; 12 miles in circumference.—Also, a town of the same archbishopric; a see of the bishop of Passau; 12 miles N. of Salzburg.

MATTUSCHKÆA, in *Botany*, named by Schreber, in commemoration of count Mattuschka, a German botanist, who was born in the year 1734, and died in 1779. The following works rank him in the list of authors on botany. In 1776, and the following year, Mattuschka published his *Flora Silesiaca*, in 2 vols. 8vo.; and in 1779 appeared his *Enumeratio stirpium in Silesia sponte crescentium*, in 1 vol. 8vo., a sort of compendium of the other work.—Schreb. 788. Willd. Sp. Pl. v. 1. 606. Vahl. Symb. p. 3. 11. Mart. Mill. Dict. v. 3. (Perama; Aubl. Guian. 54. Juss. 109. Lamarck Illustr. t. 68.)—Class and order, *Triandria Monogynia*. Nat. Ord. *Vitices*, Juss.

Gen. Ch. *Cal.* Perianth inferior, cloven into four, ovate, acute, villose segments. *Cor.* of one petal; tube long; limb cloven into four roundish lobes. *Stam.* Filaments four, nearly equal, the length of the clefts of the limb; anthers roundish, two-celled. *Pist.* Germen superior, four-cleft, furrowed on each side; style thread-shaped; stigma simple, (Aubl.) *Peric.* none. *Seeds* two or four, very small, naked (Juss.)

Ess. Ch. Calyx in four deep segments. Corolla funnel-shaped, equally four-cleft. Seeds naked.

1. *M. hirsuta*. Willd. n. 1. (Perama hirsuta; Aubl. Guian. t. 18.)—A native of moist and sandy places at Aroura and Orapu, in Guiana, where it flowers in June or July. According to Aublet, the whole plant is completely covered with reddish or rusty hairs. *Stem* slender, branched, villose, from one to two feet high. *Leaves* opposite, sessile, ovate, villose, longitudinally ribbed. *Flowers* apitrate, terminal, yellow. *Receptacle* chaffy, with fringed scales between each flower.—Vahl's description of this plant differs somewhat from the former, for which reason we sub-

join professor Martyn's translation. " *Stem* thread-shaped, erect, frequently quite simple; hirsute, as is the whole plant, especially the calyx. *Leaves* almost like those of *Thymus serpyllum*, sessile, opposite, acute, veinless, obscurely three-nerved; the lowest smaller, approximating, ovate; the upper oblong, remote, three lines long. *Flowers* in a terminal sessile head, the size of a pea. This plant is a finger's length in height, or more, but never so gigantic as Aublet has drawn it, according to an observation of Van Rohr, an eye-witness, who gathered it in Guiana."

MATPUT, in *Geography*, a town of Persia, in Chulistan; 15 miles N.E. of El-Tih.

MATPY'S ISLAND, an island in the Pacific ocean, discovered by Capt. Carteret in 1767. S. lat. 145. E. long. 143° 2'.

MATUARO, an island near the N.E. coast of New Zealand, on the S.E. side of the Bay of Islands. S. lat. 35°. E. long. 156 28'.

MATUGUAN, a town of Peru, in the audience of Lima; 60 miles N. of Guanacavelica.

MATVIEV, an island of Russia, in the Straits of Vagatskoi. N. lat. 69 15'. E. long. 52 14'.

MATVIEVKA, a town of Russia, in the government of Ekaterinoflav, on the Bug; 40 miles N.W. of Cherson.

MATUUI, in *Ornithology*, a name given by Ray, Willughby, and Buffon, to the Brazilian spotted king-fisher of Latham, or *Alcedo maculata*. See ALCEDO.

MATUIFUI, a name given by Maregrave to the sea-lark or ringed-plover. See CHARADRIUS *Hiaticula*. See also TANTALUS *Gristus*.

MATULAM, *Hydrops ad Matulam*. See HYDROPS.

MATURA, in *Geography*, a small village and fort at the southernmost point of Ceylon; 30 miles E. of Point de Galle. (See GALLE.) The country round Matura is very wild, but well supplied with provisions of all sorts, and particularly game, which is abundant. The house for the commandant is tolerably good, agreeably situated near the river, which is broad here, and runs into the sea at a small distance. The circumjacent country abounds with elephants, and here they were principally caught for exportation. Every three or four years the elephant is hunted here, by order of government. In 1797, at one of these hunts, 176 were caught, and this was the greatest number ever known to be taken at one time. Matura is four miles distant from *DONDRE Head*; which see.

MATURA, a chain of villages of Egypt, on the right bank of the Nile; 12 miles N. of Enfeneh.

MATURANTIA, in *Medicine*, &c. *ripeners*; or such things as promote maturation; are supposed to favour the production and complete formation of pus in inflammatory humours. There are, certainly, says Dr. Cullen, means which may be employed for favouring these operations of nature; but as it cannot be admitted that any medicines are endowed with any specific powers to this purpose, the term, as applied to medicine, seems to be quite improper. See SUPPURATION.

MATURAQUE, in *Ichthyology*, the name of an American fish, of the harengiform kind, and having only one short fin on the back. It seldom grows to more than four inches long, and is somewhat flattish, but not very broad; its head is very broad, and covered with a shelly crust; it is caught in lakes, not in rivers, and is a well-tasted fish.

MATURATION OF FRUIT, in *Gardening*. See CAPRIFICATION, FORCING, and HOT-BEDS.

MATURATION, in *Pharmacy*, a preparation of fruits, or other simples, gathered before their maturity, to fit them to be eaten, or for other uses. See FRUIT, &c.

MATURU,

MATURU, in *Geography*, a town of Brazil, on the river Xingi; 45 miles S.W. of Curupa.

MATUSARUM, in *Ancient Geography*, a town of Lufitania, S.E. of Scalabis. The Itinerary of Antonine marks it upon the route from Lisbon to Emerita.

MATUSFALVA, in *Geography*, a town of Hungary; 25 miles N.E. of Cafchau.

MATY, MATTHEW, in *Biography*, a physician and man of letters, was the son of a refugee Protestant clergyman, from Beaufort in Provence, and was born at Montfort, near Utrecht, in 1718. He was originally intended for the clerical profession; but, in consequence of some mortifications which his father had received from the synod, on account of his sentiments relative to the Trinity, his attention was turned to the profession of medicine. He graduated at Leyden in 1740, and came to settle in England, his father having determined to quit Holland for ever. In 1747, he published at Leyden, "Essai sur le Caractère du Grand Medecin, ou Euloge critique de Boerhaave." Three years afterwards he began to publish at the Hague, in French, an account of the principal books printed in England, under the title of "Journal Britannique." This journal was well received, and answered the chief end which he had in view, by introducing him to the notice of some of the most respectable literary characters of the country, which he had adopted as his residence, and to whose active and uninterrupted friendship he owed the places which he afterwards obtained. At the institution of the British Museum in 1753, he was appointed an under-librarian; and at the death of Dr. Knight, in 1772, he became principal librarian to that establishment. In 1758 he was elected a fellow of the Royal Society; and in 1765, on the resignation of Dr. Birch, who soon afterwards died, and made him his executor, he was chosen secretary to that learned body. He filled these offices with great reputation, and was in general esteemed for the benevolence of his private character, and the extent of his literary information. He died in 1776. In his medical capacity, Dr. Maty was distinguished as an active and zealous promoter of the practice of inoculating the small-pox; and actually re-inoculated himself, unknown to his family, in order to disprove the supposition that it might be produced a second time in this way. He translated, in 1768, Dr. Gatti's "New Observations on Inoculation," which had been originally written by the author at his request. He had nearly completed, at the time of his death, the "Memoirs of the Earl of Chesterfield," which were finished by his son-in-law, Mr. Justamond, and prefixed to an edition of the "Miscellaneous Works" of that nobleman, in 1777. Gen. Biog. Hutchinson's Biog. Med. Anecdotes of Bowyer.

MATY, PAUL-HENRY, son of the preceding, was born in 1745. He was educated at Westminster-school, whence, in 1763, he was elected to Trinity college, Cambridge, and obtained from thence a travelling fellowship. He passed three years on the continent, after which he was appointed chaplain to lord Stormont, ambassador at the court of France. He might, from his connections, have secured preferment in the church, but scruples concerning its doctrines and ceremonies prevented him from continuing to perform the duties of a minister in it. After his father's death he retired from its service, and, in 1777, he published his reasons for this step. From this period he devoted himself to a literary life, and was almost immediately appointed assistant librarian to the British Museum; he was elected one of the under librarians, and likewise succeeded Dr. Horsley as one of the secretaries of the Royal Society. In 1782 he commenced a review of select works, English and

foreign, which he carried on almost without any assistance till 1786. He died, in the following year, at the age of forty-two. Mr. Maty published a translation of Riefbeck's travels through Germany, and translated into the French language the descriptions in the "Gemmæ Marlburienfes." After his death a volume of sermons was published for the benefit of his family: they are spirited and original compositions; but the editor, through some inadvertence, printed, as Mr. Maty's, three that had been copied from the sermons of archbishop Secker. Gen. Biog.

MATYLUS, in *Ancient Geography*, a town of Pamphylia, placed by Ptolemy between the mouth of the river Catactus and that of the river Cafer.

MATZEN, in *Geography*, a town of Austria; seven miles S. of Zillerstorff.

MATZENDORF, a town of Switzerland, in the canton of Soleure; six miles N. of Soleure.

MATZOL, a cape of Russia, at the mouth of the Ob-skaia gulf. N. lat. 72° 30'. E. long. 75° 30'.

MATZUNEA, a town of Poland, in the palatinate of Kiev; 24 miles S.W. of Kiev.

MAU, a town of the island of Ceylon; 40 miles W.N.W. of Candi.

MAVA, a river of Africa, which passes through the country of Quoja, and runs into the Atlantic near cape Monte.

MAUBAL, a town of Candahar; 65 miles N.N.E. of Candahar.

MAUBECHÉ, in *Ornithology*, a name given by Buffon to the TRINGA *Calidris*; which see.

MAUBEUGE, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Avesnes, situated on the Sambre. The place contains 4726, and the canton 14,084 inhabitants, on a territory of 205 kilometres, in 32 communes. N. lat. 50° 16'. E. long. 4° 2'.

MAUBOURGUET, a town of France, in the department of the Upper Pyrenées, and chief place of a canton, in the district of Tarbes; 15 miles N. of Tarbes. The place contains 1400, and the canton 7345 inhabitants, on a territory of 102½ kilometres, in 11 communes.

MAUCAUCO, in *Zoology*. See LEMUR and VIVERRA *Caudivolvula*.

MAUDERDALLY, in *Geography*, a town of Hindoostan, in Coimbatore; 10 miles W.N.W. of Coimbatore.

MAUDIHOCA, the cassida, or the poisonous root of which bread is made in many parts of the West Indies.

MAUDISIMILIA, in *Geography*, a town of Hindoostan, in Bahar; 35 miles S.E. of Bahar.

MAUDLIN, in *Botany*. See YARROW, and AGERATUM.

MAUDUIT, JACQUES, in *Biography*, said by M. Laborde to have been a great musician in the time of Henry IV. who accompanied wonderfully on the lute. (Essais sur la Mus. t. iii. p. 519.) We are likewise told, that he added a sixth string to viols, which had originally but five; and that he was the first in France who introduced these instruments in concert, instead of base-viols.

Père Merfenne, who had a particular regard for this musician, has given us an engraved head and eulog of him in his "Harmonie Univerfelle;" with the chief part of which we shall present our readers.

"Jaques Mauduit, descended from a noble family, was born in 1557. He had a liberal education, and travelled during his youth into Italy, where he learned the language of that country, together with Spanish and German, which, with the literature he had acquired at college, enabled him

to read the best authors of almost every kind. He had a general knowledge of most sciences as well as mechanics; and studying music with unwearied diligence without any other assistance than that of books, he rendered himself so eminent, that he was honoured, even during life, with the respectable title of *Père de la Musique*, "father of music." "And with reason," says his panegyrist, "he was the inventor of good music in France, by the many excellent works he published, both vocal and instrumental, which have been long the ornament of our concerts."

"His merit obtained him admission into the famous Academy of Music, instituted by the learned B. 1583; and many writers of his time seem to have produced their poetical effusions, in order to have them immortalized by the airs of Mauduit.

"The first composition in which he distinguished himself as a learned harmonist, was his mass of Requiem, which he set for the funeral of his friend, the celebrated poet Ronsard; it was afterwards performed at the funeral of Henry IV. and, lastly, at his own, 1627, under the direction of his son Louis Mauduit, at which ne Merfennus officiated in the sacred function as priest.

"He left behind him innumerable masses, hymns, motets, fancies, and songs. A small hereditary place at the court of requests descended to him from his father, which he seemed to exercise for no other purpose than to oblige and serve his friends. At the siege of Paris, when the Faubourg was taken by storm, he ventured through the victorious soldiers to the house of his friend Baillet, then dead, and saved all his manuscripts, at the hazard of his own life.

"Upon a similar occasion, in which there was still greater difficulty and danger, he saved the *douze moe* de Claude le Jeune, and his other manuscript works, at the time that this composer was seized at the gate of St. Denis as a Hugonot; so that all those who have since received pleasure from the productions of this excellent master, are obliged to Mauduit for their preservation, as he saved them from destruction by seizing the arm of a serjeant at the very instant that he was going to throw them into the flames; persuading the soldiery that these papers were perfectly innocent and free from Calvinistical poison, or any kind of treason against the League: and it was by his zeal and address, with the assistance of an officer of his acquaintance, that Claude escaped with his own life."

Such are the praises bestowed upon Jaques Mauduit, by his friend the learned and benign Merfennus, whose diligence, science, and candour, far surpassed his taste. The Requiem, by Mauduit, is printed in the Harm. Univ. in five separate parts; but in scoring it, neither the harmony nor modulation offer any thing that is either curious or uncommon, at any period of counterpoint. It is in literally plain counterpoint of crotchets and minims moving all together, as in our cathedral chanting. The chief merit of this production is in the exact accentuation of the words, *à l'antique*: a minim for a long syllable, and a crotchet for a short.

Merfennus, in his Commentary on Genesis has illustrated his musical remarks with many of his friend Mauduit's compositions, in which we have never been able to dig out the least fragment that would do honour to this composer or his country.

MAVEBARA, in *Geography*, a town of South America, in the province of Choco; 20 miles N. of Zitara.

MAVELAGONGUE, a river of Ceylon, which runs into the sea at Trincomalee.

MAVELICAN, a town of Hindoostan, in the Carnatic; 40 miles from Travancore.

VOL. XXIII.

MAVENHELLY, a town of Hindoostan, in the Mysore, ceded to Great Britain in 1799; 60 miles S.E. of Seringapatam.

MAUG, TUNAS, or *St. Laurence*, one of the smaller of the islands called "Ladrones," composed of three rocks, about 20 miles in circumference; 15 miles from the island of Assumption.

MAUGERVILLE, a township of Sunbury county, in the province of New Brunswick, in St. John's river, 30 miles above Belisle. N. lat. 45° 59'. W. long 66° 40'.

MAUGHOLD HEAD, a cape on the E. coast of the Isle of Man; 40 miles W.S.W. from St. Bee's Head. N. lat. 54° 18'. W. long. 3° 28'.

MAUGSEE, three small islands in the East Indian sea, between Bornes and Paraguay. N. lat. 7° 33'. E. long 117° 30'.

MAUGUIO, a town of France, in the department of the Herault, and chief place of a canton, in the district of Montpellier; six miles E. of Montpellier. The place contains 1167, and the canton 3386 inhabitants, on a territory of 160 kilometres, in five communes.

MAUHLLIA, in *Botany*. Dahl. Ohf. Bot. 25. Thunb. Prod. 60, is the same genus with the *Azapanthus* of Solander in Ait. Hort. Kew. ed. 1. v. 1. 414, the *Tulbaghia* of Heister; see AGAPANTHUS. The only genuine species is *Azapanthus umbellatus*. Curt. Mag. t. 500. Redout. Liliac. t. 6. (*Crinum africanum*; Linn. Sp. Pl. 419.) Thunberg however has added a second, by the name of *Mauhllia ensifolia*, and he is followed by Willdenow; but their plant is our *Massonia ensifolia*. See MASSONIA.

The name of *Mauhllia* was given by Dahl, (see DAILIA,) in honour of Mr. John Mauhle, who, as this author informs us, had for many years the superintendance of the Swedish mercantile affairs in China; and has, since his return, laboured, with great ardour, to promote various economical objects at home. He is said to have furnished Dahl with the sum necessary for the purchase of the Linnæan Museum; (see LINNÆUS the son,) in order that it might not go out of Sweden; and the narrator above-mentioned asserts that "the same sum of money for which it passed into foreign hands, was offered to retain it." This assertion bears hard upon the honour and patriotism of the highly respectable professor Acrel, who alone was entrusted with the sale of the collection in question, and we have his authority to say the account is incorrect. We know also that this excellent man was falsely accused of having received a bribe from the actual purchaser, because he behaved honourably and impartially in his trust; and we know moreover that he did reject with indignation an offer, from another quarter, to betray it. He had even to resist the dishonest cupidity of the heirs of the younger Linnæus, who, on receiving unlimited offers from the empress of Russia, would have left in the lurch the person with whom they were in treaty, and who did not hesitate to purchase the whole at their own price, and in their own way. S.

MAVILE, in *Geography*, a town of Hindoostan, in the circle of Cicacole; 27 miles S.W. of Cossimbotta.

MAVIS, in *Ornithology*, the common name of the song-thrush, or throistle. See TURTUS *musicus*.

MAUKS, in *Agriculture*, a provincial word applied to maggots.

MAUL, in *Rural Economy*, a provincial term signifying a beetle, mallet, &c.

MAULDAH, in *Geography*, a circle of Bengal, of a triangular form, and about 45 miles in circumference; situated between Rajamal and Dinagepour.—Also, the capital

C

of

of the said circar, which is a place of considerable trade; 52 miles N. of Moorshedabad. N. lat. $25^{\circ} 3'$. E. long. $88^{\circ} 16'$.

MAULE, a river of Chili, which runs into the Pacific ocean, S. lat. $35^{\circ} 12'$.

MAULEN, a town of Prussia, in the province of Nantangen; seven miles S.W. of Konigsberg.

MAULEON, a town of France, and chief place of a district, in the department of the Lower Pyrenées, having a castle on a rock, formerly deemed impregnable; 12 miles W. of Oleron. The place contains 1010, and the canton 12,497 inhabitants, on a territory of $317\frac{1}{2}$ kilometres, in 28 communes. N. lat. $43^{\circ} 13'$. W. long. $0^{\circ} 49'$.

MAULEON-en-Barouffe, a town of France, in the department of the Upper Pyrenées, and chief place of a canton, in the district of Bagnères; nine miles S.E. of La Barthe. The place contains 612, and the canton 6495 inhabitants, on a territory of 185 kilometres, in 25 communes.

MAULI, a river of Sicily, which runs into the sea, about eight miles S.S.W. from Ragusa. N. lat. $36^{\circ} 40'$. E. long. $13^{\circ} 45'$.

MAULIAVERAM, or SEVEN PAGODAS, a town of Hindoostan, in the Carnatic, situated on the coast; 30 miles S. of Madras.

MAULPOUR, a town of Hindoostan, in Lahore; 10 miles N. of Rahoon.

MAULSURDA, a town of Bengal; 55 miles S.S.W. of Doefa.

MAUM, in *Agriculture*, a term provincially signifying a certain dry mellow quality in land. A sort of dry fine loam.

MAUMUSSON, in *Geography*, a channel or narrow sea between the isle of Oleron and the continent of France.

MAUNCH, in *Heraldry*, the figure of an ancient sleeve of a coat, which is borne in many gentlemen's escutcheons; as in the earl of Huntingdon's.

MAUNCORE, in *Geography*, a town of Bengal; 20 miles N.W. of Burdwan.

MAUND, in our *Old Writers*, a kind of great basket or hamper, containing eight bales, or two fats; it is commonly a quantity of eight bales, of unbound books, each bale having one thousand pounds weight.

MAUND, in *Commerce*, the denomination of a weight in the East Indies. In Bengal heavy goods are weighed by the maund of 40 seers, each seer being divided into 16 chittacks. The maund of the English factory in Bengal weighs 74lb. 10 oz. $10\frac{3}{4}$ dr. avoirdupois; so that the seer is 1lb. 13 oz. $13\frac{3}{4}$ dr. and the chittack 10z. $13\frac{3}{4}$ dr. The Bengal Bazar maund is 10 per cent. heavier than the maund of the factory, and therefore weighs 82lb. 2oz. $2\frac{3}{4}$ dr. avoirdupois; and in this case, the seer is 2lb. 0 oz. $13\frac{3}{4}$ dr., and the chittack, 2oz. $0\frac{3}{4}$ dr. Grain is sold by the Khahoon of 16 foallee, which is equal to 40 maunds. Liquids are sold by the chatack of 5 ficca weight; 16 chatacks making 1 pouah, 4 pouah 1 seer, and 40 seers 1 maund. At Madras goods are sold by the candy of 20 maunds, and the maund is divided into 8 vis, 320 pollams, or 3200 pagodas. The candy of Madras is 500lb. avoirdupois. In the Jaghire, or territory belonging to the English company round Madras, and in most other parts of the Coromandel coast, the Malabar weights are used, and are as follow: the gurfay, called by the English garce, contains 20 baruays or candies; the baruay, 20 manungus or maunds; the maund 8 visay or vis, 320 pollams, or 3200 varahun; each varahun weighing $52\frac{3}{4}$ English grains; so that the visay is 3lb. 3 dr., the maund, 24lb. 2oz., the baruay, $482\frac{3}{4}$ lb., and the gurfay $9645\frac{1}{2}$ lb.

avoirdupois; 4 tons 6cwt. nearly. In corn measure, the garce is $=\frac{1}{2}$ English quarters nearly. When grain is sold by weight, $6\frac{1}{2}$ lb. are reckoned for 1 garce, being 18 candies $12\frac{1}{2}$ mds. At Bombay the commercial weight is the candy 20 maunds, the maund being subdivided into 40 seers, and the seer into 30 pice. The candy is 560lb., the maund 20., and the seer $11\frac{1}{2}$ oz. avoirdupois. Goods are likewise sold by the Surat maund, and the Pucca or Bengal mau, so that, in every contract, the particular maund, or seer, should be mentioned. A bag of rice weighs 6 mds, or 168lb. avoirdupois, and a candy is equal to 25 Winchester bushels nearly. At Calicut, on the Malabar coast the candy weight contains 20 maunds, and the maund 100pools or paloos. The maund used here by the English weighs 30lb., and the candy, 600lb. But the common weights are those of Malabar, the maund weighing 24lb. 2oz., and the candy $482\frac{1}{2}$ lb. avoirdupois. At Carwar, on the Malabar coast, the maund is 26lb. avoirdupois, and is divided into 10 seers or 1000 pice, and the candy is 20 maunds. At Cochin the maund is 27lb. $2\frac{3}{4}$ oz. avoirdupois, and the candy = 20 maunds = 543lb. 8 oz. avoirdupois. At Goa the maund contains 24 rattles, = $24\frac{3}{4}$ lb. avoirdupois, so that the candy of 20 maunds is equal to 495lb. avoirdupois. Corand rice are sold by the candy of 20 maunds, which are equal to 14 English bushels nearly. At Mangalore, the manor maund, by which goods are sold in the market, contains 46 seers, or 28lb. $2\frac{1}{4}$ oz. avoirdupois: the maund, by which the merchants buy and sell, weighs 16 rupees more, that is 28lb. $4\frac{1}{2}$ oz. avoirdupois; the baru or candy is 20 maunds. At Malulipatam the candy is 20 maunds, the maund 8 v, 40 seers, 600 neves, or 900 dabous. This maund weighs $4\frac{1}{2}$ lb. avoirdupois nearly. At Pondicherry the commercial weight is the candy of 20 maunds, or 160 vis. The maund is = 24lb. French poids de marc, or 25lb. 14oz. $5\frac{1}{4}$ dr. avoirdupois. At Scindy heavy goods are weighed by the maund of 40 seers. The cutcha or Surat maund is = 7lb. 5oz. $5\frac{3}{4}$ dr. avoirdupois, and is divided into 16 annas, or 32 pice; the Pucca maund is double the former. At Surat, the maund for weighing heavy goods is 40 seers, and the seer 30 pice: 20 Surat maunds, or 10 Pucca or Bengal factory maunds make 1 candy, or 746lb. 10oz. 10dr. avoirdupois. But these weights vary. At Tranquebar the maund weighs 68lb. Danish, or $74\frac{1}{2}$ lb. avoirdupois. At Acheen, in the isle of Sumatra, a maund of 75lb. of rice contains 21 bamboes, a bamboe being 4 and sometimes 5 cauls. Kelly's Cambist. vol. i.

MAUNDA, in *Geography*, a town of Bengal; 30 miles N.W. of Natore.

MAUNDAR, a town of Bengal; 10 miles W. of Midnapour.

MAUNDY, or MAUNDEY *Thursday, Dies Mandati*, the Thursday before Easter; so called from the French *mande*, i. e. *portula*; it being a custom on that day to give a largess or bounty to certain poor men, whose feet the king formerly washed, as a mark of humility, and in obedience to the command of Christ.

MAUNDYGAUT, in *Geography*, a town of Hindoostan, in the foubah of Delhi; 27 miles E.N.E. of Secundara.

MAUNSEE, a town of Austria, near a lake of the same name; 16 miles S.W. of Voglabruck.

MAUNSI, a river of Bengal, which falls into the Toorha, and after their confluence they assume the name of Neelcoomer, and shaping their course through Baharbund, fall with their united streams into the Berhampooter.

MAUNTRY,

MAUNTRY, a town of Hindoo tan, in Mohurbunge; 12 miles S. of Harriourpour.

MAUPERTUIS, PETER-LEWIS MOREAU DE, in *Biography*, a celebrated French mathematician and philosopher, who flourished in the eighteenth century, was born at St. Malo in the year 1698. He was privately educated till he was sixteen years of age, when he was sent to the college of La Marche, at Paris. He shortly discovered a strong inclination to mathematical pursuits, and a considerable taste for instrumental music, which he practised with success. At the age of twenty he determined on a military life, and entered among the mousquetaires, but after remaining two years in that corps, he obtained a company in a regiment of cavalry, which he held about three years. During this time he devoted all his leisure hours to scientific studies, and at length he quitted the profession of arms, and applied his mind entirely to mathematics. In 1723 he was received into the Royal Academy of Sciences, on which occasion he read his first performance, which was "A Memoir upon the Construction and Form of musical Instruments." He now paid a good deal of attention to natural philosophy, and discovered great knowledge and dexterity in observations and experiments upon animals. In 1728 he, with all the zeal of a devotee, visited the country which had given birth to Newton, of whose principles he became a zealous admirer and follower; and during his residence in London he was honoured with an admission into the Royal Society. Upon his return to France, he made an excursion to Basil, where he formed a friendship with the celebrated Bernouillis. On his return to Paris from Switzerland, he applied to his favourite studies with redoubled ardour, and enriched the transactions of the academy with a vast number of his communications, between the years 1724 and 1744. In some of these the most sublime and intricate questions in the mathematical sciences are discussed with precision, clearness, and elegance. In 1736, he was sent by Lewis XV., at the head of the French mathematicians, into Lapland, for the purpose of measuring a degree of the meridian within the polar circle, in order to determine the figure of the earth. The reputation which he acquired by this undertaking was so great, that he was admitted a member of almost every academy in Europe. In 1740 he was invited by the king of Prussia to go to Berlin, to be the president and director of the Royal Academy of Sciences and Belles Lettres in that place, which he readily accepted. When he arrived, the king was at war with the emperor, and our philosopher, whose love for his first profession of arms was not entirely effaced, determined to follow the king to the field. He was present at the battle of Molwitz; but before victory declared itself for the Prussians, his horse ran away with him into the enemy's ranks, where he was taken prisoner, and very roughly used. Being carried to Vienna, he there met with the most honourable reception from the emperor. This noble-minded prince, hearing him regret the loss of a watch by Graham, the celebrated English artist, which had been of great use to him in his experiments and astronomical observations, having another by the same maker, but enriched with diamonds, presented it to him, saying, "The hussars were only in jest with you. they have sent me your watch, and I gladly restore it to you." Notwithstanding his talents as a philosopher and mathematician, he was capable of paying well turned compliments to persons of the highest rank in life: in the course of conversation with the empress-queen, her majesty observed to him that she had heard the princess Louisa-Ulrica of Prussia was the most beautiful princess in the world. "Till this moment, madam," replied Maupertuis, "I was entirely of that opinion." He was soon after-

wards allowed to depart for Berlin, loaded with favours by the emperor and empress. From thence Maupertuis went to Paris, and in 1742 was chosen director of the Academy of Sciences: during the following year he was received into the French Academy, and was the first instance of a person being member of both the academies of Paris at the same time. After this he again assumed the character of a soldier, and was present at the siege of Fribourg, and, upon the surrender of that citadel, was appointed to carry the news of the event to the French king. In 1744 he returned to Berlin, and married a lady of great beauty and merit, to whom he was extremely attached, and his alliance with whom he considered as the most fortunate event of his life. In 1746, the king of Prussia declared our philosopher president of the Royal Academy of Sciences at Berlin, and soon afterwards honoured him with the order of Merit; and farther distinguished him with his own most intimate confidence. These accumulated honours served to stimulate him in his application to scientific researches, not only in mathematics, but in metaphysics, chemistry, botany, and polite literature. His temper was not good, and he was frequently involved in disputes with persons of distinguished talents: one of these was with Koenig, professor of philosophy at Francker, in which Voltaire took a decided part against him. Maupertuis threatened to take on him personal revenge, to which Voltaire replied by reiterating the strokes of the most ludicrous satire. The constitution of the philosopher had been long impaired by fatigues of various kinds, and particularly by the hardships which he had undergone in his Lapland expedition; but the vigour of his mind was unabated, even at a time when, from severe illness, he was incapable of taking the chair of the academy. He died in 1759, when he was about the age of sixty-one. He was author of many works, of which the following may be noticed; "An Essay on Cosmology;" "A Discourse on the different Figures of the Stars;" "Philosophical Reflections upon the Origin of Languages, and the Signification of Words;" "An Account of the Expedition to the Polar Circle, for determining the Figure of the Earth, or, the Measure of the Earth at the Polar Circle;" "Observations on the Comet of 1742;" "The Measure of a Degree of the Meridian at the Polar Circle."

MAUPHAZE-BUNDER, in *Geography*, a town of Hindoo tan, in the circar of Cicacole; 4 miles S.E. of Cicacole.

MAUPIN, LA, in *Biography*, one of the early and most extraordinary female singers in the operas of Lullu. M. Laborde has assigned, in his "Essais sur la Mus.," a piquant article to most of the favourite performers in these splendid musical dramas, with which Louis XIV. and the whole French nation were so delighted and so proud. Almost every individual of this syren troop is marked by some singularity of character, or peculiar circumstances; but none more so than La Maupin, the successor of La Rochois. She was equally fond of both sexes: fought and loved like a man, and resisted and fell like a woman. Her adventures are of a very romantic kind. Married to a young husband, who was soon obliged to absent himself from her, to enter on an office he had obtained in Provence, she ran away with a fencing-master, of whom she learned the small-sword, and became an excellent fencer, which was afterwards a useful qualification to her on several occasions. The lovers first retreated from persecution to Marseilles; but necessity soon obliged them to solicit employment there, at the opera; and, as both had by nature good voices, they were received without difficulty. But soon after this she was seized with a passion for a young person of her own sex, whom she seduced;

duced; but the object of her whimsical affection, being pursued by her friends and taken, was thrown into a convent at Avignon, where the Maupin soon followed her; and having presented herself as a novice, obtained admission. Some time after, she set fire to the convent, and, availing herself of the confusion she had occasioned, carried off her favourite. But being pursued and taken, she was condemned to the flames for contumacy; a sentence, however, which was not executed, as the young Marseillaise was found, and restored to her friends.

She then went to Paris, and made her first appearance on the opera stage in 1695, when she performed the part of Pallas, in "Cadmus," with the greatest success. The applause was so violent, that she was obliged, in her car, to take off her casque to salute and thank the public, which redoubled their marks of approbation. From that time her success was uninterrupted. Dumeni, the singer, having affronted her, she put on men's clothes, watched for him in the Place des Victoires, and insisted on his drawing his sword and fighting her; which he refusing, she caned him, and took from him his watch and snuff-box. Next day Dumeni having boasted at the opera-house, that he had defended himself against three men who attempted to rob him, she related the whole story, and produced his watch and snuff-box in proof of her having caned him for his cowardice. Thevenard was nearly treated in the same manner, and had no other way of escaping her chastisement than by publicly asking her pardon, after hiding himself at the Palais Royal during three weeks. At a ball given by Monsieur, the brother of Louis XIV., she again put on men's clothes, and having behaved impertinently to a lady, three of her friends, supposing the Maupin to be a man, called her out. She might easily have avoided the combat by discovering her sex, but she instantly drew, and killed them all three. Afterwards, returning very coolly to the ball, she told the story to Monsieur, who obtained her pardon. After other adventures, she went to Brussels, and there became the mistress of the elector of Bavaria. This prince quitting her for the countess of Arcos, sent her by the count, husband of that lady, a purse of 40,000 livres, with an order to quit Brussels. This extraordinary heroine threw the purse at the count's head, telling him, it was a recompence worthy of such a scoundrel and — as himself. After this she returned to the opera stage, which she quitted in 1705. Being at length seized with a fit of devotion, she recalled her husband, who had remained in Provence, and passed with him the last years of her life in a very pious manner, dying in 1707, at the age of thirty-four.

MAUR, in *Geography*, a town of Austria; 7 miles S. of Mauttern.

MAUR, *St.*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Chinon; 15 miles S.E. of Chinon. The place contains 2271, and the canton 8357 inhabitants, on a territory of 185 kilometres, in 12 communes.—Also, a town of France, in the department of Paris; 6 miles S.E. of Paris.

MAUR, *St.*, *Congregation of*, in *Ecclesiastical History*, a famous society of Benedictines, which was founded in the year 1620, by the express order of Gregory XV., and enriched by Urban VIII. in 1627, with several donations and privileges. This society has been distinguished by the great number of excellent rules and institutions that are observed in it, and by the regular lives and learned labours of its members. Those who have any acquaintance with the history and progress of learning in Europe, well know what signal advantages the republic of letters has derived from the establishment of this famous congregation, whose numerous

and admirable productions have cast a great light upon all the various branches of philology and belles lettres, and whose researches have taken in the whole circle of sciences, philosophy excepted. These Benedictines still maintain their literary fame, by the frequent publication of laborious and learned productions in all the various branches of sacred and profane literature.

MAURACONDA, in *Geography*, a town of Africa, in the kingdom of Burfali. N. lat. 13° 40'. W. long. 15° 25'.

MAURANDIA, in *Botany*, received its name from Dr. Ortega, the professor of botany at Madrid, in honour of the lady of Dr. Maurandy, the botanical professor at Carthage, said to be an ardent admirer and prosecutor of the same study with her husband. Cavanilles had given the generic appellation of *Ustria* to this plant, not being aware of its having been previously bestowed on another genus by Willdenow; for which reason, joined to that of complimenting the above-named lady on her botanical acquirements, Ortega was induced to change it to *Maurandya*. In the Botanical Magazine we perceive that Dr. Sims, though he has adopted the genus, is not perfectly satisfied with it, or rather that "he cannot cordially coincide with Dr. Ortega, in the propriety either of his generic or trivial name." We content ourselves with reforming his orthography. *Orteg. Hort. Matrit. dec. 2. 21. Jacq. Hort. Schoenb. v. 3. 20. Willd. Sp. Pl. v. 3. 389. (Ustria; Cavan. Ic. v. 2. 15.)*—Class and order, *Didymia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Bignonia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, cloven nearly to the base into five linear-lanceolate, acute, erect, almost equal segments. *Cor.* of one petal, two-lipped; tube shorter than the calyx; throat twice as long as the calyx, rather depressed, broad, with various furrows on each side, somewhat incurved; limb ringent, in five nearly equal, roundish, emarginate segments, two above and three below. *Stam.* Filaments four, thickened and hairy at the base, not so long as the throat of the corolla, two of them shorter; anthers oblong. *Pist.* Germen superior, ovate, with a furrow on each side; style awl-shaped, the length of the stamens; stigma simple. *Peric.* Capsule as long as the calyx, of two cells, each opening at the top with five, half-ovate, acute, reflexed valves. *Seeds* numerous, rather ovate, rough, affixed to each side of the partition.

Eff. Ch. Calyx inferior, in five deep segments. Corolla ringent; tube bell-shaped, furrowed. Capsule of two cells, opening by five teeth at their summit.

1. *M. semperflorens*. Climbing Maurandia, or Bastard Foxglove. Sims in Bot. Mag. t. 460. Jacq. Hort. Schoenb. t. 288. *Ustria scandens*; Cavan. Ic. t. 116. Andr. Bot. Repos. t. 63.

This, the only species known, is a native of Mexico, and an elegant greenhouse plant, flowering for months together in the summer. *Root* perennial, branched, sending forth numerous, annual, climbing, round, darkish, branched stems, about the thickness of a quill. *Branches* green, about three feet long, somewhat divided. *Leaves* alternate, on long twining footstalks, very numerous, spear-shaped, three, five, or seven-nerved. *Flowers* solitary, drooping, on long, twisted, axillary stalks, of a beautiful lilac, or purple and white, colour. They have great affinity to those of the Foxglove. *Seeds* oblong and black.

This truly elegant climber, which is beautifully figured in the works above quoted, from being easily propagated by cuttings as well as seeds, seems in a fair way of becoming common in our greenhouses, though said to be rather better suited to the conservatory.

MAURBACH, in *Geography* a town and chateaux of Austria; nine miles W.N.W. of Vienna.

MAURE, *Mademoiselle* CATHARINE NICOLE LE, in *Biography*, one of the last favourite singers in the French serious opera of the old school. She was born at Paris in 1704, and, according to M. Laborde, gifted with the finest voice that nature ever bestowed on a mortal. She was admitted, in 1719, only as a chorus-singer, and remained in that humble station till 1724, when she appeared in the character of Cephile, in the first part of "L'Europe Galante."

From that moment she never ceased to delight the audience, even to extacy, in every part that was assigned her. Her beautiful voice, manner of singing, and embellishments, were equally captivating. Mademoiselle le Maure, diminutive in figure, and ill made, moved on the stage with incredible dignity; she penetrated every heart so much by what she had to utter, that she drew tears from hearers the most frigid; she animated and transported them; and though she had neither beauty nor wit, she excited the most lively sensations.

She quitted the stage and returned to it several times, till 1743, after which period she never performed in public, except in the festivals given in celebration of the dauphin's first marriage, in 1745.

Her retreat was rather occasioned by caprice than fading talents; she might have remained on the stage ten years longer with her usual eclat. For after her retirement we have very frequently been present (continues M. Laborde) when she has sung and acted whole operas without appearing fatigued. The undertakers of the Colifée prevailed upon her to sing two or three times in 1771, and there never was so great a crowd assembled at a public place as she attracted to hear her. Mademoiselle le Maure continued to the end of her life superior to what might be expected from her age.

No one could dispute the perfection of her voice; and even young people, though a great change was begun in our music, found the charms of her vocal organs irresistible.

It would be an interesting inquiry to investigate the cause of that exquisite pleasure which the mere tone of a fine voice excites, without the concurrence of any reasoning faculty. Mademoiselle le Maure had no imposing figure, was neither pretty, nor gifted with superior intellects or reflections, without tale or education; yet, denied all these advantages, she had only to open her mouth, and breathe two or three sounds, to produce every effect resulting, with great difficulty, from the union of all the advantages of which she was in want. To what are we to ascribe this prodigy? It is one of those mysteries of nature which philosophy has not yet unfolded.

Mademoiselle le Maure, in 1762, was married to M. de Monbruelle; but she still remained best known, after her marriage, by her maiden name; so true it is that our place in society is determined by talents and useful faculties.

MAURE, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Rédon; 15 miles N. of Rédon. The place contains 4110, and the canton 8370 inhabitants, on a territory of 205 kilometres, in nine communes.

MAURE, *St.*, or *Leucadia*, an island in the Mediterranean sea, about 50 miles in circumference, formerly joined to the continent, but now separated from it. (See LEUCADIA.) This island produces great plenty of game, wine, oil, citrons, pomegranates, almonds, and other fruits, with fine pastures. Its inhabitants are Greeks, subject to a bishop. It had formerly three considerable towns, with a very magnificent

temple of Venus. The town which gives name to the island, contains about 6000 inhabitants; as it is situated in the water, and defended by walls and towers, it is not easy of access either by land or water. Beyond its works, in a moorass, are two well inhabited islands, or suburbs; and the little islands between this and the continent communicate by bridges. It has repeatedly changed master, being sometimes under the dominion of the Turks, and sometimes under that of the Venetians. By the treaty of Campo Formio it was ceded to France; but in 1799, it was declared one of the seven islands formed into a republic. N. lat. 39° 4'. E. long. 20° 39'.

MAUREPAS, JOHN FREDERIC PHILIPPEAUX, *Count des*, in *Biography*, a French statesman, was born in 1701, and in 1715 was appointed secretary of state; which, considering his youth, must have been a sinecure. In 1723, he was made superintendent of the marine, and, in 1738, minister of state. By the intrigues of madame Pompadour he was exiled to Bourges in 1749. He was not recalled till 1774, when Louis XVI. entrusted the public affairs to his management. He attended greatly to the marine department, and was a liberal encourager of the sciences; but the part he took in assisting America against England is a reflection on his political prudence. He died in 1781. His Memoirs, by himself, are curious, but carelessly written; they were printed at Paris in 1792, 2 vols 8vo. *Nouv. Dict. Hist.*

MAUREPAS, in *Geography*, an island on the N.E. coast of lake Superior, in Upper Canada, N.E. of Portchartrain island, about half way between Elbow island and the bay of Michipicoten; 40 miles in circumference. N. lat 47° 42'. W. long. 85° 30'.—Also, an island on the coast of cape Breton, the same as the "Isle Madame;" which see—Also, a lake in West Florida, communicating westward with the Mississippi river, through the gut of Ibberville, and eastward with lake Portchartrain; ten miles long and seven broad.

MAURIAC, a town of France, and chief place of a district, in the department of the Cantal; 18 miles N.N.W. of Aurillac. The place contains 2572, and the canton 11,337 inhabitants, on a territory of 250 kilometres, in 11 communes.

MAURICE, (MAURITIUS), in *Biography*, emperor of the East, was born, about 539, at Arabissus, in Cappadocia. He entered at an early age into the army, and was, on account of his prudence and valour, placed by the emperor Tiberius Constantine at the head of the army sent against the Persian king Hormisdas. He gained two victories over the Persians, and returning to Constantinople, was rewarded with the hand of the emperor's daughter, and the high dignity of Cæsar. At the death of Tiberius, in 582, Maurice succeeded to the throne without opposition. War was renewed with doubtful success, but in the end Hormisdas was deposed, and Chosroes, with the assistance of Maurice, was placed on the Persian throne. Peace was now restored between the two emperors, after which the arms of the emperor were turned against the Avars, a barbarian tribe on the Danube, who had made incursions into Thrace: of these it is said that 60,000 were slain, and a great number taken prisoners. The enemy, however, in the same contest, captured 12,000 of the soldiers in Maurice's army, which they put to death on the refusal of their king to pay a ransom for their lives and liberty. This and other circumstances rendered him extremely unpopular among the troops; and upon the arrival of an order for them to cross the Danube into the enemy's country, they broke out into a general mutiny, and marched back to Constantinople. The populace in that city, partaking

taking in the disaffection, rose in revolt, and assaulted the emperor with stones. He was now glad to make his escape to the Asiatic shore, whence he sent his eldest son to implore the protection and assistance of the Persian king. Phocas, a centurion, had been invested with the purple, and as the emperor quitted the capital he entered it, and was consecrated by the patriarch. Shortly after this he sent his executioners to prevent the possibility of future rivalry. They dragged the unfortunate man from his sanctuary, and having murdered five of his children before his face, slew him in the twentieth year of his reign, A.D. 602. Maurice is highly extolled by ecclesiastical historians for his piety and orthodoxy, and it is generally admitted that he was a virtuous character, possessed of very good intentions, though certainly unequal to his high station. He was well acquainted with the military art, and composed twelve books on the subject, which are still extant. They were published in 1664, at the end of the *Tactics of Arrian*. Univer. Hist. Gibbon.

MAURICE, elector of Saxony, son of Henry the Pious, of the Albertine branch of the Saxon family, was born in 1521. He came to the possession of his territories when he was about twenty years of age, at which time he was distinguished by gracefulness of person, and great dexterity in all martial exercises. He had been educated in a zealous attachment to the Protestant doctrines, yet, when the princes of that persuasion entered into the league of Smalcalde in defence of their civil and religious liberties, he refused to join in it, and attached himself to the party of Charles V. His cousin, John-Frederick, then elector of Saxony, was one of the chiefs of that league; and the unjust design of supplanting him, with the view of making himself the head of the house, was probably the spring of his conduct from his first appearance as a public character. At the diet of Worms, in 1545, he differed from his Protestant brethren, by shewing an inclination to gratify the emperor, in opening a communication with the council of Trent, and granting an aid towards the Turkish war. In the following year, when the Protestant confederacy declared war against Charles, Maurice made a secret treaty with him, by which he engaged to assist him as a faithful subject, stipulating that he should be rewarded with the dignity and territories of which his kinsman, the elector, might be despoiled. He, nevertheless, lulled the suspicions of the other party, till he actually invaded and took possession of almost the whole electorate of Saxony. For this he was branded with the names of traitor and apostate, and became the theme of the bitterest invectives from the pulpit and the press. The elector soon after recovered his dominions, and not contented with this, he seized upon a part of the hereditary possessions of Maurice. His success was short-lived, for in 1547 he lost his sovereignty and his liberty, and his antagonist Maurice was, in the same year, formally invested in the electoral dignity at the diet of Augsberg. He now entered most fully into the emperor's views, and joined him in the project to reduce the whole Germanic body to a state of subjection; nor was it doubtful that the final ruin of Protestantism was a part of his determination. Maurice, sincerely attached to his religion, and feeling his consequence as its head in Germany, resolved henceforth to appear in a character suited to his station and principles. He enforced throughout Saxony "The Interim," or temporary plan of religion, which was to continue till its final settlement, but which was highly obnoxious to the zealous Protestants. In this he was supported by Melancthon and others of the moderate party. He still professed a full adherence to his alliance with the emperor, but as his own plans approached

nearer to execution, he strengthened himself by a treaty with the French king, Henry II, the professed object of which was to restore the landgrave of Hesse to liberty, and to preserve the German constitution. At length, in March 1552, Maurice suddenly joined in Thuringia a considerable army which he had collected, and issued a manifesto containing his reasons for taking arms. The king of France added one in his own name, and both their forces began to act. Maurice now threw off the mask very completely, he advanced into Upper Germany, at every place restoring the magistrates whom the emperor had deposed, and reinstating the Protestants in the churches from which they had been ejected. By hasty marches, attended with great success, he proceeded towards Inspruck, where the emperor then was. A temporary mutiny among his troops gave that powerful monarch time to escape out of the town in a litter by torchlight, before Maurice entered it. He fled across the Alps, having first liberated the former elector of Saxony; the council of Trent broke up in confusion, and the affairs of Germany assumed a totally new face. Negotiations for peace were opened at Passau, where Maurice appeared at the head of the Protestants, and Ferdinand, king of the Romans, represented his brother the emperor. Maurice's demands were supported by the princes of the empire, as well Popish as Protestant, and the emperor found it necessary to enter into terms of accommodation. At length the "Peace of Religion," as it was called, was concluded at Passau, in August 1552, by which the landgrave was to be set at liberty, a diet was to be holden within six months for settling all religious dissensions, and in the mean time each party was to enjoy equal privileges, and the undisturbed exercise of its religion. Thus Maurice, who, by his conduct, had been suspected of apostacy from the Protestant cause, had the glory of establishing the reformation in Germany upon the solid basis on which it has ever since subsisted. After this treaty was agreed on, and signed, he accompanied Ferdinand into Hungary at the head of 20,000 men, in order to take the command of the Turks, but mutinies among the troops and dissensions between the generals prevented him from doing any thing worthy of his reputation. In the following year a confederacy was formed against Albert of Brandenburg, of which Maurice was appointed commander-in-chief, and on the ninth of June, 1553, the two armies met at Sievenhausen, when a fierce engagement ensued, which ended in Albert's total defeat. But the victors had to deplore the loss of many brave officers of distinction, among whom was Maurice himself, who, on leading a body of cavalry to a second charge, was shot in the belly with a pistol-bullet, of which wound he died two days after, in the thirty-second year of his age, and the sixth from his possession of the electoral dignity. Univer. Hist. Robertson.

MAURICE of Nassau, son of William prince of Orange, by his second wife Ann, daughter of the preceding Maurice of Saxony, was about eighteen years of age, and a student in the university of Leyden, at the time of his father's assassination in 1584. Upon that fatal event he was appointed by the states of Holland and Zealand their stadtholder and captain-general, and soon after he took his post as an antagonist of the prince of Parma, the most celebrated general of that age. In 1590 he made himself master of Breda; and in the following year, being created stadtholder of Guelderland, he took several important places, ending with Nimeguen, by which he acquired a very high degree of popularity and fame. In 1593 he captured the strong fortress of Gertruydenberg, which raised him to a parity with the ablest generals of the time, and he appeared to unite with vigour and enterprize of youth all the caution

and vigilance that are usually the result of age and experience. Attempts were made to take away his life, but they were unsuccessful, and he continued for many years in an uninterrupted course of military transactions, and gradually recovered almost all the places within the seven provinces which had been taken by the Spaniards. He gained the memorable battle of Nieuport against the archduke Albert. Several towns fell into his hands in consequence of this success, though he ever after reflected upon himself for putting his country to such a risk as was incurred by this action. After the death of the prince of Parma, Maurice had next Spinola for his antagonist. Every stratagem of war was exhausted in the campaigns between these two masters of the military art, who balanced each other's success. The Spaniards now began to be tired of war, and negotiations were entered upon for a peace, but Maurice threw obstacles in the way of an accommodation, while, on the other hand, the constitutional republicans, at the head of whom was the grand pensioner of Holland, Barneveldt, were on that account the more solicitous to promote it, and in the end they carried their point, and a truce for twelve years was concluded in April, 1609. From this period Maurice appears chiefly in the less respectable light of head of a party, and aiming at a degree of power and influence not at all compatible with a free constitution. Religious disputes succeeded the external tranquility of Holland: these gave Maurice a pretext to interpose with a strong hand, by virtue of his office as stadtholder. The Arminian doctrine was embraced by Barneveldt, Grotius, and many other illustrious characters, who united sentiments of religious liberty with republican politics. These, however, were the smaller number, and Maurice threw all his influence into the scale of their enemies, who would not acquiesce in a proposal for an equal toleration of Calvinists and Arminians: they demanded a national synod to settle their disputes, not doubting that their party would be found to be the majority. To this proposal Maurice lent his assistance, and at length, in 1618, the famous synod of Dordrecht or Dort was assembled. The result of its deliberations was the absolute condemnation of the doctrines of Arminius, and of those who held them. Maurice now exhibited in his own conduct and character the traits of a vile and infamous persecutor, for every man who lifts his arm against the rights of conscience ought, in right, to be held up as infamous: he ordered the apprehension of Barneveldt, Grotius, Hoogenberts, and other heads of that party, who were imprisoned in the castle of Louvenstein. Barneveldt was brought to trial, and though innocent of the charges exhibited against him, was condemned to death by a pusillanimous and iniquitous court, and no intercessions could avert the fate of one whom the prince was so much interested to remove. He died a martyr to his principles, and his death not only fixed an indelible stain on the memory of this prince, but greatly injured his popularity, as soon as the nation became cool enough to estimate the man they had lost. The truce between Spain and Holland expired in 1621, and a renewal of war followed, but Maurice's military transactions were not now remarkable; they were thought to denote the languor of broken spirits and declining health. A conspiracy was formed against his life by the younger son of Barneveldt, joined by some zealous Arminians: it was, however, discovered, and the leaders in it executed. Maurice died at the Hague in 1625, in the fifty-eighth year of his age. He had spent the greater part of his life in the service of his country, of which he was, notwithstanding his defects, considered the preserver, and was unquestionably the greatest statesman and warrior of the period in which he flourished.

Vigilant, indefatigable, penetrating, cautious, and sagacious, he united all the qualities of a general and a hero with the knowledge of a scholar. Ambition, said to be the weakness of a great mind, was his only foible; this rendered him dangerous to that liberty which he had before nobly asserted. There was no part of the science of war with which he was not thoroughly acquainted, but he particularly excelled in the art of fortification, and in the selection of strong posts. He cultivated a taste for the fine arts, and his temper and talents were calculated to support a tottering cause and render it triumphant, and he has been regarded as one of the founders of Batavian independence. Univer. Hist.

MAURICE, or *Morris*, in *Geography*, a river of New Jersey, which runs southerly through Cumberland county, into Delaware bay; navigable for vessels of 100 tons ten miles, and for smaller craft considerably further.

MAURICE Bay, St., a bay on the W. side of cape Farewell island, or south extremity of East Greenland, and the principal harbour of that sea.—Also, a bay on the S. coast of the island of Java. N. lat. 7° 38'. E. long. 109° 3'.

MAURICE Port, a small cove, which has anchorage before it, in 12 fathoms, about half a mile from the shore, over coral rocks, on the E. coast of Terra del Fuego island, on the W. shore of Le Maire straits, between that island and Staten Land, on the E. and N. of the bay of Good Success.

MAURICE, St., a town of Switzerland, in the Vallais, situated between the two chains of mountains that bound this country in their approach towards the Rhone. The town is built almost totally upon the rock, at the foot of steep mountains, and at a small distance from the river. This was anciently called "Agaunum;" and the name of St. Maurice is derived from an abbey erected in the beginning of the sixth century, by Sigismund, king of Burgundy, in honour of a saint who is supposed to have suffered martyrdom in this place: he was, as tradition says, the leader of the famous Theban legion, reported to have been massacred by the order of Maximin, for not renouncing Christianity. A few Roman inscriptions, chiefly sepulchral, and two defaced columns, are the only incontrovertible remains of the antiquity of St. Maurice. It is principally distinguished as being the chief entrance from the canton of Bern into the Vallais. This entrance is formed by a narrow pass, so strongly fortified by nature, that a small number of men might defend it against a considerable army. The stone bridge over the Rhone is much admired for its bold projection; it is of a single arch, and the span is 130 feet. The pass just mentioned is a great thoroughfare for all goods and persons from the lake of Geneva, through the country of Vallais, and over mount St Bernard; 35 miles E. of Geneva. N. lat. 46° 15'. E. long. 6° 52'.—Also, a town of Canada, on a river of the same name; 9 miles N.W. of Trois Rivieres.—Also, a town of France, in the department of Mont Blanc; 11 miles N.N.W. of Chambery, and another in the same department; 24 miles W. of Aosta.—Also, a town of France, in the department of the Orne; 12 miles N.E. of Murtagne.

MAURICE, St., and *St. Lazarus*, an order of knights in Savoy. The order of St. Maurice was instituted in 1440, by Amadeus VII. duke of Savoy, who was afterwards pope, by the name of Felix V. He assigned for its badge a cross pomettée, made either of white taffeta, or of white linen cloth, placed on the knight's breast. In the year 1572 Philibert, duke of Savoy, being made grand-master of the order of St. Lazarus, which, in 1565, had been renewed in Savoy by pope Pius IV., obtained permission from Gregory, then pope,

pope, for the union of the two orders; ever since which time they have been styled the order of St. Maurice and Lazarus. When this union was effected, the badge was a cross pommée argent, upon a cross of eight points vert; being the respective badges of the two orders before they were united, and to be worn pendent to a green ribband.

MAURICEAU, FRANCIS, in *Biography*, a surgeon, eminent in the practice of midwifery, was born at Paris, where he applied, with great industry, to the study and practice of surgery, for many years, especially in the great hospital of that city, the Hôtel-Dieu. He had already acquired there so much experience in the obstetrical department of practice, before he commenced public practice, that he rose almost at once to the head of his profession. His reputation was farther increased by his writings, and maintained by his prudent conduct and acknowledged skill during a series of years; after which he quitted practice entirely, and retired into the country, where he died, in October 1709. He published the following works, all relative to the particular branch of the art which he practised; they contain a great store of useful facts, though ill arranged, and mixed with false reasoning peculiar to his time. 1. "Traité des Maladies des Femmes grosses, et de celles qui sont accouchées," Paris 1688, in 4to. which has been often reprinted, and translated into Latin, as well as into most of the modern European languages. 2. "Aphorismes touchant l'Accouchement, la Grossesse, et les Maladies des Femmes," *ibid.* 1694, which contains a summary of the doctrines of his larger work. 3. "Observations sur la Grossesse et l'Accouchement des Femmes, et sur leurs Maladies, et celles des Enfants nouveaux nés," *ibid.* 1695, 4to. This may be considered as a second volume of the first treatise, and contains a great number of cases and observations, in illustration of the doctrine there stated. 4. "Dernières Observations sur les Maladies des Femmes grosses et accouchées," 4to. *ibid.* 1708; which contains an additional collection of cases. The whole of these works were collected, and reprinted together, after his death, in 1712, and subsequently with figures. *Eloy. Dict. Hist. Gen. Biog.*

MAURIENNE, or MORIENNE, *County of*, in *Geography*, was lately a province of Savoy, consisting of a long narrow valley; it now belongs to France, and is included in the department of Mont Blanc.

MAURIPIDA, one of the Laccadive islands. N. lat. $10^{\circ} 58'$. E. long. $72^{\circ} 21'$.

MAURITANIA, MAURETANIA, or, as it is called by Strabo, *Maurusia*, in *Ancient Geography*, a considerable part of the northern region of Africa, extending from Numidia towards the east to the Atlantic ocean on the west. Mauritania Propria, or Tingitania, considered as unconnected with Mauritania Cæsariensis, was bounded on the E. by the river Malva or Mulucha; on the W. by the Atlantic ocean; on the S. by Gætulia or Libya interior; and on the N. by the Mediterranean. This kingdom, being reduced to the form of a Roman province in the reign of Claudius, was denominated by that prince Mauritania Tingitana; and it was called by the Romans at that time, as well as afterwards, Tingitana, from its principal city Tingi or Tingis, and thus distinguished from Mauritania Cæsariensis. The Tingitania of the ancients very nearly corresponds to the kingdoms of Fez and Morocco. As to the extent of Mauritania properly so called, it may be estimated by considering that the Malva or Mullooiah, its eastern limit, about $1^{\circ} 15'$ W. of London, is rather more than 240 miles distant from the Atlantic ocean. Some modern geographers make the kingdom of Fez to be 270 miles long, and that of Morocco, from cape Non to the mountains which divide it from Segelmessa above 370; but

this computation, with respect to the ancient Tingitania, is, without doubt, more erroneous than that of Pliny, which amounts only to 170 miles.

Mauritania and Maurusia, the names of this country, are derived from the Mauri, an ancient people who inhabited it; and Bochart considers Maurus as equivalent to Mahar; or as an elision of gutturals is very common in the Oriental language, Maur, *i. e.* one from the west, or an occidentality, Mauritania being west of Carthage and Phœnicia. As to the origin and general history of the Mauritians, we may direct our attention to three principal epochs. 1. The period during which the first population, derived from Mizraim by his sons and grandsons, extended from the E. to the W. 2. That in which the Canaanites, expelled from Palestine by Joshua, traversed sea and land to escape from his victorious and destructive arms, established themselves along the coasts of Africa, and partly in the interior of the country. To this purpose Procopius says, that in his time two pillars of stone were to be seen in this country, with the following inscription in the Phœnician language and character upon them: "We are the Canaanites who fled from Joshua, the son of Nun, that notorious robber." 3. The time when the Phœnicians, impelled by the activity of their commercial spirit, formed upon these coasts considerable establishments. We might also mention an influx of Arabians, who came here from Arabia Felix, in the first century of the Christian era, and the invasion of the Mahometan Arabs, in the seventh and eighth centuries. This country, it is well known, bore the name of Barbary, of which there are several derivations. To those that occur under BARBARY, we shall here add, that the name may be formed from the oriental "Bar-Barca," or the sea of Barca, a town of the Pentapolis, called afterwards Ptolemais.

The Mauritians, according to Ptolemy, were divided into several cantons or tribes, which it is needless for us now to enumerate. The metropolis of Tingitania was Tingis or Tingi; which see. Some of its other principal towns were, Zelis, supposed by some to be the modern Arzilla:—Lixus, the residence of Antæus, who was here vanquished by Hercules, and not far from the gardens of the Hesperides; conjectured to be the present Larache:—the city of Hanno, called Thymiatæon:—Sala, near a river of the same name, not far from the Atlantic ocean:—the port and town of Rutubis, 213 miles S. of Lixus:—the Exilissa of Ptolemy, supposed to be the Ceuta of the moderns:—Rufadir, presumed to be Melila or Melilla; and in the interior of the country, the Asecum of Hirtius:—Herpis:—Volubilis, supposed to be the modern Fez:—Gilda, corresponding to Mequinez:—Prisciana:—the Tocolosida of Ptolemy, perhaps the modern Amergue; the Trifidis of Ptolemy:—Gontiana, answering to a small town between Fez and Mequinez, called Gamaa:—Banafa:—Chalee:—Calamintha, &c. &c. Among the rivers of Tingitania we may mention the Malva, Molochath, Mulucha, or Mullooiah; the Thaluda, Taluda, or Tamuda; the Lixus; the Subur; the Sa'a, &c. &c. The chief capes or promontories of Tingitania were, the Metagonitis of Ptolemy, and Metagonium of Strabo; the Sætiarum promontorium of Ptolemy, or the Russadi of the Itinerary; the promontorium Oleastrum; the Phœbi promontorium; the cape Cottes or Ampelusia, now cape Spartel; Mons Solis; promontorium Herulis; and Usadium. Among the principal mountains we may rank Abyla or Abyla or Abenna, called by the ancients one of Hercules's pillars, and by our countrymen Apes hill; the Septem fratres of Mela, or Heptadelphoi of Ptolemy, near Abyla; mount Cotta not far from the Lixus; and mount Atlas. The chief ports of this country were Rufadir, Sinus Emporieus, Cotta,

MAURITANIA.

Cotta, Rutubis, and Mysocaras. The principal islands on the coast of Tingitania were the *Trea Insule* of the Itinerary, N.W. of the *Mulucha*; *Gezira* or *Jezeirah*, in the river *Lixus*, about three leagues from the sea, where the ancients placed the *Hesperides*; *Ptolemy's Porne* and *Erythia*, two obscure islands in the Atlantic; the latter of which is now called *Mogador*; the *Insule Purpuraria*, said by *Hardouin* to be *Madeira* and *Porto Santo*; and the *Insule Beata*, or *Fortunate islands*, of which some reckoned ten, others seven, and others three.

The government of Mauritania, from the earliest ages, is said to have been an absolute monarchy. However *Appian* says, that several tribes of Moors were governed by their own laws, or at least under the direction of their own chiefs and leaders, in opposition to that form of government which was established in the greater part of this country. The independent Arabs, mentioned by *Dr. Shaw* in his *Travels*, who are seated in the kingdom of *Algiers* and *Tunis*, and who sometimes hover about the frontiers of *Morocco*, may probably be the posterity of these free-born Moors. Whether this be allowed or not, most of the provinces of Mauritania, if not the whole country, were subject to one prince in the reign of the elder *Dionysius*. It appears also from *Justin* and *Appian*, that at subsequent periods they had sovereigns, but it is likely that they exercised their sovereign authority according to fixed laws, or certain political maxims, which directed the conduct of their rulers.

As to their religion, *Neptune* was one of the principal objects of their adoration. They likewise paid religious honours to the sun and moon, in common with the other *Libyan* nations. *Seneca* asserts that they offered human sacrifices to their gods, in imitation of the *Phœnicians* and *Carthaginians*, or some other ancient people, from whom they derived their origin. *Bacchus* was also worshipped by the Mauritians; and, in short, we may form a notion of their religion from that of the *Egyptians*, *Phœnicians*, *Persians*, and *Carthaginians*. Their language and character scarcely differed from those of the *Numidians*. As to their customs and habits, they at first used only clubs in their military conflicts, till they were taught the use of the sword. All persons of distinction were clad in rich apparel, ornamented with gold and silver, and they took great pains in curling their hair, curiously and elegantly, cleansing their teeth, combing their beards, which were long, and paring their nails. In time of action the Mauritanian infantry used shields made of elephants' skins, and they were clad, both night and day, in those of lions, leopards, and bears. The cavalry were armed with broad short lances, and carried targets or bucklers, made of the skins of wild beasts. They used no saddles. Their horses were small and swift, and so much under command, that they would follow them like dogs. *Herodotus* intimates, that the shield and helmet came from them to the *Greeks*. Notwithstanding the fertility of their soil, the poorer Mauritians never attended to agriculture, but roved about the country in a wild savage manner, like the ancient *Scythians* or *Arabian Scenites*. They lived in small and inconvenient tents; their food was corn and herbage, which they frequently ate green, and without any preparation; their habit was the same in summer and winter, and consisted of a tattered, though thick, garment, covered with a coarse rough tunic; they reposed on the ground, sometimes spreading their garments under them, as the *African Kabyles* and *Arabs* now do. According to a passage in *Horace*, they shot poisoned arrows; in preparing and using which they were skilful, having acquired the art from self-defence against the wild beasts, to which they were ex-

posed. With regard to the arts and sciences, the Mauritians were rude and barbarous; but if they excelled in any art, it must have been in navigation. 'Tis magic, sorcery, and divination, they were much addicted. *Strabo* differs from *Mela* in his description of *Tingitania*; for he represents it, not as poor and despicable, but as an opulent kingdom.

The history of the Mauritians presents to our notice nothing remarkable, except the defeat of *Antæus*, till the Roman times. *Sallust* informs us that nothing of the Mauri, except their name, was known to the Romans so late as the *Jugurthine* war; and the most ancient Greek writers considered them merely as a branch of the *Libyans*. *Bogud*, king of Mauritania, who was contemporary with *Julius Cæsar*, contributed very much to his great success in Africa, and he assisted him also in Spain. After *Cæsar's* death, he joined *Antony* against *Octavius*, but when he attempted to make a diversion in Spain, in favour of the former, the *Tingitians* revolted, and being supported by *Bocchus's* troops in the interest of *Octavius*, *Bocchus* succeeded and was put in possession of *Tingitania*, and *Octavius* granted to the inhabitants of *Tingis* the privileges of Roman citizens. After *Bocchus's* death, *Tingitania* was reduced to the form of a Roman province. *Augustus* gave the younger *Juba* the two *Mauritanias*, together with part of *Gætulia*, some time after his marriage with the younger *Cleopatra*, instead of his father's kingdom, *i. e.* *Numidia*, which still remained a Roman province. The Mauritians, however, did not quietly submit to the Roman yoke. At the commencement of the reign of *Tiberius*, *Tarfarius*, a Numidian soldier, enterprising and courageous, famed among the Romans in the art of war, entered into a confederacy with some discontented Moors, and refused to acknowledge the authority of Rome. *Tarfarius* was defeated by the proconsul *Cornelius Dolabella*. In this war *Ptolemy*, the son of *Juba II.* and grandson of *Juba I.* rendered very considerable assistance to the Romans. However, he was put to death under *Caligula*. *Eudemon*, his freedman, raised an army in order to avenge his death. *Claudius*, who succeeded *Caligula*, sent an army against the Moors, and they were completely defeated.

In consequence of a treaty of peace between the two commanders, Mauritania was delivered entirely into the hands of the Romans; for we find it soon after divided into two provinces, the one called *Tingitania*, or *Mauritania Tingitana*, from the city *Tingis*, and the other *Mauritania Cæsariensis*, from *Cæsar*, a surname which *Claudius* had in common with the other Roman emperors.

The Mauritians, being completely subjected to the Romans, returned to their customary occupations, and having abandoned a military life, devoted themselves to the care of their lands, herds, and flocks. But the dissensions that occurred on occasion of the pretensions of *Otho* and *Vitellius* to the empire, put them again in motion. Under the immediately succeeding reigns nothing very material occurred; but under the empire of *Diocletian*, they engaged in a contest with *Maximin*, his associate in the empire. In this conflict they were great sufferers; being obliged to deliver up their arms and to abandon their country. After the abdication of *Diocletian*, they were involved in new troubles. The troops of Africa revolted and proclaimed *Alexander* their lieutenant; upon which they were attacked and defeated by *Maxentius*.

Constantine, after his accession, granted singular privileges to the African churches, which soon became very numerous. But when the seat of government was transferred to *Byzantium* by *Constantine*, the distant provinces were abandoned to the

oppression of their governors. The Mauritians suffered, and their country was once and again the scene of tumult and of war. When the Vandals were destroyed in Africa under the reign of Justinian, by the activity of Belisarius, the Mauritians found themselves exposed to the tyranny and oppression of Greek prefects. The people revolted; and at length, under the empire of Heraclius, the caliphs having conquered Egypt and Syria, sent an army on their coast. The whole country, as far as the columns of Hercules, submitted to their domination, under which it has more or less continued. See MOORS.

MAURITANIA *Cæsariensis*, or *Cæsariana*, a part of Mauritania so denominated under the reign of Claudius. This province had been separated from Numidia: it extended from Mauritania Tingitana, from which it was separated by the river Malva on the west as far as the Ampsagee. See NUMIDIA.

MAURITANIA *Sitifensis*, a part of Mauritania *Cæsariensis* on the eastern side, adjacent to Numidia, so called from Sitifi, a town in that territory.

MAURITIA, in *Botany*, a Palm so named by the younger Linnæus, after the appellation by which it is known to the Dutch settlers in Surinam, *Mauritii-Boom*, or Maurice tree. Whether this appellation originated in any compliment to the memory of their great prince Maurice, or of any other person of the same name, or whether the tree were thought to have been brought from the island of Mauritius, we are not informed.—Linn. Suppl. 70. Schreb. 779. Mart. Mill. Dict. v. 3. Juss. 40. Lamarck Dict. v. 3. 739.—Class and order, *Dioecia? Hexandria*. Nat. Ord. *Palme*.

Gen. Ch. Male an oblong sessile *catkin*, covered entirely with closely crowded flowers, having obtuse scales between them. *Cal.* Perianth of one leaf; cup-shaped, abrupt, entire, triangular, short. *Cor.* of one petal; tube short, the length of the calyx, with three sutures, by which the divisions of the limb are easily continued down to the base; limb in three deep, equal, slightly spreading, lanceolate, obtuse, channelled, rigid, and almost woody, segments. *Stam.* Filaments six, thick and very short, inserted into the mouth of the tube; anthers linear, angular, the length of the corolla, three of them spreading horizontally between its segments, the alternate three erect, closely pressed to the channel of each segment.

Female unknown.

Eff. Ch. Male an oblong sessile *catkin*. Calyx of one leaf, cup-shaped, undivided. Corolla of one petal, with a short tube, and three-cleft limb.

1. *M. flexuosa*. Linn. Suppl. 454. Syst. Veg. ed. 14. 986.—Sent, from the woods of Surinam, by Dalberg, being a part of the botanical collection, preserved in spirits of wine, which king Gustavus III. of Sweden presented to Linnæus. (See GUSTAVIA.) It is described as a nearly leafless tree, with angular, zigzag, smooth branches, composed of short joints swelling upwards and somewhat recurved, each joint terminating in a cup-like, doubly-pointed sheath. From these sheaths, over the whole stem, spring solitary sessile *catkins*, of an ovate-oblong cylindrical figure, rather above an inch in length, widely spreading in two ranks, each having at its base a pair of larger erect falcate scales. The flowers are of a rusty hue, at least in the preserved specimens, and closely cover the whole *catkin*, standing at a right angle with its common stalk. The scales which separate the flowers are round and obtuse, smaller than the pair at the bottom of the *catkin*. The flowers fall when faded, leaving the *catkin* and its scales permanent. Linnæus

justly speaks of this tree as very singular, being almost destitute of foliage, and laments that he knew nothing of the female flowers or fruit. These are presumed to be borne on a distinct individual.

MAURITIA, in *Gardening*, comprehends a plant of the exotic tree kind, of which the species cultivated is the maidenhair tree, or ginkgo, (*M. flexuosa*.)

Method of Culture.—It may be increased by laying down the young branches in the summer season, and when they have stricken root fully, taking them off and planting them with earth about their roots in pots filled with light fresh mould, placing them in the greenhouse, where they must be kept.

And the cuttings of the young shoots may also be planted in pots in the same manner, plunging them in a moderate hot-bed till they have stricken root, when they may be managed as the other plants are directed to be.

This plant affords variety in the greenhouse, and when trained against walls; but in the last case must be sheltered by mats, in severe weather in the winter season.

MAURITIO, ST., in *Geography*, a town of France, in the department of the Po; seven miles N.N.W. of Turin.

MAURITIUS, or *Isle of France*, an island in the Indian sea, first discovered by the Dutch in 1598, and so called by them in honour of the prince of Orange. On their first arrival the Dutch anchored with a fleet of five ships in a safe port capable of containing 50 large vessels, and which, in honour of their vice-admiral, they called Warwick's Haven. The country was found to abound with cattle, fowl, fish, and fruits; and afforded a seasonable supply of necessaries to the crew and of refreshments to the sick, who went on shore for their recovery. Of the importance of this island they were sufficiently apprised, inasmuch that they recorded in their journals an observation, that it might be commodiously visited by outward bound ships, as that of St. Helena might be on their return: nevertheless, they made no settlement in this island for forty years, and they were just in time to preclude the French from taking possession of it. They had the precaution to build a fort for the defence of the haven and watering place; and in 1640 they had two or three small settlements in the island, besides their fort. But as they wanted slaves to cultivate their plantations, they applied to the French governor of Madagascar, and prevailed upon him to steal 50 blacks out of the number of those who were under his protection. This fraudulent act induced the people of Madagascar to withdraw their confidence from the French; and as to the negroes that were carried to Mauritius, many of them fled into the woods and mountains, where they became robbers or banditti, or, as they are denominated in the West Indies, maroons. These were joined by other persons of a similar description, and became so powerful, that the Dutch, notwithstanding their garrison of 50 men in the fort, could not secure themselves against their insults and depredations. About the beginning of the last century, the Dutch East India company in Holland determined to abandon it; and actually withdrew their colony from it in 1712, and removed it to the Cape of Good Hope. The island, says the Abbé Raynal, was uninhabited when the French landed there in 1720, and changed its name from Mauritius to the Isle of France, which name it still bears. Its first inhabitants, he says, came over from the Isle of Bourbon; but it remained in a neglected state for almost fifteen years. At length, in 1734, the French company resolved to make some important settlement here, and the project was entrusted to the execution of Mahe de la Bourdonnais. As soon as he arrived he was

indefatigably active in executing every plan for the improvement of the island, which his sagacity devised: and to him the French were afterwards indebted for aqueducts, bridges, hospitals, and storehouses. Exciting by his example a spirit of emulation and industry in the colonists, he changed the whole aspect of the island and the condition of its inhabitants, during the twelve years of his administration. By his recommendation the French made choice of the harbour to the N.W. of this island, in preference to that which is more spacious and more commodious to the S.E.; a harbour to the leeward possessing many advantages in latitudes where the general winds prevail. The spirit which he excited led the inhabitants to the cultivation of corn, which became the most prosperous of all the branches of agriculture practised at this island; where the fields yield annually in regular succession a crop of wheat and another of maize or Indian corn. The manioc or cassava, which was brought from Brazil by M. la Bourdonnais, served as common food to the blacks. In consequence of the improvements of this governor, ships going to India found all the refreshments and conveniences they wanted after a tedious passage. The continual supplies afforded to ships and squadrons have contributed to check the increase of cattle, which it was the object of La Bourdonnais to multiply. However, the island produces excellent pasture, which springs up in the beginning of the rainy season. It completes the whole course of its vegetation in the course of three months, during which interval the inhabitants feed their herds. This island has occasionally suffered much from hurricanes, so that the colony has been preserved by the attention of the governor in procuring supplies from the Cape of Good Hope. The cultivation of corn in this island has been much promoted by M. Poivre; and in a variety of other ways, particularly by introducing the nutmeg and clove, and the rice of Cochinchina, he contributed to enrich the colony entrusted to his care. M. Cerè procured from Ceylon, and planted in this island, of which he was governor, a great number of cinnamon, clove, and nutmeg trees, which have been very prosperous. But in 1786, the Dutch, actuated by the true spirit of monopoly, sent a vagabond to the island in order to destroy these plantations; but the plot was discovered in time, and the vagabond escaped merited punishment.

The soil of this island is, generally speaking, red and stony; towards the sea-coasts it is mountainous, but within land there are many spots both level and fertile. Some of the mountains are high, but none exceed 426 fathoms in elevation: it is said, however, that their summits are covered with snow throughout the year. The whole island is well watered; and it produces all the trees, fruits, and herbs, which grow in this part of the globe, in great plenty; groves of oranges as well as citrons; and the pine-apple grows spontaneously in great perfection. The chief produce is sugar. When this island was first discovered, the ground was covered with wood up to the summits of the mountains, so that it was one immense forest full of beautiful trees. M. Rochon observed in it different kinds of the palm-tree, bamboos, ebony, mat-wood, tacamaca, stinking wood, and many other kinds of valuable trees. No venomous animals, except scorpions and millepedes, are known here. For fineness of climate, and salubrity of air, this island, as well as that of Bourbon, may be compared with the Fortunate islands. The whole extent of the island is about 150 miles, and its form is nearly circular. The population, in the year 1790, exclusive of the military, was estimated at 8000 whites and 12,000 blacks. This island,

the last remains of the French possessions in the Indian seas, was taken by the English, December 2, 1810. S. lat. 20° 12'. E. long. 58° 27'.

MAURO, *ST.*, a town of Naples, in Lavoro; 4 miles S.E. of Capua.—Also, a town of Naples, in Basilicata; 22 miles S.E. of Acerenza.—Also, a town of the county of Tyrol; 12 miles N.N.E. of Trent.—Also, a town of Naples, in Calabria Citra; 3 miles W.S.W. of Rossano.

MAUROCENIA, in *Botany*, Linn. Hort. Cliff. 103. Gen. ed. t. 85, was named by Linnæus in honour of Giovanni Francesco Mauroceno, a Venetian senator, who had a very fine and rich garden at Padua, of which a catalogue was published there by Antonio Tita in 1713, being an 8vo. of 183 pages, besides 13 pages describing a journey of the author's over the mountains of Trent. This genus was subsequently sunk in *Cassine*, the only species of which it consisted being *Cassine Maurocena*, Linn. Sp. Pl. 385. See *CASSINE*.

MAUROLICO, or MAUROLICUS, FRANCIS, in *Biography*, who flourished in the sixteenth century, descended from a noble Greek family, (but driven to seek an asylum in Sicily from the persecution of the Turks,) was born at Messina in the year 1494. He was, at a very early period, distinguished by his proficiency in polite literature, the learned languages, and, above all, in mathematical learning. He devoted himself to theology as a profession; but his favourite studies were those of the belles lettres, and the sciences properly so called. For a considerable time he was professor of mathematics in his native city, and was much followed and admired on account of the great perspicuity with which he explained and illustrated the most difficult questions. His fame, as a mathematician, extended over the whole of Europe. He excelled in geometry, astronomy, optics, and architecture; and he enjoyed the esteem and friendship of the most illustrious persons of his time. He was by his countrymen regarded as their second Archimedes. He restored the fifth book of Apollonius, which had been lost; and he discovered a new method of demonstrating the properties of the conic sections, in which he has been followed by many modern geometers. He made discoveries in the art of dialling, of which he published an account in his "De Lineis Horariis." He wrote on optics, and is mentioned by Dr. Priestley and others as the person who discovered that it is the crystalline humour which collects and unites on the retina the rays which it receives from external objects, and brings every pencil to its proper focus; and by means of it, he was able to explain the phenomena of long and short-sightedness, which had been till then inexplicable. He is said also to have given the first solution of the problem concerning the image of the sun appearing round, though the rays that form it are transmitted into a dark room through an angular aperture. He died at the advanced age of eighty, leaving behind him numerous works, that attest to the greatness of his talents, and his unceasing industry and perseverance, though he was for many years an invalid. His biographers have given the titles of the following as his principal works: "The Spherics of Theodosius;" "Eminentio et Restitutio Conicorum Apollonii Pergæi;" "Archimedis Monumenta omnia;" "Euclidis Phænomena;" "Opuscula Mathematica;" "Arithmeticonum Libri duo;" "Photismus de Lumine et Umbra;" "Problemata Mechanica ad Magnetem et ad Pyxidem nauticam Pertinentia." Priestley's Light and Colours. Moreri.

MAURON, in *Geography*, a town of France, in the department of the Morbihan, and chief place of a canton, in the district of Ploermel; 10 miles N. of Ploermel. The

place contains 4212, and the canton 9035 inhabitants, on a territory of 192½ kilometres, in 7 communes.

MAUROUSE, the name of a creature of the deer kind, mentioned by Josselyn. It seems to be the same with the *dama Virginiana* of Mr. Ray, one of which creatures was, in his time, kept alive in St. James's park.

This is not certain, however; for Josselyn's description is very imperfect: he only says it is like the moose-deer, but is small, and has small horns.

MAURS, in *Geography*, a town of France, in the department of the Cantal, and chief place of a canton, in the district of Aurillac; 18 miles S.S.W. of Aurillac. The place contains 2045, and the canton 11,029 inhabitants, on a territory of 262½ kilometres, in 13 communes.

MAURSEE, a considerable lake of Prussia, in the province of Culm; 10 miles E. of Rastenburg.

MAURUA, or MAUROGA, one of the Society islands, in the South Pacific ocean, of small size, wholly surrounded by a reef, and destitute of harbour for shipping. It is inhabited, and bears the same produce as the neighbouring islands. Its middle rises in a high round hill, that may be seen at the distance of 10 leagues. S. lat. 16° 26'. W. long. 152°.

MAURUCA, a kingdom on the east coast of Africa, situated in about S. lat. 14° 30'. E. long. 37° 14'.

MAUSAHEID, or MESEK, a town of Arabia; 35 miles N. of Mocha.

MAU-SIDS, a town of Arabia, in the province of Yemen; 24 miles N. of Mocha.

MAUSOLEUM, a magnificent tomb, or funeral monument, decorated with architecture and sculpture, and inscribed with an epitaph; erected in honour of some emperor, prince, or other illustrious person.

The word comes from *Mausolus*, the name of a king of Caria, to whom Artemisia, his widow, erected a most stately monument, that has since been numbered among the seven wonders of the world; calling it, from his name, Mausoleum. It was sixty-three feet long, almost four hundred and eleven feet in compass, and about thirty-five feet high, surrounded with thirty-six columns, that were beautified in a wonderful manner. Pliny has described it, lib. xxxvi. cap. 5. Afterwards the same name was given to all costly monuments. Thus the stately monument was called, which Augustus built, during his sixth consulship, between the Flaminia Via and the Tiber, to be a burial-place for him and his family, and which Strabo has described in his fifth book. It is also the name which Florus, lib. iv. cap. 11. gives to the monuments of the kings of Egypt, wherein Cleopatra shut herself up, and put herself to death. Many authorities testify, that the Romans gave this name to those sepulchres whose structure was magnificent.

MAUSOLEUM is also used to signify the decoration of a fictitious tomb, or catafalca, in funeral pomp.

MAUSSAC, PHILIP-JAMES, in *Biography*, a learned critic, was born at Toulouse in the year 1590, where his father was a counsellor of parliament. He was educated for the profession of the law, and became president of the court of aides at Montpellier, where he died in 1650. He was accounted one of the best Greek scholars of his time. He wrote "Notes and Corrections on Harpocration," "Remarks on the Treatise on Mountains and Rivers ascribed to Plutarch," and various other works. Moreri.

MAUTCHONG-COUNSAN, in *Geography*, a mountain of Thibet. N. lat. 31° 38'. E. long. 83° 44'.

MAUTEN, a town of Carinthia, at the conflux of the Moledin and the Geil; 18 miles S.W. of Saxenburg.

MAUTERN, a town of the duchy of Stiria; 8 miles N. of Windisch Gratz.

MAUTH, a town of Bohemia, in the circle of Beraun; 18 miles S.E. of Beraun.

MAUTHAUSEN, a town of Austria, on the left bank of the Danube; 7 miles E. of Steyregg.

MAUTOUR, PHILIBERT BERNARD MOREAU DE, in *Biography*, auditor of the chamber of accounts at Paris, and member of the academy of inscriptions. He was born at Beaune in 1654, and died in 1737. He wrote some papers in the Memoirs of the Academy of Belles Lettres, and poems. He was also the editor of an abridgment of Petavius's Chronology, 4 vols. 12mo. Moreri.

MAUTERN, in *Geography*, a town of Austria, on the south side of the Danube, opposite to Stein; 32 miles W.N.W. of Vienna. N. lat. 48° 23'. E. long. 15° 38'.

MAUTERN DORF, a town of the principality of Salzburg; 11 miles S. of Radstadt.

MAUVEZIN, a town of France, in the department of the Gers, and chief place of a canton, in the district of Lectoure; 17 miles S.S.E. of Lectoure. The place contains 2005, and the canton 9083 inhabitants, on a territory of 192½ kilometres, in 26 communes.

MAUVILLON, JAMES, in *Biography*, professor of the military sciences in the Caroline college at Brunswick, was descended from a French family, and born at Leipzig in 1743. His father being professor of the French language in the Caroline college, he had an opportunity of prosecuting his studies under the celebrated men who, at that time, were an ornament to the sciences which they taught. The favourite pursuits of the son were the languages, drawing, and mathematics. He soon displayed a strong attachment to a military life; but as this was opposed by his father, who wished him to study the law, he went privately and offered to enlist himself with general Wallmoden. Though his ardour was great, his stature was so small and diminutive, that the general refused to admit him into the service. At length, however, he was received into the corps of engineers; but, at the conclusion of the war, he was, at the persuasion of his father, induced to repair to Leipzig to study the law. His mind was not at all formed for legal studies, and he preferred to these the drudgery of assisting in a school. Here he improved himself in the Latin language, and soon after, on the recommendation of the general, was appointed engineer of bridges and highways at Cassel, and teacher of the military sciences. About this period he became a contributor to some periodical works, and wrote his "Letters on the Merits of the German Poets," which, on account of the severity of his animadversions, excited against him many enemies. In 1775 he gave proofs of his diligence, as well as his talents, by translating Raynal's "History of the Indies," a work of Turgot's, and Ariosto; besides being engaged in several journals. In 1777 he was appointed captain of a corps of cadets, and obtained the friendship of professor Dohm, afterwards the Prussian minister. To this person he addressed his "Physiocratic Letters," which were published in 1780; and in the same year he was elected a member of the Society of Antiquaries at Cassel, and wrote several papers, which were inserted in its transactions. In 1781 he published his "Introduction to the Military Sciences," with an Essay on the thirty years' war, and another on the influence which the invention of gunpowder has had in modern wars. These were all published in the French language. His situation in the corps of cadets subjected him to much uneasiness; and about this time he repaired to Potsdam, and solicited

solicited an appointment from Frederic II., which would have been readily granted; but he found his wife so averse from settling in Prussia, that he gave up the idea, and returned to his former situation at Cassel. He studied religion as well as military tactics, and in 1787 published what he entitled a "System of Religion." He had, previously to this, formed an acquaintance, which ripened into friendship, with the celebrated Mirabeau. An account of the joint pursuits of these friends may be found in Mirabeau's "Lettres du Comte de Mirabeau à un de ses Amis en Allemagne, écrites durant les Années 1786-90." Mauvillon died in 1792. The last work which he published was entitled "Man and Woman," written in opposition to a book by Brandes, in which the female sex had not been treated with that degree of justice which Mauvillon thought due to them. He began a "Life of Prince Ferdinand of Brunswick," which is said to be the best of all his productions. Mauvillon was fond of company; and in the early part of life, the whole object of his labour was that he might gratify his taste without running into debt. In his manners and dress he was exceedingly simple; he had no attachment to wine, but was excessively fond of coffee; he was a zealous advocate for the principles of toleration, and in all kinds of company avowed his sentiments with the greatest freedom. He was friendly to the French revolution, but disapproved of the horrid scenes which attended it. Gen. Biog.

MAUZAT, in *Geography*, a town of France, in the department of the Puy-de-Dôme, and chief place of a canton, in the district of Riom. The place contains 1565, and the canton 9072 inhabitants, on a territory of 242½ kilometres, in 10 communes.

MAUZE', a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Niort. The place contains 1600, and the canton 6876 inhabitants, on a territory of 145 kilometres, in 8 communes.

MAW, a sea-port of Ceylon, at the mouth of a river on the west coast; 50 miles W. of Candy. N. lat. 7° 45'. E. long. 75 55'.

MAW. See ABOMASUS.

MAW-Skin, in *Rural Economy*, a provincial word used to signify the stomach of the calf prepared for cheese-making.

MAWAR-UL-NERE, denoting "the country beyond the river, or "Transoxiana," in *Geography*, a country of Independent Tartary, lying beyond the Oxus, or modern Gihon or Jihon; and beyond the lower parts of the courses of that river, and the Sihon, or ancient Iaxartes.

MAWHELLIPOUR, a town of Hindoostan, in Bahar; 3 miles S.W. of Bahar. N. lat. 25° 21'. E. long. 84° 55'.

MAWRI, a sea-port town of Africa, in the country of Sabu, on the Gold coast, inhabited chiefly by fishermen. In the middle of the town is Fort Nassau, built by the Dutch, with a small garrison.

MAWS, Sr., a borough town in the parish of St. Just, hundred of Powder, and county of Cornwall, England, is situated on the east side of Falmouth harbour; one mile distant from Falmouth, and 270 from London. It consists only of one street, containing about twenty houses, inhabited chiefly by fishermen. A fair is held annually, but the town has never been incorporated, and has neither church, chapel, nor meeting-house; yet it sends two representatives to parliament, and has done so ever since the fourth year of queen Elizabeth. It is governed by a portreeve, who has the title of mayor. The principal influence and property of the borough are now possessed by the marquis

of Buckingham. King Henry VIII. erected a castle here, opposite to that of Pendennis, to which it is very inferior both in size and situation, though built nearly at the same time, by the same monarch, and for the same purpose, *i. e.* the security of Falmouth harbour. The works are completely commanded by a hill, which rises immediately behind them. Beauties of England and Wales, vol. ii.

MAXANTELLA, an island near the port of Matanchel, on the west coast of New Mexico, in the North Pacific ocean.

MAXDORF, a town of Bohemia, in the circle of Leitmeritz; 10 miles W. of Kamnitz.

MAXEN, a town of Saxony, famous for a victory obtained by the Austrians, commanded by count Daun, over the Prussians, in 1759, when 20,000 Prussians laid down their arms and surrendered prisoners of war; 80 miles S. of Dresden.

MAXENTIUS, MARCUS AURELIUS VALENIUS, in *Biography*, a Roman emperor, was the son of Maximian, and married the daughter of Galerius. The abdication of Maximian and Dioclesian, in 305, made room for the elevation of Galerius and Constantius to the rank of Augustus; of course, two new Cæsars were to be appointed; but Maxentius, on account of his vicious propensities, was passed over, though, from his birth and rank in the state, he seemed best entitled to that honour. Deprived of what he thought his natural right, he waited only for an opportunity of asserting his claims; and in 306 he declared himself independent emperor, and, without remorse or compunction, put to death the prefect, and other magistrates who adhered to Galerius. His abdicated father, by this time, weary of retirement, resuming his dignity, joined him; and Severus, the newly-made Cæsar, who marched against them, finding himself deserted by his army, surrendered himself prisoner to the victorious emperors. He was at first received with great humanity, and treated with a respect due to his rank. Maximian himself conducted the captive emperor to Rome, and gave him the most solemn assurances that he had secured his life and happiness, by the resignation of the purple. But, in spite of the honour of an emperor, Severus could only obtain an easy death, and an imperial funeral. In February 307, the sentence was signified to him, but the manner of executing it was left to his own choice. He preferred the favourite mode of the ancients, that of opening his veins; and as soon as he expired, his body was carried to the sepulchre which had been constructed for the family of Gallienus. Galerius, at this time, entered Italy with a powerful army, for the purpose of dethroning Maxentius; but he found the new emperor so strongly defended, and his own troops so wavering in their fidelity, that he thought it best to consult his safety by a retreat. Maximian also became his rival, and attempted to depose him; but the soldiers decided in favour of the younger claimant, and Maximian, who aimed at all, lost all, and was obliged to retire with shame and humiliation. Maxentius was now the undisputed master of Italy. He passed into Africa, where he rendered himself odious by his cruelty and oppressions. His suspicions frequently endangered the lives of persons of rank; and the honour and chastity of their wives and daughters were daily exposed to violation from his brutal desires. The heroic conduct of a Christian lady, who plunged a dagger into her breast, in order that she might escape his impure embraces, has been recorded by some writers to her honour, though others have questioned the lawfulness of the act; but none have hesitated to hold up the conduct of the tyrant to that contempt and infamy which it so justly merited. Upon the return of Maxentius

Maxentius to Rome, he was informed that Constantine was come to dethrone him. The resources of Maxentius, both in men and money, were still considerable. The Prætorian guards felt how strongly their own interest and safety were connected with his cause, and an army was speedily collected. It was far from the intention of the emperor to lead his troops in person. "A stranger," says the historian, "to the exercises of war, he trembled at the apprehension of so dangerous a contest; and as fear is commonly superstitious, he listened with melancholy attention to the rumours of omens and presages, which seemed to menace his life and empire. Shame at length supplied the place of courage, and forced him to take the field, being unable to sustain the contempt of the Roman people. The circus resounded with their indignant clamours, and they tumultuously besieged the gates of the palace, reproaching the pusillanimity of their indolent sovereign, and celebrating the heroic spirit of Constantine. Before Maxentius left Rome, he consulted the Sibylline books. The guardians of those sacred oracles were as well versed in the arts of this world, as they were ignorant of the secrets of fate; and they returned him a very prudent answer, which might adapt itself to the event, and secure their reputation, whatever should be the chance of arms." At length he assembled his forces, and gave his enemy battle; but lost the day, and fled with the utmost precipitation to the city. The bridge, over which he was to cross the Tiber, was in a decayed situation, and he fell into the river, and was drowned. This happened on the 24th of September, A.D. 312. The cowardice and luxuries of Maxentius were as conspicuous as his cruelties. He oppressed his subjects with heavy taxes, to gratify the cravings of his pleasure, or the avarice of his favourites; and he was so debauched in his manners, that neither virtue nor innocence was safe, if within his reach. He was naturally deformed, of an unwieldy body, and the smallest exertions to him were as Herculean labours. Gibbon, vol. ii. 8vo. Univer. Hist.

MAXILLA, in *Anatomy*, the jaw. The term is usually applied to the bones. The maxilla superior contains six pairs of bones, and one single bone; the maxilla inferior is a single bone. See **CRANIUM**.

MAXILLA, *Fractions and Dislocations of*, in *Surgery*. See **FRACTURE** and **LUXATION**.

MAXILLARIS, **MAXILLARY**, in *Anatomy*, an epithet applied to various parts about the jaws. There is an external, an internal, and an inferior maxillary artery (see **ARTERY**); one inferior and two superior maxillary bones (see **CRANIUM**); a maxillary gland, which is a mucous gland of the cheek, placed near the back upper teeth; a superior and inferior maxillary nerve, branches of the fifth pair (see **NERVE**); a maxillary sinus or antrum maxillare, which is a large hollow of the superior maxillary bone. See **CRANIUM** and **NOSE**.

MAXILLARY SINUS, *Abscess of*, in *Surgery*. See **ABSCESS**.

MAXILLARY SINUS, *Fungus of*. See **FUNGUS**.

MAXIM denotes an established proposition or principle; in which sense it amounts to much the same with axiom.

Maxims are a kind of propositions, which have passed for principles of science; and which, being self-evident, have been by some supposed innate.

A maxim in law is said to be a proposition, of all men confessed and granted without argument or discourse.

Maxims of the law are holden for law; and all other cases that may be applied to them, shall be taken for granted. (1 Inst. 11. 67. 4 Rep.) The maxims in our law-books,

which are many and various, are such as the following, viz. It is a maxim, that land shall descend from the father to the son, &c. That if a man have two sons, by divers venters, and the one purchase lands and die without issue, the other shall never be his heir, &c. That as no estate can be vested in the king, without matter of record, so none can be divested out of him but by matter of record. That an obligation, or matter in writing, cannot be dissolved by an agreement by word, without writing. Co. Litt. 11. 141. See **LAW**.

MAXIMA CÆSARIENSIS, in *Ancient Geography*, one of the five provinces into which Britain was divided by the Romans; but the reason of the name, and the time when this province was erected, are not certainly known. It was bounded on the south by the Humber, on the east by the German ocean, on the west by the Irish sea, and on the north by the wall of Severus; and contained the countries of the Parisi and the Brigantes, which are now the counties of York, Durham, Lancaster, Cumberland, and Northumberland. For the other four provinces, see **FLAVIA Cæsariensis** and **VALENTIA**.

MAXIMA, *Lat., Maxime, Fr.* See **MASSIMA** and **TIME-Table**.

MAXIMA et Minima, in *Analysis and Geometry*, are the greatest and least values of a variable quantity; and the method of finding these greatest and least values is called the *method de maximis et minimis*, which forms one of the most interesting inquiries in the modern analysis. This subject was considered geometrically by some of the most ancient mathematicians, particularly by Apollonius, in the fifth book of his Conics; and there are still a few problems of this kind, which succeed better by the geometrical than by the analytical method: their number, however, is very limited, compared with those which may be elegantly performed by analysis. To the latter, therefore, we shall principally direct our attention, only shewing, in a few cases, how the same may be accomplished by means of the pure elements of geometry.

The method de maximis et minimis, according to the analytical doctrine, first arose at the beginning of the seventeenth century, after the invention of Descartes for expressing the properties of curve lines by means of algebraical equations, and classing them into different orders, according to the degree of the equation which expressed the relation between the absciss and ordinate. Besides the method of Descartes, we have also those of Fermat, Hudde, Huygens, Sluse, and some others, which are now all supplanted by the general and elegant method of fluxions; yet as these several methods may be considered as so many steps towards the discovery of the latter, it will be interesting to have a brief abstract of them, in order to shew how slow and progressive are the steps to knowledge, and by what imperceptible degrees we arrive towards perfection.

Fermat's Method de Maximis et Minimis.—The principle upon which Fermat formed his operation consisted in this: that when the ordinate of a curve was the greatest possible, if we augmented the variable quantity x , which represents the absciss, by an indefinitely small quantity e , the ordinate corresponding to this absciss will be equal to the former, or will approach towards equality indefinitely near; or, which is the same, the increase or decrease of an ordinate, when it approaches indefinitely near its maximum or minimum, is nothing; and, therefore, these two ordinates may be considered as equal, whence an equation is obtained, from which cancelling the like quantities, and all those powers of e beyond the first, because they are indefinitely small with regard to the others, and dividing the other terms by e , the value

MAXIMA ET MINIMA.

value of x will be obtained, that renders the function a maximum or a minimum.

For example: let it be proposed to find that value of x , in the equation $y^3 = 2ax - x^3$, which renders y a maximum.

Increase the variable quantity by e ; then,

$$y = 2a(x + e) - (x + e)^3,$$

$$\text{or, } 2ax - x^3 = 2a(x + e) - (x + e)^3,$$

$$\text{or, } 0 = 2ae - 2ex;$$

by rejecting e^3 , which is indefinitely small: whence again,

$$2ax = 2ex, \text{ or } x = a.$$

Again: required the value of x , in the equation $y^3 = ax^3 - x^3$, which renders the whole function a maximum.

Making, as before, $x = x + e$, we have

$$ax^3 - x^3 = a(x + e)^3 - (x + e)^3,$$

$$\text{or, } 0 = +2axe - 3e^2x - e^3;$$

by suppressing those powers of e above the first: whence,

$$3ex^2 = 2axe, \text{ or } x = \frac{2}{3}a.$$

These examples will be sufficient to shew the spirit of Fermat's rule, which is in principle much the same as the fluxional method; only that it wants that generality and elegance which constitute the distinguishing characteristics of the latter.

Descartes' Method.—This consisted in making two of the roots of the equation equal to each other; in which case, two of the ordinates of the curve became equal, and thus indicated the maximum or minimum state. This, however, being much less eligible than the preceding, we will not enter into farther explanation, but proceed to Hudde's method, which is in principle the same as Descartes's, but more elegant and concise.

Hudde's Method.—This, as we have observed, consisted, like that of Descartes, in making two of the roots of the proposed equation equal to each other, and for which he gave the following rule: *viz.* multiply each term of the equation, arranged according to the power of x , by the terms of an arithmetical progression, *viz.* the first by the first, the second by the second, &c.; and the equation thus obtained will indicate the maximum or minimum required.

Let us take, for example, the equation above, $ax^3 - x^3 = y^3$.

Arranging this equation according to the powers of x , and supplying the deficient term, we have

$$x^3 - ax^3 + 0x - y^3 = 0.$$

Arith. prog. $\begin{matrix} 3, & 2, & 1, & 0. \\ \hline 3x^3 - 2ax^3 = 0 \\ 3x^3 = 2ax^3, \text{ or } x = \frac{2}{3}a, \text{ as above.} \end{matrix}$

Again: let $x^2 - ax + y^2 - 2by + b^2$, be proposed.

Writing this, $x^2 - ax + (y^2 - 2by + b^2) = 0$.

Arith. prog. $\begin{matrix} 2, & 1, & 0. \\ \hline 2x^2 - ax = 0, \text{ or } x = \frac{1}{2}a. \end{matrix}$

This rule, though not so general as could be wished, is still extremely simple and ingenious; and, considering the state of analysis at the period it was discovered, it is highly creditable to its author, to whom we are also indebted for several other analytical and geometrical improvements.

Huygens' Method.—As the rule of Hudde, described above, was a simplification of that of Descartes, so the following one is founded on the principle of Fermat, and

can only be considered as a simplification of his method. Instead of substituting $x + e$ for x , and then cancelling the like terms, suppressing those in which e rises to a higher power than the first, and finally dividing by e ; Huygens, as also Sluse, arrive at the final equation at once by the following simple rule: multiply each of the terms in which x is found by its exponent, rejecting all those into which it does not enter; divide the result by x , and make the whole equal to zero; and the equation thus arising will give the value of x required.

For example: required the value of x in the equation $3ax^3 - x^3 = y$.

Multiplying each of those terms by the exponent of x in them, we have $6ax^3 - 3x^3$; then dividing by x ,

$$6ax^2 - 3x^2 = 0, \text{ or } 3x^2 - 6ax = 0,$$

$$\text{or, } x^2 - 2ax + a^2 = a^2, \text{ or } x = a \pm a;$$

that is, $x = 0$, or $2a$.

This rule differs in no respect from our fluxional operation, except that we divide by x instead of e ; yet the generality of the latter is such, that the rules above described have long been forgotten, and are only given here as presenting an historical view of the methods employed by our predecessors; and in this respect they are entitled to particular notice; for in them is evidently contained the germ of the modern analysis. Farther advances were made in these kinds of operations in the method of tangents, but they are foreign to our present enquiry; of these the *differential triangle* of Barrow is particularly interesting. See TANGENTS.

Of the method de maximis et minimis according to the fluxional or differential calculus.

1. The fluxion of a quantity, when it is a maximum or a minimum, is equal to zero, or 0. This is obvious from the definition of a fluxion, for this being the measures or rates of increase or decrease of a variable quantity; when this quantity becomes a maximum, or a minimum, its fluxion must be = 0, because at that point it admits of no farther increase or decrease.

2. If a quantity be a maximum or minimum, any power or root of that quantity must then evidently be a maximum or minimum. For the power or root of a quantity will increase or decrease as long as the quantity itself increases or decreases, and no longer.

3. Any constant multiple, or part, of a quantity, which is a maximum or a minimum, must also be a maximum or a minimum. For the multiple or part of a quantity will increase or decrease as long as the quantity itself increases or decreases, and no longer; therefore, when its fluxion is made equal to zero, the constant multiplier may be neglected.

4. The fluxion of a constant quantity = 0. For this admitting of no increase or decrease has no fluxion, or its fluxion = 0.

1. To divide a given number (a) into two such parts x and y , that $x^m y^n$ may be a maximum.

Since $x + y = a$, and $x^m y^n = a$ maximum, the fluxions of each = 0; the former because it is constant, and the latter because it is a maximum, whence

$$\dot{x} + \dot{y} = 0$$

$$m y^n x^{m-1} \dot{x} + n x^m y^{n-1} \dot{y} = 0;$$

from the first we have $\dot{x} = -\dot{y}$; and substituting this in the second, gives

$$m y^n x^{m-1} \dot{x} - n x^m y^{n-1} \dot{x} = 0, \text{ or}$$

$$m y^n x^{m-1} = n x^m y^{n-1}, \text{ or}$$

$$m y = n x; \text{ whence}$$

$$y =$$

MAXIMA ET MINIMA.

$$y = \frac{n}{m} x$$

Consequently, $x + \frac{n}{m} x = a$, or

$$x = \frac{m a}{m + n}, \text{ and } y = \frac{n a}{m + n}.$$

If $m = n$, then the two parts are equal.

Hence, to divide a quantity (a) into three parts, x, y, z , so that $x y z$ may be a maximum, the three parts must be all equal amongst themselves. For whatever one of the parts may be, if it be constant, the product of the other two will be the greatest when they are equal to each other; and in the same manner, if we consider any one of the parts as constant, the rectangle of the other two will be the greatest when they are equal to each other; whence it is obvious, that the product will be the greatest when the three parts are equal to each other. And in the same manner, if the given quantity be divided into any number of parts, the product of them, or the product of any equal powers of them, will be the greatest when the several parts are all equal amongst themselves.

2. To divide a given number (a) into two such parts, x and y , that the sum of their alternate quotients may be a maximum.

Here we must have $x + y = a$,

$$\text{and } \frac{x}{y} + \frac{y}{x} = \text{a maximum.}$$

Now since the first is constant, and the latter a maximum, we have $\dot{x} = -\dot{y}$, and

$$\frac{\dot{x} y - \dot{y} x}{y^2} + \frac{\dot{y} x - \dot{x} y}{x^2} = 0;$$

or, substituting for \dot{x} its equal $-\dot{y}$, this becomes

$$-\frac{y \dot{y} + x \dot{y}}{y^2} + \frac{x \dot{y} + y \dot{y}}{x^2} = 0, \text{ or}$$

$$\frac{x \dot{y} + y \dot{y}}{x^2} = \frac{y \dot{y} + x \dot{y}}{y^2};$$

whence we have $\frac{1}{x^2} = \frac{1}{y^2}$, or $y^2 = x^2$, or $x = y$; that

is, each of the required quantities is equal to $\frac{1}{2} a$.

3. Of all right-angled triangles, having the same hypothenuse; to determine that which shall have the greatest area.

Let the given hypothenuse be represented by b , and the required sides by x and y ; then we have these two equations;

$$x^2 + y^2 = b^2$$

$$x y = \text{a maximum.}$$

In the first we have $2 x \dot{x} + 2 y \dot{y} = 0$, or $\dot{x} = -\frac{y \dot{y}}{x}$;

in the second $\dot{x} y + \dot{y} x = 0$.

Substitute for \dot{x} , and we obtain

$$-\frac{y^2 \dot{y}}{x} + \dot{y} x = 0, \text{ or } y^2 = x^2, \text{ or } y = x;$$

and, consequently, both x and $y = \frac{a \sqrt{2}}{2}$.

This result is also readily obtained from the pure elements of geometry; for the hypothenuse being given, let there be described upon it a semicircle; then it is obvious, that the area of that triangle will be the greatest whose perpendicular, let fall upon the hypothenuse from the right angle, is the greatest; and this evidently is the case when that perpendi-

cular is equal to the radius, or when the right-angled triangle is also isosceles.

4. To find the greatest cylinder that can be inscribed in a given cone.

Let the altitude of the cone be represented by a , the diameter of its base by b , the altitude of the cylinder by x , and the diameter of its base by y : also put $.7854 = p$.

Now by similar triangles, as

$$a : b :: b - x : \frac{b}{a} (b - x) = y;$$

and by the question $p y^2 x = \text{a maximum}$, or substituting for y , and suppressing $\frac{b^3 p}{a^2}$, because it is a constant multiplier, we have

$$b^3 x - 2 b x^2 + x^3 = \text{a maximum, or}$$

$$b^3 \dot{x} - 4 b x \dot{x} + 3 x^2 \dot{x} = 0; \text{ whence}$$

$$3 x^2 - 4 b x = -b^2,$$

which reduced, gives $x = \frac{1}{3} b$.

5. To divide a given arc A into two parts such, that the m th power of the sine of one part, into the n th power of the sine of the other, may be a maximum.

Let P and Q represent the two arcs, x and y their sines, radius being unity, then we must have

$$x^m \times y^n = \text{a maximum,}$$

and consequently, $m y^n x^{m-1} \dot{x} + n x^m y^{n-1} \dot{y} = 0$;

whence we find $m \dot{y} \dot{x} = -n x \dot{y}$.

$$\text{Now } \dot{P} = \frac{\dot{x}}{\sqrt{(1-x^2)}}, \text{ and } \dot{Q} = \frac{\dot{y}}{\sqrt{(1-y^2)}}$$

from the known doctrine of fluxions; also

$$\dot{P} + \dot{Q} = 0, \text{ because } P + Q = A, \text{ whence } \dot{P} = -\dot{Q};$$

$$\text{or, } \frac{\dot{y}}{\sqrt{(1-y^2)}} = \frac{-\dot{x}}{\sqrt{(1-x^2)}}.$$

Multiply this equation by the equation

$$m y \dot{x} = -n x \dot{y},$$

and we obtain

$$m \times \frac{y}{\sqrt{(1-y^2)}} = n \times \frac{x}{\sqrt{(1-x^2)}}$$

or, which is the same,

$$m \cdot \tan. P = n \cdot \tan. Q,$$

whence

$$m : n :: \tan. Q : \tan. P$$

$$(m + n) : (m - n) :: (\tan. Q + \tan. P) : (\tan. Q - \tan. P)$$

But

$$(\tan. Q + \tan. P) : (\tan. Q - \tan. P) :: \sin. (Q + P) : \sin. (Q - P);$$

or, $(m + n) : (m - n) :: \sin. A : \sin. (Q - P)$;

whence, $\sin. (Q - P) = \sin. A \times \frac{m - n}{m + n}$.

Now, therefore, knowing the sine of the difference, we know also the difference of the arcs, whence the sum being also given, the arcs themselves are readily determined. We might have obtained the same result from the known trigonometrical formula; viz.

$$\sin. (P + Q) = \sin. P \cdot \cos. Q + \sin. Q \cdot \cos. P,$$

that is, the above notation remaining, and making

$$\sin. (P + Q), \text{ or } \sin. A = a.$$

$$x \sqrt{1-y} + y \sqrt{1-x^2} = a,$$

and we have also $x^m y^n$ a maximum: from which two equations the values of x and y may be determined; and, consequently, the area of which they are the foci.

6. To find the value of x in the equation $x^r = a$ a minimum. Make $x^r = z$, then $x \log. x = \log. z$, and

$$\dot{x} \log. x + x \times \frac{\dot{x}}{x} = \frac{\dot{z}}{z} = 0,$$

because, x^r , or z , is to be a minimum,

whence $\log. x = -1$,

that is, x is that number of which the hyperbolic logarithm is -1 .

Application of Maxima et Minima to physical Problems.

7. Given two elastic bodies A and C to find an intermediate body x , so that the motion communicated from A to C , through x , may be a maximum.

Put a = the given velocity of A , w the velocity communicated to C , and z the velocity communicated to x ; then by the known theory of elastic bodies

$$\begin{aligned} A + x : 2A :: a : w \\ x + C : 2x :: w : z \end{aligned}$$

taking the product of corresponding terms

$$(A + x + x^2 + AC + Cx) : 4Ax :: a : z, \text{ or}$$

$$A + x + \frac{AC}{x} + C : 4A :: a : z$$

Now as the two mean terms are constant, the last term varies inversely as the first; and, therefore, as the last is to be a maximum, the first term must be a minimum; and, consequently, its fluxion = 0; that is,

$$\dot{x} - \frac{AC \dot{x}}{x^2} = 0; \text{ whence } x = \sqrt{AC};$$

that is, x must be a mean proportional between the two given bodies.

8. To determine at what angle the wind ought to strike against the sails of a windmill, so that the effect to put it in motion may be the greatest possible.

Let x = the cosine of the required angle, then the $\sin.^2 = 1 - x^2$, radius being unity; hence by the principles of hydrostatics, the effect being as the product of the cosine into the square of the sine, we must have

$$x \times (1 - x^2) = x - x^3 = \text{a maximum,}$$

whence $\dot{x} - 3x^2 \dot{x} = 0$, or $x = \sqrt{\frac{1}{3}} = \text{col. } 54^\circ 44'$, which is the required angle.

9. Given the solidity of a cone to find the base and height, when the time of its vibration shall be a minimum, the point of suspension being at the vertex.

Let x = the radius of the base, y = the altitude, $p = 3.1416$; then $\frac{2}{3} p x y^2 = s$, the given solidity.

Now the distance of the point of suspension from the centre of oscillation, in a cone suspended at its vertex,

$$= \frac{4x^2 + y^2}{5x}. \text{ See OSCILLATION. And this, from the nature}$$

of the problem, must be a minimum.

$$\text{But } y^2 = \frac{3s}{p x}, \text{ whence } \frac{4x^2 + y^2}{5x} = \frac{4p x^2 + 3s}{5p x^2}.$$

This being put into fluxions gives

$$\frac{60p^2 x^3 \dot{x} - 40p^2 x^2 \dot{x} - 30psx \dot{x}}{25p^2 x^4} = 0,$$

$$\text{or, } 6p x^3 - 4p x - 3s = 0,$$

$$\text{whence } x = \sqrt[3]{\frac{3s}{2p}}, \text{ and } y = \sqrt[3]{2s} \times \sqrt[3]{\frac{3}{2p}},$$

consequently, $x : y :: 11 \sqrt{2}$.

10. To find the position of the planet Venus, when it gives the greatest quantity of light to the earth

Let S be the sun, (*fig. 1. Plate XIII. Analysis*.) E , the earth, V , Venus, produce EV , on which let fall the perpendicular SB , and with the centre V , and distance VS , describe the circular arc SA . Put $SE = a$, $SV = AV = b$, $EV = x$, $BV = y$; then $AB = b - y$, the versed sine of the angle SVA ; and by the known astronomical theory, the quantity of light received by the earth from

$$\text{Venus varies as } \frac{b-y}{x^2} = \frac{b}{x^2} - \frac{y}{x^2} = \text{a maximum.}$$

Again, (Euclid, b. ii. p. 12.) $a^2 = b^2 + x^2 + 2xy$; therefore, $y = \frac{a^2 - b^2 - x^2}{2x} = \frac{m^2 - x^2}{2x}$ (by making $m^2 = a^2 - b^2$).

Hence, the quantity of light varies as

$$\frac{b}{x^2} - \frac{m^2 - x^2}{2x^3} = \frac{2bx - m^2 + x^3}{2x^3} = \text{a maximum;}$$

hence its fluxion

$$\frac{(2b\dot{x} + 2x\dot{x})2x^3 - 6x^2\dot{x}(2bx - m^2 + x^3)}{4x^6} = 0,$$

$$\text{or, } (2b + 2x)2x^3 - 6x^2(2bx - m^2 + x^3) = 0,$$

whence by reduction, &c.

$$-x^2 - 4bx + 3m^2 = 0,$$

$$\text{therefore, } x^2 + 4bx = 3m^2,$$

$$\text{and hence, } x = -2b \pm \sqrt{4b^2 + 3m^2}$$

Since then, we know the three sides of the triangle ESV , the angle E of elongation is readily found = $39^\circ 44'$.

We might have extended these kinds of problems to a much greater length, had the limits of our article admitted of it; but it is presumed that the above will throw considerable light on the subject; and render the application of these principles easy and familiar in most other cases. The reader who is desirous of farther information relating to the method of maxima et minima, as applicable to mechanical and astronomical subjects, may consult Dealtry's Principles of Fluxions, or Vince's Treatise on the same subject: see also Simpson's and Maclaurin's Treatises on Fluxions, to the former of which works we are indebted for the following article.

Application of Maxima et Minima to curve Lines.—Having already considered this subject at considerable length under the article ISOPERIMETRICAL Problems, we shall, therefore, be very brief in our observations with regard to them in this place; but as there are certain problems of this kind, which easily yield to the ordinary method of maxima et minima, we thought it right to touch slightly on this subject in the present article.

To find the nature of curves, in which some conditions being invariable, others become the greatest or the least possible.

1. Given the length of a curve to find the area a maximum.

It is evident, that by merely putting the fluent $y \dot{x}$ a maximum,

maximum, no solution can be obtained; for no limitation is expressed, and the fluent will admit of increase or decrease without limit. But as the length is given, the $f. \dot{z}$, so far as concerns the $f y \dot{z}$, is a given quantity; therefore, the

$$f. y \dot{x} \pm f. \dot{z} \text{ must be a maximum:}$$

or, rendering the terms homogeneous, in order that they may admit of comparison,

$$f. y \dot{x} \pm f. a \dot{z} = \text{a maximum.}$$

Now if for every individual value of y , this flowing quantity be always a maximum, the whole fluent will be so likewise; but for every such value of y , the flowing quantity is $y \dot{x} \pm a \dot{z}$. Hence the nature of the curve will be determined by ascertaining what relations of \dot{x} and \dot{z} will render $y \dot{x} \pm a \dot{z}$ a maximum for any given value of y ; or the fluxion of $y \dot{x} \pm a \dot{z} = 0$, whilst y is constant; and this must be the case for every successive value of y throughout; so that in each limiting portion of the area, for every value of y , the ratio of $\dot{x} : \dot{z}$ must be such as to make $y \dot{x} \pm a \dot{z}$ a maximum,

therefore $y \ddot{x} \pm a \ddot{z} = 0$; but $\dot{z}^2 = \dot{y}^2 + \dot{x}^2$;

whence $\dot{z} \ddot{z} = \dot{x} \ddot{x}$, and $\ddot{z} = \frac{\dot{x} \ddot{x}}{\dot{z}}$;

consequently, $y \dot{x} = \mp \frac{a \dot{x} \ddot{x}}{\dot{z}}$, and $y \dot{z} = \mp a \dot{x}$.

But from the nature of the problem $y \dot{z}$ must be positive, and, therefore, the true result is $y \dot{z} = a \dot{x}$.

Now, in the circle $a : y :: \dot{z} : \dot{x}$; whence $a \dot{x} = y \dot{z}$. Hence the curve required is a circle; in which the length being given, the area is a maximum.

Therefore, if A and B denote any functions of x and y , and $\dot{x} = \sqrt{c^2 + \dot{y}^2}$, where c is constant, the expression $A \dot{x} \mp B \dot{y}$ is a maximum, or a minimum, when $A \dot{y} = \mp B \dot{x}$, or the functions of x and y are reciprocal.

2. To determine the nature of a curve, which generates a surface, so that the surface being given, the solid may be a maximum.

Here $f. 2 p y \dot{z}$, or $f. y \dot{z}$ is given; and $f. y^2 \dot{x}$ is a maximum; hence the fluent of $a y \dot{z} \pm$ fluent of $y^2 \dot{x}$ a maximum;

or, $f. a y \dot{z} \pm f. y^2 \dot{x} = \text{a maximum};$

therefore, $a y \dot{x} = y^2 \dot{z}$, or $a \dot{x} = y \dot{z}$, which is a property of the circle, and the body is a sphere.

3. To determine the nature of the generating curve, that the solidity being given, the surface may be a minimum.

Here $f. y^2 \dot{x}$ is given, and $f. a y \dot{z}$ is a minimum; therefore, $y^2 \dot{z} = a y \dot{x}$, and $y \dot{z} = a \dot{x}$: the required curve, therefore, is a circle, and the body a sphere.

The same principles are employed in the work above quoted, to the finding of the solid of least resistance, and a few other problems of the same kind; but as we have already considered these under a more general form in the article ISOPERIMETRY, we shall not pursue the subject any farther in this place.

To ascertain the number of maxima or minima that appertain to any variable function.

In the preceding problems it has generally happened, that the equations from which we have derived our maximum or minimum have been of the first degree; and, therefore, admitted of only one rational value; but it may happen that the final equation is of a higher dimension, and, consequently, admitting of several roots, each of which may be employed, at least so far as we have considered the subject at present: also, as our operation is precisely the same, whether we are

seeking a maximum or a minimum, it is necessary to have some means of determining, *a priori*, which root gives the maximum, and which the minimum, as well as to ascertain the number of each.

In our former definition, we stated a maximum, or minimum, to be the greatest or least state of a variable function; which was done in order to simplify the idea, being in fact the real import of the word; and in any question of a physical nature, the term must be still understood in this light. That is, if the fluxional equation be of such a degree as to admit of several roots, that one must be found which makes the result the greatest, or least possible; but analytically, we must understand this term to signify that state of a variable function, which, if the variable upon which it depends be either increased or decreased, the whole function will decrease or increase, according as it is in its maximum or minimum state; but this increase or decrease is frequently limited, and being carried beyond a certain point, the whole function will again increase or decrease. This will be more obvious, from (fig. 2. Plate XIII. Analysis.) where the several ordinates AB, EF, IK , are maxima, and CD, GH , are minima, any one of which, as for example EF , will be observed to recede from its maximum towards a minimum, as it approaches towards C or D ; but beyond those points, it again approaches towards its other maximum value. The object, therefore, of our present enquiry, is to ascertain the number of maxima or minima that a function may have, and which root of the final equation gives the one, and which the other.

In order to this, let y be any function of x , and suppose that x has attained that particular value which renders the function y a maximum or a minimum; it follows then, if x be either increased or diminished by any quantity h , that we ought to obtain for the whole function a result less or greater than the preceding, according as it was in its maximum or minimum state. Now, if we represent by y' the function answering to $x + h$, and by y'' the function answering to $x - h$, we shall have from Taylor's theorem

$$y' = y - \frac{h \dot{y}}{1 \cdot \dot{x}} + \frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2} - \frac{h^3 \dot{\ddot{y}}}{1 \cdot 2 \cdot 3 \dot{x}^3} + \&c.$$

$$y'' = y + \frac{h \dot{y}}{1 \cdot \dot{x}} + \frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2} + \frac{h^3 \dot{\ddot{y}}}{1 \cdot 2 \cdot 3 \dot{x}^3} + \&c.$$

And since the powers of a quantity which is less than unity become less and less as the exponent is greater, it may be readily conceived, that h may be taken so small, that each of the terms of the preceding series may be greater than the sum of all the following ones; and, consequently, the sign of the whole series, beginning at any term, will always be the same as that of the first term, as to positive or negative.

Therefore, if $\frac{h \dot{y}}{\dot{x}}$ be any thing but zero, y will be greater than y' , and less than y'' ; and, consequently, is neither a maximum nor minimum; therefore, when it is either the

one or the other, $\frac{h \dot{y}}{\dot{x}} = 0$. In this case, we have

$$y' = y + \frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2} - \frac{h^3 \dot{\ddot{y}}}{1 \cdot 2 \cdot 3 \dot{x}^3} + \&c.$$

$$y'' = y + \frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2} + \frac{h^3 \dot{\ddot{y}}}{1 \cdot 2 \cdot 3 \dot{x}^3} + \&c.$$

where it is obvious that $y > y'$, and $> y''$; or $y < y'$,

$< y''$, according as $\frac{h^2 \ddot{y}}{1 \cdot 2 \dot{x}^2}$ is negative or positive; and

is, therefore, necessarily a maximum or a minimum.

But if $\frac{h^2 y}{1.2x^2} = 0$, then again y is neither a maximum nor a minimum; for in this case, y is $> y'$, and $< y''$. We have, therefore, the following rule for ascertaining the maxima et minima of any proposed function. Find the value of x in the equation $\frac{y}{x} = 0$, and substitute it for x in the expression $\frac{y}{x^2}$; then if the result is negative, y is a maximum, if positive, a minimum; and if it be zero, then y is neither a maximum nor a minimum, unless also $\frac{y}{x^3}$ be equal to zero; and then it will depend upon the sign of $\frac{y}{x^4}$; and so on, and the same process being observed, with regard to each of the roots of the fluxional equation, the number of maxima et minima will be obtained.

Let us illustrate the preceding rule by an example.

1. Find $y = x^4 - 8x^3 + 22x^2 - 24x + 10$, a maximum or minimum. Here

$$\frac{y}{x} = 4x^3 - 24x^2 + 44x - 24 = 0;$$

where $x = 1, 2$, and 3 .

And it is required to find which of these roots answers to the maxima, and which to the minima. Now

$$\frac{y}{x^2} = 12x^2 - 48x + 44.$$

And here, making $x = 1, 2, 3$, the results are respectively $+$, $-$, $+$; therefore the root 2 answers to the maximum, and the other two to the minima.

2. Let there now be proposed the function

$$y = x^5 - 7x^4 + 19x^3 - 25x^2 + 16x + 10.$$

Here $\frac{y}{x} = 5x^4 - 28x^3 + 57x^2 - 50x + 16 = 0$.

And the roots of this equation are $1, 1, 2, 1\frac{1}{2}$. Now

$$\frac{y}{x^2} = 20x^3 - 84x^2 + 114x - 50,$$

which $= 0$, when $x = 1$; therefore the root 1 gives neither a maximum nor a minimum, unless $\frac{y}{x^3} = 0$; which upon trial does not obtain.

But by assuming $x = 2$ in this equation, the result is -4 ; and, consequently, this value of x answers to a maximum.

And by submitting the other root $1\frac{1}{2}$ to the same test, a similar result will be obtained.

We will add another example, with which we must conclude this article.

3. To find when the function

$$y = x^3 - 18x^2 + 96x - 20$$

becomes a maximum or a minimum.

Here $\frac{y}{x} = 3x^2 - 36x + 96 = 0$,

in which equation the roots are $x = 4, x = 8$.

Now $\frac{y}{x^2} = 6x - 36$.

Here the root 8 gives $\frac{y}{x^2}$ positive.

And the root 4 gives $\frac{y}{x^2}$ negative.

Therefore the former answers to the minimum, and the latter to the maximum.

If the fluxional equation has no real root, then it follows that the proposed function admits of neither a maximum nor a minimum; but increases or decreases *ad infinitum*.

MAXIMENE, in *Geography*, a town of Walachia; 18 miles N. of Galacz.

MAXIMIANOPOLI, a town of European Turkey, in Romania, founded by the emperor Maximian; formerly the see of a bishop, in the province of Rhodope, but now a small place 60 miles S.W. of Adrianople.

MAXIMIANOPOLIS, in *Ancient Geography*, a town of Palestine, the same as Hadad-Rimmon, in the valley of Jezreel, and in the plain of Megiddo. An ancient traveller places it 17 miles from Caesarea, and 10 from Jezreel.—Also, a town of Thrace, in Media, upon the northern bank of the Marsh Buton; called also Myxxa. See MAXIMIANOPOLI.

MAXIMIANUS, HERCULIUS MARCUS AURELIUS VALERIUS, in *Biography*, a native of Sirmium, in Pannonia, was the son of parents who gained their daily subsistence by the labour of their hands. Brought up in rustic manners, and destitute of every advantage of education, he early embraced that way of life which alone presented the prospect of advancement, and enlisted as a common soldier in the Roman armies. Aspiring to something better than the servile character which he then held, he gradually rose through the several stages of command, distinguished by strength and hardiness of body, and the military virtues of courage and obedience. He fought under the emperors Aurelian and Probus on the banks of the Danube, Rhine, Euphrates, and borders of the ocean, acquiring the talents of an experienced soldier, if not of a great general. His manners were not changed in his progress, but he remained rude and ferocious, with a propensity to the grossest debauchery. In the course of his service, he contracted an intimacy with his fellow-soldier Dioclesian, who, when elevated to the imperial dignity, remembered the valour, courage, and hardihood of Maximianus, and rewarded his fidelity by making him his colleague in the empire, and by ceding to him the command of the provinces of Italy, Africa, and Spain, and the rest of the western territories of Rome. The personal superiority of Dioclesian was, however, recognized in the assumed epithet of *Jovius*, while Maximian took that of *Herculius*. Maximianus shewed the justness of the choice of Dioclesian by his victories over the Barbarian tribes with whom he was called to contend. As soon as Dioclesian entered into the twentieth year of his reign, he celebrated, in conjunction with Maximian, that memorable era, as well as his own great successes, by the pomp of a Roman triumph. (See *DIOCLESIAN*.) This triumph was dignified by several circumstances of superior celebrity and good fortune. Africa and Britain, the Rhine, the Danube, and the Nile, furnished their respective trophies; but the most distinguished ornament was of a more singular nature, a Persian victory, followed by an important conquest. The representation of rivers, mountains, and provinces were carried before the Imperial car. The images of captive wives, the sisters and the children of the great king, afforded a new and grateful spectacle to the vanity of the people. Not long after this, a severe illness inspired Dioclesian with the design of abdicating his power, which resolution he carried

into effect in the month of April or May, 305. Maximian was induced by his authority to follow his example, and on the same day divested himself of the purple at Milan, and retired to a delightful villa in Lucania. In the course of a few months, as we have seen in the article MAXENTIUS, he, at the desire of his son, re-assumed the imperial dignity, and was now anxious that this son should yield all authority into his hands. This singular contest for empire between father and son, and its decision, have already been noticed. Maximian retired in confusion into Illyricum, and endeavoured to engage Galerius in his cause. Disappointed in his expectations, he returned to the court of his son-in-law, Constantine, apparently contented with his lot, but in truth watching an opportunity for recovering his power; and while Constantine, in 309, was engaged on the banks of the Rhine in repelling an invasion of the Franks, he spread the report of Maxentius' death, and hastily resumed once more the ensigns of office. The intelligence of this event caused Constantine to return speedily into Gaul, who seized upon Maximian, and confined him to the palace under strict watch; but without intending to inflict a severer punishment. The clemency of Constantine inspired Maximian with the dark design of murdering him; and he had the wickedness and temerity to solicit his daughter Fausta to join him in the conspiracy. She informed her husband of the plot, and through their contrivance, a slave, who was an eunuch, was placed in the emperor's bed, whom Maximian stabbed to the heart, on the supposition that it was his master. Upon this detection he was judged unworthy to live, and being permitted to choose his death, he strangled himself. Such is the generally accredited account; but Gibbon represents the matter differently: he says, that Maximian was delivered into the hands of his son-in-law by the treachery of his army, in consequence of which, a secret and irrevocable sentence of death was pronounced against the usurper, and he obtained the same favour which he granted to Severus, and it was published to the world, that, oppressed by the remorse of his repeated crimes, he strangled himself with his own hands. "After he had lost the assistance, and disdained the moderate counsels of Dioclesian, the second period of his active life was a series of public calamities and personal mortifications, which were terminated in about three years by an ignominious death. He deserved his fate; but we should find more reason to applaud the humanity of Constantine, if he had spared an old man, the benefactor of his father, and the father of his wife. During the whole of this melancholy transaction, it appears that Fausta sacrificed the sentiments of nature to her conjugal duties." Gibbon. *Univer. Hist.*

MAXIMILLIAN I., emperor of Germany, born in 1459, was son of the emperor Frederic IV. In early life he was so dull and apparently deficient, that he was for several years considered rather in the light of an idiot. About ten years of age he became remarkably addicted to learning, and acquired, with surprising quickness, the Latin, French, and Italian languages. In his twentieth year his father effected a marriage between him and Mary, the heiress of the great house of Burgundy. Lewis XI. of France having seized part of her inheritance in the Low Countries, Maximilian made war against him, defeated his troops, and recovered great part of the usurped territories. He also suppressed the revolts which broke out in various parts of the Low Countries. As he was proceeding in a career of success, he had the misfortune to lose his wife, a circumstance that gave a shock to his authority, and the guardianship of his children was immediately contested by the states. A civil war ensued, which at length was accom-

modated on the condition that he should continue tutor to his son Philip, under restrictions. In 1486, Maximilian was elected king of the Romans, and crowned at Aix-la-Chapelle: upon his arrival at Bruges to meet the states-general in 1488, the inhabitants ran to arms to secure his person, being suspicious that he was inimical to their rights and liberties; at the same time they imprisoned some of his counsellors, four of whom they beheaded. The people of Ghent followed their example; but, after suffering a kind of imprisonment for ten months, he was liberated. In 1493, he succeeded, by the death of his father, without opposition, to the imperial dignity. He marched at the head of an army against the Turks, who had invaded Croatia, but they retreated before he could reach them. In 1494, he took for his second wife Blanche, the sister of John Galeazzo, duke of Milan, an alliance which engaged him in the affairs of Italy; and when Charles VIII. of France had made himself master of the kingdom of Naples, Maximilian joined in the confederacy of the pope, the king of Spain, and several Italian powers to oppose his arms. He also effected a marriage between his son Philip and the infanta Jane, daughter of Ferdinand and Isabella, by which the Low Countries eventually fell under the dominion of Spain. After the retreat of Charles from Italy, Maximilian, in 1496, engaged in an expedition into that country, and laid siege to Leghorn; but, failing in his attempts, he returned with disgrace. He next attempted to reduce the Swiss; but seven defeats, within six months, made him glad to terminate the war in 1500 by a treaty. After the death of his son Philip, in 1507, he obtained the regency of the Low Countries, of which he constituted his daughter Margaret governess. The famous league of Cambray against the Venetians took place in 1509, to which Maximilian was one of the contracting parties. His troops took possession of Friuli and Istria, and he, at the head of a great army, laid siege to Padua, but was obliged to abandon the enterprise. When pope Julius deserted the league and declared war against the French, Maximilian endeavoured to get him deposed, in order that he himself might succeed to the papacy; but his scheme entirely failed. For a large subsidy he engaged to assist Henry VIII. in his invasion of France; but failing in his engagement, he came in person with a few German troops, and flattered the vanity of the English monarch, as well as gratified his own avarice, by serving under him for the pay of a hundred crowns a day. On the accession of Francis I. he made peace with that monarch, who thereby regained the Milanese. He took little or no part on the subject of the Reformation at its commencement; but at the solicitation of the monks he applied to Leo X. to terminate the religious disputes by his own decision, and he summoned Luther to appear, with the promise of a safe conduct, before the diet of Augsburg. He was particularly anxious to secure the succession to the imperial crown for his grandson Charles; but in the midst of his cares on this subject he died in January, 1550. In his private character he was amiable and respectable; but as a public man he wanted that decision which constitutes true dignity in a prince. He was beneficent and humane, and his memory is still cherished in Germany for abolishing the famous secret tribunal of *Weistphalia*. He was author of some poems, and composed memoirs of his life. *Univer. Hist.*

MAXIMILLIAN II., emperor of Germany, son of Ferdinand, was born at Vienna in 1527. He was educated in Spain under his uncle, Charles V., whose daughter he married, and he governed that country three years in the name of his father-in-law. After his father had ascended the

imperial throne, he conferred on Maximilian, in 1562, the crowns of Hungary and Bohemia, and caused him to be elected king of the Romans; and upon the death of Ferdinand, in 1564, he succeeded to the empire without any opposition. He was already distinguished for prudence and moderation, and well acquainted with the languages and dispositions of the various people under his sway. The spirit of his administration was pacific, and his reign, for the most part, tranquil. The Protestants of Austria, who had been very useful to the emperor in lending him money to carry on the Turkish war, and afterwards cancelled the debt, requested to be indulged in the free exercise of their religion, which he readily granted. He was not contented to do good himself, but endeavoured, by all the means in his power, and by strong remonstrances to his cousin, Philip king of Spain, to put a stop to the cruelties exercised by Alva in the Low Countries; but that bigot refused to listen to his advice, or to follow his example. Actuated by the same principles, he forbade Charles IX. to make levies in Germany for the purpose of exterminating the French Hugonots, though he could not prevent the Protestant princes of Germany from sending succours to their persecuted brethren in France. Twice he solicited the crown of Poland, with the intention of conveying it to his second son, but want of activity prevented him from attaining his object: he had, however, been successful in securing to his eldest son Rodolph the reversion of the empire, and of the kingdoms of Bohemia and Hungary, and avowed his intention of supporting his claim to the kingdom of Poland by force of arms; but this purpose, if real, was defeated by his death, which happened in 1576. He had, it was said, for some time previously to the event, devoted many of his leisure hours to the contemplation of a future state; and had been accustomed to discourse, in his familiar parties, upon the immortality of the soul, which he looked to not only without terror and dismay, but with hope and Christian confidence. Maximilian II., says the historian, "appears to have been one of the most amiable princes that ever swayed the imperial sceptre. No individual ever complained of having heard a harsh expression from his lips, none ever departed dissatisfied from his audience. So regular were his economical arrangements, that to every act of his life its appropriate hour was allotted; and every day after dinner the meanest of his subjects was at liberty to approach him. A faithful husband, an affectionate parent, and a passionate lover of truth, his example had considerable influence on the manners of his people, and the empire flourished in a peculiar manner under his administration." Univer. Hist.

MAXIMILIAN, duke of Bavaria in the 17th century, was called, on account of his courage and success, the Defender of Germany; and, for his singular prudence, he acquired the name of Solomon. He zealously opposed the Protestants, and was considered as one of the principal supporters of the Catholic religion. In 1620, he gained the battle of Prague against Frederic, prince palatine, who had been elected king of Bohemia. For these services Maximilian was named an elector of the empire. He died in 1651, aged 70. Moreri.

MAXIMIN, ST., in *Geography*, a town of France, in the department of the Var, and chief place of a canton, in the district of Brignoles; 20 miles N. of Toulon. The place contains 3717, and the canton 9778 inhabitants, on a territory of $412\frac{1}{2}$ kilometres, in nine communes. N. lat. $43^{\circ} 28'$. E. long. $5^{\circ} 55'$.

MAXIMINUS, CAIUS JULIUS VERUS, in *Biography*, a Roman emperor, raised to this high rank from almost the lowest class of society, was born in Thrace, A.D. 183.

His father was a barbarian of the Gothic nation, his mother an Alan, and he himself was brought up to attend the herds and flocks. In this station he had frequent opportunities of exhibiting his prowess in combating the bands of robbers who overran the country. He is said to have attained to a gigantic stature, and a correspondent strength of body, which produced, in an uncultivated mind, a savage and ferocious character. He was both the pride and the dread of his district, at the time when the emperor Severus, returning from the East, halted in Thrace, to celebrate the birthday of his son Geta. "The country," says Gibbon, "flocked in crowds to behold their sovereign, and a young barbarian of gigantic stature earnestly solicited, in his rude dialect, that he might be allowed to contend for the prize of wrestling. As the pride of discipline would have been disgraced in the overthrow of a Roman soldier by a Thracian peasant, he was matched by the stoutest followers of the camp, sixteen of whom he successively laid on the ground. His victory was rewarded by some trifling gifts, and a permission to enlist in the troops. The next day, the happy barbarian was distinguished above a crowd of recruits, dancing and exulting after the fashion of his country. As soon as he perceived that he attracted the emperor's notice, he instantly ran up to his horse, and followed him on foot, without the least appearance of fatigue, in a long and rapid career. "Thracian," said Severus, with astonishment, "art thou disposed to wrestle after thy race?" Most willingly, sir, replied the unwearied youth; and, almost in a breath, overthrew seven of the strongest soldiers in the army. A gold collar was the prize of his matchless activity, and he was immediately appointed to serve in the horse-guards who always attended on the person of the sovereign." As a soldier he distinguished himself no less by his attention to military discipline than by his valour, and his ferocity bent to the spirit of obedience and subordination. Under Caracalla he rose to the rank of centurion, but he nobly refused to serve under the assassin of that prince, and retiring to his native place he purchased property, and carried on a commerce with the barbarous tribes from which he derived his origin. During the reign of the monster Heliogabalus he kept at a distance from the court, notwithstanding the solicitations of his friends to take a military tribuneship. Alexander Severus knew the worth of Maximinus, and committed to his care a legion of new recruits; the duties of which station he fulfilled with the utmost assiduity, bestowing the minutest attention upon their exercise, arms, health, and apparel. When he was told by a person of considerable rank, that in such a career of promotion he need not trouble himself, he indignantly replied, "I am of a different opinion, the higher I rise the more I shall labour." Though, as an officer, he was a strict disciplinarian, his manners, and the figure of his person, rendered him extremely popular among the soldiery, who gave him the appellations of Ajax and Hercules. His elevation began to inspire him with ambitious views, which effaced the sentiments of affection, gratitude, and duty: he aspired to the throne, and was proclaimed, by the army, emperor, in the year 235. The decree of the soldiery was confirmed by an always complying senate, and one of his first acts was to confer on his son, a youth of fine talents, the title of Cæsar. His heart now became callous to the feelings of honour and humanity; he not only removed from his presence the friends and advisers of the late emperor, but put many of them to death upon the slightest and most frivolous grounds. A conspiracy against his person afforded him a better pretext for the most sanguinary cruelty, and a vast number of persons of rank lost their lives on the occasion, with various circumstances

circumstances of barbarity. He now became the object of universal dread and detestation, and was, in a short time, such is the progress of vice and cruelty, grounded on ambition, ranked among the most bloody tyrants that ever disgraced the Roman purple. He still had the art to retain the attachment of his army, in whom he confided, and crossing the Rhine into Germany with numerous and well-disciplined battalions, he laid waste a wide tract of country with fire and sword, and destroyed a great number of natives who opposed him. In these actions he displayed the skill of a general, with the bravery of a private soldier, and made it sufficiently evident that war was the true theatre of his glory. After two campaigns, he passed the winter of the year 236 at Sirmium, occupied in raising money by the severest exactions, which, by means of his officers, were extended to all the provinces of the empire. The procurator of Africa carried his extortions to such an intolerable excess that a conspiracy was formed against him, to which his life fell a sacrifice; and in the year 238, Maximinus and his son were dispatched by an indignant and suffering people, who, fixing their heads upon spears, displayed them as trophies through the army, who received the intelligence with joy, and united in declarations of fidelity to the senate and its decisions. Maximinus has been reckoned, by ecclesiastical writers, among the persecutors of the Christians, but the candid historian does not readily admit the title of "the sixth persecution" to be justly applied to the reign of this emperor. He is described, by Gibbon, as a brutal savage, destitute of every sentiment that distinguishes a civilized, or even a human being. "The body," says he, "was suited to the soul." The stature of Maximinus exceeded the measure of eight feet, and circumstances almost incredible are related of his matchless strength and appetite. Had he lived in a less enlightened age, tradition and poetry might well have described him as one of those monstrous giants, whose supernatural power was constantly exerted for the destruction of mankind. Gibbon. Univer. Hist.

MAXIMINUS, C. GALERIUS VALERIUS, a Roman emperor, son of the sister of the emperor Galerius, was in the year 305, upon the abdication of Dioclesian and Maximian, raised, by the influence of his uncle, to the rank of Cæsar, and, in the division of the empire, the provinces of Egypt and Syria were placed under his government. When Licinius, in 307, was raised by Galerius to the rank of Augustus, Maximinus, disdainful of an inferior title, insisted on the same elevation, and upon some reluctance on the part of Galerius to grant it, he caused himself to be nominated to that dignity by his assembled troops: thus at one and the same time, the Roman world, in the year 308, witnessed six Augusti or emperors. On the death of Galerius, in 311, Maximinus shared his dominions with Licinius, and added Asiatic provinces to his former possessions. In the contest between Maxentius and Constantine, Maximinus secretly allied himself with the former, though he took no open part in the war. When Galerius issued his edict in favour of the Christians, Maximinus, though an enemy to them, thought proper to concur. Still he had a great desire to re-establish the Pagan worship, with all its impostures of magic and divination. He was preparing to renew the persecution, and, in the mean time, he not only gave to the ancient religion a system of church government copied from the Christians, and threw about it all the lustre of the state, but employed every art to discourage and vilify Christianity. He is also charged with having published and carefully disseminated a false narrative of the death of Jesus Christ, filled with the most injurious representations. The principal cities of his dominions, as Nicomedia, Antioch, and Tyre,

were instigated to send addresses to him, expressing their abhorrence of the Christians, and imploring that they might be expelled. These, however obtained, led to the infliction of cruel and ignominious punishments and to the destruction of some lives. The dangers that menaced Christianity in Asia were averted by the war, which, in 313, took place between Maximinus and Licinius. The latter had made an alliance with Constantine, and the apprehension of its consequences seems to have been the chief motive of Maximinus, who began the attack. He was entirely defeated, and was obliged to seek his safety in a rapid flight; and it is said he reached Nicomedia, a distance of 160 miles, in the space of twenty-four hours from the conclusion of the battle. He retreated to Tarsus, where, in a few months, death put an end to his disgrace. His whole family was sacrificed to the vindictive rage of the conqueror. Gibbon. Univer. Hist.

MAXIMUS, M. CLAUDIUS PAPIENUS, a Roman emperor, was the son of a mechanic, but having a desire to enrol himself in the army, he enlisted at an early age, and became distinguished first as a soldier, and afterwards in some of the public offices of state. In 227 he obtained the consulate, and was afterwards proconsul of Bithynia, Greece, and Narbonnensis Gaul, and was appointed to military commands in various parts of the Roman empire. As prefect of Rome, he displayed intelligence, firmness, and severity, so that he acquired a general respect, accompanied with an awe, approaching almost to terror. In 237, when the murder of the Gordians deprived Rome of the emperors it had chosen in the place of the tyrant Maximinus, the merit of Maximus caused him to be invested with the purple together with Balbinus. Some opposition was first made to his accession, and it was resolved to add the younger Gordian, then a child, to the emperors already chosen. At length Maximus was received with joyful acclamations as the deliverer of his country, and the conduct of the three emperors seemed to promise the restoration of an equitable and wise government to the Roman world. The various nature of their talents seemed to appropriate to each his peculiar department of peace and war, without leaving room for a jealous emulation. Justice was regularly administered, wholesome laws were enacted, and oppressive taxes were repealed or moderated. Discipline was revived, and with the advice of the senate many excellent regulations were introduced into the several departments of government. The pretorian bands, accustomed to depose and to make emperors at their pleasure, soon shewed symptoms of discontent under a sovereignty which they had not established, and apprehended that the reign of law and order would be destructive of their power. They accordingly seized upon the opportunity when the citizens were occupied in the Capitoline games, rose in mutiny, and marched towards the palace: laid hold of the two emperors, treated them with every mark of insult, and, to prevent the possibility of a rescue, took away their lives, leaving their bodies, mangled with a thousand wounds, exposed to the insults or the pity of the populace. Gibbon. Univer. Hist.

MAXIMUS, PETRONIUS, an emperor of the West in the fifth century, was a Roman of noble birth. Possessed of an ample patrimony, and adorned with liberal arts and elegant manners, he obtained the favour of the prince and the senate, and of course rose to high and important offices in the state. In March 455, Maximus was elected emperor, in the room of Valentinian, who had, on account of his vices and tyranny, been assassinated. In a few hours he was convinced that happiness and sovereignty were generally at variance, and he was heard to exclaim, "Happy Damocles, whose reign began and ended with a dinner!" His own power

was very short-lived; when attacked by Genserich, king of the Vandals, in Africa, he was deprived of all courage and presence of mind, and thought of nothing but how to make his escape. Cowardice in a prince is always hateful and contemptible, and as soon as his intentions were known, the people, who would probably have rallied round him, had he been inclined to defend his country, rose upon him, and a soldier gave him a fatal blow. His body was ignominiously dragged through the streets and thrown into the Tiber. Such was his end, after a reign of less than three months. Gibbon. Univer. Hist.

MAXIMUS MAGNUS, an imperial usurper of the fourth century, a native of Spain, and probably of low origin, served in Britain with Theodosius, afterwards emperor, and established a character for valour and abilities, though it does not appear that he rose to any important rank, either civil or military. He was invested with the imperial purple in the year 383, by the army among whom he had excited discontent and disaffection against Gratian, emperor of the West. This took place while he was in Britain, but he determined to carry his arms to the continent, and contend with the lawful emperor upon his own ground. He transported into Gaul so great a number of Britons, that the emigration at that period weakened the population of the island, and they afterwards settled in Bretagne. As he advanced he was joined by the Gallic armies, and even the household troops deserted Gratian, then resident at Paris. He fled before the usurper, and was put to death at Lyons. Maximus was now acknowledged as emperor by all the provinces of the West, and he declared his infant son Victor his colleague, and proposed an alliance to Theodosius, emperor of the East, which was accepted, on condition that he should not pass the Alps, beyond which Valentinian, the brother of Gratian, reigned over Italy, Illyrium, and Africa. The ambition of Maximus, however, would not permit him to rest; in 387 he invaded Italy, and took possession of Milan, without opposition. Valentinian fled to implore the assistance of Theodosius, who, while the usurper was employed in reducing the towns of Italy, levied an army to oppose him. A battle decided the fate of Maximus; as soon as he was defeated, his own soldiers rose upon him, dragged him away and struck off his head. His son Victor met with a similar fate in Gaul. These events took place in the year 388. Maximus is stigmatized as the first Christian prince who shed the blood of his Christian subjects, on account of their religious opinions. Gibbon. Univer. Hist.

MAXIMUS TYRIUS, a celebrated philosopher, and elegant writer in the second century, was a native of Tyre in Phœnicia, whence he derived his name. He probably came to Rome in the year 146, where he received from the emperor Marcus Aurelius many tokens of esteem and regard. This emperor is said to have placed himself under the instructions of the philosopher, though some writers imagine that this high honour belonged to another Maximus of the Stoical sect. Maximus adopted the principles of Plato, but with an evident leaning to scepticism. There are forty-one of his "Dissertations," on philosophical topics, still extant, which display much sound argument, and real eloquence. These have been very frequently printed. The first Latin version was published at Basil in 1519, and the original Greek was printed for the first time by Henry Stevens, in 1557. In 1607, Daniel Heinsius published an edition of them at Leyden, in Greek and Latin, illustrated with notes. A new impression of this edition was printed at Cambridge in 1703, with corrections, additional notes and indexes, by Dr. John Davies. Enfield. Hist. Phil. Harwood.

MAXIMUS, named "The Cynic," a native of Ephesus, who studied under Celsus of Cappadocia, a philosopher of the Eclectic school, and immediate successor of Jamblichus. He was probably appointed by the emperor Constantius preceptor to Julian, surnamed afterwards "The Apostate." Some writers, however, maintain that he introduced himself to that emperor at Nicomedia, either while he was pursuing his studies, or during his expedition into the East. Whichever account be true, it is certain he was a great favourite with Julian, and had such an influence over his mind, as to excite in him the most determined hatred to Christianity, while he inspired him with an ardent attachment and enthusiasm in favour of Heathen superstitions, and the practice of pretended magical arts. Such, at length, was the folly of the deluded emperor, that he seemed to place an entire confidence in the predictions of Maximus. When the emperor intended to make war against Persia, he had recourse to his divinations, which flattered him with the idea, that he was born to rival Alexander in the glory of conquest. The event shewed the vanity of the prophet, and the emperor fell a sacrifice to his credulity. During the reign of Jovian, Maximus was treated with respect; but under the government of Valentinian and Valens he was seized and prosecuted for the crime of magic, of which he was convicted and sentenced to a long imprisonment. In 373, he was put to death by the proconsul Festus, the distinguished minister of the emperor Valens' cruelties. Enfield. Hist. Phil.

MAXINO, in *Geography*, a town of Sweden, in the government of Wafa; 12 miles N.N.E. of Wafa.

MAXULA, MO-RAISAH, in *Ancient Geography*, an ancient town of Africa, situated on the sea-coast, S.E. of Carthage. It is mentioned by Ptolemy, Pliny, and Antonine in his Itinerary.

MAXY, in *Mineralogy*, a name given by some to mundic, a sulphureous mineral, common in the tin-mines of Cornwall, and elsewhere.

MAXYES, in *Ancient Geography*, a people of Africa, in Libya, W. of the river Triton. According to Herodotus, they permitted their hair to grow on the right side of the head, shaved the left side, and painted their bodies with vermilion. They are said to have been descended from the Trojans, and to have inhabited a very mountainous country, covered with wood and full of wild beasts.

MAY. MAIUS, the fifth month in the year, reckoning from our first, or January; and the third, counting the year to begin with March, as the Romans anciently did. It was called *Maius* by Romulus, in respect to the senators and nobles of his city, who were named *majores*, as the following month was called *Junius*, in honour of the youth of Rome, in *honorem juniorum*, who served him in the war; though some will have it to have been thus called from *Maius*, the mother of Mercury, to whom they offered sacrifice on the first day of it; and Papias derives it from *Madius*, *eo quod tunc terra madaat*.

In this month the sun enters Gemini, and the plants of the earth in general begin to flower.

The month of May was under the protection of Apollo; and in it also they kept the festival of Bona Dea, that of the goblins, called *lemuria*; and the ceremony of *regifugium*, or the expulsion of the kings.

The vulgar have a great opinion of the virtues of May-dew, and May-butter.

The month of May has ever been esteemed favourable to love; and yet the ancients, as well as many of the moderns, look on it as an unhappy month for marriage. The original reason may perhaps be referred to the feast of the Lemures,

mures,

mures, which was held in it. Ovid alludes to this in the fifth of his *Fasts*, when he says,

“Nec viduæ tædis eadem, nec virginis apta
Tempora; quæ nuptiæ, non diuturna fuit:
Hac quoque de causa, si te proverbia tangunt,
Mense malum Maio nubere vulgus ait.”

MAY-apple, in *Botany*. See *PODOPHYLLUM*.

MAY-bush. See *CRATÆGUS*.

MAY-dew. See *DEW*.

MAY-duke, a species of cherry.

MAY-lily. See *CONVALLARIA*.

MAY-weed. See *ANTHEMIS* and *MATRICARIA*.

MAY-weed, in *Agriculture*, the common name of a troublesome kind of field weed, which resembles wild chamomile, and is a trailing perennial plant, which puts out roots from its branches as they lie on the ground. By these means, and by scattering its seeds long before the corn is ripe, it spreads and multiplies greatly. It flowers in May, whence its name. With regard to the best means of extirpating it, they are those of summer fallowing, repeated good harrowing, and burning the collected roots. What escapes these clearings should be very carefully pulled up by hand; for the common weeding-hook will not go deep enough to take out the whole of the long slender tap root of this plant, of which every remaining bit that has a knot in it will produce new shoots. The farmer should not regret this small additional expence, to get rid of one of the most fatal enemies his corn can have. Mr. Lisle observes, that a “good crop of wheat in the winter time, was so destroyed by the coming up of May-weed and poppies in the spring and summer, that it did not at last yield so much as the seed.” Where proper tillage is practised, this can never be a case.

MAY-wort, in *Botany*. See *ARTEMISIA*.

MAY, THOMAS, in *Biography*, eldest son of sir Thomas May, knight, of Mayfield in *Sussex*, was born in 1595. He pursued his studies in *Sidney college*, *Cambridge*, where he took his degree of B.A.; after which he entered himself a member of *Gray’s Inn*, with the view of studying the law, though he probably never pursued it as a profession. He was much attached to literature, and became acquainted with the poets and men of wit who flourished in that period. Owing to the extravagance of his father, he had only a small annuity to depend upon. Some of his first compositions were of the dramatic class, and three tragedies and two comedies are extant in his name. He translated “*Virgil’s Georgics*,” “*Selected Epigrams of Martial*,” and “*Lucan’s Pharsalia*,” with a continuation of the poem to the death of *Julius Cæsar*, in seven books, of his own composition; which have been so much admired, as to be given with several of the best editions of *Lucan*. This has rendered his name famous among classical scholars. He was author of many original poems, such as “*The Reign of Henry II.*,” “*The victorious Reign of Edward III.*,” “*The Description of Henry II. with a short Survey of the Changes of his Reign*,” and “*The single and comparative Character of Henry and Richard his Sons*.” He was in high estimation with king *Charles I.*, who designated him as his poet; but the monarch was not sufficiently liberal to secure the poet’s attachment. He even quitted the royal party, upon the breaking out of the civil wars, and entered into the service of the parliament. He was appointed secretary to the parliament, and wrote a history of its transactions; which work became famous, and was extremely obnoxious to the royal party. *Clarendon* speaks with great contempt of his performance, but *Granger* affirms that it is a very respectable work. It was his last literary labour.

He died in November 1650. His consideration with his party was shewn by a splendid public funeral in *Westminster Abbey*, with a marble monument and a laudatory epitaph. After the restoration, the royalists took their revenge, dug up his body, which they treated with ignominy, and tore down the monument intended to perpetuate his fame. *Biog. Brit.*

MAY, in *Geography*, a river of America, in *South Carolina*, which runs into the Atlantic, N. lat. 32° 15'. W. long. 80° 55'.—Also, a river of *Chiampa*, which runs into the *Chinese sea*, N. lat. 10° 42'. E. long. 107° 14'.—Also, a town of *Persia*, in the province of *Farsistan*; 120 miles S. of *Schiras*.—Also, a small island of *Scotland*, at the entrance of the *Firth of Forth*, formerly dedicated to *St. Adrian*, who was murdered by the *Danes*. On it is a light-house; five miles S. of *Fifeness*. N. lat. 56° 10'. W. long. 2° 38'.

MAY. See *MAYO*.

MAY, Cape, the most southerly point of land of *New Jersey*, and the N. point of the entrance into *Delaware bay* and river in N. lat. 39°. W. long. 74° 51'.

MAY, Cape, County, extends northward round the fore-mentioned cape, and is a healthy, sandy tract of country, 34 miles long, and 19 broad. This county is divided into *Upper, Middle, and Lower precincts*. The number of inhabitants is 3066, of whom 98 are slaves.

MAY Point, a point of the peninsula, between *Fortune* and *Placentia bays*, on the S. side of *Newfoundland island*.

MAYA, a town of *Spain*, in *Navarre*; 21 miles N. of *Pamplona*.

MAYA, in *Metaphysics*, is a term of vague import among the *Brahmans* and other *Hindoo philosophers*. It means *illusion* or *deception*, and is variously applied in cases beyond the reach of demonstration or comprehension. For instance, although their most sacred books give the title of god to the sun, and they confess generally that the sun is an emblem or image of their three great deities, jointly and individually, that is of *Brahm*, or the *Supreme Being*, who alone exists really and absolutely, yet the *three forms*, or *trimurti*, are considered as *maya*, or *delusion*, as well as the body of the sun; but since the latter is the most glorious and active emblem of *God*, that luminary is respected as an object of high veneration. This is sufficiently mysterious; but it flows from the principal tenet of the *Vedanti school* (see *VEDANTA*): “That the only being which has absolute and real existence is the *Divine Spirit*, infinitely wise, infinitely benign, and infinitely powerful, expanded through the universe; not merely as the *soul of the world*, but as the ruler of it, sending forth rays or emanations from his own essence, which are the pure vital souls of all animated creatures, whether *moveable* or *immoveable*; or, as we should express it, both *animals* and *vegetables*, and which he calls back to himself, according to certain laws established by his unlimited wisdom.” *Brahm*, as the *Molt High One*, is neuter; in the character of *Supreme Ruler* he is named *Parameßwara*; but, through the infinite veneration to which he is entitled, the *Hindoos* meditate on him with silent adoration, and offer prayers and sacrifices only to the higher emanations from him. This silent adoration is by some called *Jap*, (see that article,) in which description of worship the holy *gayatri* and the sacred monosyllable *O’M* is mentally recited. (See *O’M*.) In a mode, incomprehensible to inferior creatures, they are involved at first in the gloom of *maya*, and subject to various taints from attachment to worldly affections; but they can never be reunited to their source, until they dispel the illusion by self-denial, renunciation of the world, and intellectual abstraction, and have removed the impurities of their nature

by repentance, mortification, and successive transmigratory passages through the forms of animals or vegetables, according to their demerits. In such a reunion consists their final beatitude; and to effect it by the best possible means is the object of their supreme ruler, who, in order to reclaim the vicious, to punish the incorrigible, to protect the oppressed, to destroy the oppressor, to encourage and reward the good, and to shew all spirits the path to their ultimate happiness, has been pleased (say the Brahmans) to manifest himself in a variety of ways, from age to age, in all parts of the habitable world. When he acts immediately without assuming a shape, or sending forth a new emanation; or when a divine sound is heard from the sky, that manifestation of himself is called *Akashvani*, or an ethereal voice: when the sound proceeds from a meteor, or a flame, it is said to be *Agnipuri*, or formed of fire: a descent of the deity in the shape of a mortal, is an *avatara*. Of this last description there have been many; but the chief of them as detailed in the Puranas, and to which the word is generally applied, are the ten, or *dashavatara*, of Vishnu; as enumerated under the article *VISHNU*, and described briefly under the references therefrom. A similar incarnation of an inferior kind, intended to answer some purpose of self-moment, is called *Avantara*. Of this description is that noticed under *KANDEU RAO*; though in common language called also *avatara*. The supreme being, and the celestial emanations from him, are *nirakara*, or bodiless, in which state they must be invisible to mortals; but when they are *pratyaksha*, or visible, they become *sakara*, or embodied, and expressive of the divine attributes; thus Krishna revealed himself to Arjun, as described in an extract from the Gita under the article *KRISHNA*, or in a human form, which Krishna usually bore. And in that mode of appearing, the deities are generally supposed to be born of a woman, but without any carnal intercourse. The excessive libertinism of Krishna, his sectaries declare to be apparent only; he was chaste and pure in reality; such appearances were *maya*, or delusion.

These doctrines, however, are by no means received by all Hindoos, though they be very popular with certain sects. A reformation of the above, called *Purva mimansa*, was introduced by Jaimini, who denies the incarnations of deities. See *JAIMINI*.

Although not particularly in its place, we will here insert four verses translated by sir William Jones from the Bhagavat, one of the Hindoo Puranas, as connecting some of their philosophical tenets. The translation we are assured is "most scrupulously literal."

"Even I was at first, not any other thing; that which exists unperceived, supreme; afterwards *I am that which is*; and he who must remain, am I.

"Except the *First Cause*, whatever may appear, and may not appear, in the mind, know that to be the mind's *maya*, or delusion, as light, as darkness.

"As the great elements are in various beings, entering, yet not entering, (that is, pervading, not destroying,) thus am I in them, yet not in them.

"Even thus far may enquiry be made by him who seeks to know the principle of mind, in union and separation, which must be *every where always*." Asiatic Ref. vol. i.

The above verses are stated to have been spoken by the supreme being to Brahma, and wild and obscure as they are, the learned translator doubts if the poetry or mythology of Greece and Italy afford conceptions more awfully magnificent; the brevity and simplicity of the Mosaic diction is, however, unrivalled.

The first of the four verses above quoted will strongly re-
Vol. XXIII.

mind the reader of the inscription in a temple at Basa in Lower Egypt; see the article *EGYPT*, where further traces of resemblance will be found between the theology and philosophy of that country and of India, as exhibited in this, and the other articles connected with Hindoo mythology.

"As the soul of the world, or the pervading mind, so finely described by Virgil, we see Jove represented by several Roman poets; and with great sublimity by Lucan, in the speech of Cato concerning the Ammonian oracle: "Jupiter is wherever we look, wherever we move." This is precisely the Indian idea of Vishnu, according to the four verses above exhibited—not that the Brahmans imagine their male divinity to be the *divine essence* of the Great One, which they declare to be wholly incomprehensible; but, since the power of *pervading* created things, by a superintending providence, belongs eminently to the Godhead, they hold that power to exist transcendently in the preserving member of the Triad, whom they suppose to be *every where always*, not in subsistence, but in spirit and energy. Here, however I speak of the Vaishnavas, for the Saivas ascribe a sort, of pre-eminence to Siva." Jones, ib. See *VAISHNAVA* and *SAIVA*.

The accomplished writer above quoted addressed a spirited hymn to Narayana, and in the argument prefixed says, "that a complete introduction to it would be no less than a full comment on the Vedas and Puranas of the Hindoos, the remains of Egyptian and Persian theology, and the tenets of the Ionic and Italic schools: but this is not the place for so vast a disquisition. It will be sufficient here to notice, that the inextricable difficulties attending the *vulgar notion of material substances*, concerning which 'we know this only, that we nothing know,' induced many of the wisest among the ancients, and some of the most intelligent among the moderns, to believe that the whole creation was rather an *energy* than a *work*, by which the infinite Being, who is present at all times in all places, exhibits to the minds of his creatures a set of perceptions like a wonderful picture, or piece of music, always varied, yet always uniform; so that all bodies and their qualities exist, indeed, to every wise and useful purpose, but exist only as they are *perceived*: a theory no less pious than sublime, and as different from any principle of atheism as the brightest sunshine differs from the blackest night. This *illusory operation* of the Deity the Hindoo philosophers call *maya*, or *deception*." The Berkelyan theory of immaterialism seems to coincide with these doctrines. See *BERKELEY*.

Maya, in a more mythological view, is described as the mother of Kama, the god of love. Under this personification she represents the general *attracting* power; and some Hindoo scholars explain the word to mean the 'first inclination of the Godhead to diversify himself,' such is their phrase, 'by creating worlds.' She is thus dignified to be the mother of universal nature and of all the inferior gods. Lakshmi, the bounteous giver of all good, is also represented to be the mother of Kama, and one of her appellations is *Maya*, or *Ada-maya*, as noticed under *LAKSHMI*.

MAYA, in *Ornithology*, a name given by the people of the Philippine islands to a small species of sparrow, much less than our's, and very common among them. It feeds on rice, and is very destructive of it.

MAYACA, in *Botany*, a name of which no explanation is given. Anbl. Guian. 42. t. 15. Juss. 45. Lamarck Illustr. t. 36. Michaux Boreal-Amer. v. 1. 20. See *SYENA*; Schreb. 36. Willd. Sp. Pl. v. 1. 254.

MAYACARI, in *Geography*, a river of Guiana, which runs into the Atlantic, N. lat. 2° 11'. W. long. 51° 46'.
F
MAYA.

MAYAGUANA, one of the Bahama islands; 24 miles in length. N. lat. $22^{\circ} 32'$ to $22^{\circ} 44'$. W. long. $72^{\circ} 15'$ to $72^{\circ} 30'$.

MAYAHOUN, a town of the Birman empire, on the Irawaddy, which formerly belonged to Pegu, and was called "Loonzey" or "Lundsey." It is large, and contains many temples and convents, besides granaries filled with rice, produced in the environs, and belonging to the king; 120 miles N.N.W. of Rangoon.

MAYALS, a town of Spain, in Catalonia; 16 miles S. of Lerida.

MAYAMBA, a town of Africa, and capital of a province of the same name, in the kingdom of Loango, near the Atlantic ocean. Within its territory, which extends far eastward, is a salt lake, above 15 miles in compass, which empties itself by some rivulets into the sea, about half a league N. of cape Negro. The town stretches along the coast, but lies so low that the inhabitants are frequently under a necessity of removing at high water to some of the neighbouring high lands. The river Banna, which runs near the town, is saltish, and has at its mouth a good fishery for oysters. By means of this river, logwood is brought to the port in canoes from the province of Sette, where it abounds; the river extends 150 miles within land. The soil of Mayamba is dry and sandy, and produces little or no grain, but furnishes plenty of bananas and palm-trees, and of the latter a wine is made, and also roots of maxondo, which they use instead of bread. The lakes and rivers supply abundance of fish, on which the inhabitants chiefly subsist. The oysters are opened and smoked, and are thus preserved in an eatable state for several months. The country abounds with game, which is caught by dogs, with wooden clappers to their necks, by the noise of which they follow them, as they are not able to bark. The government of this province is commonly conferred on a counsellor of state, who is also prince of Loangiri, and gives no account to the king of Loango of any commodities, except of the logwood, which pays a duty of 10 per cent. The people are rude and savage, and their governor is an absolute tyrant. The commerce of elephants was formerly considerable and lucrative, but has lately been almost annihilated. S. lat. $3^{\circ} 20'$. E. long. $13^{\circ} 4'$.

MAYAPARA, the proper name of Point Palmiras; which see.

MAYAPIL, a town of Mexico, in New Biscay; 75 miles S.S.E. of Parral.

MAYAPOUR, a town of Bengal; eight miles S.W. of Palamow.—Also, a town of Bengal; 12 miles S.W. of Calcutta.

MAYAR, a town of Persia, in the province of Irak, containing about 300 houses, and a caravanfera; 24 miles S. of Ispahan.

MAYASQUER, a town of South America, in the audience of Quito; 70 miles N. of Quito.

MAYBACA, a river of Guiana, which runs into the Atlantic, N. lat. $6^{\circ} 40'$. W. long. $58^{\circ} 26'$.

MAYBOLE, or MINNEBOIL, a town of Scotland, in the county of Ayr, which has manufactures of woollen and cotton. The population returned to parliament in 1791 was 3162, of whom 1626 were employed in manufactures, chiefly of blankets. At this time here were ten persons, whose ages amounted together to upwards of 900 years; 18 miles S. of Ayr.

MAYCAWINI, a river of Guiana, which runs into the Atlantic, N. lat. $6^{\circ} 35'$. W. long. $58^{\circ} 26'$.

MAYCOCK BAY, a bay on the W. coast of Barbadoes; three miles N. of Speight's town.

MAYDOOH, a town of the Birman empire; 42 miles S.W. of Monchaboo.

MAYEM, a town of Hindoostan, in Baglana; 20 miles N. of Basseen.

MAYEN, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Coblentz; 15 miles W. of Coblentz. The place contains 2200, and the canton 5358 inhabitants, in 15 communes N. lat. $50^{\circ} 26'$. E. long. $7^{\circ} 8'$.

MAYEN'S *Island*, an island lying S.W. of Spitzbergen; formerly resorted to for the whales which frequented its coast, but now forsaken, as these fishes have removed farther north. A very high mountain, called Beerenbergen, or Bear mountain, extends quite across the island, which may be seen from the sea, at the distance of 30 miles. This island has many good bays, and the land abounding with deer, and the coast with fish, render it habitable; but the floats of ice, towards the E. especially, make it inaccessible in spring. N. lat. $71^{\circ} 13'$.

MAYENCE. See MENTZ.

MAYENNE, CHARLES of Lorraine, Duke of, in *Biography*, second son of Francis of Lorraine, duke of Guise, was born in 1554. He displayed great courage at the sieges of Poitiers and Rochelle, and at the battle of Montcontour. He also defeated the Protestants in Guienne, Dauphiny, and Saintonge. When his brothers were killed at the meeting of the Estates at Blois, he declared himself head of the league, and assumed the title of lieutenant-general of France. He proclaimed the cardinal of Bourbon king, by the name of Charles X.; but was defeated by Henry IV. at the battle of Arques, and again at Ivry. In 1599 he was reconciled to the king, who made him governor of the Isle of France. He died in 1611. Moreri.

MAYENNE, in *Geography*, a town of France, and capital of a department of the same name, and principal place of a district, near the river Mayenne, defended by a castle on a rock: the river rises near Linieres in the department of the Charente, and passing by Ambrieres, Mayenne, Laval, &c. joins the Sarthe, about three miles N. from Angers, and forms the Mayne, which joins the Loire, about four miles below. The town contains 7575 inhabitants; one of its cantons contains 14,834, on a territory of 162½ kilometres, in eight communes, and the other contains 14,946 inhabitants, on a territory of 200 kilometres, in twelve communes.

MAYENNE, one of the nine departments of the N.W. region of France, formerly Lower Maine, lies in N. lat. $48^{\circ} 15'$, and is bounded on the N. by the departments of the Channel and the Orne, on the E. by the department of the Sarthe, on the S. by the Mayne and Loire, and on the W. by that of the Ille and Vilaine. Its length is about 22 French leagues, and breadth 16; its extent is 5452½ kilometres, or about 266 square leagues, and the number of its inhabitants is computed at 328,397. It is divided into three circles, 27 cantons, and 288 communes. Its circles are Mayenne, including 157,256 inhabitants in 116 communes; Laval, containing 106,141 inhabitants in 93 communes; and Chateau-Gonthier, having 65,000 inhabitants in 79 communes. According to M. Hassenfratz, this department comprehends seven circles, 68 cantons, and 323,607 inhabitants. Its contributions in the 11th year of the French era amounted to 3,111,618 fr., and its expences for administration, justice, and public instruction, were 234,804 fr. Its capital is Laval. A great proportion of this department is hilly and covered with forests; it has many sandy tracts, and few cultivated plains. The borders of the rivers Sarthe and Mayenne yield some grain, fruits, and pastures in abundance.

Here are mines of iron, quarries of marble and stone, mineral springs, &c.

MAYENNE, or MAYNE, and *Loire*, so called from the union of two rivers, formerly Anjou, is one of the nine departments of the western region of France, lying in N. lat. 47° 20', and bounded on the N. by the departments of the Mayenne and Sarthe; on the E. by the department of the Indre and Loire; on the S. by the departments of the Vendée, the Two Sevres, and the Vienne; and on the W. by the department of the Lower Loire. Its length is 26 French leagues, and breadth 21 leagues; and its territorial extent is 70,37½ kilionetres, or about 370 square leagues; and its number of inhabitants is 376,033. It is divided into five circles or districts, 34 cantons, and 385 communes. The circles are Segré, comprehending 58,176 inhabitant in 77 communes; Baugé, including 60,669 in 61 communes; Saumur, having 90,104 in 115 communes; Beaupreau, with 74,657 in 73 communes; and Angers, having 92,434 in 59 communes. According to M. Hassenfratz, the circles are eight, the cantons 99, and the number of inhabitants 445,500. Its contributions in the 11th year of the French era amounted to 4,182,024 fr. and its expences for administration, justice, and public instruction, were 348,331 fr. 99 cents. Its capital is Angers. This department, diversified with hills and plains, yields grain, flax, hemp, fruits, abundant pastures, considerable forests, mines of coal, &c. and quarries of marble, stone, and slate.

MAYEPEA, in *Botany*. See CERANTHUS, and CHIRONANTHUS *Incrassata*. Notwithstanding the doubts of our learned predecessor in the place last cited, we are convinced that this genus of Aublet and Schreber is rightly referred by Swartz and Vahl to *Chionanthus*, and that Jussieu was widely mistaken in ranking it among his *Rhamnii*.

MAYER, JOHN FREDERIC, in *Biography*, a learned German divine in the seventeenth century, was born at Leiplic in 1650; he acquired a profound knowledge of the ancient languages, and became professor at several of the universities of his country. He died in 1712 with a high character for learning. He was author of "Bibliotheca Biblica," which treats of the most celebrated commentators of the scriptures; a treatise "On the best Method of studying the Sacred Scriptures;" "The History of Martin Luther's German Version of the Bible, with a short Account of the Translations of the Sacred Books before his Time;" and other pieces. Moreri.

MAYER, TOBIAS, a German astronomer and mechanic, was born at Marpach, in Wirtemberg, in the year 1723. At the very early age of four years he shewed a strong attachment to the mechanical arts, and actually began to design and construct little machiæ with dexterity and accuracy. His father was a civil engineer, and encouraged him in his pursuits; but upon his death the son was left almost destitute, and was obliged to depend on his own energies for future support. By these he made himself acquainted with mathematical learning, and qualified himself in a short period to be an able instructor of others. He acquired, at the same time, a considerable share of classical knowledge, so as to be able to write the Latin tongue with elegance. At the age of twenty-eight, he was nominated mathematical professor at the university of Gottingen, and soon after was admitted a member of the Royal Society in that town. From this time every year of his life was distinguished by discoveries in geometry or astronomy. He invented many useful instruments for the measurement of angles: he applied himself to study the theory of the moon: he extended his observations to the planet Mars, and the fixed stars, determining the places of the latter, and ascer-

taining that they possess a certain degree of motion relative to their respective systems. Towards the close of his short life the magnetic needle engaged his attention, to which he assigned more certain laws than those before received. To all his pursuits he applied with such indefatigable assiduity, that he died literally worn out with labour in 1762, at the age of thirty-nine. The principal works which he gave to the public were, "A New and General Method of resolving all geometrical Problems, by means of geometrical Lines;" "A mathematical Atlas, in which all the mathematical Sciences are comprised in sixty Tables;" "A Description of a Lunar Globe, constructed by the Cosmographical Society of Nuremberg, from New Observations;" "Miscellanea;" and several valuable papers in the Memoirs of the Royal Society of Gottingen. His table of refraction, deduced from astronomical observations, agrees with that of Dr. Bradley; and his theory of the moon, and astronomical tables and precepts, were so well received, that they were rewarded by the English Board of Longitude with the premium of three thousand pounds, which sum was paid to his widow after his decease. These tables and precepts were published in 1770.

MAYERGA, in *Geography*, a town of Spain, in the province of Leon; 23 miles S. S. E. of Leon.

MAYERNE, Sir THEODORE TURQUET DE, BARON D'AUBONNE, in *Biography*, an eminent physician, was born at Geneva in the year 1573. His father, Lewis de Mayerne, author of "A General History of Spain," and of "The Monarchie arillo-democratique," and a Calvinist, had removed thither the preceding year, on account of religious persecution, from Lyons. After being instructed in the rudiments of literature in his native city, Theodore was sent to the university of Heidelberg, where he remained some years; after which, as he had made choice of the profession of medicine, he removed to Montpellier, where he received the degree of doctor in 1597. He then went to Paris, where he became acquainted with Riverius, first physician to king Henry IV., through whose influence he was, in the year 1600, appointed to attend the duke de Rohan, as physician, in his embassy to the diet at Spire; and also nominated one of the physicians in ordinary to the king. On his return, he availed himself of the privilege which the latter office afforded him, and practised in the metropolis, where he also gave public lectures in anatomy and in pharmacy to the young surgeons and apothecaries. The latter of these subjects led him to treat of chemistry, to the practice of which he had paid peculiar attention; and his recommendation of chemical remedies drew upon him a considerable degree of enmity from the faculty of Paris, who manifested their attachment to Galen, by an indiscriminate abuse of all who ventured to employ any mode of treatment not mentioned in his works. Quercetanus was joined with Mayerne in this attack; and one of the faculty, in 1603, published a book against these heterodox brethren, entitled "Apologia pro Hippocratis et Galeni Medicina, contra Mayerneum et Quercetanum." To this Mayerne replied immediately in another "Apologia, in qua videtur, inviolatis Hippocratis et Galeni legibus, Remedia chemicè præparata tuto usurpari posse," in which he made some severe strictures on the Parisian physicians. The Galenists, however, not only replied, but proceeded to issue a decree of the faculty against consulting with him, conceived in very bitter and abusive terms. But the esteem of Henry IV., which he had fully obtained, so far supported him, that he continued to practise in Paris, and would have been appointed first physician to the king, provided he would have embraced the Catholic religion. Even in spite of his unyielding adherence

to Protestantism, the king would have given him that appointment, had not the Jesuits influenced queen Mary de Medicis to interpose and prevent it. In 1607, an Englishman of rank, who had been his patient, carried him over to England, and introduced him to the royal family. He returned to Paris, and remained there till after the assassination of Henry IV., which took place in May, 1610. In the following year, he received an express invitation from king James I. to come and take the office of his first physician, which he accepted, and passed the rest of his life in England, where he appears to have been considered as the first person in the profession. He was admitted to the degree of doctor in both universities, and into the College of Physicians, and treated with the greatest respect by these learned bodies. He incurred some obloquy on account of the fatal sickness of Henry prince of Wales, in October 1612; in the treatment of which he differed in opinion from the other physicians, with respect to the use of blood-letting. But his conduct obtained the approbation of the king and council, of which certificates, couched in the most satisfactory terms, were given him. He received the honour of knighthood from James, in 1624; and on the accession of Charles I. he was appointed first physician to him and his queen, and rose to high favour, particularly with the latter. During the civil commotions he still adhered to the royal party, for he was appointed first physician to Charles II. after the death of his father, although the office was now merely nominal. Thus he enjoyed the extraordinary honour of serving four kings successively in his medical capacity; and during all this period he was most extensively employed by persons of the first rank in this kingdom, by which he accumulated a large fortune. He died at Chelsea, March 15, 1655, in the eighty-second year of his age, and was buried in the church of St. Martin's-in-the-Fields. Sir Theodore was twice married; but left only one daughter, who was married to the marquis de Cugnac, grandson of marshal de la Force. He bequeathed his library to the College of Physicians.

The only work which sir Theodore Mayerne published himself, was the "Apologia," before-mentioned. But in Germany a letter of his was printed in 1619, "De Gonorrhæa inveteratæ, et Carunculæ et Ulceris in meatu urinario curatione ad Geo. Mat. Koningium." After his death were published "Medical Counsels and Advices," and "A Treatise on the Gout," which had been written in French, translated into Latin by Theoph. Bonetus, and thence into English by Dr. Thomas Sherley, in 1676. Also, "Præxeos Mayernianæ in Morbis internis gravioribus et chronicis Syntagma," published in 1690, by his godson, sir Theodore de Vaux, who also communicated to the Royal Society, in 1687, "Mayerne's Account of the Diseases of Dogs, with several Receipts for Canine Madness," printed in the Philosophical Transactions for that year. "Tractatus de cura Gravidarum," added to an edition of the "Praxis." Most of these were included in Dr. Joseph Browne's publication, entitled "Mayernei Opera Medica, complectentia Consulta, Epistolæ, et Observaciones, Pharmacopœiam variasque Medicamentorum formulas," folio, 1701. The first book in this volume consists of medical cases treated by the author, to most of which the names of the patients are prefixed, who are in general persons of the first quality in France and England. They comprehend a series from 1605 to 1640. The descriptions are generally distinct, minute, and judicious, and the reasonings, though commonly founded upon the erroneous doctrines of that time, are yet acute and learned. His prescriptions are mostly of the compound form of the Galenic school; yet his Pharmacopœia exhibits a number

of chemical preparations, and he, doubtless, contributed much to their introduction. Nor did he confine his chemical knowledge to medicinal subjects; for he is said to have discovered, by a course of experiments, the principal colours to be used in enamelling, and to have communicated them to Petitot, the famous painter in that branch. He was, likewise, conversant with natural history, and edited Mouffet's posthumous "Theatrum Insectorum." Aikin's Biog. Memoirs of Med. Gen. Biog.

MAYET, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of La Flèche; 15 miles S. of Le Mans. The place contains 3165, and the canton 10,049 inhabitants, on a territory of 210 kilometres, in seven communes.

MAYET-de-Montagne, *Le*, a town of France, in the department of the Allier, and chief place of a canton, in the district of La Palisse; 10 miles S.E. of Cusset. The place contains 3945, and the canton 14,443 inhabitants, on a territory of 180 kilometres, in 12 communes.

MAYETA, in *Botany*, Aubl. Guian. 443. t. 176. Juss. 330; is *Melastoma Maïeta*, Lamarck Dict. v. 4. 34. Willd. Sp. Pl. v. 2. 589. See MELASTOMA.

MAYFIELD, in *Geography*, a township of America, in Montgomery county, New York, incorporated in 1793, and containing 876 inhabitants.

MAYHEM. See MAHIM.

MAYHEM, *Appeal of*. See APPEAL.

MAYL, in *Falconry*, signifies to pinion the wings of a hawk.

MAYLLO, in *Geography*, a town of Spain, in the province of Leon; 14 miles E.S.E. of Ciudad Rodrigo.

MAYNA, in *Botany*, (why so called does not appear,) Aubl. Guian. 921. t. 352, a diœcious shrub, of which the male only was observed in Cayenne by Aublet. He describes it by the name of *M. odorata*, as having several upright, simple, flexible, brittle stems, about six feet high. Leaves alternate, stalked, ten inches long, and three wide, lanceolate inclining to obovate, pointed, entire, somewhat wavy, of a fine shining green, and a firm texture, with a prominent rib and numerous veins beneath. Stipules lanceolate, deciduous. Flowers axillary, several together, on short stalks, white, and very agreeably scented, produced in the month of December. The calyx is in three deep concave segments, externally hairy. Petals eight, roundish, with short erect claws. Stamens 28 or 30, disposed upon a conical receptacle; their filaments short, anthers long and quadrangular, opening at the top. Aublet could find no traces of a pistil, nor could he discover the female plant, though he carefully sought for it. Jussieu has justly referred this genus to his order of *Magnoliæ*; see that article.

MAYNARD, FRANCIS, in *Biography*, a French poet, born in 1582, was son of a counsellor in the parliament of Toulouse. He was introduced, while very young, to court, and was appointed secretary to queen Margaret. In 1634, the duke de Noailles, being appointed ambassador to the court of Rome, took Maynard with him. He was member of the French Academy from its first institution, and endeavoured to ingratiate himself with the cardinal Richelieu, but failing in his object, he gave him the appellation of tyrant, and wrote satires upon him. At length, weary in the pursuit of fortune, he retired to his native province, where he died in 1646, at the age of sixty-four. His works consist of Songs, Epigrams, Odes, Miscellaneous Poems, and Letters in prose. They must be read with caution, for though esteemed as a man of honour and a sincere friend, his principles were very licentious. Moreri.

MAYNARD,

MAYNARD, Sir JOHN, an eminent English lawyer, who distinguished himself by his patriotism, as well as his knowledge of jurisprudence, and integrity in his profession. When the prince of Orange was declared king after the abdication of James II., Sir John waited upon the new monarch with an address; and William having observed to him that from his age he must have outlived most of the judges and eminent lawyers of his standing; he replied, "and I should have outlived the law too had it not been for the arrival of your majesty." He died in 1690, aged 88. *Biog. Brit.*

MAYNAS, in *Geography*, a government of South America, in the eastern limit of the audience of Quito, lying contiguous to those of Quixos and Jaen de Bracamoros towards the east. In the territories of this jurisdiction are the sources of those rivers, which form by their conflux the Marañon. The streams of these rivers environ and pervade the government of Maynas. Its limits, both towards the N. and S., are little known. Eastward it joins the possessions of the Portuguese, from which it is separated by the line of demarcation that forms a boundary between the Spanish and Portuguese possessions. Santiago de la Laguna, which is the residence of the governor, is properly the capital of Maynas; though San Francisco de Borja has been usually considered as such. (See *COCAMA*.) The missionary villages of this jurisdiction are numerous; and they trade with each other, and also with Quito and Lamas, in salted fish, chocolate, of which the arroba (25 lbs.) is sold for two rials, wax, yuca, and vegetable candles, called by the natives "pallas," being the fruit of a tree, which, when lighted, presents at once wax and wick. Whether this tree be the "croton sebifera" of Linnæus has not been ascertained. There are also some poor manufactures, chiefly cloaks and hats, made of the rich plumage of the birds, with which they are formed after any pattern. The manners and customs of the inhabitants of Maynas differ little from the other nations of the Pampas del Sacramento, except where they are tinged with a faint dye of Christianity.

MAYNBERNHEIM, a town of Germany, in the margraviate of Anspach, near the Maine; 12 miles S.E. of Wurzburg.

MAYNE. See *MAYENNE*.

MAYNE, a river of Ireland, in the county of Antrim, which, rising towards the centre of the county, flows into Lough Neagh, a little below Randalstown.

MAYNOOTH, a post-town of Ireland, in the county of Kildare, and province of Leinster. In this town is the Royal College of St. Patrick, for the education of persons professing the Roman Catholic religion, instituted by act of parliament in the year 1795. The building consists of lodging-rooms, schools, a church, library, hall, and different offices suitable to the accommodation of 200 ecclesiastical students, besides professors, officers, and servants. There is also a Lay College, established by private subscription in 1802. When the evils attendant on a foreign education, especially under the circumstances in which the Roman Catholic clergy of Ireland were educated. At the expence of foreign powers, are considered, it must be admitted to have been a wise step in the parliament of Ireland to provide a place of education for them at home; and it is surprising that the expence thus incurred should ever be objected to by Protestants. The question is not, whether the tenets of popery are deserving of support? but whether the population of Ireland is to be supplied with priests educated at the expence, and of course attached to the interest, of foreign powers, or supplied with them from a college supported at the national expence? Maynooth had formerly a college, founded in

1518 by an earl of Kildare, whose descendant, the duke of Leinster, has a princely residence in the neighbourhood. It has also a charter-school for fifty girls. Maynooth is 12 miles W. by N. from Dublin.

MAYO, a county of Ireland, in the province of Connaught, the third in size, but one of the least populous in proportion to its extent. It is bounded on the N. and W. by the Atlantic ocean, on the E. by Sligo and Roscommon, and on the S. by Galway. Its length, from N. to S., is 49 Irish or 62 English miles; and its breadth 45 Irish or 57 English miles. It contains 790,600 acres, or 1235 square miles Irish, equal to 1,270,144 acres, or 1984 square miles English. Its population was estimated, when Dr. Beaufort wrote, at 140,000, but there must have been since that time a considerable increase in this as well as every other county. There are 68 parishes, but these are combined into eighteen benefices, having about as many churches, which would be a dreadful grievance, if the great mass of the people were not Roman Catholics. The soil of the county of Mayo varies prodigiously, from the bleak and rugged mountain to the fertile and cheerful plain. The eastern and southern parts are arable and champaign, and though not arrived at a high degree of cultivation, they produce a sufficiency of corn and flax for home consumption, and supply other counties with abundance of fat and store cattle. In the mountainous district of Burischoole there are some fruitful grounds along the coast and in the vallies. But a large extent in the N.W. is overspread with an immense mass of uninhabited mountains, and trackless bogs without roads, and very difficult of access to the few farmers and fishermen who dwell upon the coast, and to the inhabitants of the Mullet; a peninsula, which is said to be fertile, pleasant, and well inhabited. Among the mountains in the S.W. Croagh-Patrick claims the pre-eminence, the conic summit of which is distinguished at a vast distance rising 2666 feet above the level of the sea, and being by some esteemed the highest mountain in Ireland, but others consider the Reeks in Kerry to surpass it. On the top of Croagh-Patrick is a very large and remarkable cairn. M'Nephin, though little inferior to it in height and sublimity, being 2640 feet high, is of a very different character, for it stands almost insulated, and appears rounded on all sides, and at top like a huge rath or barrow. There are, in the flat country that borders upon the lakes of Mask and Carrah, many miles of rocky ground, which, at a distance, appear like one immense sheet of white stone. But upon a nearer inspection of these singular rocks, they are perceived to stand in parallel lines, from one to three feet above the surface, like flag-stones pitched in the ground upon their edges; and however they may vary in shape, size, and distance, they are all calcareous, and have all the same direction. Fissures of a great depth are found in some of the narrowest interstices; but, in general, the verdure between them is beautiful, and the pasture excellent for sheep. Large caverns and subterraneous waters are also frequent in this part of the country, especially near Cong. At the back of that small village, a very broad river rushes at once from beneath a gently-sloping bank, and after a rapid course of about a mile, loses itself in lough Corrib. It is supposed to be the outlet of a subterraneous channel, through which the superfluous waters of lough Mask and lough Carra are discharged into Corrib. This rocky part of Mayo abounds also with *turlachs*, as they are called in Irish. These are plains, some of them very extensive, which having no visible communication with any brooks or rivers, in the winter are covered with water, and become in the summer a rich and firm pasture, the waters rising and retiring through
rocky

rocky clefts in the bottoms. There are many fine lakes in this county. Lough Conn, at the foot of M'Nephin, is nine miles long; Lough Mask is longer by two miles, and considerably broader. There are some fine harbours, and many islands, the most remarkable of which are noticed in distinct articles. Castlebar is the county town. The only members of parliament returned from this county are the two knights of the shire. Beaufort's Memoir.

MAYO, or *May*, one of the Cape de Verd islands, about 21 miles in circumference, of an oval form, with a variety of rocks and points projecting into the sea. Its elevation above the sea is considerable; nevertheless its surface is level and plain, if we except two mountains of considerable height. The shore, according to the description of Dampier, presents sandy bays between the promontories, which afford good anchorage. On the W. side of the island, are a bay of this kind, where ships drop anchor, and a sand bank, forty paces wide, and extending nearly three miles along the shore, within which is a large salt pond, two miles long, and half a mile broad, from the N. end of which salt is obtained in the whole dry season, that is, from November to the month of May. The soil of the island is dry, with little moisture from rivulets or springs, its humidity being occasioned by the nightly dews, or the showers that fall in the wet season. In the whole island there is only one spring, near its centre, the water of which runs off in a small stream through a valley confined by the hills. The island of course must be in a very considerable degree barren and unproductive. It has three small towns, which contain all the inhabitants of the island. The chief fruits are figs, watermelons, citrons and oranges of a very indifferent quality, and pumpions, which, together with calwanas, a sort of bean, furnish the natives with their ordinary diet. The sea supplies great variety and plenty of fish. The number of inhabitants is estimated at 7000. N. lat. $15^{\circ} 10'$. W. long. $23^{\circ} 8'$.

MAYO, a river of New Mexico, which runs into the gulf of California, N. lat. $27^{\circ} 40'$.—Also, a town of South America, in the government of Caraccas; 35 miles W. of Caraccas.—Also, a province of New Mexico, bounded on the N. by the province of Hiscui, on the E. by New Biscay, on the S. by Cinaloa, and on the W. by the gulf of California.

MAYOBAMBA, a town of Peru, in the diocese of Truxillo. S. lat. $6^{\circ} 58'$.

MAYOMBA, or JAMBO, a town of Africa, in Loango, on the coast. S. lat. $3^{\circ} 45'$. E. long. $10^{\circ} 24'$.

MAYOMBO, a town of Congo; eight miles S.S.W. of Bombi.

MAYOR, a small island in the South Pacific ocean, near the coast of New Zealand. S. lat. $36^{\circ} 57'$. E. long. $183^{\circ} 31'$. Near this is a cluster of small islands and rocks, to which Cook gave the name of "The Court of Aldermen."

MAYOR, *Cape*, a cape on the N. coast of Spain. N. lat. $43^{\circ} 29'$. W. long. $3^{\circ} 46'$.

MAYOR, or *Mayor*, the chief magistrate or governor in the cities, and most corporation towns of England; chosen annually by his peers out of the number of the aldermen. See ALDERMAN.

The word, according to Verstegan, comes from the ancient English *maier*, *able*, *potent*, of the verb *may*, or *can*. The mayor of the place is the king's lieutenant, and, with the aldermen and common-council, can make laws, called *bye-laws*, for the government of the place. He has also the authority of a kind of judge, to determine matters, and to mitigate the rigour of the law.

King Richard I., A.D. 1189, first changed the bailiffs of London into mayors; by whose example others were afterwards appointed. See LONDON.

Mayors of corporations are justices of peace *pro tempore*, and they are mentioned in several statutes; but no person shall bear any office of magistracy concerning the government of any town, corporation, &c. that hath not received the sacrament, according to the church of England, within one year before his election; and who shall not take the oaths of supremacy, &c. stat. 13 Car. II. cap. i.

MAYOR'S-COURT. See COURT.

MAYORGA, in *Geography*, a town of Portugal, in Estremadura, on the W. coast, near the Atlantic; 50 miles N. of Lisbon.—Also, a cluster of small islands in the South Pacific ocean, discovered in 1780 by don Francisco Antonio Maurelle. S. lat. $18^{\circ} 38'$. E. long. $179^{\circ} 52'$.

MAYORGA *Island*. See MAJORCA.

MAYOTTA, the most southerly of the Comorra islands, about 240 miles from the coast of Africa, and 150 from the island of Madagascar. Although this island is cold, low, and damp, and not inhabited near the coast, it abounds with provisions and fruits. S. lat. 13° . E. long. $45^{\circ} 16'$.

MAYOW, JOHN, in *Biography*, an ingenious physician and physiologist, was born in Cornwall in 1645. He was educated at Oxford, where he became a probationer fellow of All-Souls' college, having first been entered a student of Wadham. He took a degree in civil law, but afterwards studied medicine, and entered upon the practice of that profession. He seems to have resided chiefly at Bath; but died at the house of an apothecary in York-street, Covent-garden, in the year 1679.

These are all the brief memoirs that are recorded of a man, who went before his age in his views of chemical physiology, and in some measure anticipated, darkly and imperfectly it is true, some of the most remarkable discoveries in pneumatic chemistry, which the present age has produced. He published at Oxford, in 1699, "Tractatus duo, quorum prior agit de Respiratione, alter de Rachitide." These were afterwards reprinted, in 1674, with three additional dissertations, under the title of "Tractatus quinque Physico-Medici, quorum primus agit de Sale Nitro, et Spiritu Nitro-æreo, secundus de Respiratione, tertius de Respiratione factis in utero et ovo, quartus de motu musculari et spiritibus animalibus, ultimus de Rachitide." It is from the first of these treatises, on nitre and nitro-ærial spirit, that Mayow derives his claim to the originality of discovery just alluded to. His nitro-ærial or igneo-ærial spirit, the existence of which he proves by many ingenious and decisive experiments, is a constituent part of the atmospherical air, and the food of life and flame, and is the same with the oxygen, or vital air, of the modern chemists, which has become so important an object in chemical philosophy. His speculations about it are indeed mixed with much of the absurd hypothesis of the times; but some of his ideas relative to its agency nearly accord with the more recent doctrines; especially that of its absorption by the blood in the lungs, during respiration, and the production of animal heat by its means. He also anticipated the mode of operating with aerial fluids, in vessels inverted over water, and the method of transferring them from one vessel to another, under this fluid. In a word, had he lived at a later period, and possessed the lights of his successors, he would in all probability have been a distinguished improver of his science and profession. His theory of the nitro-ærial spirit runs through all his hypotheses, and he regards it as the cause of muscular motion and of the nervous energy; in which respect, he still more nearly approached some of our own contemporaries in his views of this spirit.

spirit. Dr. Beddoes republished his chemical tracts in 1790, with a view of showing his claim to some share of the credit which has been awarded to modern discoverers. Gen. Biog. Elov.

MAYPO, in *Geography*, a river of Chili, which runs into the Pacific ocean, N. lat. 33° 26'.

MAYRI, a town of Cuba; 25 miles S. of Havana.

MAYS, in *Botany*. See ZEA. This name, which we usually write Maize, seems to be an Indian word, and was introduced along with the plant which bears it, otherwise called Indian wheat, at the very earliest period of the introduction of exotic plants into Europe. Maize appears, by Turner's herbal, to have been cultivated here in 1562, and was probably brought much earlier from the east.

MAYSVILLE, in *Geography*, a post-town of America, in Mason county, Kentucky; 484 miles from Washington.

MAYTENUS, in *Botany*, a barbarous word, formed of the Chili name *Maiten*. Moiss. Chil. 152. Vahl. Enum. v. 1. 304. Juss. 449.—Class and order, *Dianthia Mongynia*. Nat. Ord. *Jasminae*, Juss.

Gen. Ch. Cal. Perianth inferior, very small, of one leaf, five-lobed. Cor. of one petal, bell-shaped, undivided. Stam. Filaments two, inserted into the corolla; anthers. . . . Pist. Germen superior, roundish; style undivided; stigma simple. Peric. Capsule small, ovate, compressed, of two cells and two valves, bursting at the edges, the partitions continued half way along the middle of the valves, which are at length reflexed. Seeds solitary, ovate-oblong, attached to the bottom of each cell; embryo flat, in a fleshy albumen.

Ess. Ch. Calyx five-lobed. Corolla bell-shaped, undivided. Capsule superior, compressed, of two cells and two valves. Seeds solitary.

1. *M. boaria*. (*Maiten*; Feuill. Chil. v. 3. 39. t. 27.) Native of Chili. A shrub or small tree, with the habit of a *Phillyrea*. About twenty feet high, much branched. Leaves sometimes opposite, sometimes alternate, evergreen, nearly sessile, elliptical, acute, serrated, smooth; dark green above, brighter beneath; with a prominent rib, and several veins. The flowers, which Feuillée did not meet with, are described by Jussieu as scattered. The last-mentioned author says one cell of the fruit, with its seed, is frequently abortive. He errs in supposing the genus akin to Forster's *Bankfia*, which is the *Pimela* of later writers, and belongs to the order of *Thymelaeae*.

"The *Maiten*," says Feuillée, "is the counter-poison of the *Llithi*;" (Feuill. Chil. v. 3. 33. t. 23, a plant whose class and genus are unknown to us), "the meer shade of which causes such swellings as to deform the human body. In case of similar accidents, a decoction of the branches of the *Maiten*, used as a fomentation to the parts afflicted, is the most speedy cure."

MAYTO, in *Geography*, a town of Mexico, in the province of Xalisco; 50 miles W.N.W. of Purification.

MAYTZ, a town of Prussia, in the province of Bartenland; 18 miles S. of Raitenburg.

MAYZE, CAPE, or *Cape Maizo*, the eastern point of the island of Cuba. N. lat. 20° 18'. W. long. 74° 10'.

MAZA, a name given by the ancients to a sort of food, in common use among the poorer sort of people. It is made of the meal of parched barley, sprinkled with some liquid, and was eaten with honey, or with defrutum.

Hippocrates every where speaks of this as of a coarse kind of bread, and advises the changing the common finer bread, in the spring season, for this coarser kind, as a thing

very conducive to health. He seems every where to consider bread as the drier, and maza the moister diet.

MAZA, *Maza*, among the Athenians, a sort of cake, which was the common fare of such as were entertained at the public expense in the common hall, or *prytaneum*.

These cakes were made with flour boiled with water and oil. Puffe. Lex. Ant. 11507.

MAZACA, in *Antient Geography*, a town of Cappadocia, in the prefecture of Cilicia, called also Maza, and sur-named Casarea. Strabo gives it the title of metropolis of Cappadocia, sur-named Eusebia, and places it on mount Argæus.

MAZAGAN, in *Geography*, a town of Africa, in the empire of Morocco; 4 leagues S. Azamore, built by the Portuguese in 1506, and named by them "Castillo Real." Under the walls of this town a dock has been made, which will admit small vessels; but large ships are obliged to anchor two leagues out at sea, on account of the cape of Azamore, which stretches to the W., and which it would be difficult to double, if a S.W. wind should drive them from their anchors. This town remained in the possession of the Portuguese till the year 1769, when the emperor of Morocco laid siege to it just as it was about to be abandoned by its former masters. It is at present entirely ruined, and almost uninhabited. At a little distance to the S.W. of Mazagan is an old tower, called Borisha, whence is derived the name of Bridja, which the Moors confound with that of Mazagan; 61 miles N. of Morocco. N. lat. 32° 54'. W. long. 8° 46'. Chenier's State of Morocco, vol. i.

MAZALIG, a town of Africa, in the country of Sulgumessa; 50 miles N.E. of Su umeffa.

MAZAMET, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Castres; 9 miles S.E. of Castres. The place contains 5474, and the canton 12,410 inhabitants, on a territory of 257½ kilometres, in 11 communes.

MAZANDERAN, or MAZENDRAN, a province of Persia, situated along the southern coast of the Caspian sea, and bounded on the E. by Khorasan, encircled on the S. by a lofty branch of the Caucasian chain, which was the seat of the Mardi of antiquity, and on the W. by Ghilan. The southern part is mountainous, and nearly desert, interspersed with some pleasant vallies, and enjoying a salubrious air; this part is called Taberistan. Towards the north this province is extremely fertile, inasmuch that it is called the "Garden of Persia," and from September to April, the whole country appears like a vast parterre of flowers. The chief productions are silk, far inferior to that of Ghilan, rice and cotton, of which articles there is a large exportation. The cotton the inhabitants dye and manufacture. The province also affords sugar, excellent fruit, especially raisins, of some of which they make wine, but the greatest part is dried for sale, corn, and salt. Among the animals are tygers, deer, sheep, goats, &c. Mazanderan is well situated for trade on the Caspian sea; but the coasts are much infested by pirates. The capital is Fahrabad, or *Farabat*, which see. This province, and also those of Shirvan, Ghilan, and *Astrabad*, (which see,) are much affected by the unsettled state of Persia, and the civil wars which continue to harass that divided empire. On the death of Kerim Khan, the successor of Nadir Shah, in 1779, Persia became exposed to all the horrors of a disputed succession, and was divided between the two principal competitors. Akau Mahomed Khan, a Persian of high distinction, was castrated in his infancy by order of Nadir Shah, but possessing great civil and military talents, he became master, in 1788, of Mazanderan and Ghilan, as well

as the cities of Ispahan and Tauris. Jaafar Khan, nephew of Kerim Khan, was at that period sovereign of Shirauz, the capital, and of the southern provinces. In general, however, these provinces are governed by their own khans, who, though tributary to the sophy, render themselves occasionally independent; and as they are continually at war with each other, their governments are almost always the seat of hostility, rapine, and devastation; and the trade flourishes or declines in proportion as the exactions of the sovereigns are more or less frequent and exorbitant.

MAZANO, a town of Italy, in the Veronese; 8 miles N. of Verona.

MAZARA, a sea-port town of Sicily, in the valley of Mazara, situated on the S.W. coast, near a river of the same name, near or upon the ruins of Selinuntium. At a distance its appearance is not unpromising, as it presents to view several convents and chapels richly ornamented; but its streets are narrow and winding, and it has only one square before the cathedral. Mazaran was of some note in the time of the Romans, and many of their tombs and inscriptions are found in it. In the cathedral are some valuable sarcophagi, and one in particular, which, on account of the style of its composition, as well as its design and workmanship, is attributed to the Greeks. Mazaran was laid waste by the Saracens, and was taken from them by earl Roger, who vowed to build a church if he obtained a victory. The church does not now exist. At Mazara have been found some Punic, and many Roman coins, and those of the Saracens in their tombs. It has not now more than 7000 inhabitants, without trade or manufacture. The chief cultivation is that of cotton. Here is no harbour, but the sea enters by a channel above half a mile into the country, which would form an excellent shelter for shipping, if merchants had any inducement to come hither. Mazara is the see of a bishop; 50 miles S.W. from Palermo. N. lat. $37^{\circ} 46'$. E. long. $12^{\circ} 28'$.

MAZARELLI, a town of Sicily, in the valley of Noto; 15 miles S.W. of Noto.

MAZARIN, JULIUS, in *Biography*, cardinal, and a celebrated minister of state, was born in 1602, at Piscina, in Italy, of a noble family named "Mazarini." In the course of his education he was distinguished for his talents, and was introduced into the household of Jerome Colonna, afterwards cardinal. He followed that nobleman into Spain, where he studied the law, and on his return he took the degree of doctor. He frequented the court of Rome, and attached himself to Schetti, as he did afterwards to cardinal Barberini, to whom he afforded much assistance in his attempts to effect an accommodation between the different powers. When the French were just preparing to attack the Spanish lines before Casal, Mazarin rode out of them, exclaiming "Peace, Peace," and brought proposals to the French general, which caused a suspension of arms, which was followed by the treaty in 1631. His service was rewarded by the pope with a place, and in 1634 he was sent as vice-legate to Avignon, and nuncio to the court of France. He there acquired the esteem of Richelieu, and of the king, Lewis XIII., who procured for him a cardinal's hat: and after the death of Richelieu, the monarch created him counsellor of state, and one of the executors of his will. At the death of Lewis, in 1643, Mazarin was immediately placed at the head of the government by the regent queen Anne of Austria, who had the most unbounded confidence in him; he was a very different man from Richelieu; he was simple and modest in his appearance and equipage; insinuating in his manners and he ever affected

to carry his points rather by gentle means than by the force of authority. The rapacity of his disposition soon raised a powerful party against him, while his foreign manners threw a ridicule over him which rendered him contemptible. Some edicts of taxation being refused verification by the parliament of Paris, Mazarin caused the president Blancmesnil, and the counsellor Broussel to be imprisoned. This was the signal for the civil wars which commenced in 1648, in which the Parisians were excited to revolt by De Retz, with several princes of the blood and nobles. The queen, the young king, and the minister, were obliged to take refuge at St. Germain. Mazarin was proscribed as a public disturber of the peace: Condé, then on the side of the court, besieged Paris, and the "war of the Fronde" ensued, which was more fertile in satirical songs and epigrams, than in important events. An accommodation was effected in 1649; by which the parliament preserved its right of assembling, and the queen kept her minister. In the following year, fresh disturbances led the parliament to issue a decree, banishing Mazarin from the kingdom. He made his retreat to Cologne, whence he continued to govern the kingdom by his counsels. In 1652 Mazarin returned to France with 7000 men whom he had raised, but being regarded by parliament as a public enemy, he was obliged a second time to retire. In 1653 he entered Paris amidst the acclamations of the inconstant people, and even the parliament, from which a more steady line of conduct might have been expected, received him with distinguished honours. Henceforward his powers were unlimited: in 1655 he made a treaty with Cromwell, of which one of the conditions was the refusing Charles II. an asylum in France. The war with Spain was terminated in 1659, by the peace of the Pyrenées, negotiated in person between Mazarin and the Spanish prime minister. The cession of Alsace to France was one of its conditions, and the marriage of the young king to the infanta of Spain was another. After this the cardinal assumed a greater state, and ruled with a more absolute sway; while the queen-mother lost all her influence, and was reduced to insignificance. History has handed down a variety of heavy charges against him; such as having purposely brought up the young king in ignorance, not having signalized his administration by a single grand or useful national establishment; and having amassed such a fortune as no other minister ever had, amounting, it was said, to two hundred millions of livres, or eight millions sterling. His prosperity was of no long duration: he was attacked by a disease which his constitution could not resist. When sensible of his danger he began to feel scruples concerning the wealth which he had heaped together, and his confessor plainly told him that restitution was necessary for his salvation. He gave the whole to the king, in the hope that, as was the case, his majesty would restore it to him. He died in 1661, at the age of fifty-nine. The letters of cardinal Mazarin, containing his negotiations at the peace of the Pyrenées, were published in two volumes 12mo. in 1745. The tracts on the controversy respecting the war of Fronde were so numerous, that a complete collection of them amounted to forty-six volumes 4to. The administration and talents of Mazarin have been compared with those of Richelieu, but the commanding features which distinguished the latter are in vain sought for in the former. Prudent, subtle, and avaricious, he endeavoured to soothe rather than command; to deceive than to vanquish; and the love of glory either did not exist in his bosom, or was lost in his insatiable thirst of money. Moreri. Hist. of France. 1790.

MAZARINA, in *Geography*, a town of Sicily, in the valley of Noto; 20 miles N.E. of Alicata.

MAZAT-

MAZATLAN, a town of Mexico, in the province of Chiametlan, on a river of the same name, which runs into the Pacific ocean; 40 miles N.W. of Chiametlan. N. lat. 23° 15'. W. long. 106° 46'.

MAZE, in *Gardening*. See **Labyrinth**.

MAZEAS, JOHN-MATHURIN, in *Biography*, a mathematician, was born at Landernau, in Brittany, in 1713, and died in 1802. He wrote *Elements of Arithmetic, Algebra, and Geometry*, with an Introduction to Conic Sections; he was also the author of "*Institutiones Philosophicæ*," three vols. 12mo. He was an ecclesiastic, and held a canonry in the church of Notre Dame, at Paris, before the Revolution. *Nouv. Dict. Hist.*

MAZERAY, in *Geography*, a town of Persia, in Khorasan; 100 miles W.S.W. of Naffapour.

MAZEUTOXERON, in *Botany*, Billard. *Voy.* (English edition), v. 2. 8, and 65. t. 17 and 19. See **COUZA**.

MAZIERA, or **MEDJARE**, in *Geography*, an island in the Indian sea, near the E. coast of Arabia, 60 miles long and 8 wide. N. lat. 20°. E. long. 74°.

MAZIERES, a town of France, in the department of the Two Sevres, and chief place of a canton, in the district of Parthenay. The place contains 605, and the canton 8447 inhabitants, on a territory of 257½ kilometres, in 12 communes.

MAZIL, a town of the island of Cuba; 20 miles W.S.W. of Bayamo.

MAZOCHI, ALEXIO SYMMACHO, in *Biography*, an Italian antiquary, was born near Capua in 1684. He acquired in early life an attachment to literature, and became distinguished for his acquirements. He went through a regular course of philosophy and theology at Naples, and he afterwards became professor of the Greek and Hebrew languages, and obtained some preferment in the church. He was author of several ingenious works, of which the principal was the result of the discovery of the ruins of an amphitheatre at Capua: it was entitled "*Campani Amphitheatri Titulum, aliasque nonnullas Campanas Inscriptiones Commentarius*," 1727. This he afterwards very much enlarged. In 1739 he published an epistle "*De dedicatione sub Aescia*," on which he employed much erudition. He published many other antiquarian pieces: as "*A History of the Cathedral of Naples*:" "*Commentarium in Regii Herculanensis Musæi Æneas Tabulas Heraclienfes*:" "*Spicilegium Biblicum*," three vols., of which the two first relate to the Old Testament, the last to the New. He died at Naples in 1771, at the age of 86. He was a man void of ambition, and attached to a sober, studious, and retired life. He bequeathed to the poor his library and the little property which he had accumulated. *Gen. Biog.*

MAZONOMUS, among the *Ancients*, a very large dish, commonly of wood, in which the maza was served.

MAZORBO, in *Geography*, one of the islands in the dogado of Venice, and podestaria of Torcello, composed of three small islands, united by bridges. It has two churches.

MAZORMO, a town of the state of Venice, on the N. bank of the Po; 22 miles S. of Venice.

MAZOUNAH, a town of Algiers, nearly surrounded by the river Shelliff, and celebrated for its woollen manufacture; 30 miles S. of Mustyganain.

MAZULA, in *Ancient Geography*, the name of two towns in Africa propria, according to Ptolemy. He places one on the coast, and gives it the title of a colony, and the other a little inland.

MAZULA, in *Geography*, a town of Africa, in Congo, on the coast; 50 miles S.S.W. of Bombi—Also, a small

island in the Atlantic, near the coast of Africa. *S. lit.* 8° 5'.

MAZUR, a species of birds which the Arabian sailors esteem very lucky, because it lays its eggs close by the sea-shore before good weather; so that when these are observed, they promise themselves a safe voyage. They also pretend that this bird gives notice to sailors, when the ship approaches any danger, by flying and fluttering up and down.

MAZUS, in *Botany, so denominated by Loureiro, from *μαζο*, a nipple, on account of the little stalked tubercles, which fill up the mouth of the corolla. *Lourei. Cochinch.* 385. *Brown Prod. Nov. Holl.* v. 1. 339.—Clas. and order, *Dialymania Angiospermia*. *Nat. Ord. Personate, Lami. Scrophularia*, Juss.*

Gen. Ch. Cal. Perianth inferior, of one leaf, large, bell-shaped, five-sided, permanent, with five lanceolate, spreading, nearly equal segments. *Cor.* ringent; its upper lip pointed, in two lobes, reflexed at their tips; lower longer, in three rounded, inflexed, undivided lobes, and two prominences at its base; the throat marked externally with two furrows, and lined with stalked glands. *Stam.* Filaments four, two of them longer, approaching each other in pairs; anthers oblong, combined. *Pist.* Germen superior, roundish; style thread-shaped, equal in length to the longer stamens; stigma spatulate, of two spreading plates. *Peric.* Capsule roundish, enclosed in the calyx, compressed, of two cells, and two undivided valves, with partitions from their centre. *Seeds* numerous, ovate, small.

Ess. Ch. Calyx bell-shaped, in five equal segments. Corolla ringent; upper lip cloven, reflexed at the sides; lower three-lobed, with two swellings at the base. Capsule of two cells, with many seeds. Anthers combined.

1. *M. rugosus*. Lour. (*Lindernia japonica*; Thunb. *Jap.* 253? *Brown.*)—Flowers numerous, in a long cluster.—Native of fields in Cochinchina, where it is called *Rau dâng lông lá*. An annual herb, about six inches high, branched, and nearly erect. *Leaves* opposite, ovate, serrated, rugose. *Flowers* pale violet, in long loose clusters.

2. *M. Pumilio*. *Brown*. Stalks bearing from one to four flowers, smooth as well as the calyx. Gathered by Mr. Brown in Van Diemen's land. A small herb. *Leaves* clustered at the root. *Flower-stalks* radical, either simple or racemose.

We cannot perceive any clear distinction between this genus and *Mimulus*, to which Mr. Brown allows it is nearly allied. See **MIMULUS**.

MAZZAFERRATA, GIO. BAT., in *Biography*, a musical composer, who published at Bologna, in 1677, "*Cantate*," or "*Canzonette da Camera a Voce sola*," not very good music indeed; but the author seems to have been one of the first composers who used the technical terms *vivoce*, *largo*, and *ardito*, to indicate the time of the several movements. Before that it was done by *moods* at the side of the clef.

MAZZANTI, FERDINANDO, an opera singer in soprano, of great eminence in the bravura style of the middle of the last century. He sung, when we heard him at Rome in 1770, not only with an exquisite taste, but was a good musician, and not a mean performer on the violin. He was not only a reader, but a writer of music, having himself composed operas and motets for voices; but trios, quartets, and quintets for violins. He had a great collection of Palestrina's compositions, of which he was truly sensible of the superiority to those of all other ecclesiastical composers of his country, a *capella*, and had made, by way of study, an abridgment of the modulation of that venerable father of sacred music of the most pure and reverential style, which

he had digested with great judgment and intelligence. He came to England as a singing-master about the year 1773, and remained here till the time of his death. During the last years of his existence, oppressed with age, infirmities, and poverty, he was reduced to the utmost misery and wretchedness. His temper was not amiable: he was naturally peevish, impatient, and disputatious, so that his sufferings were not diminished by philosophy or resignation. He seems not to have made a friend in this country during more than thirty years residence, except La Blancherie, who solicited those who had been long laid under contributions for himself, to extend their benevolence to Mazzanti, and for a certain time procured him succour; but subscriptions and collections at length failing, and having no possessions left that were convertible to money or food, except his favourite violin, which he brought from Italy, he reluctantly permitted his sole friend, Blancherie, to negotiate a raffle for it, at half a guinea a ticket, and in a short time the requisite number being disposed of, chiefly to musical professors, on Saturday, May 11th, 1805, the raffle took place at Menzani's music shop, when the blind and capricious goddess, Fortune, for once, seems to have had a glimmering of light and reason, in throwing her handkerchief at Francis Cramer, who so well knew the use of the lot with which he was crowned. But, alas! during the conflict of the adventurers for Fortune's favour, the poor mortal who furnished the prize expired!

MAZZARUNI, in *Geography*, a river of Sicily, which runs into the sea, on the S. coast; three miles S.E. of Teranova.

MAZZO, a town of Italy, in the Valteline; nine miles W. of Sondrio.

MAZZOCCHI, DOMENICO and VIRGLIO, in *Biography*, two brothers, the most eminent musicians in Rome during the early part of the seventeenth century. Domenico was a voluminous and excellent composer. He is much celebrated by Kircher, and was almost the last successful madrigalist in Italy, after Luca Marenzio. He seems to have penetrated deeper into latent effects and refinements than his contemporaries. In 1638, he dedicated a set of madrigals, which he published at Rome, to cardinal Barberini. In his dedication, he pronounces madrigals to be "the most ingenious species of composition that music could boast. And yet," he says, "that few were then composed, and still fewer sung; as they were nearly banished from all academies, or concerts."

As secular melody was improved by the cultivation of dramatic music, so choral harmony was meliorated by the new combinations that were hazarded in madrigals. And the two Mazzocchi, during this period, contributed greatly, by their numerous works for the church, to improve the more solemn and grave manner of writing for sacred purposes, by extending the bounds of harmony, without which ecclesiastical music could not sustain its dignity, or be suitable to the purposes of its destination. A clear, picturesque, and graceful melody seems infinitely more necessary for the stage than the church; as it is there the voice of passion, and medium through which lyric and narrative poetry can alone be rendered intelligible. In the church, where new poetry, prayers, or sentiments of piety seldom have admission, and where nothing is sung that has not often been previously read and heard by every member of the congregation, the clothing such portions of scripture, or of the liturgy as are appointed to be sung, in rich and complicated harmony, adds greatly to their solemnity, by precluding all such frivolous and fantastical strains as remind the hearer of secular amusements.

Domenico Mazzocchi, besides several new combinations, and a more bold and masterly use of discords in ligature than can be found in the works of his predecessors, if we except Monteverde, first proposed several refinements in the execution of his madrigals, and invented characters of *crescendo*, *diminuendo*, *piano*, *forte*, and the enharmonic sharp. In his eighth madrigal he has made the most frequent use of these new indications. Page 73, there are, indeed, misapplications of the enharmonic diesis to E and B sharp, which is at present rightly appropriated, by the most accurate contrapuntists, to notes that have been already sharp, as a sign of their being still raised a semitone minor. Enharmonic, similar to that of the ancients, we have none, nor is it practicable in modern counterpoint, where, having no fundamental base for quarter tones, their use in harmony would produce no other effect to the hearer than that of singing or playing out of tune.

The only madrigalists after Mazzocchi, who much distinguished themselves, were Stradella, Alessandro Scarlatti, Bononcini, Lotti, Perti, and Caldara, of whom we shall have occasion to speak among the most eminent composers of operas and cantatas.

It seems an indispensable duty to inform the curious reader, that there is a madrigal (*Cor mio*) by this composer, for four sopranos and a contralto voice, inserted in the second part of P. Martini's "Saggio di Contrap," which surpasses in art and ingenuity all the compositions of that kind which we have seen. The expression of the words, and passages of imitation, are still elegant and new. The learned editor has pointed out all its beauties in an excellent commentary.

MAZZOCCHI, VIRGLIO, brother to Domenico, first maestro di cappella to the pope, and master to Bontempi, the musical historian.

MAZZONO, in *Geography*, a town of Naples, in the province of Lavora; seven miles S.W. of Capua.

MAZZUCHELLI, GIAMMARIA, Count, in *Biography*, who flourished in the eighteenth century, was distinguished for his acquaintance with Italian literature. He was author of several works, of which we may notice "Notizie Historiche e Critiche intorno alla Vita, alle Inventioni, ed agli Scritti di Archimede Siracusano;" "La Vita di Pietro Aretino;" he began a biographical work on the writers of Italy, entitled "Gli Scrittori d'Italia. &c." of which he only finished the two first letters in the alphabet.

MAZZUOLI, FRANCESCO. See PARMEGGIANO.

MAZZUOLI, GIROLAMO, the cousin and pupil of Francesco, is little known as a painter beyond Parma and its districts, though for "impasto," and the whole mystery of colour, he has few equals. There is reason to believe that several pictures painted by this artist, especially those of a higher and gayer tone, are constantly ascribed to Parmeggiano. He was more attached to the style of Correggio than Francesco, and seized its character with great avidity in the nuptials of Santa Catherina in the church del Carmine. He excelled in perspective, and in the Last Supper, in the refectory of Santa Giovanni, placed and painted a colonnade with all the illusions of Pozzo. To the most harmonious chiaroscuro, he added grandeur, variety, and vivacity in fresco. He had a son, Alessandro Mazzuoli, who painted in the dome of Parma 1571. He is a feeble imitator of the family style. Fuseli's Pilkington.

MBACQUA, in *Geography*, a town of South America, in Buenos Ayres; 120 miles E. of Corrientes.

MBOMBOY, a river of Paraguay, which runs into the Parana.

MBOTELEY,

MOPELEY, a river of Paraguay, which runs into the Parana.

MEACO, or **MIACO**, called also *Kio*, a city of Japan, in the island of Nippon, the ancient metropolis of the whole empire, and now the spiritual capital, being the residence of the Dairi, and second city of the empire, is situated near the middle of the southern coast, on a spacious and fertile plain, about 160 miles S.W. from Jedo, the reputed capital. Nevertheless this is the first commercial city, and is celebrated for the principal manufactures. It is also the seat of the imperial mint, and as the Dairi's court is literary, all books are printed here. It is surrounded at some distance by high mountains, much covered with stately temples, monasteries, burying-places, and pleasure houses, all of which are adorned with gardens and orchards, and a great variety of verdure, as they are watered by a great number of rivulets which flow from those mountains. These streams unite in the centre of the city, and there divide it into the Upper and Lower Towns. The whole city, when in its greatest splendour, appears by its high and stately walls to have been about 20 miles in length and nine or ten in breadth; to which we may add its spacious suburbs, and the imperial palace, which of itself is a kind of city, separated from the rest. The streets are narrow, but long and straight; and we learn from Kæmpfer, that by an enumeration of the inhabitants in 1674, they amounted to 405,642, of whom 182,070 were males, and 223,572 females, without including the numerous attendants of the Dairi, and probably the children, together with an immense number of strangers, who resort thither from all parts of the empire. Its temples are numerous, and beyond conception magnificent and splendid. Although Meaco has suffered much from pillage, massacre, and conflagration, it is still the grand storehouse of all the manufactures of Japan, and of all foreign as well as domestic merchandize, and the principal seat of commerce. Here they refine their metals, coin their money, print their books, and carry on all sorts of manufactures: here they weave and dye the richest silks and stuffs, make and sell the most beautiful Japan work, porcelain, musical instruments, paintings, carvings, all sorts of gold, silver, and copper articles, and particularly steel of the most excellent quality, and most curious workmanship: they also prepare in this place dresses of all sorts for both sexes, which are fit for use, and they manufacture a variety of toys and trinkets. In a word, there is no kind of commodity which may not be procured at Meaco, nor any kind of workmanship which its artists will not imitate. N. lat. 35 24'. E. long. 153 30'.

MEAD, RICHARD, in *Biography*, a very eminent physician, was born at Stepney, "a small village near London," as it is called by his biographer, in August, 1673, of which parish his father, the Rev. Matthew Mead, a Presbyterian, was one of the two ministers; but had been ejected, for non-conformity, in the year 1662. As he had a handsome patrimony, being descended from a considerable family in Buckinghamshire, he continued to reside in the parish, (preaching to a numerous congregation of dissenters,) and bestowed a liberal education on his large family, under a private tutor, at home. This little domestic school, however, was broken up in 1683, when Mr. Mead, having been accused of participating in a plot against government, thought proper to retire to Holland, leaving Richard, his eleventh child, under the care of Mr. Singleton, an able classical scholar, who had been ejected from the office of second master of Eton school as a non-conformist. Richard made great progress in his classical studies, which he proceeded to finish at Utrecht, under the learned Grævius, in 1689. After

a residence of three years at that place, he determined upon the study of physic, and went to Leyden, where he attended the lectures of Hermanus Boerhaave, and of Peter van der Meer, and practised his profession. He received much friendly attention from the latter, from whom he imbibed the mathematical principles of that science, which were prevalent in his early writings. He then commenced his travels, and visited the principal cities of Italy, where he graduated in philosophy and physic, at Padua, in August 1695. On his return to England, in 1696, he settled in the very house in which he was born, and prosecuted his profession for several years with considerable success; and, in 1699, he married the daughter of a merchant in London. His first publication, entitled "A Mechanical Account of Poisons," which contained the result of many experiments, made with the poison of the viper, &c. appeared in 1702, and gained him considerable credit. In subsequent editions, however, he candidly retracted some points of his mechanical theory, which more mature observation convinced him was inadequate to explain the functions of a living body. Soon after the publication of this treatise, he was elected a member of the Royal Society, of which he was afterwards appointed one of the vice-presidents by Sir Isaac Newton. In 1703, he was chosen physician to St. Thomas's hospital, when he took up his residence in Crutched Friars. In 1704, he published his treatise, "De Imperio Solis et Lunæ in Corpore humano, et Morbis inde orituris," 8vo. Physicians have always been prone to apply the fashionable philosophy of their day to the explanation of the phenomena of the animal economy; and in this essay, Mead built his reasoning on the theory of attraction, which Newton had promulgated, attempting to shew that periodical influences were produced on the living body, as upon the tides of the sea and the atmosphere. In 1707, he received the diploma of doctor of physic from the university of Oxford, through the interest, as is supposed, of Dr. Radcliffe, who was not averse to patronising a junior of rising reputation, when he was himself declining. In 1711, he removed to Austin Friars, into the house which had been inhabited by Dr. Howe, then deceased. About the same time he was appointed by the company of surgeons to read the anatomical lectures in their hall, which he continued to do during six or seven years with great applause. In 1714, his friend and patron, Dr. Radcliffe, died, and Dr. Mead took his house, in Bloomsbury-square. He was now a fellow of the College of Physicians, and he had been called into consultation in the last illness of queen Anne, a few days before her death, and pronounced more decisively on her danger than the court physicians. From this time he seems to have stood among the first of the profession; and in the beginning of 1715 resigned his office at St. Thomas's hospital, partly in consequence of his full employment, and partly of the distance of the hospital from his residence.

The occurrence of the plague at Marseilles, in 1719, occasioned great alarm in London, where the dreadful mortality of 1665 was not forgotten; and by the direction of the lords of the regency, the secretary of state applied to Dr. Mead for his opinion of the nature of the malady, and of the best means of preventing its introduction into this country. In consequence of this application, he published, in the following year, "A short Discourse concerning pestilential Contagion, and the Methods to be used to prevent it," dedicated to Mr. Craggs, the secretary of state. In this work he decidedly maintained the contagious nature of the plague, which had been questioned in France, and laid down a plan for the purpose of cutting off all communication of

the infection, by quarantine, lazarettos, and other means of seclusion. This tract passed through no less than seven editions in one year: to the eighth, in 1723, was added a new chapter on the method of cure; and the last, published in 1744, was still farther enlarged: it was translated into Latin by Mattaire, and afterwards by professor Ward.

In the year 1721, Dr. Mead was directed by the prince of Wales (afterwards George II.) to superintend the experiment of inoculating the small-pox in the persons of some criminals, which had been recommended by Mr. and lady M. W. Montague, in consequence of their knowledge of the salubrity of the practice, as performed at Constantinople, and other eastern countries. His report was favourable; so that the example of the practice was immediately set by the royal family, and its general introduction thus accelerated.

As Dr. Mead was ever anxious to support the honour of his profession by his liberal conduct, and by associating with it the character of a friend and patron of learning, so he asserted its dignity in his "Harveian Oration," read before the College in October, 1723, and afterwards published. In this oration he endeavoured to shew, that the profession was exercised by several families of distinction among the Romans; and he annexed to it a dissertation on some coins, which had been struck at Smyrna, in honour of physicians. This publication was the origin of a controversy, which was begun by Dr. Conyers Middleton, and in which Mead was supported by his friend professor Ward, of the Gresham college. Dr. Middleton, perhaps with the greater weight of erudition on his side, undertook to prove the servile condition of the Roman physicians. The controversy was carried on in a manner honourable to both parties; and Dr. Middleton, in a subsequent work on Greek and Egyptian antiquities, spoke of Dr. Mead in terms of great respect. In the same year, Dr. Mead gave an example of the honourable conduct that is due between the members of a liberal profession, in the services which he performed towards Dr. Freind, when the latter physician was committed a prisoner to the Tower, upon the suspicion of being concerned in Atterbury's plot, in consequence of some free observations which had fallen from him in the house of commons. (See the article **FREIND**.) Dr. Mead obtained his liberation in a spirited manner, and paid over to him a considerable sum, received from his patients during his imprisonment.

In 1727, Dr. Mead was appointed physician in ordinary to George II. His professional occupations were now so extensive, that for many years he had no leisure for writing. He had, so early as the year 1712, communicated to Dr. Freind his opinions respecting the importance of purgatives in the secondary fever of small-pox, upon which subject Dr. Freind published a letter in 1719. But it was not till the year 1747, that Dr. Mead printed his treatise "De Variolis et Morbilibus," which contains many valuable observations on both these diseases, and also strong recommendations of the practice of inoculation. Both this work and the Letter of Dr. Freind were made the subject of animadversion by Dr. Woodward, (whose skill in pathology appears to have been much inferior to his knowledge of natural history,) in a work entitled "The State of Physic and Diseases, &c." which gave rise to a controversy that engendered considerable acrimony in the two learned advocates for the practice. Dr. Mead subjoined to his treatise, which was written in a pure Latin style, a translation of Rhazes's commentary on the small-pox, into the same language, a copy of which he had obtained from Leyden, through the assistance of his fellow-student, Boerhaave, with whom he had maintained a

constant correspondence. It was chiefly through the patronage and interposition of Dr. Mead, that Mr. Sutton's ventilator, for the purpose of cleaning the foul air from ships, was received into the service of the navy, by an order from the admiralty, after a delay of ten years: and he still farther recommended it, by adding to a publication of several tracts that had been written on the subject, in 1749, "A Treatise on the Scurvy," in which he ascribed that fatal disease to moisture combined with putridity.

About this time, as he began to retire in some degree from the fatigues of practice, he employed his leisure in revising his former publications, and in composing others. He published in the year 1749 his "Medicina sacra, seu de Morbis insignioribus qui in Bibliis memorantur," 8vo. The object of this work was to reconcile men's minds to the sacred writings, by shewing that the diseases, mentioned in them, were explicable on natural grounds; and he supported the doctrine of some divines, who maintained especially that the *dæmoniaks* mentioned in the gospel were only insane, or epileptic persons. His last work was a summary of the experience of his active professional life, which might be deemed a bequest to his medical brethren, and was published in 1751, under the title of "Monita et Præcepta Medica," 8vo. This little volume was almost purely practical, consisting of detached observations on a variety of diseases and medicines, many of which have stood the test of subsequent experience: it was frequently reprinted, and was translated into English.

Soon after this period, the infirmities of age rendered him incapable of exertion, either as a practitioner or an author, and he gradually sunk under increasing debility, until the 16th of February 1754, when he expired, without any visible signs of suffering, in the eighty-first year of his age. He was interred in the Temple church, near his brother Samuel, an eminent counsellor, who died twenty years before him; and a monument was erected to his memory, in Westminster Abbey, by his son. He was twice married, but had issue only by his first wife, of whom four survived him; namely, a son and three daughters. Two of the daughters were married to eminent physicians, sir Edward Wilmot and Dr. Frank Nichols, who were, with himself, physicians to the king. His second wife, who was daughter to sir Rowland Allston, survived him.

The medical character has rarely obtained more respectability than in the person of Dr. Mead. He was not only in high and universal esteem on account of his professional skill, but was the greatest patron of science and polite literature of his time. He maintained a correspondence with the principal literati of Europe; all men of talents found a ready assistance from him in every undertaking; and no foreigner of any learning or taste visited London, without being introduced to Dr. Mead. His ample income was spent in a noble and hospitable way of living, in gratuities to men of science, and the encouragement of learned publications, and in the collection of scarce and valuable books, manuscripts, and literary curiosities, of which no individual of his time, in this kingdom, possessed so choice and ample a collection. Of all his treasures he made the most liberal use; for he not only freely admitted learned men of all countries to see and examine them, but he likewise entertained them at his table, and treated them with singular urbanity; uniting, as his biographer observes, "the magnificence of princes with the pleasures of philosophers."

The whole works of Dr. Mead have frequently been collected and published in various countries of Europe. A French translation of them by Coste, 1774, in two vols.

8vo. is esteemed for its numerous notes. See "Authentic Memoirs of the Life of Richard Mead, M. D." 1755. Gen. Biog.

MEAD, a wholesome agreeable liquor, prepared of honey and water.

One of the best methods of preparing mead is as follows: Into twelve gallons of water slip the whites of six eggs; mixing these well together, and to the mixture adding twenty pounds of honey. Let the liquor boil an hour, and when boiled, add cinnamon, ginger, cloves, mace, and a little rosemary. As soon as it is cold, put a spoonful of yeast to it, and tun it up, keeping the vessel filled as it works; when it has done working, stop it up close; and when fine, bottle it off for use.

Thorley says that mead, not inferior to the best of foreign wines, may be made in the following manner: Put three pounds of the finest honey to one gallon of water, and two lemon-peels to each gallon; boil it half an hour, well scummed; then put in, while boiling, lemon-peel: work it with yeast; then put it in your vessel with the peel, to stand five or six months, and bottle it off for use. If it is to be kept for several years, put four pounds to a gallon of water.

Macquer, in his "Dictionary of Chemistry," directs to choose the whitest, purest, and best-tasted honey, and to put it into a kettle with more than its weight of water; a part of this liquor must be evaporated by boiling, and the liquor scummed till its consistence is such, that a fresh egg shall be supported on its surface, without sinking more than half its thickness into the liquor; then the liquor is to be strained, and poured through a funnel into a barrel; this barrel, which ought not to be nearly full, must be exposed to heat as equable as possible, from twenty to twenty-seven or twenty-eight degrees of Reaumur's thermometer, taking care that the bung-hole be slightly covered, but not closed. The phenomena of the spirituous fermentation will appear in this liquor, and will subsist during two or three months, according to the degree of heat; after which they will diminish and cease. During this fermentation, the barrel must be filled up occasionally with more of the same kind of liquor of honey, some of which ought to be kept apart, on purpose to replace the liquor which flows out of the barrel in froth. When the fermentation ceases, and the liquor has become very vinous, the barrel is then to be put into a cellar, and well closed; a year afterwards the mead will be fit to be put into bottles.

Every maker of metheglin or mead for sale shall take out a licence, for which he shall pay 1*l.*, and shall renew the same annually, on pain of 10*l.* (42 Geo. III. c. 38.) If any maker of metheglin or mead for sale shall conceal any of it from the view of the gauger, he shall forfeit for every gallon 5*s.* 15 Car. II. c. 11.

MEADIA, in *Botany*, so called by Catesby, in compliment to Dr. Richard Mead, the celebrated physician, who, whatever might be his merit in his profession, was not judged by his contemporaries to deserve this botanical honour; and Linnæus therefore did not confirm it. The only work of Dr. Mead's ever mentioned as giving him a claim to such distinction, is his "Mechanical Account of Poisons," in which however there is nothing botanical. Crantz, a petulant critic of Linnæus, affected to oppose him in this trifling point, saying that "Mead was perhaps more deserving than many others who had obtained such honours." If this be all that can be said for him, the matter may remain at rest. See DODECATHÉON.

MEADIA, in *Geography*, a town of Hungary, in the bannat

of Temesvar, on a small river which runs into the Danube; 51 miles S.E. of Temesvar. N. lat. 45 10'. E. long. 21 59'

MEADOW, in *Agriculture*, a name generally applied to such natural grass lands as are annually mown for hay; but more particularly to those which are so low in their situation as to be too moist for cattle to graze upon in winter, without breaking the sward, or poaching the surface, which would be highly injurious.

Meadows, from their being generally enriched with the fine mould washed down from the adjacent rising grounds, are usually of a good soil, and seldom require much other improvement than the removing of temporary imperfections, and the superabundant moisture by proper draining. But they may be of such a nature as to stand in need of a more particular treatment; as is the case when their surfaces are of a mossy, loose earthy, or a binding clayey quality, where harrowing or scarifying, and the application of top-dressings will be necessary.

They are also farther distinguished into natural and artificial, or common and watered meadows.

The former, from their being situated in the hollows and sloping sides of the vallies, where the depth of the soil has been constantly increasing by the deposition of various sorts of vegetable and other matters brought down from the higher grounds, are, it is supposed by a late writer, in a considerably greater state of fertility, and evidently better fitted for the permanent production of grass, than those from which they have derived their riches. And it has been well observed, in the report of Staffordshire, that this, of all others, is "the most productive of grass and hay, yielding sustenance for cattle through the summer and the winter, and producing an everlasting source of manure for the improvement of the adjoining lands. Also, that in all cases of extensive inclosures, the improvement of the vale land, or that formed by nature for meadow and pasture, should be first attended to. In this view, the low lands in all situations come under the head of natural meadows."

And the latter are those which lie contiguous to rivers or brooks, whence the water can be easily carried or conveyed so as to overflow the grass at pleasure. Of these there are large tracts in several parts of the kingdom, which, where skilfully managed, become highly profitable to their owners, affording not only immense crops of hay, but yielding an abundant early grass for the use of ewes and lambs, in the beginning of the spring long before the pasture or other grounds are ready to receive them.

However, as the former sort of meadow lands, from their retention of moisture in consequence of their situation, and the great depth of vegetable matter which they contain, are suggested by a late writer to be liable to throw up much more coarse herbage, of the aquatic or other kind; in many cases more drainage as well as other management will be necessary to bring them into the proper condition for the growth of good herbage than is requisite in the hay grounds in more elevated places. And that, "by a more particular attention in these respects they would, in many instances, be rendered a vast deal more productive than they are at present, and, at the same time, afford a much better and less coarse herbage. They would also admit stock upon them a much greater length of time, both in the autumn and spring season."

It may be noticed, that "the most proper season for surface draining grass lands is in the autumn, when they are firm and dry, as in the early spring months such lands are too full of moisture. The grips, or small open drains, should

MEADOW.

should be cut obliquely in the most suitable directions for conveying off the superficial stagnant water. It is a practice, in some cases, to suffer the sods or grippings that are taken out of the trenches to remain on their sides; but it is much better, and a less slovenly mode, to have them conveyed from the land and laid up in heaps, in order to their being acted upon by the winter frosts and other causes, so as to be brought into a state proper for being formed into composts with well rotted farm-yard dung. Much of this sort of draining may be performed at a small expence, and the beneficial effects be very considerable, especially where the lands are very much loaded with moisture, in the quantity of produce." Besides, such meadow lands "demand much more attention in their management in other respects, as those of their being fed by cattle, and the performing of the different operations that are proper for rendering them productive of good herbage. In these cases, stock should be turned upon the lands, and manures be applied with much care, and only when the land is in such a state of dryness as not to be injured by the poaching or breaking of the sward. The higher sorts of grafs lands, in most instances, admit of considerably more latitude in performing these different operations, as they are capable of admitting the stock as well as the dung-cart more early in the spring months, and of suffering them to remain or be applied at later periods in the autumn without inconvenience. The advantage of this attention is rendered sufficiently plain by the effects which the contrary practice produces in such meadow and other hay lands as are in a state of commonage, where the stock is admitted at all seasons, and under all circumstances."

It is evident that "these sorts of grafs lands must be applied to different purposes, according to their nature, situation, and other circumstances. Those which are of the more moist and wet kinds, whether from the nature of the soil, or the peculiarity of situation, and which have been a long time in the state of sward, are for the most part kept under the scythe; while those of the contrary descriptions, that are situated at a greater height, and of course, in most cases, possess a greater degree of firmness, are, in general, appropriated to the purpose of pasturage; though, in particular situations, where grafs land is scarce, and consequently of great value, they are occasionally likewise converted to the purpose of hay. And as grafs plants grow to the greatest height in situations where a considerable degree of moisture is constantly preserved, and, of course, afford the largest produce, it would seem that the practice of keeping them under the scythe is right on this account; as well as that of their being less firm and solid in their texture, and their mostly producing a coarser herbage. The more elevated grounds, as they bear the stock generally with less injury, and often afford both a more fine and sweet feed, are with propriety converted to the use of being fed down by animals. By a suitable management in the feeding and use of manure, the latter sort of lands may even be brought to afford a considerable produce in hay in numerous instances.

And "as it must be evident to the most superficial observation, that the breaking of the surface texture or sward of grafs lands must, in all cases, be prejudicial, not only by the destruction of plants which is thereby immediately produced, but also by the retention and stagnation of water upon them in the holes, and depressions from small portions of the turf being forced in, the necessity and utility of clearing and removing all sorts of live stock, and especially those of the heavy kinds, on both these descriptions of meadow land when mown, becomes strikingly obvious."

There is a striking fact of this sort stated in the Agricultural Report of Middlesex. "In a piece of clayey meadow land exposed to the treading of cattle during the wet season of winter, with a view of fully ascertaining the effects of the practice of suffering cattle to remain too long upon grafs hay lands, it was found that after three years, notwithstanding every possible care and attention in rolling, manuring, and sowing grafs seeds was employed, it was not restored to its former state of sward." And it has been remarked, that on the deep tough yellow clayey grafs lands in the same district, every care is taken to prevent the least degree of poaching, as "it is well known that wherever a bullock makes a hole with his foot in this kind of soil, it holds water, and totally destroys every vestige of herbage, which is not quite replaced till several years after the hole is grown up."

In regard to the exact period of continuing the feeding down of grafs lands of the hay kind, it cannot be easily regulated by any fixed rules, as it must depend much on seasons; but it should never, on any account, be continued after the grounds have become so much impregnated with moisture as to easily give way to the tread of animals. In the autumn season the heavy cattle should seldom be suffered to remain on the softer sorts of lands longer than the beginning of November, but in those of the more dry kinds, they may be let remain to the end of that month. Sheep stock may, in drier cases, be continued till February, or later; and in the spring season, if pastured at all, they should not be admitted upon such lands till they begin to possess a proper degree of firmness, which will depend on the various circumstances of the preceding season. On the more low and moist sorts of meadow land, it can probably seldom be ventured earlier than the middle of March.

It is, however, obviously a much better practice, especially where hay is the main object, not to eat them down at all, or very little, with cattle in the spring, and not so much as is the usual custom with sheep; as it is plain, that by this means the cultivation will not only ensure a more abundant produce, but a much earlier one, and, of course, have more advantage in the making it into hay and securing it.

Besides, where the lands are fertile and the grafs springs quickly, as is often the case near large towns where manure is plentiful, it may be advantageous in the view of having a second crop, as by that means the after-grafs may be cut more early, and be less in danger of being well secured; and, in all events, the after-grafs will be in a more forward state, and, of course, ready at a more early period for the admission of stock of different kinds, which, in many cases, is a circumstance of great importance to the farmer where grazing is the main object.

With respect to the most proper periods of shutting up such grafs lands as are designed for hay, they must, like those of eating them down by stock, depend on various circumstances that can only suit the particular cases. In general, however, it is the best practice not to delay it too long. When the lands are not eaten at all in the spring by cattle, after the sheep have been removed about the middle of February; nothing farther is allowed, according to the writer of the Middlesex Report, to enter the meadows, by which means a quick vegetation is promoted, as well as a more plentiful crop and more early harvest. And in other cases it should probably seldom much exceed the beginning of April, as when eaten much later, especially in the southern districts, there is not time for the grafs to produce a full crop before the commencement of the hay season, of course the farmer sustains more loss than can be repaid by any advantage in the additional feeding he may obtain. This

is therefore the best practice where the view of the farmer is hay; and it should be particularly adopted and attended to in cow-farms, where it is of much importance to cut early and at different times, in order to secure hay of a fine grassy quality, for the purpose of producing large supplies of milk. In these cases it is cut two, three, or more weeks before the usual period, as it is better not to let the feed stems rise much.

Immediately after the meadows or other grass-lands have had the cattle and other sorts of live stock removed from them, in the early spring months, and been shut up for hay, they should be prepared for the scythe, by having all sorts of obstructions picked up and removed from the surface. This work should always be executed as soon as possible, before the grass begins to spring up too much and conceal them, as it is difficult to perform the business effectually afterwards. And it has been observed, that "it is an excellent practice, but one that is too much neglected by grass-farmers in general, to have all sorts of coarse plants of the aquatic and other kinds, such as rushes, fern, docks, thistles, and various others, effectually drawn up and eradicated both from the hedge-rows and other parts of the fields, in order to prevent their running up to seed and dif-feminating themselves over the lands, and thus not only fill them progressively with all sorts of trumpery, but greatly injure the herbage. In a field on an extensive hay-farm in Middlesex, on perceiving the whole surface thickly fludded with thistle-plants, it was found that this sort of weed had been suffered to flower and perfect its seed annually, until the lands on every side had become fully stocked, to the vast injury of the hay-crops. The same thing takes place with the dock, and several other noxious plants, which strongly enforces the utility of the practice just recommended. The annual expence of performing the business is but a mere trifle, while the advantage will be real and permanent. The saving to the farmer would be considerable, by having the work regularly done as soon as the weeds shew themselves, and at the same time his young hedge-plants be prevented from being destroyed, by being shaded and choaked up by so many weeds. In order to take them up in a perfect manner, a narrow implement of the spade kind, such as is made use of in forming narrow drains, may be employed with advantage, as cutting or breaking them off is by no means effectual. After such plants have been removed, and the ground well cleared, sowing the banks and hedge-rows with the best grass-seeds, such as white clover and other similar plants, might be an excellent practice, as in this way the lands may be improved rather than injured."

In regard to plants of the rush kind, they may be easily removed by preventing the stagnation of moisture near the surface, by judicious under or surface draining, and the application of substances of the saline or calcareous kinds, such as ashes, lime, drift from the roads, and other similar materials. These are the best made use of in a dry season, in either the autumn or spring; but the latter is probably the best, as these absorbent matters will thereby be made use of at the time such plants begin to shoot and establish themselves, and when there will be the least danger of their operation being lessened or prevented by too great a degree of moisture. It has been observed, that in natural coarse meadows, or such as become so in consequence of rushes growing upon them, before they have been rendered sufficiently dry by draining, it forms a great improvement to apply a thin coat of sand evenly over the surface of them, in the proportion of from twenty to thirty common loads. By this means the sward is rendered much finer, and a much

better sort of herbage brought up; white clover being predominant in most cases where this is practised.

But there is another method that, in particular situations, may be more easy and convenient, and which has been found to quickly destroy plants of this coarse kind, by bringing up those of a finer description. This may appear extraordinary at first sight to those who have not seen its sudden and astonishing effects in this way. It is that of conducting water over the surface of such grounds; but, in this intention, it should not be suffered to have the least degree of stagnation, but be conveyed off with as much expedition as possible, by suitable drainage or other means.

M. de Chateauxvieux many years ago invented a machine, called a cutting-plough, with three sharp coulters for cutting the land about six or seven inches deep, that the manure laid upon it might be washed into the incisions made by the coulters and which also, by cutting the old roots of the grass, many new roots were produced, and a very great improvement afforded, particularly where the meadows were hide-bound and overrun with moss. And afterwards Mr. Wynn Baker, in Ireland, added two more coulters, and named it a *scarificator*; which is considered a very useful tool for the purpose of improving meadows, as well as pastures. For it has been found in practice, that if the land is first scarified, and then manured, the improvement is greater than scarifying the land after laying on the manure. And this business is said also to be well performed by a sward-dresser, invented by Mr. Amos in Lincolnshire. See *SWARD-DRESSER*.

In cases where meadow-lands are properly situated for the purpose of being watered, they may be formed properly for the purpose, probably with the most advantage, in the early autumn; but when that season cannot be conveniently employed, the work may be performed early in the spring. The methods of cutting the gutters and trenches, and of managing the whole of the process, as well as the vast utility which is the result of it, may be seen detailed under the heads *IRRIGATION* and *WATERING of Land*.

Where this practice is attempted, the farmer should commence the watering of his meadow-lands early in November, which, in most instances, affords more improvement than a dressing of the best manure that can be provided. As they are commonly the lower parts of the ground that can be made use of in this way, much may often be effected by a proper attention to the ditches in the lands that lie at higher levels, as by keeping them in such a state that they may discharge themselves freely into a large main ditch, a little above the lower parts of them, from which the water may be let off occasionally, so as to float the meadow grounds below; care being taken that it does not stagnate upon them in any way. And in managing this sort of operation afterwards, Mr. Wright advises that the floater should take care to keep the land sheltered by the water from the severity of frosty nights. And in the winter, as about January, it is necessary, he conceives, every ten days or fortnight to give the land air, and to lay it as dry as possible, for the space of a few days. "Whenever the frost has given a complete sheet of ice to the meadow, it is advisable to discontinue floating; for the frost will sometimes take such strong hold of the land, as to draw it into heaps, and injure the evenness of the surface. Attention is also to be paid to prevent the equal distribution of the water being obstructed, by the continual influx of weeds, leaves, sticks, &c." And, as the season advances, still greater attention is required from the floater in the succeeding month: "if the water be suffered to flow over the meadow, for the space of many days without intermission, a white scum, it is observed, is generated, which is found
very

very destructive to grafs; and if the water be taken off, and the land expofed in its wet ftate to a fevere frofty night, a great part of the tender grafs will be cut off. In Gloucefterfhire, two methods of avoiding thefe injuries are prafticed: one is, to take the water off by day, to prevent the fcum, and to turn it on again at night, to guard againft the froft; the other method is to take the water off early in the morning, and if that day be dry, to fuffer it to remain off for a few days and nights; for if the land experiences only one drying day, the froft at night will do little injury. The former of thefe praftices, where it is found not too troublefome, is preferable to the latter." About the middle of February, the floater fhould begin to ufe the water more fparingly than in autumn or winter; for his chief object now is to encourage or force vegetation. It is moftly found, that about the laft week of this month, if the preceding management has been good, there will be a pretty full bite for ewes and lambs. Some advife rolling in the beginning of the year, as about January.

The fame writer alfo ftates, that "about the beginning of March, the grafs on the old floated meadows will generally be fufficient to afford an abundant pafturnage to any kind of farming ftock; and the water muft be taken off for nearly a week, that the land may become dry and firm before heavy cattle are admitted. It is proper, in the firft week of eating off the fpring feed, if the feafon be cold and rainy, to give the cattle a little hay in the evening to intermix with their moift food. But the grand application of the young meadow-grafs is for ewes and lambs; and attention fhould always be paid to hurdling off the grafs, and giving ftripes acrofs the meadow, exactly in the way turnips are hurdled for fheep. The caution of Mr. Bofwell, never to feed on thefe meadows any heavier ftock in fpring than fheep or calves, feems to be judicious, but muft obviously depend much on foil; for, upon a found gravel, a praftice may be admitted, which would be mifchievous on a peat meadow." But good rich meadows, whether watered or not, are moftly ready to be cut about the middle of June.

Mr. Bofwell advifes, that "as foon as the hay is cleared from thefe meadows, cattle of any fort (no fheep) fhould be turned in for a week to eat the grafs out of the trenches, and what may be left by the mowers. Then the water fhould be worked on them, care being taken to let it only dribble over every part as thinly as poffible; this being the warmeft feafon of the year. The firft watering fhould not laft longer than two or three days, before it is fhifted to another meadow. There will foon be an after-grafs of fuch a rich and beautiful verdure as will aftonifh a fpeftator not accuftomed to it; and the quantity and quality will be beyond conception, compared with the ftate the lands were in before they were watered. He alfo further cautions us to guard by all means againft keeping the water too long upon the meadows, in warm weather. It will very foon produce a white fubftance like cream, which is prejudicial to the grafs, and fhews it has been upon the ground too long already; but if permitted to remain a little longer, a thick fcum will fettle upon the grafs, of the confiftence of glue, and as tough as leather, which will quite deftroy it."

MEADOW-Grass, in *Botany*. See POA, CYNOSURUS, and GRASS.

MEADOW-Fox-tail Grass, in *Agriculture*, a fort of field grafs, that may be cultivated to advantage on the more moift forts of foil. It is faid to be early and productive, but rather coarfe. See ALOPECURUS *Pratensis* and GRASS.

MEADOW Rue. See THALICTRUM.

MEADOW Saffron. See COLCHICUM.

MEADOW Saxifrage. See PEUCEDANUM and SESELI.

MEADOW Sweet. See SPIRÆA.

MEADOW Trefoil. See TREFOIL.

MEADOW River, in *Geography*, a river of America, which runs into lake Huron, N. lat. 45° 38'. W. long. 84° 30'.

MEADVILLE, a thriving poft-town, feated on French creek, a branch of the Alleghany, in Crawford county, Pennsylvania (N. lat. 41° 36'), and the feat of juftice for the counties of Warren and Crawford, to the latter of which it belongs. It contains about 100 houfes, and feveral ftores, and is a place of confiderable bufinefs.

MEAGOM, a town of Hindooftan, in Guzerat; 20 miles N. of Baroach.

MEAHGURRY, a town of Hindooftan, in Candeifh; 30 miles S.E. of Chuprah.

MEAHMAO, a large town of the Birman empire, on the Irawaddy, fhaded by groves of palmyra trees, and remarkable for a manufacture of coarfe cloth, fuch as is worn by the lower clafs of people; 42 miles W. of Ava.

MEAKING, a town of the Birman empire, on the right bank of the Ava; 8 miles N. of Penongmew.

MEAL. The meal or flour of England is the fineft and whitest in the world. The French is ufually browner, and the German browner than that. Our flour keeps well with us; but in carrying abroad, it often contracts damp, and becomes bad. All flour is fubject to breed worms: thefe are white in the white flour, and brown in that which is brown; they are therefore not always diftinguifhable to the eye: but when the flour feels damp, and fmells rank and mufty, it may be conjectured that they are there in abundance.

The colour and the weight are the two things which denote the value of meal or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions thefe two characters as the marks of good flour, and tells us, that Italy, in his time, produced the fineft in the world. This country, indeed, was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles, in particular, fays, that no flour is fo white or fo good as that of Italy. The corn of this country has, however, loft much of its reputation fince that time; and the reafon of this feems to be, that the whole country being full of fulphur, alum, vitriol, marcafites, and bitumens, the air may have, in time, affected them fo far, as to make them diffufe themfelves through the earth, and render it lefs fit for vegetation; and the taking fire of fome of thefe inflammable minerals, as has fometimes happened, is alone fufficient to alter the nature of all the land about the places where they are. Defland. *Trait. Phyf.*

The flour of England, though it pleafes by its whitenefs, yet it wants fome of the other qualities valuable in flour: the bread that is made of it is brittle, and does not hold together, but, after keeping a few days, becomes hard and dry, as if made of chalk, and is full of cracks in all parts; and this muft be a great difadvantage in it, when intended for the fervice of an army, or the like occafions, where there is no baking every day, but the bread of one baking muft neceffarily be kept a long time.

The flour of Picardy is very like that of England, and, after it has been kept fome time, is found improper for making into pafte or dough. The French are forced either to ufe it immediately on the grinding, or elfe to mix it with an equal quantity of the flour of Brittany, which is coarfer, but more unctuous and fatty; but neither of thefe kinds of flour keeps well.

The flour of almoft any country will do for the home confumption of the place, as it may be always fresh ground; but

but the great care to be used in selecting it is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea-air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find, that the flour of Poitou, Normandy, and Guienne, all bear the sea-carriage extremely well, and they have formerly made a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships: the keeping it dry is the grand consideration in regard to this; the barrels in which it is put up ought to be made of dry and well-seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will moisten and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since, when once well dried and seasoned, it will not contract humidity afterwards. The beech-wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable, because of its being free from these faults; and when the several kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so, than this for the purpose. The great test is their having more or less sap. See FLOUR and WOOD.

MEAL *Worm*. See WORM.

MEALY-*Tree*, in *Botany and Gardening*. See VIBURNUM.

MEAMBOLANGAM, in *Geography*, a town of the Birman empire, on the Ava; 36 miles N. of Prome.

MEAMOY, a town of the Birman empire, on the right bank of the Ava; 16 miles W. of Ava.

MEAN, the middle, between two extremes.

Thus we say, the mean motion of a planet; its mean distance, &c. meaning a motion or distance, which as far exceeds the least distance or motion, as it is exceeded by the greatest.

MEAN, middle, mean proportion, is the second of any three proportions; but in music, mean is more properly the title of the second violin in trios, as being the mean between the first violin and base. In madrigals of five and six parts, a third treble is generally termed the mean part.

MEAN, in *Lazv*, refers either to time or dignity. Thus, in the first sense we say, his action was mean betwixt the dissipation made to him, and his recovery; *i. e.* in the interim.

In the second sense, we say, there is lord *mean* or *mesne*.

MEAN, in *Logic*. See MEDIUM.

MEAN *Anomaly*, in *Astronomy*. See ANOMALY.

MEAN *Axis*, in *Optics*. See AXIS.

MEAN $\left\{ \begin{array}{l} \text{Conjunction,} \\ \text{Opposition,} \end{array} \right\}$ in *Astronomy*, is when the mean place of the sun is in $\left\{ \begin{array}{l} \text{conjunction} \\ \text{opposition} \end{array} \right\}$ with the mean place of the moon in the ecliptic. See CONJUNCTION and OPPOSITION.

MEAN *Diameter*, in *Gauging*. See GAUGING.

MEAN *Distance of a Planet from the Sun*, in *Astronomy*, is

the right line drawn from the sun, to the extremity of the conjugate axis of the ellipse in which the planet moves; and this is equal to the semitransverse axis, and is so called because it is a mean between the planet's greatest and least distance from the sun.

MEAN *Motion*, that whereby a planet is supposed to move equally in its orbit, and is always proportional to the time.

MEAN *Proportion*. See EXTREME *Proportion*.

MEAN *Time*. See TIME.

MEANA, in *Geography*, a town of Hindoostan, in Kitchwarra; 10 miles N.E. of Budawar.—Also, a town of the island of Sardinia; 21 miles S.S.W. of Lode.

MEANG, a town of Hindoostan, in Guzerat; 40 miles N.W. of Puttan-Sumnaut.

MEANGIS, a cluster of small islands in the North Pacific Ocean. N. lat. 4° 58'. E. long. 126° 55'.

MEANY, a town of Hindoostan, in Guzerat, near the coast; 40 miles S.W. of Junagur.

MEANY, *Chuppa*, a town of Hindoostan, in Guzerat, on the coast; 55 miles W. of Junagur.

MEAO, one of the small Molucca islands. N. lat. 1° 12'. E. long. 127° 3'.

MEARIM, a river of Brazil, which runs into the bay of Baranhan, S. lat. 2° 40'. W. long. 45° 30'.

MEASLES, in *Medicine*, a contagious fever, accompanied by a rash or efflorescence on the skin, of a peculiar form or distribution, which molly appears on the fourth day of the fever, and, after a continuance of four days, gradually declines together with the febrile symptoms.

This disease, like the small-pox and scarlet-fever, was not particularly described or named by the Greek and Roman physicians, but is first mentioned by the Arabians. The translators of the writings of the latter into Latin applied the term *morbilli* to the disease; as it were a *little plague*, the word *il morbo*, in Italy, signifying the plague, or *the disease*, by way of eminence. Subsequently, from the red colour of the rash, the terms *rubiole* and *rubeole* were given to this disease, and to scarlet-fever, which was confounded with it. The appellation of *rubeola* has been adopted for the measles by our best nosologists, Sauvages and Cullen. The English term *measles* seems to have been borrowed from an appearance, which was so denominated in the flesh of pork, to which the eruption of rubeola was supposed to bear some resemblance.

The disease in question is propagated solely by contagion; and it commences in children, or in adult persons of an irritable constitution, from ten to fourteen days after they have been exposed to the infection. Others, who are less susceptible, may have frequent communication with persons affected with the disease during several successive weeks, but the contagion does not act upon them, unless the body be brought into a feverish state by some incidental cause, as by taking cold, by watching, fatigue, or mental distress. Dr. Willan, in his valuable and elaborate treatise on cutaneous diseases, has described three varieties of measles, which it is important to attend to: these are the rubeola *vulgaris*, or common form of the disease; the rubeola *sine catarrho*, in which fever and catarrh do not accompany the eruption; and the rubeola *nigra*, or purple-measles.

1. The *rubeola vulgaris*, or usual form of measles, exhibits the following character. The symptoms which precede the efflorescence are, on the first and second days, irregular shiverings alternating with heat of the skin, general debility or listlessness, flushing of the cheeks, giddiness, a sensation of pain or weight across the forehead and eyes, with drowsiness; sometimes pain of the back and limbs,

MEASLES.

slight soreness or roughness in the throat, loss of appetite, frequent nausea, thirst, a white fur on the tongue, clear high-coloured urine, the pulse much increased in frequency, and somewhat labouring or irregular. On the third and fourth days, the same symptoms continue, but with greater violence: the eyes become tender and inflamed; the eye-lids and tarfi appear a little turgid; at the same time a serous humour is copiously discharged both from the eyes and nostrils, which occasions repeated sneezing. The disease during this period, and usually for two or three days longer, is accompanied with a frequent dry cough, hoarseness, difficulty of breathing, and a sense of constriction across the chest. In children, indeed, in whom all the symptoms of the first stage are more severe than in adults, the disease is often preceded by a harsh sounding cough for a week, or even a fortnight, before it formally commences; and sometimes, especially during the period of dentition, is attended with frequent twitchings, or even with strong convulsive fits.

We have said that the efflorescence mostly appears on the fourth day of the fever: this, however, is not invariably true. In persons who have a very delicate skin, it sometimes appears partially on the third day; while in others, of a dark and thick skin, or who have been exposed much to cold, it may not be manifest till the fifth or sixth day: and as the contagion is, in many persons, only called into action by some incidental feverishness; so it is not easy, in these cases, to ascertain the commencement of the proper eruptive fever.

The rash is first visible on the face, especially on the forehead and under the chin, and exhibits in other parts only a few scattered specks, with a somewhat warmer colour of the skin than usual. On the following (fifth) day, it is formed on the neck and breast in the morning, and is diffused, towards evening or in the night, round the trunk of the body, and along the extremities; during this day it is most full and vivid on the face. On the sixth day of the disease, the rash on the face begins to fade and subside, while the patches on the body are most red and extended; but these gradually change their appearance the day after. The patches on the back of the hand and wrist, which usually appear latest (in some instances on the sixth or seventh day), do not always decline till the eighth day. On the ninth day, there remain only vestiges of the efflorescence, marked by a slight discoloration; this, however, disappears before the end of the tenth day. When the rash begins to decline on any part, the cuticle becomes dry and rough, and soon after separates into scurf. Hence arises a very disagreeable itching of the skin which continues from the seventh to the tenth day.

The progress of the eruption is sometimes checked by exposure to continued cold; and its retrocession occasions delirium, restlessness, difficulty of breathing, pain of the bowels, diarrhoea, &c. and endangers the life of the patient. The inflammation of the eyes, the discharge of tears, the sneezing, and hoarseness, generally cease on the decline of the efflorescence, about the seventh day; at least they are always much abated at that time, and the appetite for food returns. Between the fourth and sixth days there is often a hæmorrhage from the nose, and in females an appearance of the catamenia out of their course; but these circumstances occur in other eruptive diseases.

It is necessary, however, to attend to the form and mode of distribution of the efflorescence, as well as to its progress and periods, with a view to avoid mistakes as to the nature of the disease; which has been frequently, and indeed for many centuries was constantly confounded with scarlet-fever, and other febrile rashes. The colour of the rash in the

measles, Dr. Willan observes, is less bright than in some other diseases of the exanthematous class. It verges towards the raspberry tint, rather than the scarlet or rose hue of some other rashes. On the eighth day, when the efflorescence declines, it changes to somewhat of a yellowish hue. The rash commences with distinct, red, and nearly circular dots, about the size of common flea-bites, to which most writers have compared them. Larger patches afterwards appear, or rather these dots, becoming more numerous, coalesce into larger patches, which, although not exactly defined, approach nearest in their form to the figure of a crescent, or semicircle. These patches are slightly raised, and give to the finger the sensation of an unequal surface. Many of the patches are interpersed with the same small circular dots; but there are, for the most part, large interstices of cuticle retaining its usual colour.

From these characteristic appearances of measles there are only partial variations: as, 1st. The flushed and tumefied state of the cheeks, while the fever continues, may obliterate or obscure the form of the rash on those parts. 2dly. In infants less than a year old the efflorescence is much scattered; and on the cheeks, nose, backs of the hands, &c. it often consists of distinct pimples (*papule*). The wrists, hands, and fingers are also frequently papulated in adults. 3dly. In many persons, at different ages, there are, during the height of the efflorescence, lymphatic or miliary vesicles on the neck, breast, and arms. Willan on Cutan. Diseases, p. 217, & seq.

Dr. Heberden has noticed the following particularities of the measles: "One patient was seized with a spitting on the fourth day, which continued to tease him for forty-eight hours, without suffering him to rest at all by day, or to sleep at night: the cough in the mean time almost ceased, and all the other symptoms were as mild as in a favourable sort of the measles.

"In one or two patients I have seen the eruption appear on the arms a few hours after its having been observed on the face and neck.

"Once or twice the distemper has been observed never to have reached the arms, which parts, through the whole of it, shewed none of the usual spots.

"The eye-lids have been so swelled, on the second day of the eruption, that for twenty-four hours they could not be opened.

"In several patients the marks on the face have been on the third and even fourth day of the eruption, of as bright a red as ever. In others, I have observed them to disappear entirely on this day, and all other symptoms likewise to retreat.

"I have noted a very troublesome and constant sneezing, which first came on upon this day.

"A child, five years old, became comatose the third day of the eruption, and died the next.

"The longer the preparatory symptoms have continued and the worse they were, so much the less mild the distemper proved.

"Those who have shewn the least remains of the eruption after the seventh day of the disease (and some have hardly shewn any) have appeared the best; and in those where it was still in undiminished vigour, the cough and fever have been the worst." See a Paper in the Med. Transf. of the Coll. of Phys. vol. iii. Also, Dr. Heberden's Comment. de Morb. cap. 63.

The eruptive stage of the measles is not attended with much danger, either to infants or adults. The fever, indeed, does not receive any immediate alleviation, but is often somewhat aggravated on the appearance of the rash: yet the nausea and

and vomiting seldom continue beyond the fourth day of the fever, as Sydenham has justly remarked; and the distressing heat, panting, and restlessness abate on the sixth day. The subsequent period of the disease, however, may prove fatal to patients of any age. Between the ninth and twelfth day, some children are unexpectedly attacked with great difficulty of breathing, or suffocation, and die in a few hours. In others, the diarrhoea, which usually supervenes on the disappearance of the rash, about the ninth or tenth day, continues, without intermission, for so long a period that it exhausts their strength, and they become pale and emaciated; under these circumstances aphthous ulcerations of the mouth are generally the fore-runners of death. Adults, as well as children, fall sometime into a state of hectic fever, which returns twice in twenty-four hours, without any cough or diarrhoea; and during the intervals there is great restlessness and a quick irregular pulse. The patients thus affected, for two or three successive weeks, gradually sink under the complaint; but in some instances a fatal termination seems to be averted by the appearance of boils, pustules, or suppurating tubercles on the skin, which operate very favourably with respect to the internal disorder, both in this hectic state, and in cases where the bowels or the lungs are severely affected. Sometimes this alleviation is speedily produced by an eruption of inflamed watery vesicles round the chest, or more slowly by a discharge from behind the ear, or from the ear itself, accompanied with suppuration in some of the lymphatic glands. When nothing of this kind appears externally, the inflammation of the lungs in adults is sometimes on a sudden greatly aggravated; the cough ceases, respiration becomes more and more laborious, with a sense of oppression and anxiety: the eyes are glassy, the countenance livid, the extremities cold, and the pulse scarcely discernible. After a struggle of three or four days, the disease has a fatal termination, the cause of which dissections have ascertained, in several cases, to be an effusion of lymph, mixed with blood or matter, into the cavity of the thorax. Willan.

Even when the measles pass through their course moderately and mildly, however, various disorders follow them, or a tendency to some other disease is not unfrequently left behind; so that the consequences of this fever are often more to be dreaded than the original disease itself. In many persons the cough, soon after the disappearance of the rash, recommences with violence, being attended with difficulty of breathing, fixed pain in the sides, flushing of the cheeks, quick pulse, and often with paroxysms, as in a hectic. This state is protracted much longer than pneumonic inflammation produced by cold, and more frequently terminates by effusion into the cavity of the chest, or by spitting of blood, suppuration, and confirmed pulmonary consumption. There are also some other appearances which occasionally succeed the measles, especially diseases of the skin and glandular system, which mark a cachectic state of the habit. Among these are small hard tumours, like boils, occurring on the back, loins, and lower extremities, which are very much inflamed in the beginning, and afterwards suppurate with great pain, and a sanious discharge; herpetic eruptions, in patches of watery vesicles, with an inflamed base, about the chest, mouth, &c. producing much heat, pain, and tingling of the skin; soft pustules, containing a viscid straw-coloured fluid on the head, face, breast, and thighs, succeeded by ulcerations at the corner of the mouth, with tumour of the upper lip, inflammation of the eyes, and ulcerations at the edges of the eye-lids, discharges behind the ears, enlargement and tedious suppuration of the lymphatic glands under the jaw, in the neck, arm-pits, and groin, sometimes with

pain and swelling of the joints, and every other form of serofulous disease.

Treatment of Common Measles—The *rubeola vulgaris* is usually a mild disease in the summer months, being attended with a moderate degree of fever, and but little cough; in January, February, and March, it is most frequent, and likewise most severe and dangerous.

In the eruptive stage of the disease, it is necessary to enjoin a very light diet, with mild tepid drinks; and to keep the patient in a moderate temperature, carefully guarding against any great or sudden changes. An emetic given on the second or third evening affords some slight alleviation to the violence of the catarrhal symptoms. During the eruption, however, no considerable effect appears to be produced by antimonials, or other diaphoretics; and emulsions and mucilages afford but a very feeble palliation of the cough and difficulty of breathing. The first of these objects, to wit, of softening the skin, seems to be more efficiently accomplished by the use of the warm pediluvium every evening; and the latter by the inspiration of the steam of hot water. If a diarrhoea comes on during the continuance of the efflorescence, it is generally favourable, relieving the cough, and allaying the inflammatory symptoms: where this does not supervene, therefore, it is advisable to administer occasional purgatives, which will be found to produce a similar relief, and often supersede the necessity of more violent remedies.

Almost all authors, down to our own time, have asserted the necessity of blood-letting in this disease, differing only in regard to the period when it may be practised with most advantage. Morton deemed it requisite during the height of the eruption, when he thought the disease was most inflammatory; and Sydenham recommended it after the disappearance of the eruption, when symptoms of pulmonary inflammation ensue. Whistl Mead and Heberden considered the period of the disease as of little moment in determining the propriety of the practice, which the degree of inflammatory affection in the chest, they contended, ought alone to decide. Dr. Heberden, however, recommended the use of the lancet as a general remedy in the measles. "Bleeding may be used at any time of the measles," he says, "and is always beneficial where the symptoms are very distressing, particularly an oppression of the breath, to which every stage of this distemper is liable; and *bleeding*, together with such medicines as occasional symptoms would require in any other fever, is the whole of the medical care requisite in the measles." *Med. Transf.* vol. iii. p. 404.

In case the breathing becomes suddenly difficult, threatening to suffocate the patient, at the conclusion of the disease, as Sydenham states, there cannot be a doubt that blood-letting, even in children, may be resorted to with great benefit, and ought not to be omitted: in infants the application of leeches to the chest may be sufficient. With respect to the treatment of the oppression, however, conjoined with anxiety, heaving of the chest, and a labouring pulse, which take place on the third, fourth, or fifth day of the disease, Dr. Willan justly observes, that this remedy may be dispensed with, unless there are at the same time pains in the chest, and a hard dry cough. "Those who from doubt, or from some collateral motive," he states, "are led to await the event, usually find the pulse become moderate, and the uneasy laborious respiration terminate in twenty-four hours. This oppressed breathing is, indeed," he adds, "common to other eruptive fevers, and if it were universally considered to be an indication for bleeding, the practice would often be more fatal than the disease." *Lec. cit.* p. 232.

MEASLES.

He goes on to remark, that "when the efflorescence in measles has wholly disappeared, and the cough, difficulty of breathing, and pains in the chest are very severe, bleeding and cupping may perhaps be repeatedly necessary. Yet, even in robust habits, some limitation is requisite to this mode of practice; since it has not an effect in alleviating the symptoms, equal to that which is experienced from it in pulmonic inflammations originating from cold. Hence we should employ as auxiliaries to bleeding, at the latter period of the disease, blisters, opium, and demulcent liquors. Sydenham prescribed an opiate every night through the whole course of the measles; but this plan seems not beneficial in the eruptive stage; I have observed, and myself felt, while labouring under the disease, that opium did not conciliate sleep, but produced an increase of heat and restlessness, and therefore seldom direct it till the efflorescence has declined. A diarrhoea occurring at this period may be accounted a most favourable circumstance, since nothing so effectually relieves the peripneumonic symptoms, or contributes more to prevent the troublesome consequences of the disease formerly mentioned. The necessity of bleeding, as a remedy for the diarrhoea, is insisted upon by Dr. Sydenham from theoretical reasoning. Experienced practitioners in London seem to have now decided, that we ought not much to interfere with this critical evacuation, but rather allow it a free course, at least for some days. Where the diarrhoea does not thus take place, it is proper to imitate the usual process of nature, by the occasional use of purgatives, which will always be found to relieve the cough, and by allaying the inflammatory symptoms, often to supersede the necessity of blood-letting."

2. The *Rubeola sine catarrho*, which is so mild as to require no medicine, is particularly entitled to notice, in consequence of a circumstance pointed out by Dr. Willan, and not observed by other writers who had mentioned its occurrence; namely, that when the eruption of measles occurs without the accompanying fever and catarrhal symptoms, it does not appear to secure the constitution from the future influence of the contagion, nor to prevent the accession of the ordinary form of the disease at a subsequent period. In this way he supposes that the instances of the recurrence of measles in the same individual, which have been recorded, are probably to be explained, unless where other diseases, scarlatina, roseola, strophulus, &c., have been mistaken for measles; for he never saw the *febrile* measles occur more than once in the same person. In some cases the non-febrile eruption has occurred at the interval of two years before the rubeola vulgaris; in other instances, a very short time has intervened. "I have seen other instances of the same kind," Dr. Willan says, "wherein the efflorescence without fever or catarrhal symptoms having declined, there appeared on the fourth day from its commencement a new efflorescence, and violent disorder of the constitution. These instances are perfectly analogous to some cases of small-pox, in which distinct pustules arise without any material complaint, and when these decline, about the eighth or ninth day after their appearance, the variolous fever takes place, with an eruption of confluent pocks over the whole surface of the body." P. 236.

The appearance of the efflorescence of measles, when the ordinary febrile and catarrhal symptoms are absent, is to be distinguished from other rashes, as well as from lichen and strophulus, which are *papular*, by a careful examination of its form and distribution, as above described. In infants, Dr. Willan observes, the eruption of measles "is more papulated, and the patches often less extensive, so that to discriminate with exactness, the patient being under two years

of age, requires both minute attention, and some previous habitude."

3. The *Rubeola nigra* is that variety of the measles, which sometimes occurs, in which, about the seventh or eighth day, the rash becomes suddenly black, or of a dark purple colour, with a mixture of yellow. This appearance has continued ten days, and in some cases longer, without much distress to the patient, and with no other symptoms of fever than a quick pulse, and a slight degree of languor. The mineral acids were administered in these cases with evident advantage. Sydenham ascribes the change of the appearance of the rash to a black or purple colour, which he occasionally witnessed in adults, to the pernicious perseverance in a heating regimen. To the influence of such a regimen, indeed, he affirms that the pulmonary inflammation, which is the most fatal symptom, as well as the diarrhoea, that continued many weeks, was generally to be imputed. See his excellent chapter on Measles, which contains the prototype of the description of the disease, that has been given by the majority of subsequent writers. Sect. iv. cap. 5.

Under the denomination of "putrid measles," sir Will. Watson described a disease, which prevailed among the children of the Foundling Hospital, in 1763 and 1768. (See Med. Obs. and Inquir. vol. iv.) On examining the symptoms of this disease, however, as detailed by sir W. Watson himself, as well as the varying appellations, which he gave to it, at different times, in his journal of the cases, Dr. Willan has shewn most clearly, that the disease in question was not measles, but scarlet-fever. There were, indeed, a cough and watery eyes among the symptoms of these "putrid measles;" but "the eruption appeared over nearly the whole body on the second day;"—"the fauces were of a deep red colour;"—"the pulse was very quick, but low;"—"the patients complained of extreme weakness, and could not bear bleeding;"—"their oppressed and difficult breathing was attended with great restlessness and anxiety, but with scarce any expectoration throughout;"—"some died under laborious respiration, more from a dysenteric purging;"—"some cases terminated in mortification of the rectum, pudenta, cheeks, gums, &c. others with caries of the jaw-bones." Now these circumstances obviously belong to scarlatina, and not to measles: indeed sir W. Watson refers them to the morbilli maligni, or epidemii, described by Morton. (De Morbillis et Febre Scarlatina.) But Morton, who calls the disease also morbilli *spurii*, expressly maintains that the measles and scarlatina are the same disease, with no more variation in their form, than there is between the distinct and confluent small-pox: he has therefore conjoined the principal symptoms (cap. iii.), and wishes to banish the distinction, and the very name of scarlatina, from medical language. Hence those readers who attend not to the names of things, but to the things themselves as described, will find that the morbilli maligni, epidemii, and spurii, and the febris morbillosa petilentialis, in his writings, have no relation to the measles, but constitute the disease, to which other writers have given the titles of angina maligna, scarlatina anginosa, and maligna, &c. Willan, loc. cit.

The original writers on the measles, however, not only laid the foundation for this error, but created a much greater confusion, by describing the small-pox and the measles as one and the same disease, which admitted of considerable variety in its form. This confusion was transmitted from the Arabian physicians, who first described these diseases, through eight or nine centuries. But as the measles and scarlet fever were deemed one and the same malady, even down to our own times; so this confusion was greater than

at first sight it appears to have been; inasmuch as these three specific contagions were treated of as one disease, including also the chicken-pox, which was separated during the last century. This circumstance enables us to explain the opinion of the Arabian physicians, that the small-pox or measles not unfrequently occurred *twice*, but rarely *thrice*, in the course of the life of an individual; since the occurrence of any one of these four diseases would be considered as a recurrence of the small-pox. It would seem extraordinary, indeed, (if we did not know how completely the observation of mankind is obscured and perverted by pre-conceived opinions,) that the almost universal occurrence of both the small-pox and the measles, in the same individuals, should have escaped their notice. Yet even so late as the time of Sennertus, this fact was not known: for that able and learned physician discusses the question, Why the disease in some constitutions assumes the form of small-pox, and in others that of the measles? (See his *Med. Pract. lib. iv. cap. 12.*) He refers it merely to some indelible idiosyncrasy, or peculiarity of habit. In his time, indeed, physicians had not entirely agreed upon the appropriation even of the names *variole* and *morbilli*; for some applied the term *variole* to the eruption of the measles, "*quæ colorem cutis variant*," they said Diemerbroeck, an able Dutch professor, still later expressed his opinion, that small-pox and measles differed only casually and in degree, not in kind. "*Differunt (morbilli) à variolis accidentaliter, vel quoad magis et minus.*" *Tractat. de Variol. et Morbill. cap. xiv.*

When the most able physicians did not step aside from the path which the Arabians had marked out for them, so as to ascertain the essential difference between the *pustular* small-pox and the *rasb* called measles, it can scarcely be expected that they should have made out the distinction between the two rashes of measles and scarlatina. It is obvious, however, that the scarlatina was known to them, and they deemed it a variety of measles, as many later writers have done.

There is no trace in medical history of the origin and primary cause of the measles, nor of the other contagious eruptive fevers; but it is commonly supposed, that they had no existence in the time of the older Greek and of the Roman physicians; since, among the accurate descriptions which they have left of many diseases, that are at present familiar to us, no distinct account of these striking and formidable maladies is to be found. This is, indeed, an extraordinary circumstance; and by those who look back to the fathers of physic, as to the only correct and unbiassed observers of nature, it is deemed conclusive evidence on the subject. We have seen above, however, that the most accomplished physicians of later times were for ages blinded by the opinions of their predecessors, so as to overlook the most glaring facts; and it is not necessary to inform the learned reader, that no succession of writers ever displayed a more servile adherence to the doctrines of their ancestors, or composed their works by a more systematic transcription of those which had gone before, than the series of Greek physicians from Galen down to Aëtarius; nor has any other class of observers been more enslaved by hypothesis, than the Greeks by the four humours of Hippocrates, and the four qualities which Galen engrafted upon them. Inasmuch that they satisfied themselves, with giving general appellations to the eruptions, connected with fevers, which they classed together, as pestilential; and deemed the *anthraxes* and carbuncles of the true plague, and the *erysipelata*, *æthymata*, *phlydænæ*, *erythemata*, *exanthemata*, *herpetes*, &c., under which most probably they included the small-pox, measles, scarlet-fever, nettle-rash, &c., as mere varieties of pestilential fever, arising from different combinations of the four humours. These eruptions

are frequently mentioned as accompanying malignant fevers by Hippocrates and Galen.

Further, it is remarkable, that the first writers (of the Arabian school) who treat of small-pox and measles, do not speak of them as new or unusual diseases. Aaron, a physician of Alexandria, and contemporary with Mahomet, considers them as the result of putridity, and similar to the carbuncles of the groin, axillæ, &c., which were often epidemical in the climate where he resided, and fatal within four or five days. Rhazes, a physician of Bagdad, who, about the middle of the ninth century, collected the observations of his predecessors, in a curious tract on this subject, takes it for granted that the small-pox and measles were known to Galen, more than six hundred years before his own time. Although we may admit, however, that the passages which Rhazes quotes (from an incorrect translation of the works of Galen, and not from the original Greek), do not bear him out in this opinion; yet it is scarcely possible to deny that the diseases in question were known *before* the time of Galen, if we carefully peruse a chapter "*de Puslulurum (ἔρυνιαζών)* in febrili curatio," written by Herodotus, and preserved by Aëtius. (See Aëtii, *tetrab. ii. ferm. i. cap. 129.*) This Herodotus was an eminent physician at Rome, in the reign of Trajan, more than half a century before the arrival of Galen in that city; the fragments of his writings, which have been transcribed by Oribasius and Aëtius, contain so much original observation and perspicuity of description, as to excite a regret that the greater part of them has been lost. Herodotus begins this chapter, by mentioning the herpetic eruptions that break out about the mouth and alæ of the nose, at the termination of catarrhal and other slight fevers. "*In febricitibus assidue sunt exanthemata circa labia et nasum, juxta febrim solutionem.*" And he recommends these to be treated with a simple liniment, or a saturnine ointment. "But," he proceeds, "in the beginning of fevers, which are not simple, but the result of vitious humours, there arise *over the whole body* patches like flea-bites; and in malignant and pestilential fevers these ulcerate, and some of them have an affinity with carbuncles. All these eruptions are signs of the redundancy of corrupt and corrosive humours in the habit; but those which appear on the face are the most malignant of all. They are worse if numerous, than if few;—the larger are worse than those which are smaller,—and those which have a short course, than those which remain a long time. Those are more dangerous too which are hot and inflamed, than those which are accompanied by itching. And those again which are conjoined with a colic or gently open state of bowels, are favourable; while those accompanied by diarrhœa and vomiting are dangerous; but if, while the successive eruptions appear, the diarrhœa ceases, it is favourable. These exanthemata are attended by malignant symptoms of fever, and often by syncope." The first species, resembling the flea-bites, (by which he probably means the measles) "are to be treated by blood-letting in the beginning, if nothing contra indicate that remedy; for if the eruptions be repelled inwards, they are wont to produce danger, unless the acrimony be carried off by vomiting or by stool." Hence he recommends "emollient clysters of pisan, with egg, and oil of chamomile, and that the evening injection should be retained all night; and likewise a spare diet, quo undique multitudo solatur." But "at the accession of the disease, on account of the violent pains at the region of the stomach, we order warm water to be given," he says, "and vomiting to be excited, by putting the finger or a feather into the throat; light cooling food, &c. &c." But in those cases where the eruptions are pestilential and carbunculous, "we employ blood.

blood-letting at the very outset, but not abstinence; for fasting renders the matter more malignant, and diminishes the vital powers, which we should support in all fevers, especially pestilential ones." He then tells us, that "the same cerates and plaisters, which are useful in burns, may be applied to the pustules, and that those on the face may be alleviated by washing with warm water." When they ulcerate, he recommends the application of poultices of bread, lentils, &c., boiled with honey; and at the same time a diet of goat's milk, to correct the morbid state of the humours. After the decline of the eruption, a proper purgative is to be administered; and the cure is to be completed by an antidote of theriaca or mithridate, "which may destroy the poisonous relics of the humours."

This account is applicable only to the exanthematic fevers, and especially to the small-pox, including measles and scarlatina; for we are acquainted with no other fevers, "occasionally pestilential, with eruptions over the whole body, that often ulcerate, especially on the face." And it appears from the conclusion of this chapter, that Herodotus was well acquainted with the danger of the confluent, and highly red or livid forms of these eruptions. "Moreover," he says, "those which are extremely red, are of the worst kind; but those which are livid, black, and tumid, like flesh that has been dotted, are still more fatal; and these are abundant on the face and breast, abdomen, sides, and back." His advice as to the conduct of the physician in these desperate cases, is curious. "In such instances it is prudent not to attempt any thing in the beginning, but to wait; for if it terminates ill, the blame will fall upon him, who endeavoured or promised to effect a cure; but if the disease goes on to its acme, without any increase of malignancy, then it should not be altogether left to itself; a little occasional assistance should be given, medicine should be administered at proper opportunities, and the cure be conducted with great vigilance. For those eruptions, which arise from beneath in a mortifying state of the surface, what can they denote but that the life is passing from within?"

It appears pretty obvious, from the preceding extracts, that the contagious exanthemata were familiarly known at Rome, at the end of the first century. For this is the language of observation and experience, and implies that the diseases, thus distinctly described, were of ordinary occurrence; their recent appearance is not once hinted at. If we trace the accounts of these exanthemata, down to the seventeenth century, even after appropriate names had been given to them, we still find a similar communion of nature, origin, and treatment, ascribed to them; and it was not till the end of the 18th century, that their peculiar characteristics were pointed out. The Arabians themselves have distinctly described the scarlatina, as a variety of measles [see Haly Abbas, Theorice. lib. viii. cap. 14. where the translator has distinguished it from the *morbilli* (or ordinary measles) by giving it the appellation of *rubeola*, from its scarlet colour]; yet the disease was still confounded with the measles, so late as the publication of sir W. Watson's paper, above referred to; so difficult it is to see with our own eyes through the veil of prejudice! Consult Rhazes de Variolis et Morbillis, translated by Channing. Sydenham, Obs. Med. sect. iv. chap. 5. Morton, de Morbis acutis, exercit. iii. Sennert. de Febribus, lib. iv. cap. 12. Diemerbroeck de Variol. et Morbill. cap. xiii. Heberden, in Med. Transact. vol. iii., and Commentar. cap. 63.; and Willan on Cutaneous Dif. order iii.

MEASURE, MENSURA, in *Geometry*, denotes any certain quantity assumed as one, or unity, to which the ratio of other homogeneous or similar quantities is expressed.

This definition is somewhat more agreeable to practice than that of Euclid, who defines measure a quantity, which being repeated any number of times, becomes equal to another; which only answers to the idea of an arithmetical measure, or quota part.

MEASURE of an *Angle*, is an arc described from the vertex in any place between its legs. Hence angles are distinguished by the ratio of the arcs, described from the vertex between the legs, to the peripheries.

Angles then are distinguished by those arcs; and the arcs are distinguished by their ratio to the periphery. See ANGLE.

It is, however, in many cases, a more simple and more convenient method to estimate angles, not by the arcs subtending them, but by their sines, or the perpendicular falling from one leg to the other. Thus it is usual, among miners, to say that the ground rises or falls one foot, or one yard, in ten, when the sine of the angle of its inclination to the horizon is one-tenth of the radius. Angles of different magnitudes are indeed proportional to the arcs, and not to the sines, so that in this sense the sine is not a true measure of the comparative magnitude of the angle; but in making calculations, we are more frequently obliged to employ the sine or cosine of an angle than the angle or arc itself. Nevertheless, it is easy to pass from one of these elements to the other by means either of trigonometrical tables, or of the scales engraved on the sector.

To measure the height of a hill, see ALTITUDE, and the latter part of the article LEVELLING.

MEASURE of a *Figure*, or plane surface, is a square; whose side is one inch, foot, yard, or some other determinate length.

Among geometricians, it is usually a rod, called a *square rod*, divided into ten square feet, and the square feet into square digits. Hence square measures. See MENSURATION.

MEASURE of a *Line* is any right line taken at pleasure, and considered as unity.

The modern geometricians use a decempeda, or rod, divided into ten equal parts, called feet. The feet they subdivide into ten digits, the digit into ten lines, &c. This decimal division of the measure was first introduced by Stevinus, probably from the example of Regiomontanus. The index or character of the decempedæ he made o, that of feet 1, of digits 2, of lines 3, &c. which, because the measure was subdivided in a decuple ratio, were the logarithms of the division. Bayer, in lieu of these, expressed the logarithms by the Roman characters; v. g. 5 perches, 4 feet, 3 digits, and 2 lines, he expressed thus; 5°, 4', 3", 2'''. It is frequently most commodious to separate the integers, or rods, from the fractions, by a point; thus, instead of 5, 4', 3'', 2''', to write 5.432. F. Noel observes, that, among the Chinese, the decimal division obtains in their common measures, and even in their weights.

MEASURES, *Line of*. See LINE.

MEASURE of the *Mass*, or quantity of matter, in *Mechanics*, is its weight; it being apparent, that all the matter which coheres and moves with a body, gravitates with it: and it being found by experiment, that the gravities of homogeneous bodies are in proportion to their bulks: hence, while the mass continues the same, the absolute weight will be the same, whatever figure it put on: but, as to its specific weight, it varies as the quantity of surface varies. See WEIGHT.

MEASURE of a *Number*, in *Arithmetic*, is such a number as divides another, without leaving any fraction; thus 9 is a measure of 27.

MEASURE, *Common.* See COMMON MEASURE.

MEASURE of a Solid, is a cube, whose side is one inch, foot, yard, or other determined length.

Among geometers, it is sometimes a rod, or perch, called a *cubic perch*; divided into cubic feet, dials, &c. Hence cubic measures, or measures of capacity. See CUNZ and MENSURATION.

MEASURE of Velocity, in *Mechanics*, is the space passed over by a moving body in any given time.

To measure a velocity, therefore, the space must be divided into as many equal parts as the time is conceived to be divided into. The quantity of space answering to such an interval of time, is the measure of the velocity.

MEASURE, *Universal and Perpetual*, is a kind of measure unalterable by time, to which the measures of different nations and ages might be reduced, and by which they might be compared and estimated. Such a measure is very desirable, if it could be attained. Huygens, in his *Horol. Oscill.* proposes, for this purpose, the length of a pendulum, vibrating seconds, taken from the point of suspension to the point of oscillation. The third part of such a pendulum may be called the horary foot, and serve as a standard to which the measure of all other feet may be referred. Thus, *v. g.* the proportion of the Paris foot to the horary foot would be that of 864 to 881; because the length of three Paris feet is 864 half lines, and the length of a pendulum, vibrating seconds, contains 3 horary feet, or 3 feet $8\frac{1}{2}$ lines, *i. e.* 881 half lines. But this measure, in order to its being universal, supposes, that the action of gravity is every where the same, which is contrary to fact; and, therefore, it would really serve only for places under the same parallel of latitude; and in order to its being perpetual, it supposes that the action of gravity continues always the same in the same place. (See PENDULUM) See also on the subject of a standard of measures, the article STANDARD, under which head the different modes of ascertaining it will be detailed and discussed.

MEASURE, in a legal, commercial, and popular sense, denotes a certain quantity or proportion of any thing bought, sold, valued, or the like. It denotes also a vessel of capacity employed in measuring grain and other articles; the fourth part of a peck.

The regulation of weights and measures ought to be universally the same throughout the kingdom, and should, therefore, be reduced to some fixed rule or standard; the prerogative of fixing which was vested, by our ancient law, in the crown. This standard was originally kept at Winchester; and we find, in the laws of king Edgar, cap. 8, near a century before the Conquest, an injunction, that the one measure, which was kept at Winchester, should be observed throughout the realm. With respect to measures of length, our ancient historians (Will. Malm. in Vita Hen. I. Spelm. Hen. I. apud Wilkins, 299.) inform us, that a new standard of longitudinal measure was ascertained by king Henry I. who commanded that the ulna, or ancient ell, which answers to the modern yard, should be made of the exact length of his own arm; and one standard of measures of length being once gained, all others are easily derived from hence; those of greater length by multiplying, those of less by subdividing the original standard. Thus, by the statute, called "*Compositio ulnarum et perticarum*," $5\frac{1}{2}$ yards make a perch; and the yard is subdivided into 3 feet, and each foot into 12 inches; which inches will be each of the length of 3 grains of barley. The standard of weights was originally taken from corns of wheat, whence the lowest denomination of weights which we have is still expressed by a "grain;" 32 of which are directed by the statute, called "*Compositio mensurarum*,"

to compose a pennyweight, of which 20 make an ounce, 12 ounces a pound, and so upwards. Upon these principles the standards were first made; which, being originally so fixed by the crown, their subsequent regulations have been generally made by the king in parliament. Thus, under king Richard I. in his parliament holden at Westminster, A.D. 1197, it was ordained that there should be only one weight and one measure throughout the kingdom, and that the custody of the assise or standard of weights and measures should be committed to certain persons, in every city and borough. (See ALMAGER.) In king John's time, the ordinance of king Richard was frequently dispensed with for money (Hoved A.D. 1201); which occasioned a provision to be made for enforcing it, in the great charters of king John and his son. Stat. 9 Hen. III. c. 25.

The statute of Magna Charta, cap. 25, ordains, that there shall be but one measure throughout England, according to the standard in the exchequer; which standard was formerly kept in the king's palace; and in all cities, market-towns, and villages, it was kept in the churches. (4 Inst. 273.) By 16 Car. I. cap. 19, there is to be one weight and measure, and one yard, according to the king's standard, and whoever shall keep any other weight or measure, whereby any thing is bought or sold, shall forfeit for every offence five shillings. And by 22 Car. II. cap. 8, water measure, (*viz.* five pecks to the bushel,) as to corn or grain, or salt, is declared to be within the statute 16 Car. I. And if any sell grain or salt, &c. by any other bushel, or measure, than what is agreeable to the standard in the Exchequer, commonly called Winchester measure, he shall forfeit 40s. &c. (22 Car. II. c. 8. 22 and 23 Car. II. c. 12.) Notwithstanding these statutes, in many places and counties there are different measures of corn and grain; and the bushel in one place is larger than in another; but the lawfulness of it is not well to be accounted for, since custom or prescription is not allowed to be good against a statute. (Dalt. 250.) It is now settled, that no practice or usage can countervail the statutes 22 Car. II. c. 8. 22 and 23 Car. II. c. 12. above cited. 4 Term Rep. 750. 5 Term Rep. 353.

There are three different measures, *viz.* one for wine, one for ale and beer, and one for corn. In the measure of wine, 8 pints make a gallon, 8 gallons a firkin, 16 gallons a kilderkin, half barrel or rundlet, 4 firkins a barrel, 2 barrels a hogshead, 2 hogsheads a pipe, and 2 pipes a tun. (Stat. 15 R. II. c. 4. 11 H. VII. c. 4. 12 H. VII. c. 5.) In a measure of corn 8 pounds or pints of wheat make the gallon, 4 gallons a peck, 4 pecks a bushel, 4 bushels a sack, and 8 bushels a quarter, &c. And in other measure, 3 barley corns in length make an inch, 12 inches a foot, 3 feet a yard, 3 feet and 9 inches an ell, and $5\frac{1}{2}$ yards or $16\frac{1}{2}$ feet, make the perch, pole, or rod. (Stat. 27 Edw. III. c. 10.) Selling by false measure, being an offence by the common law, may be punished by fine, &c. upon an indictment at common law, as well as by statute. See the statute 11 Hen. VII. c. 4. which inflicts particular fines for offences, pillory, &c. The more easy and usual mode of punishment is by levying, on a summary conviction, by distress and sale, the forfeiture imposed by the several acts of parliament adapted to particular frauds.

MEASURES are various, according to the various kinds and dimensions of the things measured. Hence arise *lineal* or *longitudinal* measures for lines or lengths; *square* measures for areas or superficies; and *solid* or *cubic* measures for bodies and their capacities. All these again are very different in different countries, and in different ages, and even many of them for different commodities. Whence arise

MEASURES.

arise other divisions of *domestic* and *foreign* measures, *ancient* and *modern* ones, *dry* and *liquid* measures, &c.

Under this head the reader will find enumerated and exhibited in tables, the various general standing measures, long, square, and cubic, now or heretofore in use, with their

proportions and reductions: for particulars we refer to the following heads; as FOOT, DIGIT, ELL, TUN, GALLON, BUSHEL, PERCH, LEAGUE, FURLONG, &c.

MEASURES, *Affay of*. See ASSAY.

MEASURES, *Standard of*. See STANDARD.

The Tables of different Measures, extracted from various Publications, are as follow; beginning with Measures of Length.

TABLE I.—Scripture Long Measures.

										Engl. Feet	Inch. Dec.		
Digit	— — — — —									0	0.912		
4	Palm	— — — — —									0	3.648	
12	3	Span	— — — — —								0	10.944	
24	6	2	Cubit	— — — — —							1	9.888	
96	24	8	4	Fathom	— — — — —						7	3.552	
144	36	12	6	$1\frac{1}{2}$	Ezekiel's reed	— — — — —					10	11.328	
192	48	16	8	2	$1\frac{1}{2}$	Arabian Pole	— — — — —					14	7.104
1920	480	160	80	20	$13\frac{1}{2}$	10	Scœnus, measuring line	— — — — —			145	1.104	

N. B. There was another span used in the East, equal to $\frac{1}{4}$ th of a cubit.

TABLE II.—Grecian Long Measures reduced to English.

										Engl. Paces.	Feet.	Inch. Dec.			
Dactylus, Digit	— — — — —									0	0	0.7554 $\frac{1}{5}$			
4	Doron, Dochme, Palesta,	— — — — —									0	0	3.0218 $\frac{1}{2}$		
10	$2\frac{1}{2}$	Lichas	— — — — —								0	0	7.5546 $\frac{2}{3}$		
11	$2\frac{3}{4}$	$1\frac{1}{10}$	Orthodoron	— — — — —							0	0	8.3101 $\frac{9}{17}$		
12	3	$1\frac{1}{5}$	$1\frac{1}{11}$	Spithame	— — — — —						0	0	9.0636 $\frac{1}{2}$		
16	4	$1\frac{6}{10}$	$1\frac{5}{11}$	$1\frac{1}{3}$	Pous foot,	— — — — —					0	1	0.0875		
18	$4\frac{1}{2}$	$1\frac{2}{3}$	$1\frac{2}{11}$	$1\frac{1}{2}$	$1\frac{1}{3}$	Pygme, cubit	— — — — —					0	1	1.5984 $\frac{1}{2}$	
20	5	2	$1\frac{9}{11}$	$1\frac{2}{3}$	$1\frac{1}{4}$	$1\frac{1}{5}$	Pygon	— — — — —				0	1	3.109 $\frac{3}{4}$	
24	6	$2\frac{2}{3}$	$2\frac{2}{11}$	2	$1\frac{1}{2}$	$1\frac{1}{3}$	$1\frac{1}{5}$	Pecus, cubit larger	— — — — —			0	1	6.13125	
96	24	$9\frac{3}{4}$	$8\frac{8}{11}$	8	6	$5\frac{1}{3}$	4^4	4	Orgya, pace	— — — — —			0	6	0.525
9600	2400	960	$872\frac{8}{11}$	800	600	$533\frac{1}{3}$	480	400	100	Stadium Aulus > furlong	—	100	4	4.5	
76800	19200	7680	$6981\frac{9}{11}$	6400	4800	$4266\frac{2}{3}$	3840	3200	800	8	Million, Mile	—	805	5	0

N. B. Two sorts of long measures were used in Greece, *viz.* the Olympic and the Pythic. The former was used in Peloponnesus, Attica, Sicily, and the Greek cities in Italy. The latter was used in Theffaly, Illyria, Phocis, and Thraee, and at Marfeilles in Gaul.

The Olympic foot, properly called Greek, according to Dr. Hutton, contains 12.108 English inches,

Folkes — 12.072

Cavallo — 12.084

The Pythic foot, called also natural foot, according to Hutton — 9.768

Pauçon — 9.731

Hence it appears, that the Olympic stadium is $201\frac{1}{2}$ English yards, nearly; and the Pythic or Delphic stadium, $162\frac{1}{2}$ yards, nearly; and the other measures in proportion.

The Phyleterian foot is the Pythic cubit, or $1\frac{1}{2}$ Pythic foot. The Macedonian foot was 13.92 English inches; and the Sicilian foot of Archimedes, 8.76 English inches. See TABLE VII.

TABLE III.

MEASURES.

TABLE III.—Jewish Long or Itinerary Measures.

						Eng. Miles	Paces	Feet	Dues	
Cubit						—	0	0	1.24	
400	Stadium					—	0	145	4.6	
2000	5	Sab. day's journey				—	0	729	3.0	
4000	10	2	Eastern mile			—	1	423	1.0	
12000	30	6	3	Parasang		—	4	153	3.0	
96000	240	48	24	8	A day's journey		—	33	172	4.0

TABLE IV.—Roman Long Measures reduced to English.

								Engl. Paces	Feet	Inch.	Dues			
Digitus transversus								—	0	0	0.725 $\frac{1}{2}$			
1 $\frac{1}{3}$	Uncia, or Inch							—	0	0	0.967			
4	3	Palma minor					—	0	0	2.901				
16	12	4	Pes, or Foot				—	0	0	11.604				
20	15	5	1 $\frac{1}{4}$	Palmipes			—	0	1	2.505				
24	18	6	1 $\frac{1}{2}$	1 $\frac{1}{5}$	Cubitus		—	0	1	5.406				
40	30	10	2 $\frac{1}{2}$	2	1 $\frac{2}{3}$	Gradus		—	0	2	5.01			
80	60	20	5	4	3 $\frac{1}{2}$	2	Passus		—	0	4	10.02		
10000	7500	2500	625	500	416 $\frac{2}{3}$	250	125	Stadium		—	120	4	4.5	
80000	60000	20000	5000	4000	3333 $\frac{1}{3}$	2000	1000	8	Milliare		—	967	0	0

N.B. The Roman measures began with 6 scrupula = 1 sicilicum; 8 scrupula = 1 duellum; 1 $\frac{1}{2}$ duellum = 1 feminaria; and 18 scrupula = 1 digitus. Two passus were equal to 1 decempeda.

TABLE V.—Proportions of several long Measures to each other, by M. Picard.

The Rhinland or Leyden foot (12 whereof make the Rhinland perch) supposed	696
The English foot	675 $\frac{1}{2}$
The Paris foot	720
The Amsterdamb foot, from that of Leyden, by Snellius	629
The Danish foot (two whereof make the Danish ell)	701 $\frac{9}{17}$
The Swedish foot	658 $\frac{1}{4}$
The Brussels foot	609 $\frac{3}{5}$
The Dantzick foot, from Hevelius's Selenographia	636
The Lyons foot, by M. Auzout	757 $\frac{2}{3}$
The Bologna foot, by the same	843
The braccio of Florence, by the same, and father Merfenne	1290
The palm of the architects at Rome, according to the observations of Messrs. Picard and Auzout	494 $\frac{7}{8}$

The Roman foot in the Capitol, examined by Messrs. Picard and Auzout	653 or 653 $\frac{1}{2}$
The same from the Greek foot	652
From the vineyard Mattei	657 $\frac{1}{2}$
From the palm	658 $\frac{1}{4}$
From the pavement of the Pantheon, supposed to contain 10 Roman feet	653
From a slip of marble in the same pavement, supposed to contain 3 Roman feet	650
From the pyramid of Cestius, supposed to contain 95 Roman feet	653 $\frac{1}{2}$
From the diameters of the columns in the arch of Septimius Severus	653 $\frac{1}{2}$
From a slip of porphyry in the pavement of the Pantheon	653 $\frac{1}{2}$

See on this subject Phil. Transf. vol. li. art. 69. p. 774. For other measures, see FOOT.

MEASURES.

TABLE VI.—Proportions of the long Measures of several Nations to the English Foot, taken from Messrs. Greaves, Auzout, Picard, and Eifenchmid.

The English standard foot being divided into 1000 equal parts, the other measures will have the proportions to it which follow :

	Feet.	Inches.
English foot	1000	12
Paris foot	1068	12.816
Venetian foot	1162	13.944
Rhinland foot	1033	12.396
Straßburg foot	952	11.424
Norimberg foot	1000	12
Dantzick foot	944	11.328
Danish foot	1042	12.504
Swedish foot	977 ³ / ₄	11.733
Derahor cubit of Cairo	1824	21.888
Persian arith	3197	38.364
Greater Turkish pike	2200	26.4
Lesser Turkish pike	2131	25.572
Braccio at Florence	1913	22.956
Braccio for woollen at Sienna	1242	14.904
Braccio for linen at Sienna	1974	23.688
Canna at Naples	6880	82.56
Vera at Almeria and Gibraltar	2760	33.12
Palmò di Archtetti at Rome	7320	87.84
Fanna di Archtetti	7320	87.84
Palmò di bracchio di mercantia	695 ¹ / ₂	8.346
Genoa palm	815	9.78
Bolognian foot	1250	15
Antwerp ell	2283	27.396
Amsterdam ell	2268	27.216
Leyden ell	2260	27.12
Paris draper's ell	3929	47.148
Paris mercer's ell	3937	47.244

TABLE VII.—Ancient Measures taken from Folkes, Raper, Shuckburgh, Hutton, Cavallo, and others.

Arabian, foot	1.095	Engl. H.
Babylonian, foot	1.144	H.
	1.135	H.
Drusian, foot	1.090	H.
Egyptian, foot	1.421	H.
Egyptian, stadium	730.8	
Greek, foot	1.009	H.
	1.006	} Folkes, 1 ¹ / ₄ Roman f.
	1.007	
	1.007	
Greek, phyleterian foot	1.167	H.
Hebrew, foot	1.212	H.
Hebrew, cubit	1.817	H.
Hebrew, sacred cubit	2.002	H.
Hebrew, great cubit	= 6 common cubits.	H.
Macedonian, foot	1.160	H.
Natural foot	.814	H.
Ptolemaic = Greek foot		H.
Roman, foot	.970	Bernard.
	.967	Picard and Greaves.
	.966	} Folkes.
	.967	

Roman, foot	.970	before Titus. Raper.
	.965	after Titus. Raper.
	.9672	from rules. Sh.
	.9681	from buildings. Sh.
	.9696	from a stone. Sh.
	.967	H.

Roman mile of Pliny	4840.5	C.
Roman mile of Strabo	4903.	
Sicilian foot of Archimedes	.730	H.

The length of the Roman foot in inches is stated as follows :

By Bernard	11.640	English inches.
By Picard and Hutton	11.604	
By Folkes	11.592	
By Raper (before Titus)	11.640	
By the same (after Titus)	11.580	
By Schuckburgh, from rules	11.6064	
By the same, from buildings	11.6172	
By the same, from a tomb-stone	11.6352	

N.B. Hence, 11.6 English inches seem to be a medium ; and, therefore, the Roman mile = 1611 English yards, being 149 yards less than the English mile. See FOOT.

TABLE VIII.—Ancient Greek superficial Measures. Olympic Land Measure.

36 Olympic square feet	=	1 Hexapodon.
6 Hexapoda	=	1 Hemihectos.
2 Hemihecti	=	1 Hectos or Modius.
6 Modii	=	1 Medimnus or Jugerum.

Hence it appears, that the Olympic jugerum was equal to 103 English perches, or nearly ⁵/₈ths of an acre.

Pythic Land Measure.

1666 ² / ₃ Square cubits	=	1 Hemihectos.
2 Hemihecti	=	1 Modius.
6 Modii	=	1 Medimnus or Jugerum.

Hence the Pythic jugerum appears to have been equal to 109 English perches, or nearly ¹¹/₁₀ths of an acre.

N.B. The plethron, or acre, is said by some to contain 1444, by others 10,000 square feet ; and aroura, the half of the plethron. The aroura of the Egyptians was the square of 100 cubits.

TABLE IX.—Ancient Greek Corn Measure.

2 Xestes	=	1 Chœnix.
4 Chœnices	=	1 Hemihectos.
1 ¹ / ₂ Hemihectos	=	1 Tetarlon.
2 Hemihecti	=	1 Modius.
6 Modii	=	1 Medimnus or Achana.

Paucetron states the medimnus to have been 3¹/₂ French boisseaux = 1.27 English bushels, and the inferior measures in proportion.

MEASURES.

TABLE X.—Attic Dry Measures reduced to English.

Cochliarion						Pots	Gals	Pins	Sol. Inch		
10	Cyathus	—	—	—	—	0	0	0	0.276 $\frac{1}{2}$		
15	1 $\frac{1}{2}$	Oxybaphon	—	—	—	0	0	0	2.763 $\frac{1}{2}$		
60	6	4	Cotylus	—	—	0	0	0	16.579		
120	12	8	2	Xestes, sextary	—	0	0	0	33.158		
180	18	12	3	1 $\frac{1}{2}$	Chœnix	—	0	1	15.705 $\frac{1}{2}$		
8640	864	576	144	72	48	Medimnus	—	4	0	6	3.501

TABLE XI.—Attic Measures of Capacity for Liquids, reduced to the English Wine Measure.

Cochliarion						Gall.	Pints	Sol. Inch.	Dec.			
2	Cheme	—	—	—	—	0	$\frac{1}{12}$	0	0.0356 $\frac{1}{2}$			
2 $\frac{1}{2}$	1 $\frac{1}{4}$	Myflon	—	—	—	0	$\frac{1}{8}$	0	0.0894 $\frac{1}{4}$			
5	2 $\frac{1}{2}$	2	Concha	—	—	0	$\frac{1}{4}$	0	0.178 $\frac{1}{2}$			
10	5	4	2	Cyathus	—	0	$\frac{1}{2}$	0	0.356 $\frac{1}{2}$			
15	7 $\frac{1}{2}$	6	3	1 $\frac{1}{2}$	Oxybaphon	—	0	$\frac{1}{2}$	0.535 $\frac{1}{2}$			
60	30	24	12	6	4	Cotylus	—	0	2.141 $\frac{1}{2}$			
120	60	48	24	12	8	2	Xestes, sextary	0	1	4.283		
720	360	288	144	72	48	12	6	Chous, congius	0	6	25.698	
8640	4320	3456	1728	864	576	144	7	12	Metretes, amphora	10	2	19.626

Others reckon 6 choi = 1 amphoreus, and 2 amphorei = 1 keramion or metretes. The keramion is stated by Pauſon to have been equal to 35 French pints, or 8 $\frac{1}{2}$ English gallons, and the other measures in proportion.

TABLE XII.—Measures of Capacity for Liquids, reduced to English Wine Measure.

Ligula						Gall.	Pints.	Sol. Inch.	Dec.				
4	Cyathus	—	—	—	—	0	$\frac{1}{12}$	0	0.117 $\frac{1}{2}$				
6	1 $\frac{1}{2}$	Acetabulum	—	—	—	0	$\frac{1}{8}$	0	0.704 $\frac{1}{2}$

TABLE XV.—Ancient Roman Land Measure.

100 Square Roman feet	=	1	Scrupulum of land
4 Scrupula	=	1	Sextulus
1 1/3 Sextulus	=	1	Actus
6 Sextuli or 5 Actus	=	1	Uncia of land
6 Unciæ	=	1	Square Actus
2 Square Actus	=	1	Jugerum
2 Jugera	=	1	Heredium
100 Heredia	=	1	Centuria

N. B. The actus was a slip of ground four Roman feet broad, and 120 long. The jugerum or acre was considered as an integer, and divided, like the libra or as, in the following manner :

		Jugerum contained						
		Unciæ	Square Feet.	Scrup.	Eng. Woods.	Sq. Pol.	Sq. Feet.	
1	As	12	As	28800	288	2	18	250.05
1 1/2	Deunx	11	Deunx	26400	264	2	10	183.85
5/8	Dextans	10	Dextans	24000	240	2	2	117.64
3/4	Dodrans	9	Dodrans	21600	216	1	34	51.42
2/3	Bes	8	Bes	19200	192	1	25	257.46
7/8	Septunx	7	Septunx	16800	168	1	17	191.25
1 1/2	Semis	6	Semis	14400	144	1	9	125.03
1 1/3	Quincunx	5	Quincunx	12000	120	1	1	58.82
4/3	Triens	4	Triens	9600	96	0	32	264.85
2/3	Quadrans	3	Quadrans	7200	72	0	24	198.64
1/2	Sextans	2	Sextans	4800	48	0	16	132.43
1/4	Uncia	1	Uncia	2400	24	0	8	66.21

N. B. If we take the Roman foot at 11.6 English inches (see TABLE VII.), the Roman jugerum was 5980 English square yards, or 1 acre 37 1/2 perches.

MEASURES.

TABLE XVI.—Roman Dry Measures reduced to English.

Ligula						Peck	Gall	Pint	Sol. Inch	Des.
						0	0	0 $\frac{1}{4}$	0.01	
4	Cyathus					0	0	0 $\frac{1}{2}$	0.04	
6	1 $\frac{1}{2}$	Acetabulum				0	0	0 $\frac{1}{2}$	0.06	
24	6	4	Hemina or Trutta			0	0	0 $\frac{1}{2}$	0.24	
48	12	8	2	Sextarius		0	0	1	0.48	
384	96	64	16	8	Semi d.	0	1	0	3.84	
768	192	108	32	16	2 Modius	1	0	0	7.68	

TABLE XVII.—Ancient Roman Liquid Measures.

6 Sextarii	= 1 Congius
4 Congii	= 1 Urna
2 Urnae	= 1 Amphora
20 Amphoræ	= 1 Dolium.

N. B. The sextarius and its divisions were used as in the preceding table. If the sextarius be, as above supposed, = 36.94 English cubic inches, the amphora will be = 7 $\frac{1}{2}$ English gallons, and the dolium = 153 $\frac{1}{2}$ English gallons.

The principal modern measures will be found either in the following tables, or under the names of the countries and towns in which they are used, or under their own appropriate titles.

TABLE XVIII.—English Long Measures, or Measures of Application.

Barley-corn

3	Inch									
9	3	Palm								
27	9	3	Span							
36	12	4	1 $\frac{1}{2}$	Foot						
54	18	6	2	1 $\frac{1}{2}$	Cubit					
108	36	12	4	3	2	Yard				
180	60	20	6 $\frac{3}{4}$	5	3 $\frac{1}{2}$	1 $\frac{2}{3}$	Pace			
216	72	24	8	6	4	2	1 $\frac{1}{5}$	Fathom		
594	198	66	22	16 $\frac{1}{2}$	11	5 $\frac{1}{2}$	3 $\frac{3}{10}$	2 $\frac{1}{2}$	Pole, or Rod	
23760	7920	2640	880	660	440	220	132	110	40	Furlong
190080	63360	21120	7040	5280	3520	1760	1056	880	320	8 Mile

N. B. To the above measures we may add a link = 7.92 inches, a chain = 792, a nail of cloth = 2 $\frac{1}{4}$, a quarter = 9, an ell = 45, and a hand = 4 inches.

TABLE XIX.—Scotch Long Measures.

An Ell	= 37.2 English inches.
A Fall	= 223.2
A Furlong	= 8928
A Mile	= 71424
A Link	= 8.928
A Chain, or Short Road	= 892.8
A Long Road	= 1339.2

TABLE

MEASURES.

TABLE XX.—English Square or Superficial Measures.

Inches					
144	Feet				
1296	9	Yards			
3600	25	2 $\frac{2}{3}$	Paces		
39204	272 $\frac{1}{2}$	30 $\frac{1}{4}$	10.89	Poles	
1568160	10890	1210	435.6	40	Rood
6272640	43560	4840	1743.6	160	4 Acre

N. B. English square or superficial measures are raised from the yard of 36 inches, multiplied into itself; and this producing 1296 square inches in the square yard, the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the table. The Scotch acre is 55353.6 square feet English, or 1.27 English acre. See ACRE.

TABLE XXI.—English Dry or Corn Measures.

Solid Inches								
34 $\frac{1}{2}$	Pint							
272 $\frac{1}{4}$	8	Gallon						
544 $\frac{1}{2}$	16	2	Peck					
2178	64	8	4	Winchester Bushel				
	128	16	8	2	Strike			
	265	32	16	4	2	Carnock or coom		
17424	512	64	32	8	4	2	Seam or quarter	
	3072	384	192	48	24	12	6	Weigh
	5120	640	320	80	40	20	10	1 $\frac{2}{3}$ Laft

But if the corn gallon contain only 268.8 solid inches, the measures will be as follows :

Solid inches			
268.8	Gallon		
537.6	2	Peck	
2150.42	8	4	Winchester bushel *
17203.36	64	32	8 Quarter

According to this estimate of the corn gallon, the pint will be 33.6 solid or cubic inches, a quart = 67.2, a pottle = 134.4.

* A heaped bushel is one-third more.

N. B. Some make five quarters a weigh or load, and two weighs a laft of wheat; and others reckon ten quarters to the weigh, and twelve weighs to the laft. A bushel of wheat, at a mean, weighs 60 pounds, of barley 50, of oats 38; a chaldron of coals is 36 heaped bushels, weighing about 2988 pounds. See CHALDRON.

MEASURES.

English dry or corn measures are rated from the Winchester gallon, which contains 272½ solid inches, and is to hold of pure running or rain-water, nine pounds, thirteen ounces. This seems to stand on the foot of the old wine gallon, of 224 cubic inches; 12 being to 14½, as 224 to 272½. Yet by act of parliament, made 1697, it is decreed, that a round

bushel, eighteen inches and a half wide, and eight deep, is a legal Winchester bushel. But such a vessel will only hold 2150.42 cubic inches: and consequently the gallon will contain 268½ cubic inches. The divisions and multiples are in the preceding table.

TABLE XXII. — English Measures of Capacity of Liquids.

Solid or Cubic Inches.		Wine Measure.						
28.875	Pint							
231	8	Gallon						
4158	144	18						Rundlet
7276.5	252	31½	1½					Barrel
9702	336	42	2½	1½				Tierce
14553	504	63	3½	2	1½	Hoghead		
19404	672	84	4¾	2½	2	1½	Puncheon	
29106	1008	126	7	4	3	2	1½	Butt or Pipe
58212	2016	252	14	8	6	4	3	2 Tun

Solid Inches.		Ale Measure.				
35.25	Pint					
282	8	Gallon				
2256	64	8				Firkin
4512	128	16	2	Kilderkin		
9024	256	32	4	2	Barrel	
13536	384	48	6	3	1½	Hoghead

Solid Inches.		Beer Measure.					
35.25	Pint						
282	8	Gallon					
2538	72	9					Firkin
5076	144	18	2	Kilderkin			
10152	288	36	4	2	Barrel		
15228	432	54	6	3	1½	Hoghead	
30456	864	108	12	6	3	2 Butt	

MEASURES.

English liquid measures were originally raised from troy weight; it being enacted by several statutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine measure; the divisions and multiples whereof were to form the other measures: at the same time it was also ordered, that there should be but one liquid measure in the kingdom; yet custom has prevailed; and there having been introduced a new weight, *viz.* the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter standard are raised two several measures, the one for ale, the other for beer. For the method of reducing one into the other, see WEIGHT.

The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches; and, on this supposition, the other measures raised therefrom will contain as in the preceding tables; yet, by actual experiment made in 1688, before the lord mayor and the commissioners of excise, this gallon was only found to contain 224 cubic inches; it was however agreed to continue the common supposed contents of 231 cubic inches; so that all computations stand on their old footing. Hence, as 12 is to 231, so is $14\frac{1}{2}$ to $281\frac{1}{2}$, the cubic inches in the ale gallon: but in effect the ale quart contains $70\frac{1}{2}$ cubic inches; on which principle the ale and beer gallon will be 282 cubic inches. See on this subject Phil. Transf. vol. xlii. art. 15. p. 54.

The several divisions and multiples of these measures and their proportions, are exhibited in the preceding tables.

It is conjectured, that some centuries before the conquest, a cubic foot of water weighing 1000 ounces, 32 cubic feet weighed 2000 pounds, or a ton; that the same quantity was a ton of liquids, and a hoghead eight cubic feet, or 13824 cubic inches, one sixty-third of which was 219.4 inches, or a gallon. A quarter of wheat was a quarter of a ton, weighing about 500 pounds, a bushel one-eighth of this,

equivalent to a cubic foot of water. A chaldron of coals was a ton, and weighed 2000 pounds. (Barlow, Phil. Transf. for 1740.) At present 12 wine gallons of distilled water weigh exactly 100 pounds avoirdupois.

Whereas it has been thought expedient that the quantities to be returned as and for a barrel of beer or ale brewed by the common brewer and the allowances for waste should be in all places the same, it is enacted that after the 5th day of July, 1803, every thirty-six gallons of beer or ale brewed by the common brewers in Great Britain, whether within the weekly bills of mortality or without the same, taken according to the standard of the ale-quart, four thereof to the gallon in the exchequer, shall be reckoned and returned by the gauger or other officer of excise for a barrel of beer or ale; and the allowances to be made in Great Britain to the common brewer not selling beer ale or worts in any less quantity than the whole cask, containing $4\frac{1}{2}$ gallons, whether within or without the said limits, for waste by fillings and leakage, or otherwise, out of the returns by the gaugers or other officers, shall be three barrels upon every thirty-six barrels, both of strong beer, or table beer and ale, and after that rate for any greater or less quantity. 43 Geo. III. c. 69.

TABLE XXIII.—Scotch Measures of Capacity of Liquids.

A Gill is -	-	6.462 English cubic inches.
A Mutchkin -	-	25.85
A Choppin -	-	51.7
A Pint -	-	103.4
A Quart -	-	206.8
A Gallon -	-	827.23
A Hoghead -	-	13235.7, or 16 gallons.

N.B. By the Act of Union, twelve Scotch gallons are reckoned equal to an English barrel, or 9588 cubic inches, instead of 9927.

A lippie or feed is 200.345 cubic inches.

TABLE XXIV.—French Measures, according to the Old System before the Revolution.

A Point is -	-	.0148025 English inch, or nearly $\frac{1}{735}$.
A Line -	-	.088815, or nearly $\frac{1}{112}$.
An Inch or Pouce -	-	1.06578, or $\frac{1}{93\frac{1}{2}}$, or $\frac{8}{76}$.
A Foot -	-	12.78933
An Ell or Aune -	-	46.8947, or 44 French inches, or according to Vega, 43.9
A Sonde -	-	63.9967, or 5 French feet, about $\frac{8}{9}$ English fathom.
A Toise or Fathom -	-	76.7360, or 6 French feet; formerly 76.71, Phil. Transf. for 1742.
A Perche -	-	230.2080, or 18 French feet.
A Perche, mesure royale -	-	22 French feet.
A League -	-	2282 toises, or $\frac{1}{25}$ of a degree.
A Square Inch -	-	1.13582 English square inches.
An Arpent -	-	100 square perches, about $\frac{2}{3}$ acre English, used near Paris.
An Arpent, mesure royale -	-	about $1\frac{1}{4}$ English acre.
A Cubic Inch -	-	1.21063 cubic inches English.
A Litron -	-	65.34
A Boisseau -	-	1045.44, or 16 litrons.
A Minot -	-	2090.875, or 3 boisseaux, nearly an English bushel.
A Mine -	-	4181.75, or 2 minots.
A Septier -	-	8363.5, or 2 mines, or 6912 inches French.
-	-	double for oats.
A Muid -	-	100362, or 12 septiers.

N.B. A ton of shipping contains 42 cubic feet. The aune or ell of Paris varies, being for silk stuffs 527.5 lines, or $46\frac{1}{10}$ English inches; for woollens, 526.4 French lines, or $46\frac{3}{4}$ English inches; for linens, 524 French lines, or $46\frac{1}{10}$ English inches; and it varies still more in other parts of

France. The perch, which determines the measure of the acre, varies in different parts of the country: but the arpent of wood-land is every where the same, the perch being 22 feet long; and this arpent contains 48,400 French square feet, or 6108 Eng. square yards, or one acre, one rood, one perch.

MEASURES.

perch. The arpent for cultivated land, in the vicinity of Paris, contains 900 square toises, or 4088 English yards, so that 43 such arpents are equal to 38 English acres nearly.

TABLE XXV.—French Measures, according to the New System, with the amended Nomenclature of Dr. Young.

Measures of Length.

	English Inches.
Millimetre - - - -	.03937
Centimetre - - - -	.39371
Decimetre - - - -	3.93710
Metre - - - -	39.37100, or 3.281 feet, or 1.09364 yds. or nearly 1 y. 1½ nail, or 443.2959 French lines, or .513074 toise.
Decametre - - - -	393.71000, or 10 yards, 2 feet, 9.7 inches.
Hecatometre - - - -	3937.10000, or 100 yards, 1 foot, 1 inch.
Chiliometre - - - -	39371.00000, or 4 furl. 213 yards, 1 foot, 10.2 inches: so that 8 chiliometres are nearly 5 miles.
Myriometre - - - -	393710.0000, or 6 miles, 1 furl. 136 yds. 0 f. 6 inch.

N. B. An inch is .0354 metres; 2441 inches 62 metres, 1000 feet nearly 305 metres.

Superficial or Square Measures.

Are, a square decametre, is -	3.95 Eng. perches, or 119.6046 square yards.
Decare - - - -	1196.0460 square yards.
Hecatare - - - -	11960.4600 square yards, or 2 acres, 1 rood, 35.4 perches.

Measures of Capacity.

	Cubic Inches English.
Millilitre - - - -	.06103
Centilitre - - - -	.61028
Decilitre - - - -	6.10280
Litre, a cubic decimetre - -	61.02800, or 2.113 wine pints.
Decalitre - - - -	610.28000, or 2.64 wine gallons.
Hecalitre - - - -	6102.80000, or 3.5317 cu- bic feet, or 26.4 wine gallons.
Chilolitre - - - -	61028.00000, or 35.3170 cu- bic feet, or 1 tun, 12 wine gallons.
Myriolitre - - - -	610280.00000, or 353.1700 cubic feet.

Solid Measure.

	Cubic Feet.
Decistre, for fire wood - -	3.5317
Stere, a cubic metre - -	35.3170
Decastere - - - -	353.1700

N. B. In order to express decimal proportions in this

new system, the following terms have been adopted. The term *Deca* prefixed denotes 10 times; *Heca*, 100 times; *Chilo*, 1000 times; and *Myrio*, 10,000 times. On the other hand, *Deci* expresses the 10th part; *Centi*, the 100th part; and *Milli*, the 1000th part: so that *Decametre* signifies 10 metres; and a *Decimetre*, the 10th part of a metre, &c. &c. The *Metre* is the element of long measures; *Are*, that of square measures; *Stere*, that of solid measures; the *Litre* is the element of all measures of capacity; and the *Gramme*, which is the weight of a cubic centimetre of distilled water, is the element for all weights. (See WEIGHT.) For the principle on which this system of measures is founded, see STANDARD. See Dr. Young's Philof. vol. ii. Kelly's Un. Cambist. vol. ii.

Dr. Kelly, always actuated by a desire of promoting literature and science, has, with a polite attention, which we thus respectfully acknowledge, allowed us to extract several of the preceding tables from his very valuable work, the "Universal Cambill:" a work which is planned with judgment, and executed, at the expence of much time and labour, with accuracy, and which will be no less acceptable and useful to men of science in general, than to mercantile persons in particular.

MEASURES used by different artificers are 144 square inches = a square foot, 9 square feet = a square yard, 63 square feet = 7 square yards = a rood, 100 square feet = a square, and 272½ square feet = 30¼ square yards = a rod, perch, or square pole.

MEASURE of fire-wood. See *CORD of wood*.

MEASURE for Horses. See *HAND*.

MEASURE is also used to signify the cadence and time observed in poetry, dancing, and music, to render them regular and agreeable.

The different measures or metres, in poetry, are the different manners of ordering and combining the quantities, or the long and short syllables. Thus hexameter, pentameter, iambic, sapphic verses, &c. consist of different measures. In English verses, the measures are extremely various and arbitrary, every poet being at liberty to introduce any new form that he pleases. The most usual are, the heroic, generally consisting of five long, and five short syllables; and verses of four feet; and of three feet and a cæsura, or single syllable.

The ancients, by variously combining and transposing their quantities, made a vast variety of different measures. Of words, or rather feet, of two syllables, they formed a spondee, consisting of two long syllables; a pyrrhic, of two short syllables; a trochee, of a long and a short syllable; and an iambic, of a short and a long syllable.

Of their feet of three syllables, they formed a molossus, consisting of three long syllables; a tribrach, of three short syllables; a dactyl, of one long and two short syllables; and an anapæst, of two short and one long syllable. The Greek poets contrived a hundred and twenty-four different combinations or measures, under as many different names, from feet of two syllables to those of six. See *METRE* and *PROSODY*.

MEASURE, in *Music*, the interval, or space of time, which the person who beats time, takes between the raising and falling of his hand or foot, in order to conduct the movement, sometimes quicker, and sometimes slower, according to the kind of music, or the subject that is sung or played.

The measure is that which regulates the time we are to dwell on each note. See *TIME*.

The ordinary or common measure is one second, or sixtieth part of a minute, which is nearly the space between the beats of the pulse or heart; the systole or contraction of the heart answering to the elevation of the hand; and its diastole, or dilatation, to the letting it fall. The measure usually takes up the space that a pendulum, of two feet and a half long, employs in making a swing or vibration. The measure is regulated according to the different quality or value of the notes in the piece; by which the time, that each note is to take up, is expressed. The semi-breve, for instance, holds one rise, and one fall; and this is called the *measure*, or *whole measure*; sometimes the *measure-note*, or *time-note*; the minim, one rise, or one fall; and the crotchet, half a rise, or half a fall, there being four crotchets in a full measure.

MEASURES, *Musical*, are now much simplified, compared with those which our ancestors described, we cannot say used, as some of them are impracticable. In the musical MS. of Waltham holy-crofs, in the possession of the marquis of Lans-

downe, N^o 9, by Chilton, we have not only double and triple proportions, but quintuple, sesquialterate, and sesquioctavan; that is, when one minim in the base is as long as a semibreve, or two minims in the treble; as three minims; as five; as one and a half; as 16 to 12, or 12 to 9.

Whether all these measures were ever received in practical music, does not appear; but we can be very certain, if they were, that the result would be nothing but dislocation and confusion.

All measures and species of time in modern music are reduced to two proportions; the *binary, dual, or even measure*, in which the rise and fall of the hand are equal; and the *ternary, triple, or odd measure*, in which the fall is double to the rise. The first, usually called *common time*, is the measure consisting of two semibreves, two minims, or two crotchets; the second, or *triple time*, of three minims, three crotchets or three quavers.

To this purpose the number 3 is placed at the beginning of the lines, when the measure is intended to be triple; and a C, when the measure is to be common or double. This rising and falling of the hands was called by the Greeks *αγορη* and *τερη*. St. Augustine calls it *plausus*, and the Spaniards *compas*. See ARSIS and THESIS.

There is likewise a mixed or compound measure of 6 or 12 crotchets or quavers in a bar, indicated at the beginning of a movement, thus: $\frac{6}{4}$, or $\frac{12}{4}$, $\frac{9}{8}$, or $\frac{6}{8}$. But as all these measures move in triplets, for each portion of a bar, they are reducible to binary and ternary measures.

MEASURES, *Powder*, in *Artillery*, are made of copper, and contain from an ounce to twelve pounds: these are very convenient in a siege, when guns or mortars are loaded with loose powder, especially in ricochet firing, &c.

MEASURING, MENSURATION, defined *geometrically*, is the assuming any certain quantity, and expressing the proportion of other similar quantities to the same.

MEASURING, defined *popularly*, is the using of a certain known measure, and determining thereby the precise extent, quantity, or capacity of any thing.

Measuring, in the general, makes the practical part of geometry. See MENSURATION.

From the various subjects on which it is employed, it acquires various names, and constitutes various arts. Thus,

MEASURING of *Lines*, or quantities of one dimension, we call *longimetry*; and when those lines are not extended parallel to the horizon, *altimetry*. When the different altitudes of the two extremes of the lines are alone regarded, we call it *levelling*.

MEASURING of *Superficies*, or quantities of two dimensions, is variously denominated, according to its subjects: when conversant about lands, it is called *geodesia*, or *surveying*: in other cases, it is called simply *measuring*. The instruments used are the ten-foot rod, chain, compass, circumferentor, &c.

MEASURING of *Solids*, or quantities of three dimensions, we call *stereometry*; where it is conversant about the capacities of vessels, or the liquors they contain particularly, *gauging*.

The instruments for this art are the gauging-rod, sliding-rule, &c.

From the definition of measuring, where the measure is expressed to be similar or homogeneous to, *i. e.* of the same kind with, the thing measured, it is evident, that in the first case, or in quantities of one dimension, the measure must be a line; in the second, a superficies; and in the third, a solid. For a line, *v. gr.* cannot measure a surface; to measure, being no more than to apply the known quantity to the unknown, till the two become equal. Now a surface has breadth, and a line has none: and if one line have no breadth,

two or a hundred have none. A line, therefore, can never be applied so often to a surface, as to be equal to it, *i. e.* to measure it. And from the like reasoning it is evident, a superficies, which has no depth, cannot become equal to, *i. e.* cannot measure, a solid, which has.

While a line continues such, it may be measured by any part of itself: but when the line begins to flow, and to generate a new dimension, the measure must keep pace, and flow too; *i. e.* as the one commences superficies, the other must do so too. Thus we come to have *square* measures, and *cubic* measures.

Hence we see why the *measure of a circle* is an arc, or part of the circle; for a right line can only touch a circle in one point, but the periphery of a circle consists of infinite points. The right line, therefore, to measure the circle, must be applied infinite times, which is impossible. Again, the right line only touches the circle in a mathematical point; which has no parts or dimensions, and has consequently no magnitude; but a thing that has no magnitude or dimensions, bears no proportion to another, that has; and cannot therefore measure it. Hence we see the reason of the division of circles into 360 parts or arcs, called *degrees*. See ARC, CIRCLE, and DEGREE. See also MENSURATION.

MEASURING of *Triangles*, or from three given sides or angles to determine all the rest, is called *trigonometry*.

MEASURING of *the Air*, its pressure, spring, &c. is called *aerometry*, or *pneumatics*.

MEAT, CIBUS. See FOOD and DIET.

MEATS, *Dressing of*. See DRESSING.

MEATS, *Dry*. See XEROPHAGY.

MEATS, *White*. See WHITE.

MEATH, in *Geography*, a county of Ireland, which, though only the tenth in size, is one of the most distinguished on account of its many natural advantages. It is bounded on the north by the counties of Cavan, Monaghan, and Louth; on the east by the Irish channel and port of Dublin; on the south by the county of Kildare, and on the west by Westmeath. It extends from N. to S. 29 miles (36 English), and from E. to W. 35 (44½ English) miles, including an area of 512 square miles, or 327,900 acres Irish measure, which are equal to 822 square miles, or 526,700 acres English measure. This county, united with Longford, Westmeath, and part of some adjoining counties, was formerly one of the five kingdoms into which Ireland was divided; and long after the English obtained possession of the country, it was considered as a distinct province, though it is now part of Leinster. It derived its name, according to some, from a corruption of Media, from its being surrounded by the other kingdoms, but others derive its name from the Irish Magh or Maith, which signifies a plain or level country. On the establishment of the English in Ireland, Henry II. made a grant of Meath to Hugh de Lacy, who planted several colonies, and erected many castles, and was more powerful in Ireland, as he boasted, than Henry himself. In 1234 the inheritance of Meath passed, by marriage, to Jeffery de Geneville, from whom it, in like manner, passed to Mortimer, earl of March, whose daughter and heir married the duke of York, father of Edward IV. Meath formed a principal part of what was called the English Pale, and from the number of parishes into which it was divided, and the many ruins it contains, it is probable that it was then very populous. In 1792, the 147 parishes were, by unions, reduced to 59 benefices, of which 44 had churches, and 19 only glebe houses. The population was estimated by Dr. Beaufort at 112,400, the number of houses amounting to 22,468. Since the time that calculation was made (1792) a very great increase has probably taken place, but the writer knows of no *data* from which it can be estimated. The country

country is, in general, level, having few hills, and those of inconsiderable height. The soil is variable, but that most generally met with is a strong deep clay upon limestone gravel, at a greater or less distance from the surface, in different places. That land which borders on the county of Louth, north of the river Boyne, is the worst and most unprofitable, whilst the north-western and south-eastern districts are the most productive. Though some peculiar districts in other counties are richer, yet there is no tract of equal extent in Ireland of such excellent quality, and so appropriate to every purpose of grazing and tillage. Meath is indeed proverbial for cattle, and not only supplies the Dublin market, but also buyers from the north of Ireland, and from different parts of England. There is also a number of dairy farms, especially in the south-eastern part, which send their produce to the metropolis. Some butter is also made for exportation, but it is not highly prized. At Slaine there is a manufactory of cheese carried on by natives of England. The pastures yield a luxuriant crop of natural grasses, and there is little attention paid to the introduction of others. Some marshes on the Moynalty river feed an immense number of horses in the summer season; and the Kiltrew hills in the western angle adjoining Cavan, are remarkable for fattening sheep. Agriculture has of late years extended much, and about one-third of the county is at present under tillage. The crops commonly cultivated are, wheat, oats, barley, rye, clover, flax and potatoes. Cabbages, turnips, rape, and peas are also frequently met with, though not very general. The quantity of waste land, exclusive of bog, is very small, and chiefly consists of the commons belonging to some of the towns, which will probably be soon enclosed.

The manufactures of this county are few. The principal is that of facking, which is made from tow, brought out of the northern counties. This manufacture is chiefly carried on in the neighbourhood of Navan. Dowlas and three-quarters wide coarse linens are made in the parts near Drogheda, which are exported thence to the West Indies to clothe the negroes. In the north-western parts linen of a finer texture is made, which is sold in the county of Cavan. In the southern parts spinning is generally neglected, and there is no manufacture except of some coarse frieze for home consumption. It may be added that the manufacture of straw hats, both of split and whole straw, has been brought to great perfection, and is carried on to a great extent. In the western and northern parts of the county are some considerable bogs, which supply a large quantity of fuel, though not equal to the wants of the inhabitants; whilst the eastern parts have coal from Dublin or Drogheda. There are supposed indications of coal in several parts of the county, but no mine is worked. The other mineral productions are of little importance. There is a copper mine at Skreen, from which the proprietor has yet derived no benefit; and a valuable potters' clay near Dunshaughlin, reckoned equal, if not superior (says Mr. Thompson) to most of the potters' clay found in Staffordshire, which, though within fifteen miles of Dublin, has been turned to no account. Marble is found at some depth under the bogs, similar to that found in Louth, which is useful in agriculture; and the limestone at Ardracran has been thought ornamental in building.

Meath is well watered, and the attention paid to inland navigation cannot fail of contributing to its rapid improvement. The principal river is the Boyne, which rising in the county of Kildare, enters Meath in the south-western angle, and divides it into two nearly equal parts. Its course lies through some of the most fertile and best improved parts

of the county. Its banks in most parts rise to a considerable height, gradually sloping from the water's edge to their verdant brow, and in others bold projecting rocks and steep precipices overhang its limpid surface. Though in some places the river is much disturbed in its course by sharps and rocks, yet in others it flows silently along through flats of considerable extent, adding elegance and beauty to scenes scarcely to be equalled in Ireland. On this river, in its course within the county, are six extensive bolting mills, besides several grist and cloth mills, and one for the manufacture of cotton. A canal has been made, called the Boyne navigation, which is for the most part contiguous to the river. This canal has been completed as far as Navan, but the other projected cuts to Trim, Athboy, and Kells, remain unfinished, which appears, from Mr. Wakefield's account, to be the case with most of such undertakings in Ireland. The Blackwater, flowing from lough Ramor in the county of Cavan, enters the county in the north-west, and passing near the town of Kells, joins the Boyne at Navan. The Moynalty flows into the Blackwater, and the Athboy, Knightsbrook, and some other small rivers, add their waters to the Boyne. The river Nanny, or, as it is usually called, the *Nanny water*, rises near Navan, and takes nearly an easterly direction to the Irish sea. The water of this river has, like the Bann, the character of being peculiarly adapted to the purposes of bleaching. The sea-coast is principally a shelving strand with shallow water, so that little advantage is derived from it. The land adjoining is a light soil, resembling sea sand, without much vegetative power, and well adapted for rabbits. The towns in Meath are numerous, but generally small and ill built. Trim is the county town, but Navan is more thriving, from its easy communication with Drogheda. Tarah hill, on which there is now an insignificant village, is said to have been formerly the royal residence, not only of the kings of Meath, but also of the monarchs of Ireland. A Danish invader is supposed to have also taken up his abode there, and to have built the fine Danish fort or rath on the south-east side of the hill, which is now beautifully planted. Thompson's Statistical Survey of Meath. Wakefield's Account of Ireland.

MEATH, a bishopric in Ireland, the bishop of which takes precedence of all other Irish ones. Several small bishoprics gradually coalesced into one see, which received the name of Meath at the end of the 12th century, being the only one not taking its name from a city or town. In 1568 the bishopric of Clonmacnoife was incorporated with it by act of parliament. It extends from the sea to the Shannon, over part of six counties, and contains 663,600 Irish acres. The parishes are 224, but unless late improvements have been made, the churches are little more than a third part of the number. There is no cathedral in this diocese; neither is there a chapter, nor even a dean of Meath; the only dignities are the deanery of Clonmacnoife and the archdeaconry of Meath. The revenue of this see is stated by Mr. Wakefield to be 6000*l.* per annum. The episcopal residence is at Ardracran, near Navan. Dr. Beaufort's Memoir of a Map of Ireland.

MEATUS, in *Anatomy*, a term applied to two passages belonging to the ear. The meatus auditorius externus is the tube leading from the external ear to the membrana tympani. The meatus auditorius internus is the opening in the petrous portion of the temporal bone receiving the nerves of the seventh pair. See CRANIUM and EAR.

MEATUS Auditorius, Imperforate, in *Surgery*. Obstruction of the external tube of the ear is sometimes a congenital malformation. In particular cases, the outer opening

ing of the passage is closed by a membranous substance; in others, the canal is entirely obliterated, either by the approximation of its cartilaginous and bony parietes to each other, or by being filled up with a fleshy mass. In all these cases of simple closure, or complete obliteration, the deafness, that is unavoidably produced, is not equally easy of cure. When the opening of the meatus auditorius externus is merely shut up by membrane, this may have a crucial incision made into it, or it may be removed altogether by cutting in a circular manner. After either of these operations, the new opening must be kept from becoming again impervious, by the introduction of tents, until the part is entirely healed. When the membrane is more deeply situated, the operation is less easy of accomplishment. In this sort of case Richerand advises us to draw the external ear upwards, in order to efface the natural curvature of the meatus, and let the entrance of the light make the state of the inside of the passage visible. We are then to introduce a narrow straight bistoury, the blade of which is wrapped round with lint nearly to the point, and make an incision with great caution, taking particular care to avoid injuring the membrane of the tympanum. It was the apprehension of doing mischief to the latter part, that induced Lefchevin to prefer, in such examples, the application of caustic, to the employment of a cutting instrument. (Prix de l'Acad. de Chirurg. tom. i. p. 67. 118. 4to.) He advises us to apply the caustic to the bottom of the meatus auditorius several times, so as to destroy the preternatural membrane. It appears to us, however, that the use of caustic must here be exceedingly inconvenient, and hardly so safe as a bistoury. Perhaps caustic may be attended with the advantage of making an opening, that will be less likely to close again. Experience can alone determine such points.

When the bony and cartilaginous parietes of the meatus auditorius are in contact, the obliteration of the passage is incurable. But when the canal is filled up with a fleshy substance, the disease sometimes admits of relief. In such a case, M. Lefchevin recommends us to introduce a trocar, in the natural direction of the meatus auditorius, to the depth of from 15 to 18 lines. Should the point of the trocar now meet with no resistance, the instrument must be withdrawn, and a tent passed into the artificial opening, in order to keep it from becoming closed. When the trocar, after being introduced to such a depth, that there is reason to believe it has reached the natural situation of the cavity of the tympanum, and yet the same resistance to its further introduction is experienced, we are recommended to abandon the operation. Were any one, says M. Lefchevin, here to ascribe the want of success to unskilfulness in the surgeon, he would be very unjust.

A preternatural narrowness of the meatus auditorius externus is not so bad a case as its obliteration, and the deafness produced by it is incomplete. But it is not to be imagined, that a cure is practicable when the bony portion of this tube is the seat of the contraction. Should the cartilage alone be concerned, a gradual dilatation may be accomplished by means of prepared sponge, or tents made of lint, the size of which is to be increased every day. Richerand acquaints us, that he has preserved several temporal bones which belonged to subjects who were very hard of hearing; and in all of them the bony portion of the meatus auditorius is remarkably narrow. M. Lametrie has recorded an instance, in which this passage was so narrow in a young person, that it would scarcely admit of the introduction of a needle into it. Nosog. Chir. tom. ii. p. 124.—126. edit. ii.

There was a curious case (which was seen a few years ago by many medical gentlemen in London), of a total deficiency of the external ears, unattended with any meatus auditorius, the situation of this opening, on each side of the head, presenting only the common integuments. It was remarkable, that notwithstanding such malformation, the faculty of hearing was far from being altogether destroyed. In all probability, the internal and most essential parts of the ear were, in this example, altogether perfect; and it seems not unlikely, that, by removing a portion of the skin over the orifice of each meatus auditorius, the hearing might have been rendered still less dull.

Meatus Auditorius Externus, Extraneous Substances in.—Besides the defects of which we have been speaking, and which are, for the most part, congenital, the meatus auditorius may be obstructed by foreign bodies. With respect to water and other liquids, they readily escape on putting the head in a favourable position. Small solid substances, like a pea, bean, &c. are usually extracted with a pair of forceps, the blades of which should be of a slender construction. But if the foreign bodies cannot be thus extracted, surgical authors recommend us to try to break them to pieces with a stronger pair of forceps, in order to facilitate their removal. They also advise us to instil into the ear a few drops of the oil of almonds, both before and after the operation. The lodgment of extraneous substances in the ear may give rise to a train of most unaccountable and perplexing symptoms, as may be seen by referring to the fourth observation of Fabricius Hildanus, cent. 13.

Meatus Auditorius Externus, obstructed with Cerumen. See DEAFNESS.

Meatus Auditorius Externus, Polypi and other Tumours of.—These, when their situation will permit, must be removed with a knife, and the part to which they were attached may be touched with the argentum nitratum. When they cannot be cut away, they sometimes admit of extraction, or of being tied in the manner of other excrescences, situated in cavities. (See POLYPUS.) The application of caustic to them can scarcely ever be a prudent mode of treatment.

Meatus Auditorius Externus, containing Insects.—Worms which make their appearance in the meatus auditorius are always produced subsequently to ulcerations in the passage, or in the interior of the tympanum, and, very often, such insects are quite unsuspected causes of particular symptoms. In the cases of surgery, published in 1778 at Stockholm, by Olaus Acrel, there is an instance confirming the statement just offered. It is the case of a woman, who, having been long afflicted with a hardness of hearing, was suddenly seized with very violent convulsions, without any apparent cause, and soon afterwards complained of an acute pain in the ear. This affection was followed by a recurrence of convulsions, which were more vehement than before. A small tent of fine linen, moistened with a mixture of oil and laudanum, was introduced into the meatus auditorius, and on removing it the next day, several small round worms were observed upon it, and from that period all the symptoms disappeared. To this case we shall add another from Morgagni. A young woman consulted Valsalva, and told him, that when she was a girl a worm had been discharged from her left ear; that another one, about six months ago, had also been discharged, very much like a small silk-worm in shape. This event took place after some very acute pain in the same ear, the forehead, and temples. She added, that since this she had been tormented with the same pains at different intervals, and so severely, that she often swooned away for two hours together. On recovering from this

state, a small worm was discharged of the same shape as, but much smaller than, the preceding one, and that she was now afflicted with deafness and insensibility on the same side. After hearing this relation, Valsalva no longer entertained any doubt of the membrane of the tympanum being ulcerated. He proposed the employment of an injection, in order to destroy the nest of worms, which he presumed to exist. For this purpose distilled water of St. John's wort, in which mercury had been agitated, was used. Murgagni adds, that nothing appears to him more proper in such cases, to prevent a recurrence of such worms, than to avoid going to sleep, particularly in autumn and summer, without taking care to stop up the affected ear. If this be not done, flies, attracted by the suppuration, enter the meatus auditorius, and, while the patient is unconscious, deposit their eggs in the ear. Acrel, in speaking of worms generated in the meatus auditorius, observes, that there is no better remedy for them, than the decoction of ledum palustre, injected into the ear several times a day. However, as it is not always possible to procure this plant, we shall recommend in such cases, in preference to all other remedies, a slight infusion of tobacco in oil of almonds, a few drops of which are to be dropped into the ear, and to be retained there by means of a little bit of cotton. This application, which is not injurious to the lining of the passage, is fatal to insects, and especially to worms, as various experiments have convinced naturalists. This method may also succeed in cases, in which caterpillars, ants, and other insects, have insinuated themselves into the meatus auditorius; but it is always better, first to endeavour to extract them. A piece of lint, smeared with honey, often suffices for this purpose; and when they cannot be extracted by this simple means, they may be taken out with a very small pair of forceps, however little of them may be visible.

Meatus Auditorius Externus, Purulent Discharges from.

—The secreted matter may either proceed from suppuration of this passage itself, or from disease in the tympanum, the membrane of which is imperfect. The latter case may be the consequence of blows on the head, abscesses after fevers, the small-pox, or the venereal disease. In most instances, the little bones of the internal ear are detached, and escape externally, complete deafness generally ensuing. A total loss of hearing, however, does not invariably follow this kind of mischief, as we have ourselves witnessed in one or two examples. Greater hopes of such an event being avoidable may be indulged, when the disorder is confined to the meatus; as judicious treatment may now avert the most serious consequences. In Acrel's surgical cases, there is a case relative to the circumstance of which we are speaking. Suppuration took place in the meatus auditorius externus in consequence of acute rheumatism, which was followed by vertigo, restlessness, and a violent head-ache. The matter discharged was yellowish, of an aqueous consistence, and acid smell. The meatus auditorius was filled with a spongy flesh. On introducing the probe, our author felt a piece of loose rough bone, which he immediately took hold of with a pair of forceps, and extracted. From the time, when this was accomplished, the discharge diminished, and, with the aid of proper treatment, the patient became perfectly well.

Meatus Auditorius Externus, Inflammation of.—This passage, like every other part of the body, is subject to inflammation, which is frequently brought on by exposure to cold. It is hardly necessary to say, that topical bleeding and antiphlogistic means in general are indicated. The meatus auditorius should also be protected from the cold

air, particularly in the winter season, by means of a piece of cotton.

Mr. Saunders observes, "When the means employed to reduce the inflammation have not succeeded, and matter has formed, it is generally evacuated; as far as I have observed, between the auricle and mastoid process, or into the meatus. If it has been evacuated into the meatus, the opening is most commonly small, and the spongy granulations, squeezed through a small aperture, assume the appearance of a polypus. Sometimes the small aperture, by which the matter is evacuated, is in this manner even closed, and the patient suffers the inconvenience of frequent returns of pain from the retention of the discharge. When the parts have fallen into this state, it will be expedient to hasten the cure by making an incision into the sinus, between the auricle and mastoid process."

"It occasionally happens, that the bone itself dies, in consequence of the sinus being neglected, or the original extent of the suppuration. The exfoliating parts are the meatus externus of the os temporis or the external lamina of the mastoid process." See Saunders on the Anatomy of the Human Ear and its Diseases, p. 24, 25.

Meatus Auditorius, Herptic Disease of. See DEAFNESS.

Meatus Urinarius, Imperforate. See URETHRA, Imperforate.

MEAVAUA, in *Geography*, a town of Italy, in the county of Bormio; five miles N.E. of Bormio.

MEAUDEE, a town of the Birman empire, on the left bank of the Ava; 10 miles N. of Prome.

MEAUX, a town of France, principal place of a district, in the department of the Seine and Marne, before the revolution the see of a bishop, and distinguished by having been the first scene of the reformation in the time of Francis. The chief traffic consists in grain, wool, and cheese. The city contains 6447, and the canton 14,484 inhabitants, on a territory of 127 kilometres, in 15 communes. N. lat. 48° 58'. E. long. 2° 57'.

MEBOREA, in *Botany*, a word of whose origin no account is given, Aubl. Guian. 826. t. 323. (See RHORIVUM.) Jussieu places this genus amongst his *Planta incerte sedis*. We should have supposed it one of his *Euphorbia*, though it may not answer to all the characters he has given of that order.

MEBU, in *Geography*, a town of Japan, in the island of Nippon; 160 miles N.W. of Jedo.

MECATINA, an island in the gulf of St. Lawrence. N. lat. 50° 48'. W. long. 59° 10'.

MECCA, a city of Arabia, known to the Greeks under the name of "Macoraba," is situated in a dry and barren tract of country, a full day's journey from Jidda, which see. "Some latent motives perhaps of superstition," says Gibbon (Decl. Rom. Emp. vol. ix. p. 223.) "must have impelled the founders of this city to the choice of a most unpromising situation. Their habitations were erected of mud or stone, in a plain about two miles long and one broad, at the foot of three barren mountains; the soil being a rock; the water even of the holy well of Zemzem being bitter or brackish; the pastures remote from the city; and grapes transported to it above 70 miles from the gardens of Tayef. The fame and spirit of the Koreishites, who reigned in Mecca, were conspicuous among the Arabian tribes; but their ungrateful soil refused the labours of agriculture, and their position was favourable to the enterprizes of trade. By the sea-port of Gedda (or Jidda), at the distance only of 40 miles, they maintained an easy correspondence with Abyssinia; and the Christian kingdom afforded the first refuge to the disciples of Mahomet. The treasures

treasures of Africa were conveyed over the peninsula to Gerra or Katif, in the province of Bahrein, a city built, as it is said of rock salt, by the Chaldean exiles; and from thence, with the native pearls of the Persian gulf, they were floated in rafts to the mouth of the Euphrates. Mecca is placed almost at an equal distance, a month's journey, between Yemen on the right, and Syria on the left hand. The former was the winter, and the latter the summer station of her caravans: and their seasonable arrival relieved the ships of India from the tedious and troublesome navigation of the Red sea. In the markets of Saana and Merab, in the harbour of Oman and Aden, the camels of the Koreishites were laden with a precious cargo of aromatics; a supply of corn and manufactures was purchased in the fairs of Bosra and Damascus; the lucrative exchange diffused plenty and riches in the streets of Mecca; and the noblest of her sons united the love of arms with the profession of merchandize." On an approach to the high lands, a few leagues beyond it, abundance of excellent fruits is to be found. In the summer months, the heat is excessive at Mecca, and in order to avoid and moderate it as much as possible, the inhabitants take care to shut their windows and water the streets. Instances have occurred, of persons that have been suffocated in the streets by the burning wind, called "Samoum," or "Samiel." As many of the first nobility in Hedjas reside at Mecca, the buildings are better here than in any other city in Arabia. Among its elegant edifices the most remarkable is the Kaba or Caaba, or house of God, which was held in high veneration by the Arabians, even before the days of Mahomet. (See CAABA.) Niebuhr says, that no Christian dares to enter Mecca, on account of the prejudices of the people with respect to the sanctity of the place, who think that it would be profaned by the feet of infidel Christians; though there is no prohibition to this purpose in the laws of Mahomet. The superstitious people persuade themselves, that Christians are restrained from approaching it by a supernatural power. We may hence presume, that the Christians of Europe, who describe Mecca as eye-witnesses, have been renegadoes, who have escaped from Turkey. The Mahometans have such high ideas of the sanctity of Mecca, that they suppose it to extend even to the environs of the city. Its territory is reputed sacred, to a certain distance round it, which is indicated by marks set up for this purpose. Every caravan finds one of these marks in their way, which warns the pilgrims to put on the modest garb which it becomes them to wear on that sacred ground. The government of this holy city is seated in a Sherriff, who is a temporal prince; and his revenue is increased by the donations of Mahometan sovereigns. N. lat. $21^{\circ} 47'$. E. long. $56^{\circ} 46'$.

Every Mussulman, it is well known, is obliged, once in his life, to visit Mecca, and to perform acts of devotion in the sacred places. But if this duty were universally performed, the concourse of pilgrims would be immense, and the city would not contain the crowds that would resort to it from every country in which the Mahometan religion has been introduced. Those, whose circumstances do not admit of their undertaking this pilgrimage, are allowed to have a person to perform it for them. But a pilgrim of this description can act for no more than one person at the same time; and, in order to prevent imposture, he must bring back a formal attestation from an Imam at Mecca, testifying, that he has actually performed the appointed devotional exercises in the holy places, in the name of such a person, living or dead; for even after the death of any person, who, during life, has neglected this duty, it may be

discharged in his name, and for his benefit. The caravans that visit this city, are frequently composed of persons who become pilgrims more from motives of interest and traffic than from those of devotion. (See CARAVAN) A pilgrim who has not been present from the commencement at the celebration of all the ceremonies, and performed every act of devotion, cannot obtain the title of "Hadgi;" an honour much courted by the Turks, because it confers substantial privileges, and commands respect to those who bear it. (See MAHOMET and MAHOMETANISM.) We shall here observe, that a similar custom prevails among the Christians in the East, who are very anxious to obtain the title of "Hadgi" or "Mokdasi," which they give to pilgrims of their communion. In order to acquire this title, it is not sufficient for a person to go in pilgrimage to Jerusalem: he must spend the season of the passover in that city, and assist at all the ceremonies in the holy weeks. See PILGRIM.

MECCA, a town of Morocco, near the coast of the Atlantic. S. lat. $29^{\circ} 45'$. W. long. $9^{\circ} 45'$.

MECHADER, a town of Arabia, in Yemen; 27 miles S. of Sana. N. lat. $14^{\circ} 7'$. E. long. $44^{\circ} 15'$.

MECHAIN, PETER FRANCIS ANDREW, in *Biography*, a very able French mathematician and astronomer, was born at Laon in the year 1744. At an early age he discovered a strong inclination for mathematical pursuits, and while he was under the instruction of his tutors, corresponded with Lalande, whom he was desirous of assisting in his labours. In 1772, Mechain was invited to Paris, where he was employed at the depôt of the marine, and assisted M. Darquier in correcting his observations. Here his merit brought him acquainted with M. Doisy, director of the depôt, who gave him a more advantageous situation at Versailles. At this place he diligently observed the heavens, and, in 1774, sent to the Royal Academy of Sciences, "A Memoir relative to an Eclipse of Aldebaran," observed by him on the 15th of April. He calculated the orbit of the comet of 1774; and discovered that of 1781. In 1782, he gained the prize of the academy on the subject of the comet of 1661, the return of which was eagerly expected in 1790; and in the same year he was admitted a member of the academy, and soon selected for the superintendance of the Connoissance des Temps. In the year 1790, M. Mechain discovered his eighth comet, and communicated to the academy his observations on it, together with his calculations of its orbit. In 1792 he undertook, conjointly with M. Delambre, the labour of measuring the degrees of the meridian, for the purpose of more accurately determining the magnitude of the earth and the length of a metre. In the month of June 1792, M. Mechain set out to measure the triangles between Perpignan and Barcelona; and notwithstanding that the war occasioned a temporary suspension of his labours, he was enabled to resume and complete them during the following year. He died on the 20th of September 1805, at Castellon de la Plana, in the sixty-second year of his age. Lalande deploras his loss as that of not only one of the best French astronomers, but one of the most laborious, the most courageous, and the most robust. His last observations and calculations of the eclipse of the sun on the 11th of February, are inserted in the Connoissance des Temps for the year 15, and he also published a great many in the Ephemerides of M. Bode of Berlin, which he preferred to a former work after Lalande became its editor. A more extensive memoir of his labours may be seen in baron von Zach's Journal for July 1800; and Lalande's History of Astronomy for 1804.

MECHANICS, that branch of practical mathematics which

MECHANICS.

which considers motion and moving powers, their nature, laws, effects, &c. This term, in a popular sense, is applied equally to the doctrine of the equilibrium of powers, more properly called statics, and to that science which treats of the generation and communication of motion, which constitutes dynamics, or mechanics strictly so called. See **STATICS, POWER, MOTION, and DYNAMICS.**

This science is divided by Newton into practical and rational mechanics, the former of which relates to the mechanical powers, *viz.* the lever, balance, wheel and axis, pulley, wedge, screw, and inclined plane; and the latter, or rational mechanics, to the theory of motion; shewing, when the forces or powers are given, how to determine the motion that will result from them, and conversely when the circumstances of the motion are given, how to trace the forces or powers from which they arise.

Mechanics, according to the ancient sense of the word, considers only the energy of *organa*, or machines. The authors who have treated the subject of mechanics systematically have observed, that all machines derive their efficacy from a few simple forms and dispositions, that may be given to the *organa*, which are interposed between the agent and the resistance to be overcome; and to those simple forms they have given the name of mechanical powers, simple powers, or simple machines. See **MECHANICAL Powers.**

The practical uses of the several mechanical powers were undoubtedly known to the ancients, but they were almost wholly unacquainted with the theoretical principles of this science till a very late period; and it is therefore not a little surprising that the construction of machines, or the instruments of mechanics, should have been pursued with such industry, and carried by them to such perfection. Vitruvius, in his 10th book, enumerates several ingenious machines which had then been in use from time immemorial. We find, that for raising or transporting heavy bodies, they employed most of the means which are at present commonly used for that purpose, such as the crane, the inclined plane, the pulley, &c.: but with the theory or true principles of equilibrium they seem to have been unacquainted till the time of Archimedes. This celebrated mathematician, in his book of Equiponderants, considers a balance supported on a fulcrum, and having a weight in each scale; and taking as a fundamental principle, that when the two arms of the balance are equal, the two weights supposed to be in equilibrio are also of necessity equal, he shews, that if one of the arms be increased, the weight applied to it must be proportionally diminished. Hence he deduces the general conclusion, that two weights suspended to the arms of a balance of unequal length, and remaining in equilibrio, must be reciprocally proportional to the arms of the balance; and this is the first trace any where to be met with of any theoretical investigation of mechanical science. Archimedes also farther observed, that the two weights exert the same pressure on the fulcrum of the balance, as if they were directly applied to it; and he afterwards extended the same idea to two other weights suspended from other points of the balance, then to two others, and so on, and hence, step by step, advanced towards the general idea of the centre of gravity, a point which he proved to belong to every assemblage of small bodies, and consequently to every large body, which might be considered as formed of such an assemblage. This theory he applied to particular cases, and determined the situation of the centre of gravity in the parallelogram, triangle, trapezium, parabola, parabolic trapezium, &c. &c. To him we are also indebted for the theory of the inclined plane, the pulley, and the screw, besides the invention of a multitude of compound machines, of which, however, he

has left us no description, and therefore little more than their names remain.

We may judge of the very imperfect state in which the theory of mechanics was at that time, by the astonishment expressed by king Hiero, when Archimedes exclaimed, "Give me a place to stand on and I will move the earth," a proposition which could have excited no surprise in any person possessing a knowledge of the simple property of the lever. Of the theory of motion, however, it does not appear that even Archimedes possessed any adequate idea; the properties of uniform motion seem only to have engaged the attention of the ancients, and with those of accelerated and variable motion they were totally unacquainted: these were subjects to which their geometry could not be applied, the modern analysis being necessary to bring this branch of the science to perfection.

From the time of Archimedes till the commencement of the sixteenth century, the theory of mechanics appears to have remained in the same state in which it was left by this prince of Grecian science, little or no additions having been made to it during so many ages; but about this time, Stevinus, a Flemish mathematician, made known directly, without the introduction of the lever, the laws of equilibrium of a body placed on an inclined plane: he also investigated, with the same success, many other questions on statics, and determined the conditions of equilibrium between several forces concurring in a common point, which comes, in fact, to the famous proposition relating to the parallelogram of forces; but it does not appear, however, that he was at all aware of its consequences and application. In 1592, Galileo composed a treatise on Statics, which he reduced to this single principle, *viz.* it requires an equal power to raise two different bodies to heights having the inverse ratio of their weights; that is, whatever power will raise a body of two pounds to the height of one foot, will raise a body of one pound to the height of two feet. On this simple principle he investigated the theory of the inclined plane, the screw, and all the mechanical powers, and Descartes afterwards employed it in considering the statical equilibriums of machines in general, but without quoting Galileo, to whom he had been indebted for the first idea. To Galileo we are also indebted for the theory of accelerated motion, and its complete coincidence with the observed phenomena of nature may be considered as one of the greatest steps made at one time in the science of physics. Since all bodies, said this philosopher, are heavy, into whatever number of parts we divide any mass, it follows, that its total weight is proportional to the number of material atoms of which it is composed. Now the weight being thus a power always uniform in quantity, and its action never undergoing any interruption, it must, in consequence, be continually giving new impulses to a body, in every equal and successive instant of time, and while the body is falling, these impulses are incessantly accumulating, and remain in the body without alteration, the resistance of the air alone being deducted, and hence the motion must be accelerated by equal degrees.

Torricelli, a pupil of Galileo, prosecuted the subject after his master, and added several curious propositions concerning projectiles, to those which the latter had previously investigated. Huygens considered the motion of bodies along given curves, and demonstrated that the velocity of a heavy body, which descends along any curve, is the same at every instant in the direction of the tangent, as it would have acquired by falling freely from a height equal to the corresponding vertical absciss. Then applying this principle to the inverted cycloid, the axis of which is vertical, he found that

that a heavy body, from whatever part of the cycloidal arc it falls, always arrives at the lowest point of that arc in the same space of time. This very remarkable proposition includes what is commonly called the *isochronism* of the cycloid, and would alone have been sufficient to establish the fame of a geometrician. In 1661, Huygens, Wallis, and sir Christopher Wren, all discovered the true laws of percussion separately, and without any communication with each other, a proposition which Descartes had previously attempted, but failed in giving it a general solution. The finding of the centres of oscillation in compound bodies soon followed that relating to percussion, and here again Huygens equally distinguished himself by the accuracy and elegance of his solution; but as the principles which he employed were not well understood by the philosophers and mathematicians of that period, his investigations were much criticised at the time; but the honour of the discovery was finally attributed to him, and those of Descartes and Roberval admitted to be erroneous, or at least not sufficiently general. However, before the discovery of the fluxional calculus, there were many curious and interesting mechanical properties which the ancient geometry was incompetent to investigate, and which could never have been brought to light but by the assistance of this modern branch of analysis.

After the foundation of statics was laid by Archimedes, it was not difficult to discover the conditions of equilibrium in every particular case, and these had guided the genius of invention in a number of machines, but they were not yet reduced to a general and uniform principle.

Varignon undertook and accomplished this plan of combining them, by means of the theory of compound motions. He gave some sketches of this in 1687, in his Project of a new System of Mechanics, and he in some degree exhausted all the combinations of the equilibrium of machines, in his "General Mechanics," not published till after his death, in 1725. In 1695, la Hire published a "Treatise on Mechanics," the general object of which, like that of Varignon's, is the equilibrium of machines, beside which it contains various applications of machines to the arts, in which the author was well versed. He also subjoined a treatise on epicycloids, and their use in this science, particularly as relating to the forms of teeth in wheel-work. This is a beautiful theory, and is highly creditable to its author, who it appears from the testimony of Leibnitz was not la Hire, though he published it as such, but was due to the celebrated Danish mathematician Roemer, who had communicated it to Leibnitz twenty years before la Hire's work appeared. After this period, several elementary treatises on the subject of mechanics were published, without, however, adding much to the previous stock of knowledge, unless indeed we except that of Cornus, a work highly valuable for the strictness and perspicuity of its demonstrations.

At this time very little had been done with regard to the theory of variable motion; this now began to engage the attention of mathematicians, and opened an extensive field to their researches. Galileo, as we have seen, made known the properties of rectilinear and uniformly accelerated motions; Huygens had treated of curvilinear motion, which finally led to the beautiful theory of central forces in a circle, and which is equally applicable to motion in any curve, by considering them as infinite series of small arcs of a circle, agreeably to the idea which he himself had employed in his general theory of evolutes. The laws of the communication of motion, likewise sketched by Descartes, and farther pursued by Wallis, Huygens, and Wren, had made a new and very considerable step, by means of the solution which Huygens gave of the celebrated problem of the centres of oscillation.

All these acquisitions, at first separate and in some measure independent of each other, having been reduced to a small number of simple, commodious, and general formulæ, by means of the analysis of infinites, the science of mechanics acquired fresh vigour, and was prosecuted with the most unbounded success. The problems relating to motion were reduced into two classes; the first comprising the general problem of the motion of a single body acted upon by any given powers; and the second, the motions which result from the action and re-action that several bodies exert on each other in any given manner.

In the motion of a single body, we observe that matter, being of itself passive, if once set in motion, must uniformly persevere in it; and that its motion can neither increase nor diminish, unless by the action of some external power, which may be either constant or variable. And hence arise two principles, that of *vis inertiae* and that of compound motion; and on these are founded the whole theory of motion, rectilinear or curvilinear, constant or variable, according to a given law. By virtue of the *vis inertiae*, motion at every instant is essentially rectilinear and uniform, setting aside resistance and every obstacle that might otherwise impede or change its direction; and by the nature of compound motion, a body exposed to the action of a given number of forces, all tending at the same time to change the quantity and direction of its motion, takes such a path through space that in the last instant it reaches the same point at which it would have arrived, had it successively and freely obeyed each of the forces proposed.

On applying these principles to rectilinear motions uniformly accelerated, we perceive, 1st, that in this motion, the velocities increasing by equal degrees, or proportionally to the time, the accelerating force must be constant, or incessantly give equal impulses to the moving body, and that, consequently, the final velocity is as the product of the accelerating force multiplied by the time. 2dly. Each elementary portion of space passed through being as the product of the corresponding velocity multiplied by the element of the time, the whole of the space passed through is as the product of the accelerating force multiplied by the square of the time; and these two properties equally take place for each elementary portion of any variable motion whatever. Thus in every rectilinear motion variable according to a given law, the increment of the velocity is as the product of the accelerating force into the element of the time, and the second fluxion of the space passed through is as the product of the accelerating force into the square of the element of the time. Now if to these principles we add that of compound motion; we shall arrive at the knowledge of all curvilinear motion whatever. In fact, whatever forces be applied to a body describing a curve, we may at each instant reduce these forces to two, the one acting in the direction of the tangent at any point of the curve, and the other perpendicular to it; the first produces an instantaneous rectilinear motion, to which the principle of *vis inertiae* applies; and the second is expressed by the square of the actual velocity of the body, divided by the radius of curvature, agreeably to the theory of central forces in the circle, which equally reduces to the same principle the motion in the direction of the radius of curvature. Such were the general principles introduced into the science of mechanics by means of the modern analysis, and there seems to be no doubt that it was by pursuing this theory, Newton was led to those brilliant discoveries which he afterwards published in his "Principia" under a different form. In 1716, Hermann published his "De Phoronomia," in which he undertook to explain all that regards mechanics, both of
solids

solids and fluids, that is to say, statics, dynamics, hydrostatics, and hydraulics, in which he employs the synthetic method, although, like Newton, he doubtless derived most of his results from analysis, a circumstance which frequently interrupts the unity and connection of his problems.

The Mechanics of Euler, published in 1736, contain the whole theory of rectilinear and curvilinear motion in an isolated body, acted upon by any accelerating forces whatever, either in vacuo or in a resisting medium. The author has every where followed the analytical method, which, by reducing all the branches of this theory to uniformity, greatly facilitates the connection of it, and the whole is managed with an elegance and perspicuity, of which, before this time, we had no example. As to the principles of mechanics by which he puts his problems into equations, he employs those above mentioned.

This manner of laying the foundation of the calculation, however, though sufficiently commodious, was not the only one that might have been employed, nor was it the most simple. For the forces and motions at every instant may be resolved into other forces and motions parallel to fixed lines of given position in space. In which case nothing more is necessary than to apply the equations of the principles of *vis inertia* to these motions and forces, by which means the theorem of Huygens may be avoided. This simple idea, which was first employed by Maclaurin in his "Treatise on Fluxions," threw new light on the theory of mechanics, and much facilitated the solution of various problems. When the body moves constantly in one plane, two fixed axes only are to be taken, which are supposed to be perpendicular to each other, for the sake of greater simplicity; but when we are obliged, by the nature of the forces, to change the path continually in all directions, and to describe a curve of double curvature, three axes are to be employed perpendicular to each other, or forming the edges of a right-angled parallelepipedon. But the problems relating to the communication of motion, commonly called *dynamic problems*, required new principles. These, for instance, consist in determining the motions that result from the percussive of several bodies; the centre of oscillation of a compound pendulum; the motions of several bodies strung upon a rod, which has a rotatory movement round a fixed axis; &c.

Now it is evident, that in all cases of this kind the motion of the bodies is not the same as if the bodies were isolated and at liberty, but that there must be a distribution of the forces among all the bodies forming one whole, so that the motion gained by some of them is lost by others. The motion gained or lost is always estimated by the product of the mass into the velocity received or lost, whether the communication or the loss of motion be produced every instant by finite degrees, as in the shock of hard bodies, or whether the velocity change at each instant only by degrees infinitely small, as in motion of several bodies strung on a moveable rod, and generally in all cases where forces act in the manner of gravitation.

When Huygens gave his solution of the problems of oscillation, some unskillful mathematicians attacked it in reviews. James Bernouilli defended it in the Leipzig Transactions for 1686, and undertook to give a direct demonstration by means of the principle of the lever. At first, he considered only two equal weights fastened to an inflexible rod devoid of gravity, which was in motion round an horizontal axis. Having then observed that the velocity of the weights, nearest to the axis of rotation, must necessarily be less, and that on the other greater, than if each acted on the rod separately, he concludes that the force lost and the force

gained balance each other, and that, consequently, the product of the quantity of matter in one, into the velocity it loses, and that of the other multiplied by the velocity it gains, must be inversely proportional to the arms of the lever. This reasoning is in fact accurate, only James Bernouilli mistook in setting out, by considering the velocities of the two bodies as finite, instead of which he should only have considered the elementary velocities, and compared them with the similar velocities produced every instant by the action of gravitation. De l'Hôpital remarked this error, and in correcting it, he found the centre of oscillation of the two weights, without departing in other respects from the principle of Bernouilli. In order then to proceed to a third weight, he united the former two at their centre of oscillation, and combined this new weight with the third, as he had combined together the former two, and so on. But the proposed union was a little precarious, and could not be admitted without a demonstration. This led Bernouilli to revive his former solution, in order to extend it generally to any number of bodies, which he finally accomplished. His method consists in resolving the motion of each body at any given instant into two other motions, the one, that which the body actually takes; and the other, that which is destroyed, and in forming equations which express the condition of equilibrium between the motions lost; by which means the problem is brought under the general laws of statics. The author applies this principle to several examples, and demonstrates strictly, and in the most evident manner, the proposition which Huygens employed as the basis of his solution. See Memoirs of the Academy of Sciences for 1703.

This solution of the problem of the centres of oscillation, seemed to leave nothing to be desired; yet, in 1714, it was brought forward again by John Bernouilli and Dr. Taylor, which were fundamentally the same. This occasioned warm disputes between them, as to the originality of their performances. Here, instead of the elementary weights of which the pendulum is composed, other weights are supposed to be substituted, in one and the same point, such that their motion of angular acceleration, and their motion with respect to the axis of rotation, shall be the same, and the new pendulum oscillate as the former. But these solutions are not considered so luminous as that of James Bernouilli, which was founded immediately on the laws of equilibrium. Leibnitz estimated the momenta of bodies by the mass into the square of their velocities, and John Bernouilli having adopted the same opinion, gave to the principles of Huygens, for the problem of the centres of oscillation, the name of the principle of conversion of the *vires vivæ*, which it has retained, because, in fact, in the motion of a system of heavy bodies, the sum of the products of the masses into the squares of the velocities remains the same, when the bodies descend conjointly, and when they afterwards ascend separately, with the velocities they acquired by their descent. This principle was also followed with success in dynamical problems, by several able analysts of the last century; but as it gives only a single equation, from which the velocity or the time must afterwards be expunged, the second object was attained by different means.

John Bernouilli employed for this purpose the principle of *tensions*; Euler, that of *pressures*; Daniel Bernouilli, that of *virtual power*, which a system of bodies has of re-establishing itself in its former state; and in certain cases both he and Euler made use of the constant quantity of circulatory motion round a fixed point. And when at length all the differential, or fluxional equations of the problem

were established, it remained only to resolve them, which was of course the least difficult part of their investigations.

The principle which had been employed by James Bernoulli, in the solution of the problem relating to the centre of oscillation, was generalized by D'Alembert; he shewed, that in whatever manner the bodies of one system act upon each other, their motions may always be resolved at every instant into two sorts of motions, those of the one being destroyed in the successive instant, but the other retained; and that the motions retained are necessarily known from the conditions of the equilibrium between the motions destroyed. This general principle applies to all the problems of dynamics, and at least reduces all their difficulties to those of the problems of simple statics; and renders useless that of the conversion of *vires vivæ*. By this means D'Alembert has resolved a number of very beautiful and very difficult problems, some of which were absolutely new, as, for example, that relating to the precession of the equinoxes. These general principles were first developed by D'Alembert in 1743, but they were more fully treated of in his Treatise of Dynamics, published in 1749; a truly interesting and original work, highly creditable to the talents of this celebrated author. The science of dynamics having thus gradually attained a high degree of perfection, was still farther enriched, in 1765, by an important discovery, which is due to Segner; who has shewn in a short paper entitled "Specimen Theoriæ Turbinum," that if a body, of any size and figure, after rotatory or gyratory motions in all directions have been given to it, be left entirely to itself, it will always have three principal axes of rotation; that is, that all the rotatory motions, by which it is affected, may constantly be reduced to three, which are performed round three axes perpendicular to each other passing through the centre of gravity or inertia of the body, and always preserving the same position in absolute space, while the centre of gravity is at rest, or moves uniformly in a right line; the position of these three axes being determined by an equation of the third order. This theory, which its author had not sufficiently developed, Albert, the son of the celebrated Euler, treated at length in his paper "On the Stowage of Ships," which shared the prize of the Academy of Sciences at Paris for 1761, as did likewise his father, according to the same method, in the Memoirs of the Academy at Berlin for 1759, and in his work entitled "Theoria Motus Corporum rigidorum, 1765." Lastly, D'Alembert shewed in his "Mathematica Opuscula," vol. iv. published in 1768, that the solution of the problem was deducible from the formulæ which he had given in a memoir for determining the motion of a body of any figure, acted upon by any forces whatever, printed in vol. i. of his Opuscula in 1761. The knowledge of these motions of free rotation round three principal axes, naturally led to the determination of the motion round any variable axes whatever; and hence, if we consider the body to be acted upon by any given accelerating forces, we must begin with determining the rectilinear or curvilinear motion of the centre of gravity abstractedly from all rotatory motion, and then combining this progressive motion with the rotatory motion of a given point of the body round a variable axis, we shall know at every instant the compound motion of this point in absolute space. On these principles Euler has resolved many curious and interesting problems relating to dynamics, and the same have been since farther proved by subsequent mathematicians. (Bossut's Hist. Math.) We have thus given a sketch of the history and successive improvements of the science of mechanics, which is all that is necessary under the present

article, as the particular branches connected with this subject are treated of separately under their respective heads in the different articles of this work. But as we have only directed our attention to the more prominent parts of the history, the works to which our references have been made are very limited. It remains, therefore, before we conclude this article, to enumerate some of the principal writers on mechanics, or on particular branches of it, which are as follows, *viz.*

Newton, in his "Principia;" Guido Ubaldo, in his "Liber Mechanicorum;" Torricelli, "Libri de Motu Graviorum naturalitatis Decendentium et Projectorum;" Balianus, "Tractatus de Motu naturali Graviorum;" Huygens, "Horologium Oscillatorium," and "Tractatus de Motu Corporum ex Percussione;" Leibnitz, "Resistentia Solidorum," in Acta Euroditus, ann. 1684; Guldinus, "De Centro Gravitatis;" Wallis, "Tractatus de Mechanica;" Varignon, "Projet d'une Nouvelle Méchanique," and his papers in the Memoires Acad. ann. 1702; Borelli, "Tractatus de Vi Percussionis, de Motionibus naturalibus, &c.;" De Chales, "Treatise on Motion;" Pardies, "Discourse on Local Motion;" Parent, "Elements of Mechanics and Physics;" Casatus, "Mechanica;" Oughtred, "Mechanical Institution;" Robault, "Tractatus de Mechanica;" Lamy, "Méchanique;" Keil, "Introduction to true Philosophy;" De la Hire, "Méchanique;" Mariotte, "Tracti du Choe du Corps;" Ditton, "Laws of Motion;" Hermann, "Phoronomia;" Gravesande, "Physics;" Euler, "Tractatus de Motu;" Muschenbroeck, "Physics;" Bossu, "Méchaniques;" La Grange, "Méchanique Analytique;" Atwood, "On Motion;" Prony, "Architecture Hydraulique," and "Méchanique Analytique;" Francear, "Méchanique;" Gregory, "Mechanics in Theory and Practice," &c. &c. to which may be added the names of Nicholson, Enfield, Wood, Ferguson, Young, and Marat. For those works which relate principally to the description of machinery, see the article MACHINE.

MECHANICAL, something that relates to mechanics, or is regulated by the nature and laws of motion.

In which sense we say mechanical powers, mechanical properties or affections, mechanical principles, reasoning, knowledge, &c.

MECHANICAL Affections, are such properties in matter, as result from their figure, bulk, and motion.

MECHANICAL Causes, are those founded on such affections.

MECHANICAL Force. See FORCE.

MECHANICAL Solutions, are accounts of things on the same principles.

MECHANICAL Philosophy, is the same with what we otherwise call the *corpuseular philosophy*; *viz.* that which explains the phenomenon of nature, and the operations of corporeal things, on the principles of mechanics; *viz.* the motion, gravity, figure, arrangement, disposition, greatness, or smallness of the parts which compose natural bodies. See CORPUSCULAR.

MECHANICAL Powers, (so called,) are those machines which are used for raising greater weights, or overcoming greater resistances than could be effected by the natural strength without them; the power of strength being applied to one part of the machine, and another part of the machine applied to the weight or resistance.

There are two principal problems that ought to be resolved in treating of each of them.

The first is, to determine the proportion which the power and

MECHANICAL POWERS.

and weight ought to have to each other, that they may just sustain one another, or be in equilibrio.

The second is, to determine what ought to be the proportion of the power and weight to each other in a given machine, that it may produce the greatest effect possible, in a given time.

As to the first problem, this general rule holds in all powers; suppose the engine to move, and reduce the velocities of the power and weight to the respective directions in which they act; find the proportions of those velocities; then if the power be to the weight as the velocity of the weight is to the velocity of the power; or, which amounts to the same thing, if the power multiplied by its velocity, gives the same product as the weight multiplied by its velocity, this is the case wherein the power and weight sustain each other, and are in equilibrio; so that in this case the one would not prevail over the other, if the engine was at rest; and if it is in motion, it would continue to proceed uniformly, if it were not for the friction of its parts, and other resistances.

The second general problem in mechanics is, to determine the proportion which the power and weight ought to bear to each other, that when the power prevails, and the machine is in motion, the greatest effect possible may be produced by it in a given time. It is manifest, that this is an enquiry of the greatest importance, though few have treated of it. When the power is only a little greater than that which is sufficient to sustain the weight, the motion is too slow; and though a greater weight is raised in this case it is not sufficient to compensate the loss of time. When the weight is much less than that which the power is able to sustain, it is raised in less time; and this may happen not to be sufficient to compensate the loss arising from the smallness of the load. It ought, therefore, to be determined when the product of the weight, multiplied by its velocity, is the greatest possible; for this product measures the effect of the engine in a given time, which is always the greater in proportion as the weight which is raised is greater, and as the velocity with which it is raised is greater. For other considerations necessary to be regarded in the construction and use of machines, we refer to the articles MACHINE and MACHINERY.

The simple machines by which power is gained, are six in number, viz. the lever, the wheel and axle, or axis in peritrochio, the pulley (or rather system of pulleys), the inclined plane, the wedge, and the screw. Of these, all sorts of mechanical engines consist; and in treating of them, so as to settle their theory, we must consider them as mechanically exact, and moving without friction. Although these machines are treated of at large under their proper heads, it may not be amiss to give a short account of them all here.

1. A lever is an inflexible bar, turning upon a supporting prop as its centre of motion, which must be firm enough to bear the lever and the weight with which it is charged. There are three kinds of levers, and in each of them the velocity of each point is directly as its distance from the prop.

A lever is said to be of the first kind when the prop is between the weight and the power. Here the power and weight balance each other, when the power is in proportion to the weight as the distance of the weight from the prop is to the distance of the power from it; so that if a weight be twenty pounds, and at one foot from the prop, a power of one pound at twenty feet from the prop will balance the weight, supposing the lever itself to have no weight. To this sort of lever may be reduced all iron crows, scissars, pinchers, candle-snuffers, and the like.

A lever is said to be of the second kind, when the weight is between the prop and the power. Here the lever and weight balance each other when the power is in proportion to the weight as the distance of the weight from the prop is to the distance of the power from it. Of this sort are doors turning on hinges, oars, and such knives as are fixed at the point.

A lever is said to be of the third kind when the power is between the weight and the prop. In this, the power and weight balance each other, when the power is in proportion to the weight, as the distance of the weight from the prop is to the distance of the power from it: but this lever is never used where power is wanted to be gained; for in it, the intensity of the power applied, must always exceed the intensity of the weight to be raised, or resistance to be overcome. Of this sort are the bones of our legs and arms, and the wheels of clocks and watches. See LEVER and BALANCE.

2. In the wheel and axle, where the power is applied to the wheel, and the weight drawn up by a rope winding round the axle, the velocity of the power is to the velocity of the weight, as the circumference of the wheel is to the circumference of the axle, and the advantage gained by the machine is in the same proportion: for the power and weight balance each other when the power is in proportion to the weight, as the circumference of the axle is to the circumference of the wheel. This machine is the principal part of a common crane. See AXIS in Peritrochio.

3. A pulley, that only turns on its axis, and does not rise with the weight, serves only to change the direction of the power; for it gives no mechanical advantage thereto. But when, besides the upper pulleys, which turn round in a fixed frame, or block, there is a block of pulleys moving equally fall with the weight, the velocity of the weight is to the velocity of the power as one is to twice the number of pulleys in the moveable block: and the power and weight balance each other when the power is in proportion to the weight, as one is to twice the number of pulleys in the moveable block. See PULLEY.

4. An inclined plane is like one-half of a wedge which has been cut in two equal parts lengthwise. A weight raised, or a resistance moved, by an inclined plane, moves only through a space equal to the height of that machine, in the time that a power drives it through a space equal to its whole length. Therefore, the velocity of the power is in proportion to the velocity of the weight, as the length of the machine is to its thickness or height at the back; and the power and weight balance each other when the power is in proportion to the weight, as the thickness of the plane is to its length. All edge tools, which are chamfered (or ground down only on one side to the edge) are inclined planes, as far as the chamfer goes from the edge. See INCLINED PLANE.

5. A wedge, in the common form, is like two inclined planes, joined together at their bases; and the thickness of these planes (opposite their sharp edges) makes the back of the wedge, to which the power of the sledge or hammer is applied in cleaving of wood.

When two equal resistances act perpendicularly against opposite sides of the wedge, and a power acts perpendicularly against the back of the wedge, the velocity of the power is in proportion to the velocity of the resistance on either side, as the length of the side is to half the thickness of the back: and the power balances the resistance of the wood, when the power is in proportion to the resistance, as half the thickness of the back of the wedge is to the length of either of its sides, if the sharp edge goes to the bottom

MECHANICAL POWERS.

of the cleft in the wood. But when the wood splits before the wedge, as it generally does, the power balances the resistance, when the former is to the latter as half the thickness of the wedge (when it is driven quite into the wood) is to the whole length of the cleft below the back of the wedge. See WEDGE.

6. The *screw* may be considered as if it were an inclined plane, wrapt round a cylinder. In this machine, the power must turn the cylinder quite round, in the time that the weight or resistance (as in a common press) moves through a space equal to the distance between the threads or spirals of the screw. Therefore, the velocity of the power is in proportion to the velocity of the weight or resistance, as the circumference of a circle, described by the power, is to the distance between the spirals of the screw; and the power and resistance balance each other, when the former is to the latter as the distance between the spirals is to the circumference of the circle described by the power. This machine, besides the advantage peculiar to itself, has generally the benefit of the wheel and axle, on account of the winch or lever by which it is turned. See SCREW.

Of these six simple machines, all the most compound engines in the world are made. As the screw includes the inclined plane, and two equally inclined planes make the wedge, we have all the mechanical powers combined together in a common jack, if it be turned by the fly; for then we have also the lever, the wheel and axle, and the pulleys.

Thus, in a frame $ABCD$, (*Plate XXXII. Mechanics, fig. 5.*) fastened by the nut O upon the stand OO , and held together by the pillars VW and Bq , is adapted first the piece EF , whose fans or flies may be put in motion by the wind, or drawn by a hair fastened at F , which represents the lever and balance: at right angles to this piece is joined the perpendicular spindle GH , having upon it the endless screw H , which may be also considered as a wedge. This endless screw or worm takes the skew teeth of the wheel K , which is the axis in peritrochio, and, in turning round, winds up the string LM upon its axis, which passing round the pulleys at M and N , or drawing by a tackle of five, raises the weight P . But as the screw has no progressive motion on its axis, it cannot here be said to comprehend the inclined plane; therefore, in order to make this machine take in all the mechanical powers, we may add the inclined plane, $rqqR$, by making it rest on the ground at QR , and on the pillar qB , at qr , and thereby the force of the power drawing at F , will be farther increased in the proportion of QT to TS . The whole force gained by this machine is found by comparing the space gone through by the point F , with the height through which the weight is raised, in any determinate number of revolutions of F . An hundred pounds weight at P will be easily raised by the hair of a man's head drawing at F .

If an engine constructed in this manner be used for raising a weight, by means of a power applied to the fly, the power will balance the weight, if it be in proportion to the weight as the velocity of the weight is to the velocity of the fly. Now, considering how fast the fly moves with respect to the motion of the weight, it is evident, that a crane, constructed in the manner of a common jack, would be an engine of very great power. But then the time lost in raising the weight would also be very great: for, in any machine or engine whatever, the time lost in working it will be as great as the power gained by it.

If machines or engines could be made without friction, the least degree of power added to that which balances the weight would be sufficient to raise it. In the lever, the friction is next to nothing; in the wheel and axle it is but

small; in the pulleys it is very considerable; and in the inclined plane, wedge, and screw, it is very great. The universal law or principle in all mechanical machines or engines, made to gain power, is, that the power gained will be always as great as the velocity of the power exceeds the velocity of the weight or resistance: and, upon this principle, it is easy to compute the power, force, or advantage, of any simple machine or compound engine whatever.

E gr. If the body A (*Plate XXXII. Mechanics, fig. 6.*) be triple the body B , and each of them be so fixed to the extremities of a lever AB , whose fulcrum or fixed point is C , as that the distance of BC be triple the distance CA ; the lever cannot be inclined on either side, but the space BE , passed over by the less body, will be triple the space AD , passed over by the great one. So that their motions or moments will be equal, and the two bodies in equilibrio.

Hence that noble challenge of Archimedes, *datis viribus, datum pondus movere*; for as the distance CB may be increased infinitely, the power or moment of A may be increased infinitely. So that the whole of mechanics is reduced to the following problem.

Any body, as A, with its velocity C, and also any other body, as B, being given; to find the velocity necessary to make the moment or quantity of motion, in B, equal to the moment of A, the given body. Here, since the moment of any body is equal to the rectangle under the velocity, and the quantity of matter; as $B : A :: C : c$: to a fourth term, which will be c , the celerity proper to B , to make its moment equal to that of A . Wherefore in any machine or engine, if the velocity of the power be made to the velocity of the weight, reciprocally as the weight is to the power, such power will always sustain, or, if the power be a little increased, it will move the weight.

Let, for instance, AB be a lever, whose fulcrum is at C ; and let it be moved into the position aCb . Here, the velocity of any point in the lever is as the distance from the centre. For let the point A describe the arc Aa , and the point B the arc Bb ; then these arcs will be the spaces described by the two motions: but since the motions are both made in the same time, the spaces will be as the velocities. But it is plain, the arcs Aa and Bb will be to one another as the radii AC and CB , because the sectors ACa and BCb are similar: wherefore the velocities of the points A and B are as their distances from the centre C .

Now if any powers be applied to the ends of the lever A and B , in order to raise its arms up and down; their force will be expounded by the perpendiculars Sa and bN ; which, being as the right lines of the former arcs, aA and Bb , will be to one another also as the radii AC and CB ; wherefore the velocities of the powers are also as their distances from the centre. And since the moment of any body is as its weight, or gravitating force, and its velocity, conjunctly; if different powers of weights be applied to the lever, their moments will always be as the weights and the distances from the centre conjunctly. Wherefore, if to the same lever there be two powers or weights applied reciprocally proportional to their distances from the centre, their moments will be equal; and if they act contrarily, as in the case of a steel-yard, the lever will remain in an horizontal position, or the balance will be in equilibrio. And thus it is easy to conceive how the weight of one pound may be made to equilibrate a thousand, &c.

Hence also it is plain, that the force of the power is not at all increased by engines; only the velocity of the weight, in either lifting or drawing, is so diminished by the application of the instrument, as that the moment of the weight is not greater than the force of the power. Thus, for instance, if

if any force can raise a pound weight with a given velocity, it is impossible by any engine to effect, that the same power shall raise two pound weight with the same velocity: but by an engine it may be made to raise two pound weight, with half the velocity or 1000 times the weight with $\frac{1}{1000}$ of the former velocity.

We shall here introduce into our view, an account of the principal methods that have occurred to us of explaining and demonstrating the fundamental property of the several mechanical powers. It has been already observed, that, with regard to the lever, when any two forces act against each other on its arms, they will continue in equilibrio, if their quantities are inversely as the distance between the points to which they are applied, and the point or fulcrum round which the lever turns. The demonstration commonly ascribed to Archimedes is founded upon this principle, that when any cylindric or prismatic body is applied upon a lever, it has the same effect as if its whole weight was united and applied at the middle point of its axis. Let *AD*, *Plate XXXII. Mechanics, fig. 7.* be a cylinder, of an uniform texture, *C* its middle point; and it is manifest, that if the point *C* be supported, the equal halves of the cylinder, *CA* and *CB*, will balance each other about the point *C*, and the body will remain in equilibrio. Let the cylinder *AB* be distinguished into any unequal parts, *AD* and *DB*; bisect *AD* in *E*, and *DB* in *F*; then a power applied at *E*, equal to the weight of the part *AD*, with a contrary direction, will sustain it; and a power applied at *F*, equal to the weight of the part *DB*, with a contrary direction, will sustain that part; so that these two powers acting at *E* and *F*, respectively equal to the weights of *AD* and *DB*, have precisely the same effect as a prop at *C*, sustaining the whole cylinder *AB*, and may be considered as in equilibrio with a power, acting at *C*, equal to the whole weight of the cylinder. But the distance $CE = CA - AE = \frac{1}{2} AB - \frac{1}{2} AD = \frac{1}{2} DB$; and, in like manner, the distance $CF = CB - BF = \frac{1}{2} AB - \frac{1}{2} DB = \frac{1}{2} AD$; consequently *CE* is to *CF* as *DB* to *AD*; that is, as the power applied at *F* to the power applied at *E*, these being in equilibrio with the weight of the whole cylinder applied at *C*. From which it appears, that powers applied at *E* and *F*, which are to each other in the proportion of *CF* to *CE*, sustain one another about the centre *C*.

It has been objected by *M. Huygens* and others, to this demonstration of *Archimedes*, that when the whole cylinder is distinguished into two segments, part of the weight of the greater segments acts on the same side of the fulcrum with the lesser segment; and, therefore, when the whole weight of the greater segment is contracted into its middle point on one side of the fulcrum, and acts altogether against the lesser segment, it requires some proof to shew, that this contracted weight will be balanced by the weight of the lesser segment. *M. Huygens* proposed a method of his own, depending on a postulation assumed in common with *Archimedes*, and needing demonstration, *viz.* that when equal bodies are placed on the arms of a lever, the one which is farthest from the fulcrum will prevail and raise the other up.

Sir Isaac Newton demonstrates the fundamental proposition concerning the lever, from the resolution of motion: let *C*, *fig. 8.* be the centre of motion in the lever *KL*; let *A* and *B* be any two powers applied to it at *K* and *L*, acting in the directions *KA* and *LB*. From the centre of motion, *C*, let *CM* and *CN* be perpendicular to those directions in *M* and *N*; suppose *CM* to be less than *CN*, and from the centre *C*, at the distance *CN*, describe the circle *NHD*, meeting *KA* in *D*. Let the power *A* be represented by *DA*, and let it be resolved into the power *DG*

acting in the direction *CD*, and the power *DF* perpendicular to *CD*, by completing the parallelogram *AFDG*. The power *DG*, acting in the direction *CD* from the centre of the circle, or wheel, *DHN*, towards its circumference has no effect in turning it round the centre, from *D* toward *H*, and tends only to carry it off from that centre. It is the part *DF* only that endeavours to move the wheel from *D* towards *H* and *N*, and is totally employed in this effort. The power *B* may be conceived to be applied at *N* as well as at *L*, and to be wholly employed in endeavouring to turn the wheel the contrary way, from *N* towards *H* and *D*. If, therefore, the power *B* be equal to that part of *A* which is represented by *DF*, these efforts, being equal and opposite, must destroy each other's effect; that is, when the power *B* is to the power *A*, as *DF* to *DA*, or (because of the similarity of the triangles, *AFD*, *DMC*) as *CM* to *CD* or as *CM* to *CN*, then the powers must be in equilibrio; and those powers always sustain each other that are in the inverse proportion of the distances of their directions from the centre of motion; or when the product of the one power multiplied by the distance of its direction from the centre, is equal to the product of the power on the other side multiplied by the like distance from it.

Mr. Maclaurin proposes a new method of demonstrating the law of equilibrio in the lever, which seems, he says, to be founded on the plainest and most evident principles: these principles are the following, *viz.* that if equal powers act at equal distances on different sides of the fulcrum or centre of motion, with directions opposite and parallel to each other, they will have the same effect: and that, if gravity be supposed to act in parallel lines, and the fulcrum be between the bodies, whose powers are estimated, it must bear the sum of their weights; because the lever being loaded with those weights, it must give way, if the fulcrum does not sustain their sum: but if the powers are on the same side of the fulcrum, in which case one of them must pull upwards whilst the other pulls downwards, that there may be an equilibrio, it is then only loaded with the difference of the powers.

Supposing, therefore, first, two equal powers, *A* and *B*, *fig. 9.* acting in the directions *AF*, *BH*, to carry a body *C*, upon the lever *AB*, placed at *C* at equal distances from them; it is evident that, in this case, each of the powers *A* and *B* sustains one-half of the weight *C*, by dividing it equally between them. Imagine now that the power *A* is taken away, and that, instead of resting upon it, the end *A* of the lever rests upon a prop at *A*; it is manifest that the power *B* and the prop at *A* sustain, as before, each one-half of the weight *C*; the prop now acting, in every respect, as the power at *A* before; and, the equilibrium continuing, it appears that, in this case, a power *B* equal to one-half of the weight *C* sustains and balances it, when the distance of *C* from the prop *A* is one-half of the distance of *B* from the same; that is, when *B* is to *C*, as *CA* to *BA*, or $B \times BA = C \times CA$. From this simple instance we see, that powers act upon a lever not by their absolute force only, but that their effect necessarily depends upon the distance of the point where they act from the prop, or centre of motion; and particularly, that a power balances a double power which acts at half its distance from the prop, on the same side of it, with an opposite direction.

The case when the two powers act on the different sides of the prop, follows from this, by the principles already laid down. For let *BH* and *CG* (*fig. 10.*) represent the directions and forces with which the powers *B* and *C* act upon the lever; upon *BA* produced take *AE* equal to *AC*, or $\frac{1}{2} AB$, and in place of the power *CG* substitute

MECHANICAL POWERS.

an equal power $E K$ at E , with an opposite direction; and, by the first of those principles, this power $E K$ will have the same effect as $C G$, only the prop or centre of motion A will now sustain the sum of the forces $E K$ and $B H$, by the second of those principles. But the equilibrium between the powers $B H$ and $E K$ will continue as it was before, between $B H$ and $C G$; so that the powers $B H$ and $E K$ will be in equilibrio, when the power $B H$ is one-half of $E K$, and the distance of $E K$ from the prop A is one-half of the distance of $B H$ from the same; that is, when the power at B is to the power at E , as $A E$ to $A B$, or $B \times B A = E \times E A$. In this case, the prop A being loaded with both the powers B and E , which act with the same direction, its re-action must be equal to their sum, $E K + B H = 3 B H$, and must be in the opposite direction $A F$. In place of this re-action, let us now (*fig. 11.*) substitute a power $A F$ at A , equal to thrice $B H$; and in place of the power $E K$, let us substitute a prop at E , sustaining that end of the lever $B E$; and since the equilibrium continues as before, it follows that the prop or centre of motion, being at E , the power $B H$ sustains the power $A F$, which is triple of $B H$, when the distance of $B H$ from the prop E is triple of the distance of the power $A F$ from the same, that is, when $B H \times B E = A F \times A E$.

If we suppose the power $E K$ to remain (*fig. 12.*) but the end B of the lever $E B$ to rest upon a prop, then the powers $A F$ and $E K$ will sustain and balance each other, the prop at B now coming in place of the power $B H$; in which $A F = 3 B H$, and $E K = 2 B H$; so that $A F$ is to $E K$ as 3 to 2; and the distances $E B$ and $A B$ being in the same proportion, it appears that when two powers in the same proportion, it appears that when two powers in the proportion of three to two act upon a lever on the same side of the prop, or centre of motion, with opposite directions, at distances in the proportion of two to three, they then sustain each other. We have demonstrated therefore, that when the powers are in the proportion either of two to one, or of three to one, or of three to two, and the distances of their application from the centre of motion are in the inverse proportion, then those powers balance each other, or are in equilibrio.

Upon $B E$ produced (*fig. 13.*) take $E L = E A$; and in place of the power $A F$ substitute a power $L M = A F$, but with a contrary direction; this power $L M$ will have the same effect to turn the lever round the centre of motion E as $A F$ had; consequently it will be in equilibrio with the power $B H$, as $A F$ was. Therefore, when two powers $L M$ and $B H$, in the proportion of three to one, act upon a lever with the same direction, they are in equilibrio, if their distances from the centre of motion $L E$ and $E B$ be in the ratio of one to three: that is, when $L M \times L E = B H \times B E$. In this case, the powers $L M$ and $B H$ acting with the same direction, the prop E must sustain their sum $L M + B H = 4 B H$, by the second principle above premised. Therefore a power at L , as 3, and a power acting at B with the same direction, as 1, are sustained by a power acting at E , with a contrary direction, as 4. From which it follows, by substituting in the place of the power $L M$ a prop at L , that a power at B , as 1, sustains a power at E , as 4, acting with a contrary direction, when $B L$ is to $E L$ as 4 to 1; that is, when the powers are inversely as their distances from the prop, or centre of motion. By substituting the prop at B in the place of the power $B H$, it appears that a power $L M$ at L , as 3, sustains a power, acting with an opposite direction at E , as 4, when their distances $L B$ and $E B$, from the prop B , are to each other as 4 to 3, or when $L M \times L B = E K \times E B$. By taking upon $L B$ produced $B e = B E$ (*fig. 14.*), and in place of the

power at E , substituting an equal power at e with a contrary direction, it appears, that a power at L , as 3, sustains a power acting at e , with the same direction, as 4, when the distance $L B$ is to the distance $e B$, as 4 to 3. In this case, the prop at B sustains the sum of the powers acting at L and e , that is, a power equal to seven times $B H$. From which it follows, by substituting a prop at L or e , in place of the powers that act there, that a power at e , as 4, sustains a power at B , as 7, about the centre of motion L , when their distances from it, $e L$, $B L$, are to each other as 7 to 4: and that a power at L , as 3, sustains the power at B , as 7, about the centre of motion e , when their distances from it, $L e$ and $B e$, are to each other as 7 to 3.

By proceeding in this manner it appears, that when the powers are to each other as number to number, and when their distances from the centre of motion are in the inverse ratio of the same numbers, then the powers sustain each other, or are in equilibrio. From which it is easy to shew, in general, that when the powers are to each other in any ratio, though incommensurable, and the distances of their application from the centre of motion in the same inverse ratio, then they are in equilibrio; because the ratio of incommensurable quantities may be always limited to any degree of exactness at pleasure, between a greater and a lesser ratio of number to number. To Mr. Maclaurin's demonstration it has been objected, that it cannot be applied when the arms of the lever are incommensurable, and as it cannot conclude generally, it must, therefore, be imperfect.

Dr. Hamilton, having observed that these several methods of demonstrating the fundamental property of the lever are liable to objections, proposes a new proof, depending on the following postulatum, *viz.* if a force be uniformly diffused over a right line, so that an equal part of the force acts upon every point of the line, and if the whole force acts according to one and the same plane, this force will be sustained, and the line kept in equilibrio; by a single force applied to the middle point of the line equal to the diffused force, and acting in a contrary direction. He also premises this lemma: if a right line be divided into two segments, the distances between the middle of the whole line and the middle points of the segments, will be inversely as the segments. This is self-evident when the segments are equal; and, when they are unequal, since half of the whole line is equal to half of the greater and half of the lesser segment, it is plain that the distance between the middle of the whole line and the middle of one segment, must be equal to half of the other segment, so that these distances must be to each other inversely as the segments.

Let the line $G H$, then, *fig. 15*, whose middle point is D , be divided into the unequal segments $G L$ and $L H$, whose middle points are C and F , and let two forces or weights, A and B , which are to each other as the segments $G D$ and $L H$, be applied to their middle points C and F , and let them act perpendicularly on the line $G H$: then, (by the lemma) the weights A and B will be to each other inversely as $C D$ and $F D$ (the distances of the points C and F , to which they are applied, from the middle of the whole line); if then a third force or weight E , equal to the sum of the forces A and B , be applied to the point D , and acts on the line in an opposite direction; I say these three forces will sustain each other, and keep the line in equilibrio. For let us suppose the force E to be removed, and instead of it another force, equal also to the sum of A and B , to be uniformly diffused over the whole line $G H$, and to act directly against the forces A and B , then the part of this force which acts on the segment $G L$, will be equal to the force A , and therefore will be sustained by it (postulatum);

MECHANICAL POWERS.

latum); and the other part, which is diffused over the segment LH , will be equal to and sustained by the force B , so that the forces A and B will sustain this diffused force and keep the line in equilibrio. Let now two other forces act also on this line in opposite directions, one of them the force E acting on the point D , as it was first supposed to do, and the other an uniformly diffused force equal to E (and consequently equal to the other diffused force), then these two additional forces will also balance each other, and therefore the equilibrium will still remain. So that the two forces A and B , and a diffused force acting on one side of the line sustains the force E , and a diffused force acting on the other side: but it is manifest, that in this equilibrium, the two diffused forces acting on opposite sides are perfectly equivalent, and therefore if they are taken away from both sides, the equilibrium must still remain. Hence it appears that the three weights or forces A , B , and E , any two of which are, (by the construction) to each other inversely as their distances from the third, will sustain each other and keep the line on which they act in equilibrio; which is the first and most simple case of the property of the lever; for here the directions of the weights are supposed to be perpendicular to the line on which they act, and it is evident that, if one of the points C , D , or F be fixed or considered as a fulcrum, the weights acting on the other two points will continue to support each other. The second case of the property of the lever is easily deduced from the first; for when two weights act on the arms of a lever in oblique directions, and are to each other inversely as the perpendicular distances of the lines of direction from the centre of motion, then by the resolution of forces, it is easily proved that the parts of those forces which act perpendicularly on the arms of the lever, and which only are exerted to turn the lever, are to each other inversely as the lengths of those arms; and therefore by the first case they must balance each other.

From what has been above demonstrated, it appears, that the powers with which any two forces move or endeavour to move the arms of a lever, are as the rectangles, under lines proportional to the forces, and the perpendicular distances of their lines of direction from the fulcrum; and also that when two bodies acting on the arms of a lever sustain each other, if one of them be removed farther from the fulcrum, it will preponderate; but if it be brought nearer to the fulcrum, the other weight will prevail: because the product to which its force is proportional will be increased in the first case, and diminished in the second.

When a weight is to be raised by means of an axle and wheel, it is fastened to a chord that goes round the axle, and the power, which is to raise it, is hung to a chord that goes round the wheel. If then the power be to the weight as the radius of the axle to the radius of the wheel, it will just support that weight; as will easily appear from what was proved of the lever. For the axle and wheel may be considered as a lever, whose fulcrum is a line passing through the centre of the wheel and middle of the axle, and whose long and short arms are the radii of the wheel and axle which are parallel to the horizon, and from whose extremities the chords hang perpendicularly. And thus an axle and wheel may be looked upon as a kind of perpetual lever, on whose arms the power and weight always act perpendicularly, though the lever turns round its fulcrum. And in like manner, when wheels and axles move each other by means of teeth on their peripheries, such a machine is really a perpetual compound lever; and, by considering it as such, we may compute the proportion of any power to the weight it is able to sustain by the help of such an engine. And since the radii of two contiguous wheels, whose teeth are applied to each other, are as

the number of teeth in each, or inversely as the number of revolutions, which they make in the same time: we may, in the computation, instead of the ratio of these radii, put the ratio of the number of teeth on each wheel; or the inverse ratio of the number of revolutions they make in the same time.

The most natural method of explaining the effects of the pulley, that is, of computing the proportion of any power to the weight it can sustain by means of any system of pulleys, is, by considering that every moveable pulley hangs by two ropes equally stretched, which must bear equal parts of the weight: and, therefore, when one and the same rope goes round several fixed and moveable pulleys, since all its parts on each side of the pulleys are equally stretched, the whole weight must be divided equally amongst all the ropes by which the moveable pulleys hang. And consequently if the power which acts on one rope be equal to the weight divided by the number of ropes, or double the number of moveable pulleys, that power must sustain the weight.

The several cases in which the wedge is applied may be comprehended in one general proposition: let the equicrural triangle ABC (*fig. 16.*) represent a wedge, the lines AB and CB will be the sides of the wedge, AC its base, or back, and its height will be the line PB bisecting the base AC , and also the vertical angle ABC .

When any two resisting forces act on the sides of a wedge, in directions which make equal angles with the sides, (as they are always supposed to do,) a power acting perpendicularly at P on the base of the wedge will keep the resisting forces in equilibrio, when it is to the sum of these forces, as the sine of half the vertical angle of the wedge, to the sine of the angle which the directions of the forces contain with the sides of the wedge.

For let E and F be two bodies acting on the sides of the wedge, and let them be first supposed to act in the directions EP and FP perpendicular to the sides; then since the power P acts perpendicularly on the base AC , if these three forces keep the wedge in equilibrio, they will be to each other, as the sides of a triangle to which their directions are parallel, or (which is the same thing) as the sides of the triangle ABC , to which their directions are perpendicular. Therefore, the power P is to the sum of the resisting forces which it sustains as AC , the base of the wedge, to the sum of the sides, or as PA , half the base, to AB , one of the sides; but PA is to AB as the sine of PBA , half the vertical angle of the wedge, to the radius which is the sine of a right angle, and the directions of the resisting forces are supposed in this case to contain a right angle with the sides of the wedge.

Let now the resisting bodies E and F be supposed to act on the wedge in directions parallel to the lines DP and OP , which make oblique angles with its sides, draw EG and FK perpendicular to those lines. From what has been proved, it appears that the power P is to the force with which it is able, by means of the wedge, to protrude the resisting bodies in the directions PE and PF , as the sine of half the vertical angle to the radius; let this protruding force be expressed by the line PE , and let it be resolved into two forces expressed by the lines PG and GE , the former of these only will act in opposition to the resisting bodies, therefore the whole protruding force of the power is to the force with which it acts against the resisting bodies E and F in the directions PD and PO as PE to PG , or (because the triangles EPG and DPE are similar) as PD to PE , that is, as the radius to the sine of the angle PDE ; compounding, therefore, the ratio of the sine of half the vertical angle to the radius, with the ratio of the radius to the sine of the angle PDE ,

the

the power P, when the wedge is kept in equilibrio, will be to the force with which it protrudes the resisting bodies in directions opposite to those in which they act, as the sine of half the vertical angle to the sine of the angle PDE or POF, which the directions of the resisting forces contain with the sides of the wedge.

Hence, when the directions in which resisting bodies act on a wedge are given, we may easily find two lines that will express the proportion between the resistance and the power which sustains it by means of the wedge. For from P, the middle point of the wedge, draw the line PD meeting one of the sides, and parallel to the direction in which the resisting force acts on that side, then the power will be to the resistance as PD to PB the height of the wedge. For PD and PB are to each other as the sines of the opposite angles, in the triangle PBD, that is, as the sines of half the vertical angle, and the angle which the direction of the resisting force contains with the side of the wedge.

From what has been demonstrated we may deduce the proportion of the power to the resistance it is able to sustain, in all the cases in which the wedge is applied.

First, when, in cleaving timber, the wedge fills the cleft, then the resistance of the timber acts perpendicularly on the sides of the wedge; therefore, in this case, when the power which drives the wedge is to the cohesive force of the timber as half the base to one side of the wedge, the power and resistance will be in equilibrio.

Secondly, when the wedge does not exactly fill the cleft, which generally happens because the wood splits to some distance before the wedge: let E L F represent a cleft, into which the wedge ABC is partly driven; as the resisting force of the timber must act on the wedge in directions perpendicular to the sides of the cleft, draw the line PD in a direction perpendicular to EL, the side of the cleft, and meeting the side of the wedge in D; then the power driving the wedge, and the resistance of the timber, when they balance, will be to each other as the line PD to PB, the height of the wedge.

Thirdly, when a wedge is employed to separate two bodies that lie together on a horizontal plane, for instance two blocks of stone; as these bodies must recede from each other in horizontal directions, their resistance must act on the wedge in lines parallel to its base CA; therefore, the power which drives the wedge will balance the resistance, when they are to each other as PA, half the breadth of the wedge, to PB its height; and then any additional force, sufficient to overcome the resistance arising from the friction of the bodies on the horizontal plane, will separate them from each other.

With respect to the inclined plane: let the line AB, (*fig. 17.*) represent the length of an inclined plane, AD its height, and the line BD, we may call its base. Let the circular body GEF be supposed to rest on the inclined plane, and to be kept from falling down it by a string CS tied to its centre C. Then the force with which this body stretches the string will be to its whole weight as the sine of ABD, the angle of elevation, to the sine of the angle which the string contains with a line perpendicular to AB, the length of the plane. For let the radius CE be drawn perpendicular to the horizon, and CF perpendicular to AB, and from E draw EO parallel to the string, and meeting CF in O: then, as the body continues at rest, and is urged by three forces, to wit, by its weight in the direction CE, by the re-action of the plane in the direction FC, and by the re-action of the string in the direction EO; the re-action of the string, or the force by which it is stretched, is to the weight of the body as EO to CE; that is, as the sine of

(the angle ECO, which is equal to) ABD, the angle of elevation, to the sine of the angle EOC, equal to SCO, the angle which the string contains, with the line CF perpendicular to AB, the length of the plane.

When, therefore, the string is parallel to the length of the plane, the force with which it is stretched, or with which the body tends down the inclined plane, is to its whole weight, as the sine of the angle of elevation to the radius, or as the height of the plane to the length. And in the same manner it may be shewn, that when the string is parallel to BD, the base of the plain, the force with which it is stretched is to the weight of the body as AD to BD, that is, as the height of the plane to its base. If we suppose the string, which supports the body GEF, to be fastened at S, and that a force by acting on the line AD, the height of the plane, in a direction parallel to the base BD, drives the inclined plane under the body, and by that means makes it rise to a direction parallel to AD: then, from what was proved in the third case of the wedge, it will appear, that this force must be to the weight of the body as AD to BD, or rather in a proportion somewhat greater; if it makes the plane move on and the body rise.

From this last observation we may clearly shew the nature and force of the screw; a machine of great efficacy in raising weights, or in pressing bodies closely together. For if the triangle ABD be turned round a cylinder whose periphery is equal to BD, then the length of the inclined plane BA will rise round the cylinder in a spiral manner, and form what is called the thread of the screw, and we may suppose it continued in the same manner round the cylinder, from one end to the other; and AD, the height of the inclined plane, will be every where the distance between two contiguous threads of this screw, which is called a convex screw. And a concave screw may be formed to fit this exactly, if an inclined plane every way like the former be turned round the inside of a hollow cylinder, whose periphery is somewhat larger than that of the other. Let us now suppose the concave screw to be fixed, and the convex one to be fitted into it, and a weight to be laid on the top of the convex screw: then, if a power be applied to the periphery of this convex screw to turn it round, at every revolution the weight will be raised up through a space equal to the distance between the two contiguous threads, that is, to the line AD, the height of the inclined plane BA; therefore, since this power applied to the periphery acts in a direction parallel to BD, it must be to the weight it raises as AD to BD, or as the distance between two contiguous threads, to the periphery of the convex screw.

The distance between two contiguous threads is to be measured by a line parallel to the axle; if we now suppose that a handspike or handle is inserted into the bottom of the convex screw, and that the power which turns the screw is applied to the extremity of this handle, which is generally the case; then as the power is removed farther from the axis of motion, its force will be so much increased, and therefore so much may the power itself be diminished. So that the power which, acting on the end of a handle, sustains a weight by means of a screw, will be to that weight, as the distance between two contiguous threads of the screw, to the periphery described by the end of the handle. In this case we may consider the machine as composed of a screw and a lever, or, as Sir Isaac Newton expresseth it, *Cuneus a veste impulsus*.

Professor Vince, premising that Dr. Hamilton's demonstration depends upon this proposition, that when a body is at rest, and acted upon by three forces, they will be as the three sides of a triangle parallel to the directions of the

forces, allows this principle to be true, when the three forces act at any point of a body; but, considering the lever as the body, the three forces act at different points, and therefore the principle, as applied by the author, is certainly not applicable. If in this demonstration we suppose a plane body, in which the three forces act, instead of simply a lever, then the three forces being actually directed to the same point of the body, the body would be at rest. But in reasoning from this to the case of the lever, the same difficulties would arise, as in the proof of sir I. Newton. But admitting that all other objections could be removed, the demonstration fails when any two of the forces are parallel. Another demonstration is founded upon this principle, that if two non-elastic bodies meet with equal quantities of motion, they will, after impact, continue at rest; and hence it is concluded, that if a lever which is in equilibrio be put in motion, the motions of the two bodies must be equal; and therefore the pressures of these bodies upon the lever at rest, to put it in motion, must be as their motions. Now in the first place, this is comparing the effects of pressure and motion, the relation of the measures of which, or whether they admit of any relation, we are totally unacquainted with. Moreover, they act under very different circumstances; for in the former case, the bodies acted immediately on each other, and in the latter, they act by means of a lever, the properties of which we are supposed to be ignorant of. When forces act on a body, considered as a point, or directly against the same point of any body, we only estimate the effect of these forces to move the body out of its place, and no rotatory motion is either generated, or any causes to produce it, considered in the investigation. When we, therefore, apply the same proposition to investigate the effect of forces to generate a rotatory motion, we manifestly apply it to a case which is not contained in it, nor to which there is a single principle in the proposition applicable. The demonstration given by Mr. Landen, in his Memoirs, is founded upon self-evident principles, nor does our author see any objections to his reasoning upon them. But as his investigation consists of several cases, and is besides very long and tedious, something more simple is still much to be wished for, proper to be introduced in an elementary treatise of mechanics, so as not to perplex the young student either by the length of the demonstration, or want of evidence in its principles. What the ingenious Professor proposes to offer will, he hopes, render the whole business not only very simple, but also perfectly satisfactory.

The demonstration given by Archimedes would be very satisfactory and elegant, provided the principle on which it is founded could be clearly proved; viz. that two equal powers at the extremities, or their sum at the middle of a lever, would have equal effects to move it about any point. Now, that the effects will be the same, so far as respects any progressive motion being communicated to the lever when at liberty to move freely, is sufficiently clear; but there is no evidence whatever that the effects will be the same to give the lever a rotatory motion about any point, because a very different motion is then produced, and we are supposed to know nothing about the efficacy of a force at different distances from the fulcrum to produce such a motion. Besides, the two motions are not only different, but the same forces are known to produce different effects in the two cases; for in the former case the two equal powers at the extremities of the arms produce equal effects in generating a progressive motion; but in the latter case they do not produce equal effects in generating a rotatory motion. We cannot therefore reason from one to the other. The principle, however, may be thus proved.

Let A, C, (fig. 18.) be two equal bodies placed on a straight lever, AP, moveable about P; bisect AC in B, produce PA to Q, and take BQ = BP, and suppose the end Q

to be sustained by a prop. Then as A and C are similarly situated in respect to each end of the lever, that is, AP = CQ, and AQ = CP, the prop and fulcrum must bear equal parts of the whole weight; and therefore the prop at Q will be pressed with a weight equal to A. Now take away the weights A and C, and put a weight at B equal to their sum; and then the weight at B being equally distant from Q and P, the prop and fulcrum must sustain equal parts of the whole weight, and therefore the prop will now also sustain a weight equal to A. Hence if the prop Q be taken away, the moving force to turn the lever about P in both cases must evidently be the same; therefore the effects of A and C upon the lever to turn it about any point are the same as when they are both placed in the middle point between them. And the same is manifestly true if A and C be placed without the fulcrum and prop. If, therefore, AC be a cylindrical lever of uniform density, its effect to turn itself about any point will be the same as if the whole were collected into the middle point B; which follows from what has been already proved, by conceiving the whole cylinder to be divided into an infinite number of laminæ perpendicular to its axis, of equal thicknesses.

The principle, therefore, assumed by Archimedes is thus established upon the most self-evident principle, that is, that equal bodies at equal distances must produce equal effects; which is manifest from this consideration, that when all the circumstances in the cause are equal, the effects must be equal. Thus the whole demonstration of Archimedes is rendered perfectly complete, and at the same time it is very short and simple. The other part of the demonstration we shall here insert, for the use of those who may not be acquainted with it.

Let XY (fig. 19.) be a cylinder, which bisect in A, on which point it would manifestly rest. Take any point Z, and bisect ZX in B, and ZY in C; then, from what has been proved, the effects of the two parts ZX, ZY to turn the lever about A is the same as if the weight of each part were collected into B and C respectively, which weights are manifestly as ZX, ZY, and which therefore conceive to be placed at B and C. Now AB = AX - XB = $\frac{1}{2}$ XY - $\frac{1}{2}$ XZ = $\frac{1}{2}$ YZ; and AC = AY - YC = $\frac{1}{2}$ XY - $\frac{1}{2}$ ZY = $\frac{1}{2}$ XZ; consequently AB : AC :: $\frac{1}{2}$ YZ : $\frac{1}{2}$ XZ :: YZ : XZ :: the weight at B : the weight at C.

The property of the straight lever being thus established, every thing relative to the bent lever immediately follows. See Maclaurin's Account of sir Isaac Newton's Phil. Disc. book ii. chap. 3. Hamilton's Phil. Ess. ess. 1. or Phil. Transf. liii. p. 116. Phil. Transf. vol. lxxxiv. art. v. p. 33; &c.

MECHANICAL is also applied to a kind of reasoning, which of late has got great ground, both in physics and medicine; thus denominated, as being conformable to what is used in the contrivance, and accounting for the properties and operations of machines. See MEDICINE.

MECHANICAL is also used, in Mathematics, to signify a construction or proof of some problem, not done in an accurate and geometrical manner, but coarsely and unartfully, or by the assistance of instruments; as are most problems relating to the duplicature of the cube, and the quadrature of the circle.

MECHANICAL Arts. See ARTS.

MECHANICAL Curve. See TRANSCENDENTAL CURVE.

MECHANICAL Pathology, the system of medicine adopted by Borelli, Pitcairn, and others, at the end of the seventeenth and beginning of the eighteenth centuries, by which they endeavoured to explain the phenomena of disease upon the principles of mechanical philosophy; principles which were very partially applicable to the operations of animal

life; the system, therefore, was exploded by the more philosophical researches into the laws of the sensorial power, or nervous energy, peculiar to living beings, by the pathologists of succeeding times. See *MEDICINE, History of*, near the end.

MECHELEN, in *Geography*, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Maestricht. The place contains 906, and the canton 7736 inhabitants, on a territory of 390 kilometres, in 17 communes.

MECHLIN. See *MALINES*.

MECHOACAN, a province or large district, in the domain of Mexico, bounded on the N. by part of Guatetea, or Panuco, and the provinces of Zacatecas and Guadalajara, on the E. by another part of Guatetea, and Mexico proper, and on the S. by the latter and the South sea, which, together with Xalisco or New Galicia, bounds it also on the W. and N.W. It extends about 210 miles along the coast, and still further inland. The air is singularly healthy, and the soil very fertile. In this province are mines of silver, and, as it has been said, some of gold and copper. Among its productions we may reckon maize and cotton, the cacao or chocolate nut, the root mechoacan, several odoriferous gums, and balsam, sarsaparilla, ambergris, vanillas, cassia, honey, wax, &c. The natives, since they have been incorporated with the Spaniards, have acquired the knowledge of several trades, and are curious in the manufacture of cabinets, weaving silk, and earthen pottery; and they particularly excel in making images of small feathers, equal to the most exquisite painting. The country is infested with foxes, squirrels, lions, wild dogs, and tygers; but it has also a numerous breed of excellent horses for the saddle or harness. The sea, as well as its lakes and rivers, supply abundance of excellent fish. In this province there are two considerable lakes one of which gave name to the lake, implying "fishery," as it used anciently to supply the capital. This lake is situated on the N. of Pasquaro, the capital of the province, while Valladolid, or Mechoacan, has only the bishopric. According to Alcedo, it is about 12 leagues in circumference, probably about 40 English miles, perhaps equalling that of Tezeuco, though represented in our maps as of far inferior size. The fish is exquisite; and many Indians dwell in picturesque islets, occupied in fishing, or bringing to the capital in canoes fish, fruits, flowers, and pot-herbs. Mechoacan was formerly a kingdom, but the Spaniards have reduced it into a bishopric, in which are about 200 towns of converted natives. As in this province there are scarcely any harbours that deserve the name of ports, the greatest part of the trade is carried on by land.

MECHOACAN, or *Valladolid*, a city of Mexico, in the province of Mechoacan, and a bishop's see, situated on a river near the W. side of a lake, which abounds with fish. It is large and well decorated; 108 miles W. of Mexico. N. lat. 20° 5'. W. long. 102° 11'.

MECHOACAN, *Mechoacanna*, called also *white jalap*, *white rhubarb*, and *American scammony*, a medicinal root, taking its name from a province of Mexico, from whence it is brought in thin transverse slices, like jalap, but larger and whiter. (See *JALAP*.) Mechoacan scarcely yields one-sixth part so much resin as jalap does. It is a species of bindweed. See *CONVOLVULUS*.

Mechoacan was first introduced about the year 1524, and used as a purgative before jalap, though the latter is now in more general use, as being found more efficacious: yet mechoacan is the milder and more gentle of the two, and on that account is preferable. The seat of its action is chiefly in the extreme parts; for which reason it is accounted

good in arthritic pains. It has the advantage of needing no preparation, or corrective; and of purging in its own proper substance, as it grows.

It purges serous humours from all parts of the body; and helps the dropsy, jaundice, the rheumatism, working with gentleness, and without griping; and, therefore, it is fit for weakly tender constitutions; but by reason that a larger quantity must be given than most people are willing to take, it is grown very much out of use. The dose in substance is from one drachm to two or more.

M. Boulduc found, by analysing it, that it contains twelve times as much salt as resin; but neither the saline nor resinous extract purge so freely as the substance, even though taken in larger doses; nor do they even purge so easily.

In the choice of mechoacan, prefer those pieces which are the brownest within, and whose substance is the closest, and most compact.

MECKENHEIM, in *Geography*, a town of France, in the department of the Rhine and Moselle, seated on the Erft; 7 miles S.S.W. of Bonn. N. lat. 50° 40'. E. long. 6° 57'.

MECKLENBURG, a town of the duchy of the same name, anciently the capital of the Obotrites, and called by some old historians, probably on account of its extent, "Megapolis." Formerly it contained three convents, and in 1058 a bishopric was founded. Since the founding of Wismar, it has sunk into a village; 2 miles S. of Wismar.

MECKLENBURG, *Duchy of*, might formerly be said to consist of three parts, *viz.* Schwerin, Güstrow, and Strelitz. But now only those of Schwerin and Strelitz are preserved, and the duchy of Mecklenburg Güstrow has fallen to the house of Schwerin, and, becoming incorporated with it, has lost its distinctive name. Wismar, which was formerly ceded to the Swedes, was afterwards purchased of the king of Sweden, and now belongs to this branch of the house of Mecklenburg. This principality is bounded on the N. by the Baltic, on the E. by Pomerania, on the S. by Brandenburg, and on the W. by the territory of Lubeck and principality of Luneburg. When the Vandals, in a considerable number, quitted this country in the fifth century, the Wends occupied their habitations, and became intermixed with the inhabitants that remained. Of these Wends, the most considerable tribe was that of the Obotrites, which had its own particular princes. From these descended Prebislau, who, in the 12th century, embraced the Christian religion, and rebuilt Mecklenburg, the ancient capital of the Obotrite princes, and took his name from it. His son, Henry Borwin, was father of two princes, one of whom, *viz.* John, was the founder of the Mecklenburg line, and the other, *viz.* Nikolot, that of Wenden: but when this latter became extinct, the principality of Wenden devolved to the Mecklenburg branch, which was raised to the dignity of duke by the emperor Charles IV. At the peace of Westphalia, in 1648, Wismar was ceded to the Swedes; but the dioceses of Schwerin and Ratzeburg were converted into temporal principalities. The Güstrow line failed, and, after some disputes, a compromise took place at Hamburg in 1701, on condition that the principality of Güstrow should be added to that of Schwerin, and that the principality of Ratzeburg, with some other territories, should be annexed to that of Strelitz. At the same time, the right of primogeniture, and the lineal succession, were established in both houses, and the compact was ratified by the emperor Leopold. Two lines of the dukes of Mecklenburg are still subsisting. The Schwerin line commenced in duke Frederic William; and the Strelitz line commenced in duke Adolphus Frederic II. The annual revenues of the Schwerin line are considerable; and they were formerly rated

rated at 300,000 six-dollars *per annum*. The duke of the Mecklenburg Strelitz line is said to receive about 126,000 six-dollars. The two duchies are divided into three circles, *wiz.* Mecklenburg, Wenden, and Stargard.

The accounts of the soil and produce of this country are various and contradictory, even among the Mecklenburgers themselves. According to the remonstrance of the nobility in 1718 to the imperial court against the contribution exacted from them, the country was represented as full of lakes, which were almost wholly unproductive, and as abounding with heaths, moors, woods, fens, and quarries. The soil was said to be sandy, and capable of producing only a small quantity of rye and oats, and the pastures and meadows afforded but poor food for their sheep. The arable lands, even when well manured, produce for the most part only barley, and very little wheat. The account given by Clavier and Frank, who have described the country, is very different. About $\frac{1}{3}$ th of the country, they say, is sandy, but the worst of the sandy land produces excellent rye, and, when suffered to lie fallow, affords good sheep-walks; but the country in general is represented as incomparable, and not exceeded by Pomerania or Holstein. When well tilled and dunged, it yields barley and wheat, generally five, six, or eight-fold. The country is interspersed with delightful eminences, pleasant and profitable woods; nor is it destitute of good fruit trees. Several forests have been afforted, fens drained, and, together with the moors and quarries, improved into arable and pasture land. The commons and meadows, not inferior to those of Holstein and Pomerania, afford grass in such plenty, that the country exports annually some thousands of cattle: the lakes and rivers, by their abundance of fish, yield large revenues.

The principal rivers are the Elbe, Stor, Reckenitz, and Havel. In both duchies, exclusive of Rostock, are 45 great and small cities. The inhabitants of both duchies are Lutherans. In the country also there are some congregations of Calvinists; and in Schwerin the Roman Catholics are permitted the free exercise of their worship. The towns have German schools, and Rostock has an university. The country is not destitute of woollen manufactures, tanners, leather-dressers, tobacco-spinners, and other trades. The exports of the country are corn, flax, hemp, hops, wax, honey, cattle, butter, cheese, wool, and several kinds of wood.

MECKLENBURG, a county of Virginia, bounded S. by the state of North Carolina; containing 8332 free inhabitants, and 8676 slaves.—Also, a county of North Carolina, in the district of Salisbury, bounded S. by the state of South Carolina; containing 10,317 inhabitants, of whom 1931 are slaves. Its chief town is Charlotte.

MECKLEY, a country of Thibet, occupying the space between Bengal and China, is bounded on the E. by China; on the S. by Ava, or the Birman empire; and on the W. by thick forests, which separate it from Bengal; it is about 350 miles in length, and 170 in breadth, subject to the king of the Birman empire. N. lat. $22^{\circ} 30'$ to $27^{\circ} 20'$. E. long. $93^{\circ} 20'$ to $98^{\circ} 40'$. See **ARRACAN**.

MECKMUHL, a town of Wurtemberg, on the Jaxt; 32 miles N.N.E. of Stuttgart. N. lat. $49^{\circ} 20'$. E. long. $9^{\circ} 23'$.

MECOBANISH, a lake of Canada. N. lat. $48^{\circ} 58'$. W. long. $83^{\circ} 45'$.

MECON, or **MENAN**, a large river of Asia, which rises in the mountains of Thibet, between the 34th and 35th degrees of N. latitude, and pursuing a southerly course bearing eastward, it passes through the Chinese province of Yun-nan, the kingdom of Laos, Cambodia, &c., and runs

into the Eastern sea, about 200 miles S. of the city of Cambodia. At first this river is called "Kion-long," and retains this name till it enters Laos, when it takes the name of Mecon; when it enters Cambodia, it receives the name of the country, till at the city of Cambodia, it separates into two branches, the eastern of which is called Cambodia, or the Japanese river, and the western Oubequeme.

MECONIUM, *Meconium*, from *popus*, poppy, in *Pharmacy*, is the juice of the heads or capsules of poppy, or papaver somniferum drawn by incision, and dried.

Opium differs from the meconium, which, by the ancients, was made of the expressed juice or decoction of the poppies, and it was deemed by them much more inactive in its operation than the opium. See **OPIMUM**.

The college of London directs an extract of white poppy to be prepared by decoction of the poppy capsules in water, and subsequent inspissation. For this purpose, take a pound of white poppy capsules bruised, and a gallon of boiling water. Macerate for 24 hours; then boil down to four pints, strain the hot liquor, and evaporate it to a proper consistence. This differs from opium, which is believed to be the concrete milky juice which exudes on making incisions into the fresh capsules, though probably some additions are made to it. Six grains of this extract are about equivalent to one of opium; but much of the comparative narcotic power of the plant itself may depend upon the influence of climate. The seeds are first to be separated from the capsules, for they produce no narcotic effect; they yield oil and mucilage, and readily rub into an emulsion.

A decoction of poppy, decoctum pro fomento, P. L. 1787, fofus communis, P. L. 1745, is thus prepared: take of white poppy capsules bruised four ounces, and of water four pints; boil for a quarter of an hour and strain. For various purposes, especially fomentation, advantage is derived from the solution of the narcotic matter contained in poppy heads; this may, therefore, be considered as an useful addition, and as reducing into form a decoction in very common use.

MECONIUM is also a black thick excrement, gathered in the intestines of a child during the time of gestation.

In colour and consistence it resembles pulp of cassia. It is also thought to resemble meconium, or juice of poppy; whence it takes its name. See **INFANT**.

MECRAN, or **MERKAN**, in *Geography*, a large province of Persia, extending to the Indian deserts, is bounded on the N. by Segeltan and Candahar; on the E. by Hindoostan; on the S. by the Indian sea; and on the W. by Kerman. This is the ancient Gadruftan, or Gedrosia. A chain of mountains crosses it, and divides it into two almost equal parts. This province has been always unfertile, and full of deserts; and classical geography, says Pinkerton, here presents only one mean town, called Pura, probably Borjian, on the most W. frontier. The extensive sea-coast on the Indian ocean, far from being the seat of commerce, scarcely presents one harbour, being almost an uniform line of sterility, inhabited by Arabs, like most of the southern coasts of Persia, which are divided by mountains and deserts from the fertile and cultivated land. Travellers in their journies are often stopped, and sometimes overwhelmed by deep and moving sands. In this province water is scarce, and it has few rivers. The capital is Kidge.

MECRINHOS, a town of Portugal, in the province of Tras los Montes; 24 miles S.E. of Mirandela.

MECZARA, a town of Africa, in the kingdom of Tambut.

MEDA, a town of Portugal, in the province of Beira; 20 miles N.E. of Pinhel.

MEDACO, a town of Africa, in the country of Meetka. N. lat. $14^{\circ} 30'$. E. long. $23^{\circ} 20'$.

MEDAL, MEDALIA, a small figure, or piece of metal, in form of a coin, destined to preserve to posterity the portrait of some great man, or the memory of some illustrious action.

Scaliger derives the word from the Arabic *methalia*, a coin whereon is impressed the figure of a human head. Menage and Vossius rather derive it from *metallum*. Du Cange observes, that the obolus was anciently called *medalia quasi medietas nummi*; as being half of another coin.

Medals may be distinguished by the metal of which they are made; which is commonly one of the three metals, *aurum*, *argentum*, and *æs*, signified by the three A's, which, on several coins, are placed after the name of the mint-master, viz. gold, silver, and copper, or brass.

The most usual purity of coined gold amounts to about 22 carats, two carats being deducted from the standard of the utmost purity, which is fixed at 24 carats, and consisting of alloy. See COIN.

The most ancient gold coins existing, those of Lydia and other states in Asia Minor, are not of the purest gold. Many of the earliest coins seem to be formed of the metal anciently called "electrum;" and consisting of gold and silver. But when Philip of Macedon coined the first gold of Greece, procured from the mines of Philippi in Thrace, the art of refining gold had attained great perfection, for his coins are of the utmost purity. They are rivalled, however, by those of his son Alexander, and of other princes and cities within a few centuries of that age. The gold coins of the Egyptian Ptolemies are 23 carats three grains fine, with only one grain alloy. The Roman gold coinage is very pure from the earliest times, and remained in this state till the reign of Severus. Pliny says, that most gold was found mixed with silver; of which the latter amounted to one-fifth. The metal was called "electrum." The most ancient silver is, like the gold, less pure than that of succeeding time, and this was particularly the case with that of the Greeks. The Roman silver was rather inferior to the present standard, even from the beginning; but in the time of Severus very bad silver appeared, and continued till that of Diocletian. The brass of the ancients, when pure, which is rather uncommon, consisted of two kinds; the red, or what the ancients called Cyprian brass, which we call copper, and the yellow, or brass. As medals of these metals are generally covered with patina, the difference has not excited attention; though in Roman coins brass was double the value of copper; and the Greeks, it is supposed, followed the same rule.

The ancients had also numerous coins made of mixed metals. The first mixture was that of gold and silver, and called "*Electrum*;" which see. The next metal of value was Corinthian brass, which was employed in the fabrication of vases and other ornamental toys; but it does not appear, according to Mr. Pinkerton, that they ever struck a single medal in this metal. The real fact is, that the coins, which some medallic authors have called Corinthian brass, are only struck as a modification of common brass. The zinc which is mingled with the copper in the furnace for the manufacture of brass, gives it a great variety of hues in proportion to the quality of the zinc, or of the copper. The best and finest of these hues belongs to what is now termed "Prince's metal," which seems to have been that which the first medallists called Corinthian brass. Of Egyptian coins, struck under the Roman emperors, some were at first of tolerable silver; but by degrees they degenerated into a metal, called by the French Medallic writers

"Potin," being a mixture of copper and tin, with a little silver. These coins are remarkably thick; but many of them are elegantly executed, in a peculiar style, with uncommon reverses. There are, likewise, brass coins of Egypt, of three sizes, from the earliest Roman emperors there, and of a different fabrication. Some coins of that which is called large brass, are of the mixtures now called pot-metal and bell-metal. After the time of Valerian and Gallienus coinage of brass, with a small addition of silver, is that authorized by the state, being that of the "denarii aërii." The coins of lead or copper, plated with gold or silver, are those of Roman forgers. Coins have been found in lead of undoubted antiquity. Some such of Tigranes are mentioned as genuine by Jobert; but they are now well known to be forgeries. An ancient writer informs us, that tin money was issued by Dionysius, one of the Sicilian tyrants; but no such coins have been found. In Rome leaden coins must have been pretty ancient, for Plautus mentions them in one or two passages of his plays; and a few imperial ones have been found, but they are chiefly trial-pieces, in order to enable the artist to judge of the progress of the dye. Others are those which have been plated by forgers, but the covering worn off.

It has been said that there are also some medals composed of two different metals, not by melting them together, but either by plating over brass or iron with silver; a sort of false money, which had its rise in the triumvirate of Augustus; or by laying a rim of a different metal round the edge of a medal. Those of the latter sort are called by antiquaries *contorniatæ*, from the French *contour*, which signifies the outline that defines a figure. See CONTOURNIATED.

It is considered as a certain rule in this science, says Pinkerton, that none of the ancient money was cast in moulds, except the most ancient and very large Roman brass, vulgarly called weights, and other Italian pieces of that sort. All other cast coins are forgeries of ancient or modern times: for this was a manœuvre of the ancient forgers, as we learn from several Roman moulds which have been found, and which have led the unskilful to imagine that the ancients first cast their money in dyes, and then stamped it, to make the impression more deep and sharp. Dr. Jennings, in his "Introduction to the Knowledge of Medals, &c." 1764, 12mo., has fallen into this mistake, besides several others which are noticed by Mr. Pinkerton. The ancients, though strangers to the art of impressing legends upon the edge of their money, like the "*DEUS ET TUTAMEN*" upon our crown pieces, and to the fine indentation observable on our gold, yet knew something of crenating the edges of their coin. This they did by cutting out regular notches on the edges. Some of the Syrian coins, and of the Roman consular, with a few other early ones, are ornamented in this manner. The former were cast in this shape, then struck; the latter was done by incision to prevent forgery, by shewing the inside of the metal. They were anciently called "*ferrati*," and Tacitus says, that the Germans preferred them to other Roman coins. But this was also imitated by the old forgers; and Mr. Pinkerton has in his possession a serrated consular coin, of which the incisions, like the real, are plated with silver over copper.

Medals may again be distinguished by their different sizes. The size of the ancient medals is from three inches to one-fourth of an inch in diameter. Those of the larger size or volume are called *medallions*. The others, which are very various, are ranked into three classes, viz. large, middle, and small; and the class is determined, not so much by the breadth and thickness of the medal itself, as by the size of the

MEDALS.

the head that is stamped upon it. The shape of medals is rather roundish than perfectly round. No Roman or Etruscan coins have been found of the globular form, or indented on the reverse, like the early Greek. The first Greek coins are small pieces of silver, while the Roman are large masses of copper. The former are struck; the latter are cast in moulds.

MEDAL, the Parts of a, are the two sides; one whereof is called the *face, head, or obverse*, the other the *reverse*.

On each side is the *area*, or field, which makes the middle of a medal; the *rim*, or border; and the *exergue*, which is beneath the ground whereon the figures represented are placed. (See **EXERGUE**.) On the two sides are distinguished the *type*, and the *inscription* or legend. The *type*, or device, is the figure represented; the *legend* is the writing, especially that around the medal; though, in the Greek medals, the inscription is frequently in the area. See **LEGEND**.

What we find in the exergue is frequently no more than some initial letters, whose meaning we are usually unacquainted with; though sometimes too they contain epochs, or words that may be accounted an inscription. The exergue contains sometimes the date of the coin, expressing in what consulship of the emperor it was struck: as *cos III.* upon the reverse of an Antoninus. Sometimes it signifies the place where it was struck, and to which the coin properly belonged, as *S. M. AL.* for *signa Moneta Alexandria*, upon the reverse of a Licinius. Sometimes the name of a province, the reduction of which the medal is designed to celebrate; as *Judæa* in the reverse of a Vespasian.

On the face of medals we have commonly the portrait of some great and illustrious person; usually, if not always, in profile. The coins of the kings of Macedon are the most ancient of any yet discovered on which portraits are found; and Alexander I., who began his reign about 500 years B.C. is the earliest monarch whose medals have yet been discovered. Then follow those kings and queens who reigned in Sicily, Caria, Cyprus, Heraclea, and Pontus. To these succeeds the series of kings of Egypt, Syria, the Cimmerian Bosphorus, Thrace, Bithynia, Parthia, Armenia, Damascus, Cappadocia, Paphlagonia, Pergamus, Galatia, Cilicia, Sparta, Præonia, Epirus, Illyricum, Gaul, and the Alps. This series extends from the time of Alexander the Great to the birth of Christ, comprehending a period of about 330 years. The last series of ancient kings descends to the fourth century, and includes some of Thrace, the Bosphorus, and Parthia; those of Commagene, Edessa or Osrhoene, Mauritania, and Judæa. The portraits of the kings above enumerated are found on medals struck with Grecian characters.

The Roman emperors present a most distinct series from Julius, the first of them, to the destruction of Rome by the Goths, or even to a much later period, if the coins after this were not so barbarous as to destroy the beauty of the series while they add to its perfection. Of modern coins many proper serieses might be formed, consisting of the kings and other potentates of the different countries. Medals of illustrious men in modern times are not likewise wanting to form a collection.

The kings, upon Greek coins, have generally the diadem, without any other ornament. The side face is always preferred; though upon very ancient Greek coins of cities, and Roman consular coins, full faces are found of amazing relief and expression. Sometimes several heads are found on the same coin, either impressed on both sides, or only upon one. Thus the beautiful gold coin of Ptolemy Phi-

ladelphus, king of Egypt, bears his own head and that of Arsinoë, his queen, on one side; and those of his father and mother, Ptolemy I. and Berenice, on the other. Coins are found also of Antioch and Cleopatra, Nero and Agrippina, Agrippina and Germanicus, and many others, both Greek and Roman. Sometimes two or more heads are found upon one side, while the other bears a reverse in the usual way. These heads are either *adverse*, that is, opposite to each other, face to face; or *joined*, and both looking one way. Of the adverse are coins of Licinius, father and son, and others. Joined heads are found on the finest Greek coins, as in that of Ptolemy above-mentioned, and in the Roman are Commodus and Marcia his concubine, and others. Sometimes real portraits are joined with ideal ones, as Carausius and Apollo, Posthumus and Hercules, &c. Sometimes three heads are found upon one side, as in that of Valerian, with his sons Gallienus and Valerian, &c. All such coins are very rare and valuable.

As for the ornaments of portraits, the chief is the diadem, or "vitta," which was a ribbon worn about the head, and tied in a floating knot behind, anciently the simple, but superlative, badge of kingly power. It is observable upon the Greek monarchic medals, from the earliest æra to the last; and is almost an infallible sign of the portrait of a prince. In the Roman coins it is seen on the consular one with Numa and Ancus; but never after, as Mr. Prokerton apprehends, till the time of Licinius.

The Romans had such an abhorrence of this badge of kingly distinction, that their emperors had, for two centuries, wore the radiated crown, peculiar to the gods, before they dared to assume this tyrannic badge. However, in the family of Constantine the diadem became common, but divested of its ancient simplicity; being ornamented on either side with a row of pearls, and various other decorations. The radiated crown, at first, as in the posthumous coins of Augustus, a mark of deification, was, in little more than a century after, put upon most of the emperors' heads in their several medals. The crown of laurel, at first the honorary prize of conquerors, was afterwards commonly worn, at least in their medals, by all the Roman emperors from Julius, who was permitted by the senate to wear it always, in order to hide the baldness of his forehead. In the lower empire, the laurel is often held by a hand above the head, as a mark of piety. Agrippa appears on his coins with the rostral crown, a sign of naval victory or command, being made of gold, in resemblance of prows of ships tied together. He is likewise seen with the mural or turreted crown, the prize of first ascending the walls of an enemy's city. The oaken, or civic crown, is frequent on reverses, as of Galba and others; and was the badge of having saved the life of a citizen, or of many citizens. (See **CROWN**.) Besides the diadem, the Greek princes sometimes appear with the laurel crown. The Arsacidæ, or kings of Parthia, wear a kind of fash round the head, with their hair in rows of curls like a wig. Tigranes, and the kings of Armenia, wear the tiara. Xerxes, a petty prince of Armenia, appears on a coin in a conic cap, with a diadem around it. Juba, the father, has a singular crown like a conic cap, all hung with pearls.

The successors of Alexander assumed different symbols of deity on the busts of their medals; such as the lion's skin of Hercules, surrounding the head of the first Seleucus; the horn placed behind the ear, an image of their strength and power, or of their being the successors of Alexander, called the son of Jupiter Ammon; the wing, placed in like manner behind the ear, symbolic of the rapidity of their conquests,

MEDALS.

quests, or of their descent from the god Mercury, &c. Pyrrhus, as Plutarch informs us, had a crest of goat's horns to his helmet; and the goat was a symbol of Macedon. The successors of Alexander might take this badge on that account. The helmet also appears on coins, as in those of Macedon under the Romans, which have Alexander's head, sometimes covered with a helmet. Probus has the helmet: and Constantine I. has helmets of different forms, curiously ornamented.

The Greek queens have the vitta or diadem. Most queens of Egypt have the sceptre. The Roman empresses never appear with the diadem, the variety of their head-dresses compensating the want of it. The remarkable part of the Roman head-dress among the ladies was the "Sphendonæ," or sling, on the crown of the head, which was of gold, and so prominent, as to be even remarkable on a coin. Sometimes the bust of an empress is supported by a crescent, denoting that she was the moon, as her husband was the sun of the state. There are other symbolic ornaments of the head observable on some Roman coins. Such is the veil, or rather toga, drawn over the head, and seen on the busts of Julius Cæsar, when Pontifex Maximus, and others. Latterly the veil was only a mark of consecration, and is common on coins of empresses, as Faustina and others. In the coins of Claudius Gothicus, it is first found as a mark of the consecration of an emperor; and it was continued in those of Constantian I., Maximian I., and Constantine I. These coins, says Mr. Pinkerton, rank with those that are valuable for their rarity.

The "nimbus," or glory, now peculiar to the saints, was formerly applied to emperors. A nimbus appears round the head of Constantine II., in a gold coin of that prince, and of Flavia Maxima Faustina, in a gold medallion; and of Justinian in another. But the idea is as ancient as the reign of Augustus. Havercamp gives a singular coin, which has upon the reverse of the common piece with the head of Rome, *URBS ROMA*, in large brass. Constantine I., sitting amid victories and genii, with a triple crown upon his head for Europe, Asia, and Africa: legend *SECURITAS ROMÆ*. This medal, says Pinkerton, might haply have afforded a curious argument, in an ignorant age, for Constantine's donation to the pope, and for the papal triple crown. But in fact the universal spiritual power of the pope was totally unknown till the 12th century; before which time his election was obliged to be confirmed by the exarch of Ravenna, and afterwards by the emperor of Germany; and his temporal power is so late as the beginning of the 16th century, only commencing in the crimes of Borgia. The bust alone is generally given on ancient coins; but sometimes half the body, or more; in which latter case the hands often appear, with tokens of majesty in them. Such is the globe, said to have been introduced by Augustus, to express possession of the world; the sceptre, sometimes confounded with the consular staff; the roll of parchment, symbolic of legislative power; and the handkerchief, expressing that of the public games, where the emperor gave the signal. Some princes hold the thunderbolt, shewing that their power on earth was equal to that of Jupiter in heaven. Others hold an image of victory.

The reverses of medals contain figures of deities at whole length, with their attributes and symbols; public buildings and diversions; allegorical representations; ceremonies civil and religious; historical and private events; figures of ancient statues; plants, animals, and other subjects of natural history: ancient magistracies, with their insignia; and, in short, almost every object of nature or art. Some reverses bear

the portrait of the queen, the son, or the daughter of the prince who appears on the obverse. Such are highly esteemed by antiquaries, not merely because coins stamped with portraits on both sides are valuable, but because they identify the personage on the reverse to have been the wife, the son, or the daughter, of such a particular prince, and thus help in the adjustment of a series. Some medals with two portraits are very common; such are Augustus reverse of Caligula, and M. Aurelius reverse of Antoninus Pius. The reverses of the Roman coins have more of art and design than the Greek; but the Greek have more exquisite relief and workmanship than the other. In the very ancient coins, no reverse is found except a rude mark struck into the metal, as of an instrument with four blunt points, on which the coin was struck. Afterwards, by degrees, we see some little image of a dolphin, or other animal, inserted into one of the departments of the rude mark, or into a hollow square. Then follows a perfect reverse of a horse, or the like, with a slight mark, and at length without any mark, of the hollow square. Some ancient Greek reverses are struck in intaglio, not in cameo, hollow, not in relief. Such are those of Caulonia, Crotona, Metapontum, and some other ancient cities of Græcia Magna. These reverses sometimes bear the same type in intaglio, which the obverse has in cameo; and sometimes they are quite different. When complete reverses appear on the Greek coins, about 500 years B.C. they are of exquisite relief, minute finish, and beauty. The very muscles of men and animals are seen, and will bear inspection with the largest magnifier, as ancient gems.

Of Roman coins, the reverses are very uniform, the prow of a ship, a car, or the like, till about 100 years B.C., when various reverses appear on their consular coins in all metals. The variety and beauty of the Roman imperial reverses are well known. The medallist much values those which have a number of figures, as the "Puellæ Faustinae" which has twelve figures:—that of Trajan, "Regna adsignata," which has four:—the "Congiarium" of Nerva, with five:—the "Allocution" of Trajan, with seven; of Hadrian, with ten; of Probus, with twelve. Some Roman medals, to which no peculiar name has been appropriated by medallists, have small figures on both sides, as the "Apolloni Sancto" of Julian II. Others have only a reverse, as the noted "Spintriatii," which have numerals I. II. &c. on the obverse.

The figures of deities and personifications on the Roman coins, are commonly attended with their names, besides being distinguished with their attributes. These names, without an adjunct, are put down merely because it was necessary that the coin should have a legend. Thus, in a coin of Lucilla, Venus, though well known by the apple which she always holds in her hand, has nevertheless the name round her, *VENUS*, without any addition. But an adjunct is most commonly added, and this renders the insertion of the name very proper and necessary, as in the instance of a Neptune, with *NEPTUNO REDUCI*:—a Venus, with *VENERI VICTRICI*, and others similar. The like may be said of the coins with a figure of Modesty, *PUDICITIÆ AUGUSTÆ*; of Virtue, *VIRTUS AUGUSTI*, &c.; for it is the legend which appropriates the virtue to the emperor or empress, and thus leaves no doubt as to the meaning of the reverse.

In the Greek coins, a superior delicacy is observed by not expressing the name of the deity, but leaving it to the easy interpretation of fixed symbols. This remarkable difference is observable in the earliest coins of the two countries, on which only the bust of the deity or personification is given.

MEDALS.

The Romans have almost always the name, as *PIETAS*, *LIBERTAS*, &c., while the Greeks content themselves with giving Ceres with her wheaten garland; Jupiter with his mild countenance, laurel crown, and beard; Minerva with her helmet, &c. &c.

Mr. Pinkerton has given an account of the symbols found on the Greek coins, and also of those very few on the Roman, which are not immediately illustrated by the legend of the medal. The principal deities symbolized in the Greek coins, as divided into male and female, are as follow: 1. *JUPITER*, in the first rank of gods, occurring frequently on reverses of Alexander the Great, and easily known by his eagle and thunderbolt: when the bust only occurs on obverses of coins, it is known by the laurel crown, and placid bearded countenance. Jupiter Ammon is distinguished by the ram's horn twirling round his ear. 2. *NEPTUNE* seldom occurs on the coins of Greece; but when he appears, he is well known by the trident, or the dolphin, and is sometimes drawn by sea-horses. His bust has a trident behind. 3. *APOLLO* is frequently seen on the reverses of the Syrian princes, and is known by the harp, the branch of laurel, or the tripod; sometimes he has a bow and arrows. When the bust only occurs, he has a fair young face, and is covered with laurel; and in the character of the sun, his head is surrounded with rays. 4. *MARS*, often seen on Greek civic medals, is distinguishable by his armour, and sometimes by a trophy on his shoulders. The bust is known by the helmet and ferocious countenance. 5. *MERCURY* appears with the "caduceus," or wand twined with serpents, and the "marsupium," or purse, which he holds in his hand. He is delineated as a youth, with a small cap in his hand, and wings behind his ears and at his feet. The bust is known by the cap, which resembles a small hat, and the wings. 6. *ÆSCULAPIUS* is remarkable on account of his bushy beard, and his leaning on a club with a serpent twisted round it. He is sometimes seen with his wife Hygeia, or Health, and their little son Telesphorus, or Convalescence, between them. 7. The attributes of *BACCHUS* are the tiger, the satyrs around him, the "thyrsus," or rod twisted with ivy or vine, and the crown composed of one of those plants. His bust is known by the latter symbol, and by the diadem and horn. 8. The club, lion's skin, and sinewy strength, reveal *HERCULES*; with sometimes the addition of a cup, denoting that wine inspires courage, and the poplar tree, symbolic of vigour. He often appears as breaking the neck of the Nemean lion, by crushing it in his arms. His bust is common on the obverse of coins of Alexander the Great, and other princes, and those of Sicilian cities: it is that of a youth without a beard; with the lion's skin wrapped around it; and on the coins of Alexander has been erroneously taken for the portrait of that prince. He is sometimes drawn with a beard, and called Hercules; without it he is denominated the young Hercules. 9. *SERAPIS*, one of the fantastic gods of Egypt, is known by his bushy beard, and the measure upon his head. *APIS* appears as a bull, with a flower of the *lotos*, lotos, the water-lily of the Nile. Macrobius says it was a symbol of creation; and Janblichus says that Osiris was supposed to have his throne in it. (See *LOTOS* and *LOTUS*.) 10. *HARPOCRATES*, the god of silence, is known by the familiar token of putting his finger to his mouth. He has sometimes the "siltrum" in his left hand, which is a symbol common to most of the Egyptian deities. 11. *CANOPUS* is very common on the coins of Egypt, in the singular shape of a human head, placed upon a kind of pitcher. (See *CANOPUS*.) 12. To the above-mentioned symbolized gods we may subjoin the *ΙΕΡΑ ΣΥΝΚΛΗΤΟΣ*, and *ΙΕΡΟΣ ΔΗΜΟΣ*, the holy senate, and holy people, so

frequent on Greek imperial coins. These ideal persons are commonly seen in the same image of an ancient bearded head, crowned with laurel: sometimes both appear as youths.

Among the female deities, the first in dignity is, 1. *JUNO* known by the peacock, a bird sacred to her from the fable of Argus. As the goddess of marriage, she is veiled to the middle, and sometimes to the toes. Her bust is that of a beautiful young woman, sometimes without any badge, which sufficiently distinguishes her, as the rest of the goddesses have badges; and sometimes with a diadem. 2. The symbols of *MINERVA* consist in her armour, with a spear in her right hand, and the "argos," or shield with Medusa's head, in the other; an owl commonly standing by her. Her bust is distinguishable by the helmet, which she always wears: this is very common on the gold coins of Alexander the Great. 3. *DIANA* is manifest by the crescent, by her bow and arrows, and often by her hounds. The Ephesian Diana, common upon Greek imperial coins, appears with a number of "maamæ," being supposed the same with universal nature; she is supported by a couple of deer, and bears on her head a pannier of fruit. The bust of Diana is known by the crescent on her brow, and sometimes by the bow or quiver engraven on one side. 4. *VENUS* is declared by the apple in her hand, the prize of beauty. Sometimes she may be known by her total want of dress, without any other symbol. Her bust is distinguishable by her supreme beauty, and is often adorned with pearls around the neck. We may here mention that *CUPID* sometimes appears on the Syrian coins, in half-length, as the painters call it, and is known by his infancy and wings. 5. *CYBELE* has the turreted crown and lion; or is seen in a chariot drawn by lions. Her bust is known by the first mentioned attribute. 6. *CERES* has the torches in her hands, with which she is fabled to have gone in search of her daughter Proserpine. She has sometimes two serpents by her, and is sometimes drawn in a chariot by them. Her bust is readily known by the wheaten garland, and is most common on coins of Sicily, an island celebrated for its fertility. Her daughter, Proserpine, is also common with the name *KOPH*, or the *girl*. 7. *ISIS*, an Egyptian goddess, has the sistrum in her hand, and a bud, or flower, on her head, symbolic of the eternal bloom of the inhabitants of heaven. The flower is said to be that of the *αβροβιον*, or southern-wood; but most probably it is a species of amaranth. 8. *ASTARTE*, a Sidonian goddess, appears on a globe, supported by a chariot of two wheels, and drawn by two horses.

Mr. Pinkerton enumerates other deities that are less frequent on Greek coins; such are Saturn with his scythe, or his bust with a hook on those of Heraclea:—Vulcan's head, with his tongs:—Adranus, a Sicilian god, with his dog:—Anubis of Egypt, with his dog's head:—Atis, in the Phrygian bonnet:—Castor and Pollux, with a star on the head of each:—Dis, having an old face with dishevelled hair and beard, and a hook:—Flora, crowned with flowers, on coins of Marseilles:—Nemesis, with a wheel:—and Pan with small horns and brutes' ears. Some symbols are figurative of persons or circumstances: such are vases, with sprigs of plants issuing out of them, symbolic of solemn games:—the small chest, or hamper, with a serpent leaping out of it, exhibiting the mystic rites of Bacchus, coins with their image being called "Cistophori":—the anchor, on Seleucian medals, ascertaining their having been struck at Antioch, where an anchor was found in digging the foundation of the city, though at a considerable distance from the sea:—Apollo sitting upon a singular seat, resembling a hamper inverted, perhaps a tripod with a covering of net-work,

MEDALS.

work, on different coins of the princes of Syria:—the bee, a mark of Arilteus, son of Apollo and Cyrene, much worshipped in the isles of the Adriatic and Ægean seas:—the laurel of Apollo:—ivy and grapes of Bacchus:—the poppy of Ceres and of Proserpine:—corn of Ceres:—owl and olive of Minerva:—dove of Venus:—and torch of Diana, Ceres, and Proserpine. The *μυδρος*, *mudrus*, or conic stone, was a token of the Sun, of Belus, and of Venus.

The most remarkable symbols of countries and cities on Greek coins are the flowers of the pomegranate for Rhodes:—owl for Athens:—pegasus for Corinth:—wolf's head for Argos:—bull's head for Bœotia:—minotaur's head, and the labyrinth, for Crete:—horse's head for Phœnalis:—lion for Marseilles:—tortoise for Peloponnesus:—sphinx for Scio:—three legs joined for Sicily:—and a horse for Thessaly. The badge of Byzantium was the crescent, which appeared early on the coins of Byzantium, with the legend *ΒΥΖΑΝΤΙΝΗ ΣΩΤ.*; the preserver of Byzantium. The occasion was this; when Philip of Macedon besieged Byzantium, and was proceeding to storm it in a cloudy night, the moon shone out, and discovered his approach, so that the inhabitants observed and repulsed him. The Turks, upon entering Constantinople, found this ancient badge in many places; and suspecting some magical power in it, assumed the symbol and its power to themselves; so that the crescent is now the chief Turkish ensign. (See *CRESCENT*.) The bull is very frequent on Greek coins, signifying, as Mr. Pinkerton suggests to be the most probable opinion, a river, on which the country or town was situated: accordingly, the river Acheilus is called *Βουκεφαλος*, or bull-headed, by Sophocles in *Trachin*, v. 13: and Cephissus is said to have *ταυρομορφου ομοια* *Κηφισου παλαιο*; by Euripides, *Ion*, v. 1261. The Latin poets speak of the horns of rivers; thus Horace describes the Aufidus, “*Sic tauriformis volvitur Aufidus.*” The bull was a token of fertility, but the horns seem to allude to the force of the stream, &c. See *CORNUCOPIA*.

On Roman coins the deities and personifications have not only attributes, but their names likewise in the legend of the medal, so that it is not necessary to dwell upon the explanation of them. Some, however, it may not be improper to mention. On the reverses of Roman colonial coins, easily distinguished by their rude fabric, and the name of the colony on them, commonly beginning with *COL.*, when an ensign stands alone, and without any persons, it shews a colony drawn from one legion; but when the ensigns or banners appear in the like circumstances, they evince the colony to have been drawn from as many legions as there are ensigns. A bull on these coins often represents Apis as a symbol of strength and security: such was, probably, the bull upon the reverse of the common coin of India, with two stars over him, and the legend *SECURITAS REIPUB.* The caduceus marks peace and concord; the *cornucopia*, abundance; the pontifical hat, the priesthood. They all appear upon a reverse of Julius, and are symbols of the concord of the empire, and the plenty which attended his power: the last symbol merely denotes that Cæsar was Pontifex Maximus. The “*parazonium*” on Roman coins was a baton of command, and not a pointless dagger, as it has been described by many antiquaries. In later times the globe on an altar, with three stars, is supposed to typify the world preserved by the gods for the three sons of Constantine I. The fort and the gate are symbols of security. The altar is a well-known mark of piety: the tripod was a portable altar, used in temples for liquid offerings, as the altar was for solid sacrifice. A dolphin is sometimes twined among the legs of the tripod; the dolphin was sacred to Apollo, as appears from Servius on the 3d Æneid. The “*lectist-*

terna” also appear on medals. (See *LECTISTERNIUM*.) The instruments of sacrifice appear on many Roman coins: such are the “*secespita*,” or oblong hatchet, or large knife for killing the victim:—the “*asperforium*,” a vessel for holy water, with which the priest sprinkled the assistants:—the “*simpullum*,” or vessel for pouring wine on the sacrifice:—the “*patina*,” or “*patera*,” a dish for the fat, and other portions sacred to the gods:—and the “*acerra*,” or little coffer for incense. The “*lituus*,” or wand twisted round at the top, somewhat like the episcopal staff, is a badge of the augurship, as the “*apex*,” or cap with strings, and terminating with a tuft, is of the pontificate. (See *LITUUS*.) The “*thensa*,” or divine chariot, which carried the image of a deity in sacred processions, (improperly termed “*carpentum*” by some,) is a badge of consecration of an empress; as is also the peacock, which was the bird of Juno, the queen of heaven. These sometimes appear without the legend “*consecratio*,” as the *thensa* on a coin struck under Tiberius for the consecration of Livia, the wife of Augustus, called Julia, *S. P. Q. R. IULIÆ AVGVST.*; and the peacock on that most rare gold coin of Julia, the daughter of Titus, the front of which has her bust, *IULIA AVGVSTA*, and the reverse a peacock, *DIVI TITI FILIA*. The eagle is the sign of consecration of an emperor.

The palm-tree, on both Greek and Roman coins, is symbolic of Phœnicia, where that tree flourished; as the silphium is of Cyrene, from the earliest times down to those of the Roman empire. Pinkerton's *Essays*, vol. i.

The titles are generally found upon the face of the medal. These are titles of honour, as *Imperator*, *Cæsar*, *Augustus*, given to all the Roman emperors after Octavianus; *Dominus*, first assumed by Aurelian, and used by his successors (see *DOMINUS*): other titles are ascribed to particular persons on account of their virtues, as *Pius* to Antoninus, assumed also by Commodus, with the addition of *Felix*; *Pater Patræ*, first bestowed on Cicero for discovering and defeating the conspiracy of Cataline, and afterwards assumed by the emperors; *Iustus*, the title of Pescennius; *Beatissimus* and *Felicissimus* of Dioclesian; *Optimus* and *Clemens*, decreed to Trajan by the senate; *Maximus*, assumed by Constantine; and *Invictus*, by Victorinus. In the lower empire, *Stauracius* first, and then Michael Ducas, and others, assumed the proud addition of *ΒΑΣΙΛΕΥΣ*, or king; which was followed by that of *ΔΕΣΠΟΤΗΣ*, or despot. Other titles are the names of offices; as *cos.* for consul, with a number annexed to it, signifying how many times the person had been thus elected: *Tribunitia potestas*, with the year of the tribuneship commonly expressed after the title, as *TRIB. POT. X.* or *XVI.* &c. The office of *Pontifex maximus*, expressed among their titles, from Augustus to Constantine, by whom it was refused: it was re-assumed by Julian, and laid aside by Gratian. Julius Cæsar assumed the title of *Dictator perpetuus*; Claudius, that of *Censor*; and Domitian made himself *Censor perpetuus*.

The large early copper coins only bear *ROMA* in the reverse. Afterwards we find the names and titles of the *Quæstor* or Director of the public treasury, the *Triumviri* who managed the mint, the *Prætor*, the *curule Edile*, the *Edile* of the people, the *Præfect* of the city, the *Pontifex Maximus*, *Augur*, *Quindecimvir sacris faciundis*, *Flamen Martialis* and *Quirinalis*, *Septemvir Epulonum*, and latterly, *Triumvir Reipublicæ constituendæ*, and *ad Frumentum emundum*. Of the great magistrates out of Rome, who had moneys with them, in order, from bullion and the spoil of the enemies, to coin money for paying the troops engaged in foreign service, we have the names and titles of *Imperator*, *Proconsul*,

Proconsul, Proprator, Legatus, Legatus pro Pratore, Quæstor, Proquæstor, Legatus Classis, Triumvir Coloniae deducendæ, or reficiendæ sacris ædibus. All these titles appear on the reverse of what are called consular coins; while the obverse bears the head of a deity, generally without a legend. In time the magistrates put the head of some illustrious ancestor on the coins, with his name; as Numa, Ancus Martius, Quirinus or Romulus, Brutus, Alula; Caius Cælius Caldus, obverse of Caldes III. vir, and the like. This led the way to Cæsar, who first put his own head on his coins, when made perpetual Dictator; with the legend of names and titles on the obverse, and not on the reverse as before. The inscription VOT. V. MVLT. X. VOT. X. MVLTISAN. occurs on many reverses of Roman medals, and most commonly marked on a shield, or within a crown of laurel. This Du Cange interprets to refer to the artifice of Augustus, who pretended to lay down his power, and resume it for 10 years longer as at the request of the senate. This term, he says, was by succeeding emperors shortened to five; and solemn vows were entered into by their subjects for their safety to the end of that period; nay, that the double of that period might be allotted to their reign, again to be prolonged, on the wishes of their people, to a future date. This inscription is also found upon coins of Crispus, and other Cæsars, or heirs of the empire; and it hence appears, that the honour of such solemnities was also conferred on them, who created Cæsars. The "Vota Decennalia," as on coins of Pertinax and of Papianus, were only vows to perform the Decennalia, if the emperor should reign 10 years; whereas "Primi Decennales," or "Secundi Decennales," imply these games to have been actually performed; and the emperor to have reigned 10, or 20 years. On coins of Lucilla, Hadrian, Severus, Caracalla, and others, we find VOTA PVBLICA, with a sacrifice; shewing that the vows were undertaken, with that rite, as they were afterwards performed with solemn games and rejoicings. Coins of Constantine II., and of Constantian, only bear SIC. X. SIC. XX. to express the wishes of the people, that, as the emperors had happily reigned 10 years, so they might reign 20. There were also "Vota Quinquennalia" for the emperor reigning five years, and games called "Quinquennalia" performed when he had accomplished that period. From Aurelius Victor, in his life of Gordian III., it appears that Nero introduced this practice; which is mentioned by Tacitus, and by Lampridius in his life of Diadumenus. There were also "Vota Novi Anni," as appears from Spartian's life of Hadrian, and from Dio, l. 58; and there is a coin of Antoninus with S. P. Q. R. A. N. F. F. OPTIMO PRINCIPI, Senatus populûsque Romanus annui novum fastum felicem, &c. *i. e.* the senate and people of Rome wish a prosperous and happy new year to the best of princes. See LEGEND.

MEDALS, *Greek*, claim that place in a cabinet from their antiquity, which their workmanship might ensure to them, independently of that adventitious consideration. The invention of coinage, as we have elsewhere observed, is ascribed by Herodotus to the people of Lydia, upwards of 1000 years before the Christian era. The abbé Barthelemy, cited by Mr. Pinkerton, arranges the following stages of the progress of coinage. 1. Coins without any impression. 2. Those with a hollow indented mark or marks on one side, and impression in relief on the other. This class, it is suggested, seems to extend from about the year 900 before our era, to about 700. 3. Such as have an indented square divided into segments, with a small figure in one of the segments, the rest being vacant; and impressions on the obverse, as usual. These may extend to the year 600 B. C. 4. Those which are struck hollow on the reverse, while the obverse is

in relief commonly with the same figure; which coins may be considered as of equal age with those in the last class. 5. Coins in which a square dye is used, either on one or both sides. These were discontinued about the year 420 B. C. 6. Complete coins both in point of obverse and reverse. Some of these occur in Sicily, where this art was carried to a perfection unknown in any other country, so early as the time of Gelo, who began his reign in the year 491 B. C. Coins of most remote antiquity, say, Froelich, quoted by Pinkerton, may be distinguished by these infallible marks. 1. Their oval circumference, and globe swelling shape. 2. Antiquity of alphabet. 3. The characters being retrograde; or the first division of the legend in the common style, while the next is retrograde. 4. The indented square. 5. The simple structure of the mintage. 6. Some of the very old coins are hollowed on the reverse, with the image impressed on the front. 7. The dress, symbols, &c. are often of the rudest design and execution. The coins of Possidonia, Crotona, Sybaris, and two or three other cities, bear these marks of profound antiquity. Some Persian pieces, with the archer upon one side, and the hollow square upon the other; and several coins of the first kings of Macedon, are examples. In the British Museum, there is a medal of silver ascribed to Leobus, of this description. In a short time the Greeks assumed great elegance; and it is observed by Mr. Pinkerton, that innumerable of the medals of cities, which, from the character, we must judge to be of the highest antiquity, have a surprising strength, beauty, and relief, in their impressions. About the time of Alexander the Great, the art seems to have attained to its very highest perfection. Of the Greek medals, those of cities are the most ancient. The civic medals are generally stamped on the obverse, with the head of the genius of the city, or some favourite deity; while the reverse often presents some symbol used by the city, at the time when the piece was struck. The legend contains the initials, monogram, or whole characters of the name of the city. Some connoisseurs prefer the regal coins of Greece; others the civic. The former interest by their portraits; the latter by their variety. The former are perhaps more important to ancient history; and the latter to ancient geography. The civic coins are interesting, as they present us with a view of the customs, religion, &c. of ancient cities; they likewise afford a kind of political barometer of the wealth and power of each city and country. *E. G.* The numerous and beautiful gold coins of Cyrene, a country, from its remote situation, little known in history, afford sufficient proofs of its great power and wealth. The small civic coins of gold, electrum, and silver, struck in Asia Minor, are perhaps some of the earliest; though if we judge from workmanship, these coins are so exquisite, that the coins of Greece, from their rudeness, seem to claim priority of era; and Mr. Pinkerton suggests, that it is dubious whether Greece or Lydia first invented coinage.

The Greek monarchic coins are often of the same construction with the civic; only that they bear the name of the prince on the reverse; many such occur with the bust of some deity in front, for one which presents the image of the prince. The most ancient series is that of Macedon, commencing, as we have observed already, with Alexander I., who began his reign 501 years before our era. With Philip, the Macedonian coins begin to be beautiful. Those of Alexander the Great are wonderful. The head of Minerva on his gold, affords a variety of exquisite faces; and the coins of Alexander and his father, exceed all that were ever executed, except those of Sicily, Græcia Magna, and the ancient ones of Asia Minor. Sicilian coins are famous

MEDALS.

for workmanship, even from Gelo's time. The coins of the Syrian kings, successors of Alexander, almost equal his in beauty. Those of Antioch VI. are peculiarly exquisite, both for the beauty of the coin and that of the king. The Egyptian Ptolemies have fine relief, but do not equal the Syrian in delicacy and finish. The family coin of Ptolemy Philadelphus, before mentioned in this article, is extremely fine and interesting. There is a coin of Alexander, son of Neoptolemus, king of Epirus, with a head of Jupiter Dodonæus, crowned with oak, of miraculous workmanship, and thought to be done in Magna Græcia, when he came to assist the Tarentines. This has been engraven by Bartolozzi. Even the earlier Parthian coins of the Arsacidæ are worthy of the Grecian workmen, whose they are, as is evident from the Greek legends impress on them, in many of which these monarchs assume the title of ΦΙΛΕΛΑΗΝΟΣ, or lover of the Greeks. It is to the Greek coins that were struck before the Roman empire swallowed up the Greek cities and sovereignties, that the high praise bestowed by good judges upon the Greek mint, must be chiefly confined; for the Grecian imperial medals are not equal to the former, though they do not always yield to the Roman.

In the series of Grecian imperial coins, we meet with very uncommon portraits and reverses. In attention to the fair sex, the people of Mitylene, the chief city of Lesbos, and the birth-place of Sappho, have peculiarly distinguished themselves. Those Greek coins of cities, which have the head of an emperor or empress, are called Imperial Greek coins; but those which have no such impressions are classed with Grecian civic coins, though struck under the Roman power. Of imperial Greek coins none occur in gold; but there are those of silver of Antioch, Tyre, Sidon, Tarsus, Berytus, Cæsarea, and one or two other trading cities in that opulent and commercial region. Those of Antioch present, now and then, the genius of the city sitting, with the river Orontes flowing beneath her feet, as on coins of Syrian monarchs. Syrian silver coins sometimes bear the club of Hercules, the founder, or the famous Tyrian shell-fish, whence the Tyrian purple, our crimson, was derived. Sidon gives the car of Astarte, or a head of the goddess: Tarsus has sometimes only a monogram, expressing the name of the city. Cæsarea, in Cappadocia, abounds in silver of various sizes; and silver coins of Lycia appear to be of good work, and good metal; the reverse having two harps and an owl sitting on them. Silver coins of Gelon, a town of Sarmatia, much resemble the Syrian; and have the ΔΗΜΑΡΧ. ΕΕΘΥΣΙΑΣ, with an eagle holding a stag's foot. The Greek imperial brass coins are so abundant, that it is hardly necessary to specify any of them. Those of Antioch, generally with a Latin legend on the obverse, and Greek on the reverse, are so numerous as to furnish a series of almost all the emperors; being apparently struck for the purpose of paying the forces in the East. Those of Ceretapa, in Phrygia, are distinguished by their good workmanship, as also are those of Bithynia and Phrygia. On those of Tarsus are curious views of objects, almost in perspective; and there is a singular coin of Gangra in Paphlagonia, with a view of two castles and houses between them. This is in the late Dr. Hunter's collection. The coins of Egypt under the Roman emperors, being marked with Greek legends, range with the Greek imperial medals; they are remarkable for thickness, and baseness of metal. Those of the silver series are at first about the size of an half crown, but three times as thick; after the time of Commodus, they declined both in size and baseness, and became reduced to the size nearly of a sixpence, and the metal is only bad brass washed with silver. The silver coins of Egypt are not so well done from Augustus to Nero, as

afterwards. From Nero to Commodus, they are often admirable, and of a style of workmanship that can be called neither Greek nor Roman. The reverses are extremely various and singular, exhibiting the capricious religion and manners of the people. From Commodus the Egyptian silver gradually declines till the reign of Constantius I., when it ends. The series consists of 1000 coins, or more. Many scarce portraits of emperors and of empresses decorate the series. The Egyptian brass coins of the Roman period claim notice. Until Vespasian there are only two sizes, equal to the second and third Roman brass. Vespasian indulged the Egyptians with the privilege of issuing large brass, as used in Rome itself. All the Egyptian Othos, the most common coins of that prince in brass, are of the second size; and bear for reverse an head of Isis, or Serapis, with L.A. or year first. Some have names of towns, and in Dr. Hunter's cabinet, there is a fine one of Cebennutus in first brass, of Domitian, who appears decorated with a wheaten, as Gallienus does in Roman gold. On the brass coins of Egypt, a female figure, with part of a ship in her hand, and the Pharos behind, is very common, probably expressive of Alexandria. One of Antoninus Pius, in third brass, presents to us Isis sitting on the flower of the lotus. With this emperor very fine work begins in the Egyptian brass. The 12 coins of this prince, with the 12 signs are very curious, and published by Barthelemy, Mem. de l'Acad. xli. The last brass coins of Egypt, are of Marcia Otacilia Severa, wife of Philip the Elder, A.D. 244. The genuine brass coins of Egypt are thinner than the silver, and of a distinct fabric.

MEDALS, Roman. It was in the reign of Servius Tullus that the first Roman coins appeared, which were large pieces of brass, rudely impressed, only on one side, with the figure of an ox, a ram, or some other animal, whence, it is said, money was denominated "pecunia." These symbols were derived from the Tyrrheni or Etruscans, a people of Italy, originally Lydians. In process of time the impression of the *as* was changed to that of a bust of Janus, upon the front, and the prow of a ship on the reverse; and for more general use, pieces of inferior weight and value were coined. See **AS** and **MONEY**.

The Roman coins, considered as medals in a cabinet, comprehend the two grand divisions of *consular* and *imperial* coins. The Roman *consular* coins seldom or never bore the names or titles of consuls till towards the close; nevertheless they are not improperly called consular, because they were struck in the consular times of Rome. They are also called coins of families; and are always arranged alphabetically in families, according to the names which appear on them. The brass consular coins are rather uninteresting; as they consist chiefly of large unwieldy pieces, with types of insipid similarity. Few of them have any imagery or symbol. The large ancient pieces are generally kept in boxes apart, by those who are versed in them. (See **AS**.) The next coinage to that of brass was that of silver, which took place, according to Pliny, in the 485th year of Rome, that is, about 300 years after the first brass coinage, and 266 years B.C. The denarius was the first and the last form which it assumed, for the other sizes are so scarce, that it is certain very few were struck. (See **DENARIUS**.) Until the age of Julius no portrait of a living personage appears upon any Roman medal; Cæsar was indeed the first who assumed that high honour, and a competent judge asserts, that the plan of engraving on coins the names of great men and magistrates was only introduced about the time of Marius and Sylla. The reverses of some few consular medals are fraught with much erudition and curious matter. On a coin of the family of Æmilia, we have this legend, M. LEPIDUS PONT. MAX. TVIOR RE-

cus, and Lepidus appearing in the dress of a consul, and putting the crown on the head of young Ptolemy, whom his father had left to the tutorage of the Roman people. On the obverse is the turreted head of the city of Alexandria in Egypt, with ALEXANDRIA. In the late family there is a medal, with a youth on horseback, carrying a trophy, with this legend, M. LEPIDUS ANTORUM XV. P. F. P. T. A. T. I. T. I. U. S. H. O. S. T. I. U. M. O. C. C. I. D. I. T. C. I. V. I. M. S. E. R. V. A. V. I. T. Agrippa, L. Æmilius Paulus, on a coin of the same family, appears dedicating a trophy for his victory over Perseus, who, with his two children, stand by, their hands being tied behind their backs. Portraits of Bacchus, Jugurtha, the last Philip of Macedonia, the 11 and 2d Brutus, Metellus, Marcellus, Regulus, Sylla, Pompey, Cælius, and others appear on consular coins. Rome and Italy are personified; Victory crowns Rome; with other specimens of that fine personification afterward displayed on the imperial coins. Gold was first coined at Rome, 62 years after the application of the mint to silver. The general gold coin is the *Aureus*, which see. The consular coins, whose number is estimated at 200 in brass, and 2000 in silver, extend not to above 100 in gold, of which most are curious. The beautiful Pompey with his sons on the reverse, and the Brutus with his brother Lucius, commonly classed with imperial coins, should rank with the consular. Most of the gold consular coins are of great beauty and high value. Of consular medals father Joubert reckons about fifty or sixty of gold; two hundred and fifty of copper; and near a thousand of silver. Goltzius has described them in a chronological order, according to the *Falci Consulares*; and Urfinus has disposed them genealogically, according to the order of the Roman families. M. Patin has collected an entire series of them, in the same order with Urfinus; and only computes one thousand and thirty-seven consulars, which relate to one hundred and seventy-eight Roman families. M. Vaillant, and M. Morel, have also published on the same subject. See the sequel of this article. The Roman *imperial* coins claim our attention from a variety of considerations; and more particularly from the extent of the Roman empire, and from our own connection with it. The Roman coins may be called those of the emperors of Europe, and interest us like those of our own country. Some have distinguished the imperial coins into those of the *upper* and *lower empire*; the upper empire commenced under Julius Cæsar, and ended about the year of Jesus Christ two hundred and sixty; the lower empire comprehends near one thousand two hundred years; viz. till the taking of Constantinople. It is the custom, however, to account all the imperial medals, till the time of the Palæologi, among the antique; and yet we have no imperial medals of any considerable beauty, later than the time of Heraclius, who died in 641.

After the time of Phocas and Heraclius, Italy became a prey to the Barbarians; so that the monuments we have remaining of those two emperors, finish the set, or series of imperial medals. To these are added the medals of the lower empire, and of the Greek emperors; whereof a series may be made as low as our times, taking in the modern ones. M. Patin has made an ample collection of the imperial medals, till the time of Heraclius.

The Gothic medals make part of the imperial ones; they are so called, as having been struck in the times of the Goths, and in the declension of the empire, and favouring of the ignorance and barbarity of the age.

Cæsar, who begins the imperial series, was conqueror of Gaul; Claudius of Britain. As to the brass coinage it has been already observed, that at the time of Marius and Sylla, about 50 years before that of Cæsar, some elegance and variety commence in the Roman coinage. In the times of

Julius Cæsar this elegance was carried to a great height. In the family of Marcia, there is a beautiful *As*, with the heads of Numa and Ancus; the reverse Victory in a chariot, and the prow at her feet. Indeed it is only in the last named *As* that variety can be found. Sylla, as we are informed by Cicero, and by gold coins remaining, introduced great confusion into the coinage; and it is not improbable, that the brass had its share, by alteration of form and type. The imperial brass is of three sizes, *large*, *middle*, and *small*. The *large* brass form a series of surprising beauty and vast expense. In this series the various colours of the patina have the finest effect; and the great size of the portraits and figures compares to render it the most important of all the Roman coinage. It even exceeds the gold in value.

The series of the *middle* brass exceeds the former in number; but doth not present such elegance of work, or of type. Many coins are common in second brass, which have rare in brass; but very few examples occur to the contrary. Hence this series yields much to the former in price, as well as in dignity. However, many rare and curious coins occur in this series. There is a Tiberius, with this inscription on the reverse, TRIB. POT. XXVIII. A Gallienus, obverse with his head, bearing a laurel over a turret on his forehead, GENIUS P. N. reverse with this inscription ANT. URN. S. C. Coins of Paulina the elder are common in this size; but those without DIVA are very scarce, and always bear ANTONINI PII AUG.; a circumstance, which seems to indicate, that most of these coins were struck by her good husband, after her death. In the first and second brass there are many coins, which particularly interest us as Britons, because they relate to the history of this island. Such are the triumphal arch of Claudius, inscribed DE BRITANNIS, also occurring in gold and silver; the ADVENTUS AUG. BRITANNIE, and EXERC. BRITANNICUS of Hadrian; the coins of Antoninus Pius, Commodus, Severus, with a victory, VICTORIA BRITANN., but especially those personifying the country *Britannia*.

The *small* brass series abounds with curious coins. Till the times of Valerian and Gallienus, they are generally scarce; but afterward extremely common. In the former period portraits of the emperors are rare in small brass, but in the latter many are found which occur in no other series, as most of the usurpers, Zenobia, Vaballathus, and many others. All real brass coins have the s. c. till the time of Gallienus; as the senate alone had the power of striking brass, while the emperor himself had that of gold and silver. When the s. c. therefore is wanting, the coin was certainly once plated. With Pertinax A. D. 192, there is a temporary cessation in the small brass; nor after him do any princes occur in that series till Valerian, A. D. 254, excepting Trajanus Decius A. D. 250, only. After Valerian, the series is continuous, and common. The brass coinage declined in size from the time of Severus, and Trajanus Decius in vain attempted to restore it; and Valerian and Gallienus were forced to issue denarii ærei of billon, and small assaria. The series of large and of middle brass are of two fixed and known sizes; the former about that of our crown, and the latter of our half-crown, till after Severus they gradually lessen. But the small brass takes in all the parts of the *As*, and every brass coin not larger than our shilling in size belongs to this series. Our limits will not allow our enumerating the coins of this series, but we refer to Pinkerton's *Ess.* vol. i. p. 272. &c. The series in small brass extends from the beginning to the close of the Roman empire, nay, far into the Byzantine, closing with Constantine Pogonatus, A. D. 670.

The silver imperial coins are very numerous and various. This series is as complete as any, and of far cheaper purchase, very few emperors being scarce in silver. Most types

MEDALS.

even of the large brass and gold are found in the silver, which thus unites the advantages of all metals. Sometimes the silver and gold coins, as being of one size, are struck from the same die, as the young Nero, reverse a votive shield *EQUEST. ORDO PRINC. JUVENT.* and others. One of the rarest silver coins is that of Gneius Pompey, son of the great Pompey, in Dr. Hunter's collection. It is supposed to have been struck in Spain, before the battle of Munda, soon after which he was slain.

The imperial gold forms a series of wonderful beauty and perfection; but it is only attainable by men of princely fortunes. In these the workmanship is carried to the greatest height; and the richness of the metal surpassed by that of the types. As gold refuses rust, the coins are generally in the same state as they came from the mint. The number of Roman gold imperial coins may amount to 5000; the silver to 10,000; and the brass to 30,000. The whole of the different ancient coins may amount to about 80,000; but the calculation cannot be very accurate.

Before we close this account of Roman medals, the *colonial* ought to be mentioned. As Roman colonies were settled in various parts of the empire, their coins have sometimes Greek, sometimes even Punic legends; though generally that on one side of such is Latin. But those with Latin legends only are far more numerous. Some of these coins are elegant, though most are rude and uninteresting. The colonial coins only occur in brass; those in first brass are very rare till the time of Severus. They begin with Julius and Antony. The Spanish colonial coins cease with Caligula, who took away this privilege from Spain. The colonial coins of Corinth are the most various and beautiful; presenting triumphal arches, temples, gates, statues, baths, and figures of gods and goddesses. Other remarkable colonial coins are of Emerita, of Illice, of Tarraco. The coins of Cassandria in Macedon are generally small brass, with the head of Jupiter Ammon on the reverse, and furnish that series with many fine heads of emperors, with Latin legends, from Claudius to Severus, but always with the same reverse. Many scarce portraits are found in colonial coins of that size; as the two Agrippinas, Agrippa, Cæsar, Drusus Cæsar, Octavia Neronis, Cæsonia, Messalina, and others. It is remarkable, that while Spain had perhaps 50 colonies, Camalodunum is the only one in Britain of which there are coins. There is one of Claudius, reverse a team of oxen, *COL. CAMALODON. AUG.* The smallest imperial silver alone are quinarii, the gold being semisses and trientes, and the brass at first small parts of the As, and latterly only the half assarion. These, instead of being denominated quinarii, might, more properly, be called "minimi;" as including the very smallest coins of all metals and denominations. The Roman coins have had a most extensive spread; some of them have been found in the Orkneys; and they have likewise been found in numbers in the most remote parts of Europe, Asia, and Africa, at that time discovered.

As for the medals of other ancient nations, besides Greece and Rome, some notice should be taken of them; premising that by *ancient* coins, all preceding the ninth century, or age of Charlemagne, are meant; and all posterior to that period are *modern*. No coins are found which can even be imagined to belong to Assyrian, Median, or Babylonian kings. The oldest coins found in their empire are palpably Persian and similar to the Greek. The Phœnicians do not appear to have coined money, till after the Greeks had set the example. No Phœnicians were ever found of much antiquity; and not one, without both obverse and reverse, nor are any of them older than about 400 years before our era. Weight alone was used in the famous cities of Tyre and

Sidon, as we learn from scripture; and in Egypt coinage was unknown, not a coin with a hieroglyphic being found; and in the mouths of the mummies there are only thin broad pieces of unstamped gold, to pay Charon's fare. India appears to have no claim to an early use of coinage. No Indian or Chinese coins exist till within a late period; and those of both countries are so rude as hardly to deserve being collected. Upon the whole the Lydian coins seem to be the most ancient in Asia. Next to these are the Persian, well known from the archer on them, and from Mithras the Persian deity, the dress of the princes and other marks. None of these coins can be older than 570 years before our era, when the Persian empire began. The famous darics were issued by Darius Hystaspes, who began to reign 518 or 521 years B.C. See *DARIC*.

Of Persian coins, there is a second series, that of the Sassanidæ, beginning about 210, when Artaxerxes overturned the Parthian monarchy. The Parthian coins have all Greek legends, but those later Persian bear only Persian characters: they are large and thin, with the king's bust on one side, and the altar of Mithras on the other, generally with a human figure on each side. The letters on Persian coins seem to partake of the ancient Greek, Gothic, and Alanic. The later Persian coins extend to the year 636, when Persia was conquered by the Arabian caliphs.

The Hebrew shekels are of silver, and originally didrachms, but, after the Maccabees, about the value of the Greek tetradrachm; and the brass coins, with the Samaritan characters, are most of them later than the Christian era, and generally the fabrications of modern Jews. F. Soucier has a dissertation on the Hebrew medals, commonly called Samaritan medals, in which he distinguishes between the genuine and the spurious: and shews, that they are true Hebrew coins, struck by the Jews, on the model of the ancients; and that they were current before the Babylonish captivity. The same impression of a sprig on one side, and a vase upon the other, runs through all the coins of this nation. The Phœnician coins are of Phœnicia, and the Punic of Carthage; and they are rendered interesting by the ancient civilization and great power of the Phœnicians and Carthaginians. The alphabets, which are nearly allied, have been illustrated by their relation to the Syriac, Chaldaic, and Hebrew. The same may be said of the Palmyrene coins and inscriptions. (See *PALMYRA*.) The Etruscan coins are inscribed with the Etruscan character, which is satisfactorily explained by its connection with the Pelasgic, or oldest Greek and Latin. The Spanish coins are inscribed with two or three different alphabets allied to the old Greek, or to the Punic. The ancient coins of Spain are numerous, and evidently not all struck by the Punic colonies, for the legends are in different characters. The ancient coins of Gaul are also numerous, and many of them in base gold, but unhappily the most ancient have no legends at all.

In speaking of the coins of Britain, Cæsar says of the natives, "they make use of brass instead of gold coin, or iron rings reduced to a certain weight instead of (our brass) coins." Mr. Pinkerton understands his meaning to be, that our ancestors used brass, apparently coined, as a superior metal, in like manner as more advanced nations used gold: and that *pro nummis*, instead of the brass coinage of Rome, (*nummus* being a peculiar name of the brass sesterlius,) they used iron rings, examined and reduced to a certain weight. Rude coins of copper, much mingled with tin, are frequently found in Eng^land, and may perhaps (as Pinkerton intimates) be the copper coins used by our ancients; for Cæsar's expression merely infers, that their copper was

MEDALS.

in the form of coins. These pieces are of the size of a didrachm, the common form of the "nummus aureus" among the ancients. We have many coins of Cunobelin, who was king of the Trinobantes, and educated, as it has been said, in the court of Augustus. He is mentioned by Suetonius and Dio. These coins of Cunobelin are the only ones apparently British. Most of them yet found have *CVNO* on one side, with an ear of wheat, a horse, a kind of head of Janus, or some such symbol, and often *CA MV*, thought to be the initials of Camulodanum, on the other side, with a boar and tree, and a variety of other badges. They have likewise frequently the word *TASCA* upon them, which has not yet been satisfactorily explained; but it has absurdly, as Mr. Pinkerton conceives, been thought to be the name of the Moneyer, as the putting of the name of the Moneyer on coins was a late practice, unknown till the sixth century, and gradually introduced a century after the Roman mints had ceased in Europe, with the empire, and when private persons contracted with the kings for the little mints, and put their names to identify the mintage. In old German *tasg* is a purse: and the figure thought to be the mock moneyer *Tasg* is Vulcan making a helmet. All the kings of France down to Charlemagne range in this division. Liuva I. who began his reign in the 567th year of our era, and the other kings of the West Goths in Spain, appear upon their coins encircled with Roman characters. Other Gothic kings, who reigned in Italy and other countries, after the fall of the Roman empire in the West, likewise use the Roman language in their coinage. They most commonly occur in the size of medals termed small brads. Many coins also occur with legends, which, though meant for Latin characters, and in imitation of Latin coins, are so perverted as to be illegible. Such are in general termed *Barbarous* medals. Pinkerton's *Ess.* vol. i.

MEDALS, Conservation of, is a matter among medallists of peculiar importance. When a medal is in the least defaced in figures, or in legend, the true judge will reject it, hardly excepting even the rarest coins. Nothing contributes so much to the conservation of brads or copper coins as that fine rust, sometimes called "æruge," appearing like varnish, which their lying in a particular soil occasions. Gold admits no rust but iron mold, when lying in a soil impregnated with iron. Silver takes many kinds; but chiefly green and red, which yield to vinegar. In gold and silver the rust is prejudicial, and ought to be removed; whereas in brads and copper it is preservative and ornamental; a circumstance remarked by the ancients, as the "pocula adorandæ rubiginis" of Juvenal may prove, and that exquisite Greek phrase, which terms "patina" $\chi\lambda\alpha\upsilon\alpha\sigma\iota\varsigma$, the flower of brads. "This fine rust," says Pinkerton, "which is indeed a natural varnish not imitable by any effort of human art, is sometimes a delicate blue, like that of a turquoise; sometimes of a bronze brown, equal to that observable in ancient statues of bronze, and so highly prized; and sometimes of an exquisite green, a little on the azure hue, which last is the most beautiful of all. It is also found of a fine purple, of olive, and of a cream colour, or pale yellow: which last is exquisite, and shews the impression to as much advantage, as paper of cream colour, used in all great foreign presses, does copper-plates and printing. The Neapolitan patina is of a light green; and when free from excrecence or blemish, is very beautiful. Sometimes the purple patina gleams through an upper coat of another colour, with as fine effect as a variegated silk or gem. In a few instances a rust of deeper green is found; and it is sometimes spotted with the red or bronze shade,

which gives it quite the appearance of the East Indian stone called blood-stone. These rusts are all, when the real product of time, as hard as the metal itself, and preserve it much better than any artificial varnish could have done; concealing at the same time not the most minute particle of the impression of the coin." Medals are subject to various blemishes. Sometimes the letters are displaced, as is commonly the case in those of Claudius Gothicus; sometimes the coins, for want of being well fixed in the dye, so as to have slipped at every stroke of the hammer, present a double or treble image. Of these last many are found, in which the portrait is deranged, while the reverse is distinct, and others have the portrait perfectly well struck, while the reverse confuses the eye by its double or triple contours. Ancient coins are subject to another blemish, which rather recommends them to the curious than otherwise. It is when, after having struck a coin, the workmen, through forgetfulness, put another into the dye, without withdrawing the first. Hence, the portrait of the other piece being commonly upward, and in the upper part of the dye, the second coin is impressed with it by the dye, and at the same time made hollow on the other side with the form of the portrait already stamped on the former medal. Some coins are found with a small stamp impressed on a part of them, bearing sometimes a minute head, or some letters, as *AVG.* or *N. P. NOV.* or the like. Such are called "countermarked" by medallists; and being very rare are the more valued, so that such must not be rejected or blemished. These countermarks are thought to infer, that an alteration had been made in the value of the coin; as was the case with the countermarked coins of Henry VIII. and of Mary of Scotland in modern times. Other coins are found with holes pierced through them; and sometimes with a small ring fastened. Such were worn as ornaments of the head, neck, and wrist; either by the ancients themselves, as bearing images of favourite deities, or in modern times, when the Greek girls thus decorate their persons. Coins of genuine antiquity are often found split on the edges, or even in the middle, by the force of the hammer. This, so far from being regarded as a fault, is looked upon as a great merit by the collector; being considered as a proof that the coin is undoubtedly of ancient fabric. Silver coins often acquire a particular yellow tarnish, giving them the appearance of having been gilt; but it is merely owing to their being deposited in a soil, whence a peculiar vapour arises, or some similar circumstance. Mr. Pinkerton has given the following hints concerning the method of clearing coins from any prejudicial rust. "Gold is cleaned by any acid: spirit of nitre eats every thing but gold, and is therefore an effectual cleanser of that metal. The green, blue, or red rust, may be removed from silver, by sleeping in vinegar for a day or two: but a more effectual way is to boil with a mixture of three parts tartar, and one sea-salt in water. On gold and silver the rust is always in spots, and never forms an entire incrustation, as on brads and copper; whence it is always regarded as a blemish in the former metals. Very different is the case with brads and copper, and they are never to be cleaned, for coins in these metals would be disesteemed if rendered bright, and would be full of small holes, occasioned by the rust. But sometimes brads and copper coins are found wholly obscured with rust; and one of the best ways of clearing them, if used by a skilful hand, is a graver. Another way is to boil in water for twenty-four hours, with three parts tartar, and one part alum, (not sea-salt as in silver,) and then cleanse with brao. But it is a dangerous business to cleanse coins; and ought always to be committed to a skilful hand, or let alone."

See

MEDALS.

See Joubert des Medial. sect. viii. Act. Erud. Lips. 1694, p. 226.

Some authors imagine, that the ancient medals were used for money. M. Patin has a chapter expressly to prove, that they had a fixed regular price in payments, not excepting even the medallions. F. Joubert is of the same opinion. Others, on the contrary, maintain, that we have no real money of the ancients; and that the medals we now have, never had any course as coins. Between these two extremes there is a medium, which appears by much more reasonable than either of them. See MONEY.

MEDALS and Coins, *Modern*, as contradistinguished from those that are denominated *ancient*, comprehend, as we have already observed, all those that have been struck since the time of Charlemagne, or the commencement of the 9th century. Mr. Pinkerton, of whose valuable "Essay on Medals" we have been allowed to avail ourselves in the compilation of this article, has divided the subject into "Modern Coins" and "Modern Medals." He observes, that down to the revival of literature in the beginning of the 16th century, modern coins are so very rude, that curiosity suggests the sole inducement to examine them. Without dates or epochs they cannot serve one purpose of utility. The very portraits found on them are so uncouth, that the human face divine is hardly discernible. The reverses always bear a most beautiful cross garnished with pellets, or a dish of some such exquisite flavour. Yet such is the lust of curiosity, of completing a series, or of self-love indulged in the extreme, by possessing a bauble which nobody else does, that ten or twenty guineas are often given for one of these pretty little things. To us, however, as Britons, the study of these coins may be regarded as peculiarly interesting, as they furnish monuments illustrating, or relating to, persons or actions, in the glory of which the common passion of national vanity warmly interests our affections. Thus, the noble of Edward III., on which he appears in a ship, as asserting the British dominion of the ocean, would, though uncouth in the execution, which it by no means is, justly command our highest regard and attention; and doubtless any patriot, or any Briton, would, even in these days, place most justly a higher value upon this coin, than upon the most perfect medal which Grecian skill has produced. Upon the same principle, the coins of Edward the Black Prince are interesting; and, indeed, the whole English series must be interesting to every one who feels himself particularly concerned in English history.

In this place modern coins are regarded merely as they appear in a cabinet; but for their commercial value, we refer to other articles, such as COIN, MONEY, &c. Beginning with the most eastern part of Asia, the coins of *Japan* first attract notice. These are thin plates of gold and silver, large and oval, stamped with little ornaments and characters. The only coins of *China* are in copper, about the size of a farthing, with a square hole through the middle, in order to their being strung for the convenience of enumeration or of carriage. They bear an inscription in Chinese characters, expressing the year of the prince's reign, without his name, distinguished as the "*Happy year*," "*The Illustrious year*," and the like. It is said, that Canghi, the emperor, who died in 1722, after a reign of 61 years, formed a complete cabinet of Chinese coins, and appointed a Mandarin to keep it. The coins of *Tartary*, which are posterior to Genghis-Khan, are rude, and generally present only inscriptions. In *Thibet*, *Pegu*, and *Siam*, the coins are various; but evidently of late origin, and generally bearing inscriptions on both sides. Such also are those of many smaller states in Eastern Asia.

In the country so celebrated anciently by the name of *India* the Mahometan faith is predominant, as it is in most countries of Western Asia. The precept of Mahomet, which forbids the representation of any living creature, has had a pernicious effect upon the arts. It is doubtful whether or not any Indian coins exist before the time of the Moguls, or the 13th century. Some old coins have been found near Calcutta, of gold, silver, copper, and tin, all mingled in one base mixed metal. On one side they bear a warrior with a sword, and on the other an Indian female idol. The later coins of India are well known, such as the pagoda, rupee, and cash, the most common copper, whence our word. All these coins are very thick, like the old Egyptian. On one remarkable set of rupees, are presented the twelve signs, a lion on one of them, a bull on another, &c. &c. The Portuguese, English, French, and Dutch, sometimes struck coins in their settlements with Persian inscriptions on one side and Latin on the other. Rupees and cash are known of Elizabeth, of Charles II., of the year 1730, and of other periods. The coins of *Persia* have continued on the Arabian model, even after the Arabian caliphs lost their dominion in that country, and bear on both sides pious inscriptions from the Koran. The Persian copper, however, has the sun and lion, the arms of Persia, on one side. Of Manlius, and some other petty kings in *Arabia*, we have coin during the imperial period of Rome. The brass coins of Haroun Al Raschid, the Charlemagne of Asia, and his contemporary, and of other powerful princes who resided at Bagdad, have an Arabic inscription on the reverse; the obverse is a mere transcript of any old Greek or Roman coin that fell in the way of the Moneyer. The gold and silver coins have many inscriptions. The later Arabian coins, which are silver, bear the name and titles of the prince on one side, and some sentence from the Koran, or the like, upon the other. The more modern are in the shape of a fish-hook, with Arabic inscriptions. The coins of *Turkey* resemble those of Persia and Arabia, having merely inscriptions on both sides. The coins of Africa, comprehending Morocco, Fez, Tripoli, Algiers, &c. are upon the Mahometan plan of mere inscriptions. Passing over Abyssinia, and the interior kingdoms of Africa, as little known, and the civilized empires of America, Mexico on the N., and Peru on the S., where coinage was not practised, we shall proceed to the coins of Europe. In *Italy*, when the Roman empire in the west ceased with Romulus, in the year 476, the Gothic kings struck coins till Teias, the last of them, was conquered in 552 by Narfes, the general of Justinian. Then the exarchs of Ravenna, viceroys for the Byzantine emperors, issued copper with FELIX RAVENNA, &c.; but the gold and silver of the Greek emperors sufficed for Italy. After Charlemagne, about the year 780, made a great revolution in Italy, there are coins of him struck in Rome and Milan. In the next century the modern coins of Italy begin with the silver pennies of various states. The papal coins originate with Hadrian I. 772—795, to whom Charlemagne gave leave to coin money. The silver pennies continued till a late period, with the name of the pope on the one side, and SCUS PETRUS on the other. On these coins there are rude portraits of some of the popes. Afterwards, when the pope ceased to have power in Rome, from Paschal II. till Benedict XI. in 1303, there are pennies of the Roman senate and people, bearing on one side Peter, ROMAN. PRINCIPE, on the other Paul, SENAT. POPUL. Q. R. In the middle ages the chief bishops of Italy, France, and England, struck coins, as well as the pope. The first gold coin is of John XXII. 1316. The coins of Alexander VI., Julius II., and Leo X. are remarkable for elegance.

elegance. The coins of *Milan* begin with Charlemagne, a cross, reverse the monogram of Carolus, with *MMML.*, and they are found of the other emperors to the 13th century. These coins are of silver. In *Naples* the coins of duke Sergius, 840, and bishop Athanasius, 880; and they are followed by those of several others. The coinage of *Pavia* begins in the 10th century, with silver pennies, marked *VN. N. E. C. I.* In 1280 the first Venetian gold appears; and the first copper in 1471. The silver groats are as old as 1109. *Florence* surpasses all the cities of Italy in the dignity of her coinage. Some silver pieces occur from the 12th century, or an earlier period; but in 1252, the famous gold coins, called Florins, from the flower of the lily upon them, appeared; and were imitated by the popes, France, and England, as being the first gold coins struck in Europe, after the eighth century, for during five centuries no gold worthy of notice was struck in Europe. The florins of Florence have on one side St. John the Baptist standing, s. JOHANNES. n. on the other a large fleur-de-lis, FLORENTIA; and the coins of the popes, France, and England resembling them, have the same types, but different legends. They weigh a drachm, and are no less than 24 carats fine, according to Italian writers; being intrinsically worth about 12s. The first coins of *Genoa* are of Conrad the emperor, 1120, DUX JANVÆ. Those of the dukes of *Saxony* begin in the same century. The patriarchs of *Aquilia* issued coins from 1204 till 1440. *Ferrara* has coins of marquises from 1340. In France, the coins of the first race from Clovis 490, till its termination in 751, are chiefly gold trientes, well wrought, with the heads of the kings. Some solidi and semisses also appear. These coins, which properly belong to the class of ancient coins, have on the obverse the king's head and name, but sometimes the name of the Monever; the reverse has a cross with the name of the town. The coins of the second race, beginning with Pepin in 750, and extending to Hugh Capet in 987, commence the modern class. These are no less barbarous than the others are elegant: they are almost all silver pennies, and very seldom bear the head of the king. Those of Charlemagne have only CAROLUS in the field, while the reverse bears n. f. or some such inscription. One piece alone, struck at Rome, has a rude bust of him. The third race, beginning with Hugh in 987, and extending to the revolution, are unfortunate in their coins, till the time of St Louis, in 1226, when the groat appears, and the coinage began to improve. The groat, or grosso, so called in comparison with the penny, passed from Italy to France, Germany, and England. In the time of St. Louis, deniers of billon were issued, and were followed by other pieces of the same metal, as the liard or hardi of three deniers, the maille or obole of half a denier, the pougeoise or pite of one quarter. In the time of Henry III. 1574, copper was first used in French coinage. Other remarkable coins of France are the blancs, or billon groats, first issued in 1348; the ecus a la couronne, or crown of gold, the most famous French coin, so called from the crown on one side, and begun by Charles IV. in 1384; the tesson, or piece with the king's head, of Louis XII.; the elegant Henri of Henry II. which has Gaul sitting in armour, with a victory in her hand, OPTIMO PRINCIPI; exergue GALLIA. The first Louis d'or is of 1640. *Spain* vies with France in the elegance of her early series, which consists almost wholly of trientes of gold finely executed. On one side they bear the head of the king, with his name, and on the other a cross with the name of the town. While the Moors, or Arabs, possessed Spain, from the eighth to the 13th century, and Granada in particular till the end of the 15th, such was the influence of the Mahometan faith, that the Moresque coins of Spain

only present us with insipid inscriptions on both sides: they are chiefly in gold; and the inscriptions are in the old Arabic character, used in Mahomet's time, called the Coptic. From Charlemagne the coinage of *Germany* commences; and the series of emperors is thought to be nearly complete. The coinage of *Denmark* begins with Canute the Great, in 1014. After Canute, we find coins of Harold and Hardicanute, then of Magnus Bonus in 1041, with Runic reverses and of most workmanship. But without enumerating those of Sueno II., which rarely have the bust, with an arched crown, and on the reverse curious ornaments of a tessellated form running across the field, with the mmm on either edge of the ornaments; and those of Harold I. in 1074, with generally two heads; the rude coins of Nicolas or Niel, of Waldemar I. and of his successors; those of Olaf in 1376, bearing a grinning full face, with a crowned O on the other side; and the billon coins of Eric in 1426:—we pass into *Sweden*, which is said to have begun her coinage under Biorno in 818, on the plan of that of Charlemagne; these coins have a cross, though Biorno was not a Christian; the next coins are of Olaf, OLUF REX SVEVORVM, &c. &c. the series proceeding till Margaret in 1387. From her time to that of Gustavus Vasa, in 1520, the coins are of Danish monarchs, struck for Sweden. Of Gustaf Wase, or Gustavus Vasa, and his successors, there are many fine coins. In 1634 ducats were coined with the bull of Gustaf Adolf, who died in 1632; reverse the arms of Sweden, with the chymic types of mercury and sulphur. In 1716, and the two following years, the small copper coins with Saturn, Jupiter, Mars, &c. were issued by Charles XII. to pass for dollars, on account of his want of money. The coins of *Norway* begin with Olaf, in 1066, and are followed by those of Magnus, Harold, &c. &c. Of Denmark, Sweden, and Norway there are also ecclesiastic coins, as of Germany, France, &c. struck by the chief bishops. *Bohemia*, the most westerly Slavonic kingdom, boasts the earliest coinage; the first coins are those of duke Boleslaus I. in 909, with his head and name. The coinage of *Poland* is nearly as ancient as that of Bohemia; and it may be observed in general, that the coinage of the Slavonic kingdoms follows the model of the German. The coins of *Russia* are of very late date. None of her coins seem to be more ancient than the 13th century. The first Russian coins have rude figures of animals on one side; and a man, standing, with a bow or spear, on the other. Some have St. George and the dragon, and various other types. Such are all kopeks, or silver pennies. The rouble or dollar, and its half, began under Ivan or John in 1547. Those of the false Demetrius, in 1605, are very scarce. In 1230, the knights of the Teutonic order, having conquered the Pagan inhabitants of *Prussia*, coined silver pennies on the German plan, at Culm. In the next century were struck shillings, groats, and schots, the last being the largest and very rare; they have the Prussian shield, an eagle surmounting a cross, within a rose-shaped border, MONETA DOMINORVM PRUSSIE; reverse a cross fleurie, within a like border, HONOR MAGISTRI JUSTITIAM DILIGIT. In the same century gold coins were struck. In 1525 the money was so debased, that 12 or 13 marks were worth but one mark of silver. The coins of Brandenburg and Poland are the later coins of Prussia.

We shall now proceed to give a brief enumeration of the coins of *Britain*. The Heptarchic coins are only of two sorts; the silver sceatta or penny, and the copper or billon styca, the latter being known only in Northumbria, and being a very small piece, worth about half a farthing. The silver penny may be regarded as the general heptarchic coin. The sceattas were struck in Kent, and the other states of the

Heptarchy

MEDALS.

Heptarchy from the sixth to the eighth century, or from about the year 500 till 700. No heptarchic pennies occur till after the year 700; but sceattas, which Dr. Combe, by causing two plates of them to be engraved, has brought into notice, are found with the name of Ethelbert I., king of Kent, A. D. 560—616, and of Egbert, also king of Kent, A. D. 664. The heptarchic pennies are, therefore, almost all of the eighth century, or from 700 till 832, when Egbert terminated the seven kingdoms. The coins of the chief monarchs present almost a complete series, from Egbert 832 to Edgar 959. Of Ethelbald 857, and Edmund Ironside, A. D. 1016, there are no coins. Most of them bear rude portraits, and the reverses have views of cathedrals and other buildings, &c. The inscriptions are also sometimes curious. Ecclesiastic coins also appear of the archbishops of Canterbury, Wulfred, A. D. 804, Ceolnoth, 830, and Phlegmund, 889. The Norman conquest in 1066 made no alteration in the English penny, the only coin. The old English penny, or *anglicus*, Mr. Pinkerton observes, was a coin celebrated all over Europe in the middle ages, and almost the only money known in the northern kingdoms. In neatness of fabric, and in purity of metal, it is superior even to the Italian and French coins of that period. The series of English pennies extends almost without any failure from Egbert to the present reign. The kings wanting are John and Richard I. The Rev. Mr. Southgate, generally learned and peculiarly skilled in medals, has in his cabinet as neat and complete a series of this kind as is perhaps to be found. Several unlikes, or almost such, are found there in the best preservation; such as the French penny of Richard I., the penny of Richard III., the full-faced penny of Henry VIII. in fine silver, and others. The first English pennies weigh $22\frac{1}{2}$ grains troy: toward the close of Edward III. the penny weighs but 18 grains, and in the reign of Edward IV. it fell to 12. In Edward VI's time, 1551, the penny was reduced to eight grains, and after the 43d of Elizabeth to $7\frac{2}{3}$ grains, at which weight it continues to this day. The next coins in antiquity, pursuing the silver coinage, are the halfpennies and farthings, first struck by Edward I. about 1280, some having been previously issued in Ireland by John. The first were continued down to the commonwealth, since which time none have been struck in silver; the farthings ceased with Edward VI. To these succeeds the groat, from Fr. *gros*, a large piece, introduced by Edward III. in 1354. The half-groat, or two-pence, is of the same date. Next to the groat is the testoon, or shilling, first coined by Henry VII., in 1503. The appellation of testoon was derived from the teste, tête, or head of the king upon it. The shilling was at first a German appellation, *schelling*; coins of that name having been struck at Ham-burgh in 1407. The crown was published by Henry VIII. in silver, whereas it had before appeared only in gold; whence the old phrase "crowns of gold;" and the half-crown, six-pence, and three-pence, by Edward VI. Elizabeth, in 1558, coined three-halfpenny, and in 1561 three-farthing pieces, but they were dropped in 1582. From the 43d of Elizabeth, 1601, the denominations, weight, and fineness of English silver remain the same to the present time. It was about the year 1257 that Henry III. formed the design of a gold coinage, and ordered it to be current in the kingdom: however, no more than two specimens of it have reached us. It is called a gold penny, but larger than a silver one. But it is from Edward III. that the series of gold coinage commences, for no more occurs till 1344, when that prince first struck florens, so called from the best gold then coined at Florence. The floren was then worth 6s., but is now intrinsically worth 19, from the increased value

of gold, and diminution of silver coins. The half and quarter of the floren were struck at the same time, and of the same proportional value. In the same year the noble was announced, of 6s. 8d. value, and consequently forming half a mark, being then the most general ideal mode of money. This was attended by its half and quarter; the proportion of silver to gold being then 1 to 11. This coin, together with its subdivisions, continued the only gold coins till the angels of Edward IV. 1465, stamped with the angel Michael and the dragon, and the angelets, half the angel, or 3s. 4d. was substituted in their place. Henry VIII. in 1527, added to the gold denominations the crown and half-crown, at their present value; and, in the same year, gave sovereigns of 22s. 6d. and ryals of 11s. 3d., angels of 7s. 6d. and nobles at their old value of 6s. 8d. In 1546, the same sovereign, making the value of silver to gold as 1 to 5, struck sovereigns of the former value of 20s., and half-sovereigns in proportion. The gold crown of Henry VIII. is about the size of our shilling, and the half-crown of a sixpence, but thin, as all hammered money was in modern times. His gold coin, like his silver, is much debased. These coins continued, with a few variations, till Charles II. established the present sort of gold coin. Till Edward VI. our monarchs appear upon their gold coin at full, or three quarters, length; that prince being the first whose bust only is seen. Silver, which had been to gold for some time as 1 to 4, was again reduced in 1551 to its old proportion of 1 to 11. Upon the union of the crowns, James I. of England gave the sovereign the name of unite, it being then of 20s. value. Of him are likewise rose ryals of 30s. and spur ryals of 15s. angels of 10s. and angelets of 5s.; till his ninth year, when gold was raised in the proportion of 1s. in 10s. Silver, which had fallen in its proportion to gold from the degree of 1 to 12, now sunk further, as 1 to 13½ in weight. The gold crown and half-crown continued to this prince inclusive, and the crown to his successor. The sovereign, which had been commonly termed the broad-piece, under the commonwealth assumed the univindious name of the twenty-shilling piece, which it retained till it was supplanted by that of the guinea. The commonwealth likewise struck ten-shilling and five-shilling pieces in gold. Oliver published none but forty-shilling and twenty-shilling pieces, and very few even of these; the former in particular being mostly patterns. The guinea, so called from the Guinea-gold out of which it was first struck, was proclaimed in 1663, and to pass for 20s.; but it never went for less than 21s. by tacit and universal consent. It is only twenty-two carats fine, and two alloy, which is the standard of our gold coinage to this day. Charles II. likewise issued half-guineas, double-guineas, and five-guinea pieces, which have been all continued through every reign to the present time, though the latter two are not in common circulation. Geo. I. published quarter-guineas, an example imitated by his present majesty; but these last of George III. were found so troublesome and apt to be lost, that they were stopped within a year or two when received at the bank of England, and thus silently annihilated. Pieces of 7s. were likewise coined, and have been continued: they are known by the lion above the helmet. The last coinage is that of copper. The first money coined in ancient Britain seems to have been copper. But the Saxons never thought of coining except in the instance of the *lyca*. While copper coin continued to be wanting in the English authorized money till the year 1672, with a few small exceptions after the time of Elizabeth, we need not much wonder that in more remote periods its deficiency was not at all felt. The known averion of that queen,

queen, and of the nation in general, to a copper coinage, was owing to the counterfeit money called "black money," being always of copper mixed or washed with about a fifth part of silver. The term of "black money" evidently arose from contradistinction to "white money," which is yet a name for that pure silver which it was made to imitate. When it is considered, therefore, that the base money was always of copper, it is no wonder that the idea of a copper coinage should be confounded with that of an imposition of authorized bad money. In 1591, when the practice of coining tokens, upon the returning which to the issuer, current coin, or value was obtained, had got to a great length, government had serious thoughts of a copper coinage; and a small copper coin was struck, of about the size of a silver two-pence, with the queen's monogram on one side, and a rose on the other, the running legend being *THE PLEASOR OF A HALF-PENNY*. The queen, however, retaining her aversion to a copper coinage, the scheme proved abortive; nor was it revived till the succeeding reign, when, on the 19th of May 1613, king James's royal farthing tokens commenced by proclamation. They are mostly of the same size with the above, and have upon one side two sceptres in saltire, surmounted with a crown, and the harp upon the other. Their legend is the king's common titles running upon each side. These pieces, which were issued merely as pledges or tokens, for which government was obliged to give other coin if required, were not favourably received; but continued in a kind of reluctant circulation through this reign and the beginning of the next. In 1635 Charles I. struck those with the rose instead of the harp. But their currency was stopped by the number of counterfeits and the king's death in 1648; and then the tokens of towns and tradesmen again took their run, and increased prodigiously till 1672, when farthings, properly so called, were first published by government. After many trials for improving the copper coinage, and the issuing of many copper farthings, current half-pence and farthings first began in 1670 to be struck at the Tower; but they were not proclaimed till August 1672. These continued till the last year of Charles II., 1684, when disputes arising about the copper, tin farthings were coined with a stud of copper in the centre, and inscribed round the edge as the crown pieces, with *NUMMORUM FANULUS*, 1685 or 1686. Half-pence of the same kind were issued in 1685, and tin continued to be coined till the year 1692. But in 1693 the tin was called in, and the copper coinage commenced anew. All the farthings of the following reign of Anne are trial pieces, except that of 1714, her last year. They are beautifully executed; but the one whose reverse is Peace in a car, *PAX MISSA PER OREM*, is the most esteemed. It is observable with regard to the copper coinage, that the intrinsic worth of the metal is not one-half of its currency. The pound of copper, worth 10*d.*, yields 46 half-pence, or 23 pence, when coined. Hence forgeries even of good metal yield a large profit, and the whole kingdom swarms with counterfeit copper, inasmuch that not a fiftieth part of that currency is legitimate; an evil which requires remedy. Before we close this subject of the English coinage, we shall mention the Portcullis coins of Elizabeth, issued in rivalry of the Spanish king, for the service of the East India company, in their settlements abroad. They are of different sizes from the crown downward, and are easily distinguished by the portcullis on the reverse. To them succeeded the various siege pieces of Charles I. in gold and silver, some of the latter being so large as to be of 20*s.* value.

The coinage of Scotland did not commence till a late period. There is room to believe, says Mr. Pinkerton, that silver pennies exist of Alexander I., 1107, as some are found

with that name, apparently of ruder and more ancient fabric than those of Alexander II., 1214. Of David, 1124, there are coins. Those of William, 1165, are numerous, with *WILIAM*, or *WILIAM* III, or *III*; the last word used in Scandinavia for king, or perhaps a various spelling of the old French *Roi*. A large hoard of William's pennies was found near Inverness in 1780. The Scottish money continued to be the same with that of England in size and value till the time of David II., 1355, whose vast ransom drained the Scottish coin, and occasioned the size of that which remained to be diminished. After this ransom, the Scottish coin gradually diminished, in the first year of Robert III. it passed only for half its nominal value in England; and at length, in 1393, Richard II. ordered that it should pass only for the weight of the genuine metal in it. It sunk by degrees, till, in 1600, it was only a twelfth part value of English money of the same denomination, and so remained till the union of the kingdoms cancelled the Scottish coinage. In silver, we have only pennies of Alexander II., who reigned till 1249; but Alexander III., who reigned till 1293, coined half-pence. Of Robert I., 1306, and David II., there are silver farthings. The groat and half-groat, introduced by David II., completed the denominations of silver money till the reign of Mary, when they all ceased to be struck in silver. In 1544, the second year of Mary, Scottish money was a fourth of that of England. About the year 1553, shillings or tessoons were first coined, bearing the bust of the queen, and the arms of France and Scotland on the reverse: they were then worth 4*s.* Marks of 13*s.* 4*d.* Scottish were also struck, worth 3*s.* 4*d.* English. In 1565 the coin was to the English as 1 to 6; the silver crown being then first struck, weighing an ounce, and passing for 30*s.* Scottish; and lesser pieces of 20*s.* and 10*s.* were struck in proportion; and these have the marks upon them xxx, xx, x, to express their value. In the time of James VI., 1571, the mark and half-mark Scottish were struck, the former being worth about 22 pence and the latter 11 pence English. In 1578 the famous *NEMO ME IMPUNE LACESSET* occurs first upon the coin; the invention of which is ascribed to Buchanan. The Scottish silver, coined after the union of the crowns, it is hardly necessary to mention.

The gold coinage of Scotland resembled the English; Edward III. having given the first currency in this metal in 1344. About 30 years afterwards, Robert II. issued his. The gold coins of Scotland, however, are of much smaller model than the English. They were first called St. Andrews, from the figure of that tutelary saint upon his cross, who appears upon them, with the arms of Scotland, a lion in a shield, on the reverse. The lion was another name for the largest gold coin, from the Scottish arms upon it; next was the unicorn under James III.; and the chief gold pieces of James V. were the bonnet pieces, so called from the bonnet in which that king's head appears upon them. The last gold coinage of Scotland is the pistole and half-pistole, coined by William III. in 1701, worth 12*l.* and 6*l.* Scottish. They have the sun under the head.

The copper coinage of Scotland, though more current than that of England, is not of so early a date as some would ascribe to it. Buchanan speaks confidently of copper coinage in Scotland before James III.; but in this he is mistaken. During the reign of James III., says Pinkerton, the copper coinage began, and speedily increased in its pieces. The old Scottish coins of copper stood thus:

A Penny	=	$\frac{1}{2}$	of a penny English.
A Bodle	=	2	pennies.
A Hardie	=	3	pennies, the farthing English.
		P	A Plack

MEDALS.

A Plack = 4 pennies.

A Baw-bee = 6 pennies.

An Atkinson = 8 pennies.

N. B. The penny has a little dot behind the lion; the bodle, also called two-penny piece and turner, has two dots. This coinage continued the same through the reigns of Charles I. and II. The Scottish pennies of Charles II. are not very uncommon; they weigh only 10 grains. In Scotland there are no ecclesiastical coins; though they occur in Denmark, Norway, and almost all other kingdoms.

With respect to the coins of Ireland it may be observed, that, from their form and fabric, the old mace pennies found in this country were struck by the Danes there. Of Anlaf, 930, and Sihtric, 994, there are coins struck at Dublin, ON DYELL, or DYELL, Dufin or Dyflin being the real Danish original name of this fine city, as of towns in Scandinavia. Coins of Donald, an Irish monarch, probably Donald O'Neal, 956, are published by Simon. Other Danish and Irish kings have coins. The pennies struck by English monarchs in Ireland are remarkable: such, with the name of Dublin, occur of Ethelred, 866; Edred, 948; Edgar, 959; and one of Canute, 1017. The Irish coins from John to Henry V. are known by the triangle enclosing the king's head, and by the names of Irish towns on them: after Henry V. they are only distinguished by the names of Irish cities where they were struck. The harp is never seen upon Irish coin till the reign of Henry VIII. The difference between the Irish coin and the other money struck by the kings of England begins in the time of Henry VIII., who coined six-pences for Ireland, only worth four-pence in England. Mary issued base shillings and groats for Ireland; and Elizabeth's base money for Ireland is notorious. In 1601, copper pennies and half-pence were coined for Ireland by Elizabeth, though she would not consent to a copper coinage in England. In 1635 a mint was established in Dublin by Charles I.; but the massacre and disturbances in that country put a stop to it, and the plan was never resumed. After that massacre, 1641, the Papists struck what are called St. Patrick's half-pence and farthings, known by the legends FLOREAT REX, reverse ECCE GREX; and the farthing QUIESCAT PLEBS. In Cromwell's time, copper tokens were struck by towns and tradesmen, as in England. In 1680, half-pence and farthings were given by authority, with the harp and date. James II., arriving in Ireland from France in 1689, instituted a mint, and issued shillings and half-crowns, struck of all the refuse metal which could be procured: for this purpose some brass guns were used, so that the coinage is generally called gun-money. Pennies and half-pennies of lead mixed with tin were published in 1690; and other crowns of gun-metal, of the size of half-crowns, without the mark of the month, in the same year. The crowns of white metal, which are very scarce, have James on horseback, with titles no longer his; and on the reverse the arms, CHRISTO VICTORE TRIUMPHO, with this legend on the rim, MELIORIS TESSERA FATI ANNO REGNI SEXTO. The patent of William Wood, esq., acquired from George I., for coining half-pence and farthings, occasioned great discontent, on account of the great loss that attended it. These coins are of very fine copper and workmanship, and have the best portrait of George I., perhaps, any where to be found. Sir Isaac Newton, then at the head of the mint, said they were superior to the English in every thing but size. In 1737, both of George II., Irish half-pence and farthings were again coined of just size and weight, with the harp only on the reverse; and the like are continued to this day. As they have no mint in Ireland, they are all coined here, and sent to that kingdom. In

1760 the scarcity of copper coin in Ireland was relieved by a society of Irish gentlemen, who obtained leave to coin half-pence; which appeared with a very bad portrait of George II., and VOCE POPULI round it. Since the abolition of the mint erected by Charles I., which happened about 1640, no gold or silver coins have been struck with the Irish badge, but copper only. See COIN, COINAGE, and MONEY.

Modern Medals.—In the middle ages medals were quite unknown. Till the 15th century no medals appear of any country in Europe, if we except Scotland, which can boast of gold medals of David II. 1330—1370, struck in England during his captivity. In the next century medals appeared in Italy, and from that time successively in most countries of Europe. The gold medal of the council of Florence, 1439, is one of the earliest of these medals. Some indeed have mentioned, that of the famous reformer, John Hufs, in 1415, as the first. Vittore Pisano, a painter of Verona, is celebrated as perhaps the chief restorer of this branch of art. His medals, however, have no similarity to those of antiquity, being very large, and all cast: they were first modelled in wax, then a mould was taken from the model in fine sand and other ingredients. When a good cast was procured, it was touched up, and made a model for the rest. Vasari, in his lives of the painters, gives us a catalogue of the medals done by Pisano. The papal medals are not only the most elegant, but the most ancient series in modern Europe. Paul II., created pope in 1464, is the first pontiff who has medals of his own time. After Paul II., coeval medals are found of all the popes. In the time of Alexander VI., 1492—15 3, the elegance of the papal medals begins to dawn; but his successors Julius II., Leo X., Hadrian VI., and Clement VII. were singularly fortunate in having many of their medals designed by Raffaele, Julio Romano, and other great painters; and executed with corresponding workmanship. The medal of Julius II., with Saul, CONTRA STIMULUM NE CALCITRES, is the first medal, according to Venuti, that was struck, not cast. The medal of Julius III., reverse a Ganymede ΦΕΡΝΗ ΖΗΝΟΣ ΕΥΦΑΙΝΕΙ, the dower of Jove delights, the design of which is ascribed to Michael Angelo, is denied to be genuine by the pontifical writers. But there is a fine medal, designed by Parmegiano, of Gregory XIII., upon the correction of the calendar; reverse a serpent, with his tail in his mouth, and a ram's head for the sign Aries, in the centre, ANNO RESTITUTO, M.D. LXXXII. marked I. PARM. beneath the pope's bust, in the obverse. Besides the papal medals, there are many of the various states in Italy. Next to Italy, France is the most remarkable country for medals. But the French medals are neither fine nor numerous, till the reign of Louis XIV., who has exceeded all modern princes in this way. In Denmark, there are medals of Christian II. 1516, and of Frederic and Sophia, 1532. Of Frederic II. and Christian IV. there are many medals. The elephant of the house of Oidenburg is very frequent on Danish medals. In Sweden there are many fine medals of Gustaf Vasa, or Gustavus Vasa. Christina appears on several, struck chiefly at Rome after her abdication. Of Charles XII., there are several curious medals. The medallic history of Holland begins in the year 1566. In the Spectator a Dutch medal is quoted as English; namely, that on the defeat of the Spanish armada, a fleet, FLAVIT ET DISSIPATI SUNT, 1588. Many Dutch medals are remarkable for maps and plans. The Spanish medals begin, as Mr. Pinkerton suggests, with Consalvo, the great captain, in 1503; and many of them are curious and interesting. Germany and Spain were as one empire under Charles V., of whom there are many medals.

But

But the German ones begin with Frederic III., of whom there is one struck at Rome 1453; next is Maximilian 1534, who appears in the honour, worn before hats were invented about 1565, and a wheel on the reverse, *PER ROTAM CRISTINA*. There is a curious medal upon the death of Louis, king of Hungary, at Mohatz, 1576, when he fell fighting against the Turks; observe his head, and that of his queen, face to face; reverse a battle. The medals of John of Leyden, leader of the Anabaptists, 1534, 1535, are singular monuments of folly and fanaticism. They bear his bust, with German inscriptions and legends. Amongst other curious medals, there is one of Sebastian, King of Portugal, famous for his unfortunate expedition in Africa, 1575, with his bust, full face, and three quarters length, *SEBASTIANUS D. G. REX PORTUGALIE, ARABIE, INDIE, ET AFRICÆ ANNO ÆTATIS XVI.*, reverse a shell-fish in the sea, the moon and seven stars, *SERENA CELSA FAVENT*. There is another singular medal of Catherine of Medici, queen of France, notoriously addicted to astrology. It represents her naked, between Aries and Taurus, with the name *NULLA ASMODEA*, over her head: she holds a dart in one hand, and a heart in the other: in the exergue is *OXIUS*.

As soon as medals began to revive, they became satiric; a quality almost unknown to the ancient mint. Medals among the moderns have been the chief article of satire, till the printshops took up the trade. The first satiric medal, it is believed, was struck by Frederic, king of Sicily, in 1501, against his enemy, Ferdinand, king of Spain. It bears the head of Ferdinand, *FERDINANDUS R. AR. VETUS VULPES ORNIS*; reverse a wolf carrying off a sheep, *JUGUM MEUM SUAVE EST ET ONUS MEUM LEVE*. It is said that in 1588, Elizabeth, queen of England, struck a medal, with the Spanish and English fleets, *HESPERIDUM REGEM DEVICTA VIRGO*. Philip, king of Spain, caused medals of the same impression to be distributed in England; but with this addition, *NEGATUR, EST MERETRIX VULGI*. The queen suppressed them, and published another medal, with this legend,

“ Hesperidam regem devicit virgo Negatur,
Est meretrix vulgi, Res eo deterior.”

Above all nations, the Dutch have most distinguished themselves for satiric medals; and have paid dearly for this kind of presumption. A great number of medals have been struck for private men of eminent learning or talents, and in this respect modern medals are superior to the ancient.

Mr. Pinkerton closes his account of modern medals with a comparison between these and the ancient medals. The most surprising difference between the ancient and modern works of art lies in the portraits. The ancient artists, even of the lowest class, marked the character, and exhibited the life and spirit of the person whom they represent; while the moderns only produce a kind of model, with very faint features of the character. The ornaments of the portraits have also this effect; the ancient being simple and picturesque in real life; whereas ours are discordant and ungraceful. The reverses of ancient medals, when consisting of human figures, or detached objects, exceed the modern in every view of strength, elegance, or taste. But in landscape, and all that belongs to perspective, the modern excel the ancient to a prodigious degree. A great fault of modern reverses, as of modern portraits, is that the manners of the time and country are very often totally perverted in them. Personifications are of all ages and countries and languages; but what title have heathen gods or goddesses to exist on our medals, and attract the adoration of our connoisseurs? Mr. Pinkerton, taking advantage of Dr. Coningham's tract on modern me-

dals, makes some remark on the legends. But for the different kinds of legends that are contained, we refer to the article *LEGENDS*, to which the reader is desired to consult the end of the present volume of Coningham.

The first English medals are the duke of Devonshire's coronet. It is in gold, of a large size, upon the plan of the early Italian medals, being one without doubt in Italy, and bears on one side a shield 10. *RICARDUS REX ANGLIÆ ET FRANCIE, 1381*, reverse the arms of Richard I. *RICARDUS REX ANGLIÆ ET FRANCIE, 1198*. The next English medal is that of Henry VIII. struck in 1545; it is of gold, larger than a crown-piece, and has the king's head full-face on the obverse, with three legends within each other, of his initials and other matter. The reverse contains two inscriptions, declarative of his being head of the church, &c. the first in Hebrew, the other in Greek. This was imitated in all points by his successor Edward VI. in his coronation medal, being the full we have. Elizabeth presents us with a good number of medals, one or two of which are tolerable, but the rest very poor, inferior to those of Philip and Mary, two of whom in silver by Trezzo are of high relief, and good execution. Decent medals appear of James I. and his queen; and a very large one of Charles I. and Henrietta, in 1636, deserves notice for its fine workmanship. The reverse represents Justice and Peace, kissing, awkwardly enough; but the execution of the king's bust, and that of his lovely queen, is very masterly. The medals of Charles I., who was a lover of the arts, are various and curious; but we cannot enlarge in the enumeration of them. The commonwealth and Oliver Cromwell, were singularly fortunate in having the celebrated Simon for their artist in this line. The medals and coins of Simon are deservedly regarded as the most admirable which modern times have produced. Of Charles II. there are several good medals, as on his leaving Holland, his restoration, and coronation. The short reign of James II. has several medals, the most remarkable of which are the *NEMO ME IMPUNE LACESSET*; that with his queen, *FORTES RADII SED BENIGNI*; those on the Pretender's birth, *FELICITAS PUBLICA*. William III. gave occasion for many interesting medals. Those after his accession to the English crown, have generally his head and Mary's joined, as the *MAJUS PAR NOBILE*; *ATAVUM PRO LIBERTATE*; *NEC LEX EST JUSTIOR VLLA*; *NISI TU QUIS TEMPERET IGNES*; and others. Many medals also occur of James II., after his abdication, and of the other pretenders, done in foreign countries by eminent artists. Queen Anne has several fine gold, silver, and copper medals; of the first only two or three different pieces were struck; but in the other medals of this princeps, we have a series of all the great events with which Marlborough illuminated her reign. About 1740, and for some years before and after, Daffier, a native of Geneva, settling in London, engraved a series of medals of all the English kings, with great taste and spirit. They are struck upon fine copper, and amount to thirty-six in number. He likewise gave medals of many illustrious men of this and other nations, which, says Pinkerton, deserve considerable praise. The various medals of eminent private persons in England are very numerous. Those who wish for fuller information of English medals than our limits allow, and the preceding extracts furnish, may consult Pinkerton's Essay so often cited, and Mr. Snelling's plates of them.

Of medals of Scotland, which are numerous, we can only mention some of the principal. The fine gold pieces of David II. 1330—1370, which we have already noticed, are certainly medals. Another Scottish medal occurs of James III. 1478; it is of gold, weighing near two ounces, and its diameter is $2\frac{1}{2}$ inches. The obverse bears a beard-

MEDALS.

els king, with long hair, sitting on a throne, holding in one hand a naked sword, in the other a shield with the Scottish arms. On the borders of the canopy, above the throne, is a Gothic inscription, IN MI DEFFEN, in my defence: the legend of the obverse in Gothic letters is, MONETA NOVA IACOBI TERTII DEI GRATIA REGIS SCOTIÆ. The reverse bears St. Andrew and his cross, SALVVM FAC POPVLVM TVVM DOMINE. Another remarkable Scottish medal is that inaugurative of Francis II. of France and Mary of Scotland, struck upon their coronation as sovereigns of France, and presenting busts of them face to face, with three legends, the outermost of which contains their titles, and the middle one this singular sentence, HORA NONA DOMINUS IHS EXPIRAVIT HELLI CLAMANS: the innermost legend is the name of the city of Paris. The fine crown of Mary and Henry, 1565, is so rare as to be esteemed a medal of the highest value; it is supposed to be worth 40 or 50 guineas. Henry and Mary appear on it face to face, with their titles, and the reverse bears the arms of Scotland, with this legend, QVOS DEVS CONIUNXIT HOMO NON SEPARET. Another remarkable medal of Mary gives her portrait full-faced, and weeping, O GOD GRANT PATIENCE IN THAT I SUFFER VRANG. The reverse has this inscription in the centre, QVIVO CAN COMPARE WITH ME IN GREIF—I DIE AND DAR NOCHT SEIK RELEIF; and this legend around, HOVRT NOT THE (figure of a heart) QVHAIS IOY THOV ART. The last Scottish medal, which we shall mention, is the celebrated coronation medal of Charles I., when he underwent his inauguration at Edinburgh, 18th June, 1633. It was executed by Briot, an eminent French artist; and was the first piece struck in Britain with a legend on the edge, being, it is supposed, the only one ever coined of gold found in Scotland. On the front is the king's bust, crowned and robed, with his titles. The reverse bears a thistle growing, HINC NOSTRÆ CREVERE ROSÆ. Around the edge is EX AVRO VT IN SCOTIA REPERITVR BRIOT FECIT EDINBVRGI, 1633. Few of these were struck on the Scottish gold, three only being known to exist, of which one is in the museum. The piece is not uncommon in silver, in which metal it wants the legend on the edge, which constitutes its chief curiosity and merit. It was in rivalry to this that Simon gave his fine medal of Oliver, the reverse of which is an olive tree, NON DEFICIENT OLIVÆ.

MEDALS, History of, and Account of Writers on this Subject. The study of medals affords such a variety of amusement and of instruction, that we may naturally suppose it to be almost as ancient as medals themselves; and yet ancient writers do not furnish us with a single hint of collections of this kind. In the days of Greece, a collection of such coins as then existed would not be regarded as an acquisition of any great value, because it must have consisted only of those that were struck by the innumerable little states, which then used the Greek characters and language, and of course it would be regarded as a sort of domestic coinage, precluded from extension by the narrow limits of the intercourse that subsisted between different provinces and countries. As soon as any communication was opened between the Romans and the Greeks, the Grecian coins were imitated by the Roman workmen, and preserved in the cabinets of their senators among the choicest treasures. In a more advanced period of the Roman empire, individuals must have formed serieses of Roman coins: for we find, in fact, that a complete series of silver was lately found in our island, containing, inclusively, all the emperors down to Carausius. From the decline of the Roman empire, most branches of science were enveloped in great darkness, till the revival of litera-

ture towards the end of the 15th century. When literature began to be cultivated in Italy, the study of medals, connected with that of ancient erudition, began to engage attention. Accordingly Petrarch, who in modern times was amongst the first persons in Europe that aspired to the celebrity of learning and of genius, was likewise the first to constitute an example of the science of medals. This eminent writer, being desired by the emperor Charles V. to compose a book that should contain the coins of illustrious men, and to place him in the list, with a noble pride answered, that he would comply with his desire, whenever the emperor's future life and actions deserved it. Availing himself of this circumstance, he sent that monarch a collection of gold and silver coins of celebrated men. "Behold," says he to the emperor, "to what men you have succeeded! Behold whom you should imitate and admire! To whose very form and image you should compose your talents! The invaluable present I should have given to nobody but you; it was due to you alone. I can only know or describe the deeds of these great men. Your supreme office enables you to imitate them."

In the next age Alphonso, king of Arragon, caused all the ancient coins, that could be discovered throughout all the provinces of Italy, to be collected, which he placed in an ivory cabinet and always carried with him; that he might be excited to great actions by the presence, as it were, of so many illustrious men in their images. Anthony, cardinal of St. Mark, nephew of Eugene IV., who ascended the pontifical chair in 1431, had a vast collection. Soon afterwards Cosmo de Medici began the grand museum of the family of the Medici at Florence; the most ancient, as well as the most noble, in the universe. Among a profusion of other monuments of ancient art, coins and medals were not neglected. About the same period Matthias Corvinus, king of Hungary, formed a noble collection of coins, along with ancient MSS. and other valuable reliques of antiquity. The first person who seems to have examined medals, and adduced them as vouchers of ancient orthography and customs, was Agnolo Poliziano, or Angelus Politianus. Maximilian I., emperor of Germany, formed a cabinet of medals, by means of which Joannes Huttichius was enabled to publish a book of the lives of the emperors, enriched with their portraits, delineated from ancient coins. M. Grollier, treasurer of the armies of France in Italy during part of the 16th century, had a great collection of coins in all metals. When, after the death of Grollier, these were about to be sent into Italy, the king of France bought them at a high price for his own cabinet of antiquities. Besides medals of brass, this collection contained an assortment of gold and silver. Guillaume du Choul, a contemporary of Grollier, had also a good collection of medals, many of which were published in his treatise on the religion of the ancient Romans, printed at Lyons in 1557. From the letters of Erasmus we learn that the study of medals was begun, in the Low Countries, about the beginning of the 16th century. About the middle of that century, Goltzius, a printer and engraver, travelled over a great part of Europe in search of coins and medals, for works relating to them, which he proposed to publish. At this time, as he informs us, there were in the Low Countries 200 cabinets of medals, 175 in Germany, more than 380 in Italy, and about 200 in France: to which we may add about 500 for our own country, which Goltzius did not visit. The greater number, however, of these cabinets were of that class called caskets of medals, including from 100 to 1000, or 2000 in number. If we except Italy, there are few countries, in which more ancient coins are found

found, than in Britain. Mr. Pinkerton suspects, that Camden was one of the first, if not the very first, of our writers, who produced medals in his works, and who must have had a small collection. In the 17th century, Speed's Chronicle, published in 1610, was illustrated with coins from Sir Robert Cotton's cabinet. Henry, prince of Wales, bought the collection of Gorlaun, amounting, as Joseph Scaliger says, to 30,000 coins and medals, and left it to his brother, Charles I. Archbishop Laud bought 5500 coins for 600*l.* and gave them to the Bodleian library. Thomas, earl of Arundel and Surry, earl marshal of England, had, in his exuberant collection of antiquities, a rich cabinet of medals, gathered by Daniel Nilfum. The dukes of Buckingham and Hamilton, Sir William Paillon, Sir Thomas Fanshawe, Sir Thomas Hammer, Ralph Sheldon, Esq. Mr. Selden, and many more, are enumerated by Mr. Evelyn, as having collections. To this number we may add the earl of Clarendon, the historian, and Charles I. The fine cabinet of this unhappy monarch was dissipated and lost in the civil commotions. Oliver Cromwell had also a small collection; and that of Charles II. is mentioned by Vaillant. We may add, that his present majesty possesses a tolerable collection of ancient gold coins. Since the time of Mr. Evelyn, many noble cabinets have been formed in this country, which we cannot recount. At present, the chief cabinets in Britain are those of the duke of Devonshire, the earl of Pembroke, earl Fitzwilliam, formerly the marquis of Rockingham's, the Hon. Horace Walpole, the Rev. Mr. Crachode, the Rev. Mr. Southgate, Mr. Townley, Mr. R. P. Knight, Mr. Edward Knight, Mr. Tyson, Mr. Barker, Mr. Brown, Mr. Bootle, Mr. Hodful, Mr. Aulien; with Mr. Ord's Egyptian, Mr. Douce's small brads, and Mr. Jackson's British.

The museum, lately enriched by some of those above-mentioned, and the universities, have also collections; and also the Lawyer's library, and one or two colleges in Scotland; to which might be added private collections both there and in Ireland. But that of the late Dr. Hunter deserves notice, as the greatest in Europe, if we only except that of the late French king. From the middle of the 17th century down to these times, almost every year has produced some new work, or new discovery, in the science of medals.

Of writers in this department of science, Mr. Pinkerton has enabled us to mention the following: in Italy, Enea Vico published, in 1548 or 1555, his "Discourses on the Medals of the Ancients." His example was imitated in France by Antoine le Pois, who in 1579 gave his "Discourse on the Coins and Seals of the Ancients." In 1665, Charles Patin published his "History of Medals, or Introduction to that Science." The last edition appeared in 1695. In 1692, Pere Jobert, or Joubert, presented to the public his "Science des Medailles," the best edition of which is that of 1739, by M. le Baron Bimard de la Baillie. In the year in which Jobert published his book, a work somewhat similar to it was published in the English language, entitled "The Greek and Roman History illustrated by Coins and Medals, representing their Religion, Rites, &c. by O. W. (Obadiah Walker,) London 1692, 12mo." In 1695, a translation of Jobert's work appeared under the title of "The Knowledge of Medals," ascribed to Walker. The "Numismata, or Discourse on Medals, ancient and modern," by Mr. Evelyn, was printed in 1697, fol. In 1720, Nicolas Haym, an Italian musician, published at London his "Tesoro Britannico," or British Treasury, in Italian and English. They who wish to proceed in this science, says Mr. Pinkerton, may peruse the most excellent and useful work of Froelich, entitled "Notitia Numismatum antiquorum illorum, quæ

Urbium Libensium, Regum et Principum, ac Personarum illustrium, appellantur," Vienna, Prægæ, et Terræ, 1758, 4to; and afterward such books of medals as they please, in chronological order as published, from Goltzius down to Pellerin and Combe. The following list of the best authors is given by Mr. Pinkerton. For the general science he recommends Vico's work, and Patin's already mentioned. The study of the Greek coins may be begun with Goltzius "Hiberna Sicilicæ et Magnæ Græciæ ex antiqui Numismatibus," Antwerpæ 1644, fol. Recourse may then be had to Goltzius's "Thesaurus Numismatum," Tiguri 1738, two vols. fol. The productions of Pellerin, Paris 1762, and following years till 1778, making, with all the supplements, 10 vols. 4to, ought next to be perused. Dr. Combe's publication of Dr. Hunter's coins of Greek cities, London, 1782, 4to., as it is the last, so it is the very best of the kind ever yet given. Of the Greek monarchic coins Gessner's is the most ample assemblage. The Roman consular coins will also be found in full detail in Gessner; and descriptions may be found in Vaillant's "Nummi Antiqui Familiarum Romanorum," Amst. 1703, two vols. fol., or the "Thesaurus Morellianus," Amst. 1734, two vols. fol., a later and a better work. The imperial coins of Rome are likewise amply displayed by Gessner; with whom, for the rare coins, should be read Vaillant's "Numismata Imperatorum Romanorum," published by Baldini at Rome, 1743, three vols. 4to., and Khehl's "Numismata Imperatorum Romanorum," Vindobonæ 1767, 4to., a supplement to the Roman edition of Vaillant; Banduri's "Numismata Imp. Rom. a Trajano Decio usque ad Palaeologos," (or to the termination of the Byzantine empire) Lutetiae, 1718, two vols. fol.; Occo's "Numismata Imp. Rom." The best edition is the second of Occo himself.

Of books on modern coins and medals, the first which ought to be perused by a British subject are those relating to his own country. He should begin with Mr. Clarke's "Connection of the Roman, Saxon, and English Coins," London 1767, 4to.; Mr. Lowndes's excellent "Report, containing an Essay for the Amendment of Silver Coins," Lond. 1695, 8vo.; Snelling's "Views of English Money," Lond. 1763, and following years, 4to.; and Folkes's "Tables of English Coin," Lond. 1763, 4to. Ducarel's "Letters on Anglo-Gallic Coins" are very considerable. English medals are published by Snelling and in Vertue's Account of Simon's works. On the Scottish coins the only books are those of Anderfon and Snelling. The Irish are well displayed by Simon, in his "Historical Essay on Irish Coin," Dublin, 1749, 4to., with the supplement by another author 1767, 4to. For the account of the sources of information with regard to other modern countries, we must refer to Mr. Pinkerton's preface. The second edition of Mr. Pinkerton's "Essay on Medals" will supersede the necessity of constant reference to other works, not easily procured; and the reader will find, that the author has cited original authors, and availed himself of an examination of many of the coins themselves, which he has described. This elaborate work, in two small volumes, Lond. 1789, will afford to the student in this branch of science ample satisfaction. This edition, besides many corrections and additions, that very much contribute to the increased value of the work, is illustrated with prints of coins, engraven exactly of the form and size of the originals, forming specimens of all the principal sorts. In the advertisement to this new edition, the author expresses himself in terms of high commendation concerning Monaldini's "Istituzione antiquariou Numismatica," printed at Rome, 1772, 8vo., which, he says, is much superior to Jobert's "La Science des Medailles."

MEDALS.

MEDALS, Utility of the Study of. Medals are of great importance to the study of history. They, indeed, furnish the principal proof of historic truth, as their evidence reaches to the most remote ages and the most remote countries. Vaillant set the first example, in his learned history of the Syrian kings, printed at Paris in 1681, of fixing the dates, and arranging the order of events in ancient historians, by means of these infallible vouchers. Thus he was enabled to ascertain, in a very great degree, the chronology and progress of events of three of the most important kingdoms of the ancient world, *viz.* those of Egypt, of Syria, and of Parthia. Father Hardouin, Noris, and Bayer, have pursued the same plan; and to them we may add Froelich, Corfini, and Cary. The study of the Roman medals has a superior advantage to that of the Greek coins, as they serve not only to illustrate the chronology of reigns, but to aid us in the interpretation of particular events. To this purpose, besides the portrait of the prince, and date of his consulship, or of his tribunitian power, we have a representation, or poetical symbol, of some grand event on the reverse. In a word, the series of Roman coins presents the very best suite of documents of the Roman history, which the art of man could have invented. Besides its service to history, the science of medals is without doubt of considerable use to geography, to natural history, to the illustration of ancient writers, to architecture, and to the knowledge of a connoisseur, or that of ancient monuments, busts, statues, ceremonies, and the like; in all which views its utility is well illustrated by examples in Pinkerton's valuable work. He has also evinced the connection of the study of medals with the fine arts of poetry, painting, sculpture, and architecture. In the first respects, he has greatly improved upon Mr. Addison's "Dialogues on the Usefulness of ancient Medals." On this very interesting subject, which Mr. Pinkerton has rendered no less amusing than instructive, we cannot forbear making a few extracts. The Roman coins to a man of poetical imagination are very entertaining by means of the fine personifications and symbols, which are to be found on their reverse. *Happiness* has sometimes the caduceus or wand of Mercury, which Cicero tells us was thought to procure the gratification of every wish. In a gold coin of Severus, she has heads of poppy, to express that our prime bliss lies in oblivion of misfortune. *Hope* represented as a sprightly damsel, walking quickly and looking straight forward. With her left hand she holds up her garments, that they may not hinder the rapidity of her pace; while, in her right hand, she holds forth the bud of a flower, an emblem infinitely more fine than the trite one of an anchor, which is the symbol of Patience, not of Hope. *Abundance* is imaged as a sedate matron, with a cornucopia in her hands, of which she scatters the fruits over the ground; but does not hold up her cornucopia, and keep its contents to herself, as many poets and painters make her do. *Security* stands leaning on a pillar, indicative of her being free from all designs and pursuits; and the posture itself corresponds to her name. The emblems of *Piety*, *Modesty*, and the like, are equally apposite and poetical. The happiness of the state is pictured by a ship, sailing before a prosperous breeze; an image of which Gray has admirably availed himself in his "Bird." The different countries of the then known world are also delineated with great poetical imagery. To a Briton, it affords peculiar satisfaction to see his native island often represented upon the earliest imperial coins, sitting on a globe, with a symbol of military power, the "labarum," in her hand, and the ocean rolling under her feet. Coins also present us with countries and rivers, admirably personified. On the reverse of a colonial coin, rude in execution, of

Augustus and Agrippa, inscribed IMP. and DIVI. F., the conquest of Egypt is represented by the apposite metaphor of the crocodile, an animal almost peculiar to that country, and at that period esteemed altogether so, which is chained to a palm-tree, at once a native of the country and symbolic of victory. Moreover, a cabinet of medals, of which Rubens is said to have had a very fine collection, may be considered as forming the classic erudition of a painter. We may add, that almost all the uses which connect the science of medals with painting, render it also subservient to the art of the sculptor, who cannot less than profit by the study of the Greek coins in particular. The connection of the study of ancient coins with architecture, consists in the views of many of the ancient edifices, which are found in perfect preservation on medals. Froelich observes, that the coins of Tarsus are very remarkable for a kind of perspective in the figures. On others are found triumphal arches, temples, fountains, aqueducts, amphitheatres, circuses, hippodromes, palaces, basilicas, columns and obelisks, baths, sea-ports, pharos, and the like.

MEDALS and Coins, Rarity of. The scarcity of coins, bearing any particular impression, must be principally owing to the few that were struck with that impression, or their being called in, and issued from the mint in another form. The first is the case with the copper of Otho, and gold of Pescennius Niger; the latter with the coinage of Caligula. Sometimes coins, formerly esteemed almost singular, will, in later times, become much more common in consequence of the high price at which they are rated, so that they are brought to market as hoards of them are found. The first was the case with the farthings of queen Anne; some of which, formerly sold at five guineas, would not now fetch five shillings; the latter with respect to the coins of Canute, king of England, which were very rare till a large hoard of them was discovered in the Orkneys. The coins of Greek cities are esteemed to be more common in copper than in silver; double the number existing in the first metal: those of Greek princes the reverse, with a few exceptions, those of silver being more numerous. Of the Greek monarchic coins, the tetradrachms of the Syrian kings, the Ptolemies, the princes of Bithynia and Macedon, excepting Alexander the Great and Lysimachus, are all rare. Those of Cappadocian kings are not found, except of small size, and are scarce. Of the kings of Numidia and Mauritania, Juba, the father, is common, the son and nephew Ptolemy are scarce. The kings of Sicily, in large silver, are rare: as are also those of Parthia. The kings of Judæa are rare; those of Arabia and Commagene only occur in brass, and are scarce; and likewise the kings of Bosphorus, who appear in electrum, and a few in brass. The kings of Pontus, and Phileterus, king of Pergamus, are all rare. All didrachms, both of kings and cities, are scarce, except Corinth and her colonies. The gold coins of Macedon, Alexander the Great, or Lysimachus, are common: the others very rare. All silver tetradrachms of kings are accounted medallions, and bear a high price. One of the scarcest of the small silver coins of the Greek princes is the didrachm of Alexander the Great. The Grecian monarchic money of copper may, in most instances, be considered as rare.

Of the Roman coins, the consular ones restored by Trajan are the rarest of their class. The gold consular coins are the most rare, and the silver the most common; excepting the coin of Brutus, with a cap of liberty between two daggers, EID. MART. which is scarce, and a few other instances.

Among the Roman imperial coins, we shall only mention that

MEDALS.

that of Otho in brass; the scarcity of which is owing to the shortness and tumult of his reign. The scarcity of other imperial coins is largely stated by Mr. Pinkerton in his tables. The Roman coins in gold are all extremely rare. The heptarchic coins of Britain are mostly rare: the money of Alfred, bearing his bull, is rather scarce; his other coin is very rare. The coins of Hardeknute are very scarce. Of kings after the conquest no English coins of John are found, except Irish only, and of Richard I. only French. In the Scottish series Alexander II. is rather scarce. Coins of John Balliol are rare, and none of Edward Balliol are found. The gold money of Scotland has always been scarce. See farther on this subject the Appendix to Pinkerton's Essay on Medals.

In the sale of medals, those that are rare are sold separate, but the common ones are put into large lots, so that they are seldom bought but by dealers. The old coins of Greek cities are generally very small; and not above a dozen states have those in gold: of these only Carthage, Cyrene, and Syracuse are rather common, and worth but double their intrinsic value. The other gold civic coins are worth from 5*l.* to 30*l.* The only two gold coins of Athens known to exist are in Dr. Hunter's collection, and if they were sold, they might bring the very highest price a coin can bear. The silver coins of Greek cities are many of them extremely scarce; the common ones are priced according to their size, for the largest are always the rarest. Those of Syracuse, Dyrrachium, Massilia, Athens, and a few other states, are common; drachmas, and lesser sizes, might bring 5*s.* each; didrachms and tridrachms from 5*s.* to 10*s.* according to their beauty and preservation. The tetradrachms, which are always most valued, may, when belonging to cities whose coins are common, bring from 7*s.* 6*d.* to 1*l.* 1*s.* Civic coins of silver that are rare are not easily valued. Ten guineas have been given for one, and competition might triple that value. The common Grecian civic coins in small brass bring from 3*d.* to 1*s.* 6*d.*, according to their preservation. Others belonging to cities, which have not above two or more coins that are known, and those of brass, bring much higher prices. With respect to the gold coins of the Greek princes, those of no rarity in the coinage of Philip of Macedon, and Alexander the Great, bear but from 5*s.* to 20*s.* above the intrinsic value. But those of the other princes are rare, and bring from 3*l.* to 30*l.* a-piece, or more. Of the silver monarchic money, with Grecian legends, the tetradrachms, which are dearest, fell from 5*s.* to 50*s.*, and those that are very rare from 3*l.* to 30*l.* The drachmas may bring half these prices, and that of other denominations in proportion. The copper coins of the Greek kings are, generally, scarcer than the silver, and ought to bring a high price. Ancient Roman *Aes*, with their divisions, bring from 2*s.* to 2*l.*, according to the singularity of their devices. Consular gold coins are worth from 1*l.* to 5*l.*: the Pompey, with his lions, 21*l.*, and the two Bruti, 25*l.* The silver rate universally from 1*s.* to 2*s.* 6*d.*, except that with the cap of liberty and daggers, and a few others, which, if genuine, may bear from 10*s.* to 5*l.* The consular copper, though rarer than the silver, may be put at an equal price. The consular silver coins, restored by Trajan, bear 1*l.* a-piece. Among the Roman imperial coins, with uncommon reverses, we may reckon a silver piece of Augustus, which will fetch from 4*s.* 6*d.* to 1*l.* 11*s.* 6*d.*; that with the legend C. MARIVS TROGVVS bears 3*l.* 3*s.* Common gold coins of Trajan are not worth above 1*l.* The medals, with unknown characters, are scarce and dear. Saxon pennies of the heptarchic princes are generally rare, and worth from 10*s.* to 10*l.* each, according to scarcity and

preservation. Those of the kings of all England, which are rare, are worth from 10*s.* to 2*l.* 10*s.*; excepting one or two very large ones, such as Henry 1*st.*, which would fetch 1*l.* 10*s.* Of English medals, the gold one of Henry, 1515, and of Edward's coronation, are worth 20*l.* each; the Mary of Trezzo, 3*l.* The dust of Simon's works are in the field of Phaulx, in gold, 1*l.*; his oval medal, in gold, upon Black's victory, is 1*l.* 3*l.*; his oval piece, if brought to sale, would bring a large sum. Queen Anne's medals in gold, intrinsically worth above 2*l.* 10*s.* 6*d.*, bear about 3*l.* a-piece. The silver, of about the size of a crown-piece, will bring 10*s.* each; the copper from 5*s.* to 10*s.* The Scottish coins are on a par with the English, excepting that the gold sell higher. The shilling of Mary, with the bull, is very rare, and brings 30*s.*; the half, 3*l.*; the ryal, 5*l.* 5*s.* The French talon of Francis and Mary brings 10*l.* 10*s.*; the Scottish one of Mary and Henry would bring 50*s.*; as would also the medal of James IV. The coronation medal of Francis and Mary is worth 20*l.* Brit's coronation medal in gold sold only for 2*l.* 2*s.* at Dr. Mead's sale in 1755, but would now bring 20*l.* The English coins struck in Ireland, or appropriated to that kingdom, are mostly of the same price as the other English coins. The St. Patrick's halfpence and farthings are rather scarce. The gun-money of James II. is quite common. The rare crown of white metal brings about 4*l.* All other Irish coins are very common. See the Appendix to Pinkerton's Essay.

MEDALS, Counterfeit, are forged imitations of ancient coins; the art of doing which is said to have arisen at the beginning of the 16th century, and has since prevailed to an astonishing degree. These counterfeit medals are distributed into six classes: 1. Medals known to be modern imitations of the ancient; but which being executed by masters, such as the Paduan, &c. have their value. 2. Medals cast from these modern masterly imitations. 3. Medals cast in moulds taken from the antique. 4. Ancient medals which are retouched, and the obverses or reverses altered. 5. Medals which are impressed with new devices, or which are soldered. 6. Counterfeit medals which have clefts, or which are plated. For the method of distinguishing these counterfeits from the true, in which the possessors or purchasers of medals are particularly interested, we refer to Mr. Pinkerton's Essay, vol. ii. p. 167, &c.

MEDALS, for the manner of striking, see COINAGE.

MEDALS, Academy of See ACADEMY.

MEDALS, Cabinet of, may be divided into three distinct sizes: 1. The large and complete cabinet, containing, or intended to contain, every issue of the mint, in every age and every country. The late king of France had the most richly furnished cabinet of this kind in existence, and which is calculated to have cost near 100,000*l.* sterling. That of the late Dr. Hunter was, perhaps, one of the best private cabinets ever formed in this style; and cost about 21,000*l.* 2. The smaller cabinet, the collector of which, confining himself to the forming of five or six sequences, as of middle and small Roman brass only, of English pennies, or of groats, or any other particular series, considers other medals as out of his line of collecting, though he may purchase a few desolate ones, or such as belong to other sets, in order to give variety to his collection. Such a cabinet may incur an expence of from 200*l.* or 300*l.* to 1000*l.* 3. The least cabinet, or casket of medals, which may include all little collections of coins, from 100 to 1000 or 2000. In this not above one or two sequences can well be formed; but the amateur pleases his fancy by the miscellaneous insertion of any article which curiosity or other motives may incline

cline him to procure. In the formation of the large cabinet, it is to be observed, that in the grand division of ancient coins, as distinct from the modern, the Greek medals, of every denomination, can never be arranged by the metals, or sizes, like the Roman; for no series of any one metal, or size, can be found of this class in the most opulent cabinet. On this account the civic coins of all metals and sizes, are digested in alphabetical order, and the monarchic in chronological. The same rule is to be observed in the Roman consular medals, which are arranged in alphabetical series of the families, like those of the Greek cities. The proper divisions of a grand and complete cabinet, comprehending the part allotted to ancient coins, are stated by Mr. Pinkerton as follows: 1. The coins of cities and free states, in alphabetical order; whether using Greek, Roman, Punic, Etruscan, or Spanish characters. 2. Kings in chronological series, both as to foundation of empire and seniority of reign. 3. Heroes, heroines, and founders of empires, and of cities. 4. Other illustrious men and women. 5. Roman *Aves*. 6. Coins of families, commonly called consular. 7. Imperial medallions. 8. Imperial gold. 9. Imperial *minimi*, of all metals. 10. Imperial silver. 11. Imperial first brads. 12. Second brads. 13. Third brads. 14. Colonial coins, which are all of brads. 15. Greek cities under the emperors, of all metals and sizes. In a smaller cabinet they may be put with the Roman, according to their metal and size. Those without the emperor's head go to class 1, though struck in Roman times. 16. Egyptian coins struck under the Roman emperors, of all metals and sizes. They are mostly of a base metal, called by the French writers "potin," being a kind of pot-metal, or brittle brads. 17. "Contorniat," or ticket medals. 18. Coins of Gothic princes, &c. inscribed with Roman characters. 19. Coins of southern nations, using unusual alphabets; as the Persian, Punic, Etruscan, Spanish. 20. Coins of northern nations, using unusual characters; as the Runic and German.

In the modern part no series can be found of copper that will go back above two centuries; but sequences of gold and of silver may be arranged of all the different empires, kingdoms, and states, so far as their several coinages will allow. Those of England and France will be the most perfect. Modern silver is commonly arranged in three sequences; the dollar size, the great size, and the penny size. The metals of each modern country ought of course to be separated; though it is best to arrange each set in chronological order, whatever be their size or the metal.

The formation of a cabinet of the second class will admit of observing the directions for the former, so far as this is meant to extend. But as it includes only a few complete sequences, either of ancient or modern coins, some particular instructions may be necessary. If, *e.g.* the collector means to form a series of the large brads, he will find the coins of four or five emperors so scarce as not to be attainable in that series, even at any price. He must, therefore, supply their places with a middle brads, as is allowed with regard to Otho even in the best cabinets, there not being above three coins of that emperor in large brads known in the world, whereas of the middle brads two or three hundred may exist. If this be allowed in one instance, why not in others? Why may not Tiberius or Pertinax appear in the middle brads as well as Otho? In cabinets of the second class the collector may mingle the middle with the large brads as he thinks proper; and in like manner the small with the middle. In the small sequences there can be no harm in his mixing gold, silver, and brads, as chance or curiosity may lead him to purchase any of these metals.

In like manner, if, in the modern part of the smaller cabinet, any coin of a series is of high price, or of bad impression, there can be no impropriety in putting another of the same reign which is cheaper, or better executed, though of a different denomination, and a little larger size. In short, the collector has no rules, but in the Greek cities and Roman families to observe alphabetical order, and chronology in every thing else. The management in a cabinet of medals may be conducted by the observations already made upon those of the two higher descriptions.

MEDALS, Cast, are those which are not struck, but cast in a mould.

MEDALS, Contourniated. See **CONTOURNIATED.**

MEDALS, Covered or Plated, are those which have only a thin silver leaf over the copper, but which are struck so artfully, that the cheat does not appear without cutting them; these are the least suspected.

MEDALS, Countermarked, are those which have marks cut either on the side of the head, or of the reverse. These countermarks serve to denote the change of their value; and this kind is much inquired for by the curious. See **MEDALS, supra.**

MEDALS, Dipt, are struck of pure copper, and afterwards silvered. This is a contrivance that the curious have frequent recourse to, in order to complete their silver sets.

MEDALS, Grained or Indented, are those whose edges are cut, or notched like teeth, which is a sign of purity and antiquity. They are common among the consulars, but we have none later than Augustus. There are several of them, however, among those of the kings of Syria.

MEDALS, Impressions or Casts of. A very easy and elegant way of taking impressions or casts of medals and coins is this: melt a little isinglass glue, made with brandy, and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, till it is thoroughly dry and hardened, and then taking it off, it will be fine, clear, and hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. In order to render the relief of the medal more apparent, a small quantity of carmine may be mixed with the melted isinglass; or the medal may be previously coated with leaf-gold by breathing on it, and then laying it on the leaf, which will by that means adhere to it; but the use of leaf-gold is apt to impair a little the sharpness of the impression. Impressions of medals may be likewise taken in putty of the true kind, made of calx of tin and drying oil. These may be formed in the moulds, previously taken in plaster or sulphur; or moulds may be made in its own substance, like those of plaster. These impressions will be very sharp and hard; but the greatest disadvantage attending them is their drying very slowly, and being liable in the mean time to be damaged.

Sulphur is sometimes used to take off impressions of medals, coins, &c. The method is this: having made a ledge of clay about the work whose impression is desired, and carefully oiled the whole, gently pour brimstone melted in a covered vessel, to prevent its firing, upon the metal. About the edge of this mould make a border of clay, as before, and lightly oil the internal surface of both; then gradually put into it, to the thickness of about a quarter of an inch, a mixture made up with calcined alabaster and water, to the consistence of stiff honey. This soon growing hard, may be taken out of the mould, and gives figures of the coin or medal. Boyle's Works, abr. vol. i. p. 151. A method somewhat different is described under the article **BRIMSTONE.**

The brittleness of sulphur is a great objection to this method, and the plaster of Paris, which is often used for taking

taking impressions, is too soft: however, a coat or layer of thin metal, formed over the plaister, would be a considerable defence. This is the cheapest and most convenient metal for this purpose: let thin tin-foil, such as is used for silvering looking-glasses, be laid over the medal or coin intended to be taken off, and then rubbed either with a brush, the point of a skewer, or a pin, till it has received perfectly the impression of the medal; then pare off the tin-foil round the edge of the medal, till it is brought to the same circumference; afterwards the medal must be reversed, and the tin-foil will drop off into a chip-box, or mould ready to receive it; the concave side of the foil, or that which is laid on the face of the medal, being uppermost; upon this pour plaister of Paris, made in the usual manner, and when dry the cast figure may be taken out of the box or mould, with the tin-foil sticking on the plaister, the convex side being now uppermost, in which position it is to be kept in the cabinet after it becomes dry. To have an impression very perfect, the thinnest tin-foil should be made use of. The impressions taken in this manner almost equal silver medals in beauty, and are very durable. If the box or mould be rather larger than the impression of tin-foil, the plaister, when poured on, runs round its edges, and forms a kind of white frame, or circular border round the foil, whence the new made medal appears more neat and beautiful. If this tin-foil is gilt with gold-leaf, by means of thin isinglass glue, the medal will resemble gold.

Casts of medals may be made likewise with iron, prepared in the following manner: Take any iron bar or piece of a similar form; and having heated it red-hot, hold it over a vessel containing water, touch it very slightly with a roll of sulphur, which will immediately dissolve it, and make it fall in drops into the water. When a sufficient quantity of iron is thus dissolved, pour the water out of the vessel, and pick out the drops formed by the melted iron from those of the sulphur which contain little or no iron, and will be distinguishable from the others by their colour and weight. The iron will, by these means, be rendered so fusible, that it will run with less heat than is required to melt lead; and may be employed for making casts of medals, and many other such purposes, with great convenience and advantage.

We have an easy method of procuring the true impression or figure of medals and coins, by Mr. Barker in the *Philos. Trans.* N^o 472. sect. 13. vol. xliii. p. 77.

Take a perfect and sharp impression on the finest black sealing-wax, of the coin or medal you desire. Cut away the wax round the edges of the impression; then with a preparation of gum-water, of the colour you would have the picture, spread the paint upon the wax impression with a small hair-pencil, observing to work it into all the sinking or hollow places, these being the rising parts of the medal; and the colouring must be carefully taken from the other parts with a wet finger. Then take a piece of very thin post-paper, a little larger than the medal, and moisten it quite through. Place it on the wax impression, and on the back of the paper lay three or four pieces of thick woollen cloth or flannel of about the same size. The impression, with its coverings, should be placed between two smooth iron plates, about two inches square, and one-tenth of an inch thick.

These must be carefully put into a small press, made of two plates of iron, about five inches and a half long, one inch and a half wide, and half an inch in thickness, having a couple of long male serews running through them, with a turning female screw on each, to force the plates together. These being brought evenly together by means of the serews,

will take off a true and fair picture of the medal; which, if any deficiencies should appear, may easily be repaired with a hair-pencil or pen, dipped in the colour made use of.

If a relief only be desired, nothing is necessary but to take a piece of card, or white paste-board, well soaked in water, then placing it on the wax mould, without any colouring, and let it remain in the press for a few minutes, a good figure will be obtained.

This method of taking off medals, &c. is convenient, and seems much more so than the several inventions usually practised in sulphur, plaister of Paris, paper, &c. wherein a mould must be formed, either of clay, horn, plaister, or other materials, which requires time and trouble.

Some take impressions on paper from the medals themselves, by passing them through the rolling-press, and colouring them afterwards; but this is not only more difficult, but does great injury to the medals, by impairing the sharpness of their most delicate and expressive strokes: whereas wax does not hurt the finest medal in the least degree; and though a brittle substance, yet it effectually resists the force of a downright pressure.

Red seems the best colouring, and therefore black wax is directed to be used; but if the pictures are chosen in black and white, to resemble copper-plates, the wax should be red; for the wax and paint ought to be of different colours, in order to distinguish when the colour is laid on properly, or rightly cleared away.

The substance of medals, being metalline, is liable to be corroded; and the figures being raised, are also liable to be effaced by friction. Hence it is rare to find any perfectly preserved. Gems are not subject to these inconveniencies. See GEM.

MEDALS, *Mutilated*, are those that are not entire, or are much defaced.

MEDALS, *Redintegrated*, are those wherein we find the letters rest, which shew that they have been restored by the emperors.

MEDAL, *Repairing a*. See REPAIRING.

MEDALS, *Restitution of*. See RESTITUTION.

MEDALS, *Votive*. See VOTIVE.

MEDALS *without Reverse*. See REVERSE.

MEDALETS, a name given by Mr. Pinkerton to those small coins or missilia, scattered among the people on solemn occasions, those struck for the slaves in the Saturnalia, private counters for gaming, tickets for baths and feasts, tokens in copper and lead, and the like. Baudelot, in his curious and entertaining work, "*L'Utilite des Voyages*," has produced many singular specimens of medalets; for some of which see Pinkerton's *Essay on Medals*, vol. i. p. 227, &c.

MEDALLION, or MEDALION, a medal of extraordinary size.

The word is formed from the French *medaillon*, or Italian *medaglione*, which signify the same, or a large medal; and which were originally formed from *metalliones*, a name by which these pieces are frequently called in ancient Latin writers.

Medallions were never any current coins, as some medals probably were: they were struck purely to serve as public monuments, or to be presented by the emperor to his friends, and by the mint-makers to the emperor, as specimens of fine workmanship.

They were struck upon the commencement of the reign of a new emperor, and other solemn occasions; and frequently, the Greek medallions in particular, as monuments of gratitude, or of flattery. Sometimes they were trial or pattern-pieces, "*testimonia probatæ monetæ*;" and such abound after the reign of Maximian, with the "*Tres Monetæ*"

netz" on the reverse. It is observed, that all Roman pieces in gold, exceeding the denarius aureus; all in silver, superior to the denarius; and all in brass, superior to the sestertius, or what the medallists term large brass, are comprehended under the description of medallions. Mr. Pinkerton, however, thinks that the gold medallions, weighing two, three, or four aurei only, passed in currency as the Greek gold didrachms, tridrachms, or tetradrachms, according to their size. The like may be said of the silver, which are commonly of the value of a Greek tetradrachm, which went in currency for four denarii. But it is not of much moment whether any of the pieces called medallions passed as coin with the ancients; it is sufficient to know what kind of coins passed under that denomination. The brass medallions, which are the largest, are commonly of the most exquisite workmanship, and uncommon device. Many of them are composed of two sorts of metal, the centre being copper, with a ring of brass around it, or the contrary. The inscription of such sometimes bites upon both metals, and at other times runs upon one. Medallions of this kind are inimitable, and of undoubted antiquity. Medallions from the time of Julius to that of Hadrian are very uncommon, and of very high price; from Hadrian to the close of the western empire they are, generally speaking, less rare. The types of the Roman medallions are often repeated upon common coin: hence they appear of less importance than the Greek, impressions of which are frequently most uncommon, and no where else to be found. A remarkable distinction between the Greek and Roman medallions lies in their different thickness; the Roman being often three or four lines thick, while the others seldom exceed one. By the Greek medallions we mean those struck in the imperial periods; for few Greek medallions are found prior to the emperors of Rome. Of Greek medallions, preceding the Roman empire, few are known. Some occur of Rhodes; and there is a fine one struck at Syracuse, upon the defeat of Icetas by Timoleon. The medallion is of silver, with the head of Ceres upon one side, and upon the other a female figure, perhaps representing Sicily or Syracuse, in a car, a victory crowning her, and spoils in the exergue. Its workmanship is fine, but not equal to the gold coin of the same Icetas, struck at Syracuse, ΕΠΙ ΙΚΕΤΑ, under Icetas, which is a perfect gem, surpassing all description. Syracuse also affords a most remarkable medallion on another great occasion. The only one perhaps existing formerly belonged to Dr. Combe, and was engraven by his order. It is exquisitely wrought, in high relief, and perfect preservation; of copper, and about two inches in diameter. Upon one side is a female head, covered with a helmet, on which is a caduceus, and ΡΟΜΑ. Upon the other is a man's head, with a helmet wreathed with laurel, and M. M. Dr. Combe thinks this fine piece, now in Dr. Hunter's cabinet, was struck by Syracuse, in honour of Marcus Claudius Marcellus, who besieged and took that city, 210 years B.C. This medallion is most remarkable for its being unique; for its beauty, for its preservation, and for the portrait of this great man. There are perhaps the only Greek medallions prior to the Roman empire. Many Roman medallions have s. c., as being struck by order of the senate; others have not, as being by order of the emperor. Of Augustus a noble medallion was found in Herculaneum, and Khell published a dissertation upon it. There are medallions of Augustus and Tiberius, struck in Spain; and one of Livia, at Patrae in Achaia: one in brass of Antony and Cleopatra; reverse, two figures in a car, drawn by sea-horses. Of Tiberius there are many, and also of Claudius. There are also some of Agrippina, Nero, Galba, Vespasian, and Domi-

tian. Those of Trajan and Hadrian have generally a very broad rim, beyond the legend, with indented circles; and of Hadrian, Baldini gives no less than 47. There are fine medallions of Commodus, and his famous mistress Marcia; their heads are joined, and she wears a helmet. One of Pertinax bears, for reverse, that emperor sacrificing, with VOTIS DECENNALIBUS. There are many of Severus, Gordian III., and Philip; afterwards they are numerous of Gallus, Valerian, Gallienus, Aurelian, Probus, Diocletian, Maximian I., Constantius I., Constantine I. and II., Constans, and Constantius II. Of other emperors they are scarcer. In Dr. Hunter's cabinet, among many others, there is one of Otacilia. The Greek medallions of Roman emperors are far more numerous than the Roman. All medallions, one or two instances excepted, are very rare, and of princely purchase. Even in the richest cabinets, 20 or 30 medallions are esteemed of great weight. In the 17th century, however, queen Christina was so fortunate as to procure about 300; and the king of France's cabinet was possessed of about 1200 medallions. Dr. Hunter's cabinet contains about 400, exclusive of Egyptian. There are also Latin medallions, of a size between first and second brass, or larger than our half-crown, easily distinguishable by their thickness, and uncommon neatness and manner. These are, by Italian medallists, called "Medaglioncini," or little medallions. In Dr. Hunter's collection is a fine one of Alexander Severus and Julia Mammæa, face to face; reverse their figures, with FELICITAS TEMPORVM. Pinkerton's Essay on Medals, vol. i.

MEDALLION, in *Architecture*, is any circular tablet on which are imbossed figures or busts.

MEDAMA, in *Geography*, a town of the island of Ceylon; 16 miles N. of Candi.

MEDAMPE, a town of the island of Ceylon; 36 miles N. of Columbo.

MEDANIPEK, a town of Servia, on the river Ipek; 22 miles S.W. of Orsova.

MEDARD, St., a town of France, in the department of the Lot; 8 miles N.W. of Cahors.

MEDAUAR, a town of Arabia, in the province of Yemen; 28 miles N.W. of Dsejebi.

MEDAUSO, a town of Africa, in the country of Bergeoo; 150 miles S.W. of Wara.

MEDE, JOSEPH, in *Biography*, a learned divine, was born in 1586, at Berden in Essex, and in 1602 entered of Christ's college, Cambridge, where he studied with intense application, was chosen fellow, and proceeded to his degree of bachelor in divinity. He refused several preferments, particularly the provostship of Trinity college, Dublin, which was repeatedly offered him by archbishop Usher. He died in 1638. His works have been collected into one volume folio. The principal is his Commentary on the Apocalypse; in explaining which, his plan has been followed by bishop Newton, and a number of other great divines. Biog. Brit.

MEDEA, in *Geography*, a town of Algiers, in the province of Titterie, surrounded with mud walls. anciently "Lamida;" 32 miles S.W. of Algiers. N. lat. 26 5'. E. long. 2° 50'.

MEDEA, *El, Mebdia, or Mehedia*, a town of Africa, in the kingdom of Tunis, on a peninsula, on the east coast, formerly a place of great strength and importance. The port, which was an area of nearly 100 yards square, lies within the walls of the city, with its mouth opening towards Cap-oudia; but at present not capable of receiving the smallest vessel; 80 miles S. of Tunis. N. lat. 35° 20'. E. long. 11°.

MEDEBACH,

MEDEBACH, a town of Westphalia; 32 miles W. of Cassel. N. lat. 51° 10'. E. long. 8° 48'.

MEDELAIN, a town of Spain, in Ultramaradura, on the Guadiana, being the native place of Fernando Cortez. It is an ancient town, having been founded by Q. C. Metellus, the Roman consul, and called by him "Metellum;" 13 miles S. E. of Merida. N. lat. 38° 43'. W. long. 5° 47'. — Also, a town of Mexico, in the province of Tlaxcala, 25 miles S. of Vera Cruz, on a river of the same name, which runs into the gulf of Mexico, N. lat. 19°.

MEDELPAD, a province of Sweden, in the division called Nordland, bounded on the north-east by Angermandland, on the east by the gulf of Bothnia, on the south-west by Helsingland, and on the north-west by Jamtland, or north by the river Indal, and south by the Niirunda; from 13 to 20 leagues from north to south, and upwards of 30 from west to east. This province, though mountainous and woody, contains several valleys of meadow and arable land, interspersed with rivers and lakes, which yield abundance of fish. The grain, which is sown here about Whitsuntide, produces corn that ripens in ten weeks; and it is sufficient to supply the inhabitants. The forests abound with game of all sorts, elks, rein-deers, beavers, martins, weasels, lynxes, foxes, and wild fowl. The inhabitants have plenty of cattle, and traffic in timber, hops, flax, hemp, butter, fruits, and dried fish. The only sea-port is Sundswall, which is a mean though trading town, situated in a dry and sandy tract, near the bottom of a bay, with a convenient port. This province lies in N. lat. 62° 30'.

MEDELSHEIM, a town of France, in the department of Mont-Tonnerre, and chief place of a canton, in the district of Deux-Ponts. The place contains 338, and the canton 4521 inhabitants, in 15 communes.

MEDEMA, a town of Arabia, in the province of Yemen, and the Imam's dominions: it is the capital of Hamdan, and the residence of a schiech; 10 miles N. N. W. of Sana.

MEDEMBLICK, a sea-port town of Holland, at the entrance into the Zuyder see, small though ancient, and, before Enckhuysen and Hoorn were built, the capital of North Holland. The inhabitants trade chiefly in timber, which they bring from Norway, and other northern parts of Europe. Its vicinity abounds with rich pastures. As the land is here lower than the waters, it requires very strong dykes and dams to defend it from the fury of the waves; 26 miles N. of Amsterdam. N. lat. 52° 29'. E. long. 4° 58'.

MEDEN, a river of the Isle of Wight, which runs into the sea between East and West Cowes, but is navigable for small vessels to Newport. — Also, a river, which rises from a lake in the duchy of Bremen, and discharges itself into the Elbe, two miles below Otterndorf, N. lat. 53° 55'. E. long. 8° 44'.

MEDENA, in *Surgery*, a name given by Paracelsus to a particular class of ulcers.

MEDENAM, in *Geography*, a town of Prussia, in the province of Samland; 12 miles N. W. of Konigsberg.

MEDEOLA, in *Botany*, is the Linnæan name of this genus, thought by Professor Martyn to be "a diminutive of *Medea*, the famous sorcerers of antiquity." Linn. Gen. 179. Schreb. 240. Willd. Sp. Pl. v. 2. 270. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 327. Michaux. Boreal-Amer. v. 1. 214. Juss. 42. Lamarck Illustr. t. 266. — Class and order, *Hexandria Trigynia*. Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* Perianth none. *Cor.* inferior, deeply cloven into six, ovate-oblong, equal, spreading, revolute segments. *Stam.* Filaments six, awl-shaped, the length of

the corolla; anthers incumbent. *Pist.* Germens three, oovulate, ending in the styles; stigmas recurved, thickish. *Peric.* Berry roundish, trisid, three-celled. *Seeds* solitary, heart-shaped.

Ess. Ch. Calyx none. Corolla deeply six-cleft, revolute. Berry three-seeded.

Obs. Linnæus remarks that *M. virginiana*, which he received from the celebrated Gronovius, had four petals; and Jussieu further says, that the same species having verticillate leaves, and the habit of *Trillium* or *Paris*, is very nearly akin to those genera. *Jacquinia rusticifolia* was originally considered by Linnæus as a *Medeola*.

1. *M. virginiana*. Virginian Medeola, or Indian Cucumber. Linn. Sp. Pl. 483. Sims in Bot. Mag. t. 1316. — Leaves verticillate. — A native of Virginia, flowering in June. Michaux says that it is common in moist woods throughout the whole of North America. *Root* tuberous and fibrous. *Stem* scarcely a f. or high, simple, erect or somewhat scandent, about the thickness of a quill, covered with a reflexed, hairy down. *Leaves* whorled, from six to eight in the upper and three in the lower whorl, ovate, pointed. *Flowers* on pendent stalks, greenish-yellow, with purple filaments, without smell. Its root, which is eaten by the Indians, is said to resemble the Cucumber in flavour, and hence the English name.

2. *M. asparagoides*. Broad-leaved shrubby Medeola. Linn. Sp. Pl. 484. (*Asparagus africanus scandens*, myrtilifolius; Til. Pis. t. 12. f. 1.) — Leaves alternate, ovate, unequally heart-shaped at the base. — A native of the Cape of Good Hope. It flowers during the greater part of the winter, and was cultivated in 1702 by the dukes of Beaufort. *Root* composed of several oblong knobs, uniting at the top like that of a *Ranunculus*. *Stems* round, twining, branched, several feet long. *Leaves* sessile, acutely pointed, light-green beneath, but dark above. *Flowers* one or two on a stalk, dull white. Michaux is of opinion that *M. asparagoides* should be referred to another genus, and Mr. Gawler says, in the Botanical Magazine, that the following, *M. angustifolia*, together with this, should be excluded from *Medeola*.

3. *M. angustifolia*. Narrow-leaved Medeola. Willd. n. 3. (*Asparagus africanus scandens*, myrtilifolius angustiflorus; Til. Pis. t. 12. f. 2.) — Leaves alternate, lanceolate. — A native also of the Cape, flowering in the early spring. *Root* similar to the preceding. *Stalks* weaker, not so much branched, but climbing higher. *Leaves* long and narrow, of a greyish colour. *Flowers* lateral, two or three on a stalk, of an herbaceous white appearance.

Professor Martyn observes that "the flowers of these two latter species making no great appearance, the plants are not preserved for their beauty; but as their stalks are climbing, and their leaves are in full vigour in winter, during that season they add to the variety of the green-house."

MEDEOLA, in *Gardening*, comprises plants of the herbaceous climbing kind, of which the species cultivated are the Virginian medeola (*M. virginiana*); the broad-leaved shrubby medeola (*M. asparagoides*); and the narrow-leaved medeola (*M. angustifolia*).

Method of Culture. — These sorts of plants may be increased by planting off-sets, taken from the roots in the summer season, about July, in pots filled with good, rich, light mould, remaining in the open air till autumn, when they should be removed into the green or hot-house; but the latter, when intended to fruit. While the plants have a vigorous growth, they should be frequently refreshed with water; but, as the stems decay, very little, especially when placed in an eastern aspect.

The second and third forts may also be raised from feed ; but they commonly remain long in the earth before they come up.

The first fort is sufficiently hardy to stand in the open air during the winter season.

They all afford variety in green-house and stove collections, in the winter season, among other plants.

MEDERA, or MEDRA, in *Geography*, a town of Africa, in the kingdom of Bournou.

MEDES, *Empire of*. See EMPIRE and MEDIA.

MEDFIELD, in *Geography*, a township in Norfolk county, Massachusetts; 20 miles S.W. of Boston; incorporated in 1650, and containing 745 inhabitants.

MEDFORD, a pleasant, thriving, compact town in Middlesex county, Massachusetts, situated on Mytlick river, three miles from its mouth, and four miles N. of Boston. The river is navigable for small vessels to this place, where it meets the Middlesex canal. The township was incorporated in 1630, and contains 1114 industrious inhabitants. Here are four distilleries, which have distilled in one year 252,450 gallons of rum. About four millions of bricks are made annually in this town, most of which are conveyed to Boston.

MEDHERAM, a town of Africa, in the kingdom of Fezzan; 330 miles S.S.E. of Mourzouk.

MEDHERAM *Iza*, a town of Africa, in the desert of Berdoa. N. lat. 24° 35'. E. long. 16 24'.

MEDHRA, among Hindoo metaphysicians and mythologists, is a name of the *Yoni*; which see.

MEDIA, or, as it was sometimes called, *Medena*, in *Ancient Geography*, an extensive country of Asia, and the seat of a powerful empire, bounded, according to Ptolemy, on the north by part of the Caspian and Hyrcanian sea, on the south by Persia, Susiana, and Assyria, on the east by Parthia and Hyrcania, and on the west by Armenia Major. In ancient times it was divided into several provinces, which by a later arrangement were reduced to two, the one called "Media Magna," and the other "Media Atropatra," or simply *Atropatene*; which see. The cities of note in this latter part of Media were Gaza, the metropolis (which see); Sanina, situated between the Araxes and the Cambyfes; Fazina, between the Cambyfes and the Cyrus; and Cyropolis, between the Cyrus and the Amardus. This tract was inhabited by the Cadusians and Caspians, a barbarous and inhuman race, originally sprung from the Scythians.

Media Magna was bounded by Persia, Parthia, Hyrcania, the Hyrcanian sea, and Atropatene. The most remarkable cities in it were Ecbatana, Laodicea, Apamea, Rega or Regaia, and Arfacia. This part of Media was inhabited by the Carduchians, Marandæans, Gehans, Syro-Medians, Margasians, &c. The mountains of this country, according to Ptolemy and Strabo, are Choatra, parting Media from Assyria; Xagrus, dividing it from the same Assyria on the east, which, according to Polybius, was 100 cubits high; Parachoatra, placed by Ptolemy on the borders towards Persia, and by Strabo on the confines of Media, Hyrcania, and Parthia. To these, which are the boundaries between Media and the adjacent provinces, may be added the Orontes, the Jafonius, and the Coronus, in the interior of the country. The rivers of note, according to Ptolemy, are the Straton, the Amardus, the Cyrus, and the Cambyfes; properly belonging to the provinces of Ghilan and Mazanderan, and not to Media Proper, as described by the ancients. The northern parts of Media, lying between the Caspian mountains and the sea, are very cold and barren: the present inhabitants make their bread of dried almonds, and their drink of the juice of certain herbs. The snow

lies on the mountains for nine months in the year. But the southern parts produce all sorts of grain, and necessaries of life, and are so pleasant, that the country adjoining to Tauris, probably the ancient Ecbatana, is called the garden of Persia. It has large plains, one of which was called Nyfa, and was famous for its numerous studs of horses, that were kept in it for the use of the Persian monarchs. The climate of Media is various: that part which lies between the mountains and sea is cold and swampy, and subject to vapours exhaling from the Caspian sea; but the provinces that are more remote from the sea, enjoy a very salubrious air, though liable to heavy rains and violent storms, especially in the spring and autumn. In the neighbourhood of Tauris, it is said that 60 different kinds of grapes, of exquisite flavour, have been found.

The Medes are said to have sprung from Madai, the third son of Japhet; and in process of time several persons from the adjacent countries settled here, on account of the fertility of the soil, and gave rise to the various tribes into which these people were anciently divided. Their government was originally monarchical, and they seem to have had their own kings in the earliest times. They were first brought under the Assyrian yoke by Pul, said to be the founder of that monarchy, or by his immediate successor Tiglath-Pileser. In the reign of Sennacherib they shook off this yoke, and fell into anarchy until the reign of Dejoces. Their kings after the revolt were quite absolute, and controuled by no law. The Medes were once a very warlike people, but in process of time became one of the most effeminate nations of Asia. They used the same armour with the Persians, whom, it is said, they instructed in the art of war; and it is likewise asserted, that they first introduced luxury into Persia, which ultimately occasioned the downfall of that empire. Polygamy was so far from being disreputable among them, that they were bound by law to maintain, at least, seven wives, and those women were regarded with contempt, who maintained fewer than five husbands. In war they smeared their arrows with a bituminous liquor called naphtha; so that when the arrows were set on fire and shot from a slack bow, they burnt the flesh with such violence that water served to increase rather than to extinguish the flame. They are said likewise to have bred a number of large dogs, to whom they threw the bodies of their friends, parents, and relations, when at the point of death, considering it as dishonourable to die in their beds, or be laid in the ground. Some writers charge the Medes with being the first who made eunuchs; but others impute this execrable practice to the Persians. With the Medes originate the custom of confirming alliances with the blood of the contracting parties, which afterwards prevailed among all the eastern nations, even in the Roman times. When they concluded alliances, they tied together, with a hard bandage, the thumbs of their right hands, until the blood starting to the extremities was, by a slight cut, discharged. This they mutually sucked, and a league thus confirmed was esteemed most awful, as mysteriously solemnized with the blood of the parties. The laws and religion of the Medes were much the same with those of the Persians. (See PERSIA.) When a law was once enacted, it was not in the king's power to repeal it, or to reverse a decree he had once made; whence the laws of the Medes are, in the sacred writings (Dan. vi. 8.) called unchangeable. Their kings were treated with great respect; and whenever they appeared in public, they were attended by music, and numerous guards, consisting of the prime nobility; their wives, children, and concubines, forming part of their retinue, even when they headed their armies in the field. We are ignorant of their arts, learning, and trade; but this is known, that during

during the short period of their monarchy, they seem to have applied their thoughts only to warlike exercises, viz. to horsemanship and archery, in which they surpassed all other nations; the Median horse being no less celebrated by the ancients than the Persian infantry in subsequent ages.

In detailing their history, we begin with Pul, or Tiglath-Pileser, already mentioned, who first brought them under subjection. From the time of Pul, or Tiglath-Pileser, who succeeded his father in the year 740 B.C., they remained subject to the Assyrians till about the latter end of the reign of Sennacherib, 710 B.C., when, emancipating themselves from Assyrian bondage, they fell into a state of anarchy. This circumstance, as Herodotus informs us, gave Esar-Haddon, or Assar-Haddon, who succeeded Sennacherib, an opportunity of reducing a great part of Media, if not the whole country, under subjection. This anarchy is supposed to have lasted one year; for Dejoces, called Arphaxad in the book of Judith, was killed by Saoduelius or Nebuchadonosor, in the year 656. From the commencement of the reign of Dejoces to the destruction of Nineveh, 601 B.C., Media may properly be styled a kingdom. From the destruction of Nineveh, we may therefore date the rise of the empire of the Medes. (See *ΕΜΠΡΟΚ.*) Their empire lasted till the taking of Babylon; for we learn from Xenophon, that after the reduction of that city, Cyrus went to the king of the Medes at Ecbatana, and succeeded him in the kingdom. The empire of the Medes lasted 65 years, at the period in which the Persian empire took rise in Cyrus. Passing over the fabulous history of the Medes, we shall begin with the reign of Dejoces, who was chosen by them as their judge, and who, aspiring to the sovereign power, performed that office with the strictest regard to justice. Upon his resignation of this office, licentiousness prevailed, and it was found necessary to appoint a king; upon which Dejoces was named to the sovereignty, and with universal applause placed upon the throne 710 B.C. As soon as he was elected king, and vested with the supreme power, he threw off the mask, and became a tyrant. Ecbatana was built and chosen for the royal residence, and a stately palace was erected for the sovereign. Dejoces, having enacted various laws for the government of the kingdom, and having, in a considerable degree, civilized his unpolished subjects, entertained thoughts of extending the limits of his new kingdom, and with this view he invaded Assyria. Nebuchadonosor, however, at that time king of Assyria, met him in the plain of Ragau, and a battle ensued, in which the Medes were utterly defeated, and Dejoces was slain, after a reign, according to Herodotus, of 53 years. The Assyrian king, availing himself of his success, reduced several cities of Media, and among the rest Ecbatana, which he almost utterly destroyed. Dejoces was succeeded by his son Phraortes, 647 B.C., and, not satisfied with the kingdom of Media, he invaded Persia, and is said to have brought that nation under subjection to the Medes. Such is the account of Herodotus; but others ascribe the conquest of Persia, not to Phraortes, but to his son and successor Cyaxares. Phraortes, however, subdued several neighbouring nations, and made himself master of almost all the Upper Asia, lying between mount Taurus and the river Halys. Emboldened by his success, he invaded Assyria, subdued a great part of the country, and even laid siege to Nineveh, the metropolis. Here he perished, with the greater part of his army, after having reigned 22 years. Upon the death of Phraortes, his son, Cyaxares I., a brave and enterprising prince, succeeded him, 625 B.C. Having well disciplined his troops, and recovered the territories which the Assyrians had taken during the reigns of his father and grandfather, he marched against Nineveh, but after

having laid close siege to the city, he was obliged to retreat, and to employ his troops in the defence of his own kingdom, against a formidable army of Scythians, who, having driven the Cimmerians out of Europe, pursued their flying enemies, and were ready to enter Media. The two armies engaged, and the Medes were utterly routed. The conquerors overran, not only all Media, but the greater part of Upper Asia, extending their conquests into Syria, as far as the confines of Egypt. Cyaxares, despairing of being able to overpower the Scythians by force, had recourse to stratagem; and invited them to a general feast, which was prepared in every family. Each host intoxicated his guest; and in that condition the Scythians were massacred, and the kingdom delivered from a long and cruel bondage. The Medes were afterwards engaged with the Lydians; and during the engagement there happened a total eclipse of the sun, said to have been foretold by Thales the Milesian. Both parties were terrified, and soon after concluded a peace by the mediation of Labynetus, that is Nebuchadnezzar, king of Babylon, and Syennesis, king of Cilicia. This peace was confirmed by the marriage of Aryenis, the daughter of Halyattes, and Astyages, the eldest son of Cyaxares; and of this marriage was born in the ensuing year Cyaxares, who, in the book of Daniel (ch. v. 31.) is called Darius the Mede. Cyaxares, disengaged from the Lydian war, returned the siege of Nineveh; and having formed a strict alliance with Nebuchadnezzar, king of Babylon, they joined their forces, and took and destroyed the city. (606 B.C.) With this prosperous event commenced the great successes of Nebuchadnezzar and Cyaxares; and thus was laid the foundation of the two collateral empires, as they may be called, of the Medes and Babylonians, which rose on the ruins of the Assyrian monarchy. After the reduction of Nineveh, the two conquerors led the confederate army against Pharaoh-Necho, king of Egypt, who was defeated near the Euphrates, and compelled to resign what he had formerly taken from the Assyrians. After this victory they reduced all Cœlesyria and Phœnicia; then they invaded, and laid waste Samaria, Galilee, and Scythopolis; and at last besieged Jerusalem, and took Jehoiakim prisoner. Nebuchadnezzar afterwards pursued his conquests in the west, and Cyaxares subdued the Assyrian provinces of Armenia, Pontus, and Cappadocia. Again uniting their forces, they reduced Persia and Suriana, and accomplished the conquest of the Assyrian empire. The prophet Ezekiel (ch. xxxii. 22 &c.) enumerates the chief nations that were subdued and slaughtered by the two conquerors Cyaxares and Nebuchadnezzar.

Cyaxares, having thus erected the kingdom of Media into a powerful empire, and shared the new acquisitions with his Babylonian ally, died in the 40th year of his reign, and was succeeded by his son Astyages, called in scripture Ahafuerus. This prince had by Aryenis, already-mentioned, Cyaxares II., called in scripture Darius the Mede, who was 62 years of age when Belshazzar was slain at the capture of Babylon. In the year when Cyaxares was born, Astyages gave his daughter Mandane, whom he had by a former wife, to Cambyles, a Persian; from which marriage sprung Cyrus, the founder of the Persian monarchy, and the restorer of the Jews to their country, their temple, and their former condition. (See *CYRUS.*) Astyages, after a reign of 35 years, was succeeded by his son Cyaxares, uncle to Cyrus, 560 B.C. Whilst Cyaxares lived, Cyrus held the empire only in partnership with him, though he had entirely acquired it by his own valour; but as Cyrus was entrusted with the command of the army, and the whole management of affairs, he alone was regarded as the supreme governor of the empire. From

Josephus we learn, that Cyaxares, or Darius the Mede, with his ally, Cyrus, destroyed the kingdom of Babylon. After the reduction of Babylon, Cyaxares, in concert with Cyrus, settled the affairs of their new empire, and divided it into 120 provinces. The governors of these provinces were under the direction of three presidents, of whom Daniel was appointed the chief. (See DANIEL.) From this time Media became a province of Persia. See EMPIRE and PERSIA.

MEDIANA, in *Anatomy*, median, a name given to certain veins of the upper extremity. These are the median veins of the fore-arm, occupying the middle of the limb, between the radius and the ulna. These divide at the elbow into two chief trunks, of which one joins the basilic, and the other the cephalic vein of the arm: they are named respectively, vena mediana basilica, and v. m. cephalica. See VEIN.

MEDIANA, in *Geography*, a town of Spain, in Arragon; 12 miles S.E. of Saragossa.

MEDIANÆ, *Columnæ*, in Vitruvius, are the columns in the middle of a portico, whose intercolumniation is to be larger than those of the columns.

MEDIANTE, *Fr.*, in *Music*, is the string or sound which divides the fifth of a key into two thirds, the one major, and the other minor; and it is their relative position which determines the key. When the major third is the lowest, that is to say, between the mediant and key note, the key is major, or with a sharp third; when the major third is uppermost, and the minor at the bottom, the mode or key is minor, or with a flat third above the base.

MEDIASTINUM, in *Anatomy*, the partition which divides the chest into the right and left halves. See LUNG.

MEDIATE, or INTERMEDIATE, a term of relation to two extremes, applied to a third, which is in the middle between them. See MEAN and MEDIUM.

Substance is a genus with regard to man; but between the two there are other mediate genusses, as body and animal.

Mediate stands opposed to immediate: thus when we say that God and man concur to the production of man; God is the *mediate* cause, man the *immediate*.

MEDIATE *Mode*. See MODE.

MEDIATIO, *Lat.*, MEDIATION, *Fr.*, in *Canto Fermo*, implies the middle of a chant, or the sound which terminates the first part of a verse in the psalms. The punctuation of the psalms in the English psalter, where a colon is constantly placed in the middle of a verse, and frequently when the sense requires not so long a pause, expresses this mediatio, or breath-place, marked out for those who chaunt the psalms in the cathedral service.

MEDIATOR, in *Theology*, is an appellation which belongs in a peculiar, appropriate, and eminent sense, to Jesus Christ, the instructor and saviour of mankind; accordingly, as the doctrine of mediator between God and man is a matter of pure revelation, the New Testament expressly asserts that "there is one God, and one mediator between God and man, the man Christ Jesus," 1 Tim. ii. 5. Divines, however, have differed in their sentiments with respect to the nature and extent of this office, and the mode of its accomplishment. In a general view of this subject, it is argued by bishop Butler in his 'Analogy, &c.' that the whole analogy of nature removes all imagined presumption against the general notion of a mediator between God and man; so that, as the visible government which God exercises over the world, is carried on by the instrumentality and mediation of subordinate beings, there is no sort of objection against the general notion of a mediator, considered as a doctrine of Christianity, or as an appointment in this dispensation; since we find by experience, that God does appoint mediators to be the instruments

of good and evil to us, the instruments of his justice and mercy. He adds, that it is clearly contrary to all our notions of government, as well as to what is, in fact, the general constitution of nature, to suppose that doing well for the future should, in all cases, prevent all the judicial bad consequences of having done evil, or all the punishment annexed to disobedience. And though the efficacy of repentance itself alone, to prevent what mankind had rendered themselves obnoxious to, and recover what they had forfeited, is now insisted upon, in opposition to Christianity; yet, by the general prevalence of propitiatory sacrifices over the heathen world, this notion of repentance alone being sufficient to expiate guilt, appears to be contrary to the general sense of mankind. As there was, therefore, room for an interposition to avert the fatal consequences of vice, revelation affords us such representations of the compassion and goodness of God in the administration of the world, as to give us reason to expect such an interposition; and, moreover, it informs us, that an interposition of this kind has been mercifully provided, in order to prevent the destruction of the human kind. (See John, iii. 16.) As for the particular manner in which Christ interposed in the redemption of the world, or his office as mediator, in the largest sense, *between God and man*, it is, as the learned prelate conceives, thus represented to us in the scriptures: 1st. He was, by way of eminence, "the prophet that should come into the world" (John, vi. 14.) to declare the divine will. He published anew the law of nature, which men had corrupted, and the knowledge of which was, to a great degree, lost among them. He taught mankind, authoritatively, to "live soberly, righteously, and godlily in this present world," in expectation of the future judgment of God. He confirmed the truth of this moral system of nature, and gave us additional evidence of it; the evidence of testimony. He distinctly revealed the manner in which God would be worshipped, the efficacy of repentance, and the rewards and punishments of a future life. Thus he was a prophet in a sense in which no other ever was. To which is to be added, that he set us a perfect "example, that we should follow his steps." 2dly. He has a "kingdom which is not of this world." He founded a church, to be to mankind a standing memorial of religion, and invitation to it; which he promised to be with always, even to the end. He exercises an invisible government over it himself, and by his spirit; over that part of it which is militant here on earth, a government of discipline. (See Eph. iv. 12, 13.) Of this church, all persons scattered over the world, who live in obedience to his laws, are members. 3dly. Christ offered himself a propitiatory sacrifice, and made atonement for the sins of the world; which is mentioned last, in regard to what is objected against it. Sacrifices of expiation were commanded the Jews, and obtained amongst most other nations, from tradition, whose original probably was revelation. And they were continually repeated, both occasionally and at the returns of stated times: and made up great part of the external religion of mankind. "But now once in the end of the world Christ appeared to put away sin by the sacrifice of himself." (Heb. ix. 26.) And this sacrifice was, in the highest degree, and with the most extensive influence, of that efficacy for obtaining pardon of sin, which the heathens may be supposed to have thought their sacrifices to have been, and which the Jewish sacrifices really were in some degree, and with regard to some persons.

How and in what particular way it had this efficacy, there are not wanting persons who have endeavoured to explain: but we do not find that the scripture has explained it. We seem to be very much in the dark, concerning the manner in which the ancients understood atonement to be made, *i. e.* pardon

pardon to be obtained by sacrifices. And if the scripture has, as surely it has, left this matter of the satisfaction of Christ mysterious, left somewhat in it unrevealed, all conjectures about it must be, if not evidently absurd, yet at least uncertain. Nor has any one reason to complain for want of farther information, unless he can shew his claim to it.

Some have endeavoured to explain the efficacy of what Christ has done and suffered for us, beyond what the scripture has authorized; others, probably because they could not explain it, have been for taking it away, and confining his office as redeemer of the world to his instruction, example, and government of the church. Whereas the doctrine of the gospel appears to be; not only that he taught the efficacy of repentance, but rendered it of the efficacy which it is, by what he did and suffered for us: that he obtained for us the benefit of having our repentance accepted unto eternal life: not only that he revealed to sinners, that they were in a capacity of salvation, and how they might obtain it; but moreover that he put them into this capacity of salvation, by what he did and suffered for them; put us into a capacity of escaping future punishment, and obtaining future happiness. And it is our wisdom thankfully to accept the benefit, by performing the conditions upon which it is offered, on our part, without disputing how it was procured, on his.

Another writer, *viz.* Mr. Tomkins, in his treatise entitled "Jesus the Mediator between God and Man," seems to have entertained similar views with those of bishop Butler concerning the mediation of Christ. The scripture, says this writer, expressly gives Christ the title of mediator (the one mediator): this will be allowed even by those who understand it of his mediating on the part of God towards us, or of his being invested with a mediatorial kingdom, in consequence of which he dispenses the favours of God to men. But this, in the judgment of the author to whom we now refer, is merely half of what the scripture designs, when it calls Christ the mediator; for he supposes this office to include what he doth or hath done on our behalf towards God. The apostle, he thinks, evidently and directly refers to this (1 Tim. ii. 5.) when he adds, "who gave himself a ransom for us." If, then, it appears that Christ offered himself a sacrifice; that he makes intercession for us: that he is ordained for us an high-priest in things pertaining to God; and that we are required to come unto God by him under this character: if these, and the like, are in the plain literal sense the doctrine of the New Testament, none, he supposes, can make it matter of dispute, whether the title of mediator hath not respect to these things, as well as to his acting on the behalf of God towards us: in confirmation of which it may be observed, that the term itself seems to imply a transacting with each party on the behalf of the other; according to the language of the apostle "a mediator is not of one." The object of the author in the treatise which we have cited, is to lay before the reader the declarations of scripture on the subjects above stated; or to shew that they represent what it was appointed for Christ to do on our behalf, and consequently what he hath done, or now does for us, in order to our reconciliation with God. Another writer, after shewing that the general notion of a mediator is not at all repugnant to the most honourable sentiments we can entertain of the mercy of God, states the substance of what he conceives to be the true Christian doctrine of a mediator in the following terms: *viz.* "that our blessed Saviour was appointed by the supreme authority of heaven and earth, to *reconcile* apostate and rebellious men to their offended maker and sovereign, and to be the *distributor* of God's favour to mankind." He thinks, that there

are several probabilities that incline us to believe, that our blessed Lord never expressly assumed to himself the title of mediator, during the time of his public ministry upon earth, and that it never was ascribed to him, all else of his exaltation to regal dignity and power; and of course that the mediatorial character of Christ did not properly commence till after his resurrection, when he had all power committed to him, and was constituted the *one Lord*, through whom are all things. Adverting to the death of Christ, as a prominent event in his history, he observes, that it was not intended to render the Deity propitious *i. e.* willing to be reconciled to his creatures upon fit and honourable terms, because it was proposed by *himself*, and the whole use and efficacy of it sprung from his appointing and declaring it to be an accepted sacrifice, so that it must necessarily suppose him to have been antecedently propitious. The truth of the case in his opinion seems to be, that it was "an expedient originally proceeding from the mercy of God, and not the argument or motive, inducing him to be merciful." The great purposes, as this author states them, which are evidently served by the express command of God to consider the death of Christ under the notion and character of a sacrifice, are those which follow.

First, that it might be a standing memorial of God's being propitious, and inclined to pardon the sins of men; and an enforcement of that fundamental principle of all religion, that he is a rewarder of them that diligently seek him: "A memorial coinciding with the almost universal sentiment and practice of the world (among whom sacrifices were esteemed as an essential part of religion), and likely, upon that account, to have a more certain and powerful influence."—Secondly, that it might be a standing memorial, likewise, of the evil and demerit of sin; and, consequently, a perpetual incentive to humility and repentance.—And, thirdly, it seems to have been wisely appointed with this view likewise, *viz.* to supersede the use of all future sacrifices; which, extending even to human sacrifices, had been the most depraved and unnatural branch of heathen superstition. And, therefore, that it might the better produce this effect, which was worthy the care of infinite wisdom and goodness, we are expressly informed, that Jesus Christ hath, by one offering, "perfected for ever them that are sanctified." Heb. x. 14.

And, in the last place, "there is formed, by this constitution, a beautiful analogy in a very considerable and important point, between the settled methods of God's natural providence, and the extraordinary operations of his grace;" which perhaps may justly be esteemed as one of the principal reasons of it. Foster's Sermons, vol. iv. serm. xvi. See ATONEMENT.

MEDIATORS of Questions, in our *Old Writers*, were six persons authorized by statute, who, upon any question arising among merchants, relating to any unmercable wool, or undue packing, &c. might, before the mayor, or officers of the staple, upon their oath, certify and settle the same; to whose order and determination therein, the parties concerned were to give entire credence, and submit. 27 Ed. III. stat. 2. c. 24.

MEDIATORS, *Μεταφοροι*, under the emperors of Constantinople, officers of state, who had the direction of all affairs transacted at court. Their chief, or president, was called *megas mesazon*, *μεγα: μεζων*, and answered to the prime or grand vizier of the Turks. H. 4m. Lex. in voc.

MEDICA, in *Botany*, an old name for some plants of the Trefoil or Lucerne family, which Tournefort has retained for the genus *Medicago* of Linnæus. It is supposed to be derived from Media, the native country of the plants to which it was applied. See MEDICAGO.

MEDICA is also the Linnæan specific name of the Citron, *Malus medica*, or Median Apple, of the old writers. See CITRUS.

MEDICAGO, so called by Tournefort, from *Medica*, which is indeed the proper name of the plant, (under of Dioscorides), and arose from its having been introduced into Greece by the Medes, during the Persian war in the time of Darius Hytaspes. This name being restrained by Tournefort to a few species with a flat, not spiral, legume, he calls the very numerous ones in which that part is more or less convoluted, or spiral, *Medicago*, as resembling, or approaching to, his *Medica*. Both tribes are united under the above appellation by Linnæus. The original *Medica* of the ancients, which was a valuable fodder, or, in the modern phrase, *artificial grass*, is probably one of the genus; though we cannot determine which, and it may possibly be some *Trifolium*, or perhaps a *Trigonella*. Lucern, Medick, or Snail Trefoil. Linn. Gen. 389. Schreb. 510. Willd. Sp. Pl. v. 3. 1403. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 795. Ait. Hort. Kew. ed. 1. v. 3. 96. Juss. 356. Lamarck Illustr. t. 612. Gært. t. 155. (Cochleata; Riv. Tetrap. Irr. t. 88. Falcata; ibid. t. 84. 85. 87.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Char. *Cal.* Perianth inferior, of one leaf, straight, cylindrical, somewhat bell-shaped, divided about half way down into five pointed, nearly equal, segments. *Cor.* papilionaceous. Standard ovate, undivided, inflexed at its edges, the whole reflexed. Wings ovate-oblong, affixed to the appendages of the keel, cohering by their edges within it. Keel oblong, cloven, spreading, obtuse, bent down by the pistil, and divaricating from the standard. *Stam.* Filaments in two sets, united almost to the top; anthers small. *Pist.* Germen stalked, oblong, incurved, compressed, enfolded by the filaments, starting from the keel, and forcing back the standard, terminating in a short, awl-shaped, nearly straight, style; stigma terminal, minute. *Peric.* Legume compressed, long, inflexed. *Seeds* several, kidney-shaped or angular.

Obs. The *Cochleata* of Rivinus have a spirally convoluted legume; his *Falcata* a curved, or sickle-shaped one.

Ess. Ch. Legume compressed, spiral, forcing back the keel of the corolla from its standard.

The latest edition of Linnæus enumerates but ten species of *Medicago*, because he always confounded, under his *M. polymorpha*, a numerous tribe, which, though they generally accord very nearly in herbage, differ too widely and constantly in their fruit to be esteemed mere varieties of one species. Willdenow, following Gærtner, has distinguished them all, and has even added several new ones, making all together 37. He has perhaps gone too far, and the subject appears to demand revision, which we shall here attempt.—*Medicago virginica*, Linn. Sp. Pl. 1096, is supposed to be the same plant as *Hedysarum frutescens*, and is therefore omitted here. On this point however the Linnæan herbarium affords no information.

* *Legumes* *lunate*, somewhat twisted.

1. *M. arborca*. Tree Medick, or Moon Trefoil. Linn. Sp. Pl. 1096. (*Cytisus septimus cornutus*; Ger. em. 1305.)—Legumes *lunate*, entire at the margin. Stem arborescent.—Native of rocky places in various parts of Greece and the Archipelago, as well as about Naples, flowering in the early spring. It is with us a hardy green-house shrub. *Stem* bushy. *Leaves* ternate, on long stalks; their leaflets inversely heart-shaped, hoary and silky beneath, like all the stalks. *Flowers* in axillary, stalked heads, or very short clusters, of a full yellow. *Legume* reticulated, making

scarcely more than one complete turn.—This shrub has been shewn by M. Amoureux in the *Mem. de la Soc. d'Agriculture de Paris*, for 1787, part 2d, to be the real *Cytisus* of Virgil, celebrated by him for causing cows to yield abundance of milk, while its flowers are grateful to goats and to bees.

2. *M. radiata*. Radiated Medick. Gært. f. 5. (*Lunaria radiata italorum*; Lob. Ic. v. 2. 38. *Trifolium filiquâ lunatâ*; Ger. em. 1207.)—Legume kidney-shaped, toothed at the edge. Leaves ternate.—Native of Italy. *Root* annual. *Stem* erect, more or less branched from the bottom, a span high. *Leaves* stalked, ternate, obovate, sharply toothed, somewhat hairy. *Flowers* small, yellow, two or three on each axillary stalk. *Calyx* hairy. *Legumes* singularly elegant, curved into an orbicular flat form, near an inch broad, naked, glaucous, purplish, finely reticulated, fringed with bristly teeth. *Seeds* numerous, transversely corrugated.

3. *M. circinata*. Pinnate Kidney Medick. Linn. Sp. Pl. 1096. (*Falcata foliis anthyllidis*; Riv. Tetrap. Irr. t. 87.)—Legume kidney-shaped, toothed at the edge. Leaves pinnate, lyrate, entire.—Native of Spain, Italy, and the Levant. Annual. *Leaves* somewhat like those of *Anthyllis vulneraria*, pinnate, with obovate, entire, thick, hairy leaflets, the odd one very large. The earliest leaves are simple. *Flowers* yellow, two or three on a long bracteated axillary stalk, like those of a *Lotus*. *Legume* smaller and less elegant than in the last, hairy. Willdenow and Gærtner describe a variety whose legume is smaller, without teeth, which may well prove a species. We have never seen it.

4. *M. sativa*. Lucern, or Purple Medick. Linn. Sp. Pl. 1096. Mart. Ruft. t. 48. Engl. Bot. t. 1749. (*Medica legitima*; Clus. Hist. v. 2. 242.)—Flower-stalks racemose. Legumes contorted. Stem erect, smooth.—In dry pastures and by road sides in France and Spain, as well as occasionally in England, but it is hardly wild with us. For its description, and agricultural use, see LUCERN. The legume is frequently so much convoluted, that it rather belongs to the next section.

5. *M. falcata*. Yellow Sickle-podded Medick. Linn. Sp. Pl. 1096. Mart. Ruft. t. 86, 87. Engl. Bot. t. 1016.—Flower-stalks racemose. Legumes moon-shaped. Stem procumbent.—Found in dry gravelly places in various parts of Europe. In England chiefly about Norwich and Bury. It greatly resembles the last, but does not grow erect, and the legume is merely sickle-shaped, not contorted. The flowers vary from yellow to purple, and are often of a green hue, combined of both the former tints. These two last species are perennial, and perhaps nearest akin to the first, *arborca*.

6. *M. glutinosa*. Clammy Medick. Willd. Sp. Pl. v. 3. 1406.—Flower-stalks racemose. Legumes falcate, twisted, hairy and viscid, like the calyx. Leaflets obovate, toothed at the summit.—Native of grassy land in Gauria. Willdenow says it is very similar to *M. falcata*, but differs in having obovate leaflets, and a hairy viscid calyx. The stems are ascending, and downy.

7. *M. lupulina*. Black Medick, or Nonefuch. Linn. Sp. Pl. 1097. Curt. Lond. fasc. 2. t. 57. Engl. Bot. t. 971. Mart. Ruft. t. 19. (*Trifolium luteum lupulinum*; Ger. em. 1186.)—Spikes ovate. Legumes kidney-shaped, rugged and veiny, single-seeded. Stem procumbent.—Frequent in the meadows and pastures of Europe. It is annual, flowering all summer long, and is much cultivated, as an artificial grass, for a crop of hay, or as fodder for sheep. The stems spread widely. The leaflets are broad, roundish-obovate, finely toothed. *Flowers* yellow, small, in dense ovate stalked spikes, very much resembling some of the common yellow species

species of *Trifolium*, with which indeed the whole habit of the plant accords, but the curved, black, rugged *legumes*, as they ripen, conspicuously distinguish it.

8. *M. obscura* Doubtful Medick. Retz. Obf. fasc. 1. 25. t. 1.—Flower-stalks racemose. Legumes kidney-shaped, with two seeds. Stipulas toothed. Leaflets obovate, somewhat rhomboid. Stems recumbent.—Supposed by Retzius, who had it by accident with other seeds, to be a native of Germany. Root annual. The habit and flowers are like many of the next section, but the *legume* is merely orbicular, not cochleated, or truly spiral; its diameter scarcely a quarter of an inch.

** *Legumes spirally convoluted*

9. *M. prostrata*. Slender Prostrate Medick. Linn. Suppl. 340. Jacq. Hort. Vind. v. 1. 39. t. 89. Ehrh. Pl. Select. 49.—Flower-stalks racemose. Stem procumbent, thread-shaped, much branched. Legumes thrice convoluted, thick-edged, without prickles. Stipulas bristle-shaped, undivided. Leaflets nearly linear.—Native of exposed stony ground in Hungary and Italy. It is known by its long, slender, much branched stems, simple stipulas, very narrow leaflets toothed merely at the point, and small orbicular *legumes*, consisting of two or three complete spiral turns, thick at the edge, destitute of teeth or prickles, and very slightly downy. The flowers are yellow, and, like the rest of the plant, vary much in size according to the richness of the soil. The root is perennial, in which it differs from most of this second section, and agrees with *sativa* and *fuleata*, which also it approaches in habit; but the whole nature of the *legume* has induced us to remove it hither.

10. *M. orbicularis*. Flat Snail Medick. (*M. polymorpha orbicularis*; Linn. Sp. Pl. 1097. Cochleata fructu orbiculato; Riv. Tetr. Irr. t. 88. f. 1.—Morif. sect. 2. t. 15. f. 1, 2.)—Stalks one or two-flowered. Stipulas in many capillary segments. Legumes orbicular, depressed, with radiating veins, and no teeth.—Native of fields in the south of Europe. Annual. Stems long and prostrate, angular, slender, smooth. Leaflets obovate, sharply toothed, smooth. Stipulas deeply pinnatifid. Flowers very small, yellow, on slender axillary stalks. Legumes smooth, orbicular, depressed, above three quarters of an inch in diameter, singularly neat, marked with elevated radiating veins, and of a glaucous or purplish hue. This is one of those hardy annuals, cultivated in curious gardens, by the name of *Snails*, the *Scorpiurus vermiculata* generally accompanying them under the appellation of *Caterpillars*, which its legumes strikingly resemble.

11. *M. rugosa*. Rugged Snail Medick. Lamarck Dict. v. 3. 632. (*M. elegans*; Willd. Sp. Pl. v. 3. 1408. Cochleata fructu rugoso; Riv. t. 88. f. 5. Morif. sect. 2. t. 15. f. 4.)—Stalks about two-flowered. Stipulas toothed. Legumes orbicular, depressed, with radiating elevated veins, a thick edge, and no teeth.—Native of Sicily. We have seen no specimen of this, but it should seem to be only a slight variety of the last, except the stipulas may serve to distinguish them.

12. *M. scutellata*. Common Snail Medick. Lamarck Dict. v. 3. 633. (*M. polymorpha scutellata*; Linn. Sp. Pl. 1097. Cochleata fructu scutellato; Riv. t. 88. f. 2. t. 89. f. 1. Morif. sect. 2. t. 15. f. 3.)—Stalks about two-flowered. Stipulas half arrow-shaped, toothed. Legumes globular, spiral, convex beneath, the convolutions erect, rugose, without teeth.—Frequent in corn fields in the south of Europe, and the most common kind in our gardens. It differs specifically from *M. orbicularis* in having broad stipulas, often strongly toothed, but not divided into deep capil-

lary segments. The *legume* moreover differs widely in being globose, in consequence of the edges of its convolutions being turned upwards, or erect, and they may be pulled asunder like a rolled slip of paper. The whole herb is more or less downy.

13. *M. Helix*. Small Snail Medick. Willd. Sp. Pl. v. 3. 1409. (*M. lavis*; Desfont. Atlant. v. 2. 213.)—Stalks many-flowered. Stipulas strongly toothed. Legumes orbicular, flat, of two spiral distant turns, concentrically veined, without spines.—We have from the south of France what answers well to Willdenow's description, nor have we the least doubt concerning the synonym of Desfontaines. The leaflets are obovate, rounded, with shallow teeth. Stipulas much like the last. Flowers four or five on a stalk. Legumes hairy, a quarter of an inch only in diameter, marked with concentric or spiral interbranching veins, in which respect it differs essentially from the three last, as well as from *M. obscura*, to which Willdenow compares it; a character which seems to have been noted by Desfontaines.

14. *M. tornata*. Screw-turned Snail Medick. Willd. Sp. Pl. v. 3. 1409. (*M. polymorpha tornata*; Linn. Sp. Pl. 1098. Herb. Linn. Cochleata fructu tornatili; Riv. t. 88. f. 4.)—Stalks many-flowered. Stipulas deeply toothed. Legumes cylindrical, flat at each end, of many, rather distant, horizontal, smooth, thin-edged turns, without spines.—Native of the south of Europe. The only specimen we have ever seen is that of Linnæus, who by quoting a figure of Morifou which belongs to the following, has led some botanists astray. Lachenal took one for the other, and Desfontaines has confounded the two. Whether they are more than varieties may perhaps be doubted, as is the case with some others of the genus; but they appear distinct. The real *tornata*, figured by Rivinus in that curious tab. 88, which is wanting in many copies of his book, has a small *legume*, that appears to be neatly turned, exactly like a screw, the convolutions being flat and horizontal, rather distant, with a thin smooth even edge, parallel and near to which runs a principal concentric spiral rib or nerve, connected by reticulated veins with the centre, and sending off a minute branch, here and there, to the margin. The stipulas have generally a few deep taper-pointed teeth. The flowers are rather large, four or five on a stalk. Leaves sharply toothed.

15. *M. turbinata*. Close-turned Snail Medick. Willd. Sp. Pl. v. 3. 1409. (*M. polymorpha turbinata*; Linn. Sp. Pl. 1098. Cochleata fructu turbinato; Riv. t. 88. f. 3. Morif. sect. 2. t. 15. f. 5.)—Stalks many-flowered. Stipulas deeply toothed. Legumes ovate, convex at each end, of many, closely imbricated, thick-edged, even turns, without spines.—Native of Italy and the south of France. Like the last in habit and general characters, but the *legume* is twice as large, ovate, its convolutions crowded close together, as if imbricated upwards, presenting a thick edge outwards, along which runs the same spiral concentric nerve which in the *M. tornata* is situated within the margin. Willdenow, who appears to have paid great attention to these plants, has removed a synonym of J. Bauhin, cited here by Linnæus, to the following, to which it evidently belongs. Linnæus indeed confounded the two, and Lachenal, led perhaps by Bauhin's synonym, took the *tuberculata* for *turbinata*. We cannot however follow Willdenow in here quoting Bauhin's *Medica scutellata*, v. 2. 384, which appears to us the real *Medicago scutellata*, our n. 12.

16. *M. tuberculata*. Warty Snail Medick. Willd. Sp. Pl. v. 3. 1410. (*M. polymorpha tuberculata*; Retz. Obf. fasc. 2. 23. *Medica magna turbinata*; Bauh. Hist. v. 2. 385. Cochleata fructu verrucoso; Riv. t. 88. f. 6. Morif. sect. 2. t. 15. f. 6.)—Stalks about two-flowered. Stipulas

MEDICAGO.

deeply toothed. Legumes nearly cylindrical, flattish at each end, of many horizontal crowded turns, beset with a double row of corrugated warts.—Native of the south of Europe. This differs from the last in having only one or two *flowers* on each stalk, which seems to be constant, and in the rather smaller, more cylindrical, *legumes*, the outer edge of whose convolutions is closely beset with a double row of bluntish warts, imbedded in a sort of granulated skin. In an early state these warts are rather bluntish spines.

17. *M. aculeata*. Prickly Snail Medick. Willd. Sp. Pl. v. 3. 1410. (Cochleata fructu turbinato et echinato; Riv. t. 88. f. 7?)—"Stalks about two-flowered. Stipulas toothed. Leaflets somewhat rhomboid. Legumes cylindrical, flattish at each end, of many turns, beset with thick short marginal spines."—Native country unknown. Willdenow describes it as very like the preceding, but distinct, the *legumes* being beset with unequal, thick, and very short, prickles. Not having seen this plant, we quote with doubt the figure of Rivinus, which answers pretty well to the description. Willdenow seems not to have known this tab. 88.

18. *M. Murex*. Thorny Snail Medick. Willd. Sp. Pl. v. 3. 1410. (Cochleata fructu durius echinato; Riv. t. 88. f. 10?)—"Stalks about two-flowered. Stipulas deeply toothed, or fringed. Leaflets obovate. Legumes cylindrical, rather convex at each end, of many turns, beset with straight thorns."—Native country unknown, but Willdenow had the plant alive, as well as the last. He describes it with cylindrical turbinate legumes, beset with thick awl-shaped thorns, and differing from the last in having obovate obtuse *leaflets*, the lower ones *obcordate*; linear-awl-shaped *stipulas* with fringe-like teeth, not lanceolate ones toothed only at the base; and longer thorns upon the fruit. We quote Rivinus with doubt, for the same reason as before, though we have scarcely any hesitation about either of his figures.

19. *M. intertexta*. Entangled Prickly Medick. Willd. Sp. Pl. v. 3. 1411. (M. polymorpha intertexta; Linn. Sp. Pl. 1098. Cochleata fructu echinato maximo; Riv. t. 88. f. 9; and t. 90. Morif. sect. 2. t. 15. f. 7, 8, 9.)—"Stalks about two-flowered. Stipulas deeply toothed. Legumes oval, of many turns, beset with two rows of long, awl-shaped, close-pressed thorns, alternately divaricated.—Native of the south of Europe. Distinguished from all the foregoing by its nearly globular *legumes*, about the size of a gooseberry, composed of six or seven close convolutions, concealed by the long sharp thorns, which cover the whole fruit, and which being alternately depressed, in two opposite directions, appear matted together. In all our specimens these thorns are smooth; Willdenow describes them as pubescent. The *flowers* are from two to four on each stalk. *Stipulas* fringed with long sharp teeth. *Leaflets* obovate, or somewhat rhomboid, narrow, sharply toothed. This species is often met with in gardens.

20. *M. ciliaris*. Hairy Prickly Medick. Willd. Sp. Pl. 1411. (M. polymorpha ciliaris; Linn. Sp. Pl. 1099. Cochleata fructu echinato rotundo; Riv. t. 88. f. 8.)—"Stalks about two-flowered. Stipulas deeply toothed. Legumes oval, of many turns, beset with two rows of short awl-shaped hairy thorns, spreading in two directions.—"Native of the south of France." Willdenow. Sent from Sicily by Mr. Bivona Bernardi. In habit and size it altogether agrees with the last; but the *legumes* are covered with much shorter hairy thorns, ranged in two rows along the edge of their convolutions, spreading in opposite directions, but not depressed.

21. *M. carstiensis*. Creeping-rooted Medick. Jacq. Coll. v. 1. 86. Ic. Rar. t. 156. Curt. Mag. t. 909.—Stalks many-flowered. Leaflets ovate. Stem erect. Root creeping. Legumes depressed, of many turns, fringed with two rows of straight spreading bristles.—Native of the alps of Carinthia and Carniola, said to have been introduced into our gardens in 1790. It is remarkable for its perennial creeping root, and upright, square, almost shrubby stem. The *leaflets* moreover are ovate, not obovate. *Flowers* six or eight on each stalk, of a bright yellow, their standard streaked with red. *Legumes* black, not half the size of the two preceding, of fewer turns, and depressed, the edges fringed with two divaricated rows of long bristles.

22. *M. maculata*. Spotted Medick. Sibth. Oxon. 232. Willd. Sp. Pl. v. 3. 1412. (M. polymorpha arabica; Linn. Sp. Pl. 1098. Fl. Brit. 797. Engl. Bot. t. 1616. Curt. Lond. fasc. 3. t. 47. Mart. Ruft. t. 76. Cochleata fructu longius echinato; Riv. t. 88. f. 12. Morif. sect. 2. t. 15. f. 12?)—"Stalks two or three-flowered. Leaflets inversely heart-shaped, spotted. Stipulas dilated, sharply toothed. Legumes depressed, their convolutions fringed with numerous, long, spreading bristles.—Native of the more temperate countries of Europe. Found in the south of England, on a gravelly soil, flowering in May and June. The stems are prostrate. Root annual. Leaflets distinguished by their obcordate shape, and a black or purplish spot in the middle of their disk, which however disappears from the later or upper leaves. *Stipulas* half-heart-shaped, with sharp broad teeth. *Flowers* two or three on a stalk, yellow, as indeed are all of this section of the genus. *Legumes* small, depressed, of several turns, marked with concentric nearly parallel ribs, and fringed with long, spreading, slender, and rather weak spines, or bristles, the whole pale brown or whitish when ripe.—The three varieties enumerated in the Flora Britannica are now esteemed distinct species, at least the β and γ . The δ we know only by the report of Dillenius.

23. *M. truncatula*. Abrupt Medick. Gærtn. v. 2. 350. t. 155. Morif. sect. 2. t. 15. f. 17. (M. tentaculata, by mistake; Willd. Sp. Pl. v. 3. 1413.)—"Stalks about two-flowered. Stipulas toothed. Legumes cylindrical, spiral, flat at each end, beset with two ranks of smooth, lanceolate, close-pressed prickles.—Native of the south of Europe. Willdenow had it living, and describes the *leaflets* as obovate; *stipulas* awl-shaped and toothed; *stalks* two-flowered; *legumes* as above. We should think it a variety of the following, but not having seen it, we dare not decide.

24. *M. coronata*. Coronet Medick. Lamarck Dict. v. 3. 634. Willd. Sp. Pl. v. 3. 1413. (M. polymorpha coronata; Linn. Sp. Pl. 1098. Morif. sect. 2. t. 15. f. 16. Medica coronata cherleri parva; Bauh. Hist. v. 2. 386.)—"Stalks many-flowered. Leaflets inversely heart-shaped. Legumes cylindrical, hairy, flat at each end, of about two turns, bordered with an ascending and descending row of strong, close-pressed, awl-shaped spines.—Native of the south of France. We have it from Gerard. This is a very small species, about three or four inches high, hardly branched; with lanceolate ribbed *stipulas*, scarcely toothed except at the base; several small *flowers* on each stalk; and curious little *legumes*, well represented in the figures quoted. The *leaflets* are hairy, obcordate, strongly toothed.

25. *M. apiculata*. Wheel-toothed Medick. Willd. Sp. Pl. v. 3. 1414. (M. coronata; Gærtn. v. 2. 349. t. 155. Morif. sect. 2. t. 15. f. 14?)—"Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes depressed, of three turns, strongly reticulated, with two rows of minute, diverging, marginal teeth.—Native of the south

south of Europe. We have it from Professor Lachenal under the name of *M. coronata*, but it is very distinct from the last, being a much larger plant, with deeply fringed stipulas, obovate smooth leaflets, and flattened strongly reticulated legumes, whose teeth are scarcely more prominent than their veins.

26. *M. denticulata*. Sickle-toothed Medick. Willd. Sp. Pl. v. 3. 1414.—“Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes depressed, of two turns, reticulated, with two rows of diverging marginal spines.”—Native of the south of Europe. Very near the last, differing only in its longer brittle-like marginal spines. Willd. We have from the sea-coast near Cley, in Norfolk, what seems to answer to these characters, except that in ours the leaflets are inversely heart-shaped. We know not whether this has been noticed as a British plant, or whether it be the *M. polymorpha* ♂ of Fl. Brit. adopted there from Dillenius.

27. *M. muricata*. Flat-toothed Medick. Willd. Sp. Pl. v. 3. 1414. (*M. polymorpha muricata*; Linn. Sp. Pl. 1098. Fl. Brit. 798 ♀. Morif. sect. 2. t. 15. f. 11. Trifolium cochleatum, modiolis spinosis; Pluk. Phyt. t. 113. f. 6.)—Stalks many-flowered. Stipulas deeply toothed. Leaflets obovate, somewhat rhomboid. Legumes depressed, of five turns, with short, depressed, radiating teeth.—Native of dry ground in France and Italy. Said by Ray to have been found on the sea bank at Orford, Suffolk. The structure of its legume is abundantly different from the foregoing five species, the teeth being horizontal, and in single rows, nor is the surface veiny or reticulated. The leaflets are hairy. Flowers from two to four on each stalk.

28. *M. Gerardi*. Gerardian Medick. Willd. Sp. Pl. v. 3. 1415. Waldst. and Kitaib. Hungar. Morif. sect. 2. t. 15. f. 18.—“Stalks about two-flowered. Stipulas with setaceous teeth. Leaflets obovate. Legumes hairy, depressed, of five turns, with awl-shaped, projecting, hooked spines.”—Native of Spain, Narbonne, and Hungary.—We know it only from Willdenow, who had dried specimens before him.

29. *M. recta*. Upright Dwarf Medick. Willd. Sp. Pl. v. 3. 1415. (*M. polymorpha recta*; Desfont. Atlant. v. 2. 212.)—Stalks single-flowered. Stipulas entire. Leaflets wedge-shaped, downy. Stem erect. Legumes spiral, with hooked teeth.—Native of Barbary. About four inches high, annual, downy and silky. Leaflets small, with minute teeth. Stipulas ovate, acute. Flowers axillary, on very short stalks. Legume orbicular.

30. *M. marina*. Downy Sea Medick. Linn. Sp. Pl. 1097. Willd. Sp. Pl. v. 3. 1415. Cavan. Ic. v. 2. 26. t. 130. (Cochleata incana; Riv. t. 91. f. 2. t. 88. f. 15.)—Stalks many-flowered. Herb procumbent, very downy. Leaflets obovate, crenate or entire. Stipulas undivided. Legumes very hairy, with strong radiating teeth.—Native of the sandy sea-coast in the north of Africa, and south of Europe. Root perennial. Stems prostrate, much branched, densely clothed with soft hoary hairs, as is every part of the herbage. The leaflets are wedge-shaped, broad, but scarcely obovate, either quite entire, or slightly crenate at the end only. Flowers numerous, of a full yellow, in dense round heads. Legumes with several convolutions, edged with prominent, awl-shaped, strong hairy teeth.—This can be confounded with no other, and even Linnæus keeps it separate from the varieties of his supposed species *polymorpha*.

31. *M. Terebellum*. Prickly Screw Medick. Willd. Sp. Pl. v. 3. 1416. (*M. aculeata*; Gært. v. 2. 349. t. 155. Morif. sect. 2. t. 15. f. 20, 21. Cochleata fructu rarius

echinato; Riv. t. 88. f. 11?) Stalks with several flowers. Stipulas deeply toothed. Leaflets obovate, obtuse. Legumes cylindrical, flat at each end, of five turns, with two rows of diverging, very short, awl-shaped spines.—Native of the south of Europe. In habit this is among the more luxuriant procumbent species. The leaflets are broad, strongly toothed; the lower ones most abrupt. Spines of the legumes, thick at the base, often conical, reflexed in opposite directions. The ripe legume is the size of a large pea. Hence we rather cite Rivinus's fig. 7 for our 17th species, *M. aculeata*, than, with Gærtner, for the present, that figure being nearly thrice as large.

32. *M. tribuloides*. Caltrop Medick. Lamarck Dict. v. 3. 635. Willd. Sp. Pl. v. 3. 1416.—“Stalks two-flowered. Stipulas toothed. Leaflets obovate. Legumes cylindrical, flat at each end, of five turns, with two rows of diverging conical spines.”—Native of the south of Europe. Willdenow says the legumes are very like those of his *tentaculata*, our *truncatula*, n. 23, but larger, with longer spines, which are merely reflexed, not close-pressed. We have seen no specimen that answers to this. Willdenow had it alive.

33. *M. uncinata*. Larger Bur Medick. Willd. Sp. Pl. v. 3. 1417.—Stalks many-flowered. Stipulas toothed. Leaflets obovate. Legumes cylindrical, short, flat at each end, of several distant turns, with two spreading rows of long, awl-shaped, hooked spines.—Willdenow, who had this also alive, supposes it a native of the south of Europe. We find what answers very correctly to his description in the Linnæan herbarium, marked *coronata*, which is most assuredly an error. Linnæus having referred all this tribe to one species, was not sufficiently attentive to their differences, even as varieties. The legumes of the present are nearly globose, loosely spiral, and distinguished by their hooked prickles from nearly all the foregoing, in which mark they agree with two hereafter described, *minima* and *nigra*.

34. *M. rigidula*. Bristly Medick. Willd. Sp. Pl. v. 3. 1417. (*M. polymorpha rigidula*; Linn. Sp. Pl. 1098. Medica fructu cochleato spinoso; Ger. em. 1199. Cochleata fructu echinato rotundo minore; Riv. t. 88. f. 13?) Stalks with several flowers. Stipulas toothed. Leaflets obovate. Legumes cylindrical, of many turns, with conical straight spreading spines.—Native of fields in France, Italy, and Barbary.—This differs from the last in having the convolutions of the legume closer, the spines straight, all horizontally spreading; the flowers twice as large. It is difficult to adjust the synonyms of all these species. The figure of Gerard, which is also found in Lobel's Icones, v. 2. 37. f. 1, may have been done for either, but it best agrees with this. We are much in doubt concerning Rivinus's f. 13; but we cannot refer his f. 12 to the present species, because that figure so admirably and precisely represents the concentric veins of *M. maculata*, n. 22, which being a common plant, could hardly have been unknown to Rivinus.

35. *M. minima*. Little Bur Medick. Willd. Sp. Pl. v. 3. 1418. (*M. polymorpha minima*; Linn. Sp. Pl. 1099. Fl. Brit. 798 ♀. Fl. Dan. t. 211. Medica echinata minima; Bauh. Hist. v. 2. 386. Cochleata fructu echinato minimo; Riv. t. 88. f. 14.)—Stalks many-flowered. Stipulas half-ovate, undivided. Leaflets obovate, hairy. Legumes orbicular, hairy, of three or four turns, with two divaricated rows of hooked spines.—Native of Germany, Hungary, Switzerland, France, and England, chiefly on a calcareous soil. Mr. Woodward found it at Narburgh, Norfolk. A small prostrate downy species; its leaflets strongly toothed at the very summit only. Flowers four or five on each stalk, with a hairy calyx. Legumes small, orbicular,

cular, distinguished by their numerous rigid, spreading, but strongly hooked, prickles.

β. *M. polymorpha hirsuta*. Linn. Sp. Pl. 1099. (*Medica echinata hirsuta*; Bauh. Hist. v. 2. 386.) This is said by Willdenow to be a variety, four times as large as the common *minima*, and less hairy. We know it not, but we have from Switzerland, intermixed with the common sort, a few specimens distinguished by the long spines of their fruit, hooked at the tip only. These require investigation in a living state. They may be Bauhin's plant.

36. *M. nigra*. Black Prickly Medick. Willd. Sp. Pl. v. 3. 1418. (*M. polymorpha nigra*; Linn. Syft. Veg. ed. 14. 694. *M. hispida*; Gært. v. 2. 349. t. 155. Morif. sect. 2. t. 15. f. 19.)—Stalks about two-flowered. Stipulas deeply toothed. Leaflets obovate. Legumes cylindrical, rather depressed, of several close turns, with long, spreading, black, hook-tipped spines.—Native of the south of France. We have no specimen. It seems to be distinguished by the long black prickles of the fruit, whose points are said to be hooked, though no such character is shewn in the figures quoted. Gartner surely misapplies Rivinus's f. 12, in which, as we have observed under n. 34, the veins are concentric, not reticulated as Gartner represents them in his *hispida*.

37. *M. laciniata*. Jagged-leaved Medick. Willd. Sp. Pl. v. 3. 1419. (*M. polymorpha laciniata*; Linn. Sp. Pl. 1099. *Cochleata syriaca*; Riv. Tetr. Irr. t. 91. f. 1.)—Stalks about two-flowered. Stipulas fringed with capillary teeth. Leaflets linear-wedge-shaped, abrupt, cut. Legumes cylindrical, of many turns, with two rows of alternately divaricated, strong, hook-tipped spines.—Native of the south of Europe and north of Africa. This species is readily known by its narrow jagged leaflets. The stipulas are cut into deep capillary segments. Flowers one or two, on long slender stalks. Legumes cylindrical, somewhat elliptical, the size of a large pea, composed of about five close turns, armed with a double divaricated row of peculiarly strong, awl-shaped, smooth, polished spines, very minutely hooked at their tips only.

It is proper to observe that all the species of this second section have yellow flowers on axillary stalks; the stem, where not described otherwise, prostrate, branched from the root, which is generally annual. The leaflets are always more or less toothed. In quoting Morison throughout this article, we have not thought it worth while to copy his long names or definitions, but merely to cite his figures. Many of these remain still unappropriated, for want of better descriptions. S.

MEDICAGO, in Gardening, furnishes plants of the shrubby evergreen and herbaceous annual kinds, of which the species mostly cultivated are, the tree medick, or moon trefoil (*M. arborea*); and the variable medick, or snail and hedge-hog trefoil (*M. polymorpha*.)

The second sort has numerous varieties and subvarieties, but the principal ones are, the common snail medicago, with large smooth pods, shaped and twisted like a snail; the hedge-hog medicago, with large prickly snail-shaped pods, armed with spines pointing every way, like a hedge-hog; with turbinated pods; with globular pods; with orbicular pods; with long crooked pods; with double pods; with twisted pods; and with jagged leaves.

Method of Culture.—The first sort may be raised from seeds or cuttings.

In the former mode the seeds should be sown in the early spring, on a warm border, or in pots of light mould, and plunged in a moderate hot-bed, till the plants have attained a little growth; when they should be gradually hardened to

the full air. And in both methods the plants should be kept clean, and have protection in the following winter from frost, and in the spring they should be planted out, some into pots to have the management of green-house plants, and others into borders and nursery rows, in dry warm situations, the former to remain, and the latter to be occasionally transplanted.

But when they are increased by cuttings, these should be planted on a bed of light rich earth, or in pots of the same sort of mould, and plunged in a moderate hot-bed, due shade and water being given; and when they have formed good roots, in the autumn they may be removed into other pots, or the situations in which they are to remain, shading and watering them till they are well rooted, when they should be trained up to sticks, to have straight stems and regular heads, their irregular shoots being annually pruned to keep them in order. These plants are found to grow stronger and flower better when kept in warm situations in the open air, than when managed as green-house plants. They should, however, be sheltered in very severe winters.

And the second sort and varieties may, also be raised from seed, which should be sown in the early spring months in the places where the plants are to remain, in patches of several seeds, after thinning the plants to two or three of the best, when they require no further culture. It is the double sorts that are chiefly cultivated in the garden.

They both afford variety in the borders and other parts, and the former in the green-house among other similar plants.

MEDICAL ELECTRICITY. It is natural to imagine, that a power of such efficacy as that of electricity, would be applied to medical purposes; especially since it has been found invariably to increase the insensible perspiration, to quicken the circulation of the blood, and to promote the glandular secretion. Accordingly, many instances occur in the later period of the history of this science, in which it has been tried, on various occasions, with considerable advantage and success. Among the variety of cases to which it has been applied, there are none in which it seems to have been prejudicial, except those of pregnancy and the venereal disease. In most disorders, in which it has been used with perseverance, it has given, at least, a temporary and partial relief, and in many effected a total cure. The first instance that occurs of its salutary effect, was that of a woman, who was cured in a quarter of an hour of a contracted finger, by M. Kratzenstein, at Halle, so early as the year 1744. It was afterwards applied in a variety of paralytic cases, by M. Jallabert of Geneva, in 1747; M. Sauvages of the academy in Montpellier, in the course of whose experiments it appeared, that electrification increases the circulation of the blood about one-sixth; Mr. Patrick Brydone in Scotland, in 1757; the abbé Nollet and others: in several of the cases concerned present relief was obtained; but the beneficial effect does not appear to have been permanent. One instance occurs, related by Dr. Hart of Shrewsbury, and recorded in the Phil. Trans. vol. xlviii. part ii. p. 785, in which electrification was injurious, and brought on universal palsy on a young person, whose right arm was paralytic; and though this palsy was removed by a course of medicine, the diseased arm remained incurable. It also appears from a number of experiments made by Dr. Franklin in paralytic cases, that no permanent advantage was derived from electricity in this disorder; and Mr. Wesley, who was long engaged in a course of medical electricity for the benefit of persons in his connection, observes, that though many paralytics have been helped by it, no palsy of a year's standing has been thoroughly cured by it. However, a remarkable instance more lately occurs, in which an hemiplegia was cured by this

MEDICAL ELECTRICITY.

this means, under the direction of a physician at Greenwich. The patient was in such a state, that boiling water might be applied from her hand to her shoulder, and from her shoulder to her foot, on the diseased side, without being felt. This person was electrified, by drawing sparks from the palsied side, and giving shocks, beginning with stronger shocks, till she began to feel them, and continuing moderate ones, for 18 days; and in that time, during 31½ hours, the number of shocks was 141; and this performance was attended with such success, that her feeling was quite restored, and that she became capable of walking, and of writing with the hand, the use of which she had lost. Dr. de Haen observes, that with respect to partial palsies, electrification never did the least harm; and that one or two persons, who had received no benefit from it in six entire months, were yet much relieved by persevering in the use of it; and that some persons discontinuing it, after having received some benefit from it, relapsed again; but afterwards, by recurring to the use of electricity, recovered, though more slowly than before.

Dr. Hart, in 1756, mentions a cure performed on a woman, whose hand and wrist had been for some time rendered useless, by a violent contraction of the muscles; but the most remarkable case of this kind is that related by Dr. Watson, *Phil. Trans.* vol. liii. p. 10.

The patient, about seven years of age, was seized with an universal rigidity of her muscles, so that her whole body felt more like that of a dead corpse than of a living person; Dr. Watson electrified her, at convenient intervals, from the middle of November 1762, to the end of January 1763, when every muscle of the body was perfectly flexible, and subservient to her will, so that she could stand, walk, and run like other children of her age. Mr. Miles Partington also communicated to the Royal Society a surprising instance of the cure of a very great degree of contraction and rigidity in the sterno-mastoideus muscle by means of electrical sparks and shocks. (*Phil. Trans.* vol. lxxviii. part i. p. 97, &c.) Mr. Wilson mentions a single instance, in which he had cured deafness of seventeen years continuance; but he acknowledges that he tried similar experiments on six other deaf persons without success.

Mr. Lovet and Mr. Wesley have extended the medical application of electricity to a greater variety of cases than any others. Mr. Lovet observes, in his "Essay," that electricity is almost a specific in all cases of violent pains, of however long continuance, in any part of the body; as in obstinate head-aches, the tooth-ache, the sciatica, the cramp, and disorders resembling the gout; and that it has seldom failed to cure rigidities, or a wasting of the muscles, and hysterical disorders; he adds, that it cures inflammations, and a fistula lachrymalis; that it has stopped a mortification, and dispersed extravasated blood; that it has been of excellent use in bringing to a suppuration, or in dispersing without suppuration, obstinate swellings of various kinds, even those that were serophulous; that it has cured the falling-sickness, and several kinds of fits, and a disorder that seems to have been a gutta serena. He advises to begin, in general, with simple electrification, especially in hysterical cases; then to proceed to take sparks, and lastly, to give moderate shocks. Mr. Wesley observes, that he has scarcely known an instance, in which shocks all over the body have failed to cure a tertian or quartan ague; he mentions cases of blindness cured and relieved by it, and hearing given by it to a person who was born deaf; and he further says, that it has cured bruises, running sores, the dropsy, and a palsy in the tongue; and that it has brought away gravel from the kidneys. In hysterical cases, he recommends the patient's being simply electrified, by sitting on cakes of resin, at least for half an

hour morning and evening; and then taking small sparks, and afterwards giving shocks, more or less strong as the disorder requires. Dr. Antonius de Haen, in his "Ratio Medendi," cited by Dr. Priestley (*Hist. Elect.* vol. i. p. 485, 8vo.), informs us, that a paralysis and trembling of the limbs, from whatever cause it arose, never failed to be relieved by electricity; and that it also certainly cures St. Vitus's dance; that it has been of some use in cases of deafness; but failed in its application to a gutta serena, and stromous neck. Mr. Hey, surgeon of Leeds, mentions several cases in which the power of electricity has been successfully applied to an "amaurosis." The machine was used twice a day; the patient was placed on a stool with glass legs, and had sparks drawn from the eyes and parts surrounding the orbit, especially where the superciliary and infra-orbitary branches of the fifth pair of nerves spread themselves. After this operation had been continued for half an hour, the patient was made to receive for an equal time slight shocks through the affected parts, which were sometimes directed across the head, from one of the temples to the other, but chiefly from the superciliary and infra-orbitary foramina to the occiput. *Med. Obs. & Enq.* vol. v. p. 1, &c.

In rheumatic cases, Mr. Ferguson observes, that he has generally found electricity successful, by continuing to take sparks from the places where the pain lies, till the skin has been red and pimpled, and the patient has felt a glowing warmth where the sparks were drawn off; and the same method has also proved effectual in old sprains. The use of electricity has also been recommended in cases of sudden death. See DROWNING.

In all cases where shocks are given, gentle ones should be first used: and if the disorder continues, they may be gradually increased; and they should be confined to the affected part. The efficacy of electricity in the tooth-ache is so great that it seldom or ever fails to give immediate relief, unless the tooth be very much decayed. The following instrument will serve for this purpose: it consists of two wires, A B and B E, fixed in the piece of bored wood H, and bent at C D and F G, and at A and B, as in *fig. 1, Plate XV., Electricity*. If the affected tooth be brought within the two wires at E, and the ring A or B be connected by a chain with the outside of a charged jar, and the other ring be connected by a chain with the knob of the jar, the shock will pass through the wires, and consequently through the tooth. The modes of applying electricity to the human frame, formerly used, were by the shock and spark, and sometimes, though rarely, by single electrification. These modes are now varied and multiplied according to the circumstances of the patient, and the nature of his disorder. Under the conduct of Mr. Birch, an eminent surgeon, who particularly directed his attention to the improvement and application of medical electricity, and of other gentlemen of the profession who have pursued the same course, the cases in which electricity may be employed with success have been ascertained, and its advantages evinced. For an account of this medical apparatus, and of various modes of applying it in different disorders, see Adams's *Essay on Electricity*, chap. 15, 8vo. 1785.

Dr. Cullen says, that electricity, when properly applied, is one of the most powerful stimulants that can be used to act upon the nervous system of animals. Mr. Birch considers electricity, applied under the form of a fluid, as a sedative, under that of a spark or friction, as a stimulant, and by way of a shock, as a deobstruent, in its action.

Under this head of medical electricity it may not be improper to mention those medicated tubes, the imaginary virtues of

of which were first discovered by Signior Pivati, at Venice, and which were much recommended in the years 1747 and 1748, both in Italy, and by Mr. Winkler at Leipsic. These gentlemen imagined, that odorous substances, confined in excited glass vessels, would transpire through the pores of the glass, and communicate their medicinal virtue to the atmosphere of a conductor, and to all persons in contact with it; and that these substances would yield their virtues by being held in the hands of persons electrified; and they pretended that many cures were wrought in this way by the operation of medicines, without being taken into the stomach; but the whole was soon discovered to be a fallacy; and it was incontestibly proved, that no effluvia could pass from the included substances through the pores of excited glass; and that no method was known for causing the power of medicine to insinuate itself into the human body by electricity. Dr. Franklin, by proving that glass was impermeable to the electric fluid itself, and that its electricity was collected from the rubber, &c. evinced the absurdity of every attempt to transmit the effluvia of any substance through the glass. See Franklin's Letters, p. 82, &c.

MEDICAL Stones. See STONE.

MEDICAMENTOSUS LAPIS. See LAPIS.

MEDICI, COSMO DE, in *Biography*, a citizen of Florence, born in that city in 1389, was the eldest son of John, or Giovanni de Medici, who laid the foundation of that greatness which his posterity enjoyed for several ages. By a strict attention to commerce, John acquired immense wealth; by his affability, moderation, and liberality he ensured the confidence and esteem of his fellow-citizens. Without seeking after the offices of the republic, he was honoured with them all. "The maxims," says Mr. Roscoe, "which, uniformly pursued, raised the house of Medici to the splendour which it afterwards enjoyed, are to be found in the charge given by this venerable old man on his death-bed to his two sons." These, on account of their excellence, of the authority by which they were enforced, and of the successful application of them by his posterity, we shall transcribe. "I feel," said he, "that I have lived the time prescribed me. I die content; leaving you, my sons, in affluence and in health, and in such a station, that while you follow my example, you may live in your native place honoured and respected. Nothing affords me more pleasure than the reflection that my conduct has not given offence to any one; but that, on the contrary, I have endeavoured to serve all persons to the best of my abilities. I advise you to do the same. With respect to the honours of the state, if you would live with security, accept only such as are bestowed on you by the laws, and the favour of your fellow-citizens; for it is the exercise of that power which is obtained by violence, and not of that which is voluntarily conferred, that occasions hatred and violence." At the death of this venerable man, in 1428, Cosmo had already attained to high respectability as well in the political as in the commercial world. He had engaged deeply, not only in the extensive commerce by which the family had acquired its wealth, but in the still weightier concerns of government. In the year 1414, when Balthasar Cossa, who had been elected pope, and had assumed the title of John XXIII., was summoned to attend the council of Constance, he chose to be accompanied by Cosmo de Medici, among other men of eminence, whose high characters might countenance his cause. On the death of his father, Cosmo succeeded to the influence possessed by him as head of that powerful family, which rendered him the first citizen of the state, though without any superiority of rank or title. He supported and augmented the family dignity. His conduct was uniformly

marked by urbanity and kindness to the superior ranks of his fellow-citizens, and by a constant attention to the interests and wants of the lower class of citizens, whom he relieved with unbounded generosity. By these means he acquired numerous and zealous partisans, whom he considered rather as pledges for the continuance of the power which he possessed, than as instruments to be employed in the ruin and subjugation of the state.

The authority which Cosmo and his descendants exercised in Florence during the 15th century consisted rather in a tacit influence on their part, and a voluntary acquiescence on that of the people, than in any prescribed or definite compact between them. The form of government was that of a republic, directed by a council of ten officers, and a chief executive officer, called the *Gonfaloniere*, or standard bearer, who was chosen every two months. Under this establishment, the citizens imagined they were possessed of the full exercise of their liberties; but such was the influence of the Medici, that they generally assumed to themselves the first offices of the state, or nominated such persons as they esteemed fit for those employments. In this, however, they always paid great respect to popular opinion. Notwithstanding the great prudence and moderation of Cosmo's public conduct, the discontent of the Florentines, with the bad success of the war against Lucca, gave occasion to the preponderance of a party led on by Rinaldo de' Albizi, which, in 1433, after filling the magistracies with their own creatures, seized the person of Cosmo, and proceeded judicially against him, on the pretence that his influence was hazardous to the state. He was committed to prison, in which he remained for several days, in constant apprehension of some violence being offered to his person; but he still more dreaded that the malice of his enemies might make attempts upon his life by poison. On the news of his danger, several princes and states of Italy interfered in his behalf; and in conclusion, he was banished to Padua for ten years, and several other members and friends of the Medici family underwent a similar punishment. He was received with marked respect by the Venetian government, and took up his abode in the city of Venice. Within a year of his retreat, Rinaldo was himself obliged to quit Florence, and Cosmo being recalled, he returned amidst the acclamations of his fellow-subjects. Some victims were offered to his future security, and the *gonfaloniere* who had pronounced his sentence, with a few others of that party, were put to death. Measures were now taken to restrict the choice of magistrates to the partisans of the Medici, and alliances were formed with the neighbouring powers for the avowed purpose of supporting and perpetuating the system by which Florence was from that time to be governed. The manner in which Cosmo employed his authority, has conferred upon his memory the greatest honour. From this time his life was an almost uninterrupted series of prosperity. The tranquillity enjoyed by the republic, and the satisfaction and peace of mind which he experienced in the esteem and confidence of his fellow citizens, enabled him to indulge his natural propensity to the promotion of science, and the patronage and encouragement of learned men. The richest private citizen in Europe, he surpassed almost all sovereign princes in the munificence with which he patronized literature and the fine arts. He assembled around him some of the most learned men of the age, who had begun to cultivate the Grecian language and philosophy. He established, at Florence, an academy expressly for the elucidation of the Platonic philosophy, at the head of which he placed the celebrated Marsilio Ficino. He collected from all parts, by means of foreign correspondences, manuscripts of the

Greek, Latin, and Oriental languages, which were the foundation of the Laurentian library. He gave great encouragement to the arts of painting, sculpture, and architecture, by the vast sums which he expended in the public edifices of the city, as well as in his private palaces. He also collected the valuable remains of ancient art in statues, vases, gems, and medals; and all his treasures were made liberally accessible to the curious.

Towards the latter period of his life, a great part of the time that Cosmo could withdraw from the administration of public affairs was passed at his seats at Careggi and Cassaggiolo, where he applied himself to the cultivation of his farms; but his happiest hours were devoted to the study of letters and philosophy, or passed in the company and conversation of learned men. In his country retreats he was usually accompanied by Ficino, where, after having been his protector, he became his pupil in the study of the Platonic philosophy. His attachment to the sentiments of antiquity did not render him indifferent to the religion of his country, and he displayed his piety according to the fashion of the age, by numerous religious foundations which he munificently endowed. He even erected a noble hospital at Jerusalem for the relief of distressed pilgrims. The spirit of his government was mildness and moderation. He never assumed a state beyond that of a citizen in a republic, and avoided every open exertion of authority which could lead the Florentines to suspect they had lost their liberties.

The wealth and influence that Cosmo had acquired, had long entitled him to rank with the most powerful princes of Italy, with whom he might have formed connections, by the intermarriage of his children; but being apprehensive that such measures would give rise to suspicions that he entertained designs inimical to the freedom of the state, he rather chose to increase his interest among the citizens of Florence, by the marriage of his children into the most distinguished families of that place. Piero, his eldest son, married Lucretia Tornabuoni, by whom he had two sons, Lorenzo, the subject of the following article, and Giuliano. Cosmo conversed freely with all orders of men, and there was scarcely a citizen whom he had not some time obliged by loans of money of which he never expected the repayment. His immense wealth was not the object of envy, because he chiefly expended it upon the public; so that it was a kind of common fund in which all had an interest. Parties were again formed in Florence hostile to the predominance of the Medici. The popularity of Cosmo, however, was not to be shaken, and while he withdrew from public business, he retained the influence of his benefits and virtues. He had lost his second son, Giovanni, on whom he had placed his chief expectations, as his eldest, Piero, laboured under various bodily infirmities, and he apprehended that at his own decease the splendour of his family would close. These reflections embittered the repose of his latter days: and he exclaimed, a short time before his death, as his attendants were carrying him through the apartments of his palace, "This is too large a house for so small a family." His latter days were, however, cheered by the honourable testimony to his merit, afforded by his fellow-citizens, in a public decree, conferring upon him the noble title of *Father of his Country*, which was inscribed on his tomb, and has ever since adhered to his name.

About three weeks before his death, when his strength began rapidly to decline, he entered into conversation with Ficino, lamenting the miseries of life, and the imperfections inseparable from human nature. As he continued his discourse, his sentiments and his views became more elevated, and from bewailing the lot of humanity, he began to exult

in the prospect of that happier state towards which he felt himself approaching. He died August 1st, 1464, at the age of seventy-five years, deeply lamented by a vast majority of the citizens of Florence, whom he had firmly attached to his interest, and who feared for the safety of the city from the dissensions that were likely to ensue. *Refoe's Life of Lorenzo.* Univer. Hist.

MEDICI, LORENZO DE, surnamed *The Magnificent*, grandson of Cosmo, and son of Piero de Medici, by Lucretia Tornabuoni, was born on January 1, 1448. He was about sixteen years of age when Cosmo died, and had, at that time, given striking indications of extraordinary talents. From his earliest years he had exhibited proofs of a retentive and vigorous mind, which had been cultivated by a very careful education, chiefly under the direction and good conduct of his mother Lucretia, who was one of the most accomplished women of the age, and who had distinguished herself not only as a patroness of learning, but by her own writings. The disposition of Lorenzo, which afterwards gave him a peculiar claim to the title of "Magnificent," was apparent in his childhood. Having received, as a present, a horse from Sicily, he sent the donor, in return, a gift of much greater value, and on being reproved for his profuseness, he remarked, that there was nothing more glorious than to overcome others in acts of generosity. In his youth he had the advantage of the instructions of some of the wisest and most learned men of the age, in the languages, and philosophy of antiquity, and the principles of polite literature. To the latter he displayed a decided inclination by some early poetical compositions in his native tongue; but he seemed formed for excelling in every thing that becomes an object of attention. He was not less addicted to active sports and laborious exercises, than to the studies of the closet, and was equally dextrous in the management of business, and in the pursuits of arts and science. Tall in his stature, robust in his form, Lorenzo had in his person more the appearance of strength than of elegance. From his birth he laboured under peculiar disadvantages; his sight was weak, his voice harsh and unpleasing, and he was totally deprived of the sense of smell. With all these defects, his countenance was dignified, and strongly indicated the magnanimity of his character; and the effects of his eloquence were conspicuous on many important occasions. At the death of Cosmo, on account of his father's infirmities, it was thought proper immediately to initiate Lorenzo into political life. He was, accordingly, sent to visit the principal courts of Italy for the purpose of forming a personal connection with the rulers, and making observations on the circumstances of each state. He strengthened the interests of his family in an interview with Ferdinand, king of Naples, who was impressed with a high idea of his early wisdom; and the prudence and vigour of his conduct at home were materially instrumental in restoring the superiority of the Medici. In 1469, Lorenzo married Clarice, the daughter of a member of the noble family of Orsini, and in the same year Piero de Medici died, leaving his two sons, Lorenzo and Giuliano, the heirs of his power and property. Immediately after the death of his father, Lorenzo, at the request of the people of Florence, took upon himself that post of head of the republic which Cosmo and Piero had occupied. Upon the accession of Sixtus IV. to the papacy, Lorenzo, with other eminent citizens, were deputed to congratulate him on the part of the Florentine republic. On this occasion he was invested with the office of treasurer of the holy see, and he took the opportunity of his abode at Rome to make valuable additions to the remains of ancient art already collected by his family. One

MEDICI.

of the first public occurrences after he conducted the helm of government was a revolt of the inhabitants of Volterra, on account of a dispute with the Florentine republic; by the recommendation of Lorenzo, means of force were adopted, which ended in the sack of the unfortunate city, an event that gave him much concern. In 1472, he was the means of re-establishing the academy of Pifa, and he took up his residence for a considerable time in that city for the purpose of completing the work; exerted himself in selecting the most eminent professors, and contributed to it a large sum from his private fortune, in addition to that granted by the state of Florence. Zealously attached to the Platonic philosophy, he took an active part in the establishment of an academy for its promotion, and instituted an annual festival in honour of the memory of Plato, which was conducted with singular literary splendour. While he was thus advancing in a career of prosperity and reputation, a tragical incident was very near depriving his country of his future services. This was the conspiracy of the Pazzi, a numerous and distinguished family in Florence, the rivals of the house of Medici. The instigators of this foul conspiracy, of which the object was the assassination of Lorenzo and his brother, were pope Sixtus IV. and his nephew, cardinal Riario: and the archbishop of Pifa, Salviati, was the principal agent in the horrid design. Giacomo de Pazzi, the head of that family, gave his name and assistance, and several persons of desperate character undertook to aid in the execution. Nothing could exceed the atrocity of the plan which was to assassinate the two brothers, while they were partaking of the hospitality of Lorenzo; but the absence of Giuliano, on account of indisposition, obliged the conspirators to postpone the attempt. Thus disappointed, another plan was to be adopted, and on further deliberation it was resolved that the assassination should take place on the following Sunday, in the church, at the instant of the elevation of the host.

The immediate assassination of Giuliano was committed to Francesco de Pazzi and Bernardo Bandini, and that of Lorenzo had been intrusted to the sole hand of Monteficco. This office he had willingly undertaken while he understood that it was to be executed in a private dwelling, but he shrunk from the idea of polluting the house of God with so heinous a crime. Two ecclesiastics were therefore selected for the commission of a deed, from which the soldier was deterred by conscientious motives. It was in the month of April 1478, the young cardinal Riario, apostolic legate, a guest in the palace of Lorenzo, proceeded to the church of the Reharata, since called "Santa Maria del Fiore," where the intended victims were present. The conspirators having taken their stations, waited with impatience for the appointed signal. The bell rang—the priest raised the consecrated wafer; the people bowed before it, and at the same instant Bandini plunged a short dagger into the breast of Giuliano. On receiving the fatal wound he took a few hasty steps and fell, when the other fiend, Francesco de Pazzi, rushed upon him with incredible fury, and stabbed him in different parts of his body, continuing to repeat his strokes even after he was apparently dead. Such was the violence of his rage that he wounded himself deeply in the thigh. The priests who had undertaken the murder of Lorenzo were not equally successful: they inflicted only a slight wound, which rather roused him to his defence, than disabled him. He instantly threw off his cloak, and holding it up as a shield in his left hand, with his right hand drew his sword, and repelled the assailants, who fled. Bandini came up with his dagger streaming with the blood of Giuliano, but was instantly laid dead by a servant of the Medici. In the mean time, the friends of Lorenzo

assembled round him, and conducted him home in safety. An attack upon the palace of government where the magistrates were sitting, by other conspirators, failed of success, and the people attached to the Medici, collecting in crowds, put to death or apprehended the assassins, whose designs were thus entirely frustrated, with the exception of the death of Giuliano. Signal and instant justice was inflicted on the criminals. The archbishop of Pifa was hanged out of the palace window in his sacerdotal robes, and Giacomo de Pazzi, with one of his nephews, shared the same fate. Lorenzo did himself honour by his efforts to restrain the fury of the populace, and induce them to commit to the magistrates the farther pursuit of the guilty. The name and arms of the Pazzi family were suppressed, its members were banished, and Lorenzo rose still higher in the esteem and affection of his fellow-citizens. The pope, inflamed almost to madness by the defeat of his schemes, excommunicated Lorenzo, and the magistrates of Florence, laid an interdict upon the whole territory, and forming a league with the king of Naples, prepared to invade the Florentine dominions. Lorenzo appealed to all the surrounding potentates for the justice of his cause; and he was affectionately supported by his fellow-citizens. Hostilities began, and were carried on with various success through two campaigns. At the close of the year 1479, Lorenzo took the bold resolution of paying a visit to the king of Naples, and, without any previous security, trusted his liberty and his life to the mercy of a declared enemy. The monarch was struck with this heroic act of confidence, and a treaty of mutual defence and friendship was agreed upon between them. Sixtus, however, persevered in the war, till a descent upon the coast of Italy by Mahomet II. excited such an alarm, that he consented to a peace upon the submission of the Florentine deputies to his pontifical reprimands.

Another attempt was made to assassinate Lorenzo in a church in the month of May 1481, but the plot was happily discovered, and the agent and his accomplices were seized and executed. From this time he generally appeared in public, surrounded with friends as a guard, a circumstance which has been represented by his enemies as a symptom of tyranny. His political conduct as head of the Florentine republic was chiefly directed to the preservation of the balance of power among the Italian states. The death of Sixtus IV. freed him from an adversary who never ceased to bear him ill-will, and he was able to secure himself a friend in his successor Innocent VIII. He conducted the republic of Florence to a degree of tranquillity and prosperity which it had scarcely ever known before, and by procuring the institution of a deliberative body of the nature of a senate, he corrected the democratical part of its constitution.

Lorenzo distinguished himself beyond any of his predecessors in the encouragement of literature and the arts: his proficiency in Italian poetry would have conferred distinction even upon one who had no other merit to adduce. The productions of this great man are distinguished by a vigour of imagination, an accuracy of judgment, and an elegance of style, which afforded the first great example of improvement, and entitle him, almost exclusively, to the honourable appellation of the "restorer of Italian literature." His compositions are sonnets, canzoni, and other lyric pieces, some longer works in stanzas, some comic satires, and jocose carnival songs, and various sacred poems, the latter as serious, as many of the former are licentious. Some of these pieces, especially those of the lighter kind, in which he imitated the rustic dialect, became extremely

tremely popular. His regard to literature, in general, was testified by the extraordinary attention which he paid to the augmentation of the Laurentian library. Although the ancestors of Lorenzo had the foundation of the immense collection of MSS. contained in this library, he may claim the honour of having raised the superstructure. If there was any pursuit in which he engaged more ardently and persevered in more diligently than the rest, it was that of enlarging his collection of books and antiquities: for this purpose he employed the services of learned men, in different parts of Italy, and especially of his intimate friend and companion Angelo Politiano, who took several journeys in order to discover and purchase the valuable remains of antiquity. "I wish," said Lorenzo to him as he was proceeding on one of these expeditions, "that the diligence of Pico and yourself would afford me such opportunities of purchasing books, that I should be obliged even to pledge my furniture to possess them." Two journeys, undertaken at the instance of Lorenzo, into the east, by Giovanni Lascari, produced a great number of rare and valuable works. On his return from his second expedition, he brought with him two hundred copies, many of which he had procured from a monastery at mount Athos; but this treasure did not arrive till after the death of Lorenzo, who, in his last moments, expressed to Politiano and Pico his regret that he could not live to complete the collection which he was forming for their accommodation. On the discovery of the invaluable art of printing, Lorenzo was solicitous to avail himself of its advantages in procuring editions of the best works of antiquity corrected by the ablest scholars, whose labours were rewarded by his munificence. When the capture of Constantinople by the Turks caused the dispersion of many learned Greeks, he took advantage of the circumstance, to promote the study of the Greek language in Italy. It was now at Florence that this tongue was inculcated under the sanction of a public institution, either by native Greeks, or learned Italians, who were their powerful competitors, whose services were procured by the diligence of Lorenzo de Medici, and repaid by his bounty. "Hence," says Mr. Roscoe, "succeeding scholars have been profuse of their acknowledgments to their great patron, who first formed that establishment, from which, to use their own classical figure, as from the Trojan horse, so many illustrious champions have sprung, and by means of which the knowledge of the Greek tongue was extended, not only through all Italy, but through France, Spain, Germany, and England; from all which countries numerous pupils attended at Florence, who diffused the learning they had there acquired throughout the rest of Europe."

The services of Lorenzo to the fine arts were not less conspicuous than those which he rendered to letters. Cosmo had collected all the most valuable remains of ancient taste and skill that he could obtain. His treasures were vastly augmented by Lorenzo, who proposed to himself the improvement of modern art as the chief end of his magnificence in this point. Of the earnestness with which Lorenzo engaged in this pursuit instances may be adduced. It is said that those who wished to oblige him were accustomed to collect from every part of the world medals and coins, estimable for their age or their workmanship, statues, busts, and whatever else bore the stamp of antiquity. By his constant attention to this pursuit, and by the expenditure of considerable sums, he collected, under his roof, all the remains of antiquity that fell in his way, whether they tended to illustrate the history of letters or the arts.

It is not, however, on this account only that he is entitled to the esteem of the professors and admirers of the arts. He determined to excite, among his countrymen, a good taste, and, by proposing to their imitation the remains of the ancient masters, to elevate their views beyond the forms of common life, to the contemplation of that ideal beauty which alone distinguishes works of art from mere mechanical productions. With this view he appropriated his gardens in Florence to the establishment of an academy for the study of the antique, which he furnished with a profusion of statues, busts, and other relics of art, the most perfect in their kind that he could procure. The attention of the higher rank of his fellow-citizens was incited to these pursuits by the example of Lorenzo; that of the lower class by his liberality. To the latter he not only allowed competent stipends, while they attended to their studies, but appointed considerable premiums as rewards of their proficiency. To this institution, more than any other circumstance, Mr. Roscoe ascribes the sudden and astonishing proficiency which, towards the close of the 15th century, was evidently made in the arts, and which commencing at Florence, extended itself to the rest of Europe. The gardens of Lorenzo de Medici are frequently celebrated as the nursery of men of genius, but if they had produced no other artist than Michael Angelo Buonarrotti, they would have sufficiently answered the purposes of the founder. It was here that this great man began to imbibe that spirit which was destined to effect a reformation in the arts, and which, perhaps, he could have derived from no other source. The art of architecture he encouraged by the numerous buildings which he erected, or induced others to erect in Florence and its vicinity, after designs furnished by the ablest artists. By these exertions he prepared the way for those wonders which have rendered the age denominated from his son Leo X. one of the most splendid in the records of mankind.

Lorenzo, in his domestic concerns, deserves considerable, but by no means unmixed praise. The licentiousness which characterizes several of his poems is said to have tainted his manners with respect to the female sex. He was nevertheless a very affectionate and attentive father, solicitous for the instruction of his children, whom he placed under the care of Politiano, and he was fond of partaking in their sports and amusements. The exigencies of the republic in consequence of its wars had obliged him to borrow, in his own name, large sums, which the negligence or infidelity of his commercial agents and correspondents rendered it difficult for him to repay; and a decree for the discharge of his debts out of the public treasury was necessary to relieve him from his embarrassments. From this period he determined to quit his mercantile concerns, for the improvement of his estates under his own eye. He had a numerous family, in the settling of which he was as successful as an ambitious parent would generally desire. His eldest son Piero, designed for his own successor in the Florentine state, was sent, at the age of fourteen, to visit the pope, and cultivate the family interest of Rome. The object of his close connection with the pontiff, and the profound respect which he always testified for the holy see, was the attainment of the favourite point of his ambition, the elevation of his second son Giovanni to the cardinalate, with the future prospect of his filling the papal chair. By means of incessant applications, he prevailed upon the pope to confer upon Giovanni, at the age of thirteen, the high dignity of one of the princes of the Roman church, which was unquestionably a flagrant violation of decorum, dishonourable to both.

“It was,” says one of the biographers of Lorenzo, “a deserved consequence of this prostitution of ecclesiastical honours, that this cardinal, when arrived at the popeedom, should, by his levity and extravagance, have given the immediate occasion to that defection from the church of Rome, which has so much reduced her power and authority.” (For a farther account of this pontiff, the reader is referred to LEO X.) Of his other children, Giuliano became allied to the royal house of France, and obtained the title of the duke of Nemours; and his daughters married into noble families.

In the year 1488, Lorenzo's domestic comfort was much impaired by the loss of his wife. He was at this time absent at the warm baths, which he was often obliged to use, on account of a gouty complaint that severely afflicted him, and had made an early breach in his constitution. In the intervals of ease and health, he appears to have flattered himself with the expectation of enjoying the reward of his public labours, and partaking of the general happiness, which he had so essentially contributed to promote, in a peaceful and dignified retirement, enlivened by social amusements, by philosophic studies, and literary pursuits. These expectations were built upon the most substantial foundation, the consciousness that he had discharged his more immediate duties and engagements. “Having,” says he, “now obtained the object of my cares, I trust I may be allowed to enjoy the sweets of leisure, to share the reputation of my fellow-citizens, and to exult in the glory of my native place.” This prospect of relaxation and happiness he was not destined to realize. Early in the year 1492, the complaint under which he laboured attacked him with additional violence, and while the attention of his physicians was employed in administering relief, he contracted a slow fever, which escaped their notice, until it was too late effectually to oppose its progress. He sunk, almost before his attendants suspected danger, into such a state of debility, as totally precluded all hopes of recovery. Having performed the offices of the church, and adjusted with sincerity and decorum his spiritual concerns, he requested a private interview with his son Piero, with whom he held a long and interesting conversation on the state of the republic, the situation of his family, and the conduct which it would be expedient for him to pursue. When Lorenzo had relieved his mind from the weight of its important concerns, he became more sensibly alive to the emotions of friendship. At this moment Politiano entered his chamber: Lorenzo heard his voice, and raising his languid arms, clasped the hands of his friend in his own, and at the same time steadfastly regarded him with a placid and even a cheerful countenance. Deeply affected at this silent, but unequivocal proof of his esteem, Politiano could not suppress his feelings, but, turning his head aside, attempted, as much as possible, to conceal his sobs and his tears. Perceiving his agitation, Lorenzo still continued to grasp his hand, as if intending to speak to him when his passion had subsided; but finding him unable to resist its impulse, he relaxed his hold, and Politiano, hastening into an inner apartment, flung himself on a bed, and gave way to his grief. Having at length composed himself, he returned to the chamber, when Lorenzo enquired with great kindness why Pico of Mirandola had not once paid him a visit during his sickness. Politiano apologized for his friend, by assuring Lorenzo that he had only been deterred by the apprehension that his presence might be troublesome. “On the contrary,” replied Lorenzo, “if his journey from the city be not troublesome to him, I shall rejoice to see him before I take my final leave of you.” Pico came, prepared with

a melancholy pleasure, to share, for the last time, the interest of his conversation. Lorenzo expressed his esteem for him in the most affectionate terms, professing that he should meet death with more cheerfulness after this last interview. He then changed the subject to more familiar and lively topics; and it was on this occasion that he expressed, with some degree of jocularly, his wishes that he could have obtained a reprieve, until he could have completed the library destined to the use of his auditors. This interview was scarcely terminated, when the haughty priest Savonarolo reminded him, that it was his duty to bear death with fortitude, “with cheerfulness,” replied Lorenzo, “if such be the will of God.” His vivacity as well as his resignation were perceptible almost to the last moment. Being asked, on taking a morsel of food, how he relished it, “as a dying man always does,” was his reply. Having affectionately embraced his surrounding friends, and submitted to the last ceremonies of the church, he became absorbed in meditation, occasionally repeating portions of scripture, and accompanying his ejaculations with elevated eyes and solemn gestures of his hands, till the energies of life gradually declining, and pressing to his lips a magnificent crucifix, he calmly expired, in the forty-fourth year of his age. Few persons of his condition have filled so contracted a space of life with so much glory and prosperity.

In summing up his character, Mr. Roscoe says, he is “a man who may be selected from all the characters of ancient and modern history, as exhibiting the most remarkable instance of depth of penetration, versatility of talent, and comprehension of mind.—Of the various occupations in which Lorenzo engaged, there is not one in which he was not eminently successful: but he was more particularly distinguished in those which justly hold the first rank in human estimation. The facility with which he turned from subjects of the highest importance, to those of amusement and levity, suggested to his countrymen the idea that he had two distinct souls combined in one body. Even his moral character seems to have partaken, in some degree, of the same diversity; and his devotional poems are as ardent as his lighter pieces are licentious. On all sides he touched the extremes of human character, and the powers of his mind were only bounded by that impenetrable circle, which prescribes the limits of human nature.”

After all that we have said of this great man, and his grandfather Cosmo, those who would rightly appreciate their talents and various virtues, will consult the life of Lorenzo De Medici by Mr. Roscoe, of which the first chapter is chiefly devoted to Cosmo, the remainder of the three volumes to Lorenzo and the fortunes of his house.

MEDICINA MUSICA, or the medicinal Power of Music; being an essay on the effects of singing, music, and dancing on the human frame, revised and corrected. To which is annexed, a new essay on the nature and cure of the spleen and vapours, by Richard Browne, apothecary at Oakham, in the county of Rutland, small 12mo. London, 1729.

This is the title of a small tract but little known; but as it is not devoid of merit, we shall give some account of the author's principles. We feared we should have had the old stories over again, of Orpheus, Linus, Amphion, and Terpander; but their names do not once occur in the work. The author does not ascribe any miraculous powers to music, as the Greeks, the Chinese, and the Arabians have done; who pretend to cure many diseases with the instrument called *Oüd*, resembling our lute: he only points out its mechanical effects on the nerves and animal spirits. He is moderate in his demands, and modest in his assertions. It is not elaborate composition,

composition, or exquisite performance, that is required to operate the effects which he describes; but the *dulce lumen* of Horace.

The gentle exercise of the lungs in singing, as well as the gratification of the ear in hearing sweet tones well accented, are among the prescriptions. And for this he only requires the patient to have an ear well organized, and the vocal performance to consist of gay and lively strains, so that the body and the mind may be reciprocally affected by the production and sensation of sound. As the motion of the blood is accelerated or retarded during the rise or fall of the mercury in the barometer; so in singing, the pressure of the air upon the lungs is greater than in common respiration.

The author supports his opinions ably and anatomically. He seems to have loved and understood music, though he never speaks of it with the enthusiasm of a rapturist.

Among the possible evils of too frequent and too violent exercise of the lungs, we with the author had cautioned parents not to let their children, whatever disposition they may discover for singing, begin to exercise the voice seriously in difficult songs, or *solfeggios*, till arrived at their teens: as we have frequently known a promising voice sung away, by tearing and straining the vocal organ beyond its power. Let them hum a tune, or sing a light and pleasing ballad if they please; but leave different intervals, and long and high notes, to a more robust and mature age.

In asthmatic complaints, when the tone of the stomach is relaxed, and appetite fails; and in nervous disorders, as music raises the spirits, and diverts our attention from ourselves and our woes, real or imaginary, singing is not only amusing but salutary.

The author, however, seems to think that nervous and low-spirited persons should refrain from pathetic, melancholy, and languid airs, which, instead of exhilarating and enlivening the spirits, rather tend to their depression. But on the contrary, in affliction, pain, and sorrow, as well as in hypochondriac and calamitous cases, when gay and lively music is to the last degree offensive, we rather enlist with those who think grave music, if it cannot radically cure, can sooth, alleviate, and afford a temporary relief.

And among the medicinal effects of modern music that border on the marvellous, we read in the memoirs of the Acad. des Sciences at Paris, that a musician was cured of a violent fever, by a concert of well selected and well executed music in his bed-chamber. And the effect which Farinelli's singing had on Philip V. king of Spain, who like Saul seemed to have been troubled with an evil spirit, has never been disputed.

As to the author's *Medicina Gymnastica*, as a specific for spleen, vapours, and hypochondriac affections, we shall leave the consideration of these mysterious disorders to the profound sons of Æsculapius, who peradventure may be perfectly acquainted with their nature and existence. Mr. Browne, who has not defined them very clearly, prescribes, however, after other preparatory medicines, dancing to a good band of music for the completion of the cure. And as the music is meant to exhilarate and excite motion, the whole process seems reduced to the two most simple of all Hygeia's agents, *Air* and *Exercise*.

To these Armitrongs adds *Sun-shine*.

“Cheer'd by thy kind invigorating warmth,
We court thy beams, great majesty of day!
If not the soul, the regent of this world,
First-born of heaven, and only less than God!”

MEDICINAL WATERS. See WATERS.

MEDICINAL Sacculus. See SACCULUS.

MEDICINE, MEDICINA. from *in dei*, to heal or cure, is the art of restoring health to the sick.

It must be obvious, from a slight consideration of the subject, that various and comprehended knowledge must concur to give perfection to this art. It is not from the labours of an individual, though he were an Æsculapius, nor even from the united collections of an age, that the nature and means of curing the disorders of the animal frame can be fully ascertained. For, to trace the matter in detail, it is necessary to be previously acquainted with the structure of the animal machine, or with the *anatomy* of the body; and likewise with the uses and actions of its various organs, in a state of health, the knowledge of which constitutes the science of *physiology*. But to the proper cultivation of this science, a previous knowledge of many other departments of science is absolutely necessary. Almost every branch of natural philosophy, indeed, contributes to the explanation of the functions of the animal economy. The uses of the eye are intelligible only upon the principles of *optics*, as applied to inorganic instruments; the functions of the ear upon those of *acoustics*; and the various mechanical operations of the body, such as those of muscular motion, the circulation of the fluids, the action of respiration, &c. upon the common principles of *mechanics* and *hydrostatics*: not to mention the numerous changes in the combinations and properties of the fluids; in the blood, as it passes through the lungs; in the food and drink, under the process of digestion; and in the various secreted fluids, as the urine, milk, bile, &c.; for the elucidation of which, the science of *chemistry* lends its aid. Upon these branches of knowledge the foundation of medicine is laid; but the superstructure requires many additional materials for its erection. The animal machine differs materially from all other examples of mechanism; principally in the possession of a self-sustaining and self-moving power, upon which alone the operation of every external influence must be directed; and from which result many phenomena, that belong exclusively to its constitution, and are inexplicable on any of the principles of mechanical or chemical philosophy: but it differs likewise, secondarily, in the circumstance that its motions are not (as in other machines) exposed to our view; that we cannot remove, repair, and renew, (as in them,) those parts or organs which become inadequate to their functions, and cannot suspend the motion of the whole but for a moment, without the imminent risk of stopping it for ever. Hence then, in addition to the principles of mere mechanism, the study of the animal constitution includes a series of minute observations on those phenomena, which are the result of *life*; and this study is necessarily rendered more obscure and difficult, from the circumstance last alluded to: for the internal operations of the vital machine, not being directly cognizable, can only be ascertained by indirect inference from external and obvious signs or symptoms. These signs or symptoms, therefore, are the sole object of the examination of the practitioners of the art of medicine, and the sole guides of their proceedings. But as the existence and the nature of disease are known only by a comparison of those signs, which are exhibited by the body in health, with those which occur in disease; so the study of symptoms includes not only the science of *pathology*, but also a knowledge of the various *temperaments*, as they have been called, or of those various appearances of the structure, complexion, size, strength, &c. which are all compatible with health. (See TEMPERAMENT.) The signs of the respective diseases of the different organs of the body we have detailed under their proper appellations, in

the various articles in *medicine* and *surgery*; and a series of the signs which are to be investigated, as the indications of disease in general, will be found under the article DISEASE.

Possessed, however, of this knowledge, we should still be little more than useless, though learned, spectators of the phenomena of disease, if we were ignorant of all means of controlling the actions of the vital power. The art of medicine, then, obviously requires also a knowledge of the various productions of the material world, and of their properties, *i. e.* their agency upon the animal system: for these productions afford the instruments by which alone art can effect any physical change in its condition. A series of ages would be requisite to teach mankind the physical properties of the animal, vegetable, and mineral substances, by which they are surrounded; and the nature of many of them could only be ascertained by accidental trials, from the fatality, injury, or benefit derived from which, a slow but multiplying experience would ultimately arise. "Hæc similiaque cum quotidie inciderent, diligentes homines notasse, quæ plerumque melius responderent; deinde ægrotantibus ea præcipere cæpisse: sic medicinam ortam, subinde aliorum salute, aliorum interitu, perniciofa discernentem a salutaribus." (Celsus. Præf.) The knowledge of the *materia medica* has thus been gradually brought to that comprehensive extent, in which it exists at present, by a long series of experiments, aided by the researches of travellers and naturalists, and by the discoveries and combinations of chemists.

The progress of the art of medicine, however, as Celsus has intimated, was the reverse of the foregoing statement. "Repertis deinde medicinæ remediis, homines de rationibus eorum differere cæpisse; nec post rationem, medicinam esse inventam; sed post inventam medicinam, rationem esse quaesitam." (Loc. cit.) The history of the progress of medicine is, in fact, principally a history of those reasonings, or hypothetical systems, adopted by different individuals and their followers; and these consisted chiefly in transferring to the science of life the doctrines of the collateral departments of philosophy, which were successively cultivated, as the following sketch will evince.

MEDICINE, History of. The history of medicine has for its object to describe the origin and progress of the art, and to investigate the causes and consequences of the different revolutions which it has undergone.

Some authors have wasted much time and learning in attempting to depict the first origin of physic. Thus Schulze, a writer of great erudition, who was professor at Altorf in the beginning of the 18th century, has traced it to the fall of man; shewing, with great gravity, what observations Adam and Eve were likely to make on the subject of their natural appetites, and the evacuations which followed their indulgence; what a rich store of physiological knowledge they would collect, "quum se mutuo contemplantur, quum amplecterentur, coirent;" and how probable it is, that Adam, yielding to the necessity of the occasion, "laboranti amicæ, obstetricias manus adhibuisse, sicque chirurgiæ primam forte operationem exercuisse!" Even Le Clerc thinks it necessary to discuss the question, "Si la médecine est venue immédiatement de Dieu?" and to shew, that the first man must have been also the first physician. And Brambilla, a surgeon of some repute at Vienna, asserts that Tubal Cain was the inventor and manufacturer of several surgical instruments; whence he endeavours to prove the greater antiquity of surgery!

It is evident, however, that medicine must have had a very early origin: for mankind, even in the most uncivilized

ages of the world, would soon be led to remark the more or less agreeable, and more or less salubrious, qualities of the different articles of their food; and exposed, as they would be, in the common course of things, to a variety of accidents, they would, by degrees, learn the means of alleviating the pain, or averting the consequences of the more usual external injuries. They would thus, in process of time, form to themselves certain dietetic maxims and rules, for the treatment of those diseases to which they found themselves liable. Their *materia medica* would probably, at first, consist of only a few herbs, which they had discovered to be efficacious in suppressing hemorrhage, and in healing wounds, or to which they imputed virtues, real or imaginary, in the cure of internal complaints; but all the concomitant circumstances, under which they had observed recovery, in any doubtful case, to take place, would be regarded as indispensable in every similar case, and would be imitated accordingly. "Tunc non sanabat medicina," as Meibomius shrewdly remarks, "sed quidquid videbatur sanasse erat medicina." Unacquainted, however, with the economy of the human body, and unable, for the most part, to trace the progress of disease, they would ascribe the more fatal internal disorders to the powers of sorcery, or to the wrath of those deities whom they had been taught to fear; and would resort, for their cure, to those rites and ceremonies by which they conceived they could break the charm, and pacify the offended gods. Hence would arise various superstitious practices, which would be handed down from one generation to another, and of which the priests and magicians of the communities would gladly avail themselves, as affording them the means of extending their influence. Such we may conceive to have been the origin of the medical art; and such nearly is its condition at the present day, among the savages of Africa and America, New Holland, Zealand, &c. See Winterbottom's Account of the native Africans in the Neighbourhood of Sierra Leone, vol. ii. Millar's Disquisitions in the History of Medicine.

The Egyptians appear to have been the first nation which cultivated medicine in a systematic manner. Thouth, or Taout, (the *Hermes Trismegistus* of the Greeks,) who had been, according to Diodorus, the secretary of Osiris, had divine honours paid him, as the inventor of letters, and of all useful arts and sciences. His doctrines were collected, after his death, into a book, to which the title of "Embré" (*Scientia Causality*) was given. A great part of this work consisted of medical precepts, which the physicians or priests were bound to observe strictly. If they followed the directions, and the patient happened to die, they were held free from blame; but if they deviated in any manner from the rules laid down, they were punishable with death, whatever might be the issue of the case. Another of the Egyptian deities, Apis, is mentioned by some as the inventor of medicine; but greater influence is attributed to Serapis, whose most ancient temple was at Memphis, and who was worshipped by the Greeks, as well as Egyptians, as presiding over health. In whatever way these divinities may be supposed to have first attracted the adoration of the people, it is certain that the priests, from among whom the ancient kings of Egypt were chosen, appropriated to themselves the functions of the medical art. The chief priests exercised what was considered as the higher branch of the profession, which consisted of magic rites and prophesying. They are the wise men and magicians of whom Moses speaks, and they appear to have been very expert in their tricks. On the *Pastophori*, or image-bearers, who were an inferior order of the priesthood, devolved the task of studying the six hermetical

metical books on medicine. These treated of the structure of the body, of diseases in general, of surgical instruments, of materia medica, of diseases of the eyes, and of diseases of women. It was the office of the chief priests to prognosticate the course and event of the disease, while the pallaphori applied the remedies as directed in the sacred books. As the rank of the Egyptian priests was hereditary, as the son received and obeyed implicitly the instructions of the father, and as their knowledge was communicated to none but those who had been adopted into their order, it is evident that their medical knowledge would remain nearly stationary. It was obviously their interest to teach the people, that all diseases proceeded from the immediate agency of the god, and were to be cured only by sacrifices and offerings. They concealed their art under the forms of religious ceremony, and consequently we know very little concerning the details of their practice. Judging, however, from the analogy of other nations, we may infer that they left the cure of diseases, in a great measure, to nature; and were content with promoting the discharges, which seemed to be indicated. This opinion is in some degree confirmed by the remarkable circumstance which Aristotle mentions, (Polit. lib. iii.) viz. that it was contrary to their rules to venture upon any active treatment before the fourth day of the disease. We have the testimonies of Diodorus and Plutarch, that incubations were practised in the temples of Isis and Serapis; and we learn from Pliny (lib. viii. c. 46.), that predictions of life and death were delivered in those of Apis.

In the time of Herodotus, the state of physic in Egypt seems to have been somewhat altered. According to this historian, "every distinct distemper had its own physician, who confined himself to the study and cure of that, and meddled with no other; so that all places were crowded with physicians; for one class had the care of the eyes, another of the head, another of the teeth, another of the stomach, and another of occult diseases." But Herodotus would scarcely have spoken thus of the priest-physicians. We must therefore suppose that his description applies to the exoteric practice of medicine, as professed by Jatrapiæ and others; and we are inclined, notwithstanding the dogmatical commentary of Warburton, to put a somewhat similar interpretation on the passage of Genesis (c. 1 v. 2.), in which it is said, that "Joseph commanded his servants, the PHYSICIANS, to embalm his father; and the PHYSICIANS embalmed Israel." On the strength of this use of the word *physicians*, the author of the divine legation (b. iv. § 3) has amused himself with forming an ideal picture of "the grandeur, luxury, and politeness" of the Egyptian people; and the writer of the article MEDICINE in the Encyclopedia Britannica has hastily concluded that the first physicians of Egypt were not of the order of priests; but, when we consider what must have been the state of medicine in Joseph's time; and when we find, that, long afterwards, the priests of the Jews were, properly speaking, their only physicians, it will at once appear, how absurd and untenable the above cited translation of the original text is. It is far more probable, and it is certainly more consonant with all that we have learnt concerning Egyptian history, to believe that the **יִרְמְיָהוּ**, whom Joseph ordered "to embalm his father," were merely *embalmers*, or, as we might term them, *undertakers*. So, in fact, they are designated in the septuagint; *και προσηλαξιν Ιωσηφ τοις παισιν αυτου, τοις εμβασιασι, εμβασιασαι τον πατερα αυτου. Και εμβασιασαν δι εμβασιασαι τον Ισραηλ.* We know pretty accurately in what manner the ceremony of embalming was performed, and in what degree of estimation the persons who executed the office were held; we know, too, that among the ancient Egyptians, there was a great division of labour,

and that no one was allowed to meddle with the trade or profession of another; it is, therefore, not very likely that, if Joseph had been so affluent as to retain a number of physicians in his suite, as Warburton supposes, they would have condescended, or been permitted, to embalm the body of his father. From the distribution of medical practice, as described by Herodotus, however, one might be disposed to infer, that the Egyptians had already made considerable advances in the art; but as they were, in a great measure, debarred from all opportunities of acquiring anatomical knowledge, by the horror that pursued every one who cut open a dead body; and as they laboured, besides, under many other restrictions in the cultivation of the science, this could not possibly have been the case. That the Egyptian physicians were even very unskilful in the treatment of external complaints, is proved by what the author just mentioned relates (lib. iii. c. 129.) concerning their inability to cure a common luxation of the foot, which Darius, the son of Hytaspes, had met with in hunting. They appear, however, to have been acquainted with the powers of some valuable remedies, as of squills in dropsy, and of iron as a tonic in cachectic diseases.

Medicine was established on nearly the same footing among the Jews, as among the Egyptians. The priests, forming the only learned class, constituted themselves the sole judges and physicians of the people. Diseases were beheld to proceed from the wrath of "a jealous God;" and prayer was the chief means employed for their removal (Gen. xx. 17. Numb. xii. 13.); an immediate revelation to Moses even declares, that if the people would give ear to the commandments of the Lord, and keep all his statutes, he would put none of those diseases upon them which he had brought upon the Egyptians, for it was the Lord that healed them. (Exod. xv. 26.) It would appear, however, from different passages of the Pentateuch, and, in particular, from the enumeration of the different signs and varieties of leprosy, in Leviticus xiii., that the lawgiver of the Jews must have been, at least, a very accurate observer. Some persons have concluded, that he must have been also deeply skilled in chemistry, from his being able to dissolve the golden calf, in the wilderness, and from his changing the bitter waters of Marah to sweet, by means of a certain wood; but without more particular information respecting the means which he employed on these occasions, it is impossible to form any accurate estimate of his chemical proficiency. In later times, the *prophets* of the Jews signalized themselves by healing the sick, raising from the dead, and occasionally denouncing the infliction of distempers on those who had rebelled against the law of God.

Recent researches have shewn, that, at a very early period of history, the inhabitants of Hindoostan had made great progress in several branches of physical science, but there does not appear to be any reason for believing that in the art of curing diseases, they were superior to the surrounding nations. According to Strabo (lib. xv.), they trusted chiefly to diet, and to external applications; the superintendance of the sick was committed in the towns to a particular description of magistrates, under whose inspection the Samaneans (*Σαμαναις*) were permitted to practise. A law prevailed, that whoever discovered a poison, was bound to keep it secret till he had found an antidote to it; if he succeeded in discovering the latter, he was rewarded with great honours; but if he made known the poison without the antidote, he was punished with death.

Under the despotic government of China, whatever its admirers may choose to say, and whatever degree of antiquity they may ascribe to its institutions, it was utterly impossible

possible that the liberal arts could attain any high improvement. The medical code, which is ascribed to Hoangti, and said to have been composed 4000 years ago, but which has been proved to be of much later origin, forms the guide of the Chinese physicians. Formerly there were public schools in different parts of the empire, in which medicine was taught in conjunction with astrology; but these no longer exist; and the art itself, as we learn from sir George Staunton and other late travellers, is in a very degraded state. The *Specimen Medicinæ Sinicæ*, for which we are indebted to Cleyen, sufficiently proves that the Chinese were never acquainted with its fundamental principles.

There is a striking coincidence between the accounts which have been given of the medical divinities among the Greeks, and those of the Egyptians, though it may be doubted whether the Greeks derived their knowledge of the art from the latter people. Like the Isis and Osiris, Apollo and Minerva became the gods of physic in Greece, and Orpheus, who was said to be the son of Apollo and Calliope, performed the part of Thouth; instructing his countrymen in the mysteries of religion, in poetry, and in medicine. According to some chronologists, however, Melampus is reported to have flourished considerably before his time, and to have distinguished himself by his medical skill; of which he gave a remarkable proof in the cure of the daughters of Prætus, king of Argos, who were attacked with leprosy and madness. Afterwards it would appear that all the chief heroes of Greece, and particularly those of the Argonautic and Trojan expeditions, were more or less versed in the physical art; in which they are said to have received their instruction from Chiron the Thessalian, surnamed the Centaur. Cephalus, Æsculapius, Melanion, Nestor, Amphiaraus, Peleus, Telamon, Meleagrus, Theseus, Hippolytus, Palamedes, Ulysses, Menestheus, Diomedes, Castor, Polydeuces, Machaon, Podalirius, Antilochus, Æneas, and Achilles, are all mentioned by Xenophon as the pupils of Chiron. Of these by far the most celebrated is Æsculapius, or Asclepius, the reputed son of Apollo and Coronis. He was probably a Thessalian prince; and he is described as particularly successful in the cure of external diseases. That, indeed, his merits must have been very extraordinary for the age in which he lived, seems proved by the fable, that Jupiter was obliged to remove him from the world, to prevent the growing indifference of mankind towards the gods, and the desolation of Pluto's kingdom. Some time after his death, divine honours began to be paid him; in consequence, chiefly, of his descendants devoting themselves to the medical profession; pretending to have derived their knowledge immediately from him, and ascribing all the cures which they effected to his direct influence. His sons, Podalirius and Machaon, have acquired a durable celebrity from the mention which the author of the Iliad has made of their surgical skill.

From the Trojan war till the age of Hippocrates, the art of medicine continued chiefly in the hands of the priests, who exercised it for their own profit in the temples of the gods. In conformity with the superstitious character of the age, the patients were taught to expect a cure, or at least to learn the means of obtaining it, in dreams, for which they were previously prepared, or rather stupefied, by a course of imposing ceremonies. The temples were generally situated in the neighbourhood of rivers, or mineral springs, and in elevated situations, where the influence of the fresh air, and the beauty of the surrounding prospects, were likely to excite cheerful ideas, and to conduce to the recovery of the patient. Bathing was an indispensable part of the initiatory process; and this, conjoined with the strict abstinence which

was enforced, doubtless often effected a cure. When recovery took place, the patients were led, from gratitude, to present various offerings to the deity of the place; sometimes pieces of money were thrown into the spring where they had bathed, or from which they had drunk; at other times drawings and images of the diseased parts, or tablets descriptive of the disorder and cure, together with the names of the patients, were suspended in the temples. These narratives, some of which have been rescued from oblivion by the industry of Grüter (Corp. Inscript.), must have doubtless contributed to the progress of the art, and supplied the successive generations of priests with some useful practical observations. The temples in which they were recorded, particularly those of the Asclepiades, became, in fact, so many medical schools, differing however from one another, and that often materially, in their doctrines and practice. Thus, the Cnidian school distinguished itself by its strict empiricism; while that of Cos had more of a dogmatical character, laying much stress on the knowledge of the exciting causes, and the prognosis of disease, and pursuing a more methodic and rational mode of treatment. The former produced Euryphon, the author of the *Εὐρυφῶν Κηρύξεις*, and Ctesias, of whose Persian history some fragments have been preserved by Photius; in the latter was developed the genius of Hippocrates.

At first, they were only the actual descendants of Æsculapius who were instructed in the art: afterwards other persons were admitted as pupils, having previously undergone a particular initiation, and bound themselves by an oath to conform to the rules of the Asclepiades. Some philosophers of comprehensive genius, however, accustomed to speculate on the origin of things, the nature of man, &c. had already begun to extend their researches to medicine, and succeeded in rescuing the study, to a certain degree, from the dominion of the priests. Of these benefactors of their race, no one is more deserving of mention than Pythagoras, who, after visiting Egypt and India in quest of knowledge, returned to his own country and established the school of Crotona. He applied himself to the study of the animal economy; introduced a regular system of dietetics; and did not neglect the practice of medicine. His attempts to explain every thing by the power of numbers, were, indeed, sufficiently ridiculous; and his therapeutical maxims differed scarcely from those of the temples; but the rules of regimen which he inculcated were, generally speaking, very judicious, and implied considerable powers of observation; though they have, no doubt, been carried to an extravagant length by his followers. Among his immediate disciples, Alcmaeon is celebrated as the inventor of anatomy; and though his knowledge of the internal structure of the human frame may be disputed, yet the concurring testimonies of Aristotle, Diogenes, and Plutarch, abundantly prove that he made no inconsiderable figure as a comparative anatomist. He is also the author of the first theory of sleep. "When the blood," he says, "returns into the larger blood-vessels, sleep is induced: when it is again distributed, waking occurs; but a complete congestion is followed by death." (Plutarch de Plac. Philos. lib. v. c. 23.) Empedocles was another distinguished adherent of the Pythagorean sect. See EMPEDOCLES.

Besides these philosophers, and the Asclepiadæ, there were, at this period, other persons who devoted themselves to the profession of physic, and who occasionally were remunerated by a fixed salary. Thus, Democetes of Crotona was retained at the court of the Samian tyrant, Polycrates, with an allowance of two talents yearly: being afterwards taken prisoner, and carried as a slave into Persia, he acquired great repute by curing Darius of a sprained foot, after the Egyptian

Egyptian physician had failed, and also by his successful treatment of a tumour of the breast, under which Atolla, the daughter of Cyrus, and wife of Darius, had laboured for a considerable time. (Herod. iii. 133.) Such practitioners, from their wandering lives, were sometimes designated by the name of *περιδωτοι*. Of this class, one of the most conspicuous was Acron of Agrigentum, the contemporary and rival of Empedocles, respecting whom Pliny has fallen into a strange error, in describing him as the founder of the empiric sect "under the sanction of Empedocles." According to Diogenes, he was the author of some books on medicine and dietetics, written in the Doric dialect; and he signified himself at Athens, in the time of the great plague, by introducing the practice of fumigations (*πυρ κλινοειξ παρκακων τοις ιοσμοσι*), and thus affording relief to many. (Plut. de Isid. et Osir.) The *gymnasia* of ancient Greece seem also to have contributed to the improvement of the art. It belonged to the *gymnasiarch*, or *palaestrophylax*, to regulate the diet of the youths who were trained in these seminaries; the *γυμνασαι* were presumed to be conversant with diseases; and it was the business of the *αλιπτειαι* to perform venesection, to dress wounds, fractures, &c. They were sometimes called physicians. It was in these seminaries that the gymnastic system of medicine originated, under the auspices of Iecus of Tarentum, and Herodicus of Selymbria. See HERODICUS.

The first year of the eightieth Olympiad gave birth to Hippocrates, the second of that name, who was destined to effect a greater revolution in medical science than had hitherto been accomplished, and whose authority continued to be regarded with almost implicit veneration by his successors, during a period of more than two thousand years. "He saw," says Mr. Cabanis, "that too much, and yet not enough, had been done for medicine; and he accordingly separated it from philosophy, to which it had never been united by its true and reciprocal relation. He brought the science back again into its proper channel, that of rational experience. However, as he himself observes, he introduced both these sciences into each other, for he considered them as inseparable; but he assigned to them relations which were altogether new. In short, he freed medicine from false theories, and formed for it new and solid systems: this, he with justice said, was to render medicine philosophical. On the other hand, he elucidated moral and natural philosophy by the light of medical science. This we may, with propriety, call with him the introduction of the one into the other.

"The new spirit of improvement, which was thus communicated to medicine, resembled a sudden light that dispels the phantoms of darkness, and restores to bodies their proper figure and natural colour. By rejecting the errors of former ages, Hippocrates learned more fully to avail himself of the useful part of their labours. The connection and dependence, both of the facts which had been observed, and of the conclusions which had been legitimately deduced from their comparison, were now perceived with a degree of evidence, which, till then, had been unknown. All the discoveries were certainly not yet made; but from that moment inquirers began to pursue the only path which can conduct to them; from that moment, if they had been able to preserve themselves from delusion, they would have possessed sure means of estimating, with precision, the new ideas which time was destined to develop; and if the disciples of Hippocrates had understood his lessons well, they might have laid the foundation of that analytical philosophy, by the aid of which the human mind will be henceforth enabled to create to itself, as it were, daily, some new and improved

methods of advancement." *Coup d'Œil sur les Révolutions, &c. de la Médecine*, 76—78.

Unfortunately, however, for the progress of the art, the disciples of Hippocrates either did not "understand his lessons," or, misled by vanity, or other more ignoble passions, they soon deviated from the path which he had struck out. Instead of pursuing quietly the observation of nature, they consumed their time in framing fanciful hypotheses to explain her operations: instead of studying, in a sincere spirit, the works of the master whom they professed to worship, they shamelessly falsified his writings, in order to adapt them to their own peculiar views, so that it has become, as we have already had occasion to shew, (see HIPPOCRATES,) a matter of no small difficulty to distinguish the genuine from the spurious compositions that have been ascribed to the father of medicine. But, notwithstanding these errors, it cannot be doubted, that the genius of Hippocrates exerted a highly beneficial influence on the minds of succeeding inquirers; and that, without his writings for a guide, the science of physic would have remained, for a much longer period, in a state of infancy. "Au lieu de ces systèmes, sinon meurtriers, du moins ridicules, qu'a enfantés la médecine moderne pour les proferir ensuite, on y trouve des faits bien vus et bien rapprochés; on y voit un système d'observations, qui encore aujourd'hui sert de base à l'art de guérir." D'Alembert, *Mélanges*, iii. 271.

The Dogmatic school, of which Hippocrates has erroneously been considered as the head, was founded by his sons Theſalus and Draco, and his son-in-law Polybus, who are the reputed authors of many of the books that now pass under Hippocrates' name. Polybus is mentioned by Aristotle as the compiler, at least in part, of the book "On the Nature of Man," which contains all the leading tenets of the Dogmatists, and which was regarded by Galen not as the composition of one individual, but as a collection of fragments by different writers. Applying the mystical doctrines of the Platonic philosophy to medicine, the Dogmatists proceeded upon the principle which has exerted such baneful influence on the progress of science in general, *viz.* "that where observation failed, reason might suffice." (*De Arte*. Ed. Foef. 1657. p. 6.) They accordingly were led to neglect the patient study of nature; and before they had collected a sufficient store of facts, they fondly imagined that they had laid the foundation of an incontrovertible system. Hence it came, that in their inquiries, sophistry often usurped the place of observation, and futile hypothesis was preferred to experience. In this way arose a multitude of sects, who contributed little or nothing to the advancement of the art, but, on the contrary, were daily misleading their followers more and more from the right path of research. It is therefore highly unjust to refer the origin of the Dogmatic school to Hippocrates, in whose genuine writings it will be found that the most opposite principles are inculcated. For a more particular account of the doctrines of this sect, see EMPIRIC.

About the same period, Eudoxus of Cnidos introduced the Pythagorean system, and a modification of the Egyptian practice, in which he was followed by his disciple Chryſippus. With the latter, cabbage and other vegetables were the favourite remedies; to purgatives and blood-letting he had an aversion. One of the most distinguished men of the age, however, was Diocles of Caryſtus, whom Pliny (xxvi. 2.) ranks as almost equal to Hippocrates. He employed himself in comparative anatomy, and corrected many errors of his predecessors: like the two last mentioned physicians, he united the doctrines of Pythagoras with medicine; ascribing

ing great influence to the number seven and its combinations. (Macrob. in Somn. Scip. i. 6.) He was also the inventor of a surgical instrument for the extraction of arrows, called after him *Diocleus graphiceus*. His contemporary, Praxagoras of Cos, is not less deserving of notice on account of his anatomical labours, being the first person who established the distinction of arteries and veins, and who demonstrated the absence of *cotyledons* in the human uterus; whence Sprengel (Geschichte der Arzneikunde, i. 549.) has with great plausibility conjectured, that dissections of the human subject could not have been, at that time, entirely unknown. Praxagoras also introduced the doctrine of the pulse, and reduced the humoral pathology to a more regular system: he made frequent use of venesection, particularly in hemorrhage, and was a bold surgical operator; for he scrupled not, as Cælius Aurelianus informs us, to lay open the abdomen, and divide the *intestinum rectum*, in the iliac passion, in order to remove the accumulated fæces.

Many circumstances had now concurred to favour the advancement of natural knowledge. The spirit of inquiry, which the early philosophers had excited, was cherished by the establishment of so many rival schools; but, above all, by the number of learned men, who arose to adorn and instruct the world. Within the short space of a century appeared Aristotle, Pyrrho, Theophrastus, Zeno, and Epicurus, all of them endowed with transcendent genius, and conspicuous for their zeal in the cause of science. The influence which they exerted on the character of their age was accordingly very great. While Aristotle applied himself, with the most signal success, to all the branches of moral and physical research, and his pupil Theophrastus laid the foundation of true botanical science; Zeno and Epicurus developed those beautiful systems of ethics, which transported their contemporaries, and which still, in some measure, divide the minds of men. However remote from medicine the speculations of moralists may at first sight appear, a little observation will teach us, that the physicians of almost every age have allowed themselves to be carried along by the current of prevailing opinions. In the epoch of which we are now writing, the tenets of Pyrrho and Epicurus were eagerly seized upon by the empirical sect, as favouring their peculiar views; while the stoical system gave new strength to the dogmatists, particularly by the introduction of the dialectic method.

The establishment of a magnificent library and museum of natural history at Alexandria, and the liberal patronage which learning there received from the Ptolemies, rendered that city the chief resort of men of science from all parts of the world, and the great emporium of literature. In consequence, the Alexandrian school soon eclipsed all the rival seminaries, and produced a succession of eminent physicians; among whom Herophilus and Erasistratus are entitled to the first place, on account of their important contributions to anatomical knowledge. (See their respective articles.) It was in their time, and probably at Alexandria, that the memorable division of the art into three branches took place: "Iisdem temporibus, in tres partes medicina ducta est, ut una esset, quæ victu, altera quæ medicamentis, tertia quæ manu mederetur." (Cels. l. i.) But, however much this distribution of practice was calculated to accelerate the progress of medical science, in all its different parts, it does not appear that the immediate successors of Herophilus and Erasistratus turned the circumstance to great account; though Celsus affirms, that surgery improved rapidly after its separation. Lib. vii. Præf.

Of the establishment and doctrines of the Empirical sect

we have already given a sufficiently minute view under the proper article. We have there shewn how decidedly the principles of this school were opposed to those of the Dogmatists; and that there was something more than a mere dispute of words between them, as some writers maintain. Notwithstanding, however, all their points of variance; notwithstanding the violence and bitter animosity which the contending parties displayed in their controversies; it was found, that when they came to apply their respective principles to practice, and to determine on the treatment of disease, all differences, in a great measure, vanished. Nor was this to be wondered at: for the dogmatists, though they indulged too much in hypothetical reasoning, did not altogether neglect observation, and were consequently more or less guided by the same lessons of experience, on which the empirics founded their therapeutical maxims. The same remark will be found to apply to almost all the sects which have acquired any consequence in the medical world.

In the article last referred to, Heraclides of Tarentum has been mentioned as one of the adherents of the empirical school; but he deviated from the strict empirics in this respect, that he did not neglect the investigation of the hidden and remote causes of disease. His practice in some of the most dangerous diseases, as phrenitis, lethargy, cyananche, tetanus, and cholera, (for the description of which we are indebted to Cælius Aurelianus,) seems to have been highly judicious. To the materia medica he contributed largely: he wrote a treatise on the composition of medicines, in which he observed the praiseworthy maxim of noticing only such remedies as he had administered himself. He is also reported to have possessed no inconsiderable skill in surgery; and, on the whole, he appears to have fully merited the eulogies of Galen and Aurelianus, the latter of which styles him *empiricorum princeps*. After his death, the study of the materia medica took a new direction, in consequence of the attention that was paid to the subject of poisons and their antidotes, by the kings of Pergamus and Pontus. The antidote which was invented by the latter is well known, though its efficacy has never been proved. Even Serenus, who is in general sufficiently credulous, seems to have had no very high opinion of its virtues.

“ Antidotus vero multis Mithridatica fertur
 Confociata modis, sed Magnus serinia regis
 Cum caperet victor, vilem deprehendit in illis
 Synthefin, et vulgata fati medicamina risit.” Cap. ix.

Nicander of Colophon, who was the contemporary of Attalus, king of Pergamus, acquired great fame as a grammarian, a poet, and a physician. Of his works, only the two treatises in verse, entitled *Θεριακκα* and *Αλεξιφαρμακκα*, have been handed down to us. Though not abounding in poetical merit, they display no mean acquaintance with natural history.

The Roman people, as Pliny assures us (xxix. 1.), had continued without physicians, if not without physic, during a period of 600 years. On the occasion of a destructive epidemic, in the year 463 A.U.C. however, they sent a deputation to the temple of Esculapius at Epidaurus. Instead of an oracle, they received one of the sacred serpents, and following the indication of its springing from the ship upon the island of the Tiber, they there founded a temple to the god of medicine, and established his worship on the same footing as at Epidaurus. Shortly afterwards, a temple was dedicated to the Grecian Hygeia, and the worship of Isis and Serapis was borrowed from the Egyptians: but, besides these, the Romans had certain medical deities

quite peculiar to themselves. For example, on the Palatine Mount, there was a temple of the goddess Febris, who probably received divine honours from a prevalent dread of the disease. Tomafini, (in *Grev Thesaur. Roman. Antiquit.* v. xii. p. 867.) has preserved the following inscription of a votive tablet to this goddess:

“ FERRO DIVÆ FERRE
SANCTÆ FERRE MAGNÆ
CAMILLA AMPTA PRO
FILIO MALE AFFECTO P.”

There was also a goddess Ossipaga, who presided over the growth of the bones, and one styled Carna, who took care of the viscera, and who had bean-broth and bacon offered to her, as being the most nutritious articles of diet. (Macrob. *Saturnal. lib. i. p. 123.* ed. Ald.) The goddess Mephitis, who is mentioned by Tneitus, as worshipped at Cremona, had probably the same attributes as Febris.

With respect to the question, which was so warmly debated in the beginning of the last century, (*viz.* Whether the art of physic was exercised by any other persons than slaves, or freedmen, in the earlier periods of Roman history?) we would observe, that the probability is against the supposition, that it was so. Certain it is, that the inferior orders of the profession, those Greeks, for example, who were employed to perform venesection, to extract corns, or draw teeth, were all dignified with the title of *medici*, in the same way as the Jatruliptæ were often styled *ἰατροί*. But that in time they raised themselves above this servile condition, is abundantly proved by the honour of citizenship, and other privileges, which were conferred upon them. Archagathus is the first person who is mentioned as having come to Rome, of his own accord, to practise the art of surgery. The senate decreed him the freedom of the city, and purchased for him a shop in the Acilian crossway; but his cruel operations—“*sævitia secandi urendique*”—soon brought him into disrepute, and eventually led to his banishment. Pliny, *loc. cit.*

In the 654th year A.U.C., or 100 years before the Christian era, Asclepiades, a native of Prusa in Bithynia, who had studied at Alexandria and Athens, came to Rome as a teacher of rhetoric: but not finding that profession sufficiently lucrative, he suddenly turned physician, and by his consummate address, in a short time, brought himself into great notice. The prototype of all succeeding quacks, Asclepiades affected to condemn every thing that had been done before him—“*omnia abdicavit; totamque medicinam, ad causam revocando, conjecturam fecit;*” he ridiculed Hippocrates for his patient observation of nature, and called his system a *meditation on death*, *θανάτου μελέτην*. His fame, however, would have been incomplete, if he had not introduced a system of his own. Accordingly, taking, for the basis of it, the philosophy of Epicurus and Heraclides of Pontus, he attempted to explain all the functions of the human body, and all the operations of health and disease, by means of corpuscles and pores, *ὄγκοι* and *πόροι*. Anatomy was altogether neglected by him. In his practice, he professed to be guided by the maxim *tuto, celeriter, et jucunde*: but though he flattered the caprices of his patients, and soothed their complaints by the blandishments of his rhetoric; yet we learn from Celsus (*lib. iii. c. 4.*), that he subjected them to many severe mortifications; keeping them, for instance, several days without drink or sleep, in the early stages of fever. That Asclepiades, however, possessed no mean talent for observation, is proved by his description of diseases, and by the division of them into acute

and chronic, which appears to have originated with him. The remedies which he employed were chiefly dietetical; but he was no enemy to phlebotomy, though he discouraged vomiting and purgation: instead of the latter he recommended clysters. He was a great advocate for the efficacy of frictions, gelation, and other corporeal exercises; and he sedulously proscribed the use of cold water externally as well as internally; though he probably ingratiated himself with the Romans more by his free admission of wine, in disorders where it had not formerly been allowed. Sprengel supposes him to have been the inventor of the shower-bath, *balneum perfusivum*. Pliny, *xxvi. c. 3.*

Theonson of Laodicea, a disciple of Asclepiades, adopting the leading doctrine of his teacher, founded upon them the Methodic system. He discarded the study of remote causes, the theory of critical days, &c. as wholly useless; and maintained, that all that was necessary for the physician, was an acquaintance with certain general constituents of disease. In his practice he followed the footsteps of Asclepiades, first furnishing his patients, and then endeavouring to obviate the preternatural condition, which he had induced. His success, however, would not appear to have been very great, if we are to credit the insinuation contained in the line of Juvenal,

“ Quot Themison ægros autumnno occiderat uno.”

The object which the Methodic sect had in view, seems to have been the simplification of the theory and practice of the art. The investigations of the Dogmatists respecting occult causes appeared to them to rest on too fallacious grounds; nor were they satisfied with observing the *concurfus symptomatum*, like the Empirics: they therefore steered a middle course between the two, taking for the basis of their theory certain conditions of the system, which are common to different diseases (*quædam morborum communia, κοινοτήτες*); without considering, as Sprengel well observes, that these conditions of the body are as often, if not more frequently, concealed from view, than all the occult causes of the Dogmatists. The earlier adherents of this system contended, that there were two general morbid conditions to which all diseases were referrible, *viz.* a state of *constriction*, and a state of *relaxation*; but they applied these terms not, as it would appear, in the modern acceptation, to particular organs, but to the body at large. Conformably to this view of disease, all that the practitioner had to do, was to find out, in each case, the morbid condition, and to apply his remedies accordingly: if it was a disease of constriction, he prescribed relaxing medicines; and if it was one of relaxation, he employed astringents. But it was very soon discovered, that these two states would not comprehend all diseases: the Methodists therefore invented a third common condition, which they called the *mixed* state. “We may form some idea,” Mr. Cabanis observes, “of what they meant to designate by the term *diseases of constriction*, though it is certainly not so intelligible to men of science, as it appears to the uninformed class; we may also conceive the import of the phrase *relaxed fibres*; but it is difficult to divine, what they could understand by their *mixed species*, or how they could apply to practice this speculative notion, which is so very subtle, as to elude all clear conception. Besides, is it not evident, that almost all diseases belong to the *mixed* class, or may be referred to it? For this word, if it signify any thing, must mean an *irregularity of tone* in the different organs, or an *irregular distribution* of the vital power. Now the majority of diseases present the general phenomenon of a derangement of equilibrium.

brium, or irregular expenditure of living energy. In those cases, in which these deviations from the healthy standard are less obvious, an observing eye may still perceive them; and, perhaps, there is no disease in which a deficiency of equilibrium is not, in some degree, manifested, whether it be in the tone of the different organs, or in the exercise of life, and distribution of the sensibility of the system. Thus then, the *mixed species* of the Methodic sect, by comprehending every thing, becomes, in fact, applicable to nothing." Loc. cit. p. 100.

Notwithstanding the justice of these strictures, it cannot be denied, that the doctrines in question had, in one point of view, a beneficial tendency, viz. by obliging physicians to study more attentively, than they had hitherto been accustomed to do, the different indications of disease. If the Methodists had applied themselves to the investigation of such morbid conditions of the system as were manifested by the symptoms; and if they had not rashly attempted to simplify pathology, by ranging diseases in two general classes, according to characters that were but partially applicable; their school would have conducted still more to the improvement of the science of medicine. As to their mode of practice, it may be observed, that they wholly overlooked the healing powers of the system, and, without regard to the peculiar circumstances of the case, or the nature of the part affected, were solely intent on fulfilling those general indications, that were conformable to their theory. It is true, that they paid particular attention to days; not, however, as connected with the doctrine of crises, for which, as we have already hinted, the founders of this sect entertained a marked contempt; but only as affording them a measure of the duration of the disorder, and a guide for the method of treatment. In the first days, they followed the starving system; afterwards they pursued the supposed general indications of constricting, or of relaxing: during the exacerbation of the disease, they endeavoured to moderate the violence of it; during its decline, they supported the powers of the system by nutritive diet. This was their mode of proceeding in all acute diseases: but, in chronic complaints to which it was less applicable, they had recourse to what they termed the *μετασχημασις*, or *reincorporation*, of which the professed object was to restore the proper relations between the atoms and pores, and for which they prepared the patient by the *ἀναληψις*, or *resumptive circle*. It was, in fact, little else than their practice in acute diseases reversed,—they first sought to strengthen the patient by a generous diet, and then they administered a succession of violent remedies, to subdue the original malady. For the details of this mode of treatment, see Cæli. Aurel. Chron. i. c. 1. ii. c. 13. 29. &c.

Among the disciples of Themison, one Theffalus of Trallis, a man of low birth and coarse manners, made himself conspicuous by the shameless audacity with which he sought to disparage the labours of others—arrogating to himself the title of *ιατρονικης*, or *conqueror of physicians*, and that, it would appear, without the slightest pretensions to either learning or talents. (Plin. l. xxix. c. 1.) He held forth, that he could qualify any one for a physician in the space of six months, and actually succeeded in obtaining a great number of pupils; but it was from among the lowest order of artificers, such as rope-makers, weavers, cooks, butchers, fullers, and such like. These he took with him to visit his patients for the stipulated time, and then he conferred upon them the privilege of practising for themselves. From his time it became the custom for the Roman physicians to visit their patients attended by all

their pupils; in allusion to which, we have the epigram of Martial:

“Languēbam; sed tu comitatus protinus ad me
Venisti, centum, Symmache, discipulis.
Centum me tetigere manus aquilone gelatæ:
Non habui febrem, Symmache: nunc habeo!”

The methodic school acquired much greater repute from the labours of Soranus and Cælius Aurelianus; the former a native of Ephesus, who had studied at Alexandria, and came to Rome during the reign of Trajan; the latter an African by birth. Free from the prejudices, which had disgraced his predecessors, Soranus cultivated the study of anatomy, and wrote a book on the *female organs of generation*, which is still extant, and which displays considerable acquaintance with the subject. Many of his observations on disease shew, that he was possessed of great sagacity and strength of judgment. To Cælius Aurelianus, on the other hand, we are indebted for an account of his doctrines and practice, and for one of the best works on medicine, which have come to us from ancient times; written, it is true, in a barbarous style, but highly deserving of perusal on account of the accurate description of diseases, and the different methods of treatment, which it contains.

Anatomy and the other auxiliary sciences, though they had been so much neglected by the methodists, were now receiving important additions from other quarters. Rufus of Ephesus, who lived in the time of the emperor Trajan, and whose works have been edited by our countryman, Clinch, applied himself zealously to the dissection of animals, particularly of apes, and described from analogy the different organs of the human body. He traced the nerves from their origin in the brain, and divided them into those of sensation and those of voluntary motion; he pointed out the decussation of the optic nerves at the *infundibulum*, and he speaks of the capsule of the crystalline lens, under the appellation *ὑμην φλοκοειδης*. The heart he believed to be the seat of life, of animal heat, and the cause of pulsation, and he shewed the difference of structure and capacity between the right and the left ventricle. The spleen he held to be an useless organ. Marinus, whom Galen calls the restorer of anatomy, and to whose labours he was himself probably indebted for much of his knowledge on the subject, rendered still greater services to the science. He investigated the absorbent system with great care, and discovered the mesenteric glands; he distributed the nerves into seven pairs: the N. palatinus (then called the fourth pair) was first described by him; and he is said to have been the discoverer also of the *par vagum*, which he termed the sixth pair. His numerous writings have all perished.

The study of the *materia medica*, and of the other branches of natural history, was prosecuted with no less vigour; and we owe to this epoch the invention of many remedies, which are still retained in our pharmaceutical systems. The elder Pliny, second only to Aristotle in the universality of his genius, but surpassing even that great man in his insatiable thirst for knowledge, had collected in his *Historia Mundi* all that the ancients knew of natural science. Dioscorides of Anazarba, devoting himself to botany and *materia medica*, produced a work, which served for a guide in these sciences till a very late period. His descriptions of some of the more valuable drugs, such as myrrh, ladanum, assafœtida, ammoniac, opium, squills, and their different preparations, are entitled to great praise. The efficacy of several remedies, which he recommends, has been admirably confirmed by later experience, such as of

the elm-bark in cutaneous diseases, of potash as a caustic, of the male fern against worms, &c. &c. Some of the contemporaries of Dioscorides, as Scribonius Largus, Xenocrates, and Andromachus, cultivated the materia medica, but with less success. To Meneceates, who lived in the reign of Tiberius, and who, according to an inscription in Montfaucon, appears to have been the author of 155 books, we are indebted for the invention of the *diachylon* plaister; and Damocrates is well known as the author of several complicated remedies, which bear his name. Herennius Philo, of Tarsus, is mentioned by Galen as the inventor of an anodyne composition, called, after him, *Philonium*, and which consisted of opium, euphorbium, and different aromatics; and Aselepiades Pharmacion was the introducer of numerous remedies from the animal kingdom, which, though long honoured with a place in our pharmacopœias, have now deservedly fallen into disrepute.

Before quitting this period of medical history, it will be necessary to say a few words respecting two other sects, which arose soon after the establishment of the methodic school: we mean the Eclectic and Pneumatic sects. The founder of the latter, Aristæus of Cilicia, flourished as a physician at Rome about the middle of the first century, and distinguished himself by his opposition to the tenets of Aselepiades, and his attachment to the Stoical system: he extended the theory of pre-existent germs; treated the doctrine of the pulse with dialectic subtlety, referring its varieties to the exhalation of the *πνευμα* from the heart and arteries; and cultivated several branches of pathology; but was more successful in his dietetical researches, particularly with respect to the influence of the atmosphere. His pupil Agathinus, endeavouring to reconcile his principles with those of the methodic and empiric sects, acquired the name of the Episyntetic or Eclectic, and thus established the Eclectic system, on which, however, he does not appear to have conferred much repute by his own labours. That merit was reserved for Archigenes and Aretæus, who, adopting the leading tenets of the Pneumatic theory, gave it a more scientific form, and enriched it by many valuable observations. The former attempted to reform the language of medicine, but without much effect; for even Galen has occasion to complain of the obscurity of his phraseology; he was, besides, too fond of subtleties: but many of his practical observations, which Galen has recorded, are excellent. The merits of Aretæus, as a skilful and attentive observer, and as an elegant describer of disease, are familiar to every one. To Cassius, the Jatrophiist, another Eclectic, we are indebted for many valuable pathological remarks concerning the diseases of association, and the sympathies of the nervous system.

During this period, surgery received considerable improvement; particularly from the labours of Heliodorus and of Antyllus. Of the former, who was an eminent surgeon at Rome, in the time of Trajan, Nicetas has preserved several practical observations, on injuries of the head and diseases of the bones, which evince no mean proficiency in his art. The latter is perhaps still more deserving of notice, as being the first who gives any account of the extraction of the cataract: he recommends this operation to be performed while the cataract is small, being of opinion, that, when enlarged, it cannot be extracted without bringing the humours of the eye along with it. (Rhaz. Continent. lib. ii. c. 3.) His directions concerning the preparation of plasters and ointments, and concerning the choice of veins in phlebotomy, are very minute. In dangerous cases of cyanache, he advises bronchotomy; and in *hernia humoralis*

he operated by incision. Philagrius, who lived about the time of Valens, appears to have been the first who attempted to extract a stone from the bladder by the high operation. (Aët. *Tratrab.* iii. f. iii. c. 5.) The last quoted author has also transmitted to us an account of the surgical practice of one Leonides of Alexandria, whose observations on hernia, scrofula, and glandular swellings, on ulcers and warts of the genital organs, on hydrocele, and on inflammation of the scrotum, shew considerable discernment. In cancerous affections of the breast, he resorted to amputation, and the actual cautery; in *fistula*, his method of operation differed but little from that recommended by Pott.

The art of medicine was advancing thus rapidly in all its branches, when Galen appeared, a man of signal talents, who soon outstripped all his competitors in the profession, and divided with Hippocrates the admiration of the medical world. "Endowed with a genius sufficiently comprehensive to embrace all the sciences, and to cultivate them all with equal success," if we may borrow the language of Cabanis, "he, even in early infancy, gave proofs of uncommon capacity; and while pursuing his youthful studies, began to perceive the futility of the prevailing systems. Dissatisfied with what his masters taught him as incontrovertible truths, and as the immutable principles of the art, he read Hippocrates' works, and was struck, as it were, with a new light. In comparing them with Nature, his astonishment and admiration redoubled; and Hippocrates and Nature thenceforth became the only preceptors to whose instructions he would listen. He undertook the task of commenting upon the writings of the father of medicine; he presented his opinions in various lights, in which they had not hitherto been regarded; he repeated his observations, he extended them, and supported them with all the aids which philosophy and physics were capable of affording them, either by the simple comparison of facts, or by the collation of different theories, or, finally, by the combination of different methods of reasoning. In short, Galen revived the Hippocratic system of medicine, and communicated to it a lustre, which it did not possess in its primitive simplicity. But, at the same time, what it gained in his hands, must be allowed to have more the appearance of dress and ornament, than of real solid acquisition. The observations which had been collected, and the rules which had been laid down by Hippocrates, in assuming a more splendid and systematic form, lost much of their original purity; nature, whom the Coan physician had always followed with so much accuracy and caution, became obscured, and, as it were, stifled, by the foreign pomp of various sciences and dogmas; and the art of medicine, overcharged, as it already was, with subtle and superfluous rules, became entangled in a number of new and unnecessary difficulties." Q. c. p. 113.

Though possessed of more extensive erudition than either Hippocrates or Aretæus, Galen was decidedly their inferior as a pathological observer; not, however, so much from any defect of his mental powers, as from his attachment to false theory. It was on the pseudo-Hippocratic doctrines, particularly as developed in the book *περι φυσικης αιδρωτου*, that he founded his system. Although, therefore, he professed to follow Hippocrates, he did not always follow him in his genuine spirit. But all the departments of the art have been enriched by his labours: to anatomy and physiology, in particular, he made many useful additions by the information which he collected in his travels, and by his assiduous dissections of the inferior animals. For the history

MEDICINE.

of his life and writings, and for an account of the system which took its name from him, see GALEN and GALENICAL *System*.

Unfortunately the exertions of Galen, to preserve the science in the path of improvement, were not seconded by his immediate successors. During a period of thirteen centuries, medicine remained nearly stationary, and, in some instances, assumed even a retrograde course. The best writers who appeared among the Greeks, such as Oribasius, Aëtius, Alexander Trallianus, Paulus Ægineta, Nicetas, &c. contented themselves, in a great measure, with the merit of compilation; while among the eastern nations an unnatural union was attempted between medicine and the favourite studies of magic and astrology. The Arabians, from their vicinity to Alexandria, from their intercourse with the sect of Nestorians and with the Greek philosophers, who had been compelled by the persecution of Justinian to take refuge in the Mahometan states, had acquired a taste for literature and the sciences. About the commencement of the seventh century, the works of several of the Greek philosophers and physicians were translated into Arabic, under the patronage of the caliphs; several of whom were zealous encouragers of learning. In the eighth century, the caliph Almanfur established an academy and hospitals for the sick at Bagdad, which soon became so great a resort for men of letters from all parts of the world, that, as Leo Africanus assures us, it at one time contained six thousand. His successor, Harun-Arraschid, patronised the medical school of Jondisabur, the teachers in which were chiefly Nestorians; and both he and Almanfur were unremitting in their exertions to procure translations from the Greek, and the settlement of men of science in their dominions. But it was in Spain that Arabian learning rose to the highest pitch, and produced the most brilliant fruits. The university of Cordova, which had been founded by Alhakem, became the most celebrated in the world, and maintained its repute for a long course of years. As early as the tenth century, Cordova could boast of the largest library in the West; a library of 250,000 books, and of which the catalogue is said to have filled forty-four volumes. In the twelfth century, there were no less than seventy public libraries in Spain: Cordova had produced 150 authors, Almeria 52, and Murcia 62. At Seville, at Toledo, and at Murcia, academies were also established, which continued to flourish during the whole period of the dominion of the Arabians.

Notwithstanding these numerous incitements to learning, notwithstanding the multitude of authors which they produced, the labours of the Arabians in the field of science were attended with but small fruits. Worshipping the authority of Aristotle and of Galen, they consumed their time in commenting upon these writers, and neglected the path of individual observation and experiment. To anatomy they contributed nothing; the tenets of their religion forbade all attempts at dissection; and the only thing they ventured upon was the inspection of the skeleton. Their pathology, though disfigured by numberless extravagances, was enriched by the description of some new diseases, particularly of the small-pox, which, according to the Arabian writers, broke out about the year 558, and of which the first account was given by Ahrun, the author of a work in the Syriac tongue, intitled "Pandects." Their practice, in as far as it deviated from the Grecian model, was miserable quackery. The only improvement deserving of notice was the introduction of lenitive medicines, in the place of drastic purgatives, which had been too freely employed by the Greeks. A predilection for the wonderful led them to

cultivate with great assiduity the arts of astrology and uroscopy, and to deliver their judgments with all the airs of prophesying. National prejudices, and a false delicacy, prevented their making any progress in surgery; and Albucaasis had much reason to complain of the ignorance of his countrymen in that department of the science. In the auxiliary arts of chemistry and pharmacy they were more successful. The former had been cultivated by the later Alexandrians, principally with a view to the transmutation of metals; an art which seemed to possess great attractions in the eyes of the Arabians, and to which they accordingly applied themselves with eagerness. Geber, who lived in the commencement of the eighth century, and who is said to have been the first alchemist of his nation, seems to have been acquainted with various preparations of mercury, such as corrosive sublimate and red precipitate, with the nitric acid, aqua regia, &c. Pharmacy was an object of still greater attention among them; and the Arabians have the credit of having set the first example of publishing regular dispensaries, or collections of authorized formulæ. The first pharmacopœia was the production of one Sabon-ebn-Sahel, head master of the academy of Jondisabur, and appeared towards the end of the ninth century, under the title of "Krabadin." The shops of the Arabian apothecaries were placed under the immediate superintendance of the magistracy, who took care that they should be provided with genuine drugs, and that these should be sold at a reasonable price. Many of the pharmaceutical terms still employed are of Arabian origin, *e. g.* alcohol, naphtha, camphor, julep, syrup, &c. &c. For a more particular account of Arabian medicine, see Sprengel, G. d. A. Th. ii. f. 324—450 (2le Augs.): the modes of practice have been sufficiently described by Freind.

If the Mahometans, generally speaking, contributed little to the improvement of the science, they have yet more claims on our gratitude than the Christian professors of the art during the same period. To the former we owe, in some measure, the preservation and diffusion of the writings of the Greek physicians: the latter did every thing in their power to degrade the profession, and bring it back to its condition in the most barbarous times. The clergy, actuated by avaricious motives, seized upon the province of the physician, and the most ignorant priests and monks ventured upon the practice of medicine, without any proper study or preparation. At length the evil became too crying to be any longer endured; and the first Lateran council, held in 1123, forbade the regular clergy to visit any longer the sick. The prohibition was repeated, in other terms, by the council of Rheims, in 1131, and by the second general Lateran council in 1139; and those monks and canons, who applied themselves to physic, "*ordinis sui propositum nullatenus attendentes, pro detestanda pecunia sanitatem pollicentes,*" were threatened with severe penalties, and all bishops, abbots, and priors, who connived at their misconduct, were ordered to be suspended from their ecclesiastical functions. "But the French priests and monks," says Cabanis, "bade defiance to these thundering anathemas; and it was not till three hundred years after, that common sense and a regard to propriety and the public good, triumphed finally over their artifices. A special bull, procured by the cardinal d'Eltonville, which permitted physicians to marry, effected their complete separation from the clergy; and, by this means alone, put a stop to a variety of shameful abuses." To the honour of our own country, however, be it mentioned, that these abuses do not appear to have prevailed to such an extent among us; but that, on the contrary, England could reckon many scientific men among its clergy, even as early

as the seventh and eighth centuries, whose fame was so great as to procure them the chief literary appointments abroad. The learned society, which was formed at the court of Charlemagne, consisted chiefly of Britons, with the celebrated Alcin at their head; and it would appear from the verses of the last-mentioned personage, that the members practised medicine:

“ Accurrunt medici mox Hippocratica testæ;
 He venas fundit, herbas luc miscet in olla,
 Ille coquit pultes, alter sed pocula presert.”

Carmin. 228.

The Benedictine monks of Salerno, in the Neapolitan territory, after having exercised the art for several centuries, according to the taste of the age, and performed many miraculous cures with the relics of St. Matthew and other holy persons, betook themselves to the study of the Arabian and Grecian writers on physic, but especially of Galen, whom they esteemed the prince of physicians; and by their successful labours procured for their residence the title of *Civitas Medicinæ*. In the twelfth century, Salerno arrived at its highest fame; and was much frequented by the crusaders in their passage to and from the Holy Land. Among these, Robert, the son of William the Conqueror, had the honour of having the well-known “*Regimen Sanitatis Salerni*” dedicated to him. In the year 1142, the emperor Frédéric II. conferred particular privileges on the school of Salerno, and regulated the course of studies, and the probation which physicians and surgeons should undergo before they were permitted to practise. Many of the ordinances shew great judgment. The Salernian school continued accordingly to flourish till the middle of the fourteenth century, when it appears to have begun to decline. “*Fuisse Salerni*,” says Petrarch, “*medicinæ fontem fama est; sed nihil est, quod non semo exarefecat.*” Gariopontus, Nicolaus, Ægidius, Enos, and John of Milan, the author of the “*Regimen Sanitatis*,” are the chief writers whom this school boasts.

Medicine was now generally taught in the universities of Europe, among which those of Montpellier, Paris, Bologna, Padua, Ferrara, Pavia, Milan, and Piacenza, were the most distinguished; but it was taught in a slavish spirit of adherence to the dogmas of Galen and Hippocrates, and, what was still worse, in combination with the scholastic philosophy. In 1271, the College of Surgeons at Paris was established by Pitard, a man who, according to Quésnay, was born for the advancement of his art; and surgery was henceforth cultivated with much success in France, as a distinct branch of the profession. Several writers on physic appeared in England; among whom Gilbert has the merit of having furnished the best description of the leprosy of the middle ages; but he trod in the footsteps of the Arabians, and gave into the scholastic style. The same remark applies to his successors, John of St. Giles, Richard of Windermer, Nicolas Farnham, John of Gaddesden, &c. It was in Italy that medical science was revived in the truest spirit. In the year 1315, Mondini de' Luzzi, professor at Bologna, astonished the whole world, to use Vieq d'Azyr's expression, by the public dissection of two human bodies. His example was followed in other universities; but the utility of the practice was in a great degree frustrated by the predilection for ancient opinions, which made the anatomists of the age less anxious to discover facts, than to reconcile the appearances which they observed with the dogmas of Galen and Avicenna. An absurd bull of pope Boniface VIII. forbidding the maceration and preparation of skeletons, also concurred to impede the progress of anatomy (Blumenbach, *Hist. Med. Litterar.*

p. 99.); but from this time forward, the Italian professors maintained a high repute for anatomical science, and have ranked among the most zealous contributors to our knowledge of the human frame.

Though the crusades had conferred no direct benefits on science, but, on the contrary, had tended to prolong the reign of prejudice and folly, they had given a new impulse to the human mind, by the spirit of commerce which they excited. They were also the occasion of the rapid spreading of leprosy and some other diseases in the West, and of the consequent increase of institutions for the relief of the sick, after the example of the Oriental nations. Several orders of knighthood, as the Templars, the knights of St. John, of St. Lazarus, the *Hospitalarii Sancti Spiritus*, &c. were founded with this charitable view; the members devoting themselves to the cure of such pilgrims as were afflicted with disease.

In the fifteenth century several new diseases appear to have invaded mankind, or, at least, to have attacked them with a degree of violence that was before unknown; such as the hooping-cough, which was epidemic in France in the year 1414, and which, according to Mezeray, attacked all descriptions of persons, even the oldest men; the sweating sickness, that broke out first in 1486; the scurvy, of which some traces had been observed in earlier times, but which became much more common, perhaps in consequence of the greater frequency of sea voyages about this period; and, lastly, the venereal disease, the origin of which we shall investigate in a separate article. The rules of the ancients proving but little applicable to the treatment of these complaints, physicians began to doubt the infallibility of these guides, and to perceive the necessity of observing and judging for themselves. Nor was the influence of the revival of letters, and the great events by which it was followed, lost upon medicine. But, unfortunately, the taste for astronomical studies continued to prevail, and to obstruct the progress of the art in all its branches. The auxiliary sciences received little improvement during this epoch.

The very general attention which was now paid to classical literature in the universities of Europe contributed to the restoration of the Hippocratic system of medicine. Among the Italians, Leonicensus and Masardus laboured to expose the errors of the Arabians, whom the latter justly designated as *ex commentario medicos*; among the Germans, Fuchs, Koch, Winter, and Hagenbut, made known to their countrymen the merits of the Greek physicians, by their translations and commentaries; and a similar service was performed in this country by Linacre and Caius. The Parisian school was still more zealous in the cause; Houliet, Duret, and Gorræus, elucidated the doctrines of Hippocrates with much success; and Foësius produced an edition of his works, which even at this day ranks as the most accurate and the most complete. Medical literature was still farther enriched by the magnificent collections of pathological observations, which the industry of Dodonæus, Schenckius, Forestus, and Platerus accomplished. A controversy respecting the mode of performing venesection in pleurisy, was begun in the early part of the sixteenth century by Brissot, a physician of Poitou, who observing the good effects of abstracting blood as near as possible from the seat of inflammation, had the courage to oppose the Arabian method, and to revive the Hippocratic practice. This important innovation, however, was opposed by the physicians of the time with great warmth, and continued the subject of violent dispute till the anatomical discoveries of Vesalius, Faloppia, and Amatus, turned the scale in Brissot's favour. The credulous and superstitious character of the age, however, was still opposed to any great improvement in the art of observing and curing disease:

MEDICINE.

disease: physicians were more anxious to collect what was wonderful than what was useful; their practice was directed chiefly by the theory of the elementary qualities, and was disfigured by many remnants of the barbarous ages. The best observer which the sixteenth century produced was Jodocus Lommius, the author of a classical work on the cure of continued fevers, and of "Three Books of Medical Observations."

Though the futility and absurdity of astrological science had been successfully exposed by Picus of Mirandola, Marlianus, and Paulus Florentinus, yet it continued to be pursued with unabated ardour, and to obtain many votaries, among men of otherwise great judgment and learning. Even those who evinced the greatest contempt for this nugatory art, could not divest themselves of a partiality for studies of an equally frivolous nature. Of this weakness we have a remarkable instance in Picus of Mirandola himself; who, after combating astrology, applied himself to the study of the Cabbalistic philosophy. The belief in the influence of demons, the efficacy of magic, and the powers of witchcraft, became very prevalent throughout Europe, and perhaps in no part of it to a greater degree than in England, which acquired the repute of being the country of witches. Even the illustrious Luther was so completely biassed by the prejudices of his age, that he ascribed the majority of diseases to the arts of the devil, and found great fault with physicians, when they attempted to account for them by natural causes. Alchemy had been hitherto cultivated only by the most illiterate men; but the introduction of theosophism and the cabbalistic art brought the study into great vogue, and it was thenceforth profecuted with much eagerness by the monks and wandering scholastics (*scholastici vagantes*), under the patronage of kings and princes, who fondly hoped to augment their revenues by the products of this art. Though a law was passed by Henry IV., condemning as impostors the alchemists, who were then very numerous in England, yet they contrived to maintain their ground; and practised so adroitly on the weakness of his successor, Henry VI., that this monarch, finding his treasures exhausted by the unfortunate wars in which he had engaged, granted to certain transmuters of metals the privilege of making gold, and preparing the elixir of life. (Henry's Hist. of G. B. b. v. ch. iv. § 7.) The labours of Basilus Valentinus, the reputed author of the "Curus Antimonii Triumphalis," and of Isaac le Hollandois, were rather more usefully directed; but it was reserved for Paracelsus to appropriate to himself all the knowledge which his predecessors had attained in this branch of learning, and to apply it with success to medicine.

It has been too much the fashion to ridicule this singular man, and to overlook his merits as one of the great reformers of our art; though it must be acknowledged, that the extravagance of his pretensions, his insolent behaviour, and his dissolute manners, afford strong grounds for much of the contempt with which he has been visited. The early education of Paracelsus, or, as he called himself, Philippus Aureolus Theophrastus Paracelsus Bombast von Hohenheim, would appear to have been greatly neglected: and, notwithstanding his asseveration, that he had been at German, French, and Italian universities, it is sufficiently evident from his writings, that he could never have enjoyed the benefit of proper classical instruction. From his father, who is said to have been a physician, he obtained a smattering of medicine, astrology, and alchemy: he afterwards served as surgeon in several wars, and visited most of the countries of Europe, seeking information not only from physicians and other men of learning, but from old women, from the gipsies, and from con-

jurers. From these he boasts of having learned the preparation of several valuable remedies: from his intercourse with the miners, he became acquainted with various processes for extracting metals. Returning to Germany, he soon acquired great repute by his cures, and was believed to have discovered the elixir of life. In the year 1526, his increasing fame procured him the appointment of professor of medicine and surgery in the university of Basle; where he commenced a course of lectures on the theory and practice of physic, in the German language, and succeeded in attracting a considerable audience, but chiefly from among the dregs of the people, who, seduced by his vauntings, were eager to obtain the knowledge of his secrets. He began by burning the works of Galen and of Avicenna, in his auditory, assuring his hearers "that his shoe-latchets possessed more knowledge than Galen and Avicenna; that all the academics of the world had not so much experience as his beard; and that the hair of the back of his neck was more learned than the whole tribe of authors." The lectures, however, which he delivered, consisted of little else than the recommendation of a number of empirical remedies, of the infallibility of which he spoke with much assurance. But his disciples soon became disgusted with him, on account of the drunken irregular life which he led; and though he still continued to perform many wonderful cures, his fame as a practitioner began to decline, and a dispute with the magistracy compelled him suddenly to quit Basle, and to take refuge at Alsace. He, however, did not settle there, but continued to lead a wandering life through different parts of Germany and Switzerland, till the year 1541, when he died at Salzburg, in the hospital of St. Stephen.

The obscure and barbarous style in which the writings of Paracelsus are composed, has rendered it a matter of great difficulty to give a clear account of his speculative opinions. Even the indefatigable Henfler (*Geschichte der Luftfeuche*, f. 120.) complains, that it was with him the business of several months to unravel the confusion of his system. Certain, however, it is, that there never was a more glaring example of the error to which chemists have been ever prone—that of carrying into other sciences what Bacon appropriately calls "the smoke and tarnish of the furnace." The elements of the living system he fancied to be the same as those of his laboratory; and sulphur, salt, and quicksilver, were, according to Paracelsus, the constituents of all organized bodies. They were combined by chemical operations, and their relations were governed by the *Archeus*, or demon, who performed the part of alchemist in the stomach, who separated the poisonous from the nutritive part of the food, and who communicated the tincture by which the food became capable of assimilation. This governor in the stomach, this *spiritus vite*, this *astral body* of man, was the immediate cause of all diseases, and the chief agent in their cure; yet each member of the body was supposed to have its peculiar stomach, by which the work of secretion was effected. Diseases were produced by certain influences, of which Paracelsus reckoned five, viz. *ens astrale*, *ens veneni*, *ens naturale*, *ens spirituale*, and *ens deale*. When the archeus was sick, putrefescence was occasioned, and that either *localiter* or *emunctorialiter*. *Tartarus*, or a certain morbid matter, was the cause of all disorders, exhibiting a viscidness of the fluids, rigidity of the solids, or a concretion of earthy matter, and was believed to be secreted when archeus operated in an irregular or too potent a manner, and digestion was too fully performed. Such speculations, considered abstractedly, are no doubt very absurd; but when divested of the cabbalistical jargon in which they have been enveloped, they will be found to contain a certain portion of truth. Of so great value have

have the views of Paracelsus respecting the functions and diseases of the digestive organs latterly appeared, that they have been revived with little alteration, though clothed in a new dress, by a writer at the commencement of the nineteenth century, in a treatise "On Disorders of the Stomach."

The best and most original of Paracelsus' works is his treatise, in three books, on the venereal disease, entitled "Von den Imposturen in den Franzosen;" in which he has given a minute description of the various forms of syphilis, and shewn in what manner other disorders were liable to be modified by its presence; and in which he has successfully exposed the errors, or, as he terms them, "impollures," of the then prevailing practice. Instead of the inert fumigations, quintessences, and diet drinks, which were in vogue, he recommended mercury as the only remedy on which dependence could be placed, and exhibited it both internally, and by the way of friction. Medicine, in general, was indebted to him for the free introduction of this and other mineral remedies, and of opium, and for pointing out the necessity of attending to chemical actions in pharmaceutical operations. To complex prescriptions he was no friend, and he ridiculed with considerable effect the absurdity of imagining, that 40 or 50 simples in a compound would all retain and exert their separate virtues. The treatment of wounds and ulcers received great improvement at his hands, and his observations on the *balsam* (coagulable lymph), by which he supposed nature to effect their cure, display no small degree of discernment. His confidence in his *arcana* led him to condemn the use of cauterizing instruments, and even to reject the employment of sutures.

The *anatomy of Mundini* was fervently followed as a textbook in all the universities of Europe till towards the middle of the sixteenth century, when the discoveries of Achillini, Berengar of Carpi, Serveto, Sylvius, and Eustachius, but, above all, of Faloppia and Vesalius, threw a new light on the science, and established it on an unalterable basis. Galen was no longer appealed to on doubtful points; on the contrary, anatomists seemed to vie with each other in exposing his errors, and in multiplying the proofs of their observations, by repeated dissections. The structure of the organ of hearing, and other parts of the osseous system, which had escaped the notice of the ancients, was now fully investigated; the arrangement and formation of the muscles were examined, and the mistake of supposing them to consist of an union of tendinous and nervous fibres was satisfactorily confuted; the nerves were traced from their origins, and the base of the brain was minutely described. But it was in respect to the vascular system, that the most brilliant and fruitful discoveries took place. Berengar, who had paid great attention to the structure of the heart, conjectured the right use of the semilunar valves. So early as 1547, Cannani and Amatus had observed the valve at the termination of the vena azygos; but they had not turned the discovery to account; and it was reserved for Fabricius of Aquapendente to prove the presence of valves throughout the whole course of the veins. Five years afterwards, the circulation of the blood through the lungs was imperfectly described by Servetus, who had availed himself of the researches of Berengar and Vesalius. In the year 1571, Cæsalpini had the merit of stating it more clearly, and even of suggesting the first hint of the greater circulation (De Plantis, lib. i. c. 2.); but the full honour of the latter discovery, at least of its complete demonstration, must be ascribed to our countryman, Harvey. See CIRCULATION.

It is sufficiently apparent, even from the above imperfect account, that nothing but a succession of fortunate events

could ever have brought about this great improvement in physiological science. "The discovery of the circulation of the blood was one of those occurrences, which, to use the language of Bacon, "are more the birth of time than of genius;" and, though the merit of it could only belong to a man of transcendent talents, yet we rather detract from, than add to the glory of Harvey, by supposing him to have hit upon it by chance, unguided by the light which he had received from the instructions of his predecessors and contemporaries. We may also observe, that the beneficial consequences of the discovery in question have been greatly overrated, at least as far as practical medicine is concerned; and, in this point of view, we cannot help subscribing most fully to the opinions of a writer, whom we have had frequent occasion to quote. "The new light," Mr. Cabanis remarks, "which was thrown upon the animal economy by this important discovery, served only, in a manner, to redouble the rage of systems. Nothing else was thought of, but to cause the blood to circulate more freely, to destroy its viscosity, to draw off from the body that which was supposed to be corrupted, to purify it, correct it, and renew it, and to preserve the blood-vessels in a relaxed and pervious state. Hence those torrents of aqueous and diluent drinks, with which Bontekoe and his adherents deluged their patients. Hence that sanguinary fury, which the partisans of Botalli thought themselves entitled to exercise in their treatment of all sorts of diseases; a fury which, though so often damped, in some measure, by systematic murders, has ceased only for intervals, and still from time to time re-appears in the schools. Hence, too, that wretched mania of the transfusion of blood, of which the practice almost always deprived those who had the temerity to subject themselves to so dangerous an operation, of their reason, or their lives.

"Thus, one of the most beautiful discoveries of modern medicine, far from elucidating the practice of the art, as there was every reason to expect, only had the effect of misleading weak imaginations, dazzled by its splendour; and it may still be doubted, whether its application to the knowledge and cure of internal diseases has been of any real use. In surgical cases, even where its assistance is generally regarded as indispensable, might not observation almost always supply its place? And must we not limit its importance to the elucidation of a point in anatomy and physiology, very curious, no doubt, in itself; but which, if it did not indirectly affect many other interesting questions relative to the animal economy, would probably have contributed very little to our knowledge of its true laws?" Loc. cit. p. 166—8.

A system that is founded on mysticism, and clothed in obscurity of language, is sure to find numerous votaries. Accordingly, the doctrines of Paracelsus, notwithstanding the opposition of Eraſtus, Deſſenius, Libavius, and others, continued to attract adherents in all the countries of Europe, but particularly in Germany. They were eagerly embraced by the fraternity of Rosicrucians, among whom our countryman, Fludd, made himself conspicuous by his uncommon proficiency in cabbalistical and alchemical learning. But of all the followers of Paracelsus, Van Helmont was the only one who could be said to tread successfully in the footsteps of his master; attacking vigorously, on the one hand, the Galenical system; and labouring, on the other hand, with unremitting zeal in the prosecution of chemical research. Though misled in his speculations by a strong bias to theosophism, he must be allowed to have shewn himself, on many occasions, a skilful observer of nature: he was the first who pointed out distinctly the influence which the epigastric organs exert upon the other parts of the system,

system, in health as well as disease; he determined the nature and cause of inflammation more accurately than any of his predecessors had done; he gave the first satisfactory explanation of the origin of calculi; he exposed the absurdity of the prevailing theory of putrefaction of the blood; and he placed in a strong point of view the pernicious consequences and the dangers of excessive blood-letting. Chemistry owes to him the discovery of carbonic acid and hydrogen gas, and the first investigation of their properties. In his practice he made great use of calomel, of antimony, wine, and opium; and it is somewhat remarkable, that with regard to the virtues of the last mentioned remedy, he in some measure anticipated the Brunonian doctrine; for he maintained that opium was not to be considered as a *refrigerant* medicine, but as a *tonic* and *anodyne*. The utility of Van Helmont's labours, however, was lessened by his attachment to the Paracelsian phraseology; and, as his works were not published till a considerable time after his death, when other systems had come into vogue, his doctrines had few adherents, at least in their original state.

We have already had occasion to observe the influence which the prevailing systems of philosophy have exerted on medicine. In no period of medical history was this influence greater than in that of which we are now about to treat: in no period has it been productive of more marked effects. From the revival of letters to the commencement of the seventeenth century, Aristotle had continued to be the great authority of the schools; dialectic studies were considered as the best preparative for all the other branches of learning; and natural philosophy, in particular, was confined within very narrow limits by its union with the scholastic discipline. Some philosophers, it is true, had stumbled, as it were, on the proper road of its investigation, and, freeing themselves from the slavish admiration of received opinions, had prosecuted, with considerable success, their inquiries in several departments of physical research: but the slow and uncertain advances which they made, prove, that their march was wavering and their footing insecure; that they had soon deviated from the path, and had never discovered its whole extent. It was reserved for the genius of Bacon to point out the various sources of error, by which they had been misled; to demonstrate the true end and use of all scientific inquiry; to shew the only method by which it could be successfully pursued; and to deliver the code by which the study of nature must be thenceforth conducted. Embracing in his comprehensive mind the whole circle of human knowledge, he saw that in medicine much remained to be accomplished; and recalling the attention of physicians to the proper objects of investigation, he inculcated the necessity of a strict adherence to the path of observation and experiment, as the only way by which their art could be improved. By this recommendation, he justly remarks, that he was only enforcing the example of Hippocrates, which had been too long neglected; but his views were more correct and enlarged than those of the father of physic, and more fully adapted to the existing condition of the science, or rather, to speak more accurately, to its future progress; for it has been only in very late times, that some of the more important *desiderata*, which Bacon indicated, have been completely realized; as, for instance, his directions concerning the prosecution of morbid anatomy, and his suggestion of "an imitation by art of natural bathes and medicinable fountains &c." Medical science, however, has profited much less than it ought to have done by the labours of this truly great man; his writings were for a long time neglected; and, even at this day, though we talk of the reform in the method of investigation which Bacon introduced, the undi-

gested knowledge and crude speculations of too many of our physicians demonstrate, that they neither observe his model, nor fully comprehend his precepts. Till the present age, Baglivi appears to have been the only writer who knew how to appreciate the importance of the "*Novum Organum*" as a guide in medical inquiries; but his unfortunate predilection for the chemico-mechanical theory, led him too often to forget the maxims to which he had given his cordial assent, and to commit those very errors which in others he had severely reprehended.

The efforts of Bacon to overthrow the Aristotelian philosophy were powerfully seconded by Descartes. As the opinions of the latter found a much readier reception among the learned, especially on the continent, than those of our illustrious countryman, they accordingly had a more immediate operation, and impress their character more distinctly on the speculations of the age; but their tendency was in many respects injurious to the interests of medical science. Adopting some of the most objectionable parts of Van Helmont's system, particularly the doctrine of fermentation, and combining them with his own hypothesis of vortical motion, Descartes attempts to explain all the chief functions of the living body on chemico-mechanical principles. Thus, the circulation of the blood and animal heat were produced by the ebullition or fermentation that took place in the heart; digestion was likewise performed by a species of fermentation; and the sensation of hunger proceeded from the acid which was evolved during the process. To explain the nature of secretion, Descartes had recourse to the corpuscular philosophy; comparing the secreting organs to sieves, which allowed only the more minute and homogeneous particles to pass through, while the coarser and heterogeneous bodies were rejected;—the round particles were supposed by him to enter into cylindrical tubes; pyramidal particles penetrated by triangular pores, and cubical particles by square pores; and in this way each secretion remained distinct, at least in the healthy state. These ideas were eagerly embraced by the Dutch physicians of the time, and may be considered as forming the groundwork of the chemical and mechanical systems, which divided the medical world at the end of the seventeenth century, notwithstanding the claims to originality which several of their followers have put in.

If the importance of the chemical system of medicine were to be estimated by the portion of good which it has effected, its history might be brought within a very small compass; but if it should be viewed as one of the chief impediments to the free progress of the art, which so many circumstances had conspired to favour; if it should be considered in relation to the mischievous bent which it gave to medical speculations, and, above all, in relation to the fatal errors of practice which it countenanced; few systems would appear entitled to more serious notice. Its first and great supporter was Francis de le Bœ Sylvius, a man of no mean talents, a skilful anatomist, and the first institutor of clinical lectures in hospitals. Though he perceived the full value of experience in medicine, and strenuously inculcated the necessity of subjecting all theories to its test; yet he allowed himself to be dazzled by the glare of opinions, which not only were not confirmed by experience, but which were, for the most part, in direct opposition to its lessons. Fancying that all the operations of life might be explained by a few chemical principles, he could discern nothing but fermentations, ebullitions, and combustions, in the different organs of the body, except, indeed, that he supposed the animal spirits to be produced by a distillation in the brain; diseases were referred by him to an excess of either acid or alkali

alkali in the fluids, to which he gave the name of *acrimony*, and the consequent inspissation or attenuation of the blood and lymph; and they were to be cured only by neutralizing the morbid cause. Thus, he sought to correct the acrimony of the bile by opium and other narcotic remedies; in intermittent fevers, which he believed to proceed from the acid acrimony of the pancreatic juice, he administered the *sal succini volatile* and opium; and in malignant fevers, which he ascribed to an alkaline acrimony and attenuation of the humours, he gave acids, ethers, opium, absorbent earths, and cordials,—paying no regard to the different stages of the disorder, or the character of the prevailing epidemic; but solely intent on fulfilling the indications of his mistaken theory. In this way, the practice of medicine may be said to have commenced a retrograde march, from which it long suffered, and from the injurious consequences of which it has scarcely yet entirely recovered.

After a slight opposition, the doctrines of Sylvius were almost universally adopted. In England, indeed, they experienced some modification, without becoming more rational, as we have elsewhere shewn (see *HUMORAL pathology*); and in Italy, where mathematical studies had acquired the ascendancy, though they were received by many, yet they never obtained that exclusive sway which they enjoyed in other countries. The professors of Paris and Montpellier, refining upon the Helmontian and Cartesian hypothesis, divided the fermentations of the fluids into several distinct species; attempted to account for their production by the admixture of the animal spirits from the brain; and formed a classification of fevers into *fevres chylouses*, and *fevres sanguines*. Attempts were even made, and with apparent success, by Viridet, Vieussens, and others, to demonstrate, by experiment, the presence of alkali in the bile, and of acid in the blood, in the pancreatic and gastric juices. But it was in Holland and Germany that this system had its most bigotted votaries, and was pushed to the most absurd and pernicious extreme. Thus one physician conceived, that acidity was the sole and universal cause of disease; another affirmed, that gout originated from the effervescence of the synovia of the joints with the vitriolated blood, and recommended alcohol for its cure; while a third deduced all disorders whatever from inspissation of the fluids, and expatiated on the sovereign efficacy of diluent drinks, especially of tea. “Tea,” says Bontekoe, who is loudest in his praises of this panacea, and who, as Blumenbach remarks, deserved to have been pensioned by the East India Company for his services,—“tea is the best, nay the only remedy for correcting viscidities of the blood, the source of all diseases, and for dissipating the acid of the stomach; as it contains a fine oleaginous volatile salt, and certain subtle spirits, which are analogous in their nature to the animal spirits. Tea fortifies the memory and all the intellectual faculties: it will therefore furnish the most effectual means of improving physical education. Against fever there is no better remedy than 40 or 50 cups of tea, swallowed immediately after one another: the slime of the pancreas is in this way carried off.” (*Abhandlung vom Menschlichen Leben*, Budissen, 1685.) A physician of Minden, named Van der Becke, attempted an union between the chemical hypothesis and the peripatetic philosophy,—taking water, or alkali, for the *matter*, and fire, or acid, for the *form*, of all organized bodies; and was followed by one Van Rufflingh, who derived all diseases from a deficiency or a redundancy of fire or water; maintaining, for example, that, where the water predominated, the fluids became viscid, and intermittent fevers and arthritic complaints arose: these were to be cured by volatile salts, which contain many fiery particles. Condemning the em-

ployment of venesection *in toto*, this author did not scruple to adopt the same *fiery* treatment in various inflammatory distempers: so completely had false theory obscured his mind; and to such a deplorable state was medical practice reduced, in the hands of these chemical dreamers!

Some few, however, had the sagacity to perceive the inadequacy of such speculations to illustrate the phenomena of life, and ventured to call in question the propriety of applying them to the treatment of disease. Boyle, in his “*Sceptical Chemist*,” and other essays, had refuted the hypothesis of acid and alkali; and Le Mort, pursuing his ideas, attacked the doctrine of fermentation, and substituted a theory of his own, which was more immediately grounded on the corpuscular philosophy. Boiin, a professor of medicine at Leipsic, brought forward a number of arguments to prove that digestion was not effected by any fermentative process; that, in the healthy state at least, there was no acid fermentation in the stomach; and that the presence of acidity, instead of assisting, rather impaired the functions of that organ. He shewed, by experiment, that the bile did not effervesce on the addition of acids; and he controverted the doctrine of a nervous fluid, as inconsistent with the structure and properties of the nerves. Pechlin and Brunner proved, that the hypothesis of the acid nature of the pancreatic juice was utterly unfounded; that this fluid did not effervesce with the bile; and that it was not even necessary for digestion. In this manner several physiological facts became ascertained; and this is the only way in which the chemical theory can be said to have done any thing for the progress of science.

The practical errors of the chemists were ably exposed by Sydenham, who, having applied himself late, in life to the study of his profession, was never so strongly imbued with the prejudices of the schools, but that he could easily shake them off when they would not bend to his experience; and who, living on terms of intimacy with Boyle and Locke, brought into medicine many of those sound and enlightened views, which had guided their researches in other departments of learning. Adopting the suggestion of Bacon, Sydenham returned to the Hippocratic method of collecting histories of disease, and shewed the necessity of coming to its observation with an unbiassed mind; of attending more carefully to its distinguishing characters; and of marking all the circumstances by which it was liable to be modified. He saw that sufficient diligence and discrimination had not been used in these particulars; that observers either had confined their attention to uncommon cases, or, misguided by false hypothesis, had given imperfect and erroneous views of the disorders which they attempted to describe. It was only, he maintained, by discarding all hypothetical reasonings, and by investigating minutely the succession of symptoms, that we should ever be able to arrive at the knowledge of the causes, and the curative indications of disease. Accordingly, though he forgot his own precept, and indulged much in fanciful speculation, Sydenham laboured assiduously to improve the practice of medicine, and has justly acquired the title of its reformer. The descriptions which he furnished of the various epidemics of his time have served as models to succeeding writers, and in point of simplicity and accuracy have scarcely ever been surpassed; his “*Treatise on the Gout*” is still consulted as one of the best accounts of that disease. Sydenham is also to be regarded as the reviver of the antiphlogistic method; for he was the first who pointed out all the dangers of the stimulant plan which the chemists pursued in the early stages of acute disorders, and which, in many instances, but especially in small-pox, had been attended with the most fatal consequences. The practical doctrines of Sydenham, indeed, were adopted by few of his

MEDICINE.

his contemporaries; and at the commencement of the following century a large proportion of the English physicians continued to advocate the Sylvian hypothesis, or some of its modifications.

In proportion as true chemical science advanced, the partiality for chemical explications of the functions of the living system abated; and physicians seem to have discovered, for the first time, that the theory of the humours, even with all the improvements which it derived from the corpuscular philosophy, threw no light whatever on the actions of the solids. A new hypothesis, therefore, was projected; and as men, in avoiding one error, are apt to run into the opposite extreme, physiologists now attempted to explain all the phenomena of life according to the mere mechanical powers of the organs, and to reduce the laws of the animal economy to the rigid calculations of geometry. They imagined, that they could illustrate every operation of the human body, by comparing it to a system of ropes, levers, and pulleys, united with a number of rigid tubes of different lengths and diameters, containing fluids, which, from variations in the impelling causes, moved with different degrees of velocity. When the fibres of this machine were not sufficiently flexible; when the pulleys and joints of the levers were not kept in sufficient repair; or when the apertures of the pipes were not sufficiently free; the movements were necessarily suspended, or less perfectly performed, and they were only to be brought into proper regulation, according to the practitioners who adopted this fanciful theory, by removing the above described impediments. The composition of the fluids was supposed to be the result of their motion in the tubes; and in these nothing was attended to but the forces of gravity and cohesion; as in calculating the action of a pump, or other hydraulic engine. "If the chemical school," to use the words of Sprengel, "had degraded the physician to the rank of a brewer or distiller, the disciples of the iatro-mechanical school, on the other hand, were glad to be esteemed as hydraulical engineers; and several of them, in fact, served in the double capacity of engineers and professors of medicine." One of them, Dionis, a professor of surgery at the Jardin du Roi, went so far as to compare the circulatory system to the water-works at Marly, by which the water of the Seine is raised to considerable height, and from thence made to fall again upon the great wheel.

Among the causes which conduced to the establishment of this sect, the discovery of the circulation of the blood is the most prominent. When it was found that the blood flowed in a regular manner, through certain conduits, from the heart, and returned to that organ, by other vessels, from the extremities, physicians set about calculating the mechanical force which they supposed necessary for enabling the heart and arteries to produce this effect; and, elated with their apparent success, were led by degrees to transfer their calculations to the other functions of the body. Geometry had become the prevailing study of the learned; and societies for the promotion of experimental philosophy were established in the different countries of Europe, among which the Florentine academy del Cimento took, in some measure, the lead. It was in Italy that mathematics had been most assiduously cultivated; and it was there that the first attempt was made to introduce them into medicine. In the year 1614, Sanctorius published his "*Medicina Statica*," in which he endeavoured to shew the great influence which the insensible perspiration has upon health, and to calculate with precision all the variations in its quantity, in the different conditions of the body. According to his theory, diseases originated from the noxious particles of the food being retained in the system, in consequence of the stoppage

of the transpiration; and till the latter function was restored to the proper standard, no cure could well take place. Sanctorius distinguished the different alimentary matters according to their specific gravities, and according as they appeared more or less fitted to pass off in the way of insensible perspiration; he even ventured to apply his maxims to the passions of the mind; shewing how joy and equanimity favoured the excretions, while sorrow and fear impeded them; how fevers and melancholy arose from the obstructed perspirable matter, where grief was long continued; and how they were to be removed by restoring the suspended exhalation. Among the "Aphorisms" of Sanctorius, there are many sound observations; and medical science is under considerable obligations to him for having directed the attention of physiologists to the functions of the skin, which, till then, had been in a great measure overlooked; but his views, like those of most theorists, were far too partial; and there can be little doubt that, in one respect, they had a most injurious influence, *viz.* by encouraging physicians in the universal employment of sudorifics, to which they were already too prone; and no one will now subscribe to the judgment of Boerhaave, who says of Sanctorius and his work, "*Nullus medicorum, qui ante eum scripserunt, cardinem rei ita adigit—nec ullus liber in re medica ad eam perfectionem scriptus est.*"

Such were the advances towards the formation of that system on which the talents of Borelli, Baglivi, and Bernoulli, in Italy, and of Pitcairne, Keil, Wintringham, and Mead in England, afterwards shed so much lustre. Among the French it found comparatively few supporters, though a certain Peter Chirac was captivated with Borelli's ideas to that degree, that he bequeathed 30,000 livres towards the establishment of two professorships at Montpellier; the one for comparative anatomy, and the other for the iatro-mechanical theory: but in Holland and Germany it soon made its way, and was taught at all the principal universities. That the labours of Borelli and his successors were often confirmed by observation, and have served to illustrate those movements of the living body which are clearly referrible to mechanical laws, such as the compound actions of the muscles, the functions of the eye, &c. will not be denied: but when mathematical reasonings were applied to phenomena, which furnished no fixed data for calculation, and which were, in fact, to be investigated by very different methods, no useful result could be expected. Accordingly it happened, that almost every calculator came to a different conclusion from those who had preceded him in the inquiry. Borelli, comparing the mass of the heart with that of the temporal and masseter muscles, concluded that that organ was capable of supporting a weight of 3000 pounds, and that its absolute power was therefore equal to 3000; but, as it had to overcome a resistance in the smaller arteries at least sixty times greater, its relative power must be estimated at 180,000 pounds. Keil, on the other hand, applying the Newtonian doctrine of gravitation to the motion of the blood, maintained that the power of the heart was only from five to eight ounces: but his calculations were controverted by Jurin, who made it fifteen pounds three ounces. Again, with regard to digestion, which these mechanists conceived to be only a species of trituration, Borelli instituted a comparison between the human stomach and the stomachs of different species of birds, estimating, for example, the power of that organ in the turkey-cock at 1350; Hecquet calculated the power of the coats of the human stomach and abdominal muscles at 261,000; while Astruc asserted that it amounted to only four pounds three ounces. Secretion, in like manner, was supposed to depend on the various diameter

diameter of the secreting vessels, on their different convolutions, and on the angles at which they branched off from the arteries. But in order to ensure success in the most simple of these inquiries, "it would be necessary," as D'Alembert has shewn, "to know exactly to what degree the vessels are capable of dilatation; in what manner, and according to what law, they are dilated; to be perfectly acquainted with their figure, with their various elasticity, with their different anastomoses, with the number, the strength, and the position of their valves; with the heat of the blood, and the degree of tenacity which it possesses; and with the moving powers which impel it. Even supposing each of these particulars to be accurately known, still the great number of elements, which would enter into such a theorem, would probably render all our calculations fruitless." *Elements de Philosophie*, Amst. 1764, p. 268. It is almost needless to add, that not one of these circumstances was ever properly ascertained: the laborious calculations of the mechanical physicians were therefore, for the most part, wholly nugatory.

In some respects, however, they must be allowed to have had a beneficial tendency. By accustoming the mind to the strictness of mathematical methods; by fixing the attention of physiologists on points of the animal economy that had been previously but little investigated; and by inducing them to seek occasionally for experimental proofs of their theories; they led to discoveries which probably would otherwise have long remained unmade. From the time of Harvey to the middle of the last century, in fact, anatomy continued to make great progress; the errors which had obscured its study were gradually dissipated; and the more important functions of the organic frame were explained with all the rigour of demonstration. A summary view of the principal discoveries of this epoch will shew the importance, and also, in some degree, the share which the followers of the mechanical sect had in them.

The heart had been regarded as a parenchymatous vessel by the ancients, with the exception of the author of the pseudo-Hippocratic treatise, *περὶ καρδίας*, who calls it a *strong muscle*. In the year 1663, Stenon ascertained the muscularity of its structure; and three years afterwards the work of Lower appeared, in which all the circumstances of its position and organization were more fully demonstrated. Wepfer, a physician of Suabia, instituted various experiments with cicuta and other poisons, which proved that the blood was only the exciting, and not the proximate cause, of the motion of the heart; and that this motion depended solely on the organic powers of that organ. Lange, a professor at Leipzig, gave, in the year 1680, an account of some experiments with injections, by which several important facts connected with the circulation were brought to light. He succeeded, for example, in injecting the cells of the lungs from the pulmonary artery, and the placenta from the arteries of the uterus. In 1683, a Dublin professor of the name of Molyneux demonstrated, by aid of the microscope, the circulation in the amphibia; but it was chiefly through the indefatigable exertions of Leeuwenhoek, that this new instrument of anatomical observation was brought to perfection, and that full ocular proof was afforded of the Harveian discovery. By successive improvements on his magnifiers, he was at last enabled to perceive distinctly the passage of the blood from the smallest arteries into the veins, and the continuity of these two sets of vessels; and to observe the figures of the globules of the blood. The art of injection, which was carried to a great degree of nicety by Ruyfch, served also to throw new light on the vascular system. Vieussens gave a minute de-

scription of the *vena cava*, and pointed out the *fossa ovalis* and the ring by which it is encompassed; and, in the year 1700, he discovered the serous vessels of the *ura*. Galstaldi, having divided the intercostal and eighth pair of nerves, above the heart, found that it still continued to contract; whence he justly inferred, that its action did not depend on the nervous influence. The experimental labours of Hales and Wintringham served to determine several questions relating to the motion of the blood, the connection of the veins and arteries, and their relative strength; but their calculations concerning the force of the heart and the velocity of the blood were all founded on the arbitrary principles of the mechanical system. Weibrecht and De Gorter proved the independent action of the arteries; and, lastly, Senac and Haller put an end to all controversy on the subject by their masterly descriptions of the heart, and the complete analysis of its functions.

Previously to the publication of Harvey's work on the circulation, Faber, a physician at Rome, had ascertained by experiment, that no air passed into the heart by the lungs; but very erroneous ideas concerning the functions of the latter organs continued to prevail, till Malpighi ascertained their real structure, and Mayow proved the necessity of oxygen gas for the due performance of respiration. Lower, adopting the doctrines of Mayow, was led to the conclusion, that the red colour of the blood depended on the presence of the "*nitro-aëricus* particles" of the atmosphere. Borelli, however, had the merit of giving the first complete explanation of the mechanism of respiration; shewing how the ribs and sternum are elevated by the action of the intercostal muscles, and how the cavity of the thorax is in that manner enlarged, while the lungs remained in a great measure passive; and how the air, which is inspired, is never entirely expired, though it becomes more rarefied. He rejected the hypothesis of a vital heat in the heart, and referred the exhalation from the lungs to an excretion from the bronchial glands. These opinions were adopted and extended by Pitcairn, Ström, and Lister. In the year 1715, Muschenbroek published his dissertation "*De Aëre in Humoribus*," in which he refuted several erroneous notions that had been entertained on the subject of respiration, particularly the doctrine of the admixture of the air with the blood, and of the presence of air between the pleura and the lungs. A controversy that arose between Hamberger, a disciple of the mechanical school, and Haller, had the effect of determining some disputed points relative to the action of the intercostal muscles and the state of the lungs in respiration; and the experiments, which Hales instituted with the air-pump, shewed the effects of the deprivation of air on the sensible properties of the blood.

On the 23d of July, 1622, Caspar Afelli, while dissecting a live dog, at the request of some friends, in order to demonstrate the recurrent nerves, observed a number of small white threads crossing the mesentery. At first he conceived they were nerves; but happening to cut into one of them, he remarked a small portion of a milky fluid flowing from the opening. Full of joy at this unexpected discovery, he cried out to the bystanders *εὐρηκα*, and resolved to lose no time in repeating the experiment. Finding, accordingly, that these vessels were observable in living animals, only after a full meal, he concluded that they were the true *vasa chylosa*; which was further proved by their origin in the villous coat of the intestines, and by the valves with which they were furnished: but he erroneously supposed them to unite in the pancreas, and from that to pass into the liver. The observation of Afelli was soon afterwards confirmed in the human body by Peiresc, Vesling, and

others; but the same false notions of their termination continued to prevail, till Pecquet, in the year 1647, struck with the appearance of a milky fluid in the vena cava of a dog, was led to the discovery of the thoracic duct. This great discovery, like that of the circulation of the blood, was disputed with much warmth; and it is a blot in the character of Harvey, that he sided with the opponents of Aselli, and would not even be convinced by the demonstrations of Pecquet and Vesling. How different the conduct of his own adversary, Plempius, who, after having long contended against the circulation, made a voluntary acknowledgment of his error, and freely embraced the new doctrine; and who, upon the present occasion, displayed the same amiable candour. In 1651, Olaus Rudbeck discovered the absorbent vessels of the large intestines, and remarked, that the supposed lacteal vessels of the liver served only to convey a lymphatic fluid to the hepatic glands; whence he conjectured, that the received opinion concerning the assimilating powers of that organ was altogether wrong. Shortly afterwards, Glisson and Wharton produced their respective works on the Liver and on the Glands, in which their structure and functions were more fully described. The latter gave the first account of the ducts of the parotids. Experiments were undertaken by Lower, Drelin-court, Lister, and Musgrave, to determine the motion of the chyle, and the changes to which it is subjected in its course; and before the close of the century the anatomy of the absorbent system was brought to a great degree of perfection by the labours of Nuck, Pachioni, and Duverney.

The discoveries relating to the nervous system, and the organs of sense, were not less remarkable. Cafferius, Sylvius, and Willis, applying themselves to the dissection of the brain, gave accurate views of its different parts, and of their relative position, and shewed the difference between the human brain and nerves, and those of other animals. Willis gave to the hypothesis of a nervous fluid a degree of consequence, which it had never before attained, supposing it to be the vehicle of the animal spirits, and the cause of various disorders, when it became vitiated; and he may be regarded as the precursor of Dr. Gall, in referring particular faculties of the mind to certain parts of the brain. His ideas on the former of these subjects were controverted by Malpighi, who investigating, with great industry, the nature of the cortical substance, shewed, that it extended to the innermost parts of the brain, and in some animals even to the *medulla oblongata*; that its structure was fibrous; and that the fibres of which it consisted united in the great commissure and medulla oblongata, and again diverged into the brain; whence he infers, that the brain is to be considered as the appendage of the spinal marrow. The *tunica arachnoides* was described by Blaes and Swammerdam; and Leeuwenhoek and Ruyfch ascertained, by the microscope, and by injections, the vascularity of the substance of the brain. The theory of vision had received considerable improvement from the labours of Kepler, who had pointed out the true use of the crystalline lens, and shewn how the images of external objects were formed, in an inverted position, on the retina. A public experiment with the eye of an ox, which was made at Rome, in 1625, by the Jesuit Scheiner, fully confirmed Kepler's theory; but afterwards Mariotte, having found that the images of objects disappeared when they fell on the spot where the optic nerve enters the eye, called in question the sensibility of the retina, and maintained that the choroid coat was better calculated to receive and transmit the perceptions of sight; and a controversy arose concerning the actual seat of vision, which was carried on, with great eagerness, by

Pecquet, Perrault, and St. Yves, and which had the effect of eliciting many valuable observations. The Newtonian discoveries, respecting the properties of light, contributed still more to the accurate analysis of the functions of the eye; and the treatises of Du Petit, Porterfield, and Zinn, which followed soon after, have left little for their successors to accomplish.

Passing over the improved descriptions which Cafferius, Duverney, Riverius, Vicussens, and others, gave of the structure of the ear; the interesting experiments of Harvey, Malpighi, and Redi, on the generation of animals; the discovery of the seminal animalculæ by Leeuwenhoek; and the various discussions and theories to which they severally gave rise; we conceive that we have adduced sufficient proofs of the great increase which took place in anatomical knowledge, and of the indirect advantages which medical science derived from the application of mathematics, and from the improved methods of physical research, which came into use after the time of Bacon. Wherever the laws of mechanics were properly applied, as they were by Borelli to muscular motion, and by Kepler and his followers to the theory of vision, they explained and illustrated the phenomena of life; and even when they were transferred to questions, which they were altogether incompetent to determine, as in the calculations of Borelli, Keil, Hales, and Winingraham, respecting the action of the heart and arteries; they suggested and led the way to many luminous experiments. In these respects the mechanists had greatly the advantage over their chemical brethren, whose speculations being founded on vague and puerile hypothesis, and implying no acquaintance with the laws of nature, led only to an accumulation of errors.

Descartes had taught his followers to consider matter as purely passive, and to refer all the changes to which it is subjected to a spiritual cause: the union of body and spirit was, in his estimation, merely one of its modes, or accidental conditions. Malebranche, extending the Cartesian doctrine, endeavoured to explain more fully the nature of this union, and to shew that the soul had a more or less distinct consciousness of all the movements and affections of the body. The part which the animal spirits were made to perform has been already frequently noticed. From these tenets, the transition to the system which came to be afterwards developed by Stahl was very easy; and an attentive review of the progress of the opinions in question must convince every one that the Stahlian hypothesis, far from being entitled to the merit of originality which its author claimed, was nothing more than an offspring of the Cartesian philosophy. Educated under Wedel, who was a devoted adherent of Sylvius, and an assiduous teacher of his doctrines, Stahl began very early to question the sufficiency of those chemical explanations, which he heard applied to all the phenomena of life. It appeared very wonderful to him, that the humours of the body, which are, of themselves, so disposed to putrefaction, should yet so seldom fall into that state; and that the daily presence of so many saline substances, as we are in the habit of receiving in our food, should produce so few symptoms of acrimony. He also remarked the great influence which the passions of the mind had in the production of diseases, and their instantaneous operation, in general, on the corporeal frame. The intervention of animal spirits he conceived to be a very unsatisfactory supposition; and all the attempts which had been made to explain the theory of life on pure chemical and mechanical principles he held very cheap. Taking the passiveness of matter for the basis of his system, he maintained, "that the body, as body, had no power to move itself, but was put in

motion only by immaterial substances; that all motion, therefore, was immaterial, and a spiritual act." The origin of all the actions of the living system, by which it is enabled to preserve itself, and to fulfil the ends for which it is created, must, according to Stahl, be sought for in the *soul*, or immaterial principle which animates it,—the nature, or $\psi\upsilon\chi\eta$ of the ancients. A little observation will teach us, that many sensations are experienced, and many corporeal actions performed, which are either altogether unnoticed at the time, or of which we have only an obscure consciousness; but in which it cannot be doubted, that the mind more or less participates. Finding this to be the case with respect to our perceptions, and the anatomical movements, as they have been termed, of the body, Stahl thought himself justified in supposing the same power to preside over all the other functions, and accordingly referred the performance of digestion, absorption, and assimilation, to the immediate agency of the soul. As the soul regulates thus incessantly the ordinary movements of the animal machine, and is thus constantly intent on its preservation, the same salutary vigilance may be naturally expected during disease. In fact, disease may be generally said to consist in a deranged idea (*perturbata idea*) of the regulation of the animal economy; and this position Stahl conceives to be proved by the greater frequency of diseases in the human species, than among the inferior animals, and from their attacking, most readily, those persons who are endowed with a high degree of sensibility. Several secondary causes, however, appeared necessary to the further illustration of this peculiar pathology, among which plethora had the most extensive agency assigned to it. To this condition, Stahl believes that there is a constant tendency in the human body, and that it proceeds from the quantity of aliment received being always greater than is necessary for the support of the organs: it shews itself in different parts of the frame, at different periods of life; in infancy, for example, in the head; afterwards in the lungs; and finally in the digestive organs. Hemorrhages were, for the most part, occasioned by an effort of nature to moderate this disposition to plethora, by what Stahl called the *tonic vital action*; as exemplified in menstruation, and in the hemorrhoidal discharges which occur in advanced age, and which Stahl ascribed to the tonic action of the *vena portæ*, the source of the great majority of chronic distempers, "*porta malorum*." Rejecting, as altogether unfounded, the doctrine of the acidity and alealescence of the humours, Stahl inculcated the necessity of studying, in disease, the organic movements of the system, and of observing the processes by which nature effects a cure. Fever, according to his view, was merely an autocratic effort of nature, to conquer the morbid cause, and to expel it from the body, and all the symptoms, not excepting *rigor*, were only so many proofs of the tonic action which was thus excited. Congestions were supposed, in contradistinction to obstructions, to result from an afflux of the fluids occasioned by the same tonic power; when obstruction followed, or when the object of the congestion, *i. e.* evacuation, was not accomplished, inflammation took place; and the tendency of the violent actions, which accompanied it, was to disperse the obstructed humour. If this end was not attained, the obstructed matter became vitiated, and pus was formed. Hypochondriasis, gout, melancholy, and almost all cachectic disorders, were attributed to a diminution of the tonic power of the *vena portæ*, and the consequent stoppage of the blood in it; while spasmodic diseases were thought to indicate an excess of the general tonic power of the system.

In the treatment of diseases Stahl proceeded in conformity

to these views. The chief duty of a physician, he maintained, was to watch the healing efforts of nature; to leave the cure to them, when they seemed adequate to its accomplishment; but to assist them when they were too feeble, and to moderate their violence when they were too powerful. Thus, holding evacuation to be indicated in fevers, he recommended the assiduous employment of such means as were likely to promote it, particularly diaphoretics. Purgation, indeed, he conceived to be seldom necessary or useful; but venesection he had little hesitation in administering, as it served, in his opinion, to bring about the crisis, and to favour the efforts of nature to relieve herself from the superfluity of blood; it might, however, prove injurious, if due attention was not afterwards paid to the excitement of sweating. The Peruvian bark was admitted by Stahl to operate in the cure of intermittents by its alluring qualities; but he believed it rather suppressed the disease, than effected its complete removal. Generally speaking, his favourite remedies were evacuants, such as antimony, aloës, rhubarb, and jalap; to the use of chalybeate medicines in chronic complaints, he objected, that they caused too powerful contractions of the parts; and opium tended, as he thought, to counteract too much the tonic vital action; yet he prescribed hyosciamus, without any scruple.

"The ideas of Stahl," observes M. Cabanis, "have, in general, been very imperfectly understood; we may even assert, that they have been almost equally disfigured by his censurers and by his admirers. The causes of this misunderstanding deserve to be detailed in a particular work. It would be useful to exhibit the Stahlian system, in more determinate points of view, than the author himself could possibly have done. Hitherto the points, by which it is distinguished from the doctrines of the ancients, and those by which it is related to them, have never been precisely ascertained. Perhaps, too, it would be advisable to conclude a work of this description by a systematic view of the progress of medical science since the time of Stahl, and of the advances which we have reason to expect at no very distant period. It would probably result from this investigation, that the reforms, which have been already effected, and those which may be hereafter accomplished in the same spirit, must be ascribed, in a great measure, to this extraordinary man; both on account of the sound ideas which he directly established, and of the impulse which he communicated to public opinion. It would too, I am persuaded, appear, that notwithstanding the haughty manner in which the adversaries of Stahl have attacked him; notwithstanding the awkwardness with which some of his disciples have defended, explained, and commented upon his works; still his influence has not been less powerful in medicine than in chemistry, and that to both sciences he has rendered everlasting services." *Coup d'Œil*, p. 148—9.

Of Stahl's merit as a chemist we shall have occasion to speak at large in a future volume; in this place we shall be content with observing, that, although he effected a complete revolution in chemical science, and continued to lecture upon it, with great applause, during the whole period of his academical career; yet he had the good sense to refrain from all application of chemistry to medicine, and repeatedly cautioned his disciples of the futility of any such attempt; contending, that the true theory of physic consists in the study of the vital actions, and has little or nothing to do with the laws of mechanics, with the minute anatomy of the solids, or with the mixture of the fluids; that its chief object is to ascertain by experience the laws of organic life; that it is therefore little else than rational empiricism;

and in the neglect of this empirical method is to be found the origin of all the controversies of physicians. Notwithstanding these salutary admonitions, it is evident that Stahl himself forsook this empirical method, when he gave "to an airy nothing a local habitation and a name," by personifying the principle of life, and ascribing to the direct agency of a rational intelligence all the corporeal functions of the system. Some persons, it is true, have imagined that they could perceive, through the obscurity of Stahl's style, the glimpses of a more enlightened physiology, and Cabanis even contends that Stahl selected the term *anima* or *soul*, merely in order to save himself from persecution; not as thinking it by any means the best calculated to express his views: but this would have been a species of deception, to which it is not probable that the haughty spirit of Stahl would have stooped; and nothing appears in his writings to warrant the belief, that he wished the phrase in question to be understood in any but the literal and vulgar acceptance.

Stahl's contemporary and colleague, Frederic Hoffmann, though endowed with less genius, was his superior in learning, and in the faculty of displaying it to advantage; and he accordingly obtained, as a teacher, a much higher degree of repute. But while he professed himself the enemy of hypothesis, and the follower of Hippocrates, he gave in to many of the prevailing errors, and supported many doctrines which had no foundation in truth. Mathematical studies had taught him to reason closely; and, if the premises be admitted on which he constructed his system, the consequences must be allowed to be, for the most part, correctly deduced: but in his illustrations he is extremely diffuse and fatiguing; and his repetitions are endless. At first a follower of the mechanical sect, he seems to have gradually approached to the opinions of Stahl, and that at the very time when he was engaged in controverting them, and was exclaiming against their supposed atheistical tendency. His theory, accordingly, is a heterogeneous mixture of speculations, few of which would be now deserving of notice, were it not for the celebrity of their author, and the tone which he gave to succeeding theorists. Vindicating the active qualities of matter, Hoffmann considered the human body as a machine, which is governed by the laws of mechanics, and put in motion by a nervous fluid, or ether, contained in the brain and nerves, and the blood. The heart and all the organs of the system were supposed by him to receive their strength, their tone, their contractile and elastic power, from this subtle fluid: he even ascribed to it a certain degree of intelligence, "*vim sensitivam et imaginativam*," by which each particle is enabled to form a correct idea of the mechanism of the body, and to regulate its agency accordingly! Medicine, he believed, was to be improved, not so much by experience, as by the skilful application of mechanical principles, and by the sedulous study of proximate causes. All disease he held to consist in irregularity of action: when too violent, spasms were produced; when too weak, atony was the consequence. Yet he agreed with Stahl in referring much to obstructions of the humours, particularly in the *vena porta*; but maintained that they always implied relaxation, or atony, of the vessels. He even admitted the doctrine of corruption of the fluids; ascribing gout, rheumatism, calculi, and cutaneous diseases, to acids generated in the body, and converted into neutral salts, upon admixture with the blood. Plethora was also allowed by him to be one of the chief causes of disease. The *spasm*, or constriction of the membranous and minute vessels, particularly of the skin, by which the blood is repelled to the interior parts, and the heart and larger arteries are incited to greater action, till

they are enabled to overcome the resisting cause, was, according to Hoffmann, the origin of every description of fever; and inflammation was explained by him on similar principles.

As a practitioner, Hoffmann appears to have been more successful than his rival, and to have had, indeed, a just title to that fame which he enjoyed. Though he inculcated the strict observation of critical days, yet he had the courage to maintain, in opposition to the universally received opinion, that it was not always necessary to wait for the concoction of the morbid matter in fever; for he believed the disorder might be sometimes stopped, in the commencement, by the administration of powerful means. Venesection was employed by him in all violent affections of the vascular system; and he trusted much to the antiphlogistic regimen in sthenic disorders. Among sudorifics he chose only the mildest; and drastic medicines were in little repute with him. The use of Peruvian bark in intermittents was rescued by Hoffmann from the contempt with which the Stahlians affected to view it; he demonstrated the great efficacy of chalybeates in various chronic complaints, and fully refuted the notion that they produced too great a constriction of the fibres. He investigated the nature of several of the most famous mineral waters; shewed their safety and utility in disorders for which they had been thought unfit; and taught to imitate them artificially. Warm and cold bathing were much commended by him for their virtues in restoring the proper tone of the system; and wine, camphor, and the well-known *liquor anodynus*, were favourite remedies with him in most chronic diseases: the last mentioned was generally used by him in the place of opium.

While Hoffmann was thus usefully employed in diffusing more sound practical doctrines among his contemporaries, Boerhaave was labouring, with equal zeal, and even with greater success, in the same path. Like Hoffmann, he began by commending the Hippocratic method; and, like him too, he soon deviated from it, by yielding to the influence of his early studies, and by acquiescing too much in the spirit of his age. He had enjoyed but little opportunity of acquiring a practical acquaintance with anatomy; and this want, as has been justly remarked, is perceivable throughout his writings. Fancying that the best system of physic would be that which reconciled all opinions, he sought to combine the doctrines of Hippocrates with those of Sylvius and Bellini, and was therefore, in the strictest sense of the word, an *Eclectic*, and not the founder of a new theory, as he has been sometimes considered. He refuted, it is true, many of the errors of the chemical school, and, in particular, the idea of a fermentation in the stomach and blood; but he embraced, in its fullest extent, the notion of an acid and an alkaline *cacoehymia*: the tenets of the mechanists were adopted by him with less reservation. In general, however, less extravagant than his predecessors, he enlarged the boundaries of medical science by his observations; while, by the charms of his style and delivery, he gave a lustre and attraction to his doctrines, which procured him disciples from all parts of the world.

To this triumvirate, as they have been called, to Boerhaave, Stahl, and Hoffmann, pathology and therapeutics owe many of their greatest improvements. All succeeding systematics have borrowed more or less from their speculations; and, in certain universities, their theories, or at least modifications of them, are still taught. However fanciful the views of Stahl may at first sight appear, it cannot be doubted that they had the effect of fixing the attention of physicians on a most important branch of the animal economy, the influence

fluence of the nervous system upon the other organs of the body, and its co-operation in the production and cure of diseases. However much we may be tempted to laugh at Hoffmann's æthereal fluid, and the sagacity and prudence which he ascribed to it, a careful examination of his writings will probably teach us, that by this very hypothesis he was led to the discovery of the relations which he pointed out between the different functions of the living frame, and of the sympathies which are the consequence. Considering how little this part of pathology had been investigated, and by what erroneous notions the study of it was obscured, we must allow, that Hoffmann and Stahl had no small merit in opening the way to its illustration, though they afterwards may have cast, upon the object of their researches, the false colouring of their respective theories. Hoffmann, in particular, has collected many valuable observations, in his treatise "De consensu partium nervosarum," proving the reciprocal influence which the various organs exert upon one another, especially those which are connected by means of the sympathetic nerve.

Among the adherents of Stahl, Porterfield, Whytt, Bordeu, and Sauvages, are the most eminent. The last-mentioned is well-known as the author of the first methodical Nosology, a work of great labour and research, which, notwithstanding the imperfections of its arrangement, contains much practical information, and which has served as the model of all similar subsequent undertakings. Bordeu had the merit of pointing out the importance of the cellular membrane, and of determining many of its properties which had been overlooked; while Porterfield and Whytt endeavoured to trace the laws that govern the muscular actions of the body, and to shew their dependence on the nervous influence.

The majority of the physicians of the age, having studied under Boerhaave, or his immediate disciples, followed the system of the Dutch professor. But the new light which was thrown on physiological science by the experiments and the splendid discoveries of Haller, tended to wean them from opinions which were but little consonant to experience, and the fallacy of which they were now in many instances compelled to acknowledge. Boerhaave, in his posthumous work "De Morbis Nervorum," had espoused the ancient dogma of an *æther*, or *impetum faciens*, which he figured to himself as an intermediate substance between matter and spirit, and to which he attributed all the sensations and motions of the animal frame. His nephew, Kaau-Boerhaave, developed more fully his ideas on this subject; and De Gorter and Gaubius, taking up the same views, and giving them somewhat greater precision, obtained for the hypothesis of a *vital principle* that distinction which, unfortunately for the interests of science, it has, till within these very few years, been allowed to claim in physiological disquisitions.

Such was the state of things, when Cullen ascended the professorial chair. Led, by the duties of his office, to review and examine the various systems of physic which were in vogue, he soon perceived the inconsistencies of the Boerhaavian theory, and accordingly resolved to abandon it. Stahl's doctrines, to which some of his contemporaries adhered, did not appear to him more satisfactory; and, in particular, he deemed them objectionable on account of the inert practice which they countenanced. Nor could he altogether assent to the system of Hoffmann, though he conceived it to approach nearer to the truth, and was induced to adopt some of its fundamental principles. Among others, he took up the doctrines of spasm and debility, from which he deduced all the phenomena of febrile disorders; and he

endeavoured to confirm his theory by proofs drawn from the laws of the nervous system, and from the consideration of the remote causes of the diseases in question. Rheumatism was referred by him to a spasm of the muscular fibres, arising from an increased afflux of blood; but gout he conceived to originate in atony, especially in atony of the digestive organs. In these latter diseases, he rejected the idea of a peculiar morbid matter; yet in his explanations of certain other complaints, as, for instance, of serofula, he had recourse to the supposition of an acrimony of the fluids. He laid much stress on the efforts of the *vis medicatrix nature*, advocated the hypothesis of a nervous fluid and vital principle, and ascribed to the brain a peculiar faculty, by which it was enabled to excite the muscles to action, independently of the mind, and to which he gave the name of *irrevocability of the sensorium*. As we have had frequent occasion to review the opinions of Cullen, in various parts of this work, especially under the article FEVER, we may be excused from entering more fully into detail in this place; particularly as there is so little essential difference between them and those of his predecessor Hoffmann, and as the great majority of them have been exploded by the more recent improvements in physiology. Cullen, indeed, seems to have been much in the same situation with Boerhaave, as to anatomical and physiological learning, of which many of his speculations betray a miserable deficiency. Yet his system continues to be taught, and, in some measure, to form the present creed of the Edinburgh school; a distinction which it would scarcely have maintained, had it not been for the transcendent merits of the author as a practitioner, and for the rational and consistent method of treating diseases which he inculcated.

In another point of view, however, the speculative doctrines of Cullen seem to deserve notice, *viz.* as having afforded the first hint of the Brunonian theory of *excitability*. In a passage of his "Institutions of Physiology," Cullen speaks of a state of *excitement*, or *collapse*, of the brain and nervous system, on which he supposes the strength or debility of the other parts of the body to depend; and in his other writings, he is constantly labouring to prove in what manner these conditions may be occasioned by the agency of various causes. Brown, seizing upon this idea, set about the formation of a new theory, according to which all the actions of life were to be referred to the *excitement* of the body by *stimuli*, and all diseases reduced to the two general heads of *direct* and *indirect* debility, or debility arising from a deficiency, or a previous excess of excitement. That the doctrine of morbid excitement is so far founded on truth, and that many of the leading symptoms of disease may be referred to it, we are not inclined to dispute; but when Brown proceeds to account for all the deviations from health upon this simple principle, we conceive that he has generalised too much, and evinced but small power of discrimination. The excitability and the excitement of the living body doubtless vary much at different times, and disease is often the consequence; but it is not true, as Brown contends, that when the excitement of any part has been unusually increased or diminished, a correspondent increase or diminution of excitement must take place in all the rest of the system: on the contrary, it will be found, that when one part or series of organs has been incited to greater action than common, the other parts generally exhibit a decrease of action; and *vice versa*. The Brunonian theory, in truth, takes but a gross view of the laws of organic life; and, with respect to the classification of diseases, it cannot be considered as much more refined and satisfactory than the

theory

theory of the *stridium* and *laxum*, as taught by Themison and his followers. To the practical maxims which its author laboured to establish, the same observation applies. Brown mistook a single property of animal matter for the primary cause of life and disease; neglecting the consideration of those various powers which the different organs possess, according to their peculiarities of structure, and overlooking entirely those laws by which they influence each other, and communicate or modify the affections to which they are severally liable. This has been the grand defect of almost all pathological systems; and it was not to be expected that Brown, whose practical knowledge was confined, and whose acquirements in general were superficial, should have outstripped his predecessors. Many of those who were most zealous in their devotion to his system, and who defended it most strenuously on its first promulgation, have found it so incompetent a guide at the bed-side of the patient, that they have deemed it advisable to qualify their belief in several essential articles; while others, as Frank and Reid, have been reduced to the necessity of completely recanting their faith. But we are, nevertheless, disposed to think, that the general spread of Brunonianism, especially on the continent, has had the beneficial effect of loosening the attachment of physicians to ancient prejudices, and of simplifying their complex, and too often incongruous, modes of practice. See EXCITABILITY.

Previous to Darwin, no one seems to have conceived the idea of applying the doctrine of *association* to the theory and the treatment of disease; although the tenets of Hartley were embraced by a large proportion of his countrymen, and his illustrations of the associative actions of the nervous and muscular systems were universally received. It is true that Hoffmann, and even some writers before his time, had remarked the sympathy, or *consensus*, which subsists between particular organs of the body; but their observations were blended with much erroneous hypothesis, and the rude state of physiological science, at the time, prevented them from discovering the extensive application of which they were susceptible. Darwin saw that the chief errors of preceding theorists had arisen from the partial views which they had taken of the animal economy; from their considering the living system as a simple whole, and not paying due regard to the reciprocal influence which the different organs, of which it was composed, have upon one another: he saw, too, that it was only by the same organic powers, by which the body is preserved and developed, that disease was generated, and formed, and finally removed from the system. Taking advantage of all the facts which had been accumulated by his predecessors, placing them sometimes in new lights, and at other times confirming and illustrating them by his own observations and experiments, he proceeded to the construction of a system of pathology and therapeutics, founded on the general laws of animated nature. Unfortunately, however, as he advanced in his design, he fell into many incongruities; and the difficulties increasing upon him, he was led to assume positions, which were not supported by any evidence, or countenanced by the slightest analogy. Such are his doctrine of the configurations of the organs of sense, many of his remarks on the exertions of the sensorial power, and the hypothesis of a retrograde action of the absorbents. Add to this, that the language which he employed is vague and inconsistent, and has occasioned much confusion and contradiction in his statements. Nor can we highly commend his division of diseases into those of irritation, sensation, volition, and association; the distinctions being frequently arbitrary and inconclusive, and the whole arrangement fa-

vouring of metaphysical subtlety. The best part of his works, and that in which he has evinced the most penetration, is unquestionably his account of the "Catenation of Animal Motions," and of the "Diseases of Association," particularly his "Theory of Fever." Rejecting, as illusive, all the explications which had been given of febrile disorders, on chemical and mechanical principles, Darwin has traced the succession of the symptoms of fever to the irregular actions of the nervous, vascular, and absorbent systems; shewing how the derangement of one part produces a similar or opposite affection of other parts, in consequence of the intimate connection of the organs in question, and the influence which they mutually possess. (See FEVER.) This was a great improvement in pathology, and it is only to be regretted that it should have been disfigured by the imperfections to which we have before adverted. Had Darwin possessed the profound anatomical knowledge, and the acute discernment of Bichat, he would have probably erected a system as finished in its parts, and capable of as extensive application, as the theory of gravitation; and as superior to the feeble creations of his predecessors, as the philosophy of Newton is to that of Descartes. But in his eagerness to explain every thing, he sometimes mistook words for facts; and his ardent imagination too often got the better of his judgment. It cannot, however, be doubted, that he had struck into the right path, and pursued it to a certain extent; and that his views have served to elucidate the nature of many disorders, which before had been greatly misunderstood. His writings contain a rich store of physiological observations, and many useful practical hints. If his theoretical doctrines have been regarded with distrust by his countrymen, they have experienced a more favourable reception on the continent: they have been partially adopted and improved upon by some enlightened physicians, particularly by Brandis and Hufeland; and when stripped of the hypothetical phraseology in which they are enveloped, they bid fair to become the foundation of a rational system of physic.

To complete the history of medical science, of which we have now pointed out the principal revolutions, it would be necessary to enumerate and investigate the merits of the different discoveries and improvements which have taken place, in all its different branches, during the present age. But not to speak of the delicacy of such an undertaking, and the abilities requisite for its correct and impartial performance, it is obvious that this would be, in a great measure, to describe the existing condition of the art, of which the plan of our work already comprehends the details. We shall, therefore, content ourselves in this place with remarking, that however much the continental nations may have extended the boundaries of the auxiliary sciences, and however great their claims in other respects may be, this country has taken a decided lead in the reform of medical practice. It may boast of setting the example to Europe in the employment of the cold affusion, and in the generally improved treatment of fever, in the revival and extension of the purgative method of cure, in the free use of mercury in cachectic disorders, and, above all, in the introduction of the vaccine inoculation. But we must acknowledge, that much still remains for us to accomplish; that the theory of medicine is yet in an unsettled state; that its practical application is too often wavering and fallacious; and taking a survey of the various fortunes of the art, we may say, with Bacon, that "*medicine is a science, which hath been more professed than laboured, and yet more laboured than advanced; the labour having been rather in circle, than in progression.*"

We subjoin a list of the best works on medical history, with their respective characters.

1. Histoire de la Médecine, où l'on voit l'Origine et les Progrès de cet Art—avec fig. par Daniel le Clerc, 12mo. Genev. 1696—4to. 3d Part, Amsterdam, 1723.

A work of considerable merit for the time when it first appeared. It gives a very full view of the doctrines of the ancients to the time of Galen, and, generally speaking, is written with great impartiality; though, on some occasions, the author shews a want of discernment. "Nemo candidus et plenius scripsit Clerico," was the favourable judgment of Haller.

2. The History of Physic, from the Time of Galen to the Beginning of the Sixteenth Century. By J. Friend. 2 Parts. London 1725—26.

This is a useful commentary on the history of Le Clerc, and gives, besides, a minute account of the practice of the Arabian and middle ages; but the arrangement is defective.

3. J. H. Schulzii Historia Medicinæ, a rerum initio ad A. U. C. 535 deducta, 4to. Lips. 1728. Ej. Compendium Historiæ Medicæ, a rerum initio ad Hadriani excessum, 8vo. Halæ, 1742.

As far as this history extends, it deserves unqualified commendation for the learning, the accuracy, and the discrimination which it displays. The account of the state of medicine in ancient Egypt is the best which we possess; and the whole is compiled with such care, that, as Ackermann observes, it would be difficult to detect a single error in it.

4. Dictionnaire Historique de la Médecine ancienne et moderne. Par N. F. J. Eloy, 2de Ed. 4 tomes 4to. Mons. 1778.

A valuable book of reference, particularly for the lives and writings of the French physicians.

5. Biographical Memoirs of Medicine in Great Britain, from the Revival of Letters to the Time of Harvey. By John Aikin, 8vo. Lond. 1780.

It was the design of the author to furnish a complete medical biography of Great Britain; but not meeting with sufficient encouragement, although this part of his labours is highly creditable, he has never accomplished his scheme.

6. Institutiones Historiæ Medicinæ. Auctore J. C. G. Ackermann, 8vo. Noriberg. 1792.

All Ackermann's writings bear the marks of great erudition and intelligence: his contributions to the new edition of Fabricius's "Bibliotheca Græca," have, in particular, thrown much light on the lives and writings of the Greek physicians. It is to be regretted, that his elegant compendium of medical history does not extend beyond the period of the Arabians.

7. Versuch einer pragmatischen Geschichte der Arzneykunde, von Kurt Sprengel. 2te Aufl. 5 Th. Halle, 1800—1803.

This is by far the completest history of medicine which we have; but, though the labour of fourteen years, the execution of it is very unequal. Where Sprengel could avail himself of the labours of others, he has given a very satisfactory view of the advances of the art; and his researches concerning its condition among the Arabians claim the merit of fulness, and also, in some measure, of originality: but there is a great falling off in the latter parts of the work; and the concluding volume proves that the author has no pretensions to any thing like a philosophic mind. His "View of the State of Physic during the last ten Years of the Eighteenth Century," published in 1801, is a hasty and extremely feeble performance, to call it by no severer name. A French

VOL. XXIII.

translation by Geiger, of the first volume of the history, appeared in 1809; but according to the account given of it by Millin, it is very carefully executed.

8. Coup d'Œil sur les Révolutions et sur la Réforme de la Médecine. Par P. J. G. Cabanis, 8vo. Paris 1804.

A work well worthy of perusal, on account of the philosophical spirit in which it is composed, and the useful views which it suggests concerning the reform of the art. The historical part, however, is superficial, and badly arranged. A translation, with some notes by Dr. Henderson, was published in 1826.

9. J. F. Blumenbachii Introductio in Historiam Medicinæ Litterariam, 8vo. Götting. 1786.

10. Versuch einer Chronologischen Uebersicht der Litterärsgeschichte der Arzneiwissenschaft, verfasst von D. J. G. Knebel, 8vo. Breslaw, 1799.

These are two convenient manuals of the literary history of medicine. The former especially is distinguished by its neatness and accuracy.

The "Bibliotheca" of Haller are too well known to require commendation in this place.

Among the minor and less important works the following may be mentioned.

J. C. Barclufen Historia Medicinæ, in qua pleraque Medicorum Ratiocinia, ab Exordio Medicinæ usque ad nostra Tempora pertractantur, 4to. Traj. ad Rhen. 1723. H. Conringii Introductio in universam Artem Medicam, 4to. Hal. 1726. J. C. Lettsom, History of the Origin of Medicine, an Oration, 4to. Lond. 1778. Walker's Memoirs of Medicine, Lond. 1799. R. Scuderi, Introduzione alla Storia della Medicina antica e moderna, 8vo. Venezia, 1800. Millar's Disquisitions in the History of Medicine, 8vo. Glasgow, 1811.

MEDICINE, *Clinical*, *Medicina clinica*. See CLINIC

MEDICINE, *Characters in*. See CHARACTERS.

MEDICINE, *Pandects in*. See PANDECT.

MEDICINE-Chest, is a portable chest, containing all sorts of medicines necessary for a campaign or voyage, together with such instruments as are most necessary and useful for the purposes of surgery.

MEDIEDNIK, in *Geography*, a mountain of Bosnia; 10 miles N. of Zwornik.

MEDIES, or MEGIES, a town of Transilvania; 20 miles N. of Hermanstadt. N. lat. 46° 20'. E. long. 23° 58'.—Also, a town of Hungary; 10 miles N. of Zatmar.

MEDIETAS LINGUÆ, in *Law*, an inquest impanelled, whereof the one half consists of natives or denizens, the other of aliens.

It is used in pleas, wherein the one party is a stranger, and the other a denizen. Solomon de Stanford a Jew, in the time of Edward I. had a cause tried before the sheriff of Norwich, by a jury of *sex probos & legales homines, & sex legales Judæos de civitate Norwici*. See JURY.

This manner of trial was first given by the stat. 28 Ed. III. c. 13; before which it was obtained by the king's grant. He that will have the advantage of trial "per medietatem linguæ," must pray it; for it is said he cannot have the benefit of it by way of challenge. (Staufd. P. C. 158. 3 Inst. 117.) In petit treason, murder, and felony, "medietas linguæ" is allowed; but for high treason, an alien shall be tried by the common law, and not "per medietatem linguæ." (H. P. C. 261.) And a grand jury ought not to be "de medietate linguæ" in any case. (Wood's Inst. 263.) A jury "de medietate" is also allowed in some other cases, by analogy to this rule "de medietate linguæ." As on a "Jus Patronatus," the jury must consist of six clergymen and six laymen.

So also under stat. 8 Henry VI. c. 12. against embezzling records, the jury shall consist of six persons, who are officers of any of the superior courts, and six common jurors. So on a criminal trial in the university courts, the jury must be half freeholders of the county, and half matriculated laymen of the university. See *University COURT*. Bl. Com. book iv.

MEDIMNUM, *Μεδιμνον*, among the Greeks, a measure of capacity holding six Roman *modii* or bushels.

MEDIN, in *Commerce*, called also Para, Fadda, Kata, and Mesria, a coin of Syria, of the size of an English silver threepence, worth a little above a halfpenny.

MEDINA, PETER DE, in *Biography*, a Spanish mathematician, who flourished in the sixteenth century, but of whose personal history we only know that he was a native of Seville, and the friend of the learned John Vassæus during his residence in that city, who, in his "*Chronicon Hispaniæ*," speaks in the highest terms of his skill in the mathematical sciences, and particularly as they were applicable to the art of navigation. His works are, 1. "*Arte de Naviar*," which met with a very favourable reception, and which was translated into the German, French, and Italian languages. 2. "*Libro de las Grandezas y cosas memorables de Espanna*:" this work, which is descriptive of the objects that are chiefly deserving of attention in Spain, Florian Docampo has transcribed into his "*History of Spain*." 3. "*A Map of Spain*," and many other pieces.

MEDINA, in *Geography*, a city of Arabia Felix, in the province of Hedsjas, about a day's journey from Jambo, on the Red sea. It is situated in a sandy plain, of moderate extent, and surrounded with indifferent walls. It belongs to the sherriffe of Mecca, but of late has been governed by a sovereign of its own, of the family of Darii Berkad. At present the sherriffe rules it by a vizir, who must be of the royal family. Before the days of Mahomet, it was called Jathreb; but it was called Medined en Nebbi, the city of the prophet, from the period at which Mahomet, upon his expulsion from Mecca by the Koreishites, took refuge here, and continued to make it the place of his residence for the rest of his life. The tomb of Mahomet at Medina is held in respect by the Mussulmans; but they are not obliged to visit it in order to the performance of any devotional exercises; however, as the caravans from Syria necessarily pass near it in their return from Mecca, they turn aside to view the prophet's tomb. This tomb is situated in a corner of the great square; whereas the Caaba is in the middle of the square at Mecca. In order to prevent the people from superstitiously offering worship to the ashes of the prophet, the tomb is inclosed within iron rails, and is only to be seen by looking through these. It is of plain mason-work in the form of a chest; placed between the two tombs, in which are deposited the ashes of the two first caliphs. It is an idle story, of unknown origin, that vast magnets support the coffin of Mahomet in the air. Although it is not more magnificent than the tombs of the founders of most other mosques, the building that covers it is hung with a piece of silk stuff embroidered with gold, which is renewed every seven years by the pacha of Damascus. This building is guarded by 40 eunuchs, chiefly for the security of the treasure which is said to be kept in it. This treasure consists chiefly of precious stones, the offerings of rich Mussulmans. But the account given of this treasure is blended with much fable. Niebuhr was informed by an eminent Arabian, that the guard was posted for no other purpose but to keep off the populace, who had begun to throw dirt upon the tomb, which they afterwards scraped off, and preserved as a sort of relic.

MEDINA, a town of the Arabian Irak, seated on the Euphrates; 60 miles N.W. of Bassora.

MEDINA, a town of Africa, the capital of the kingdom of Woolli; it is a town of considerable size, surrounded by a high wall of clay, guarded by an outward fence of pointed stakes and prickly bushes, and containing from 800 to 1000 houses. N. lat. $13^{\circ} 38'$. W. long. $12^{\circ} 50'$.—Also, a town of Africa, in Kaffan. N. lat. $14^{\circ} 45'$. W. long. $9^{\circ} 15'$.—Also, a small island in the Atlantic, near the coast of Africa. N. lat. $19^{\circ} 45'$.

MEDINA del Campo, *Methymna Campestris*, an ancient town of Spain, in the province of Leon, situated on the Zapardiel, a small river communicating with the Duero, between Toro and Tordefillas. This town was formerly celebrated for the residence of several monarchs, and was then more considerable than it is now, and both commercial and opulent. It has still three considerable fairs, and several great privileges: it is free from all taxes, and the inhabitants have a right to fill all offices, both in the church and civil magistracy, without the interference of the pope or the king. It is still large, though decaying; it has a handsome square, in the middle of which is a fountain ornamented with a statue of Neptune. Medina del Campo is said to have contained 14,000 families, though the number is now reduced to 1000. Although the population is much diminished, the ancient churches and convents are still remaining. According to Townsend it has 9 parish churches, 70 priests, 17 convents, and two hospitals. The collegiate church, built of brick, is much admired for its roof. The old handsome house of the Jesuits is still to be seen. This town was the birth-place of the Jesuit P. J. Acosta, and of the philosopher Gomesius Pereira. Cardinal Ximenes had made this place one of his principal magazines for military stores, collected with a view to curb the great nobility; but when, A.D. 1520, the commons of Castile sought redress of grievances, they seized the magazine, and defended the city with such obstinacy, that they forced Fontesca to retire and to leave them in quiet possession of the ruins. The surrounding country is naturally fertile; 20 miles S.S.W. of Valladolid. N. lat. $41^{\circ} 23'$. W. long. 5° .

MEDINA Celi, a town of Spain, in Old Castile, on the Xalon, anciently called "*Segoucia*." N. lat. $41^{\circ} 21'$. W. long. $2^{\circ} 27'$.

MEDINA del-Rio-Seco, an ancient town of Spain, in Leon, situated on a plain, watered by the river Sequillo. The streets are narrow and ill-paved. It has three parish churches, four convents, an asylum for monks, and two well-endowed hospitals. This place was formerly famous for its population, manufactories, and fairs, on which account it was furnished Little India, in Spanish India-Chica. In 1638, it was honoured with the title of city by Philip IV. It is surrounded by mountains, and the air of it is very salubrious. Its population, which is said to have consisted of 30,000 persons, is now reduced to a fourth of that number. The surrounding country abounds in corn and wine; 15 miles W. of Palencia.

MEDINA Sidonia, a town of Spain, and capital of a duchy, in the province of Seville, anciently the see of a bishop, transferred to Cadiz; 20 miles S.E. of Cadiz. N. lat. $36^{\circ} 25'$. W. long. 6.

MEDINA de los Torres, a town of Spain, in Estramadura; 24 miles N. of Llerena.

MEDINET FARS, a ruined town of Egypt, supposed to have been the ancient Arfinoé, a little N. of Fayoum.—Also, a town of Egypt, on the right bank of the Nile, opposite to Feshn.

MEDINET Habu, or, according to Mr. Bruce, *Medinet-Tabu*, a village of Egypt, near the W. bank of the Nile, where are found the remains of four temples, shewing the place where once stood the magnificent city of Thebes; 28 miles N. of Afoa.

MEDINGEN, a town of Westphalia, in the duchy of Lunenburg; 14 miles S.S.E. of Lunenburg.

MEDINSK, a town of Russia, in the government of Kaluga; 32 miles N.N.W. of Kaluga. N. lat. 54° 58'. E. long. 53° 30'.

MEDIOLANUM, in *Ancient Geography*. See MILAN.

MEDIR, in *Geography*, a town of Persia, in the province of Keruan; 60 miles E. of Sirjan.

MEDITATION, an act by which we consider any thing closely, or wherein the soul is employed in the search or consideration of any truth.

In our religion, it is used to signify a consideration of the objects and grand truths of the Christian faith.

Mythic divines make a great difference between meditation and contemplation: the former consists in discursive acts of the soul, considering methodically, and with attention, the mysteries of faith, and the precepts of morality; and is performed by reflections and reasonings, which leave behind them manifest impressions on the brain. The pure contemplative has no need of meditation, as seeing all things in God at a glance, and without any reflection.

When a man, therefore, has once quitted meditation and is arrived at contemplation, he returns no more; and according to Alvarez, never resumes the oar of meditation, except when the wind of contemplation is too weak to fill his sails.

MEDITERRANEAN, something inclosed within land; or that is remote from the ocean.

MEDITERRANEAN is more particularly used to signify that large sea which flows between the continents of Europe and Africa, entering by the straits of Gibraltar, and reaching into Asia, as far as the Euxine sea, and the Palus Mæotis.

The Mediterranean was anciently called the Grecian sea, and the Great sea. It is now cantoned out into several divisions, which bear several names. To the west of Italy it is called the Ligustic or Tuscan sea; near Venice, the Adriatic; towards Greece, the Ionic and Ægean of the ancients, now the gulf of Archipelago. From this last a strait, called the Hellespont, conducts to the sea of Marmora, the ancient Propontis; and another, now denominated the strait of Constantinople, the ancient Bosphorus, leads to the Euxine, or Black sea; which to the north presents the shallow Palus Mæotis, or sea of Azof, the utmost maritime limit of Europe in that quarter. The breadth of this sea is very various, from 80 to 500 miles; and its length is about 2000 miles to its farthest extremity in Syria. This wide expanse of sea is beautifully sprinkled with islands, and environed with opulent coasts. Tides are not perceivable, except in the narrowest straits; but, according to physiologists, there is a current along the Italian shore from W. to E., and towards the African coast in an opposite direction. In the Adriatic the current runs N.W. along Dalmatia, and returns by the opposite shore of Italy. (See CURRENT.) The chief fisheries of this sea are those of the tunny, of the sword-fish, of the sea-dog, and of the diminutive anchovy. This sea is also the chief seminary of the coral; which see.

According to the learned Buffon, the Mediterranean sea was originally a lake of small extent, and had received, in remote ages, a sudden or prodigious increase, at the time when the Black sea opened a passage for itself through the Bosphorus, and at that period when the sinking of the land which united Europe to Africa, in the part that is now the

straits of Gibraltar, permitted the water of the ocean to rush in. It was also his opinion, that most of the islands of the Mediterranean made a part of the continent, before the great convulsions that have taken place in this quarter of the world. Sonnini, at his request, and with a view of ascertaining his opinion, founded the depth of the sea between Sicily and Malta; and he found the depth from 25 to 30 fathoms, and in the middle of the channel, where the water is deepest, never exceeding 100. On the other hand, between the island of Malta and cape Bon, in Africa, there is still less water, the lead indicating no more than from 15 to 30 fathoms throughout the whole breadth of the channel which separates the two lands.

The British trade carried on by means of the Mediterranean sea is of great consequence to Great Britain; and the permanent preservation of it depends on the possession of the town and fortifications of Gibraltar.

The counterfeiting of Mediterranean passes, for ships to the coast of Barbary, &c. or the seal of the admiralty office to such passes, is felony, without benefit of clergy. Stat. 4 Geo. II. cap. 18.

MEDITRINALIA, among the Romans, feasts instituted in honour of the goddess Meditrina, and celebrated on the thirtieth of September. They were so called from *medendo*, because the Romans then began to drink new wine, which they mixed with old, and that served them instead of physic.

MEDIUM, a Latin term, signifying *middle*, or *mean*.

MEDIUM, in *Arithmetic*, or an *arithmetical medium* or *mean*, called in the schools *medium rei*, is that which is equally distant from each extreme; or which exceeds the lesser extreme, as much as it is exceeded by the greater, in respect of quantity, not of proportion.

Thus nine is a medium between six and twelve.

MEDIUM, *Geometrical*, or *mean*, called in the schools *medium personæ*, is that where the same ratio is preserved between the first and second, as between the second and third terms; or that which exceeds in the same ratio, or quota of itself, as it is exceeded.

Thus, six is a geometrical medium between four and nine. See *Geometrical PROPORTION*.

This is a medium which virtue is supposed to observe; whence some call it *medium quoad nos*, as having a view to circumstances, times, places, persons, &c. Distributive justice observes a geometrical medium; commutative justice, an arithmetical one.

MEDIUM, in *Botany*, a name which has been applied, at different times, to different species of Bell-flower; see *CAMPANULA*. Linnæus retained it for the common biennial Canterbury bell, *Viola maritima* of old authors; because that plant had most generally received this appellation, and was universally believed to be the *mandio* of Dioscorides. The real *mandio* however, though sufficiently well figured under that name, with the synonym of *Mindium Rbafis*, in Rauwolf's Travels, t. 284, was never known to Linnæus, who erroneously referred Rauwolf's plant to his own *Campanula laciniata*. This error was detected a few years since, when the late Andrew Michaux sent seeds of the *Mindium*, or *mandio*, from Aleppo to Paris, and the fine plant they produced was described and figured by l'Heritier, in one of his Monographs, under the name of *Michauxia campanuloides*, in honour of the meritorious botanist and traveller who recovered this long lost rarity. We cannot but think, as we suggested at the time, with all possible respect for M. Michaux, that the ancient name *Medium* ought to have been retained for this newly recovered genus; nor could we wish to call it *Mindium*, with Adanson, the description in Dios-

corides being, in this case, sufficient to leave no doubt; and *Mindium* is apparently a barbarous corruption of an Arabian writer. See *MICHAUXIA* and *MINDIUM*.

MEDIUM, in *Logic*, or *medium of a syllogism*, called also the *mean*, or *middle term*, by the Italians *mezzo termino*, is an argument, reason, or consideration, for which we affirm, or deny any thing: or, it is the cause why the greater extreme is attributed to, or denied of the less, in the conclusion.

Thus, in the syllogism, "Every good thing is to be desired: but all virtue is good; therefore all virtue is to be desired:" the term *good* is the medium: *virtue* the less extreme, and *to be desired* the greater.

It is called medium, as being a kind of mediator between the subject and predicate; or because the extremes are so disposed as to affirm or deny, by means hereof. Some call it *argumentum tertium*, a third argument; and others simply *argumentum*, as being the cause why we assent to the conclusion.

Mediums, or middle terms, are the things principally sought for, in discoursing; so that the invention of mediums makes the most essential part of logic. But the rules commonly given by logicians for that purpose, are mere imperinencies. In effect, no such rules can be given; nor have we any way of coming at such mediums or reasons, but by a close attention to clear ideas.

MEDIUM, in *Music*. Rousseau has made an article of this word in his dictionary, calling it "that part of the voice which is most distant from the extremities of its compass, and which is generally the most full, sweet, and powerful." The same might be said of the middle tones of most instruments. The top of the voice is the most brilliant, but almost always in falset; the bottom is grave and majestic, but less clear and compact. The middle tones of the voice are not only produced with the greatest facility, but are the most melodious and grateful to the ear.

MEDIUM, in *Mechanical Philosophy*, is that space or region through which a body passes in its motion towards any point.

Thus ether is supposed to be the medium in which the heavenly bodies move. Air is the medium in which bodies move near our earth. And water is the medium in which fishes live and move. And glass is also a medium of light, as it affords a free passage.

That density or consistence in the parts of the medium, by which the motion of bodies in it is retarded, is called *the resistance of the medium*; which, together with the force of gravity, is the cause of the cessation of the motion of projectiles.

MEDIUM, *Subtile*, or *Ætherial*. Sir Isaac Newton makes it probable, that, besides the particular aerial medium in which we live and breathe, there is another more universal one, which he calls an *ætherial* medium; vastly more rare, subtile, elastic, and active, than air; and by that means freely permeating the pores and interstices of all other mediums, and diffusing itself through the whole creation; and by the intervention of this he thinks it is, that most of the great phenomena of nature are effected. See *ÆTHER*.

This medium he seems to have recourse to as the first and most remote physical spring; and the ultimate of all natural causes. By the vibrations of this medium, he takes heat to be propagated from lucid bodies; and the intenseness of heat increased and preserved in hot bodies, and from them communicated to cold ones.

By this medium he takes light to be reflected, inflected, refracted, and put alternately in fits of easy reflection and transmission; which effects he also elsewhere ascribes to the power of attraction; so that this medium appears the cause and source even of attraction.

Again, this medium being much rarer within the heavenly bodies, than in the heavenly spaces, and growing denser, as it recedes farther from them, he supposes the cause of the gravitation of these bodies towards each other, and of the parts towards the bodies.

Again, from the vibrations of this same medium, excited in the bottom of the eye by the rays of light, and thence propagated through the capillaments of the optic nerves into the sensory, he takes vision to be performed; and so hearing, from the vibrations of this or some other medium, excited in the auditory nerves by the tremors of the air, and propagated through the capillaments of those nerves into the sensory; and thus of the other senses.

And again, he conceives muscular motion to be performed by the vibrations of the same medium, excited in the brain at the command of the will, and thence propagated through the capillaments of the nerves into the muscles; and thus contracting and dilating them.

The elastic force of this medium, he shews, must be prodigious. Light moves, according to the estimated distance of the earth from the sun in his time, at the rate of considerably more than 70,000,000 miles in about seven minutes; yet the vibrations and pulses of this medium, to cause the fits of easy reflection, and easy transmission, must be swifter than light, which is yet 700,000 times swifter than sound. The elastic force of this medium, therefore, in proportion to its density, must be above 490,000,000,000 times greater than the elastic force of the air, in proportion to its density; the velocities and pulses of the elastic mediums being in a subduplicate ratio of the elasticities and the rarities of the mediums, taken together. And thus may the vibration of this medium be conceived as the cause also of the elasticity of bodies.

Farther, the particles of this medium being supposed infinitely small, even smaller than those of light; if they be likewise supposed, like our air, to have a repelling power, whereby they recede from each other, the smallness of the particles may exceedingly contribute to the increase of the repelling power, and consequently to that of the elasticity and rarity of the medium, and so fit it for the free transmission of light, and the free motions of the heavenly bodies. In this medium may the planets and comets roll without any considerable resistance. If it be 700,000 times more elastic, and as many times rarer, than air, its resistance will be above 600,000,000 times less than that of water; a resistance that would make no sensible alteration in the motion of the planets in ten thousand years.

And is not such a medium better disposed for the heavenly motions than that of the Cartesians, which fills all space adequately, and without leaving pores, and is vastly denser than gold, and therefore must resist more?

If any ask how a medium can be so rare? let him tell how the air, in the upper regions of the atmosphere, can be above a hundred thousand times rarer than gold; how an electrical body can, by friction, emit an exhalation so rare and subtile, yet so potent, as though its emission occasions no sensible alteration in the weight of the body, yet it shall be diffused through a sphere of two feet in diameter, and carry up leaf-copper, or leaf-gold, at the distance of a foot from the electrical body: or how the effluvia of a magnet can be so subtile, as to pass a plate of glass without any resistance or diminution of force; yet so potent, as to turn a magnetic needle beyond the glass. That the heavens are not filled with any other, but such a subtile ætherial medium, is evident from phenomena: whence else are those lasting and regular motions of the planets and comets, in all manner of courses and directions; and how are such motions consistent

consistent with that resistance which must result from that dense fluid medium, wherewith the Cartesians fill the heavens?

The resistance of fluid mediums arises partly from the cohesion of the parts of the medium, and partly from the *vis inertiae* of matter. The first, in a spherical body, is nearly as the diameter, or, at most, as the lactum of the diameter, and the velocity of the body. The latter is as the square of that lactum. Thus are the two kinds of resistance distinguished in any medium; and, being distinguished, it will be found that almost all the resistance of bodies, moving in ordinary fluids, arises from the *vis inertiae*. The part which arises from the tenacity of the medium, may be diminished, by dividing the matter into smaller parts, and making those more smooth and slippery; but the other will still be proportional to the density of the matter, and cannot be diminished any other way, but by a diminution of the same.

Thus the resistance of fluid mediums is nearly proportional to their densities; and thus the air we breathe, being about nine hundred times lighter than water, must resist about one hundred times less than water; as, in effect, the same author has found it does by experiments on pendulums. Bodies moving in quicksilver, water, or air, do not appear to meet with any other resistance but what arises from the density and tenacity of those fluids; which they must, were their pores filled with a dense and subtle fluid.

Heat, it is found, diminishes the tenacity of bodies very much; yet does it not decrease the resistance of water sensibly. The resistance of water, therefore, arises chiefly from its *vis inertiae*; consequently, if the heavens were as dense as water, or as quicksilver, they would not resist much less: if absolutely dense, without any vacuum, be the particles never so subtle and fluid, they would resist much more than quicksilver. A solid globe, in such a medium, would lose above half its motion, while it moves thrice the length of its own diameter; and a globe not perfectly solid, such as the planets, would lose more.

To make way, therefore, for the lasting motions of the planets and comets, the heavens must be empty of all matter, except, perhaps, some very fine effluvia, from the atmospheres of the earth, planets, and comets; and some such æthereal medium as we have described. A dense fluid can serve for no purpose, in the heavens, but to disturb the celestial motions, and make the frame of nature languish; and in the pores of bodies, it can only serve to check the vibrating motion of their parts, wherein their heat and activity consist. Such a medium, therefore, unless we had some evidence of its existence, must be given up; and, that given up, the hypothesis of light consisting in a pression falls also to the ground.

MEDIUM Participationis, in the *Schools*, is that said to be compounded of the two extremes. Thus, man, who is partly body, partly mind, is a medium by participation of the two extremes; so is warmth the medium of heat and cold, &c.

MEDIUM Negationis, or *Remotionis*, is that from which both extremes are derived; or it is a subject capable of receiving both extremes, and yet not necessarily possessed of either.

In which latter sense, the will is a *mean* with respect to virtue and vice; and the understanding, with respect to knowledge and ignorance.

MEDIUM Quod, or *Medium Suppositi*, is somewhat between the agent and patient, which receives the action of the one before it arrive at the other.

In this sense, air is a medium between the fire and the hand heated thereby.

MEDIUM Quo, is the form, or faculty, whereby an agent produces an effect: in which sense, heat is said to be the medium or mean whereby fire acts on the hand.

MEDIUM sub Quo, is that which renders the power to act complete in general, without determining it to any particular object: in which sense, light is the medium under which the eye perceives any colour.

MEDIUM in Quo, is that, by inspection whereof a power is produced in any thing, of knowing or perceiving another: such is a speculum, as it shews an object; an image, as it represents the reality, &c.

MEDIUS, in *Geography*, a town of Persia, in Farsistan; 30 mile S.W. of Yezd

MEDIT'S Harmonicus, Lat. in *Musie*, with the Germans implies the middle sound of a triad or common chord, as E in the chord of C. (Walther.) See **MEDIANTE**.

MEDLAR, in *Botany*. See **MESPILUS**.

MEDLAR, Parsley-leaved. See **SERVIER-Tree**.

MEDLE, in *Geography*, a town of the island of Cuba; 62 miles N. of St. Yago

MEDLERSLO, a small island in the N. part of the gulf of Bothnia. N. lat. 61° 13'. E. long. 21° 39'.

MEDLEY. See **CHANCE-Medley**.

MEDLEY, in *Musie*, during the early part of the last century, a piece of pleasantry, or rather musical buffoonery, was frequently practised by English composers in composing symphonies from fragments of vulgar tunes, and popular compositions, which were called *medley overtures*. Charke, Jack James, and even Arne, in his early days, condescended to divert himself, more, perhaps, than the public, by these musical salmagundies; of which, however, no one of these musicians can be styled the inventor. Dr. Pepusch seems to have given them the hint in his pleasant and appropriate overture to the Beggar's Opera; of which the first movement is a burlesque of the beginning of Handel's overture in Otho; and the subject of the fugue in the first part of "I'm like a skiff in the ocean tost," and the solo passages for hautbois, the second part.

MEDMAN, in *Geography*, a town of the duchy of Berg, containing three churches for persons of different religious profession; six miles E.N.E. of Dusseldorp. N. lat. 51° 17'. E. long. 6° 43'.

MEDNIKI, a town of Samogitia, the residence of the bishop; 28 miles N.E. of Konigsberg.

MEDNOE, a town of Russia, in the government of the Tver, on the Tvertza; 32 miles W.N.W. of Tver.

MEDOC, a county of France, so called before the Revolution, in form of a peninsula, between the Garonne and the sea, the north part of which is overflowed by the sea. On a rock at the mouth of the Garonne is a fine light-house, called "La Tour de Cordouan."

MEDOCTU, a settlement of America, in New Brunswick, situated on the W. side of St. John's river; 35 miles above St. Anne's. N. lat. 46° 12'. W. long. 67° 35'.

MEDOLA, a town of Italy, in the department of the Panaro; 18 miles S. of Modena.

MEDOLI, a town of Italy, in the department of the Mincio; 17 miles N.W. of Mantua.

MEDRA, a town of Africa, in Lower Guinea, capital of a country near the river Camerones.—Also, a town of Persia, in the province of Mekran; eight miles N. of Kich.

MEDRASHEM, a town of Algiers; 40 miles S. of Constantiniana.

MEDSHE-

MEDSHETISAR, a village, being one of the Persian havens on the Caspian, is situated, as is also Farabat, on the southern coast, in the province of Mazanderan. Of these two villages Medshetifar is the most convenient, from its vicinity to Balfrusch, capital of the province, where the Russians and Armenians convey their merchandize: the traffic, however, is much diminished on account of the impositions of the khan of Mazanderan. The chief productions of this country are silk, far inferior to that of Gbilan, rice and cotton, which are largely exported. Merchants from Kashan, Ispahan, Schiras, and Khorafan, resort to Balfrusch, and bring for sale the Persian and Indian commodities.

MEDUA, a town of Algiers, at the foot of mount Atlas, in the midst of springs; 180 miles S.W. of Algiers.

MEDVADITZA, a river of Russia, in the country of the Cossacks, which rises about ten miles N. from Saratov, and runs into the Don, about eight miles N.W. from Spaskaia.

MEDVEDIVA, a town of Russia, in the government of Irkutsk, on the Ilim; 64 miles S.W. of Orlenga.

MEDVEZEL, a cape on the N. coast of Nova Zembla. N. lat. $77^{\circ} 20'$. E. long. $68^{\circ} 34'$.

MEDVEZHI, five small islands of Russia, in the Frozen sea; 60 miles from the mouth of the Kolima. N. lat. 72° to $72^{\circ} 20'$. E. long. about 156° .

MEDVEZI, a small island of Russia, in the sea of Ochotz, at the mouth of the river Uda. N. lat. $55^{\circ} 10'$ to $55^{\circ} 16'$. E. long. 137° to 138° .

MEDUKKA, a town of Arabia, in the province of Yemen; 36 miles S. of Saade.

MEDULLA, in *Anatomy*, the fat substance which fills the cavity in the middle of a long bone. See MEDULLARY *System*.

MEDULLA *Oblongata*, one of the divisions of the contents of the cranium. See BRAIN.

MEDULLA *Spinalis*, the medullary cord contained in the canal of the vertebræ. See BRAIN.

MEDULLA, in *Vegetable Physiology*, the Pith of plants, is lodged in the centre or heart of the vegetable body, where it is as assiduously protected as the brain and spinal marrow of animals. In parts most endowed with life, like the root, or especially young growing stems or branches, the *medulla* is usually of a pulpy substance; but tolerably firm though rather brittle. Its colour is pale green or yellowish, with a watery transparency, the substance being very juicy. Its juices partake but little, or not at all, of the peculiar flavour of the plant, they being more of the nature of sap. Still there is no perceptible flowing from this part when wounded, at any time of the year, as far as we have observed. In branches or stems more advanced in growth, the *medulla* is found of a drier, more white, and evidently cellular texture. In this state it is known to every body in the full-grown branches of Elder, and the stems of Rushes, *Juncus conglomeratus*, *effusus*, &c. In these it is dry, highly cellular, snow-white, extremely light and compressible, though but slightly elastic. Such are its different appearances, at different periods of growth, in many common shrubs, as the Currant-tree, Lilac, Mock-orange, *Hydrangea*, &c. In the last-mentioned shrub, though nearly akin to the Elder, as well as in the *Aucuba japonica*, the pith is very abundant, and remains unusually long in its primary green juicy state. The pith of many annual stems, abundant and highly succulent while they are growing, becomes little more than a web, lining the hollow of the adult stem, as in some Thistles.

Many Grasses and Umbelliferous plants, as the Hemlock and Chervil, have always hollow stems, lined only with a thin smooth coating of pith, exquisitely delicate and brilliant in its appearance. The inner part of such hollow stems is, in some instances, divided into separate cavities, by transverse partitions. Such is the case at every joint, knot, or subdivision of the stem. There are a few grass-like plants, with unbranched hollow stems, internally divided by numerous membranous partitions, perceptible to the touch in the living plant, and to the sight in the dry one; witness *Juncus articulatus* and its allies, in which the longitudinal hollow of the stem is simple; and *Cyperus articulatus*, in which it is a congeries of parallel tubes. We mean not to say that the tubes in this last-mentioned instance are certainly medullary. They may or may not; but observations on the living plant could alone determine this. It is possible they may be sap-veins, and that the transverse stricture is not complete, so as to prevent the passage of fluids along this highly vascular substance. But as other species of this tribe have the central part of their stems filled with cells, or tubes frequently interrupted, through which no fluid can run, it is most probable that *Cyperus articulatus* differs from such merely in having all its tubes interrupted at the same point of elevation, and that the assemblage of numerous partitions gives a frequently jointed appearance to the whole stem. *Andromeda acuminata*, Sm. Exot. Bot. t. 89, is found to have its hollow stem intercepted by very numerous transverse partitions; and the same may be seen in other instances. The distinction between a hollow stem, only lined with *medulla*, and a solid one, entirely filled up with that substance, by no means indicates any material difference between the plants so circumstanced. Some species of *Hieracium* have the one sort of stem, others the other, and this difference is often of use, for specific distinction, in that difficult genus.

It is much easier to describe the appearances of the *medulla*, which are few and but little varied, than it is to understand the true nature, or physiology, of this part. There is scarcely any concerning which a greater variety of opinions, or at least more opposite ones, have been held.

Du Hamel, an excellent observer, though not always a correct theorist, considered this part as not in any respect different from the rest of the cellular substance, dispersed through the vegetable body, and serving to hold its different parts together; nor did he attribute any particular function, in the vegetable economy, to any part of this substance.

Linnaeus on the contrary thought the *medulla* the seat of life, and prime source of vegetation. He conceived that its vigour was the main cause of the propulsion of the branches. His lively fancy formed to itself an idea of this organ altogether his own, as a living body of peculiar vivacity and energy, striving to enlarge itself in every direction, and succeeding best where it found least resistance. Thus he explains the growth of plants, and especially of trees, at their extremities only; the cortical substance, as he terms it, of the vegetable being, (consisting of its wood and bark, including the vascular system,) affording less resistance where it is younger and thinner, while it derives energy itself from the powers of the substance it confines. His idea of the animal physiology was similar. He conceived the brain and nerves of animals to be analogous to the pith of plants, and that it was confined by their cortical substance, for so he called their bones and muscles, as the pith is by the more solid parts of plants. He thought he traced the origin of the stamens, or male organs of vegetables, to their wood; and that of the pistils, or female ones, to their pith. Hence he deduced

deduced a fine fanciful hypothesis, that the mule offspring of crows impregnation should resemble its father in external habit and characters, and its mother in internal qualities, which opinion he also extended to the animal creation; nor did he want facts to support it. Both kingdoms were ransacked to supply them; for some facts may be found to support any hypothesis, any at least conceived by a mind so able, ingenious, and intelligent as that of Linnæus. Mule animals, whether those properly so called, produced between different species, or whether those engendered between varieties of the same species, are often found to resemble the father in their form or coat, while their constitution and disposition are more like the mother. The same thing may be observed in mule plants. Linnæus is unquestionably right in attributing the origin of the substance of the seed of plants to the female part of the flower, the function of the pollen being only to communicate life, or a power of vegetation, to the embryo, and not to convey any substance, or corpuscule, out of which the rudiments of the future plant are to be formed. At least this seems the most reasonable opinion, even from a contemplation of the experiments of those who have laboured to overthrow altogether his doctrine of the sexes of plants. It is difficult to say whether the embryo of a seed be formed at all before impregnation, because, if formed, it is very soon obliterated in case impregnation fails, a mere cavity being found in its place when the seed is at all advanced. But we have seen much more reason to believe its obliteration, rather than the contrary; and in most cases of non-impregnation, the cotyledons are obliterated also. See *COTYLEDONES, EMBRYO, and FECUNDATION of Plants.*

In another office which he attributed to the *medulla* or pith, Linnæus was unquestionably mistaken. He thought it the origin of the wood; believing that a layer was every year added internally to the body of a tree from this substance. Du Hamel refuted this opinion, by experiments, which clearly proved the wood to be deposited by the bark, as we have explained in the articles *CORTEX, and CIRCULATION of the Sap.*

But while we thus reject opinions of the great Swedish naturalist, which have been proved to want a solid foundation, it may be worth while to examine how far his general idea of the importance of the *medulla* may be defensible. No one can deny that there is a great analogy between this part and the nervous system of animals, with respect to situation and protection, as well as in its general uniformity of appearance and texture in widely different orders of plants; while the differences in these respects which it exhibits in other tribes, are not at all greater than those found in the nervous systems and brains of different classes of the animal kingdom. If, moreover, it be said, that the pith is of too simple a construction to allow a belief of its being of so great importance to the vegetable constitution, as to be the seat of life, or immediate organ of vegetation; surely we are as little able to discover any thing in the form or texture of the brain and nerves, to account for their wonderful but undeniable properties. Scarcely any phenomenon in the animal frame is less intelligible, than the change in the pith of a plant from its succulent state, to that dry congeries of an infinite number of close cells or vesicles, impervious to fluids, and having no communication with each other. Yet the moisture escapes by no means readily from the pith in its juicy state; for a thin slice of it in that state dries very slowly. The ingenious Mr. Knight has supposed the *medulla* to be a reservoir of moisture, to which the growing vegetable may have recourse, when its sap-vessels are occasionally exhausted by inordinate perspiration. "Plants," says this excellent writer, "cannot, like animals, fly to the

shade and the brook." This is undoubtedly true; but, instead of such a resource, their leaves when exhausted droop, or fold over each other; so that their pores are contracted, and the very check which their energy receives prevents further exhaustion, and gives time for fresh supplies from the root. Mr. Knight has indeed shewn that the part in question may, occasionally at least, be dispensed with, and removed from a branch without injuring it; but, on the other hand, he has more recently shewn the importance, if not of the *medulla*, of its analogous organ, the cellular substance; having found that substance capable, as he thinks, of assuming the vascular structure, and actual vegetation, of what Linnæus terms the cortical substance of a plant.

The writer of the present article has always been partial to the opinion of the *medulla* being, some how or other, an organ subservient to the vital energy of the vegetable frame; but we can still less, if possible, comprehend its mode of action, than that of our own brain and nerves. It is branched off and diffused, like the nervous matter, to every part of the vegetable body, and hence may easily be supposed to give life and vigour to the whole, though, no more than nerves, the organ or the direct source of nourishment; for its structure is such that it can transmit no fluids for that purpose from the vascular system; at least not in any way that we can comprehend, till it has taken upon itself a different organization from what is natural to it. The pith however is certainly most vigorous and abundant in young and growing branches, and must be supposed subservient, in some way or other, to their increase. Mr. Lindfay of Jamaica (see *LINDSÆA*), many years ago communicated a paper to the Royal Society, which, for some reason unknown to us, was never printed, the object of which was to prove a medullary knot in the leaf-stalk of the *Mimosa pudica*, or Sensitive Plant, to be the seat of that remarkable irritability for which the plant in question is celebrated. We are not however able to trace any thing of this nature in the stems of the Barberry, which are no less remarkable for their irritability. Nor can we trace, to any great extent, the nervous system of the insect tribe, even where we are not prevented by the minuteness of the object of our examination; though the animals of that tribe yield to none in the susceptibility and energy of their nervous system. In both cases the transparency of the parts may account for this difficulty.

We can therefore only reason by analogy concerning the functions of parts, whose structure cannot be ascertained, much less their mode of action. We shall conclude this article with the mention of one phenomenon, easily observable by any person who will bestow attention upon it. There are several species of Grasses, amongst which are the Common Cat's-tail, *Phleum pratense*, and the Floating Fox-tail, *Alopecurus geniculatus*, whose nature is to have an entirely fibrous root. Their proper station is in moist, or even watery situations. But if they chance to establish themselves in ground whose degree of moisture varies occasionally, or especially in very dry spots, as on the top of a wall, they acquire bulbous roots, of a very juicy nature. This is evidently a provision of Nature, to guard the plant against destruction from drought; as the tribe of naturally bulbous plants are, for the most part, intended to occupy dry, sandy, or barren ground, under a burning sun. The naturally bulbous grass *Poa bulbosa*, if cultivated in the rich and regularly watered soil of a garden, gradually loses its bulbous habit, becomes excessively luxuriant, and in time perishes, in consequence of exhaustion from that very luxuriance, to which the annual formation of bulbs, in its proper sandy situation, is a seasonable check. All these instances surely prove

prove the accumulation of *medulla* in such bulbous roots, to be equivalent to an accumulation of vital energy. They cannot be mere reservoirs of moisture, for all that they can possibly contain is not adequate to the supply of a few minutes perspiration from the herbage. They may indeed husband that moisture, so as to render the scanty supplies obtained by the fibres below, or by absorption through the leaves, sufficient to keep the half-starved plant from absolute destruction; their own extraordinary luxuriance proving the salvation of the parts which they seem to starve, but to which they are a necessary and certain resource. The just consideration of fleshy roots in general will be found to illustrate this subject; for though those of biennial plants must be considered as reservoirs of nutriment, hoarded up by the growth of the first season, for the inordinate supply of the next; the physiology of perennial bulbous roots seems to indicate, that all are likewise reservoirs of vital energy, of which the *medulla* is the immediate organ, and probably the exclusive residence. S.

MEDULLARY ARTERIES, in *Anatomy*, the arteries distributed on the substance which fills the interior of bones. See **MEDULLARY System**.

MEDULLARY Substance, is the white matter of the brain and nerves. See **BRAIN**.

MEDULLARY System, is the expression employed by Bichat to denote the tissue that occupies the interior of the bones. Its organical arrangement, vital properties, functions and diseases, are imperfectly understood. Some remarks on it will be found under the article **BONE**. It is found only in the bones, and its uses seem only relative to those organs: yet its organization and properties are so different as to justify us in considering it separately.

There are two kinds of it very distinguishable from each other: one occupies the cellular structure in the extremities of the long bones, and in all the interior of the short and flat bones: the other is found only in the middle of the former.

The first appears to consist of the ramifications of those vessels, which enter by numerous small holes of the surface into the common cellular tissue of the bone. They divide very minutely on the internal surfaces of the cells, producing the red appearance which characterizes that part, and which is more strongly marked in proportion as the subject is younger. To them, and the blood which they contain, is owing the red colour of the powdery substance produced in sawing through a bone. Fine injections propel the blood contained in this tissue, and make it appear in the adult as red as that of the fœtus when uninjected.

Authors have generally admitted the existence of a fine membrane in these bony cells, and have assigned to it the office of exhaling the medullary fluid. Bichat represents it as a merely vascular texture, without any continuous surface; and observes, that the bone itself, in many points, is in contact with the medullary fluid. It possesses merely the organic sensibility and contractility necessary for the secretion of its fluid, and is distinguished in that respect from the medullary system of the middle of long bones, which is the seat of well-marked animal sensibility. There is no sign of pain when it is irritated in a living animal. If it be very extensively injured, necrosis may ensue: but smaller injuries have not this consequence. Bichat perforated the extremity of a long bone in an animal, and then introduced a hot wire: it healed without necrosis.

The vascular network forming this system is obscured in the cartilaginous state of the bone by the gelatine: as that is removed, the cells and vessels become manifest. In the fœtus, and in the early years of life, it contains no oily fluid: at this time the blood is more abundant, and the cells are

filled with some fluid, of which the nature is not well understood. Medullary oil is afterwards deposited, and its proportion increases until the growth is completed. The cellular structure of an adult bone exposed to a pretty considerable heat parts with a large quantity of oily fluid: the same experiment tried on a fœtal bone produces only desiccation of the tissue from evaporation of its fluids. When the extremity of a long bone of the adult is set on fire, the contained medullary substance keeps up the combustion; in the fœtus, the bone ceases to burn as soon as it is removed from the fire, as the fluids will not maintain the combustion. The bones, when dried, remain white and dry in the fœtus: they are yellow and greasy in the adult at their extremities. Ebullition extracts much oil from the cellular tissue of adult bones, but none from those of the fœtus.

The second medullary system occupies the large cavity in the centre of the long bones. Each of such cavities is lined by a thin membrane, prolongations of which cover the thin portions of cellular tissue that project into the cavity, or pass from one side to the other, and form cells in which the medullary fluid is contained. The situation in which it exists, gives to it, when considered altogether, a nearly cylindrical form.

It does not appear that the ends of this system have any communication with the former: the two are separated by a marked line of distinction, and not gradually confounded: yet it is difficult to prove the point clearly.

The great delicacy of the membrane conceals the nature of its texture: it cannot be referred either to the serous, mucous, or fibrous class, and has no analogy in its functions, &c. with the periosteum, to which it has been often compared. A principal artery enters at the chief hole of each long bone, and ramifies on this membrane. Its branches give it, in the fœtus, a reddish colour, which disappears afterwards. Exposure of the containing cylinder to fire renders the membrane more apparent by corrugating and curling it up.

We have no means of bringing the properties that arises from structure (*propriétés de tissu*) in this system under our observation.

It enjoys animal sensibility in a very considerable degree, as we may prove by introducing a probe into the medullary cavity of a bone, by injecting an irritating fluid, or using any other mode of irritation.

The secretion and absorption of the medullary fluid prove the existence of organic sensibility, and of insensible organic contractility.

It is obvious from the preceding account, that the vital powers are more active in this than in the bony system, consequently that the vital phenomena must be more rapid, and the diseases less prone to assume the chronic form, than those which affect the bones.

The medullary membrane appears to exist in the cartilaginous state of the middle of long bones; but gelatine is then deposited in it, so that the whole bone is homogeneous in appearance. When ossification begins, the gelatine is absorbed, and the medullary cavity formed: the membrane admits red blood. At first, however, no oily matter is deposited in the cells: instead of it, there is a reddish mucilaginous fluid, which exhibits nothing of a greasy appearance when pressed between the fingers. No particles of oil swim in the water after it has been boiled. The middle of a long bone exposed to heat burns with the formation of inflamed drops: nothing of this kind occurs in the fœtus.

The function of the medullary membrane is to deposit, by exhalation, the medullary fluid, and to convey it again into the blood by absorption. It must therefore possess

exhalants and absorbents as well as blood-vessels, although we cannot demonstrate them anatomically. In this point of view the medullary system resembles the fat. It is hardly possible for us to know whether the exhalation be augmented or diminished by any causes. It is however certain, that in phthisis, dropsy, or other affections in which extreme general debility is produced by a gradual reduction of the vital powers, the medullary fluid loses its essential characters, and assumes an appearance altogether different from its natural one, without any alteration in the texture of the membrane. It has a mucilaginous or gelatinous appearance, almost like that of the fœtus.

That the medullary membrane has a close connection with the nutrition of the bone is rendered evident by the experiments of Proja, in which it is shewn that its destruction is followed by the death of the bone, and the formation of a new one, to which the periosteum serves as a nutritive parenchyma. The common way of proceeding has been to saw off the extremity of a long bone, and to introduce a red-hot wire into the medullary cavity, so as to disorganize the part completely. Soon after the periosteum swells, becomes inflamed, and extremely sensible to the touch. The inflammation disappears, and the sensibility is gradually rendered less acute. The internal layers of the membrane receive a deposition of gelatine, and thus a cartilaginous sheath is formed including the dead bone. After a certain time, of which the length may vary from many causes, phosphat of lime is deposited, and converts the cartilaginous into a bony sheath. The inner bone is now a dead body surrounded on all sides by a living one. Bichat, *Anatomic Generale*, tom. ii.

MEDULLARY Sarcoma, in *Surgery*, a name given by Mr. Abernethy to a kind of sarcomatous swelling, the consistence of which resembles that of the medullary substance of the brain. It is supposed by some to be a species of fungus hæmatodes. See **FUNGUS** and **TUMOUR**.

MEDUMACK, in *Geography*, a river of America, in the district of Maine, which runs into the sea, N. lat. 44°. W. long. 69° 15'.

MEDUNA, a town of Italy, in the country of Friuli; 12 miles W. of Concordia.

MEDUNCOCK, a plantation of America, in Lincoln county, Maine; 40 miles E.S.E. of Wiscasset, containing 380 inhabitants.

MEDUS, or **MEDINUS**, a name given by the writers of the middle ages to a stone brought from Media, of which they say there were two kinds, the one black, and the other green. They attribute many strange virtues to these stones; the black they say was a fatal poison when taken inwardly, but that if wetted with milk, and rubbed upon the skin of a woman with child, it caused her to bring forth a boy. This seems to be only a false history of the *medea* of Pliny.

MEDUSA, in *Botany*, is a name bestowed on this genus by Loureiro, from the long curling hairs of its capsule resembling the snakes which are fabled to have covered the head of Medusa. This name however is untenable, from its having been previously applied to designate a genus of *Vermes*. We are only acquainted with this plant as it occurs in Loureiro, and being unable to refer it to any other genus, we must be content to give that author's account of it.—Loureir. *Cochinch.* 406.—Class and order, *Monadelphia Polyandria*. Nat. Ord.

Gen. Ch. *Cal.* Perianth inferior, permanent, of five, ovate, hairy, incurved, spreading leaves. *Cor.* Petals five, ovate-oblong, curved, inflexed, afterwards reflexed towards the top, longer than the calyx. *Stam.* Filaments five,

thread-shaped, united at the base into a tube, equal in length to the corolla; anthers incumbent. *Pist.* Germen superior, nearly round; style awl shaped, hairy, the same length as the stamens; stigma simple. *Peric.* Capsule ovate, three-lobed, covered with numerous, long, twisted hairs, of one cell and three valves. *Seeds* six, roundish.

Ess. Ch. Monogynous. Calyx of five leaves. Petals five. Capsule with one cell, three valves, and six seeds.

1. *M. anguifera*. Snake-bearing Medusa. Cay chôm chôm dát, of the Cochon-Chine. Loureiro.—A tree of middling size, with ascending branches. Leaves alternate, ovate-oblong, serrated, pointed, smooth. Flowers red, not many on a stalk. Capsule hairy, opening in three lobes, which expand horizontally.

MEDUSA, in *Natural History*, a genus of the *Vermes*, *Mollusca* class and order, of which the generic character is, Body gelatinous, orbicular, and generally flat underneath; the mouth central, beneath.

The animals of this genus have been commonly denominated "sea-nettles," from the opinion that the larger species, when touched, excite a tingling sensation, and a slight redness of the skin: they are supposed to constitute the chief food of ectaceous fish; and most of them shine with great splendour in the water. The form of their body, while at rest, is that of the segment of a sphere, of which the convex surface is smooth, and the flat part provided with several tentacula. The body is transparent, and so gelatinous, that it is reduced almost to nothing by evaporation, when left on the shore. Several coloured lines may be seen within, but there is nothing that would lead one to think there is a circulation going on. The lines, which are more numerous towards the borders, seem to be appendages of the alimentary cavity. These animals swim well, and appear to perform that motion by rendering their body more or less convex, and thus striking the water. When left on the shore they are motionless, and look more like flat cakes of jelly, than living animals. There are about forty-four species distributed into two sections, viz. A. Body with ciliate ribs: and B. Those that have a smooth body. Many of the species are to be found in the seas about our own country, and will be marked as such with asterisks.

A. Body with ciliate Ribs.

Species.

INFUNDIBULUM. The specific character of this is, body ovate, with nine ciliate ribs. It inhabits the Indian, Mediterranean, and North seas; is about three inches and a half long. The body is obtusely eight-angled, hollow, transparent, open at the larger extremity, and of a firm gelatinous substance. It contracts and expands with great facility: ribs purplish, and furnished with a single row of short and slender fibres.

PILEUS. The body of this species is globular with ciliate ribs, and two ciliate cirri. It is found in the Mediterranean seas.

CUCUMIS. This is oblong with eight ciliate ribs, with cirri. It is found in the Greenland seas, and moves very slowly by means of the fibres on the ribs: when touched it contracts itself into the form of an apple. The body is white mixed with blue, and covered with irregular red spots: it has two apertures, terminal meeting in the oblong middle cavity. It probably derives its name from its shape and appearance.

OVUM. Ovate, with eight ciliate ribs and two pair of cirri, one pair of which is very long. Inhabits the Greenland

MEDUSA.

land seas, and resembles a bat, seldom larger than a pigeon's egg. The body is lucid and exceedingly fragile; the fragments, while alive, are blue.

B. *Body smooth.*

Species.

PORPITA. The body of this species is flat above, beneath it is a little convex, grooved, and villous. It is found in India.

* **CRUCIATA.** This species has a body marked with a milk-white cross. It inhabits the European seas. It has the appearance of a transparent colourless jelly; the body is furrowed at the margin with very fine fibres; the cross is marked with a brown spot on each arm. It is luminous when under sun-shine.

HYSOCELLA. The body is convex, having sixteen rays, and four united tentacula beneath. It is found in the sea round Portugal. The body above is whitish, the rays composed of extremely minute reddish-brown dots; beneath it is concave; the tentacula are longer than the body, lanceolate, and marked with reddish striæ.

* **ÆQUOREA.** This is a flattish species, with a villous inflected tentaculate margin. It is extremely simple, soft, and fringed at the margin with white.

* **AURITA.** Convex above, with an inflected fringed margin; beneath with four arched cavities near the centre. It is frequently found floating on the surface of the sea; is from two to four inches in diameter. When the sun shines upon the animals of this species, they reflect a beautiful splendour.

* **CAPILLATA.** The body is convex, with sixteen indentations round the margin, and numerous slender filaments beneath. It inhabits the ocean, and is about eight inches in diameter. The body is described as whitish, semi-pellucid, fragile; above convex, beneath flat with a rough circle; within this there are eight pair of rays; and a number of curled fibres and appendages from the centre: the margin is divided into eight portions, each of which is emarginated.

* **PILARIS.** This has a capitate disk, with eight small holes on the border: beneath it is arched and hairy. The body has an irregular reflected margin.

MARSUPIALIS This is found in the Mediterranean; is semi-oval with four tentacula on the margin, and resembles a puffer.

HÆMISPHERICA. This, as its name denotes, is hemispherical, with four transverse ribs beneath, and marginal tentacula and globules: the margin is entire: is not a quarter of an inch in diameter, and is found in the European seas.

PELAGICA. Hemispherical-concave, with a crenate incurved margin and eight tentacula. It is found in the American and Atlantic seas.

NOCTILUCA. This species is depressed, with reddish-brown warts and dots: margin with eight red tentacula.

* **FUSCA.** The body of this has sixteen brown rays and a brown circle in the middle; the circumference is edged with alternate crooked fangs and oval tubercles. It inhabits the coast of Cornwall. The tentacula are four, lacerated, and a little exceeding the body.

* **PURPURA.** The body of this species is decorated with pale purple rays, and a light purple cross in the centre, between each bar of which is a deep purple horse-shoe-shaped mark.

* **TUBERCULATA.** With fifteen brown rays meeting at the centre, and small oval tubercles round the margin; it

has four tentacula plain, and much longer than the body. It inhabits the coast of Cornwall.

* **UNDULATA.** This derives its name from its undulate margin; it has fangs on the projecting parts; beneath it has four orifices, between which is a stem divided into eight ragged tentacula. It is found on the coast of Cornwall.

* **LUNULATA.** The margin is tuberculate; beneath in the centre are four conic appendages forming a cross, with several others, like ferrate leaves, furrounding it. The tentacula are eight, not longer than the margin, and between each is a semi-lunar aperture. It inhabits the coast of Cornwall.

NUDA. Orbicular, blue, without crest; the tentacula of the disk are naked, with three rows of glands. It is found in the Mediterranean, and is never an inch in diameter. The body has a whitish disk above, and radiate with concentric striæ, the margin and border blue; the tentacula are filiform and blueish-hyaline.

VELELIA. This also is orbicular, blue, with an oblique simple crest or membrane, and numerous tentacula beneath. It inhabits the Atlantic and Mediterranean seas. The body is flat, thin oval, and marked with numerous tentacula beneath.

SPIRANS. Oval, blue, with oblique divided crest or veil, and numerous tentacula beneath. It is about two inches long, and inhabits the Mediterranean. Body thin, convex, and terminating in a whitish central knob above, blue with a brown border; crest two-parted and striate; the tentacula are filiform.

PULMO. Hemispherical-concave, with a fringed border; beneath striate, the stem with four openings and eight arms. It inhabits the Tuscan sea. This has been very minutely described in the following terms:

"Body gelatinous, pellucid, tough, crystalline. The head is large, hemispherical, concave beneath, and marked with numerous striæ, crossed by sixteen distant ligaments, each emitting a short branch on both sides. Border fringed with numerous roundish scallops. Stem large, thick, square, with four semi-oval openings, each of which has a large lobe above, and a smaller beneath. Eight branches or arms proceeding from the lower part of the stem, sub-cylindric, pendent, and wrinkled behind; besides these, there are sixteen subtrigonal appendages rising from the beginning of each branch, bisid in front, and terminated on the upper side by a flat wrinkled surface; the branches end in as many sub-pyramidical branchiæ, the two exterior sides of which are prominent, and ending in a thickly wrinkled surface: these are terminated by eight oblong sub-triangular thick pendent bodies, ending in three flat acute membranaceous pieces. Within the openings is a flexuous striate blueish-yellow band."

TYRRHENA. This, as its name imports, is found in the Tuscan sea. It is convex; the margin crenate, and furnished with very long fibres or threads; beneath are four tentacula. The body is smooth, tender, hyaline, spotted with red; beneath are four cavities, each marked with a red band.

TUBERCULARIS. The disk of this is prominent; the margin is eight times divided and striate beneath; it has eight tubercles. It is found in the Tuscan sea. The body is hyaline, and it is often two pounds weight; beneath fulvous, with innumerable curved fibres; tubercles blueish-white, ending in two stems, terminated by a pellucid whitish membrane, which is flaccid and blue or white at the tip.

UTRICULUS. This species is bottle-shaped, with a very long

long granular central tentaculum beneath; margin with numerous blue tentacula tipped with white. Inhabits the ocean; is hyaline, with about thirty marginal cirri.

CARAVELLA. Body ovate, with very long central tentacula beneath, and a crenulate veil above. It is found in the Atlantic, and inflames the hand by its touch. The body is thin, smooth, shining, blueish, hyaline, and tapering on each side; the crest runs through the whole length of the back; it is semi-lunar, compressed, furrowed with branched grooves, and marked with rosy veins; tentacula jointed, blue, fragile, and intermixed with shorter tubercles.

UMBRELLA. Tentacula of the disk naked, of the margin glandular; margin membranaceous, crenate. Inhabits the Mediterranean and Indian seas. The body is rigid, depressed, with radiate grooves above; beneath with a clavate trunk in the middle, surrounded with short clavate tubes; tentacula jointed with three rows of glands.

DIMORPHA. Back eminent; beneath a minute cross surrounded with five apertures; the margin is ciliate. It is found in the North seas. The body, when expanded, is orbicular, with a square inflexed margin; beneath it is concave; the back is divided into four parts by radiate grooves, with an elevated central cross and white fibres.

CAMPANULA. The disk is gibbous; the border wide and ciliate; beneath is a hairy cross. It inhabits the Greenland seas. The body is conic-orbicular, beneath hollow and foamy; the fringe of the margin and cross yellow; the latter is often white.

DIGITATA. Hyaline, with a pitted beneath in the centre; margin ciliate. An inhabitant of the Greenland seas. It leaps with its margin bent in. Body very minute, conic, striate; fringe yellow or white, and hooked within; pitted ending in a yellow or white pencil.

FRONSOSA. Margin of the disk varied with white opaque spots; it has eight tentacula, is dichotomous, and is beset with white pedunculate warts terminating in tufts. It is small, and found in the Archipelago. The body is flattish, a little convex above; the border is membranaceous, and fringed with white fasciculi; beneath is a villous nucleus, which in the lesser ones is eight-angled, and in the larger ones ten-angled.

TETRASTYLA. This is hemispherical, without tentacula; furnished with four marginal tubes united into a prism. It is found in the Red sea, and is about a span and a half across. Body hyaline, rather rigid; the tubes of the margin are linear, three inches long, straight and flat.

OCTOSTYLA. Hemispherical, without marginal tentacula; beneath is a four-folded column, with eight many-cleft lobes at the tip, and sixteen lateral appendages. This is likewise found in the Red sea. The body is of a blueish-hyaline, and is a full foot in diameter; the column beneath is about an inch and a half long.

ANDROMEDA. Hemispherical, without marginal arms; beneath there are eight round ramified foliaceous arms. An inhabitant of the Red sea. The body is transparent, of a pale yellowish-brown or blueish colour, with white rays and an entire margin; in the middle is a small black cross; the arms are white, and a little thicker than a goose-quill at the insertion.

CORONA. Hemispherical, without marginal tentacula; beneath there are eight cultrate arms, toothed each side below. It inhabits the Red sea. Body reddish-hyaline; it is about four inches across, with a blue cross in the middle; the arms beneath are broad, and two-lobed at the tip.

PERSEÆ. Hemispherical, hyaline, with an opaque white ring within, four times interrupted; there are no marginal tentacula. It is found in the Mediterranean. The body is

about two inches wide, with a very prominent margin; it has four arms, sub-lanceolate, about an inch long, and undulate at the margin.

CEPHEA. Hemispherical, tuberculate, reddish brown; beneath are eight arms villous at their extremities, and nine long filiform tentacula. It inhabits the Red sea. The body is pellucid, with eight paler rays; arms blueish, with black extremities; the tentacula are pointed.

PHRONOSIDALIS. Hemispherical, with a long proboscis in the middle beneath, and six marginal tentacula. This species inhabits the Mediterranean. The body is hyaline, two inches and a half broad, with a prominent equal margin; proboscis sub-flexile, and truncate at the tip, with a fringed folded versatile membrane.

MOLLICINA. Depressed, with twelve lateral apertures and tentacula. An inhabitant of the Mediterranean. The body is about an inch and a half in diameter, hyaline; the margin is prominent, with twelve plates.

PLEATA. Ovate-campanulate, with a hyaline globe above; within is an oblong red nucleus; the margin has numerous tentacula that are yellow at the base. Inhabits the Mediterranean. The body is an inch and half high; the margin a little contracted.

CUCIGERA. Hemispherical, with a reddish cross as wide as the body; the body is small, with four very minute, white, approximate rings above; the margin is thin, prominent, variously flexile, and often reddish; the tentacula are numerous, but not so long as the body is wide.

UNGUICULATA. Orbiculate; above flat, with sixteen rays; the margin is crenate, with sixteen slightly incurved fangs. It is found about the shores of Jamaica, and is the size of a nutmeg. The body is diaphanous, blueish, and spotted.

For a description of several of the above species, as affording an exhibition of light, and for an account of certain changes, recommended by Mr. Macartney, in the arrangement of the genera, and of the names of some of the species, we refer our readers to the article *LIGHT, Exhibition of, by living Animals*, at the close of the 20th volume of this work, having, in the present, confined ourselves to the Linnæan representation of the genus.

Mr. (now Sir Joseph) Banks, in his passage from Madeira to Rio de Janeiro, discovered a new species of the medusa, which, when brought aboard by the casting net, had the appearance of metal violently heated, and emitted a white light. With these animals were taken small crabs of three different species, altogether new, each of which gave as much light as the glow-worm, though the creature was not so large by nine-tenths. These luminous animals gave that appearance to the sea, which has been mentioned by many navigators, and of which various reasons have been assigned. It appeared to emit flashes of light exactly resembling those of lightning, only not so considerable, but so frequent, that sometimes eight or ten were visible at the same moment.

MEDUSA'S Head, in Botany. See *EUPHORMIA*.

MEDUSÆ CAPUT, in Natural History, a name given by authors to the *Stella marina*, called by some, from its various branchings, *Stella arborescens* Rumphius, Gesner, and many other authors, have described this strange fish in its recent state; and in the *Acta Eruditorum*, we have an accurate figure, and a very remarkable account of one which was found fossil, and preserved in a singularly perfect manner in stone.

The stone in which it was found was of the fissile or flaty kind; and it was so large as to extend over a piece of this stone of four feet in length, and between three and four in breadth. The body of the fish, from which all the rest seem

originally to have arisen, lay at one corner of this stone, and the arms extended themselves lengthways in a very distinct and natural manner the whole length of the stone; and from these there parted, on every side, other smaller ones; and these were finally divided into others more minute, in such a manner as to represent the nicest painting. *Act. Erudit. ann. 1725, p. 377.*

The study of fossils is more improved by this single specimen than by thousands of others, and by the reasonings of almost as many authors. The fossils called *entrochi* have always perplexed the writers on these subjects to account for: some having judged them a sort of stony vegetables; some a *lusus naturæ*; and others, as different things; but in this table the whole fish is so perfectly preserved, that there can remain not the least doubt of its being really the *stella arborescens*; and in this both the figure and author's words express, in the plainest manner possible, that the long arms or branches, reaching from one end to the other of the stone, are composed of a number of *entrochi* as it were, tied together in the same manner as the single joints of those *entrochi*, which we meet with, are to one another: or, in plain fact, that our *entrochi*, which have perplexed us so much to account for their origin, are in reality the fragments of the arms or branches of this fish. These branches in this famous specimen were composed of what we call *trochite*, and had many rudiments of smaller branches, as well as perfect ones, growing from their sides, and would have been so many common *entrochi*, if broken off.

What was most remarkable in this fossile was, however, the separating of smaller branches which ran entire to their ends, and there terminating in an infinite number of small ramifications, all growing from one head, they formed clusters of four or five inches in diameter, and of an inconceivable beauty, resembling the compound flower of some elegant plant. The matter of the large branches, when examined, appeared to be the same with that of the common *entrochi*, that is, spar. The author calls it *selenites*, but that was a word indeterminately used by authors, till of late, for all plated and bright fossils.

It is plain that this complete fish could have no way come into this stone but at the time when it was yet moist and soft: and the author calls it *novum diluvii monumentum, a new remembrancer of the deluge.*

MEDUSÆ Caput, or *Medusa's Head*, in *Ancient Mythology*, occurs frequently both on the breast-plates and shield of *Minerva*; in some of which it is the most beautiful, and in others the most shocking object. In some figures the face is represented as dead, but with the most perfect features that can be conceived; in others, her face is full of passion, and her eyes convulsed; and in many others, the look is altogether frightful, and formed on purpose to inspire terror. The beauties and horrors of *Medusa's* face are mentioned by the Roman poets. *Ov. Met. iv. ver. 793.* *Lucan, lib. ix. ver. 680.* *Virg. Æn. viii. ver. 438.* *Spence's Polymetis, p. 61.*

MEDWA, in *Geography*, a town of *Nubia*, on the borders of *Dar-für*; 80 miles N. of *Cobbe*.

MEDWAY, a river peculiarly connected with the county of *Kent*, England, was called by the Britons *Vaga*, a name descriptive of its sinuous course and mazy wanderings. The Saxons changed this appellation to *Medweg* and *Medwege*, from which the present name is a corruption. This river has four principal sources, one in *Kent*, two in *Suffex*, and a fourth in *Surrey*. The latter rises at *Blechingly*, and entering *Kent*, flows on to *Eaton bridge* and *Penhurst*, below which it is joined by one of the branches that rise in *Suffex*, and being augmented by various smaller streams, proceeds

through a beautiful country to *Tunbridge*. A little above this town the river separates into several channels, the northernmost of which is navigable, and is again joined by the other divisions about two miles below *Tunbridge*. Thence proceeding to *Twyford bridge* and *Yalding*, it receives the united waters of the two remaining principal branches; one of which flows from *Waterdown forest* in *Suffex*, and is swelled by the *Bewle* and *Theyse* rivulets; and the other of which rises at *Goldwell*, near *Great Chart*, in *Kent*; this also receives several lesser streams in its progress, and is increased by the waters of the former branch above *Hunton*. From *Yalding*, the *Medway* flows in a winding direction to *Maidstone*, and thence in a wildly devious channel, gradually augmenting in depth and breadth, it pursues its picturesque course to *Rochester*. Proceeding hence towards *Sheerness*, it passes *Chatham*, *Upnor castle*, and *Gillingham fort*; after which it greatly increases in width, and still preserving its meandering character, flows onward to the *Thames*, which it enters between the isles of *Graine* and *Shepey*, having first united its waters to those of the *Swale*. The *Medway* and its numerous tributary streams are calculated to overspread a surface of nearly thirty square miles in the very midst of *Kent*. The tide flows nearly as high as *Maidstone*; but at *Rochester bridge* it is strong and rapid; and below that, all the way to *Sheerness*, a distance of about twenty miles, the bed of the river is so deep, and the reaches so convenient, that many of the largest line of battle ships are moored here, when out of commission, as in a wet dock, and ride as safely as in any harbour of *Great Britain*. In the great storm of 1703, the *Royal Charlotte* was driven on shore here, and lost.

The *Medway* was first made navigable to *Tunbridge* about the middle of the last century, under the provisions of an act of parliament, which passed in the year 1740; though an act had been procured for the purpose in the reign of *Charles II.* By the last act, the undertakers were incorporated by the style of "The Proprietors of the Navigation of the River *Medway*;" and were empowered to raise 30,000*l.* to complete the work, in shares of 100*l.* each. The trade on this river is very great, and includes a vast variety of articles, many of them of the very first necessity, and which, before the navigation was completed, could only be obtained by a circuitous land-carriage. The river is plentifully stored with fish of various species; and was in former times much celebrated for its salmon and sturgeon; the latter, in particular, were so abundant, that a considerable part of the revenues of the bishops of *Rochester* were derived from a duty levied on their sale. They have now in a great measure left the river, but are still occasionally taken of considerable bulk. On the *Medway*, and in the several creeks and waters belonging to it, within the jurisdiction of the corporation of *Rochester*, is an oyster-fishery; and the mayor and citizens hold a court every year, called the *Admiralty court*, for regulating this fishery, and preventing abuses in it. The powers of this court have been established and enforced by two acts of parliament. *Hasted's History and Antiquities of Kent, 12 vols. 8vo.* *Beauties of England and Wales, vol. vii. by E. W. Brayley.* *Ireland's Picturesque Views on the River Medway, 8vo.*

MEDWAY, a post-town of *America*, in *Norfolk county*, *Massachusetts*, bounded E. and S. by *Charles river*, which separates it from *Medfield*; it has two parishes of *Congregationalists*, and contains 1050 inhabitants; 25 miles S.W. of *Boston*.

MEDWAY, or *Midway*, a settlement in *Liberty county*, *Georgia*, formed by emigrants from *Dorchester*, in *South Carolina*, about the year 1780; 30 miles S. of *Savannah*.

MEDWI,

MEDWI, a town of Sweden, in East Gothland, near the Wetter lake, much frequented on account of a celebrated mineral spring.

MEDZIBOZ, a town of Poland, in Volhynia; 20 miles S. of Constantinow.

MEDZIRON, a town of Persia, in the province of Khorasan; 60 miles E. of Meshed.

MEEADAY, or **MEHEDUNG-YAY**. See **CUOCODILE Town**.

MEEKNESS, in *Ethics*, is a virtue which consists in bearing affronts, reproaches, and injuries, with a due composure of mind. Its opposite vice is *revenge*.

MELLAH, in *Geography*, a town of Algiers, in the province of Constantina, supposed to be the Milevum of the ancients, built in the midst of interspersed vallies and mountains, surrounded with gardens, and abundantly supplied with fountains; one of which bubbles up in the centre of the city, and is received into a large square basin of Roman workmanship. Its pomegranates are delicious, and it supplies Constantina with herbs and fruit; its apples are also so good, that the name of the town has been derived from that fruit; 13 miles N.W. of Constantina.

MEËN, **St.**, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Montfort. The place contains 806, and the canton 9905 inhabitants, on a territory of 202½ kilometres, in 9 communes.

MEENAH EL DSAHAN, a sea-port town of Arabia Petraea, situated on the E. coast of the gulf of Accaba, in the N. part of the Red sea, with a spacious harbour, anciently "Ezion-geber;" 50 miles S. of Ailah.

MEENDOR, a town of Hindoostan, in the circar of Condapilly; 18 miles W. of Masulipatam.

MEENEES, a small island in the Sooloo Archipelago. N. lat. 6 32'. E. long. 121 35'.

MEENKOOT, a town of Bengal; 14 miles N. of Moorshedabad.

MEER, **JOHN VANDER**, in *Biography*. There were three painters who bore this name. One was devoted to the study of sea-pieces, but he sometimes painted battles by land, and executed them with very considerable skill. Another was an historical and portrait-painter; but he who best deserves renown, was a disciple of Nicholas Berchem, and succeeded admirably in imitating the style of that master. The subjects he chose were generally rather of a more confined nature than Berchem's, but they are touched with nearly equal clearness and spirit; with more softness and delicacy in their effects. He is known by the name of De Jonghe, or the Young, to distinguish him from the ship-painter, who was called the Old Vander-Meer. De Jonghe died in 1688.

MEER, in *Mining*, a space containing twenty-nine yards in length in any vein.

MEER-flake, is a pin of wood drove into the superficies of the earth, to shew the extent or end of a meer of ground.

MEER-swain, in *Ichthyology*, a name given by some to a sea-fish, more usually known by the name of *caprifiscus*; which see.

MEERBECK, or **MELBECK**, in *Geography*, a town of France, in the department of the Lys, on a small river which runs into the Mandel; eight miles N. of Courtray.

MEERCASERAI, a town of Bengal, in the province of Chittigong; 31 miles N.W. of Islamabad. N. lat. 22° 47'. E. long. 91° 42'.

MEERGUNGE, a town of Bengal; five miles S.E. of Mahmudpour.—Also, a town of Hindoostan, in Benares;

20 miles S.S.W. of Jionpour.—Also, a town of Hindoostan, in Oude; 44 miles E. of Fyzabad.

MEERGUR, a town of Bengal; four miles N. of Dinagepour.

MEERHOLZ, a town of Germany, seated on the Kinzig, giving name to a branch of the house of Ifenburg, called Ifenburg-Meerholz; 17 miles E. of Frankfort on the Main.

MEERJAPOUR, a town of Bengal; six miles S. of Nogong.

MEERJASERRA, a town of Bengal; 25 miles N. of Mauldah.

MEERJEE, or **MEERZAW**, a town of Hindoostan, in Canara, on the coast; 10 miles N. of Onore. N. lat. 14° 28'. E. long. 72° 10'.

MEEROAT, a town of Candahar; 45 miles W. of Ghizni.

MEERPOUR, a town of Bengal; 11 miles S. of Calcutta.

MEERSCHAUM, Werner, *Ecume de Mer*, Broch., and *Keffekil*, Kirwan, in *Mineralogy*, a substance of yellowish-white colour, which occurs in mass, of fine-grained structure, earthy, passing into flat conchoidal, or small flaty, with indeterminate angular, and moderately sharp-edged fragments. This mineral is opaque, soft, easily frangible, acquires a polish by friction, and is unctuous to the touch. Its specific gravity is 1.6. In acids it may be partly dissolved without effervescence, and cannot be fused without addition by the blowpipe. The analyses of Wiegleb and Klaproth give the following results, in which there is a difference, owing to Klaproth's having analysed the fresh earth, and Wiegleb's having examined that which was formed into a tobacco pipe, and consequently baked, and deprived of its water and carbonic acid.

	Wiegleb.	Klaproth.
Silex	54.16	50.5 41
Magnesia	51.66	17.25 18.25
Lime	-	0.5 0.5
Water	-	25. } 39.0
Carbonic acid	-	5. }
	105.82	98.25 98.75

For the uses to which this substance is applied among the Turks, see **KEFFEKIL**. This latter name is derived from Kassa, a town of the Crimea, where it is shipped for Constantinople. It is also found in Natolia, and in the islands of Samos and Negropont. When dug from its thin beds, it is soft, and hardens by being exposed to the air.

A similar substance has been discovered by Fabbroni at Castell del Piano, near Sienna. This consists of 55 parts of silex, 25 of magnesia, 12 of alumine, 3 of lime, and 0.1 of oxyd of iron: and has been formed into bricks which float in the water. This manufacture revives one of the lost arts recorded by Strabo and Pliny.

MEERSEN, in *Geography*, a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Maeltricht. The place contains 1149, and the canton 11,530 inhabitants, on a territory of 115 kilometres, in 16 communes.

MEERTA, a town of Hindoostan, in the Subah of Agimere; 42 miles W. of Agimere. N. lat. 26° 23'. E. long. 74° 32'.

MEËS, **LES**, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of

of Digne; 12 miles S.W. of Digne. The place contains 2021, and the canton 6305 inhabitants, on a territory of 57½ kilometres, in 8 communes.

MEESIA, in *Botany*, a genus of Mosses, established by Hedwig, *Fund. v. 2. 97. t. 9. f. 56, 57*, and named by him in memory of David Meese, author of the *Flora Frisica*, an 8vo. of 87 pages, with two plates, published in 1760. This botanist has also published an arrangement of plants, in Latin and Dutch, founded on their cotyledons and mode of germination; and a work on the Syngeneious class of Linnaeus. Hedwig celebrates him as having first seen the stamens of the *Polytrichum*, and as being the first person who ever raised that moss from seed. *Meesia* differs from the *Bryum* of Hedwig, solely in the shortness and bluntness of the teeth of its external fringe, which are not half so long as the inner one. The author indeed, in his original species, found an auxiliary character in the reticulated structure of this inner fringe; but this differs only in degree, and that very slightly, from what is observable in every *Bryum*, nor is it found in the other *Meesia*. Three species are all that have been referred to this supposed genus, in the latest work of Hedwig, his *Species Muscorum*; and these have been reduced by the author of the *Flora Britannica* and others to *Bryum*. They are

1. *M. longifeta*. Hedw. *Crypt. v. 1. 56. t. 21, 22.* (*Bryum triquetrum*; *Turn. Musc. Hib. 115. Engl. Bot. t. 2394.* *Mnium triquetrum*; *Linn. Sp. Pl. 1578*, excluding the synonyms.)—Stem subdivided. Branches simple, erect. Leaves spreading in three rows, ovato-lanceolate, sharp-pointed, finely serrated. Capsule slender pear-shaped, oblique and incurved. Lid conical.—This fine moss, distinguished from all others by the length of its *fruit-stalks*, which extends to three or four inches, is found in bogs in Sweden, Switzerland, and, since the publication of *Fl. Brit.*, in Ireland. Hedwig erroneously describes the *leaves* as entire, notwithstanding the elaborate detail of the two folio plates which he has devoted to this species.

2. *M. uliginosa*. Hedw. *Crypt. v. 1. t. 1, 2.* (*Bryum trichodes*; *Sm. Fl. Brit. 1350. Engl. Bot. t. 1517.*)—Native of bogs in Germany and Scotland. Hedwig says it is common on alpine calcareous rocks in Austria.

3. *M. dealbata*. Hedw. *Sp. Musc. 174. t. 41. f. 6—9.* (*Bryum dealbatum*; *Sm. Fl. Brit. 1350. Engl. Bot. t. 1571.*)—Native of Sweden and Scotland; as well as of St. Faith's bogs, near Norwich. The *leaves* are of a singularly whitish green, finely reticulated.

These two last species are described by the late Mr. Wood, in our article *BRYUM*, n. 4 and 5. The first was omitted there, not being known at that time as a British plant.

MEETKA, in *Geography*, a country of Africa, W. of Bergoo.

MEFLESS, a town of Bohemia, in the circle of Königgratz; 14 miles N.E. of Königgratz.

MEGADOMESTICUS. See *DOMESTIC*.

MEGÆRA, in *Mythology*, one of the three furies. She is represented with serpents on her head, and two distinguished ones over her forehead, as her sisters have, and, like them, with torches. She is not mentioned so frequently by the Roman poets as the others are. Virgil gives us a descriptive picture of her, where he is speaking of the punishment of the Lapithæ; who were said to be always placed round a table very richly and plentifully set out, with a loose piece of rock hanging over their heads, as just ready to fall; and this fury attending close by, to watch and menace them, the moment they endeavoured to taste any one of the tempting things set before them. *Æn. vi. ver. 607.*

MEGAIZEL, in *Geography*, a town of Egypt; six miles N. of Rosetta.

MEGALA, a town of Tunis; 3 miles N.E. of Spaitla.

MEGALARTIA, Μεγαλαρτία, in *Antiquity*, a festival in honour of Ceres, being the same with Thesmophoria.

MEGALASCLEPIA, Μεγαλασκληπεία, a festival in honour of Æsculapius. See *ASCLEPIA*.

MAGALENSIA, or **MEGALESIA**, solemn feasts celebrated among the Romans on the twelfth of April, in honour of the great mother of the gods, that is, Cybele or Rhea: wherein were sports or combats held before the temple of that goddess.

They were called *megalensia*, from the Greek *μεγαλη*, great, Cybele being accounted the great goddess.

MEGALONISI, in *Geography*, a small island in the Mediterranean, near the coast of the Morea; two miles E. of Leucadia.

MEGALOPOLIS, in *Ancient Geography*, now *Leontari*, a large city, as its name imports, in the southern part of Arcadia, upon the river Helisson. Pausanias observes, that it was the most modern of the cities of Arcadia, if we except those which had been renewed by Roman colonies, after the victory of Octavius over Antony. It owed its foundation to the counsels and activity of Epaminondas, who in the year 365 B.C., being desirous of keeping the Lacedæmonians in that state of subjection to which they were reduced, induced the Arcadians to establish this city, and to settle in it a numerous colony, collected from different cities, so that it might serve as a fortress and a bulwark against Sparta. To favour them in this enterprise, and to protect them in their labours, he sent them a guard of a thousand chosen men, under the command of Pammenes. The city being thus fortified and defended, the Arcadians confided in its strength and security; and on the other hand their enemies were the more desirous of attacking it. To this object they directed their whole force; but the Megalopolitans for a long time vigorously resisted them. At length, however, *viz.* in the year 224 or 225 B.C. it fell, partly by surprize, and partly by a violation of treaties, under the power of Cleomenes, king of Sparta. The greater number of the inhabitants retired to Messenia, and emboldened by the counsels and example of Philopœmen, they refused the offer made them by Cleomenes, of remaining in their own city, on condition of concurring in the Achæan league. Philopœmen, upon their return to Arcadia, encouraged them to rebuild their city, and to adorn it with temples and magnificent edifices, which restored its former splendour. It is needless to enumerate its temples and statues, and other ornaments. The most considerable monument which the southern part of Megalopolis presented, was the theatre, a building so grand and magnificent, that it even exceeded in extent and beauty all those of Greece. We learn from Polybius that, next to Athens, Megalopolis was the grandest and most splendid city of Greece.

MEGAMETER. See *MICROMETER*.

MEGARA, in *Ancient Geography*, the capital of the territory of the Megarians, which has been commonly comprised in Attica, bounded eastward by mountains, and extends westward as far as a district of the isthmus of Corinth. Megara, which had previously been called Nisa, derived its name either from Megarius, the surname of Minos, a Bœotian chief, who succeeded the king of Nisa, or from Megara, the name given to ancient temples erected in honour of Ceres, or from Megara, a supposed wife of Hercules. Under the reign of Codrus, the Peloponnesians having declared

clared war against the Athenians, and miscarried in their enterprise, returned and took possession of Megara, which they peopled with Corinthians. Besides two citadels, this city had several magnificent structures and ornaments; one was an aqueduct, distinguished by the grandeur and beauty of its columns, constructed by Theagenes, tyrant of Megara; another was a statue of Diana, the protectress; to which we may add, the statues of the twelve great gods, attributed to Praxiteles; a group consecrated to Jupiter Olympius, in which was a statue of this deity, with the face of gold and ivory, and the rest of the body of burnt earth; and upon the path that led to one of the citadels of Megara, called Caria, were a temple of Bacchus Nyctalus, another of Venus Spiltrophia, a chapel dedicated to the Night, whence issued her oracles; a temple of Jupiter; two statues, one of Æsculapius, and one of Hygeia, executed by Briexis, and a temple of Ceres, called the Megaron; north of the citadel, near the temple of Jupiter the Olympian, was the tomb of Alcmenes, and that of Hyllus, son of Hercules; a temple of Apollo and Diana, the tomb of Hippolyta, queen of the Amazons, and the tomb of Theraea. Besides these edifices, there were in the second citadel, called the citadel of Aleathous, a tomb of Megareus, and a temple of Minerva, with her statue, the body of which was gilt, and the face, feet, and hands were of ivory, &c. &c. See Pausanias in Attica, c. 39—44.

MEGARA was also the name of a town on the eastern coast of Sicily, on the gulf of Megara, otherwise called Xiphonius, N. of Syracuse. This city, which is said to have been built here by the Greeks of Megara, the city of Achaia, (see the preceding article,) gave name to the mountain, called "Hybla Megara." This colony, 100 years after its establishment, founded Salinus, which was destroyed by Marcellus when he besieged Syracuse. The ruins of Megara are now scarcely discernible.

MEGARA, a town of Illyria.—Also, a town of Pontus.—Also, a town of Asia, in Syria, dependent upon Apamea.—And also, a town of Greece, in the Peloponnesus.

MEGARA, in *Geography*, a town of European Turkey, in the province of Livadia, on the coast of the gulf of Engia, once the capital of a republic, now very much reduced; 26 miles W. of Athens.

MEGARBE, a town of Nubia; 9 miles W.S.W. of Mafuah.

MEGARIS, or the MEGARIDE, in *Ancient Geography*, a country of Attica. See MEGARA *supra*.

MEGARIS, a town of Italy, in Campania, placed by Pliny between Naples and Paulilipo.

MEGATHERIUM, in *Natural History*, a genus of the class Mammalia, order Bruta. This is generally known by the name of *mammoth*. It has a near resemblance to the elephant, but its having never been found alive, nor with its organs in a perfect state after death, its generic character cannot be accurately ascertained. By some accounts from St. Petersburg, it is supposed that the animal still exists in a living state, though it has hitherto escaped the researches of modern naturalists. Its residence appears to have been confined to a line in the northern hemisphere, extending from Siberia to the banks of the Ohio, and the common name of mammoth was first given to the skeleton when dug from the earth by a Siberian peasant. The following is the best account we have of this animal: it was received from St. Petersburg, and relates to a specimen found, though not alive, yet in a complete and almost perfect state of preservation. A Tungoose chief, in the summer of 1799, when the fishing in the river Lena was over, repaired, according to annual custom, to the sea-side. Leaving his family in their huts, he

coasted along the shore in quest of the tusks of the mammoth, when he accidentally perceived, in the midst of a rock of ice, a large shapeless block, not at all resembling the logs of drift wood commonly found there. He climbed the rock, and examined it all round, but could not ascertain what it was. The next year he returned, and found the carcass of a *teribeus rosmarus*, and observed that the mass which he had seen before was freer from ice, but that there were two similar pieces by the side of it. These proved to be the feet of the mammoth. In 1811, the side of the animal and one of its tusks appearing very distinctly, he acquainted his wife and some of his friends with what he had found. An alarm was instantly spread: the aged people affirmed that a similar monster had been seen once before, and that the whole family of the person who discovered it soon became extinct. At first the chief, terrified at the report, abandoned his prize, fell sick, and was brought nearly to the grave; but on his recovery, he was more resolute, and was determined not to relinquish the expectation of the profit he might make of the tusks. It was not, however, till the fifth year, that the ice had melted sufficiently to disengage the mammoth, when it fell over on its side on a bank of sand. The Tungoose was quite satisfied to take away the tusks, which he bartered for goods to the value of 50 rubles, or rather more than 11*l*. Being satisfied with the prize, the carcass was left to be devoured by the bears, wolves, and foxes. Previously to this he had made a rude drawing of it, which represented it as having pointed ears, small eyes, horse's hoofs, and a bristly mane extending along the whole back. In 1806, Mr. Michael Adams, of Petersburg, being at Yakoutsk, heard of the circumstance, and proceeded to the spot, in order to investigate every thing relating to it. Before his arrival, the skeleton was stripped of its flesh, but was itself entire, with the exception of one fore-foot. The vertebræ, one of the shoulder-blades, the pelvis, and the remaining three extremities, were held firmly together by the ligaments of the joints, and by strips of skin and flesh. It received some damage in the removal to Peterburg, a distance of almost 7000 miles. The ears, however, were preserved, and the pupil of the left eye was perfectly distinguishable. From other parts it proved to be a male, with a long mane, but had neither tail nor trunk. From the structure of the os coccygis, Mr. Adams did not entertain a doubt that it had a short thick tail, and he thinks it must have had a proboscis. The skin was of a deepish grey colour, and covered with reddish hair and black bristles. The head weighed 460lb.; the two horns weigh 400lb.: the entire animal was 10½ feet high, and full sixteen feet long. Mr. Adams has seen the tusks, and says they are so curved as to form three-fourths of a circle. They are curved in the direction opposite to those of the elephant, bending towards the body of the animal. In 1801, Mr. William Peale, proprietor of the museum at Philadelphia, succeeded in obtaining a skeleton so nearly complete, that, by a few additions only, he rendered it, as it were, perfect. This skeleton was brought to London, and exhibited eight or nine years ago.

The generic name of *Megatherium* was first given to it by M. Cuvier, who has accurately examined the skeleton; and to the generic name he added the trivial one of *Americanum*. In Dr. Shaw's *Zoology* it is described as a species of the *Manis* genus, and is denominated *Manis megatherium*. According to Cuvier, the skeleton which he saw at Madrid was twelve feet long, and about six in height. The spine is composed of seven vertical, sixteen dorsal, and four lumbar vertebræ. It has sixteen ribs; the sacrum is short, the ossa ilia very broad. The thigh-bones are excessively thick, and the leg-bones still more so in proportion. The entire sole of
the

the foot bore on the ground in the act of walking. The shoulder-blade is much broader than long: the fore-limbs are longer than the hind. The head is the greatest singularity of the skeleton. The occiput is elongated and flattened, but is convex above the eyes. The two jaws form a considerable projection, but without cutting teeth, all grinders, with a flat crown, and grooved acrofs.

This quadruped, in its character, differs from all known animals: and each of its bones, considered apart, also differs from the corresponding bones of all known animals. This results from a comparison of the skeleton with that of other animals, for none of the animals which approach it in bulk, have either pointed claws, or a similarly formed head, shoulder-blades, clavicle, pelvis, or limbs. "As to its place in the system of quadrupeds," says the French naturalist, "it is perfectly marked by the sole inspection of the ordinary indicatory characters, that is, the claws and teeth. These shew that it must be classed in the family of unguiculated quadrupeds, destitute of cutting teeth, and in fact it has striking relations with those animals in all parts of its body. This family is composed of the *dasybus*, *bradypus*, *manis*, *myrmecophagus*, and Cape ant-eater, or *orycteropus*. The thickness of the branches of the lower jaw, surpassing even that of the elephant, seems to prove that this vast animal was not content with leaves, but, like the elephant and rhinoceros, broke on the ground the branches themselves; its close and flat-crowned teeth appearing very proper for that purpose." Cuvier thinks there are indications that this animal had a trunk, but that it must have been short, since the length of the head and neck together only equals that of the fore-legs. He places it between the *bradypus* and the *dasybus* genera, because to the shape of the head of the former it joins the teeth of the latter. It would be necessary to know particulars, of which a skeleton cannot inform us, in order to determine to which of these it approached the most. "This adds," says Cuvier, "to the numerous facts which apprise us that the animals of the ancient world were all different from those we now see on the earth, for it is scarcely probable that if this animal still existed, so remarkable a species would have hitherto escaped the researches of naturalists. It is also a new and very strong proof of the invincible laws of the subordination of characters, and the justness of the consequences deduced for the classification of organized bodies: and under both these views, it is one of the most valuable discoveries which have for a long time been made in natural history."

MEGE, in *Geography*, a town of Persia, in Faristan; 10 miles S. of Isfahan.

MEGEVE, a town of France, in the department of the Leman, and chief place of a canton, in the district of Boverville. The place contains 3075, and the canton 9951 inhabitants, on a territory of 180 kilometres, in seven communes.

MEGGIO, a town of Africa, in Fez; nine miles from the Mediterranean.

MEGHARISH UZZUR, or ACRA, a town of Arabia, in the province of Hedsjas; 85 miles E.S.E. of Madian.

MEGHEM, or MEGEN, a town of Brabant, on the Meuse; 12 miles S. of Nimeguen.

MEGNITZESC, a town of Sclavonia; 18 miles W.S.W. of Verovitz.

MEGRA, a town of Russia, in the government of Archangel, on the E. coast of the White sea; 72 miles N. of Archangel.

MEGUNTICK, a lake of Canada, on the borders of Maine. N. lat. 45° 44'. W. long. 70° 25'.

MEHALLE' EL KEBIRÉ, a town of Egypt, capital of

Garbia, the second province of the Delta, and the residence of a bey. As there is no town more considerable in the Delta, it is called Kebira the Great. It has manufactories of linen and some sal ammoniac works. A great deal of business is done there. The rivers which surround it serve for the conveyance of its merchandize through Egypt. Its environs are covered with villages, flocks, and the various productions of a fertile soil; 47 miles N. of Cairo. N. lat. 30° 50'. E. long. 31° 24'.

MEHALLEBEG, a town of Persia, in the province of Irak; 25 miles S.E. of Rai.

MEHALLET EL EMIR, a town of Egypt, on the Nile; six miles S.E. of Rosetta. N. lat. 30° 50'. E. long. 30° 24'.

MEHALLET *il Loben*, a town of Egypt; 16 miles S. of Faoué.

MEHALLET *Malek*, a town of Egypt; five miles S. of Faoué.

MEHALLET *il Meshak*, a town of Egypt; five miles N.N.E. of Tineh.

MEHAMA, one of the smaller Friendly islands, in the Pacific ocean; four miles E. of Neeneeva.

MEHEGAN, WILLIAM ALEXANDER, in *Biography*, was born at la Salle, in the Cevennes, in the year 1721, of a family originally from Ireland, which had followed the fortunes of James II. He was prevented from adopting the profession of arms, in which his family had been distinguished, by ill health, and cultivated the belles lettres, attaching himself particularly to the study of eloquence. When Frederic V. king of Denmark founded, in the year 1751, a professorship of the French language, M. de Mèhègan composed a discourse which was pronounced at the opening of the lectures in Copenhagen. In the following year he published a work entitled "L'Origine des Guebres; ou la Religion naturelle mise en Action," which was looked upon as breathing the spirit of modern philosophy. This was followed at distant intervals by "Considerations sur les Révolutions des Arts;" "Pièces fugitives;" "Mémoires de la Marquise de Terville;" "Lettres d'Aspasie;" and in 1759 "L'Origine, le Progrès, et la Décadence de l'Idolatrie." He died in 1766, and after that event, was published; as a posthumous work of M. Mèhègan, "Tableau de l'Histoire moderne," in three vols. 12mo. This is highly esteemed on account of the warmth and eloquence of the style, and the generally impartial and philosophical spirit by which it is animated. The history commences with the year 476, and concludes with the peace of Westphalia in 1648. "It is," says his biographer, "full of picture and portrait, upon which he sometimes throws too strong a glare of colouring; he has, however, succeeded in making his work much more interesting than abridgments usually are, and at the same time has judiciously selected the points of instruction." There is an English translation of it. In 1767 was published another posthumous work of this author, entitled "L'Histoire considérée vis-à-vis la Religion, les Beaux-Arts, et l'Etat," in three volumes 12mo. Gen. Biog.

MEHEM, in *Geography*, a town of Hindoostan, in the subah of Delhi; 27 miles W S.W. of Rodak.

MEHERRIN, a town of America, in North Carolina; 25 miles E. of Halifax.—Also, a river of Virginia, which runs into the Chouan, 20 miles N.W. of Hartford, in N. Carolina.

MEHINDEY, a river of Hindoostan, which runs into the gulf of Caubay, about 40 miles S. of Amedabad.

MEHITPOUR, a town of Hindoostan, in Labore; 45 miles S.E. of Sultanpour.

MEHRIBAN, a town of Curdistan; 22 miles S.E. of Sherezur.

MEHUN, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges, situated on the Eure; seven miles N.W. of Bourges. The place contains 1267, and the canton 7064 inhabitants, on a territory of 287½ kilometres, in 12 communes. Charles VII. had a palace in this town, where he resided, and starved himself to death for fear of being poisoned by his son Louis XI. N. lat. 47° 9'. E. long. 2° 18'.

MEHON, a small island in the straits of Babelmandeb. N. lat. 12° 20'.

MEHUNTPOUR, a town of Hindoostan, in the circar of Chanderee; 16 miles N.W. of Chanderee.

MEI, GIROLAMO, in *Biography*, a Florentine nobleman, mathematician, philosopher, and theoretical musician, who flourished in the latter end of the sixteenth century. Battista Doni, in his "Trattato secondo sopra gl'Instrumenti di Tali," or keyed instruments, says, that in the beginning of his musical studies, his partiality for the music of the ancients was greatly increased by the perusal of the dialogue of Galilei, in which Mei had the greater part (dove il Mei ebbe la maggior parte), and still more by a treatise written by this learned personage (Mei) "De Modis Musicæ," a MS. presented to the Vatican library by Monsig. Guaengo. Op. Om. t. i. p. 324. Doni has supported this assertion by no proof; but in the Vatican library, among the queen of Sweden's MSS. there is a volume of inedited tracts and letters, written by Girolamo Mei, upon the music of the ancients, in which are discoverable, not only opinions similar to those of Galilei, but frequently the words in which they are expressed in his dialogue; particularly in a letter from Mei, dated Rome, 1572, in answer to two that he had received from Galilei, in which he seems to have been consulted concerning the usual difficulties which those have to encounter who undertake to discuss the music of the ancients. We procured a copy of this letter entire, and considerable extracts from the other writings of Mei, which indeed contain the whole substance of Galilei's dialogue, except what concerns the controversy with Zarlino relative to the musical scales and proportions of the ancients.

MEI *Misere*. See MISERERE.

MEIA SAREKIN, in *Geography*, a town of Asiatic Turkey, in the government of Diarbekir; 30 miles E.N.E. of Diarbekir. N. lat. 38° 5'. E. long. 39° 55'.

MEIANE, a town of Persia, in the province of Comis; 18 miles S.S.E. of Bistan.

MEIANO, a town of Italy, in the department of the Mela; 12 miles S.S.W. of Brescia.

MEIAS-FAREKIN, a town of Asiatic Turkey, in the province of Diarbekir; 25 miles N.E. of Diarbekir.

MEIBOMIA, in *Botany*, a genus of Heister's, named after Brandanus Meibom, professor of medicine at Helmstadt, who died in 1740, aged 62, but who is not recorded as having written any botanical work. The plant on which Heister founded his genus is *Hedysarum canadense* of Linnæus. We do not find that he has given any other character, than enumerating it among papilionaceous genera with ternate leaves; see Heist. syst. 9.

There was another professor Meibom at Helmstadt, who wrote upon beer, *de cerevisiis potibusque et ebriaminibus extra vinum alius commentarius*, and died in 1655, aged 65. Dryandr. Bibl. Banks.

MEIBOMIAN GLANDS, in *Anatomy*, very small round bodies, arranged in parallel vertical lines on the inner surface of the tarsus of the eyelids, and secreting an unctuous substance, which is poured from their ducts on the ciliary edges

of the palpebræ, and prevents their agglutination. See EYE.

MEIBOMIUS, JOHN HENRY, in *Biography*, a learned physician, was born at Helmstadt, in August 1590. He spent a considerable time on his travels in Italy, for the purposes of improvement in science and literature; and, having given his attention to medicine, in which he made great progress, he went ultimately to Basle, in 1619, where he was honoured with the degree of doctor of physic. On his return to his native place, his character obtained for him, in 1620, the appointment of professor of medicine from the faculty of that university; and he continued in the office about six years, when he removed to Lubeck, where he had been chosen physician to the city, and to its bishop. Here he passed the rest of his life, which terminated in May 1655, in his sixty-fifth year. In the latter period of his life, he employed himself chiefly in the investigation of medical history, and left a manuscript to his son, entitled "De Vitis Medicorum usque ad seculum xv;" but this work was never printed. The following are the whole of his published works, the two last of which appeared after his death. 1. "Hippocratis Orkos, sive Commentarius in Hippocratis jusjurandum," Lugd. Bat. 1643, 4to. 2. "De Flagrorum usu in re venera," *ibid.* 1643, which was reprinted at London, Copenhagen, and Francfort. 3. "Epistola de Cynophoria, seu, Canis portatione ignominiosa," Helmstadt, 1645. 4. "De Mithridatio et Theriaca Discursus," Lubeck, 1652, 1659. 5. "Mæcenas, sive, de C. D. Mæcenatis vitâ, moribus, et gestis, Liber singularis," Lug. Bat. 1653. 6. "De Cerevisiis, Potibusque et Ebriaminibus extra Vinum alius, Commentarius," Helmstadt, 1668, published together with the treatise of Adrian Turnebus, "De Vino;" and 7. "Aurelii Cassiodori Formula Comitum Archiatrorum," *ibid.* 1668; which is a commentary on the 10th epistle of the 6th book of Cassiodorus. Eloy Dict. Hist.

MEIBOMIUS, HENRY, son of the preceding, was born at Lubeck, in June 1638. After having gone through various courses of study at Helmstadt, and in different Dutch universities, he travelled into Italy and France, and took his doctor's degree at Angers, in 1663. He then continued his travels into England, whence he returned to Germany. His father's name was still held in estimation at Helmstadt, and his own talents and acquirements gained him considerable respect, so that he was soon enrolled among the professors of that university; in which he held successively the chairs of medicine, poetry, and history; the last of which he retained at the time of his death, in March 1700, when he had reached his sixty-second year. Occupied as he ever was in the practice of his profession, and in his academical labours, he nevertheless found leisure to write several works, and also to superintend the publication of the writings of others. His first dissertation, "De Incubatione in Fanis Deorum, Medicinæ causâ, olim factâ," was published at Helmstadt, in 1659. It contained a history of the priest-medicine of ancient times, and of the various ceremonies, offerings, and sacrifices, instituted in different Pagan temples, in conducting this practice. He edited a treatise of Arnold de Boot, which had been published in London, in 1649, entitled "Observationes Medicæ de Affectibus omiffis;" with a preface, and many valuable notes, *ibid.* 1664. He also published "De Vasis Palpebrarum novis, Epistola ad Joëlem Lange-lottum," *ibid.* 1666. "De Ossium contusione Disputatio," *ibid.* 1668; and several other small dissertations, which evinced his great knowledge of the animal economy, and its disorders. He seems to have contemplated a history of medicine, and printed, "De Medicorum Historiâ scribendâ, Epistola ad G. H. Velschium," *ibid.* 1669; but the diffi-

culties which he met with in investigating the medicine of the Arabians arrested his progress, and deterred him from publishing the work left him by his father. He published, however, the following: "Parentatio I. Danielis Schmidt," Dantisci, 1687. "Ad Saxonice Inferioris Historiam Introductio," Helmstadt, 1687. "Scriptores Rerum Germanicarum," *ibid.* 1688, in two vols. folio; and he edited Valentin. Hen. Vogler's "Introductio universalis in notitiam cujuscumque generis bonorum scriptorum," *ibid.* 1700, with additions.

Some other individuals of the family of MEIBOMIUS were professors at Helmstadt; especially *Henry*, the grandfather of the preceding Henry, who published several works; *Mark*, whose studies were entirely confined to history and the belles-lettres; and *Brandus*, who taught medicine, and published several academical dissertations, about 1730. Eloy Dist. Hist. de Med.

MEIBOMIUS, MARCUS, a writer of great erudition, particularly in the music of the ancient Greeks, was descended from a very learned family at Helmstadt, who successively practised physic in that city, with great reputation.

Marcus Meibomius was born about 1611, and in 1652 he published from the Elzevir press, in two volumes 4to. dedicated to Christina, queen of Sweden, the following work: "Antiquæ Musicæ auctores septem Græce et Latine, Marcus Meibomius restituit ac Notis explicavit. Amstel. apud Lud. Elzivirium, cl. lx. lii." The first volume contains:

- I. Aristoxeni Harmonicorum Elementorum, libri iii.
- II. Euclidis Introductio Harmonica.
- III. Nichomachi Geraseni, Pythagorici, Harmonius Manuale.
- IV. Alypii Introductio Musica.
- V. Gaudentii, Philosophi Introductio Harmonica.
- VI. Bacchii Senioris Introductio Artis Musicæ.

The second volume.

- Aristidis Quintiliani de Musica, libri iii.
Martiani Capellæ de Musica, liber ix.

Meibomius, after this learned and elegant publication, was invited to the court of the queen of Sweden, which invitation he accepted.

Having, by his enthusiastic account of the music of the ancients, impressed this princess with similar ideas, the younger Bourdelot, a physician, and his rival (as a classical scholar) in the queen's favour, instigated her majesty to desire him to sing an ancient Grecian air, while Naudet, an old Frenchman, danced *à la Grec* to the sound of his voice. But the performance, instead of exciting admiration, produced loud bursts of laughter from all present; which so enraged Meibomius, that seeing the buffoon Bourdelot in the gallery among the scoffers, and having no doubt but that it was he who, with a malicious design, had persuaded her majesty to desire this performance, immediately flew thither, and exercised the pugilist's art on his face so violently, without being restrained by the presence of the queen, that he thought it necessary to quit the Swedish dominions before he could be called to an account for his rashness; and immediately went to Copenhagen, where, being well received, he fixed his residence there, and became a professor at Sora, a Danish college for the instruction of the young nobility; here too he was honoured with the title of aulic counsellor, and soon after was called to Elfsneur, and advanced to the dignity of Architectorié, or president of the board of maritime taxes or customs; but neglecting the duty of his office, he was dismissed, and upon that disgrace quitted Denmark.

Soon after he settled at Amsterdam, and became professor of history in the college of that city; but refusing to give

instructions to the son of a burgomaster, alleging that he was not accustomed to instruct boys in the elements of knowledge, but to finish students arrived at maturity in their studies; he was dismissed from that station.

After quitting Amsterdam, he visited France and England; then returning to Holland, he led a studious and private life at Amsterdam till 1710 or 1711, when he died at near 90 years of age.

Besides the seven Greek writers on ancient music, Meibomius published an edition of the Greek mythologists; a treatise de Fabrica Triremium; a new edition of Vitruvius, with a commentary on the *Echeia*, or harmonic vases, described book 5; correcting, for a new edition, the Hebrew bible. This daring work appeared at Amsterdam, 1698, in folio, under the title "Davidis Psalmi, et totidem sacræ scripturæ veteris Testamenti capita—restituta, &c."

The most solid and celebrated of his critical works is his edition of the seven Greek writers on ancient music, in which all subsequent writers on the subject of ancient music place implicit faith. It is from the indefatigable and learned labours of Meibomius, in his commentaries on the Greek writers in music, particularly Alypius, that we are able to fancy we can decipher the musical characters used by the ancient Greeks in their notation; which, before his time, had been so altered, corrupted, disfigured, and confounded, by the ignorance or negligence of the transcribers of ancient MSS., that they were rendered wholly unintelligible.

MEICHE, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of St. Hippolyte. The place contains 690, and the canton 7864 inhabitants, on a territory of 222½ kilometres, in 31 communes.

MEIDAN, a town of Persian Armenia; 100 miles N.E. of Erivan.

MEIDANS, in the *Eastern Nations*, are a sort of country-seats, where the greater people have often summer-houses, to which they retire on the three days of the week in which they do not attend the pasha's divan, and where they divert themselves with seeing their slaves ride, shoot, and throw the dart, while they are regaling with their pipe and coffee.

MEIDOBRYGA, in *Ancient Geography*, a town of Hispania, in Lusitania, S.W. of Nuba Cæsarea. It was formerly a powerful city; and its inhabitants were called Plumbarii, on account of the mines of lead which were found in its vicinity. Some traces of it have been discovered in a place called Armenha. South of this town was a chain of mountains, denominated "Mons Herminius."

MEIDON, or MEIDUN, in *Geography*, a town of Egypt, at some distance from the left bank of the Nile, near which is the most southerly of the pyramids; it is thought to occupy the site of the ancient Nilopolis; 32 miles S. of Cairo.

MEJEDDAH, a town of Algiers, on the Shellif; five miles N.E. of Seedy-Abid.

MEJERDAH, or MAI-SEAR-DA, a sea-port town of Algiers, in the province of Tremecen, consisting of meanly-constructed cottages. From this place a great quantity of corn is exported to Europe; 42 miles W. of Tremecen. N. lat. 35° 8'. W. long. 1° 35'.

MEJERDAH, a river of Africa, formed by the union of the Sujeras and the Serrat, on the borders of Algiers; after traversing the country from W. to E. it runs into the Mediterranean at Porto Farina. It pursues a winding course through a country, which it contributes to fertilize, and in this respect, as well as by its encroachments on the sea, it resembles

resembles the Nile. This river was anciently called "Bagrada," or "Brada." See BAGHADA.

MEILAN, a town of European Turkey, in Natolia; 18 miles W.N.W. of Kiangari.

MEILHAN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Marmande; six miles W.N.W. of Marmande. The place contains 2,414, and the canton 9,552 inhabitants, on a territory of 170 kilometres, in 10 communes.

MEILHUY, a town of Norway, in the government of Drontheim; 14 miles S.W. of Drontheim.

MEIMARG, a town of Grand Bucharia; 36 miles S.E. of Bokbara; which see.

MEIMEND, a town of Persia, in Segellan; 40 miles W. of Candahar. N. lat. 33° 5'. E. long. 65° 45'.

MEINAM, signifying the "Mother of Waters," a large river of Siam. According to Loubere, this river, when it enters the dominions of Siam, is so small that it can only convey small boats, scarcely sufficient for carrying above four or five persons. It is afterwards very much augmented, at the town of Lancocevan, by another considerable river from the north, of the same name, or rather by the reunion of a branch of the same river. Loubere's account of the smallness of the stream has been doubted, and it has been suggested, that it was only obstructed in its course by rapids or cataracts. When we advert to the regular inundations, similar to those of the Nile and Ganges, which are rivers of long course, and other circumstances, we may infer that the Meinam is of a more distant and higher origin than the mountains of Yunnan in the west of China; and that the Thibetian Alps furnish its source in that of the Nou Kian of the Lamas, supposed to be the Thaluan or river of Martaban, which has no Delta, nor any marks of so distant an origin, but is represented by Loubere and d'Anville as a short and insignificant stream. The Meinam is celebrated among the oriental rivers. Kämpfer says, that it is very deep and rapid, always full, and larger than the Elbe. He adds, that the inhabitants suppose its source to be in the mountains, which give rise to the Ganges, and that it branches through Cambodia and Pegu; an account somewhat confirmed by the discovery of the river Anau, which connects the Meinam with the rivers of Cambodia. The inundations are in September, after the snows have melted in the northern mountains, and the rainy season has commenced. In December the waters decline, and by degrees sink to their former level. The same intelligent traveller informs us, that the water in the earth swells before the river rises; that the wells are nitrous, but the water of the Meinam, though muddy, is pleasant and salutary; that the inundations are chiefly discernible towards the centre of the kingdom, not near the sea; that the rice is reaped in boats, and the straw left in the water; that a festival is celebrated in December, when the wind begins to blow from the north, and the inundation abates. The banks of the Meinam are generally low and marshy, but thickly peopled from Yuthia to Bangkok, below which are wild deserts like the Sunderbunde of the Ganges. Monkeys, fire-flies, and moskitoes swarm on the fertile shores. Pinkerton.

MEINART, a town of Germany, in the county of Hohenlohe; 7 miles S.E. of Ohringen.

MEINAU, an island in the N.W. part of the lake of Constance, with a commandery of the Teutonic order; about three miles in circumference. In 1805 it was added to Baden, once so celebrated for its wine; 14 miles N. of Constance.

MEINOR. See MAINOUR.

MEINUNGEN, in *Geography*, a town of Germany,

in the county of Henneberg, belonging to the prince of Saxe-Weimar, situated amidst mountains, on the river Werra; 21 miles N. of Schweinfurt. N. lat. 50° 37'. E. long. 10° 40'.

MEIONITE; *Hyacinthe blanche de Somma*, Romé de Pisse; *Hyacinthine*, Delameth.

The colour of this mineral is a greyish-white.

It occurs seldom massive; generally in prismatic crystals, the primitive form of which is a rectangular prism with square bases. The principal modifications are

The rectangular four-sided prism, acuminate by four planes placed on the lateral edges.

The preceding with lateral edges truncated (*diottaedre*, Haüy, fig. 76.) The truncating planes are often seen on two opposite edges only.

The same, but with lateral edges bevelled, and the bevelment again truncated; the edges formed by the lateral and acuminate planes likewise replaced by a plane, (*soustradis*, Haüy, fig. 77.)

Often one of the acuminate planes increases at the expense of the others which sometimes entirely disappear.

The crystals are small, seldom middle-sized, closely grouped together. They are splendid, with a vitreous lustre, especially when viewed in the direction of the longitudinal fracture.

Longitudinal fracture foliated, the folia parallel with the four sides of the prism; cross fracture conchoidal: the former is indicated by fissures observable in the interior.

It is semi-transparent passing into transparent.

It is hard, scratching glass.

Before the blowpipe it effervesces, and easily melts into a spongy white glass.

We are still without an analysis of this substance.

Meionite is found at Capo di Bove, near Rome, in basalt with melilite, augite, leucite; and on Monte Somma, among the volcanic ejections of Vesuvius, with calcareous spar or granular limestone.

This mineral substance was first discovered by Romé de l'Isle, who considered it as a variety of Vesuvian; Haüy afterwards found it to be a distinct species, to which he gave the name it now bears, and which has been also adopted by Werner, who at first considered it as a variety of feldspar.

From mesotype-zeolite, with which it might be confounded at first view, the meionite differs in not forming a jelly with nitric acid.

MEIOSIS, in *Rhetoric*, is a figure, which is a species of the hyperbole.

MEIRONNES, in *Geography*, a town of France, in the department of the Lower Alps, and chief place of a canton, in the district of Barcelonnette. The place contains 554, and the canton 3,252 inhabitants, on a territory of 335 kilometres, in three communes.

MEISENHEIM, a town of France, in the department of the Sarre, and chief place of a canton, in the district of Birkenfeld. The place contains 1,730, and the canton 7,512 inhabitants, in 21 communes.

MEISNER, BALTHASAR, in *Biography*, an eminent German Lutheran divine, was born in Saxony in the year 1587. At the age of fifteen he was sent to pursue his academical studies at the university of Wittemberg, where he took his degree of M.A., and acquired much reputation by his diligence and talents. He studied also at the universities of Strasburg, Tubingen, and Giessen; but in 1611 he returned to Wittemberg, and was appointed professor of moral philosophy, and in 1614 he was elected to the theological chair, which he filled with great success during the remainder

of his life. He died in 1626, leaving behind him works that bear witness to his learning and zeal, of which we may notice "Commentarius in Hoseam;" "Meditationes Sacræ in Evangelia;" "Anthropologia Sacra," in two vols. quarto, and "Philosophia Sobria, hoc est, confideratio Questionum Philosophicarum," in three vols. quarto.

MEISSANG, in *Geography*, a town of Africa, in Kaarta; 52 miles E. of Kemmoo.

MEISSAU, a town of Austria; 34 miles N.W. of Vienna.

MEISSEN, *Margraviate of*, a principality of Saxony, founded in the 10th century, and united in 1422 to the electorate of Saxony. Its boundaries have been various at different periods.

MEISSA, a city of Saxony, capital of the margraviate above-mentioned, situated on the Elbe, at its confluence with the Meisse, whence its name. Out of several jurisdictions that formerly belonged to this town arose the four prefectures of Meissen, to which pertain several villages. In the centre of the old citadel, the other parts of which are in a ruined state, is the part called "Albretschsburg," in which is carried on the celebrated manufacture of the excellent Misnian porcelain. At this place is also a manufacture of cloth. The first foundation of this town was begun by king Henry I. about the year 930; 14 miles N.W. of Dresden. N. lat. 51° 19'. E. long. 13° 27'.

MEKAM ALI, a town of the Arabian Irak, on the Euphrates, opposite to Bassora.

MEKAM ul Kidr, a town of the Arabian Irak, on the Euphrates; 26 miles S.S.E. of Hellah.

MEKARA, a name of the Hindoo goddesses *Parvati*, which see.

MEKEHOAN, in *Geography*, a town of Arabia, in the province of Oman, on the Persian gulf; 45 miles W.S.W. of Julfa.

MEKELBURG, a town of Prussia, in the province of Bartenland; 12 miles S.S.E. of Bartenstein.

MEKES, a town of Curdistan; 30 miles S.S.E. of Betlis.

MEKKIAS, signifying measure, a name given to the Nilometer, situated on an island in the front of old Cairo, about 500 yards in breadth. It is there, in front, that upon the graduations of a pillar the rise of the river is measured, and from the observations made upon it, public cryers go about the streets of Cairo, proclaiming the successive heights of the water, in which are centered all hopes of fertility and abundance. This Nilometer is said to have been built by the Arabs. The island on which it stands is called "Roudda," or gardens, because it is laid out in gardens, and inhabited only by gardeners. See NILOMETER.

MEKLAF AL ASFAT, a town of Arabia, in Yemen; 75 miles N. of Hafec.

MEKZARA, a country of Africa, on the S. side of the Niger, between Casna and Melli.

MEL, GAUDIO, FIAMINGO, in *Biography*, a Flemish musician, by whom the Italians have been generally understood to mean Claude Goudimel, a native of Franche Compté, and a Hugonot, who was one of the first composers of music to the French translation of the psalms by Clement Marot and Theodore Beza; and who was murdered at Lyons in 1572, on the fatal day of the massacre of Paris.

There are certain difficulties in this account, of which we shall speak further elsewhere. See PALESTRINA.

MEL, in *Geography*, a town of Italy, in the Trevisan; 12 miles N.W. of Ceneda.—Also, a small island in the Atlantic, near the coast of Africa. N. lat. 13° 15'.

MEL. See HONEY.

MEL *Cedrinum*, in the *Materia Medica of the Ancients*, a term used to express a sort of liquid manna, used rather as a pleasant sweet in foods than as a medicine, and which seems to have been the same with the *mel roscidum* of Galen, and with the liquid manna of mount Sinai; that mountain having been the place where it was annually collected in large quantities even in Galen's time; and the account Bellonius gives of the manner of collecting it in his time, agreeing very well with what Galen has left about it. It is, however, an error in Bellonius, to suppose this to be the *terenjabin* of the Arabians, that being evidently a solid, not a liquid substance, and being from all accounts the same with what is now called *manna Persicum*, or Persian manna.

The mel cedrinum is a term used only by Hippocrates for this substance, and seems so odd, that many are apt to believe there is an error of the text, and that the author never meant any such thing. Foesius is of opinion, that these ought to be read as two distinct names, with a comma between them, and that the author only meant by them two substances very well known in his time, which were common honey, and the liquid substance called *cedrinum*, or *cedria*.

MEL *Roscidum*, a name given to a kind of liquid manna collected in their time, as it is at present, in considerable quantities, on mount Sinai. The monks who collect it call it *terenjabin*, after the name of a kind of manna, common among the Arabians. But this is an error, the *terenjabin* of those authors not being a liquid manna, but the small round kind, collected from the *albagimaurorum*, and now called *manna Persicum*. It does not appear that the *mel roscidum*, or any other species of manna, was used in medicine by the ancients; this was esteemed a curiosity, rather than a thing of any use, by Galen; and other authors say, it was sweeter than honey itself, with no farther account; whence it seems rather to have been used as a delicacy than as a medicine. See TERENJABIN, and MANNA *Persicum*.

MELA, POMPONIUS, in *Biography*, an ancient geographical writer, was a native of Spain, and flourished A.D. 45. His great work, entitled "De Situ Orbis," divided into three books, is written with elegance, great perspicuity, and brevity. The best editions are those of Gronovius 1722, and Reinhold in 1761. Vossius gave an edition of it with copious notes. In the last edition by Gronovius are added five books "De Geographia," written by some later writer.

MELA, in *Geography*, a department of Italy, deriving its name from a river which rises on the confines of the Trenton, and after crossing the Bressan, runs into the Oglio, near Urtiano. The department is composed of part of the Bressan, and has a population of about 190,689 inhabitants, who elect 15 deputies.

MELA. See MEELAH.

MELA, a river of the Morea, which runs into the sea; 8 miles S.W. of Patras.

MELA, a surgeon's instrument, called also speculum, and by the vulgar a probe.

Its use is to probe ulcers, or draw a stone out of the penis; its form is various, according to the use it is intended for.

MELADA, in *Geography*, a small island in the Adriatic, a little to the N. of Isola Grossa. N. lat. 44° 35'. E. long 15° 56'.

MELÆNA, in *Medicine*, μελανα νόσος in the language of Hippocrates (see his book περὶ νόσων, sect. 5. book ii. edit. Fœs.) a disease characterized by a discharge of black matter by stool?

This affection sometimes occurs together with hæmatemesis, or vomiting of blood, and sometimes without that symptom. The ancients considered that the black matter thrown off by

by the bowels, was that modification of bilious matter which they denominated *black bile*: but recent observation has ascertained that it consists principally of blood, in a grumous or semi-coagulated state, which is poured out slowly from the vessels of the inner coat of the intestines. It is observed generally to be connected with obstruction or congestion of some of the abdominal viscera, as of the liver, spleen, or mesentery. Great debility, and frequent fainting accompany the disease; the pulse is often quickened, though but moderately; and other symptoms of fever are seldom urgent. There is commonly severe pain in the stomach and abdomen, with loss of appetite, nausea or vomiting, headache, and other signs of derangement of the digestive organs.

Gentle purgatives and clysters have been recommended for this complaint from the time of Hippocrates downwards: and they are as beneficial in this affection, as in the hæmorrhæmela, to which it bears much affinity. (See HÆMATEMESIS.) Dr. Home employed the diluted sulphuric acid, in addition to laxatives, and, as he believed, with considerable advantage. Emetics he justly deems useless, if not injurious, and shunned the use of opium, as tending to shut up the matter that nature was carrying off. Opiates, however, combined with gentle cathartics, tend rather to aid the operation of the latter, by removing the spasmodic constrictions which take place in the bowels, and thus also afford material relief to the pains. See Home, Clinical Experiments, sect. 7.—Alfo Hoffman, Med. Rat. Syst. tom. iv. part. i. sect. 1. cap. 3. Morgagni de Sed. et Causis Morbor. epist. xxx. art. 17. Sauvages, class. ix. gen. 11. Portal, Mem. sur plusieurs Maladies, tom. ii. p. 129.

MELAGGE, in *Geography*, a river which rises in Algiers, formed by the union of several streams; which, in its course, takes the name of "Sarratt," and runs into the Mejerda, on the borders of Tunis.

MELAIPOUR, a town of Hindoostan, in the circar of Schaurunpour; 20 miles E.N.E. of Schaurunpour.

MELALEUCA, in *Botany*, from *μειλας*, *black*, and *λευκος*, *white*, a very fine exotic genus of trees and shrubs, so named by Linnæus, because the principal, and indeed original, species was called *Leucadendron*, and *Arbor alba*; words synonymous with its appellation in the Malay tongue, *Caju-puti*, or *White Tree*. We know not why the idea of black was associated with white in the above name. Linn. Mant. 14. Sm. Tr. of Linn. Soc. v. 3. 273. Schreb. 332, excluding the synonyms. Willd. Sp. Pl. v. 3. 1428. Mart. Mill. Dict. v. 3. Juss. 323. Lamarck Illustr. t. 641. Gært. t. 35.—Class and order, *Polyadelphia Icosandria*. Nat. Ord. *Hesperideæ*, Linn. *Myrti*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, turbinate, in five deep, roundish, often coloured, equal segments. *Cor.* Petals five, roundish, inserted into the rim of the calyx, between its segments. *Stam.* Filaments very numerous, in five sets, inserted into the calyx, either opposite to, or alternate with, the petals, various in length and structure; anthers roundish, incumbent. *Pist.* Germen inferior, nearly globular; style thread-shaped, declining, shorter than the stamens; stigma obtuse. *Peric.* Capsule globose, coated, of three cells and three valves, the partitions from the centre of each valve. *Seeds* numerous, minute, angular.

Eff. Ch. Calyx superior, in five deep segments. Petals five. Stamens numerous, very long, in five parcels. Style one. Capsule of three cells.

A fine genus of aromatic trees and shrubs, with lateral inflorescence, and simple entire leaves, all, except the first

species, the produce of New Holland. This genus was confounded by the younger Linnæus, the two Försters, Schreber, and many other botanists, whom Jussieu seemed disposed to follow, with three other genera; see *FABRICIA*, *LEPTOPHYLLUM*, and *METRODORON*. From the two first it is clearly distinguished, as their characters will shew; from the last it differs merely in having the stamens assembled in five sets, not simply icosandrous; the habits of these two genera, and every part of their fructification, except the stamens, being alike. How very different the form of the filaments is in different species of *Melaleuca*, will appear by their descriptions; some being united to a great extent, others but slightly; some in a pinnate, others in a palmate manner; all which being considered, their union at all seems to afford but an artificial character. This however is a sufficiently clear, and, both genera being numerous, a very commodious distinction.

Eleven species of *Melaleuca* are described, by the writer of this article, in the third volume of the Linnæan Society's Transactions, and one in the sixth. These are all adopted by Willdenow. We shall here make some addition to the number, and Mr. Brown, in the second volume of his Prodrômus, will probably increase it much more. The whole are distributed into two sections.

* *Leaves alternate.*

1. *M. Leucadendron*. Greater Cajeput Tree. Linn. Mant. 105. Suppl. 342, 2. Sm. Tr. of Linn. Soc. v. 3. 274. (*Myrtus Leucadendra*; Linn. Sp. Pl. 676. *Arbor alba*; Rumph. Amboin. v. 2. 72. t. 16.)—*Leaves* alternate, lanceolate, pointed, obliquely falcate, five-ribbed. *Footstalks*, young branches, and germen, smooth.—Native of some parts of the East Indies, especially the Molucca islands, Ceram and Amboyna, growing in hilly places, flowering from January to March, and ripening fruit from August to November; but according to Rumphius, it is rarely propagated by seed. This is described by that accurate writer, as a large tree, as thick as a man's body, or much thicker, with many irregular widely spreading branches, but not of a lofty growth. *Leaves* scattered, on short smooth *footstalks*, lanceolate, entire, smooth, tapering at each end, but most at the extremity, curved laterally into a sickle shape, from five to eight inches long, scarcely an inch broad in the widest part, furnished with five principal ribs, connected by intermediate interbranching veins. *Stipulas* none. *Flowers* white, in long, loose, somewhat whorled spikes, whose smooth common stalk terminates in a leaf-bud, and becomes a branch. The bundles of *stamens* are $\frac{2}{3}$ ths of an inch long, and each divided nearly to the base. *Germen* scarcely so large as a hemp-seed, globose, smooth, quite sessile, the *capsules* remaining long firmly fixed to the branch, surmounted by leaves, after the seeds have fallen out, as is common to the whole genus. Rumphius speaks much of the resinous and aromatic properties of this tree, its whitish or grey aspect, and its agreeable shade. The wood is hard and heavy, but easily splits and soon decays, being neither beautiful nor useful. The outer bark is of a spongy nature, and much used for caulking vessels, as it swells in the water; but is nevertheless liable to shrink again, and give way. It is called *baru*, a name given to all substances used for that purpose. An oil is obtained by firing the tree, which soon becomes thick and is used for candles. Rumphius says nothing of any essential oil being procured by distillation from this tree; see the next species.

2. *M. minor*. Lesser Cajeput Tree. *Arbor alba minor*; Rumph.

MELALEUCA.

Rumph. Amboin. v. 2. 76. t. 17.)—Leaves scattered, elliptic-lanceolate, bluntish, straight, five-ribbed. Young branches and germens downy.—Native of Amboyna, but less frequent than the foregoing, with which it has been confounded by every body but Rumphius. We now venture, for the first time, to distinguish them. This is smaller in all its parts, and rather a shrub than a tree. The young leaves are extremely silky; adult ones nearly smooth, about two (scarcely three) inches long, and one broad, exactly elliptical, and not oblique or falcated. *Footstalks* broad and very short, somewhat hairy. Young branches, where the flowers are seated, densely clothed with white silky prominent down, as is likewise the *germen*. The *calyx* is but slightly downy. *Fruit* smooth, depressed and truncated.

The late Mr. Christopher Smith, from whom we have received specimens of both these plants, assured us of this being what yields the oil of Cajeput, and Rumphius gives the same account. (See CAJEPUT.) The bark is woody and brittle throughout, not externally corky like the former. The structure of their parts of fructification is the same in both, especially the form of the *stamens*. Rumphius's plates are by no means calculated to give a just idea of the foliage of either, especially of the present, but his descriptions are excellent.

3. *M. viridiflora*. Green-flowered ribbed Melaleuca. Gært. v. 1. 173. t. 35. Sm. Tr. of L. Soc. v. 3. 275. (*M. Leucadendron*; Forst. Prod. 38. Linn. Suppl. 342. β . *Metrofideros quinqueria*; Cav. Ic. v. 4. 19. t. 333.)—Leaves alternate, elliptic-lanceolate, straight, bluntish, coriaceous, five-ribbed. *Footstalks* and young branches downy. *Germen* nearly smooth.—Native of New Caledonia and New South Wales. The younger Linnæus confounded it with both the preceding. From the first it is abundantly distinct. With the second it more agrees in the shape of its leaves, but differs in their thick rigid texture, and much longer more downy *footstalks*. The flowers are twice as large, green, not white, with a smooth or very slightly hairy *germen*. The form of the *stamens* is the same. The young leaves of the present species are finely downy, but scarcely silky.

4. *M. suaveolens*. Sweet-scented Melaleuca. Gært. v. 1. 173. t. 35.—Leaves alternate, elliptical, single-ribbed. *Flower-stalks* axillary, forked, downy, twice as long as the *footstalks*. Filaments shorter than the petals, somewhat pinnate. Native of the warmer part of New Holland, near Endeavour river. A plate of this, communicated by sir Joseph Banks to Linnæus, is in our possession. It appears to be a handsome tree, with elliptical smooth entire leaves, tapering at each end, single-ribbed, five or six inches long and two broad. *Footstalks* an inch long. *Flower-stalks* nearly twice that length, downy, axillary, sometimes in pairs, forked, each bearing seven handsome white flowers, whose *stamens* are much shorter than the petals, and pinnated in their lower part. The *germen* and *calyx* are downy.

5. *M. laurina*. Laurel-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 275.—Leaves alternate, obovate-lanceolate, single-ribbed. *Flower-stalks* axillary, forked, downy, about as long as the *footstalks*. Filaments rather shorter than the petals, somewhat pinnate.—Native of New South Wales, communicated by sir Joseph Banks. It is very nearly related to the last, but not at all aromatic, which that should seem by its name to be, and the leaves of the present are broadest towards the top, very narrow and taper at their base. The *footstalks* are bordered, and so connected with the leaf, it is hard to fix the limits of each. *Flower-*

stalks axillary, not an inch long, forked, silky, bearing five or seven flowers, half the size of the *suaveolens*. *Stamens* hairy, rather shorter than the petals. *Germen* and *calyx* downy.

6. *M. stypheloides*. Sharp Twisted-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 275.—Leaves alternate, ovate, twisted, many-ribbed, with a spinous point. *Calyx-teeth* sharp-pointed, ribbed.—Native of Port Jackson, New South Wales. This has the habit of a *Styphelia*, and is scarcely at all aromatic. The numerous leaves are sessile, scattered, not an inch long, ovate, twisted, rigid, pungent, entire, smooth, rather glaucous, striated with innumerable nerves. Young branches very hairy, bearing in their lower part short crowded circles of sessile white flowers. *Germen* and *calyx* downy; the teeth of the latter erect, rigid, spinous, ribbed. *Stamens* palmate, much longer than the petals. M. Ventenat says, there were many fine plants of this species, in his time, at Malmaiton, but none had then blossomed.

7. *M. squarrosa*. Various-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 6. 300. Donn. Cant. ed. 4. 186. (*M. myrtifolia*; Vent. Malmaif. t. 47.)—Leaves scattered or opposite, ovate, pointless, five or seven-ribbed. *Calyx-teeth* pointless, smooth.—Native of the east and west coasts of New Holland. We first saw it in the Cambridge garden in 1799. The leaves spread in three or four rows, according as they are scattered or opposite, they have about seven remote ribs, and are blunt without any spine. Flowers white, encircling the hairy branches in long dense masses. *Germen* and *calyx* smooth, the latter blunt, without thorns or ribs. *Stamens* much longer than the petals, collected into five bundles, but not completely, many of the filaments being distinct, as in the genus *Citrus*; so that the limits between *Melaleuca* and *Metrofideros* here become almost evanescent. The stigma too in this species is quite simple, not so tumid or capitate as in most other *Melaleuca*.—Perhaps *M. decussata* of Mr. Donn's Hort. Cant. ed. 5. 186, is but a variety of this.

8. *M. diosmifolia*. Green-flowered Reflexed Melaleuca. Andr. Repof. t. 476.—Leaves scattered, reflexed, elliptic-oblong, obtuse, single-ribbed. *Calyx-teeth* rounded, smooth.—Native of King George's Sound, on the west coast of New Holland, where it was found by Mr. Menzies. We gathered it in flower, in June 1807, in the conservatory of Claude Scott, esq. at Sundridge park, Kent. A tall shrub, with many spreading branches, clothed with numerous, scattered, crowded, stalked, reflexed leaves, about half an inch long, nearly elliptical, dark green; smooth and even above; dotted and single-ribbed beneath. The flowers are green in every part, rather large, thickly crowded for an inch or two along the middle part of each branch, their long *stamens*, which are united by their base into five bundles, projecting horizontally all round. The anthers, or at least their pollen, is yellow. Stigma obtuse. Capsules large, thickly coated, crowded into irregularly angular figures.

9. *M. microphylla*. Small-leaved Melaleuca.—Leaves scattered, imbricated, cylindrical, obtuse, somewhat spreading. Flowers crowded at the upper part of the branches. This hitherto non-descript species was gathered near King George's Sound, on the west coast of New Holland, by Mr. A. Menzies, who favoured us with a specimen. The stem is shrubby, much branched in a determinate manner; the branches smooth, whitish, leafy throughout. Leaves very numerous, crowded, a little spreading, about a quarter of an inch long, cylindrical or obscurely quadrangular, very blunt,

MELALEUCA.

blunt, unarmed, smooth, pale green, with a strong aromatic resinous flavour; each supported by a short, slender, smooth *footstalk*, jointed at its base. *Flowers* white, crowded into an oval spike at the summits of a few of the branches, which are not extended beyond them, but still the inflorescence is lateral. *Stamens* in five sets, those of each set united, a good way up, into a flat linear base or common filament, which reaches beyond the *petals*. *Germs* and *calyx* smooth. *Capsule* turbinate. This is most akin to the next.

10. *M. ericifolia* Heath-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 276. Exot. Bot. v. 1. 65. t. 34.—Leaves scattered or opposite, linear, acute, nerveless, pointless, a little recurved. Flowers crowded at the upper part of the branches.—Native of Port Jackson, New South Wales. This and the last are the smallest we have seen of the genus. Both have the habit of *Erica*. The present is very smooth in all its parts, and has the taste and smell of Coriander seeds. The *branches* are prettily striped with green and white. *Leaves* from half an inch to an inch in length, flat-tish, linear, very narrow, acute, but without any spinous point, destitute of rib or veins, a little convex beneath. *Flowers* yellowish-white, crowded into oval or oblong spikes at the top of almost every branch, which is commonly a little prolonged, and leafy, above them. *Germs* and *calyx* smooth. *Stamens* strongly united in five sets, but their common claws do not extend beyond the petals. The *flower-buds* are reddish.

11. *M. nodosa*. Needle-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 276. Exot. Bot. v. 1. 67. t. 35. Vent. Malmaif. t. 112? *Metrosideros nodosa*; Gærtn. v. 1. 172. t. 34. Cavan. Ic. v. 4. 19. t. 334.—Leaves scattered, linear, straight, tipped with spinous points. Flowers crowded near the tops of the little side branches. Filaments palmate.—From the same country as the last. It has long been known in the gardens. The stouter taller habit; straight pungent *leaves* above an inch long; and the much shorter, almost globular, masses of yellow *flowers*, each of which is borne on a short lateral branch, distinguish this species from the last. The flowering branches have leafy terminations. The bundles of *stamens* are palmate, their united part shorter than the petals.

12. *M. armillaris*. Slender-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 277. (*M. ericifolia*; Andr. Repof. t. 175. Vent. Malmaif. t. 76. *Metrosideros armillaris*; Gærtn. v. 1. 171. t. 34.)—Leaves scattered, linear, somewhat recurved. Flowers crowded at the lower part of the branches. Filaments very long, linear; many-cleft and radiating at the summit.—Native of New South Wales. It has long been in the gardens. We have seen it trained against a wall to the height of several feet, in the open air, covered with flowers in May, and requiring only the shelter of a mat or glass frame in winter. It differs from *M. nodosa* in its less rigid, and somewhat recurved, *leaves*, scarcely spinous at the tip; much longer series of *flowers*, which are white; and particularly in the long linear base of each cluster of *stamens*, which is extended to twice the length of the petals, and then branches off at once into numerous radiating filaments of no considerable length. We have always found the *flowers* situated about the lower part of each branch; Ventenat represents them near the end. So, on the contrary, his plate of *M. nodosa* has the flowers on the lower parts of very long leafy branches, very different from what we have observed. It seems therefore that the relative situations of the fructification vary in these plants, though the comparative number of flowers in each is constant.

13. *M. genistifolia*. Broom-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 277. Exot. Bot. v. 1. 107. t. 55.—Leaves scattered, lanceolate, sharp-pointed, three-ribbed, closely dotted. Flowers loosely scattered. Filaments pinnate in their upper part. Style hairy.—Native of New South Wales, where the first settlers called it the White Tea-tree. It is said to grow "in a good soil, mostly near the water-side," being covered with white blossoms in November. We have met with it in no garden. In its native soil the *stem* attains the height of twenty or twenty-five feet. The *branches* and *leaves* are smooth; the latter lanceolate, scarcely three quarters of an inch long, acute, flat, marked with three ribs, and numerous resinous dots at the back. Their flavour is pleasantly aromatic, not strong. *Flowers* scattered, in alternate pairs, towards the tops of the small terminal branches, which are slightly downy in that part. The claws of the united *stamens* are about as long as the petals before they divide; they then become pinnate, and towards the top are more closely branched. *Germs* and *calyx* smooth. *Style* hairy.

•• *Leaves opposite.*

14. *M. linearifolia*. Toad-flax-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 278. Exot. Bot. v. 1. 109. t. 56. (*Metrosideros hyslopifolia*; Cavan. Ic. v. 4. 20. t. 336. f. 1.)—Leaves opposite, linear-lanceolate, three-ribbed, closely dotted beneath. Flowers loosely scattered. Filaments pinnate all the way up. Style smooth.—Native of the country about Port Jackson, New South Wales. We have seen it flowering at Mr. Scott's of Sundridge park. In its native soil this species forms a large tree, whose outer bark is easily stripped off, in large light thick spongy flaky portions, which serve the rude natives as a warm wrapper for their new-born infants. The European settlers found it answer the purpose of tinder. The *branches* are smooth. *Leaves* opposite, nearly sessile, an inch and a half, or two inches long, narrow, linear-lanceolate, acute but not pungent, marked with three slight ribs above, much dotted on both sides; the mid-rib keeled beneath. *Flowers* numerous, loosely disposed, cream-coloured, with a tinge of red in the petals. *Stamens* very long, each bundle regularly pinnate, almost from the very base to the end. *Style* short, smooth, as well as the *germs* and *calyx*. Every part is highly aromatic, with a flavour resembling pepper-mint.

15. *M. abietina*. Fir-leaved Melaleuca.—Leaves opposite, elliptic-oblong, concave, blunt, ribless. Flowers few, at the ends of the branches. Filaments long, linear, many-cleft at the summit. Communicated by Mr. Menzies, who gathered it at King George's Sound, on the west coast of New Holland. This seems to be a stout *shrub*, or *tree*, with numerous, strong, leafy, smooth *branches*. *Leaves* about half an inch long, crowded, opposite, in pairs crossing each other, on short broad *footstalks*; they are concave above, with a very blunt point; convex beneath, destitute of ribs, veins, or dots. *Flowers* reddish, few together, in short, ovate, apparently terminal spikes, beset with many imbricated, reddish, ribbed and keeled *bracteas*. It seems doubtful whether the branches be ever continued, in a leafy form, beyond the insertion of the flowers, which if they be not, would overset a character in the habit of this genus on which we have always depended. Our specimen however is insufficient to decide this question. The bundles of *filaments* are linear and simple to a considerable extent (but not to the extremities of the petals, which are longer than usual); then they suddenly branch off into numerous divisions, each bearing its *anther*, as in the other species. *Style* smooth, longer than in the last, but much shorter than the *stamens*. *Germs* and *calyx* smooth.

16. *M. thymifolia*. Thyme-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 278. Exot. Bot. v. 1. 69. t. 36. (*M. coronata*; Andr. Repof. t. 278. *M. gnidiazfolia*; Vent. Malmaif. t. 4. *Metrofideros calycina*; Cavan. Ic. v. 4. 20. t. 336. f. 2.)—Leaves oppofite, elliptic-lanceolate, acute, ribbed. Flowers few together, on fhort lateral branches. Filaments oppofite to the petals, branched more than half way down.—Native of New South Wales. It was firft raifed in England, if we miftake not, by Mr. Fairbairn at Chelsea garden, and is not very uncommon in green-houfes. This fpecies is a little, fender, fmooth, bufhy fhrub, about two feet high, with numerous fmall, fmooth, oppofite thyme-like leaves, full of refinous dots beneath, and highly aromatic. Flowers rofe-coloured, abundant, though but few together, on fhort lateral branches, not always furmounted by leaves. The germen and calyx are fmooth. Filaments oppofite to the petals, which is remarkable, and as far as we can examine our dried fpecimens of others, peculiar to this and the next fpecies. They are twice the length of the petals, and confift of one broad flat compound filament, fending off from its margin and inner furface abundance of fimple filaments with anthers, almoft to its very bafe. Style fmooth, rather fhorter than the ftamens.

17. *M. hypericifolia*. St. John's-wort-leaved Melaleuca. Sm. Tr. of Linn. Soc. v. 3. 279. Vent. Jard. de Cels, 10. t. 10. Andr. Repof. t. 200.—Leaves oppofite, fpreading, elliptic-oblong, fingle-ribbed. Flowers numerous, on fhort lateral branches. Filaments oppofite to the petals, very long, linear, radiating at the fummit.—Found in fwamps at New South Wales. This is now not unfrequent in the green-houfes and confervatories of England, where it makes an elegant appearance, being, in our opinion, the moft beautiful of the genus. The ftem is fhrubby, fix feet high, with lax fpreading branches. Leaves numerous, horizontal, oppofite, croffing each other in pairs, elliptical, fmooth, about an inch long, with much of the habit of an *Hypericum*. Flowers on fhort, lateral, fattered branches, many together, in denfe cylindrical mafles. Calyx and germen fmooth, green, very glandular and refinous. Petals green or reddifh, with refinous dots at the back. Filaments oppofite to them, the common bafe of each cluster three or four times the length of the petal, and of the fame colour, linear and narrow, terminating in a very large radiating tuft of long, capillary, crimfon, filk-like threads, each bearing a fmall red anther, with yellow pollen. Thefe crimfon threads, combining all round into a clofe maf, almoft concealing the reft of the flower, conftitute the chief beauty of the whole. It was miftaken for a *Bankfia* by one of the firft convicts who went to New South Wales, and who fent a very characteristic drawing to England of this plant, among fome of lefs accuracy.

18. *M. neriifolia*. Oleander-leaved Melaleuca. Sims in Curt. Mag. v. 26. t. 1058. (*M. falicifolia*; Andr. Repof. t. 485.)—Leaves oppofite, lanceolate, fingle-ribbed. Flower-ftalks axillary, forked, nearly fmooth. Stamens fhorter than the corolla, fcarcely cohering.—Native of New Holland, we know not precifely from what part of that extenfive country. It is faid to have been firft raifed from feed by Mr. Barr of Ifington. This is very different from all the reft of the prefent fection, having yellow flowers, on axillary forked ftalks, being next akin in habit to *M. fuaaveolens* and *laurina* of the former divifion; but its leaves are oppofite. Their figure is lanceolate, about two inches long, and the under fide is pale. The ftamens are defcribed by Dr. Sims as collected into five bundles, fhorter than the petals, but hardly cohering; Mr. Andrews delineates thefe bundles as oppofite to the petals, with the filaments feparate almoft to

the very bafe. Whether Mr. Brown, from whom in his *Prodromus* v. 2, and Ait. Hort. Kew, we may expect additions to this genus, has made any generic divifion of it, we are not informed; but Dr. Sims hints at the propriety of fuch a meafure.

Mention of more fpecies than we have defined will be found in Mr. Donn's Hort. Cant. but fome of thofe are certainly not different. His *neriifolia* and *falicifolia* are, we prefume, our laft fpecies, under the names of Sims and Andrews. His *coronata*, and probably *fimbriata*, are our *thymifolia*, which he has likewife. His *diosmeifolia* and *armillaris* we judge to be one and the fame, as perhaps is his *ericifolia*. This intelligent botanift and cultivator is neceffarily liable to be mifled, by the communications of his friends, who fend the fame thing under different names, nor are the plants always in a condition for determination till it is too late for his purpofe. S.

MELALEUCA, in the *Materia Medica*. The *Melaleuca minor* is that fpecies, which yields the *Cajeput* oil, and not the *M. leucadendron*, as mentioned under that article. See the preceding article.

The *Cajeput* oil, called alfo "Oleum Wittnebianum," from Wittneben, who gave an account of the procefs for obtaining it, though unknown in Britain, is now admitted into the *Materia Medica* of all the principal foreign pharmacopeias. It is imported into Europe from the Eaft Indies, and is diftilled chiefly in the ifland of Banda. From its exorbitant price it is frequently adulterated; and is therefore feldom found perfectly pure in Europe. *Cajeput* oil appears to be a powerful medicine, and is much efteemed in Germany, as well as in India, as a general remedy in chronic and painful complaints. It is ufed for the fame purpofes for which we employ the officinal ethers, to which it feems to have a confiderable affinity; the *Cajeput*, however, is more potent and pungent; taken into the ftomach, in the dofe of five or fix drops, it heats and ftimulates the whole fyftem, proving at the fame time a very certain diaphoretic, by which, probably, the good effects it is faid to have in dropfies and intermittent fevers are to be explained. For its efficacy in various fpafmodic and convulfive affections, it is highly efteemed; and numerous inflances of its fuccefsful employment are publifhed by different authors, cited by Murray. It has been alfo ufed both internally and externally with much advantage in feveral other obftinate diforders, as palfy, hypochondriacal and hysterical affections, deafnefs, defective vifion, tooth-ache, gout, rheumatifm, menftrual obftructions, herpetic eruptions, &c.; of which Thunberg gives a particular relation. The dofe is from two to fix and even twelve drops. Woodville Med. Bot. See CAJEPUT oil.

MELALIEH, in *Geography*, a town of Egypt; 10 miles N. of Abugirgé.

MELAMPODIUM, in *Botany*, is a Linnæan genus whole derivation may eafily be traced from μέλας, black, and ποῦς, a foot. According to the defcription of it in his *Hortus Cliffortianus*, it fhould feem that Linnæus had in view the fimilitude of the feed of the female florets to the foot of a goat.—In the *Critica Botanica* however it is faid to be named in honour of the Greek phyfician Melampus.—Linn. Gen. 445. Schreb. 583. Willd. Sp. Pl. v. 3. 2338. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 269. Juff. 188. Lamarck Illuftr. t. 713. Gært. t. 169.—Clafs and order, *Syngenefia Polygamia Necessaria*. Nat. Ord. *Compositæ Oppofitifoliae*, Linn. *Corymbiferae*, Juff.

Gen. Ch. Common calyx flat, much fpreading, of five, oblong-ovate leaves, the length of the florets. Cor. compound, radiated; the apparently perfect florets conftituting

the disk; female ones about five, making the radius: that of the florets of the disk of one petal, funnel-shaped, five-toothed, erect; of the radius ligulate, ovate, entire or three-toothed. *Stam.* in the disk, Filaments five, very small; anthers cylindrical, tubular. *Pist.* in the same florets, Germen very small, abortive; style brittle-shaped, the length of the corolla; stigma obsolete: in the female ones, Germen nearly ovate, compressed, rough at the sides, flat and membranous at the top; style very short. *Peric.* none, except the unchanged calyx. *Seeds* in the disk none; in the radius solitary to each floret, obovate, compressed, quadrangular, prickly at the sides, crowned with a heart-shaped, partial calyx, involute and converging at the margin. *Recept.* chaffy, conical; scales lanceolate, coloured, the length of the florets.

Eff. Ch. Receptacle chaffy, conical. Seed-down of one leaf, converging. Common calyx of five leaves.

1. *M. americanum.* Linn. Sp. Pl. 1303. (*Caltha americana*, &c., Banks. Reliq. Houst. 9. t. 21.)—Stem erect. Leaves linear-lanceolate, pinnatifid.—Found by Houston, near Vera Cruz, in a craggy, sandy soil, where it flowered and ripened fruit in March.—Stems herbaceous, numerous, round, villose, procumbent. Leaves opposite, an inch and half long, usually with two lateral segments, sometimes entire; hairy on both sides, but more particularly at the back. Flowers solitary, yellow, upon axillary stalks. Seeds forming a crown, and supplying the place of the florets of the radius.

The specific character of this plant given in the *Species Plantarum* of Linnaeus differs so much from Houtton's figure, as well as from the description in *Hortus Cliffortianus*, which seems made from the same specimen, that we have presumed to alter it.—Possibly when he wrote the second edition of the *Species Plantarum*, not having any specimen before him, he did not sufficiently attend to what he had previously recorded.

2. *M. humile.* Swartz. Prod. 114. Ait. Hort. Kew. ed. 1. v. 3. 269.—Stem erect. Leaves toothed, somewhat lyrate, sessile.—A native of Jamaica and St. Domingo, flowering from June to October.—Nothing is known of this species but from the authors above quoted, and not being able to refer either to a specimen or a figure of it, we must of course be content with copying their specific character.

3. *M. australe.* Linn. Sp. Pl. 1303. Willd. n. 3. (*M. australe*, semibus quinque oblongis hispida, calyce pentaphyllo, caule decumbente; Læfl. It. 268.)—Stem decumbent. Leaves oval, serrated.—Found at Cumana in South America by Læssing, who describes the Root as perennial. Stems a span long, somewhat downy, with opposite decumbent branches ascending towards their extremities. Leaves opposite, on footstalks, oval or obtusely ovate. Flowers terminal, yellow, on short footstalks. Seeds furrowed, and covered with hooked hairs.

These three species are all that are known of the genus *Melampodium*. Of the two last we are not acquainted with any figure. Professor Martyn observes, that they are all tender plants requiring much shade and warmth. The seeds should be sown in the spring in a hot-bed, and the plants removed in due time into pots filled with light sandy earth.

MELAMPEDIUM, in the *Materia Medica*. See HELLEBORE and HELLEBORUS.

MELAMPUS, in *Biography*, was enumerated among the early civilizers of Greece, who thought it necessary to travel into Egypt to qualify themselves for the high employments at which they aspired in their own country. Orpheus

proceeded thence a legislator and philosopher; and Melampus who had different views, commenced, at his return, physician and diviner, arts which in Egypt were professed together. Apollodorus says, that he was the first who cured diseases by medicinal potions. Physic had its miraculous powers during the infancy of the art, as well as music; and life and health being esteemed more precious and solid blessings than the transient pleasures of the ear, bore a much higher price: for though bards were often distinguished by royalty, and their talents recompensed by gifts and honours, yet we do not find in ancient records that any one of them ever experienced such munificence as Melampus. It is related by Pausanias, that having cured the daughters of Prætus, king of Argos, of an atrabilious disorder, with hellebore, he was rewarded with one of his royal patients for wife, and a third part of her father's kingdom in dowry.

MELAMPYRUM, in *Botany*, is the *Μελαμύρον* of Theophrastus, derived from *μύρα*, black, and *πυρός*, wheat; its seeds greatly resembling the grain of wheat, but of a darker colour. In some however, indeed in all the Linnæan species, they are so like wheat in form, size and colour, as to be scarcely discernible from it.—Cow-wheat.—Linn. Gen. 305. Schreb. 401. Willd. Sp. Pl. v. 3. 197. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 651. Ait. Hort. Kew. ed. 1. v. 2. 328. Tournef. t. 78. Juss. 101. Lamarck Dict. v. 4. 19. Illustr. t. 518. Gærtner. t. 53.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personate*, Linn. *Pedicularales*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, permanent, cloven half way down into four, slender segments. Cor. of one petal, ringent; tube oblong, recurved; limb compressed: upper lip helmet-shaped, compressed, emarginate, the lateral little margins reflexed; lower lip flat, erect, the length of the upper, obtuse, cloven half way down into three, equal segments, marked with two prominences in the middle. *Stam.* Filaments four, awl-shaped, curved, concealed under the upper lip, two of them shorter; anthers oblong. *Pist.* Germen superior, acuminate; style simple, in place and length like the stamens; stigma obtuse. *Peric.* Capsule oblong, oblique, pointed, compressed, its upper margin convex, the lower straight, of two cells and two valves, opening at the upper suture; partition contrary. *Seeds* in pairs (solitary according to Gærtner), ovate, gibbous, enlarged at the base.

Eff. Ch. Calyx tubular, four-cleft. Upper lip of the corolla compressed, folded back at the margin. Capsule of two cells, oblique, bursting at one edge. Seeds two, gibbous.

1. *M. cristatum.* Crested Cow-wheat. Linn. Sp. Pl. 842. Engl. Bot. t. 41.—Spikes quadrangular. Bractæas heart-shaped, imbricated, compact, toothed.—An English plant, though by no means a common one. It has been found both in Cambridgeshire and in Norfolk, on the borders of woods, and in corn-fields, flowering in July. The specimen figured in English Botany was sent from Madingley wood, near Cambridge.—Root annual. Stem rough, much branched. Leaves opposite, linear, entire. Spikes of flowers terminal, imbricated, very ornamental, being of a yellow, purple and tawny colour.—Linnaeus however observes that there is a variety which has white flowers.

2. *M. arvense.* Purple Cow-wheat. Linn. Sp. Pl. 842. Engl. Bot. t. 53.—Spikes conical, loose. Bractæas fringed with narrow taper teeth.—This like the last may be considered as a rare native plant, though occurring occasionally in various parts of England, in gravelly fields, and flowering in July and August.—Root annual. Stem about two feet high,

high, erect, much branched, rough. *Leaves* lanceolate, pointed, entire. *Spikes of flowers* terminal, of a yellow and purple colour, extremely ornamental, indeed so much so that Dr. Smith observes "we are scarcely worthy to possess it, for its charms, however striking, have never procured it admission into a flower-garden, though it may easily be raised from fresh seed on a dry gravelly soil."

3. *M. barbatum*. Bearded Cow-wheat. Willd. n. 3. Wadstein and Keisabel Pl. Rar. Hung.—Spikes conical, loose. Bractæas toothed and bristle-shaped, not coloured. Calyx-teeth bearded. Corolla gaping.—A native of fields in the south of Hungary. — This new species is adopted on the authority of Willdenow, who says that it is very closely allied to the last, but differs in the following particulars. Bractæas green, not coloured. Calyx-teeth furnished with long, transparent, membranous hairs at the margin. Upper lip of the corolla more hairy. Flowers by no means variegated, but altogether of a yellow colour.

4. *M. nemorosum*. Many-coloured Cow-wheat. Linn. Sp. Pl. 843. Fl. Suec. 214. Fl. Dan. t. 305.—Flowers leaning one way, lateral. Bractæas toothed, heart-shaped, lanceolate, the upper ones coloured, sterile. Calyx woolly.—A native of woods in the north of Europe, and especially of some provinces of Sweden. Dr. Smith also found it in Savoy.—It flowers in July and August.—Root annual, small. Stem somewhat more than a foot in height, upright, branched. Leaves entire, ovate, pointed, occasionally rather arrow-shaped, toothed at the base. Bractæas violet-coloured, lacinated at the base, those at the top barren. Flowers of a beautiful yellow and purple colour.—The splendour of this species has attracted the notice of various botanists. Linnæus mentions it in his *Flora Suecica* with great delight, which has drawn forth the following observation from Dr. Smith in his *Tour on the Continent*, ed. 2. v. 3. 149. Speaking of *M. nemorosum* he says, "The red and yellow flowers, amid sky-blue and purple bractæas, form the richest combination possible, which, but in the hands of nature, would be tawdry. Well might Linnæus esteem this plant worthy to decorate the palace of Flora herself."

5. *M. pratense*. Common yellow Cow-wheat. Linn. Sp. Pl. 843. Engl. Bot. t. 113.—Flowers lateral, leaning one way. Leaves in distant pairs. Corolla closed.—Common in woods and thickets throughout England, flowering through the summer.—Root annual, branched, spreading, smooth. Stem slender, branched. Leaves lanceolate, smooth, occasionally toothed at the base. Bractæas pinnatifid, often purplish. Flowers solitary, all leaning one way, yellow, their upper lip fringed with dense hairs, the lower one straight; anthers cohering together at their tips.—We find the following observation in *English Botany*. "Linnæus says, the best and yellowest butter is made where this plant abounds. All authors have copied him, and we do not scruple to do the same, in hopes that somebody will in time be induced to make experiments on the subject in England, where this plant is far from uncommon, flowering all summer long."—This property of *M. pratense* is mentioned in the *Lapland Tour of Linnæus* v. 1. 110, as well as in the *Flora Lapponica* n. 240, where he confounds it with the following as one species.

6. *M. sylvaticum*. Wood Cow-wheat. Linn. Sp. Pl. 843. Engl. Bot. t. 804.—Flowers lateral, leaning one way. Leaves in distant pairs. Corolla open, with its lip bent downwards.—Found occasionally in mountainous woods or pine forests, flowering in July.—The habit of this species is extremely similar to that of the last, but it is upon the whole considerably smaller.—Root annual. Stem roughish. Leaves a little broader, less black from drying, all of them

generally entire. Flowers twice as small, of a yellowish-orange colour, especially at the mouth. Capsule marked with a net-work of prominent veins.

7. *M. lineare*. Linear Cow-wheat. Willd. n. 7. Lamarck Dict. v. 4. 23.—Leaves linear, entire. Flowers axillary. A native of Carolina, where it was discovered by Mr. Frazer.—All that we know of this is from the authors above quoted, who tell us that it is more diminutive than any other species of this genus, in habit greatly resembling *Euphrasia linifolia*.—Root annual. Stem about five inches high, round, erect, furnished with opposite, somewhat quadrangular, branches. Leaves opposite, sessile, an inch long, little more than a line broad, acute. Flowers in the bosoms of the upper leaves, about three lines in length. Calyx half the length of the corolla, which is gaping, with equal lips, the upper one obtuse, villose at the margin.

The several species of *Melampyrum*, though extremely elegant and ornamental when fresh, are at the same time remarkable for turning brown or black when dry, losing all traces of their living beauty, and making a shabby appearance in the Herbarium. "The seeds of this genus have a remarkable resemblance to grains of wheat; on which account (says Dr. Smith) we prefer the old English name to that of *Cow-grass*, given by Dr. Stokes."

MELAN PHARMACON, a word used by Hippocrates, and by some supposed to mean common writing ink. He orders this to be poured upon the cranium, in case of a fissure, in order to discover how far it has penetrated. Galen seems to refer to this, in some places, and mentions his having treated of it in his book of ulcers; but as no such medicine is found prescribed here, it is probably one of the lost compositions of the ancients. In the spurious edition of Hippocrates, his book treating on the diseases of women, there is a black medicine ordered to be made of the squamæ and flos æris.

MELANA, or MÆLENA, in *Ancient Geography*, a town of Arcadia, in the western part, on the river Alpheus, S.W. of Tegea.

MELANAETOS, in *Ornithology*. See FALCO.

MELANAGOGUES, MELANAGOGA, from μέλας, black, and γωγῆ, I draw, such medicines as were believed to possess the particular power of evacuating black bile, one of the four humours of the ancient pathology.

MELANANTHERA, in *Botany*, was so called by Michaux, from μέλας, black, and ἀνθήρα, an anther, because of the colour of the anthers, which is strongly contrasted with the white corolla. Michaux Boreali-Amér. v. 2. 106.—Class and order, Syngenesia Polygamia-aqualis. Nat. Ord. Composita oppositifolia, Linn. Corymbifera, Juss.

Gen. Ch. Common calyx imbricated, of several, not very numerous, oval, flatish, close-pressed, unarmed leaves, in two rows. Cor. compound, discoid; florets uniform, numerous, all perfect, though some of the central ones are usually abortive; all funnel-shaped, with a short tube, and a much longer and wider, tubular, five-cleft, regular limb, whose segments are lanceolate and cohering. Stam. Filaments five; anthers forming a cylinder, shorter than the corolla. Pist. Germen obovate, angular, abrupt; style thread-shaped, projecting a little beyond the anthers; stigmas two, oblong, revolute, slightly tapering. Peric. none, except the permanent calyx. Seeds turbinate, quadrangular, smooth, abrupt at the top, with a small annular border, and a crown of very few, (about five,) erect, rough, deciduous bristles. Recep. rather convex, with a firm, keeled, concave, ribbed scale to each floret, at length overtopping the seeds and much resembling the calyx-scales.

Ess. Ch. Receptacle convex, with obovate, keeled, rigid scales.

scales. Seeds square. Crown of a few rough bristles. Calyx of two rows of uniform, ovate, imbricated leaves.

Obf. This genus differs so much in habit from *Bidens*, with which Linnæus confounded it, that we cannot but think Michaux right in separating them. The ovate uniform calyx leaves, and the scales of the receptacle, so closely resembling them, in the feeding state, that the whole head of seeds assumes one uniform scaly aspect, added to the number and nature of the bristles of the seed crown, which are not in one or two pairs, but of an indeterminate number, all uniform, and rough with minute ascending points, not barbed with sharp reflexed spines; these characters are sorely sufficient marks of distinction.

1. *M. hastata*. Michaux. v. 2. 107. (*Bidens nivea* β and γ ; Linn. Sp. Pl. 1167. *B. scabra*, flore niveo, &c.; Dill. Elth. t. 46 and 47.)—Leaves three-lobed, somewhat bilate. Scales of the receptacle lanceolate, taper-pointed—Native of Carolina. It was cultivated in the Eltham garden before the year 1732, and flowered late in autumn. The root is perennial. Stems herbaceous, two or three feet high, rough, somewhat branched, leafy. Leaves opposite, stalked, rough and harsh, serrated; sometimes slightly, sometimes very deeply, hastate. Dillenius figures both varieties. Flowers terminal, an inch broad, on long stalks. Corollas white. Anthers black. This probably is the *Bidens nivea* of Mr. Donn's Hort. Cant., which is there marked as a hardy perennial, flowering in June and July.

2. *M. deltoides*. Michaux. v. 2. 107. (*Bidens nivea* α ; Linn. Sp. Pl. 1167. Swartz. Obf. 296. Ait. Hort. Kew. ed. 1. v. 3. 154. *Cala aspera*; Jacq. Ic. Rar. t. 583.)—Leaves ovate or heart-shaped, all undivided. Scales of the receptacle bluish.—Native of the West Indies. Swartz says it grows in grassy, cultivated, elevated situations, as well as near the sea, in the south part of Jamaica. The late Mr. Aiton gave us a specimen from Kew garden, in 1783, as a great rarity. This is, of course, more tender than the former, from which it differs in the ovate, somewhat deltoid or cordate, form of the leaves, one of which is exhibited by Dillenius in his t. 47. f. 3. The flowers too are rather smaller.

MELANCHOLY. See MENTAL Derangement.

MELANCRANIS, in Botany, from $\mu\epsilon\lambda\alpha\nu\alpha$, blackness, and $\kappa\epsilon\phi\alpha\lambda\eta$, a head, alluding to the dark purplish spots with which the scaly roundish head of the flowers is besprinkled, and which give it a black aspect. Vahl. Enum. v. 2. 239.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoidæ*, Juss.

Gen. Ch. Cal. Scales of a spike, imbricated every way, ovate, pointed, each subtending an oblong, compressed, two-ranked, nearly seven-flowered spikelet, of the same length. Perianth inferior, of two valves, shorter and narrower than the corolla. Cor. of one lanceolate valve, closely dotted with purple. Stam. Filaments three, linear, the length of the scales, whitish dotted with purple; anthers linear. Pisl. Germen oblong; style solitary, smooth, cloven; stigmas simple. Seed one, without any bristles at its base.

Ess. Ch. Scales chaffy, imbricated every way. Spikelets solitary at every scale, many-flowered, two-ranked. Calyx of two valves. Corolla of one valve. Style cloven.

1. *M. scariosa*. Vahl. n. 1. (*Schoenus scarifolius*; Thunb. Prod. 16.)—Head oblong. Bractæas about three.—Native of the Cape of Good Hope. Root perennial. Stems in tufts, about a foot high, or rather less, thread-shaped, rigid, without joints, finely striated, angular at the top. Leaves shorter, brittle-shaped, channelled, dilated into a sheathing base. Head of flowers terminal, half an inch in

length, oblong, composed of imbricated, ovate, broad, membranous, rather rigid, smooth, shining scales, each a little spreading at the point, and tapering into a sort of awn; the three lower ones barren, tipped with a bristle-like leaf or bractea, which in the lowermost is three inches long. Spikelets five-flowered.

2. *M. radicata*. Vahl. n. 2.—Head nearly globose. Bractæas numerous.—From the same country. Perennial. Rather taller than the first. Bractæas, or barren scales, at the base of the head of flowers, from six to eight, one of them half an inch long, the rest gradually less, widely spreading, awl-shaped, rigid and somewhat pungent. Head the size of a cherry, composed of innumerable, ovate, crowded spikelets; these accompanying scales striated and dotted with purple.

MELANCTHON, PHILIP, in Biography, an illustrious reformer, and coadjutor of Luther, was born at Bretten, in the Palatinate upon the Rhine, on the 16th of February 1497. His family name, in the German language, literally meant "Black Earth," which was exchanged for Melancthon, a word in the Greek tongue having the same signification. He received the early part of his education at his native place, was afterwards placed under the care of a private tutor, and then proceeded to the college of Pfortsheim, where he obtained the friendship of the learned Reuchlin, from whom he received the Greek name already alluded to, by which he is generally known. In 1509 he removed to Heidelberg, where he made so rapid a progress in the classics and other branches of literature, that before he had completed his fourteenth year he was entrusted with the tuition of the sons of count Leonstein. He is accordingly celebrated by Ballet, in his "Historical Treatise of young Men who became famous by their Study or Writings." At the age of thirteen he wrote a comedy, which he dedicated to his friend and patron Reuchlin; and at that period he was employed to make the greatest part of the harangues and orations which were delivered in public, in the university of Heidelberg. In 1511 he was admitted to the degree of B.A.; but being refused his superior degree in the arts in the following year, he left the college, and entered himself at Tübingen. Here he pursued his studies with great diligence and success, and became himself a lecturer on the Latin classics. In 1513, before he had attained the age of seventeen, Melancthon was created doctor of philosophy. It was about this period that Erasmus paid him the following high compliment: "What hopes may we not entertain of Philip Melancthon, who, though as yet very young, and almost a boy, is equally to be admired for his knowledge in both languages? What quickness of invention!—what purity of diction!—what powers of memory!—what variety of reading!—what modesty and gracefulness of behaviour!" While at Tübingen, Melancthon diligently studied the sacred Scriptures, and always carried about with him a bible, which he had received as a present from Reuchlin. This treasure, it may be said, he bound to his heart; he was hardly ever seen without it; and, during divine service, he frequently referred to its contents; and on this account, those who were jealous of his rising fame endeavoured to excite prejudices against him, by insinuating that he spent his time at church in reading what did not belong to the solemnities of the service. In 1518 he was appointed by the elector of Saxony professor of the Greek language in the university of Wittenberg, and by his inaugural speech excited the highest applause and admiration. He now began to read lectures upon Homer, and the Greek text of the Epistle of St. Paul to Titus, which attracted vast crowds of auditors, and which contributed, in no small degree, to

MELANCTHON.

promote the study of Greek literature. In the year 1519 he published his "Rhetoric;" and in the following year, a treatise on "Logic;" and four years after this, his work on "Grammar." From the time of his settling at Wittenberg, Melancthon contracted a close intimacy with Luther; and in the year 1519 he accompanied him to Leipzig, to be a witness of his ecclesiastical combat with Eckius. He seems not to have been contented to be a mere bystander, but joined so much in the debate as to provoke the rage and bitterness of Eckius, who found himself completely overwhelmed with the arguments brought against the cause, which he undertook to justify and defend. Melancthon, from this moment, became an advocate in the cause of reform, and, by the services which he afterwards rendered it, made his name immortal. In the year 1520 he delivered a course of lectures at Wittenberg on the Epistle to the Romans, with which Luther was so highly pleased, that he caused it to be printed, and prefixed a preface of his own, recommending it to the use of the churches. In the following year he undertook a defence of the doctrines of Luther, in opposition to the university of Paris, which had passed a sentence of condemnation upon them. The next business of importance in which he was engaged, was to draw up, conjointly with Luther, a system of laws relating to church government, public worship, the ranks, offices, and revenues of the priesthood, and other matters of a similar nature, which John, elector of Saxony, promulgated in his dominions, and which was adopted by the other princes of the empire, who had renounced the papal supremacy and jurisdiction. After this, Melancthon was commissioned, with others, to visit all the churches in the electoral dominions, for the purpose of seeing these laws carried into execution.

In the year 1529, Melancthon accompanied the elector John to the diet at Spire, in which the princes and members of the reformed communion acquired the denomination of Protestants, in consequence of their protesting against a decree, which declared unlawful every change that should be introduced into the established religion, before the determination of a general council was known. In the year 1530 a diet of the empire was appointed to be held at Augsburg, with a view to put an end to the dissensions occasioned by religious disputes, under the eye of the emperor, in order that he might be able to form a clear idea of the real opinions of the reformers, and of the true causes of their opposition to the Roman pontiff. The Protestant princes employed Melancthon to compose a creed, which was presented to the emperor, and which reflects honour on the address, moderation, and eloquence of Melancthon. This creed, commonly known by the name of the "Confession of Augsburg," was severely animadverted upon by his opponents, which led him to draw up an able reply, notwithstanding the imperial prohibition, under the title of "A Defence of the Confession of Augsburg." Recourse was now had to conferences, in which our reformer mightily distinguished himself. It was in these that the spirit and character of Melancthon appeared in their true colours; and it was here that the votaries of Rome exhausted their efforts to gain over to their party this pillar of the reformation, whose abilities and virtues added a lustre to the cause in which he had embarked. His gentle spirit was apt to sink into a kind of yielding softness, under the influence of mild and generous treatment. Accordingly, while his adversaries soothed him with fair words and flattering promises, he seemed ready to comply with their wishes; but when they so far forgot themselves as to make use of threats, then Melancthon appeared in a very different point of light: then a spirit of intrepidity, ardour, and in-

dependence animated all his words and actions, and he looked down with contempt on the threats of power, the frowns of fortune, and the fear of death.

As every attempt at reconciliation had proved in vain, a severe decree was issued by order of the emperor, enjoining the princes, states, and cities, that had thrown off the papal yoke, to return to their duty, and their allegiance to Rome, on pain of incurring the indignation of the emperor, the patron and protector of the church. This at first oppressed the gentle spirit of Melancthon, till he was encouraged and animated by the exhortations of Luther; and he soon had the satisfaction to see the Protestant interest strengthened and extended, owing to the treaty concluded at Nuremberg, of the expediency of which the emperor was made fully sensible, by the league of Smalkalde, and other circumstances. Melancthon's fame was now spread far and wide, and he was invited by Henry VIII. to settle in England, and, about the same time, by Francis I. to take up his abode in France, with the view of employing him to pacify, or at least to moderate the disputes which had arisen there concerning religion, and to advise with the French divines about restoring the ancient discipline of the church. Melancthon felt inclined to accept the latter invitation; but the elector of Saxony would not by any means give his consent, knowing that by such a step he would expose himself to the resentment of the emperor, between whom and Francis affairs began to wear a hostile aspect. In 1541 Melancthon was at the famous conferences at Ratisbon; and in 1543 he went to Cologne, to assist the elector in introducing the reformed religion into his diocese; but the main design of his journey was frustrated, through the opposition of the canons and other divines of the see: nevertheless the elector of Cologne and the elector palatine embraced the Protestant faith. In 1548 he assisted at seven conferences on the subject of the interim of Charles V., and published a censure on that interim, and all the writings presented at these conferences. In 1551, pope Julius III. having consented to the assembling a council at Trent, the Saxon Protestants employed the pen of Melancthon, and the people of Wittenberg that of Bredlius, to draw up confessions of their faith, to be laid before the council. Soon after, the Saxon divines, with our reformer at their head, received directions from Maurice, now elector of Saxony, to set out towards Trent, but were secretly instructed to stop at Nuremberg, as Maurice had no intention to submit to the emperor's views, and the schemes which he had been long preparing, with the deepest policy, for maintaining the rights and liberties of the German empire, and the security of the Protestant faith, and which were on the eve of being carried into execution. While he was at Nuremberg, in 1552, Melancthon received intelligence of the complete success which had crowned Maurice's well-projected undertaking, and compelled the emperor to conclude the famous pacification at Passau, commonly called "The Peace of Religion."

Upon this event he intended to have returned to Wittenberg, but as that city was then infected with a plague, the university had been removed for a time to Torgau, where Melancthon discharged the duties of his professorship, till the infectious disorder was completely banished. To these duties he devoted the remainder of his life, as well as in the composition of various works, and the carrying on of controversies with his Protestant and Catholic opponents. His last conference was with the doctors of the Romish communion at Worms. The first point discussed was concerning the rule of judgment in the church, which the Catholics maintained to be perpetual consent or custom;

but the Protestants, in conformity with their own principles, held it to be the prophetic and apostolical writings. In the next place the Catholics demanded a decree of condemnation against the followers of Zuingle, and others, when the deputies of Jena perceiving the disposition of the majority to agree to this demand, broke off the conference, by seceding from the meeting; and thus the object of the Papists to promote a division among the Protestants was effectually gained. From Worms, Melancthon went to Heidelberg, at the request of Otho Henry, elector palatine, for the purpose of giving his advice in forming the constitutions of an academical institution established in that city. In 1559 he made an attempt to bring over the Greek churches to embrace the doctrine and discipline of the Lutheran church, and to live in religious communion with the Protestants; in which his laudable endeavours were ineffectual. He died in the following year at Wittenberg, in the sixty-fourth year of his age, and was interred near the remains of Luther. "Nature," says one of this great man's biographers, "had given Melancthon a peaceable temper, which was but ill suited to the time he lived in. His moderation served only to be his cross. He was like a lamb in the midst of wolves. Nobody liked his mildness: it looked as if he were lukewarm." He was a person of the middle stature, with lively eyes and well-proportioned limbs, but his constitution was delicate and his health weak, yet by the exercise of the most rigid temperance, he was enabled to pursue his studies with an intenseness of application that is almost incredible. The habits of such a man cannot fail of interesting those who reflect on what he did for the world: it was his practice to go to bed immediately after an early supper, and to rise at midnight to his labours. On retiring to rest he endeavoured to dismiss as much as possible from his mind every thing that could tend to disturb his repose, and for this purpose he always postponed reading such letters as were brought to him in the evening till next day. He was civil and obliging to all; entirely free from envy, detraction, jealousy, and dissimulation; and possessed an unrivalled degree of candour and frankness. His principal relaxation from severe studies was the conversation of his friends during his meals. He was humble and extremely disinterested, constantly refusing the valuable presents which were offered him by many great princes, and contenting himself with the small profits of his professorship; yet he managed his narrow income with such admirable economy, that he was able to indulge his benevolent and charitable disposition to an astonishing degree. According to the testimony of Mosheim, few worthies can be compared with him, if we consider the extent of his knowledge, the fertility and elegance of his studies, the facility and quickness of his comprehension, or the uninterrupted industry that attended his learned and theological labours. He rendered philosophy and the liberal arts the same eminent service that Luther had done to religion, by purging them from the dross with which they had been corrupted, and by recommending them in a powerful and persuasive manner to the study of the Germans. He had the rare talent of discerning truth in all its connections and combinations, of comprehending at once the most abstract notions, and expressing them with the utmost ease and perspicuity. His love of peace, which was partly owing to the sweetness of his natural temper, made him desire with ardour, that a reformation might be effected without producing a schism in the church. The spirit of charity led him sometimes to make concessions that were neither consistent with prudence, nor advantageous to the cause in which he was engaged. But when the hour of real danger approached, when things wore a formidable aspect, and the

cause of religion was in imminent peril, then this mild and even timorous man, in an instant, as it were, was converted into a hero, looked danger in the face with unshaken constancy, and opposed his adversaries with invincible fortitude. Had his fortitude been more uniform and steady, his desire of reconciling all interests, and pleasing all parties less excessive, he must deservedly have been considered as one of the greatell among men.

In philosophy he followed chiefly the principles of Aristotle, and had frequently recourse to the doctrines of the Platonists and Stoics, but always in due subordination to revelation, and only so far as they were likely to answer some valuable purposes. "I would have no one," says he, "trifle in philosophising, lest he should lose sight of common sense; rather let him be careful, both in the study of physics and morals, to select the best things from the best sources. He may not, therefore, improperly be considered as an *eclectic*."

Melancthon was much assisted in the execution of his plans by the labours of many learned Protestant professors of the Germanic schools from Italy and Great Britain, who brought with them an attachment to the Peripatetic system, and wherever they were appointed public preceptors, made that system the basis of their philosophical instructions. From Wittenberg, Tübingen, and Leipzig, conducted after the plan which had been introduced by Melancthon, many learned men arose, who, becoming themselves preceptors, adopted the same plan of instruction, which, from Melancthon's Christian name, was denominated "The Philippic Method," and thus disseminated the Peripatetic doctrine, till at length it was almost every where taught in the German Protestant schools, under the sanction of civil and ecclesiastical authority. The number of the works which Melancthon published, considering how much he was engaged as a public man, is truly astonishing. The titles of a great many of them are given in the General Biography. They are theological, moral, and philosophical; some, however, relate to what is usually denominated the *Belles Lettres*, and others are illustrative of various classical authors. The most complete edition was published by the author's son-in-law, Jasper Peucer, in the year 1601, in 4 vols. fol.

This celebrated and mild reformer, the friend of Martin Luther, and author of the confession of Augsburg, &c. wrote upon music. He composed his own epitaph, and died in 1560.

"Iste brevis tumulus miseri tenet ossa Philippi,
Quis, qualis fuerit nescio, talis erat."

MELANES, or MELAS, in *Ancient Geography*, a gulf that lay between the Chersonese of Thrace to the S.E., and a part of the continent to the N.W. It is now called the "gulf of Megarissa."

MELANI MONTES, a chain of mountains, placed by Ptolemy in Arabia Petræa, supposed by Jerome to be those that are called in scripture Sinai and Oreb.

MELANI, ALESSANDRO, in *Biography*, the composer of an opera, which was extremely applauded at Bologna, Florence, and in many other theatres of Italy, in 1697, called "Il Carcierier di se stesso."

MELANIPPIDES, a Greek poet and musician, who flourished about the sixtieth olympiad, and whose poetry and music rendered him famous. He had a grandson of the same name, who was likewise a great musician; though Plutarch, in a croaking fit, accuses him of having been one of the first corrupters of the ancient music, by the innovations which he introduced. See TIMOTHEUS.

MELANITE. See GARNET.

MELA.

MELANIUM, in *Botany*, from *μελας*, *black* or *dark*, *μελανιον* being a name for the purple violet. It is applied by Browne, in his History of Jamaica, p. 215, to a small weak Jamaica plant, with a peculiarly disagreeable and pungent smell, which Linnæus referred to LYTHRUM. (See that article,) by the name of *L. Melanium*. Sp. Pl. 641. Swartz. Obs. 193. The author last mentioned says the flowers are purple; and this accounts for the name, for the application of which Browne, as usual, gives no reason.

MELANOGÆTULI, or NIGRITÆ, or *Black Gætulians*, in *Ancient Geography*, a people of Africa, placed by Ptolemy between the mountains Sagapola and Ufargala, in a district S.E. of Gætulia Propria, to which it is contiguous, and N. of the river Niger. (See GÆTULIA.) The Melanogætuli were a people without doubt different from the Gætulians, and so considered by Ptolemy, though Cellarius insinuates that they were a tribe of that people. Their complexion not only evinces this fact, but likewise shews, that their progenitors were different from those of the Gætulians. The modern district of Wad-reag, in the province of Constantina, containing a collection of twenty-five villages ranged in a N.E. and S.W. direction, corresponds with a part of the country of the Melanogætuli, according to Dr. Shaw. Our learned traveller likewise supposes, that the country of the Beni-Mezzab, situated 35 leagues to the S. of the mountains of the Ammer, supposed to be part of the Mons Pharaeus of Ptolemy, the large village of Engoufah, 30 leagues to the S.W. by W. of Tuggart, the capital of Wad-reag, and the populous city of Wurglah, with their dependencies, even to the banks of the Niger, were included in Melanogætulia. As Ptolemy places the Melanogætuli next to the Pharusii in a southern direction, fixing his Nigritian Ethiopians in a tract lying to the north of the Niger; and as Mela, Pliny, and Strabo give the Nigritæ exactly the same situation with regard to the Pharusii and the Niger, but are quite silent as to the Melanogætuli; it is very probable, that the Melanogætuli and Nigritæ were the same people. If this supposition be admitted, it will appear very credible, that their territories extended to the Niger, and that they had some remarkable places in those parts; since, according to Ptolemy, many towns stood not far from that river, of which the principal were Passide, Saluce, Negira, Thige, Cuphe, Thammdicana, and Vellegia. The most celebrated rivers of this part were the Gir and Niger. If any credit be given to Leo and the African historians, Sabtecha, the son of Cush, first peopled the Sahara, between the mountains of Atlas and Nigritia, and therefore probably Nigritia itself, or at least part of it. From the same author it appears, that the various Nigritian dialects bear an affinity to the Chaldee, Arabic, and Egyptian tongues; and consequently to the Ethiopic, which does not differ widely from them. The Carthaginians had undoubtedly some knowledge of the Nigritæ, since it appears probable from Frontinus, that one part of their army consisted of Nigritian troops. This circumstance will enable us to account for several antique coins with a Negro's or Nigritian's head upon them. The Nigritæ used chariots in their wars, and were armed after the manner of the western Ethiopians with bows and arrows, as we learn from Strabo. According to the same author, the Pharusii, and therefore, probably, the Nigritæ, travelled in caravans through the deserts to Cirta, and kept open a communication with the Maurusii. On these occasions they carried bottles filled with water, tied to their horses' bellies, lest they should perish from thirst in the vast deserts through which they were obliged to traverse. Hence it is undeniably clear, that these Pharusian and Nigritian mer-

chants lived at a great distance from Cirta, and those places of Mauritania to which they resorted; and also that the Negroes or Blacks held an early correspondence with the ancient Mauritanians, Numidians, and Carthaginians. Anc. Un. Hist. vol. xvi. 8vo.

MELANOSCHOENUS, in *Botany*, from *μελας*, *μελανος*, *black*, and *σχονος*, *a rush*, Mich. Gen. 46. t. 31, is *Schoenus mucronatus* of Linnæus. See SCHOENUS.

MELANO-SYRI, in *Ancient Geography*, a name given to those who inhabited Syria, between the Euphrates and the Mediterranean sea, by way of contradistinction to the *Leuco-Syri*, who lived in Cappadocia, towards the Euxine sea. The former are black Syrians, and the latter white, as their respective appellations import.

MELANTHIUM, in *Botany*, so called by Clayton, from *μελας*, *black* or *dark*, and *ανθος*, *a flower*; but the first word is here taken in a wider sense than is usual, even in its application to flowers; for the plant of Clayton, *M. virginicum*, Linn. Sp. Pl. 483, has a dull yellowish, lurid, but not black, hue. This plant is probably a *Veratrum*; but several others, more remarkable for the darkness of their flowers, have been referred to the genus before us, which now rests upon them. It must not be supposed however that any of these is the *μελανθιον* of the ancient Greeks, for the description in Dioscorides, more particular and expressive than usual, evidently indicates the *Nigella fativa*, the name being applied by a metastasis to the flower, which is white, the seeds, for which the plant was known and cultivated, being intensely black. Sometimes indeed the plant was, for this last reason, called *μελασπιριμον*. Our present business is with the Linnæan *Melanthium*, as far as we can define its limits. Linn. Gen. 179. Schreb. 240. Willd. Sp. Pl. v. 2. 266. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 326. Juss. 47. Lamarck Illustr. t. 269. Thunb. Prod. 67. (Wurmbea; Thunb. Nov. Gen. 18. t. 1. Schreb. 239. Willd. Sp. Pl. v. 2. 265. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. ed. 2. v. 2. 325. Lamarck Illustr. t. 270.)—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronarie*, rather *Tripetaloides*, Linn. *Junci*, Juss.

Gen. Ch. *Cal* none, unless the corolla be taken for such. *Cor.* of six petals, sometimes contracted, sometimes combined, at the base, inferior, ovato-lanceolate, acute, spreading, equal, permanent. *Stam.* Filaments six, thread-shaped, erect, the length of the corolla, more or less attached to it, permanent; anthers globose. *Pist.* Germen superior, nearly globular; styles three, spreading, thread-shaped, the length of the stamens, recurved at the extremity, permanent; stigmas simple. *Peric.* Capsule ovate, with three furrows, three cells, and three valves, crowned with the styles. *Seeds* numerous, roundish.

Ess. Ch. *Calyx* none. *Petals* six, equal, bearing the stamens. *Styles* permanent. *Capsule* of three cells, with many seeds.

Obs. The found Linnæan rule, that "the genus should give the character, not the character the genus," induces us to follow Linnæus, and even Thunberg himself, the original establisher of *Wurmbea*, in reducing that genus to *Melanthium*, from which it differs merely in the combination of its petals at their base into an angular tube, a character which, by a comparison of all the species together, will appear of no essential consequence in this case. Mr. Salisbury's *Ornithoglossum*, received into Ait. Hort. Kew. ed. 2. v. 2. 327. (*Melanthium viride* of Linnæus and Thunberg), however alike to many of the species at first sight, does so materially differ, in having the stamens inserted into the receptacle, and, like the styles, deciduous, to say nothing of other characters, that we cannot well retain it here. (See

MELANTHIUM.

ORNBITHOLOSUM.) Neither are we at all certain that some of the following may not require to be placed elsewhere. *M. latum*, Willd. Sp. Pl. n. 3, is now properly referred to *Habanaria*, by Mr. Ker in Curt. Mag. t. 83.

1. *M. flavum*. Siberian Grassly Melanthium. Linn. Sp. Pl. 483. (Melanthium; Linn. Am. Acad. v. 2. 34.) t. 4. f. 11. Ornithogolum; Gmel. Sib. v. 1. 45. t. 8.)—Flower pointed. Petals combined at the base. Capsule pointed. Leaves linear.—Native of mountainous woods in Siberia, where it was gathered by Gmelin, flowering in July. We have never seen a living specimen. The root is bulbous, perennial, oblong, white. Stem slender but firm, erect, one or two feet high, nearly leafless, glaucous when young, terminating in a length, somewhat compound, bracteated panicle, of greenish-white small flowers, whose petals are reflexed. Capsule half an inch long, erect, ovate, pointed, purplish, sheathed at the bottom by the combined dilated bases of the petals, and crowded with the recurved styles. It bursts in the furrows, from the top nearly to the bottom.

2. *M. capense*. Spotted-flowered Melanthium. Linn. Sp. Pl. 483. Thunb. Prod. 67.—Flowers racemose. Petals dotted, contracted at their base. Leaves ovate-lanceolate, with a broad sheathing base.—Native of the Cape of Good Hope. Root an ovate bulb. Stem two or three inches high, with a few broad, spreading, pointed leaves, and a short terminal cluster of spotted flowers, whose stamens cohere but slightly with the petals. We find no figure of this species.

3. *M. junceum*. Rush-like Melanthium. Jacq. Ic. Rar. t. 451. Curt. Mag. t. 558. Willd. Sp. Pl. n. 7. (*M. triquetrum*; Linn. Suppl. 213.)—Leaves linear-awl-shaped, the upper ones dilated and concave at the base. Spike zigzag. Petals contracted at the bottom.—Native of the Cape. It flowers in the green-house early in the spring, like other bulbs from the same country, and indeed resembles an *Ixia* in its spike of purplish flowers, the bases of whose petals are marked with a double violet spot. The leaves are glaucous, rather succulent, and the uppermost are remarkable for their tumid or inflated figure, just above their insertion.

4. *M. ciliatum*. Fringed Melanthium. Linn. Suppl. 213. Thunb. Prod. 67.—Leaves ovate, spreading, finely fringed with cartilaginous teeth. Spike zigzag. Petals much contracted at the bottom.—Native of the Cape; we find no traces of it in the English gardens. The habit is like an *Orchis*, the lower part of the stem bearing two or three broad, ovate, spreading leaves, with a sheathing base, their edges minutely fringed. Spike rather dense, of many sessile flowers, spreading every way, whose petals are elliptic-oblong, with a considerable claw, and appear to be white, minutely streaked or dotted with purple or red.

5. *M. secundum*. Single-ranked Melanthium. Lamarck Dict. v. 4. 28. Illustr. t. 269. f. 2. Willd. Sp. Pl. n. 8.—Leaves linear. Spike inclined one way. Petals contracted at the bottom, with a tooth at each side.—Native of the Cape, where it was gathered by Sonnerat and by Bladh. The younger Linnæus confounded it with the last in his herbarium, and apparently in his Supplement. The present however is abundantly distinguished by its narrow erect leaves, and especially by a remarkable tooth at each side of the petals, just above their claw or contraction, well observed by DeFrouffieux in Lamarck. It seems doubtful to us whether the unilateral direction of the flowers be not an effect of drying. They are white or bluish-coloured, dotted like the foregoing.

6. *M. indicum*. Indian Melanthium. Linn. Mant. 226.

—Leaves linear. Flowers corymbose. Petals linear-lanceolate, tapering at the base.—Sent by Koenig from Pondicherry.

This has much the habit of *Ornithogolum luteum*. The leaves are very narrow, erect, and rise above the stem, which bears a sort of leafy or bracteated corymb of a very few upright flowers. The narrow and sharp petals are of a dark purple, as well as the stamens and style. We think, with Willdenow, that there is a connection between the filaments and petals, especially as there is but a simple row of six sears at the base of the ripening germen, after the flower has fallen, which indicates that the stamens have no separate insertion there. The styles are permanent, even on the ripe capsule. Nevertheless the whole aspect of the plant is so nearly allied to that of *M. viride*, (Mr. Salisbury's *Ornithoglossum*;) as almost to shake our faith in that genus.

7. *M. flavum*. Yellow Melanthium. (*M. uniflorum*; Jacq. Ic. Rar. t. 450. Coll. v. 4. 100. Curt. Mag. t. 767. Ant. Hort. Kew ed. 2. v. 2. 327. Willd. n. 12. *M. æthiopicum*; Herb. Linn. Lamarck Dict. v. 4. 29. Tulipa Breyntiana; Linn. Sp. Pl. 438. Willd. Sp. Pl. v. 2. 98. Thunb. Prod. 65.)—Leaves linear-lanceolate, sheathing. Flowers somewhat spiked. Petals elliptic-lanceolate, tapering at the base. Stamens united to the petals more than half way up. Germen and capsule columnar.—Native of the Cape, where it was gathered by Thunberg. It is impossible to retain the name *uniflorum* for this species, which, as Mr. Ker observes, is altogether fallacious. We have therefore ventured to translate the English appellation, given by him, and adopted by the learned authors of the Hortus Kewensis. We would have called it *Breyntianum* after Linnæus; but the synonym of Breyntius seems very evidently to belong to something else; we pretend not to say what. In this difficulty, sense is surely preferable to the mere records of confusion and mistake. The stem is from a span to a foot high. Leaves spreading, keeled and sheathing at the base. Flowers from two to six, in a close zigzag spike; very rarely solitary only. The petals are yellow on the upper side; brownish crimson beneath. In the dried specimen this last-mentioned colour runs into minute oblong spots, which induces a suspicion that the dotted appearance in some of the former species, known to us in a dry condition only, may not exist in the fresh flowers. The base of each petal in that now under consideration tapers down into a long dark-red claw, to which each filament, of the same colour, is firmly united for three-fourths of its own length. The germen is remarkably columnar, with three longitudinal furrows. Styles very short, thick, and recurved. Anthers oblong.

8. *M. eucomoides*. Dwarf Green Melanthium. Jacq. Ic. Rar. t. 450. Curt. Mag. t. 641.—Leaves ovate-oblong, spreading, sheathing at the base. Stalk with few flowers, shorter than the leaves. Base of the petals concave, with a tooth at each side.—Native of the Cape; rarely seen in England. This is very unlike any of the former, being of a dwarf habit, with several broad, sheathing, long, spreading leaves, recurved at their points. Among these stands a short stalk, bearing one, two, or three large green flowers, of a singular and not beautiful appearance. The long bases or claws of the petals are rolled in at their sides, and crowned with a pair of broad blunt teeth, analogous to those described in our fifth species. Filaments united to the claws. Anthers oblong, yellow, brown at the back. Germen oval, with three deep furrows. Styles awl-shaped, slightly recurved at the top.

9. *M. pumilum*. Little Rigid Melanthium. Forst. Comm. Gött. v. 9. 30. t. 6. Willd. n. 14.—Leaves lanceolate, rigid,

rigid, channelled, sharp-pointed, bearded at the base. Stalk with few flowers, shorter than the leaves.—Native of Terra del Fuego. By one of Forster's specimens in our possession, this appears to be a mountain plant, of a dwarf-tufted habit; having numerous, crowded, spreading, radical leaves, an inch long, ovato-lanceolate, rigid, pungent and rough-edged; channelled above, keeled beneath; their sheathing bases densely invested with long, white, shining, pellucid hairs. The flowers are said to be white; in a dry state they have a purplish tinge. They are about three or four, each supported on its own short stalk. Petals not contracted at the base. Styles, according to Willdenow, (from whom we adopt the reference to Forster,) none; the stigmas three, rarely six.

Willdenow justly observes that *M. luteum*, Thunb. Jap. 152, is probably distinct from *Veratrum luteum* of Linnæus. Having seen no specimen, by which we might judge of its genus, we decline admitting it here.

MELANURUS, in *Ichthyology*. See SPARUS *Melanurus*.

MELAONES, a word used by certain authors for a black kind of worm found in meadows in the month of May, which, when bruised, emits an agreeable smell. Some also have called a small species of beetle by the same name.

MELAPARA, in *Geography*, a town of Bengal; 10 miles E.N.E. of Dacca.

MELAS, in *Ancient Geography*, the name of several rivers; e. g. a river of the Peloponnesus, in Achaia:—a river of Bœotia, which had its source seven stadia from Orchomené, and discharged itself into the lake Cephissus:—a river of Thessaly, near Heraclea:—a river of Mygdonia:—a river of Thrace:—a river of Asia, whose source was near the town of Cæsarea ad Argæum:—a river of Asia, in Pamphylia:—a river of Asia, in Armenia Minor.

MELAS, *μελας*, in *Medicine*, signifying literally *black*, is a term applied by the ancients to a disease of the skin, which appears to be a variety of the scaly lepra; differing principally in the colour of the eruption from the more common form, which is white, and which was called *Alphos*, or *Leuce*. (See these articles.) The *leuce*, however, as we have there shewn, in strictness, ought not to be confounded with *alphos*, or put under the same genus with it and the *melas*; since all the ancients, even Celsus, who has ranked all three under the head of *vittiligo*, distinctly pointed out the essential difference of the *leuce*. See Celsus, lib. v. cap. 27. sect. 19. See also LEPROSY.

MELASICTERUS, from *μελας*, *black*, and *ικτερος*, *icterus*, the *jaundice*, a term which has been applied by some writers to that severe and inveterate degree of jaundice, which has been also termed in English the *black jaundice*. (See JAUNDICE.) Sauvages, Nofol. Method. class. ix. genus 12.

MELASMA, in *Botany*, so named by Bergius, from *μελας*, *black*, apparently because the herb assumes that colour in drying. Thunberg, who likewise established it as a genus, called it *Nigrina*, for the same reason. The younger Linnæus referred it to GERARDIA (see that article); to which Thunberg, in his Prodrum 106, accedes, and the plant stands there, as well as in Willd. Sp. Pl. v. 3. 222, under the name of *Gerardia Nigrina*. (*Melasma scabrum*; Berg. Cap. 162. t. 3. f. 4.)—Herb rough. Leaves lanceolate; serrated in their lower part. Stem square.—Native of the Cape of Good Hope. The stem is herbaceous, above a foot high, leafy, somewhat branched. Leaves opposite, narrow, about two inches long, rough on both sides, with prominent points. Flowers axillary and terminal, on long stalks, drooping, large. Nothing is recorded concerning

their colour. Every part of the dried plant is as black as ink.

MELASMA, (from *μελας*, *black*), in *Surgery*, a black and dark blue, or livid, discolouration of the skin, more commonly termed by surgeons an *ecchymosis*; which see.

MELASPHÆRULA, in *Botany*, is denominated by Mr. Gawler, now Ker, who first established the genus, from *μελας*, *black*, and *σφαιρα*, *a ball*, in allusion to the little black and shining globular bulbs, said to be produced at the ramifications of the stem, as in several lilies, the *Dentaria bulbifera*, *Saxifraga bulbifera*, and others. These however have not been observed on the cultivated *Melaspheerula* in England or France, but Jacquin delineates them. Ker in Sims and Kon. Ann. of Bot. v. 1. 231. Curt. Mag. v. 17. 615. Ait. Hort. Kew. ed. 2. v. 1. 103. (Diasia; Decand. in Bulletin des Sciences, n. 80. Brumaire an. 12.)—Class and order, *Triandria Monogynia*. Nat. Ord. *Enfate*, Linn. *Irides*, Juss.

Gen. Ch. Cal. Spatha inferior, shorter than the corolla, of two oblong, acute, permanent valves; the outermost broadest. Cor. of one petal, superior; tube none; limb irregular, two-lipped, somewhat bell-shaped, divided to the bottom into six ovate, bristle-pointed, spreading segments, the three lower ones most coloured, and rather the smallest. Stam. Filaments three, close together, shorter than the corolla, and ascending under the middle segment of its upper lip, recurved at the summit; anthers oblong, incumbent. Pist. Germen inferior, three-lobed, depressed; style thread-shaped, of the length and situation of the stamens; stigmas three, spreading, simple, bluntish. Peric. Capsule three-lobed, depressed, thin, of three cells and three valves, opening at the upper side. Seeds few, globose, without wing or border.

Eff. Ch. Spatha of two valves. Corolla two-lipped, in six deep, nearly equal, bristle-pointed segments; without any tube. Stigmas three, recurved. Capsule three-lobed. Seeds globose.

M. graminea. Grass-leaved *Melaspheerula*. Curt. Mag. t. 615. (Diasia iridifolia; Redout. Liliac. t. 54. Gladiolus gramineus; Linn. Suppl. 95, excluding the synonyms. Willd. Sp. Pl. v. 1. 221. Jacq. Ic. Rar. t. 236. Andr. Repof. t. 62.)—Gathered by Sparrmann and Thunberg at the Cape of Good Hope. Mr. Masson sent it to Kew in 1787, where it blossoms in the green-house during most part of the year. The root is a small, coated, roundish bulb. Stem near two feet high, slender and rigid like that of a grass. The leaves also are of a grassy habit, pale green, long and narrow. Flowers numerous, in a lax and slender panicle, scentless, small, compared with many of the same tribe. Spatha green, with a filmy edge. Corolla of a pale greenish-yellow, each segment marked with a purplish-brown, central line, or rib, of which those in the three lower segments are broadest and most conspicuous, evincing the natural irregularity of the flower. The seeds are brown.

No other species is known. Redouté distinguishes this, after Decandolle, into two, according to the various length and uprightiness of the foliage, but, as it seems to us, without sufficient reason.

MELASSES. See MOLASSES.

MELASSO, a town of Asiatic Turkey, in Natolia, anciently called "Mylasa," or "Mylassa." It is situated on a fertile plain near a mountain, which furnishes a great quantity of fine white marble. It had formerly a temple dedicated to Augustus Cæsar, with twenty-two columns, six of which were in front; and it was adorned with so many temples and public buildings, that a certain musician, on entering the *αγορα*, or market-place, to make a proclamation,

on, used the words *ἄνοι ἄνοι*, hear ye temples, instead of *ἄνοι ἄνοι*, hear ye people. Under the Roman it was a free city. It is now a large place, containing a great number of houses, though they are mean. The air is accounted bad, and scorpions abound; 85 miles S. of Sayrua. N. lat. 37° 10'. E. long. 27° 45'.

MELASTOMA, in *Bany*, a very extensive tropical genus of plants, most remarkable for the transcendent beauty and peculiarity of its foliage. The name was composed by John Burmann, of *μαλ*, *black*, and *στομα*, *the mouth*; being synonymous with the Portuguese appellation of one of the Ceylon species, *Bacca pinto*, or Black Mouth, which arose from the effect of the fruit upon the lips of those who eat it. Some of the West Indian species are known by the name of American Gooseberries.—Burm. Zeyl. 156. Linn. Gen. 217. Schreb. 293. Willd. Sp. Pl. v. 2. 581. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 45. Juss. 329. Lamarek Dict. v. 4. 31. Illustr. t. 391. Gartin. t. 126. Aubl. Guian. 402—437. Swartz. Ind. Occ. 764—822. (Acinodendron; Linn. Gen. ed. 1. 129. Tococa; Aubl. Guian. 437. Fothergilla; ibid. 440. Mayeta; ibid. 443.)—Clas and order, *Dicandria Monogynia*. Nat. Ord. *Calycanthemae*. Linn. *Melastomeae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, four or five-cleft, swelling at the base, permanent. *Cor.* Petals four or five, roundish, inserted into the rim of the calyx. *Stam.* Filaments eight or ten, short, inserted into the calyx; anthers very long, terminal, somewhat curved, of one or two cells, opening by an oblique terminal pore, and often accompanied by a pair of small spreading scales at the base. *Pist.* Germen roundish, in the bottom of the calyx; style thread-shaped, declining; stigma blunt or capitate. *Peric.* Berry of two to five cells, roundish, coated with the body of the calyx, and crowned with its permanent annular rim. *Seeds* very numerous, imbedded in pulp.

Ess. Ch. Calyx four or five-cleft, bell-shaped. Petals as many as the segments of the calyx, inserted, with the filaments, into its rim. Anthers beaked, opening at the tip. Berry of five cells, invelled with the calyx.

Only fifteen species of this genus are defined in the 14th edition of the *Syistema Vegetabilium* of Linnæus, but the discoveries of Swartz, and of various correspondents of sir Joseph Banks, in the West Indies, and of Aublet in Guiana and Cayenne, have very greatly increased that number, so that Willdenow describes eighty-five, notwithstanding his having referred some species of the above authors to *Rhexia*. We are possessed of a few that do not appear in Willdenow's list. The whole are distributed into various sections, distinguished by the number of stamens, which differ in different species from ten to eight or twelve; and the petals and segments of the calyx also from five to four or six. Subordinate characters of each section depend on the number and connection of the longitudinal ribs of the leaves, which, throughout the whole genus, are very remarkable, and in some form, together with the transverse veins, the most elegant appearance imaginable. The leaves in all are opposite and simple, their two sides generally different in colour and pubescence, the under one being often downy, rusty, or silky. Stem shrubby. Flowers numerous, axillary, or more generally terminal; their petals rarely yellow, usually red, purple, or whitish; with, for the most part, yellow very handsome anthers. We shall select examples of each section, marking the species by Willdenow's numbers.

Sect. 1. *Stamens* twelve. Three species in Willdenow.

1. *M. calyptrata*. Vahl. Eclog. v. 1. 40. Lamarek Dict. v. 4. 51?—Leaves elliptic-lanceolate, tapering, three-

ribbed, smooth, slightly and minutely toothed. Flowers panicled. Native of the island of *M. calyptrata*. Petals terminal, oval, four inches long; its branches spreading, the lowermost four together, the rest opposite, smooth; their ultimate divisions divaricated, three-flowered. Flowers stalked, covered with an acute conical lid, falling off all round and deciduous. *Calyx* abrupt, the size of a corn-cob seed. *Petals* yellow. Vahl.—The late Dr. Dancer sent us from Jamaica a specimen which answers to the above characters, except that the *flowers* seem fewer and larger. The teeth of the *calyx* are firmly united into a thick coriaceous conical lid, like that of an *Eucalyptus*, (see that article), which sometimes splits at the top, but more generally falls off entire, by an irregular circular separation from the body of the calyx. Within this are the *petals*. The *fruit* is crowned with a very narrow annular rim, quite distinct from the calyx.

3. *M. patens*. Swartz. Ind. Occ. 791.—Leaves with five or seven ribs, heart-shaped, hairy, somewhat toothed. Cluster terminal, spreading, bristly. Stamens twelve.—Native of the more lofty mountains of Jamaica, flowering in summer. The inhabitants call it the American Gooseberry. The *fruit* is sweet, but wants spirit. The *flowers* have rarely only ten *stamens*. It is a *shrub* eight or ten feet high, clothed with more lofty mountains of Jamaica, flowering in summer. The inhabitants call it the American Gooseberry. The *fruit* is sweet, but wants spirit. The *flowers* have rarely only ten *stamens*. It is a *shrub* eight or ten feet high, clothed with prominent, bristly, brownish-red hairs, and the branches are dark purple. *Leaves* varying in length from three to six inches, broad; green and bristly above; pale and downy beneath; ribs five or seven, besides the slender marginal ones, connected by a profusion of reticulated veins. *Footstalks* two or three inches long, bristly. *Clusters* three-forked, very bristly, with a pair of small leaves at each subdivision. *Flowers* large, with linear, bristly, elongated calyx-teeth, and whitish or flesh-coloured petals.

Section 2. *Stamens* ten; *leaves* with three separate ribs. Eighteen species in Willdenow.

5. *M. rigida*. Swartz. Ind. Occ. 768.—Leaves three-ribbed, minutely toothed, rigid, ovate, somewhat heart-shaped; roughish beneath. Clusters terminal, panicled, rough with dense rusty down.—Native of the Blue mountains of Jamaica; communicated by Dr. Dancer. A *shrub* 10' or 12 feet high; its *branches* obtusely quadrangular, compressed, rough at the extremities with dense, short, dark, rusty, somewhat starry, pubescence. *Leaves* from three to six inches long, on long rusty stalks, ovate, or slightly heart-shaped, rigid but brittle, pointed; smooth above; roughish, but of the same green colour, beneath; with three distant ribs, besides the marginal ones, and many parallel transverse veins. *Panicle* long, many-flowered, repeatedly three-forked, rusty. *Flowers* small, with white petals, each *calyx* subtended by a pair of long, awl-shaped, rusty, deciduous *bracteas*.

7. *M. montana*. Swartz. Ind. Occ. 766.—Leaves three-ribbed, very slightly toothed, nearly smooth. Cluster terminal; its branches deeply three-cleft, spreading. Petals obtuse. *Calyx* abrupt, with a deciduous lid.—Communicated by Dr. Swartz from the lofty mountains in the southern part of Jamaica. The *leaves*, *stalks*, and *calyx* are, in the dried plant at least, of a light yellowish-green, and every part is nearly, if not quite, smooth. *Flowers* small, white, their calyx-teeth combining to form a lid, as in the first species. The upper surface of the *leaves* is minutely granulated. Their lateral ribs are united, for a short space, to the middle one, so that they strictly come under the denomination of triply-ribbed. The marginal ones are distinct from the very bottom.

10. *M. aspera*. Linn. Sp. Pl. 560. (*M. foliis lanceolatis trinerviis scabris*; Linn. Zeyl. 76. n. 172. *M. scabra trinervia*;

MELASTOMA.

trinervia; Burm. Zeyl. 154. t. 72.)—Leaves ovato-lanceolate, three-ribbed, entire, rough with depressed bristles. Flowers in leafy clusters.—Native of Ceylon. We have a specimen from sir G. Staunton which answers well to Hermann's figure and description. These were mis-applied by Linnæus to his *oñandra*, as is well remarked by Retzius in his *fast.* 4. 25. In the Linnæan herbarium a specimen occurs marked *aspera*, which is not an original one, nor, in fact, different from *malabathrica* hereafter mentioned, except that the lateral ribs of the leaves are very small. *Katou Kadali*, Hort. Malab. v. 4. 91. t. 43, quoted for the present species, has strongly five-ribbed leaves, and numerous corymbose flowers, with an extremely hispid calyx. We cannot think it belongs here, and still less the *Fragarius ruber* of Rumph. Amboin. v. 4. 135. t. 71, whose flowers are described as small and white. Those of *M. aspera* are acknowledged on all hands to be large and purple. The East Indian *Melastoma* have not yet been carefully studied on the spot, by any accurate botanist, and the synonyms of this in particular have been much confused.—See *M. cyanoides*, hereafter described, a species to be introduced between Willdenow's n. 56 and 57.

12. *M. strigosa*. Linn. Suppl. 236; excluding the synonym.—Leaves ovate, three-ribbed, very bristly, entire. Flowers terminal, solitary. Calyx very bristly; its segments broad and triangular.—Sent by Mutis from New Grenada. This is a much-branched *shrub*, whose numerous leaves are ovate, stalked, about three-fourths of an inch long; paler, with three ribs very prominent, beneath. Every part is clothed with depressed yellow bristles. *Flowers* large, terminal, solitary, purple, their petals fringed with bristles; and the *calyx* is peculiarly hispid, with broad, short, triangular segments. It is a very handsome and remarkable species.

14. *M. velutina*. Willd. (*M. holosericea*; Herd. Linn Swartz. Obs. 176.)—Leaves three-ribbed, ovate, acute, entire, sessile, clothed on both sides with silky bristles. Cluster terminal, four-ranked; its branches cloven. Stem acutely quadrangular.—Native of Brasil, where it was gathered by father Panegai, and sent by Arduino to Linnæus; as well as by sir G. Staunton and sir J. Banks. We know no authority for its being found in Jamaica.—The leaves are from one to two inches long, sessile, remarkable for their dense silky bristly clothing. They have three principal ribs, with occasionally two slighter ones near the margin, towards the base. *Flowers* large and handsome, purple, with a very silky calyx, and ten long stamens.—This species is totally distinct from the original Linnæan *holosericea*, of which we shall speak hereafter. See n. 53.

14—15. *M. cuprea*.—Leaves three-ribbed, elliptic-ovate, pointed, entire, on short stalks; nearly smooth above; clothed with dense starry down beneath. Panicle terminal, thrice compound, with radiating branches.—Gathered in the Caraccas, by J. Mærtner, M. D. The branches, stalks, germen, and back of the leaves, are all densely clothed with fine starry hairs, which, in a dried state at least, are of a rich copper-coloured brown. A portion of the same is seen on the upper surface of each leaf, especially on the ribs. The segments of the calyx are smooth. *Flowers* very small and numerous, clustered, and composing a spreading, very compound panicle, whose branches spread in a radiating manner, many from one point, the lower ones at each ramification being the shortest. *Petals* not expanded in our specimen.—This should be placed between the 14th and 15th species of Willdenow. We can refer it to none that he enumerates.

14—15. *M. squamulosa*.—Leaves three-ribbed, elliptical,

obtuse, entire; smooth above; hoary beneath. Panicles terminal, compact. Calyx angular, minutely scaly.—Sent from New Grenada by Mutis to Linnæus. The stem is woody. *Leaves* on short thick stalks, rigid, elliptical, scarcely two inches long, obtuse, entire, with three distinct ribs, and numerous fine transverse veins. The upper side is green, quite smooth and rather shining; the under hoary, with very close, somewhat scaly, pubescence. *Panicles* terminal, compound, compact, about three inches long, many-flowered. *Calyx* turbinate, with ten ribs, and five broad short teeth, covered all over with close-pressed scurfy scales. *Petals* five, small, round, apparently yellow. *Berry* small, furrowed, hoary. Sometimes the flowers appear to be six-cleft.—This may stand next to our *cuprea*, though it has no particular likeness or affinity to that, or any other of this second section, being most allied to *ligustrina*, another new species hereafter described, from the same country.

20. *M. trinervia*. Swartz. Ind. Occ. 774.—Leaves three-ribbed, smoothish, elliptical, acute at both ends; the lateral ribs near the margin. Spikes long, axillary, in pairs. Flowers opposite or whorled.—Native of mountains in Jamaica. Introduced in 1793 into the stoves at Kew, where it blooms in July. The leaves are a span long, stalked, thin and pliant, of a broad, elliptical form, pointed at each end, pale beneath, with slightly downy veins. These leaves are peculiar for having the side ribs almost marginal, and very remote from the midrib, with which however they are connected by numerous transverse ribs, and reticulated veins. The inflorescence is so incorrectly described, that had we not authentic specimens, we could not have been certain of our plant. The flowers are small, numerous, in long downy spikes, two of which stand together in the forks of the branches, and are perhaps originally terminal, as Dr. Swartz describes, but the branch is soon extended on each side beyond them; neither are they racemi, for the flowers are perfectly sessile, in distant pairs, or sometimes whorls.

21. *M. repens*. Willd. n. 21. Lamarck Illustr. t. 361. f. 2.—“Leaves obovate, smooth, three-ribbed, nearly entire. Flowers solitary, terminal. Stem creeping.”—This, which is said to come from China, does not appear to us different from the *oñandra* of Linnæus, which varies in the number of parts in the flower, and will be hereafter described. We are at least certain that the synonyms of Osbeck and Retzius, cited here by Willdenow, belong to the real *oñandra*.

Section 3. *Stamens ten; leaves with three ribs combined at the base.*

23. *M. parviflora*. Aubl. Guian. 433. t. 171.—Leaves ovato-lanceolate, acute at each end, obscurely toothed, triple-ribbed, smooth. Panicle terminal, repeatedly three-forked.—Found by Aublet growing in moist situations in Cayenne and Guiana, where the inhabitants call it *tineta*, after the Portuguese, and use it in decoction to dye black. The stems are upright, shrubby, seven or eight feet high. Leaves a span long, pliant and quite smooth, green on both sides, but paler beneath, on smooth footstalks, scarcely an inch in length. They have three principal ribs, which in Aublet's specimen unite into one a little above the base, at not more than half the distance expressed in his plate. There are besides, as usual, a pair of much slighter marginal ribs, distinct to the bottom of the leaf. A large, very compound, three-forked panicle, of small white flowers, terminates each branch; but it sometimes becomes lateral by the elongation of the branch beyond. The berries are smooth, scarcely so big as a peppercorn, and of a blueish colour. The plant bears flowers and fruit in April.

25. *M. arborescens*. Aubl. Guian. 420. t. 163.—Leaves roundish-

roundish-ovate, acute, entire, triple-ribbed, smooth. Corymbs lateral. Petals divided at the base.—Native of woods in Guiana. A tree 60 feet high, with very broad ovate smooth entire leaves, rather opaque and paler beneath, four or five inches long. Their three central ribs are united for half an inch above the base; two lateral ones spring from the bottom; and there is also a pair of very slight marginal ones, not expressed in the plate. The flowers are white, produced in lateral bracted corymbs, from the sides of the branches, much below the foliage. The petals are described by Aublet with divided or double claws. Berry as big as a small medlar, yellow, sweetish, and eatable, known by the name of *mêlé* among the colonists. It ripens in November.—Willdenow justly points out the near resemblance of this plant to the Linnæan *M. grossularioides*, a species we have not seen, any more than himself, but its leaves are said to be toothed and pointed.

27—28. *M. ligustrina*. Leaves triple-ribbed, ovate, obtuse, entire, quite smooth. Panicles terminal, compact. Calyx hemispherical, furrowed, smooth.—Sent from New Granada, by Mutis to Linnæus. The stem and branches are woody, and, like the whole plant, perfectly smooth. Leaves stalked, an inch long, broadish-ovate, obtuse, entire, with three strong ribs united for a short distance from the base; the transverse veins are very slender, and the marginal ribs scarcely discernible. The upper surface is dark green, and polished; under paler and opaque, with a yellowish tinge. Flowers in compound clusters or panicles like those of Privet. Calyx short and hemispherical, most deeply furrowed in the upper part, quite smooth, with short, broad, blunt teeth. Petals small, roundish, white or purplish. Stamens short, with broad blunt anthers. Style obtuse. Stigma concave. Berry small, yellowish. All the flowers seem five-cleft. This is most akin to our *M. squamulosa*, described in the second section, though abundantly distinct, Linnæus had determined the genus of both, but left them undescribed.

Section 4. *Stamens ten; leaves with five combined ribs.*

28. *M. agrestis*. Aubl. Guian. 425. t. 166.—Very hairy. Leaves ovate, long-pointed, crenate, fringed, quintuple-ribbed. Corymbs axillary and terminal, spreading.—Native of banks of rivers, and about old walls, in Cayenne. Aublet. The specific name therefore must allude to its roughness of habit, not to its place of growth. The dense rusty-red spreading hairs, which clothe the branches, flower-stalks, footstalks, ribs and margins of the leaves, give the plant a tawny hispid aspect. The leaves are truly ovate, pointed, very neatly and closely crenate, about three inches long; their ribs disposed exactly as in the *arborescens* last described, so that both species ought to stand in the same section, whichever that may be. Aublet's figure is by no means correct in this point, according to his own specimen, and has misled Willdenow.

29. *M. scandens*. Aubl. t. 172. is more correctly quintuple-ribbed, as that figure expresses; but yet not in so striking a manner as some following species.

30: *M. alata*. Aubl. Guian. 410. t. 158.—Leaves elliptic-oblong, acute at each end, entire, quintuple-ribbed; rough above; downy beneath. Stem winged.—Native of uncultivated ground in Guiana and Cayenne, flowering in September, and fruiting a month or two afterward. The stems are six or seven feet high, remarkable for their four membranous wings. Leaves sessile, seven or eight inches long and about half as wide, much elongated at each end; rough above; paler and clothed with soft tufted down beneath. They have two pair of ribs, branching at wide intervals from the central one, besides a slight, nearly marginal, nerve. Panicle terminal, large, with square, partly winged,

stalks. Flowers in dense heads, small, whitish. Berry red, the size of a gooseberry, not very succulent. A decoction of the leaves is used to wash foul ulcers.

30—31. *M. nervosa*.—Leaves elliptic-oblong, acute at each end, slightly crenate, quintuple-ribbed; rather hairy on both sides. Spikes hairy, whorled.—Native of Jamaica. A specimen with the above name was given to the younger Linnæus from the Banksian herbarium. It was gathered by a man who deceived his employers, by pretending to have collected many of his plants at the isthmus of Darien; whereas it afterwards appeared he went no further than the West India islands. Hence some of his discoveries, being marked with a wrong place of growth, were not admitted by Dr. Swartz, (unless he had found them himself,) into his West Indian Flora. Such appears to be the case with the present *Melastoma*, which we cannot refer to any that is described. Its leaves agree much in size, form and ribs, with the *alata* last described; but they are crenate, and clothed with simple and longer hairs, especially the ribs. The stem is round, bristly, not winged. Flowers in sessile remote whorls, composing a long, terminal, hairy spike.

Section 5. *Stamens ten; leaves with at least five separate ribs.*

32. *M. hirta*. Linn. Sp. Pl. 559, excluding the synonyms of Plumier and Sloane. Swartz. Obf. 175. (M. n. 4; Browne Jam. 219. *Arbuscula Jamaicensis quinquenervis minutissimè dentatis foliis et caule pubescentibus, sifcusulis ex sinu foliorum gemellis; Pluk. Almagest. 40. t. 264 f. 1.*)—Leaves ovate, pointed, crenate, five-ribbed, hairy. Flowers axillary, somewhat corymbose, bristly as well as the branches.—Native of Brasil, as also of Jamaica. We have a specimen from Browne, nor can we account for the omission of this species in Swartz's Flora, as that author likewise mentions in his *Observationes* its growing on the woody hills of Jamaica, flowering in autumn and spring. The stem is shrubby, six feet high, the younger branches very hispid, as are the footstalks, flower-stalks, calyx, and both sides of the leaves, especially the under. All the pubescence is of a rusty hue. The leaves are broadly ovate, not at all lanceolate, with five distinct ribs, besides a pair scarcely discernible near the margin, towards the base. The flowers are white, few together, axillary and corymbose; sometimes said to be six-cleft.

34. *M. Acinodendron*. Linn. Sp. Pl. 558. Swartz. Obf. 174. (*Chrittophoriana americana, malabathri foliis acuminatis, nervosis, dentatis; Pluk. Phyt. t. 159. f. 1.*)—Leaves ovate, pointed, five-ribbed, finely toothed, slightly hairy. Panicle terminal, compound, three-forked, roughish. Flowers somewhat capitate.—Native of Surinam. Baker. *Herb. Banks*. Dr. Swartz remarks that this is an obscure species, the synonyms of which are much confounded. The Linnæan herbarium throws no light upon it, but we have received from sir J. Banks, under the name of *M. aurea*, which is very well suited to the colour of the dried leaves, a Surinam specimen, that indubitably accords with Plukenet's figure, which Linnæus commends; and as our specimen will not agree with any other described *Melastoma*, we refer it to the present, omitting all the synonyms as doubtful, except the above. The branches are smooth, slightly quadrangular upwards. Leaves about three inches long, on rather short hairy stalks, (the only character not expressed by Plukenet,) ovate, neatly toothed, with a short taper point, and five ribs connected by numerous transverse parallel veins. There is a very slight marginal rib near the base. A few golden hairs are sprinkled over the upper surface, and on the ribs of the lower. Panicle large and spreading, repeatedly three-forked, roughish with scattered stellated down. Flowers usually

MELASTOMA.

usually two or three together, sessile, with a pair of *bractes*, at the end of each stalk of the panicle. *Calyx* smooth, turbinate. *Petals* five, apparently white or yellowish, obovate.

35. *M. cymosa*. Schrad. Sert. Hannov. 18. t. 8. Vent. Malmaif. t. 14. (*M. corymbosa*; Ait. Hort. Kew. ed. 2. v. 3. 46?)—Leaves ovate, somewhat heart-shaped, pointed, seven-ribbed, somewhat hairy, with minute bristly serratures. Cyme terminal. Segments of the calyx triangular.—Native of South America according to Schrader; and, if we are right in the citation of Hort. Kew., of Sierra Leone also. It is not probable that so fine a plant, for many years past frequently seen flowering in the English stoves, should not be included in that rich catalogue, and it answers most precisely to the character there given under the name of *corymbosa*, except that the flowers are really cymose. We received a specimen in 1803, from the botanic garden at Liverpool, with the appellation of *M. purpurea*, under which it stands in the catalogue of that garden, p. 250. The *stems* are erect, about two feet high, succulent, herbaceous, scarcely shrubby. *Leaves* two or three inches long, on longish stalks, tender, of a broad, ovate, pointed figure, very slightly cordate at the base, fringed with minute bristly teeth directed forwards. The ribs are seven, besides a minute marginal pair at the base. Both sides are roughish with minute hairs; the under one palest, and most polished. *Flowers* several, rose-coloured, in a terminal, rather drooping, slightly downy cyme. There are five yellow abortive anthers; the five perfect ones are purplish.

37. *M. elegans*, beautiful as it appears in Aublet's t. 167, is in every respect so like *hirta*, see n. 32, except the deeper and double crenatures of the *leaves*, that we are persuaded it is but a variety of that species. There is no difference in the *inflorescence* or *flowers*.

40. *M. Maieta*. Lamarck Dict. v. 4. 34. (*Maieta guianensis*; Aubl. Guian. 443. t. 176.)—Leaves elliptical, pointed, five-ribbed, minutely crenate, hairy, inflated at the base. Flowers axillary, solitary, sessile.—Found by Aublet in Guiana, on the banks of a rivulet fifty miles from the sea-coast, flowering and fruiting in November. It is a *shrub* two or three feet high, the branches and foliage rough with bristly, prominent, rusty hairs. *Leaves* opposite, but very unequal in size, elliptical with a taper point and five ribs, without any at the margin besides. The larger *leaf* of each pair is from three to five inches long, and distinguished by a bladder-like swelling, of two cells, at the base, most prominent at the upper side; the smaller *leaf* is from one and a half to two inches long, and is usually destitute of any such bladder. The *flowers* are white, axillary, and solitary, bracteated at their base. It is difficult to imagine what led Aublet to distinguish this, as a genus, from *Melastoma*, to which it has not the slightest pretensions. The germen in the flower is indeed apparently superior, and distinct from the body of the calyx; but such is the case in many *Melastoma*, though those parts unite into a pulpy mass as the fruit ripens.

41. *M. heterophylla*. Lamarck Dict. v. 4. 34; and

42. *M. physiphora*. (Tococa guianensis; Aubl. 438. t. 174.) agree with the last in having a bladderly appendage to the base of the larger *leaves*, or, in the latter instance, to their *footstalks*.

49. *M. grossa*. Linn. Suppl. 236.—Leaves somewhat heart-shaped, five-ribbed, entire, very rough. Flowers terminal, corymbose. *Petals* bristly at the back.—Sent by Mutis from New Granada. This very magnificent species is distinguished by its coriaceous and bristly appearance. The *leaves* are scarcely two inches long, about one broad,

with five strong ribs, and numerous close transverse veins, clothed very densely on both sides, with innumerable, minute, rigid, curved bristles; paler beneath. The *branches* and *stalks* are all equally hispid, and of a rusty hue. *Flowers* very large, purple, about five or six in a terminal corymbose head. Segments of the *calyx* long and lanceolate. *Petals* obovate, above an inch long, clothed at the back, like the *calyx*, with rigid upright bristles.

50. *M. malabathrica*. Linn. Sp. Pl. 559. Curt. Mag. t. 529?) *M. foliis lanceolato-ovatis scabris quinquenerviis*; Linn. Zeyl. 76. n. 171. *M. quinquenervia hirta major, capitulis fericeis villosis*; Burm. Zeyl. 155. t. 73. Kadali; Rheede Malab. v. 4. 87. t. 42. *Fragarius niger*; Rumph. Amb. v. 4. 137. t. 72.)—Leaves elliptic-lanceolate, five-ribbed, entire, rough with depressed bristles. Flowers terminal, corymbose. *Calyx* clothed with fringed imbricated scales.—Native of the East Indies. It is said to have been given to Kew garden by Sir G. Staunton in 1795. We quote the Botanical Magazine with doubt, because the figure is unfortunately so contrived as not to shew the *calyx*, a most important part in this case; neither does the form of the *leaves*, or the situation of their lateral ribs, precisely agree with our wild specimens. Of the other synonyms we have no doubt. Burmann, whose remarks on this plant are very good, observes that the calyx is drawn smooth in Rheede's figure, though described rough. Rumphius most happily compares it to the calyx of *Centaurea Cyanus*. It is in fact clothed with fine sharp-pointed fringed scales, such as we have remarked in no other species. The *petals* are large and purple, smooth on both sides, but fringed with bristles. The young *branches*, *stalks*, and ribs of the *leaves*, are scaly in a degree like the *calyx*. Sometimes the lateral ribs are so small and slender as to be scarcely discernible. A specimen so circumstanced is in the Linnæan herbarium marked *aspera*; see n. 10.

50—51. *M. granulosa*. Lamarck Dict. v. 4. 44.—Leaves ovate-lanceolate, five-ribbed, entire; rough above with close-pressed bristles; downy beneath. Cluster with corymbose branches. *Calyx* silky. Stem winged.—Gathered by Commerçon in Brazil, and given by Thouin to the younger Linnæus. A magnificent species, with *leaves* five or six inches long, whose outermost ribs are united at the base to the next. Their upper surface is so granulated, as it were, with close-pressed bristles, as to look like the surface of a strawberry. The *stem* is bristly, nearly in like manner, and has four membranous wings. *Flowers* purple, large, and handsome, in a compound forked cluster. *Calyx* densely covered with silky hairs. This *shrub* is about ten feet high.

53. *M. albicans*. Swartz. Ind. Occ. 786. (*M. holosericea*; Linn. Sp. Pl. 559. Willd. n. 13. *Arbor racemosa brasiliensis, foliis malabathri*; Breyn. Cent. 1. 3. t. 2. 4.)—Leaves ovate, acute, five-ribbed, entire; polished and naked above; rusty-white with cottony down beneath. Clusters terminal, cottony, with cymose branches. Flowers sessile.—Native of Brazil and of Jamaica. A *shrub* six or eight feet high, with hoary *branches*, which are slightly angular. *Leaves* on short, thick, hoary stalks, elliptic-ovate, acute, three or four inches long, very slightly heart-shaped at the base; perfectly smooth and highly polished above, so as to look, when dried, like black Spanish leather, as Breynius very happily remarks; on the under side they are entirely clothed with dense soft cottony down, white with a rusty tinge, and have five strong ribs, all united at a very small distance above the base. The *chylers* are composed of opposite forked or cymose branches. The *flowers* are sessile, small, with a cottony *calyx* and white *petals*.

About

MELASTOMA.

About this species there has been great confusion. It is unquestionably the original *holosericea* of Linnæus, (admirably described and figured by Bryonia,) but not that which he afterwards called so in his herbarium, and which Dr. Swartz described in his *Obs. Bot.*; see *volantia*, n. 14. The name however of *holosericea* is not so applicable to the plant before us, as that given by Swartz, by which it is most generally known, and which for that reason we have retained, as the best means of avoiding mistake.

56—57. *M. cyanides*. (Fragaria ruber; Rumph. Amb. v. 4. 135 t. 71. Katou-Kadali; Rhede Malab. v. 4. 91. t. 43.)—Leaves ovate, acute, five-ribbed, entire; roughish on both sides with close-pressed bristles. Clusters terminal, forked. Calyx clothed with clustered bristles. Bractæas ovate, fringed.—Sent from Amboyna by the late Mr. Christopher Smith. We can refer it to none in Willdenow or Lamarck, but we quote without hesitation the above synonyms, which have been, surely erroneously, referred to the true *M. aspera*; see n. 10. The present is rather a small and weak shrub, with slender, grey, slightly bristly branches. Leaves bright green on both sides, paler beneath, ovate, rather pointed, three inches long, and above one broad, with five distinct ribs, of which the lateral ones are nearly as considerable as the rest. The upper surface is besprinkled with yellow close-pressed bristles; the under is chiefly bristly at the ribs and veins. Footstalks bristly, purplish, half an inch long. Panicles terminal, forked or corymbose, a little bristly, with a pair of ovate, concave, smooth though fringed bractæas, at each division. Calyx densely covered with clustered, sometimes palmate, whitish bristles, which are, as far as we have seen, peculiar to this species, and give the part in question a great resemblance to *Centauria Cyanus*. The petals are said by Rumphius to be white; in the Hortus Malabaricus they seem implied to be purple. The fruit is compared by the former author to a strawberry, being redder on one side than the other. It is agreeably acid, with some astringency, and is given to children in Amboyna, to prevent what some learned corruptor of English may hereafter call lestimition.

Section 6. *Stamens eight; leaves with three separate ribs.*

59. *M. microphylla*. Swartz. Ind. Occ. 813; is erroneously placed here. It has ovate, obtuse, hairy leaves, about an inch long, most evidently triple-ribbed. The flowers are small, with a very hispid calyx, and stand in the forks of the branches, one usually nearly sessile, with two or three others on capillary, hairy, simple stalks. The fruit looks like that of a *Croton*, but has four furrows; nor are the leaves dissimilar to some of that genus, yet we cannot refer our plant to *M. crotonifolia*, n. 35. of Lamarck. The present species is but ill compared by Swartz to his *hirtula*, which we have from himself, and which is more related to *hirta*; see n. 32. It must always be remembered that these sections of the genus, which we have adopted from Willdenow, are entirely artificial, as well as somewhat inconstant.

61. *M. capillaris*. Swartz. Ind. Occ. 808.—Leaves lanceolate, pointed, three-ribbed, smooth, nearly entire. Stalks axillary, capillary, three-flowered. Native of hills in the south parts of Jamaica. A very fair example of this section. It is remarkable for its extremely minute, whitish, short-lived flowers, which stand, three together, on roughish, capillary, axillary stalks. The calyx has four minute upright teeth. The berry also is perhaps the smallest in the whole genus. The young leaves are somewhat downy beneath, but the full-grown ones are smooth, three inches long, narrow, taper-pointed, pale at the back, with three

ribs, and strong, simple, transverse veins. We have a specimen from its discoverer.

64. *M. glandulosa*. Swartz. Ind. Occ. 799.—Leaves ovate, entire, with three ribs besides the marginal ones, hispid on both sides, with axillary tufts of bristles at the veins beneath. Panicles terminal, three-forked, very rough. Gathered by Masson and Swartz on the loftiest hills of Jamaica. This is akin to some of the roughest leaved species before described, but distinguished by pale tufts of bristles at the separation of each vein from the midrib beneath. The leaves are about three inches long, and more than one broad; the bristles of their upper side most rigid, yellow and hooked. Panicle spreading, many-flowered, excessively hispid. Petals four, with longish claws. Stamens eight. Anthers bordered at each side with a yellow membrane. Style long and prominent. We cannot but remark that this is properly a five-ribbed species, and ought to stand in a section hereafter mentioned.

67. *M. octandra*. Linn. Sp. Pl. 560. (*M. foliis lanceolatis trinerviis glabris, margine hispidis*; Linn. Zeyl. 76. n. 173, excluding the synonyms. *M. repens*; see n. 21.)—Leaves ovate, entire, three-ribbed, smooth, with a simple marginal row of close-pressed bristles. Flowers terminal, mostly solitary. Calyx bristly.—Native of Ceylon and China. The stem is rather woody, but prostrate, branched and creeping. Leaves about an inch long, of a broad ovate obtuse figure, three-ribbed, besides an occasional pair of obsolete marginal ribs; dark green above; very pale and yellowish beneath; smooth and naked on both sides, except a few hairs on the ribs beneath, and a very remarkable row of marginal close-pressed oblique bristles, on the upper side, resembling litches of thread; these are sometimes partially wanting. Flowers terminal, mostly solitary, large, purple, very handsome. Calyx clothed with simple incurved bristles. Petals fringed, barbed at the summit with a bristly tuft.

Lamarck was led by the synonym of Burmann, erroneously quoted by Linnæus, to describe and figure this real *M. octandra* of the latter as a new species, by the name of *repens*. This name however we should wish to retain, as the flowers in our specimens are most frequently five-cleft and decandrous. We know not why the leaves have ever been described as in any degree lanceolate, they being truly ovate. Half the stamens appear to be always abortive.

69. *M. tetrandra*. Swartz. Ind. Occ. 795.—Leaves three-ribbed, oblong, pointed, entire, smooth, with a notch at the base. Cluster erect, terminal. Stamens four.—Native of the Blue mountains in the south of Jamaica, but very rare. Flowering in May. This is a middling-sized tree, whose young branches are square, and nearly smooth. Leaves three or four inches in length, and one in breadth, on long stalks, smooth, entire, pointed, rounded at the base, with a notch at the footstalk. They have one strong central rib, with a slight marginal pair only. The flowers we have not seen. Dr. Swartz describes them as small and white, in a terminal compound cluster, which is rough with rusty mealiness. They are four-cleft, with but four stamens. Berry minute, roundish.

71. *M. angustifolia*. Swartz. Ind. Occ. 796.—Leaves three-ribbed, linear-lanceolate, entire; hoary beneath. Branches wand-like. Clusters terminal, repeatedly three-forked, mealy and rusty.—Native of Jamaica and other West Indian islands. A slender shrub, distinguished by its elegant narrow leaves; of a bright yellowish-green, and smooth, above; hoary and slightly rusty, with beautifully regular transverse veins beneath. Clusters terminal, stalked,
with

with many forked, spreading, cymose branches. *Calyx* mealy. *Petals* four, pale yellow. *Stamens* eight.

Section 7. *Stamens* eight; *leaves* with three combined ribs.

78. *M. Jabrofa*. Linn. Sp. Pl. 558. Swartz. Obf. 174. (M. n. 5; Browne Jam. 219. t. 24. f. 3.)—Leaves ovate, crenate, triple-ribbed, rough and hairy. Branches densely shaggy. Flowers axillary, aggregate, octandrous.—Native of the cooler mountains of Jamaica. A *shrub* about a man's height, whose branches are densely covered with short shaggy hairs, like the stalks and ribs of the *leaves*, which last are broad-ovate, three inches long, very harsh and hispid on both sides, furnished with three ribs combined at their base, and two distinct ones nearer the margin, which is irregularly crenate. Swartz describes the *flowers* as very minute, pale red, sessile and axillary. Of these Browne's specimen in the Linnæan herbarium retains two or three, which however stand on stalks, about as long as the *calyx*. The segments of the latter are awl-shaped.

Section 8. *Stamens* eight; *leaves* with five ribs.

80. *M. umbrosa*. Swartz: Ind. Occ. 817.—Leaves roundish-ovate, pointed, finely toothed, hairy on both sides. Clusters axillary, compound, bristly, spreading.—Found in several of the West Indian islands. This species has very hispid *branches* and *stalks*, and is remarkable for its large, almost round, taper-pointed *leaves*, broader than the hand, which have five ribs, besides the marginal ones, all running from the base to the extremity. The *clusters* are axillary, and in pairs, scarcely longer than the footstalks, twice compound, spreading widely. *Braçtas* spatulate, recurved, bristly. *Flowers* white, very small.

85. *M. coccinea*. Vahl. Eclog. v. 1. 48.—Leaves elliptic-ovate, pointed, five-ribbed, entire, smooth. Branches hispid at intervals.—Native of the island of Montserrat. *Stem* arboreous. *Branches* bluntly quadrangular, hollow, knotty, clothed here and there with irregular interrupted tufts of horizontal pale hairs, like radicles. *Leaves* several inches in length and breadth, smooth, entire, with five ribs besides the two marginal ones, the three in the centre slightly combined at their base. The *flowers* are said to be scarlet, or occasionally white, forming a terminal *thyrsus*, which we have seen but in an imperfect condition. S.

MELASTOMA, in *Gardening*, contains plants of the evergreen tree and shrubby exotic kinds, of which the species cultivated are, the American gooseberry of Surinam (*M. grossularioides*); and the fattiny-leaved melastoma (*M. hololicea*).

But there are other species which may be cultivated.

Method of Culture.—These tender plants are best obtained by having the entire fruits put up in their native places in dry sand as soon as ripened, and immediately forwarded, which as soon as they arrive should be taken out, and the seeds sown in pots of light earth, plunging them in a moderate hot-bed of tanners' bark: when the plants are up, and fit to remove, they should be planted each in a small pot of light earth, replunging them in the tan-bed of the stove.

Afterwards they require the management of other woody stove-plants.

And they may also be increased by laying the young branches in the spring, or by planting cuttings of the young shoots in the summer season in pots, and plunging them in a hot-bed. They should afterwards have the same culture as the other kinds.

MELASTOMÆ, in *Botany*, a very beautiful but not extensive natural order in Jussieu's system, of which the genus from whence the name is derived makes the principal part. (See MELASTOMA.) This order is the 90th of Jussieu, the

eighth of his 14th class. The characters of that class are given under the article FICOIDÆÆ. It has two cotyledons, many petals, and stamens inserted into some part of the calyx.

The *Melastomæ* are thus distinguished.

Calyx of one leaf, tubular, either superior or inferior, simple or surrounded with scales. *Petals* several, of a definite number, inserted into the top of the calyx, equal in number to its segments and alternate with them. *Stamens* inserted into the same place, of a definite number, which is double that of the petals; the top of the filaments, beneath the anthers, mostly furnished with two bristles, or two auricles; anthers long, beaked at the summit, attached by their base to the top of the filaments, and, at first, drooping, in consequence of the filaments being bent inwards; but as the latter afterwards become straight, the anthers rise upwards. *Germen* sometimes superior, enclosed by the calyx, sometimes inferior; style solitary; stigma simple. *Fruit* either pulpy or capsular, invested, when superior, with the calyx, which is contracted above; when inferior, attached to the same part, and swelling beneath it, of many cells, with numerous seeds in each cell. *Corculum* suspected by Jussieu to be unaccompanied with albumen. *Stem* rather arboreous, or shrubby, or rarely herbaceous. *Leaves* opposite, simple, with three or more longitudinal ribs. *Flowers* opposite, either axillary or terminal, their stalks either single or many-flowered.

The first section is said to have an inferior germen, and consists of *Blakea* of Browne and Linnæus, to which it is doubtful whether the *Blakea* of Aublet be properly united as one genus; *Melastoma*, see that article; and *Tristemma*, a genus of Jussieu's, brought by Commerçon from the Mauritius.

Section the second is characterized by a superior germen, and consists of *Topobea* of Aublet, with *Tibouchina*, *Mayeta* or *Maieta*, and *Tococa* of the same author, which two last are now referred to *Melastoma*, there being really no generic distinction. To these are added *Osbeckia* and *Rhexia* of Linnæus, whose fruits are capsular.

The plants of this order are, on the one hand, akin to the *Myrti*, and on the other to the *Salicariæ*, but distinguished from both by their very conspicuous large and long-beaked anthers, with appendages at their base. By the definite number of their stamens they are moreover distinguished from the *Myrti*, to which we may add the peculiarly ribbed leaves, and rigid depressed pubescence, of many species, and the want of an aromatic quality. To the *Salicariæ* they are more similar in habit.

Number of parts is one of the most variable circumstances belonging to this order, the stamens differing in different species, and even varying sometimes in the same, from eight to ten, or from ten to twelve; and consequently the petals and calyx-teeth from four to five or six; of which the genus *Melastoma* affords instances.

MELAVÉRD, in *Geography*, a town of Persia, in the province of Irak; 45 miles N.E. of Ispahan.

MELAUÏ, or MELLAVOÛÉ, a small and tolerably handsome town of Egypt, situated half a league from the W. bank of the Nile, and the residence of a "kiaschef." The plain surrounding it is very fertile, particularly in corn, a great quantity of which is exported by way of Cairo, Suez, and the Red sea to Mecca, and other parts of Arabia. The Christians have no church, but repair to the convent on the other side; 120 miles S. of Cairo. N. lat. 28° 2'.

MELAZZO, or MILAZZO, anciently *Myle*, a sea-port town of Sicily, in the valley of Demona, situated in a bay on the N. coast of the island. It consists of two parts, one of which stands on a promontory of the same name,

and

and is fortified: the other, on a bay, with a good harbour, the entrance of which is defended by a castle, 18 miles W. of Messina. N. lat. 38° 16'. E. long. 15° 23'.

MELBON, one of the cluster of the "Seven Islands," in the English channel, near the coast of France. N. lat. 48° 54'. W. long. 3° 22'.

MELBY, a town of Norway, in the province of Aggerhus, on the Glomme; 55 miles N.E. of Christiania.

MELCAPOUR, a town of Hindoostan, in the Candish; 20 miles S. of Burhampour.

MELCHITES, or MELCHITES, in *Ecclesiastical History*, were those Christians in Syria, Egypt, and the Levant, who in the seventh century, though not Greeks, followed the doctrines and ceremonies of the Greek church. They were called *melechites*, i. e. *royalists*, from the Hebrew *melech*, king, by their adversaries, by way of reproach, on account of their implicit submission to the edict of the emperor Marcian, in favour of the council of Chalcedon. For the same reason the emperor Justinian had the epithet Chalcedonensis given him.

MELCHIZEDECH, in *Biography*, king of Salem, and priest of the most high God, is mentioned in the scriptures, but without any reference to his genealogy, or to his birth or death: and in this sense, it has been asserted, he was a figure of Jesus Christ, as is affirmed in the epistle to the Hebrews, "Who is a priest for ever, according to the order of Melchizedech," and not according to the order of Aaron, whose origin, life, and death are known. When Abraham returned from pursuing the confederate kings, who had defeated the kings of Sodom and Gomorrah, and had taken away Lot with them, Melchizedech came to meet Abraham, and presented to him bread and wine with his benediction. (Gen. xiv. 17, &c.) Abraham, being desirous to acknowledge in him the quality of priest of the Lord, offered him the tythes of all that he had taken from the enemy. After this time there is no mention made of Melchizedech, till the 110th psalm, where, in allusion to the Messiah, it is said, "Thou art a priest for ever after the order of Melchizedech." It having been asserted, that he was without father or mother, some of the early Christians assumed that he was a celestial being, superior to angels. These obtained the name of *Melchizedechians*; which see.

MELCHIZEDECHIANS, or MELCHISEDEKIANS, ancient sectaries, so called, because they raised Melchizedech above all creatures, and even above Jesus Christ.

The author of this sect was one Theodotus; whence the Melchizedechians become more commonly known by the name of Theodotians; all the difference between those and the strict Theodotians consisting in that particular article relating to Melchizedech; who, according to them, was the great and supreme virtue.

This sect was revived in Egypt towards the close of the third century by Hierax. (See *HIERACITES*.) Those also in later times, who have maintained that Melchizedech was the son of God in a human form, may be distinguished by this appellation. See *Cunæus de Rep. Hæbræorum*.

MELCK, or MÖLK, in *Geography*, a town of Austria, near the Danube. In its vicinity is a famous cloister of Benedictines, seated on a rock; its library is said to consist of some curious and valuable MSS.; 11 miles W. of St. Polten.

MELCOMBE-REGIS, a borough and market-town in the hundred of Uggescombe, Dorchester division of the county of Dorset, England, is situated eight miles from Dorchester, 127 miles from London, at the mouth of the river Wey, which separates it from Weymouth. The

population of Melcombe in the year 1801, according to the return made to parliament, was 2350, occupying 471 houses. This borough has sent two representatives to parliament ever since the reign of Edward II. Melcombe and Weymouth are so frequently joined in ancient grants, that there is some difficulty in separating them; though each had distinct privileges; of which Melcombe, being the favoured borough, and part of the demesne of the crown a considerable time before Weymouth, had the greater share, and is principally noticed in succeeding charters to the exclusion of its neighbour. Hence arose disputes between the rival boroughs respecting their privileges; and the contention had arrived to so great a height in the reign of Elizabeth, that the expediency of a union became apparent; and they were accordingly incorporated by an act passed in the 13th year of that queen (afterwards confirmed by James I.) and directed to be called "The united town and borough of Weymouth and Melcombe-Regis." The civil government, with other local circumstances relative to Melcombe, will be found under WEYMOUTH. Sir James Thornhill, the celebrated painter of the cupola of St. Paul's cathedral and the halls of Greenwich hospital and Blenheim, was born at Melcombe in the year 1675, and died at his seat at Thornhill, near this town in 1734. (See *THORNHILL*.) Beauties of England and Wales, vol. iv. Hutchin's History of Dorchester, 2 vols. folio.

MELCONDA, a town of Hindoostan, in Dowlatabad; 23 miles W. of Beder.

MELDAL, a town of Norway, in the province of Drontheim; 30 miles S.S.W. of Dronheim.

MELDFÉE, in our *Old Writers*, a recompence due and given to him that made the discovery of any breach of penal laws, committed by another person, called the promoter's or informer's fee.

The word is Saxon, from *meldfeob*.

MELDOLA, in *Geography*, a town of Italy, in the department of the Rubicon; seven miles S. of Forli.

MELDORP, a sea-port of Holstein, at the mouth of the river Myle; 50 miles N.W. of Hamburg. N. lat. 54° 10'. E. long. 9° 4'.

MELDRUM, a town of Scotland, in the county of Aberdeen, being a burgh of barony, and holding a weekly market; 16 miles N.N.W. of Aberdeen.

MELEAGER, in *Biography*, a Greek poet, son of Eurates, was a native of Gadara, in Syria, or of Atthis, a village in its territory, and is supposed to have flourished about a century before the Christian era. He spent his youth chiefly at Gadara, where he formed himself upon the style and manner of Menippus, an elder poet of that place. He afterwards resided at Tyre, and finally passed over to Cos by way of refuge from the wars which ravaged Syria, and died there at an advanced age. He was the first who made a collection of the short poems called by the Greeks epigrams. Of these he formed two sets, under the title of "Anthologia," the *first* of which was a lamentable proof of the licentiousness of the age and country; the *second*, consisting of miscellaneous pieces, has formed the basis of the later anthologies of Agathias and Planudes. Many of the poems are the work of Meleager, and possess much elegance: an edition of the poems was given by Brunck in 1709. Gen. Biog.

MELEAGRIS, in *Natural History*, a genus of birds of the order Gallinæ. Bill conic, incurvate; head covered with spongy caruncles; chin with a longitudinal membranaceous caruncle; tail broad, expansile; legs spurred. According to Buffon, there is but one known species, which he says is a large unwieldy bird, the anterior part of the

head

head is strangely covered and ornamented with a pendulous, soft, and fleshy substance, as also are the sides of the head and throat; the eyes are small, but bright and piercing; the bill convex, short and strong; a long tuft of coarse black hairs on the breast, the wings moderately long, but not at all formed for supporting so large a bulk in long flights; the legs moderately long, and very robust. In Gmelin's edition of Linnæus, two species are mentioned, namely, the Gallipavo and Satyra, of which the following are the characteristics.

Species.

GALLIPAVO. Front and chin carunculate; breast of the male tufted. It inhabits America; is above three and a half feet long, is domesticated every where, and varies much in its colours; in a wild state, it lives in woods and feeds on nuts, acorns, and insects; roosts on the highest trees, is very irascible and impatient of any thing red; the cock struts with an inflated breast, expanded tail, red face and relaxed frontal caruncle, and makes a singular inward noise, which, when it is uttered, shakes the whole body; eggs numerous, white, with reddish or yellow spots; it has eighteen tail-feathers. The female has no spur.

SATYRA. Head with two horns; body red with eye-like spots. This is called the horned turkey. It inhabits India, and is less than the last species. The bill brown; nostrils, front, and area of the eyes covered with black hair-like feathers; crown red; horn callous, blue, bent back; caruncle of the chin dilatible, blue, varied with rufous; legs whitish, spurred; it has 20 tail-feathers. The female has its head covered with feathers, without horns or gular caruncle; feathers of the head and upper part of the neck black-blue, long, decumbent; rest of the body as in the male, red, with eye-like spots; spurs more obtuse.

MELEAGRIS, the Guinea-hen or Pintado, a species of *Numida*; which see.

MELEAGRIS, in *Zoology*, a species of *Anguis*.

MELEDA, in *Geography*, an island in the Adriatic, separated from the peninsula of Sabioncello by a narrow channel, belonging to the republic of Ragusa. It is about 30 miles long, and of an unequal breadth, and is intersected by many bays and inlets, which afford good harbours for fishermen. It produces vines, orange and lemon trees, but not sufficient corn for the inhabitants, who amount to about 2000, occupying six or seven villages. N. lat. $43^{\circ} 5'$. E. long. $17^{\circ} 44'$.

MELELA, a town of Africa, in Barca; 76 miles S.W. of Tolometa.

MELEMBBA, a town of Cacongo. S. lat. $5^{\circ} 30'$. E. long. $11^{\circ} 55'$.

MELENES, a small island in the English channel, near the coast of France. N. lat. $48^{\circ} 48'$. W. long. $3^{\circ} 31'$.

MELENKI, a town of Russia, in the government of Vladimir, on the Oka; 44 miles S.E. of Vladimir. N. lat. $60^{\circ} 24'$. E. long. $41^{\circ} 24'$.

MELES, BADGER, in *Zoology*, a species of *Ursus*; which see.

MELETIANUS, in *Ecclesiastical History*, the name of a considerable party, who adhered to the cause of Meletius, bishop of Lycopolis, in Upper Egypt, after he was deposed about the year 306, by Peter, bishop of Alexandria, under the charge of his having sacrificed to the gods, and having been guilty of other heinous crimes; though Epiphanius makes his only failing to have been an excessive severity against the lapsed. This dispute, which was at first a personal difference between Meletius and Peter, became a re-

ligious controversy; and the Meletian party subsisted in the fifth century; but was condemned by the first council of Nice.

MELETIN, in *Geography*, a river of European Turkey, which runs into the Pruth, 12 miles N. of Jassi, in the province of Moldavia.

MELETZKOL, a town of Russia, in the province of Tobolsk; 44 miles N. of Archinsk.

MELFI, a town of Naples, in Basilicata, the see of a bishop, containing seven churches and eight convents; five miles N.W. of Venosa. N. lat. $41^{\circ} 1'$. E. long. $15^{\circ} 39'$.

MELFORD, LONG, an extensive village, situated near the river Stour, in the hundred of Babergh, and county of Suffolk, England. It is about one mile in length, whence the characteristic appellation *long*, and contains, according to the parliamentary returns of 1801, 450 houses, and 2204 inhabitants, viz. 1034 males and 1173 females. Of these 1837 were returned as employed in different departments of trade. Few villages in England can boast of a more agreeable situation than this, the immediate vicinity being distinguished by much beautiful and picturesque scenery. The church, which stands on an elevated spot at the north end of the village, is a curious piece of architecture in the pointed style of the fifteenth century. Its length is 180 feet, exclusive of the school-house at the western extremity. The chancel, or east end, is distinguished for its masonry, consisting of flint work, and squared stones; and beneath the parapet is an inscription in old letters. In the north aisle is an altar tomb for William Clopton, esq., whose statue, in armour, rests on the top; he died in 1446. His son, John Clopton, who was sheriff of the counties of Norfolk and Suffolk in the time of Henry VI., was interred under an altar tomb in the chancel. Near the communion table is a large and stately marble monument to the memory of sir William Cordell, who was speaker of the house of commons in the reign of queen Mary. This gentleman founded an hospital here, which is still standing, almost close to the church. It is a respectable brick building, and is sufficiently endowed for the support of a warden, twelve poor men, and two women, who are required to be old and decayed housekeepers of Melford. Several Roman urns have been dug up in this parish within these few years. At a short distance east of the church is Melford Hall, the seat of sir H. Parker, bart. The house, a large brick building, appears to be of the age of queen Elizabeth. At the dissolution of religious houses, this estate was granted to sir William Cordell. About half a mile north of the church is Kentwell Hall, formerly the seat of the Cloptons, but now the seat of Richard Moore, esq. The house is large, and was formerly surrounded by a moat, three sides of which are still remaining; the fourth, or east side, has been filled up. Beauties of England and Wales, vol. xiv. by F. Shoberl. Kirby's Suffolk Traveller.

MELGAR, a town of Spain, in Old Castile; 23 miles W.N.W. of Burgos.

MELGASSO, a town of Portugal, in the province of Entre Duero e Minho, situated on the Minho, and defended by a castle; 30 miles N. of Braga. N. lat. $42^{\circ} 5'$. W. long. 8° .

MELHANIA, in *Botany*, Forsk. *Ægypt.-Arab.* 64. Juss. 277; a genus of Forskall's, named by him from Melhân the Arabic appellation of the hill upon which he gathered it, and which is rich in curious plants. He describes this as a branched spreading shrub, two cubits high, with soft, ovato-lanceolate, serrated leaves, and yellow, axillary, stalked flowers. The calyx is double; the outer of three, inner of five, leaves. Stamens five, inserted into a nectariferous

ferous crown, with five intermediate linear bodies, exceeding them in length. *Style* one, with five stigmas. *Capsule* globose, of five cells and five valves. *Seeds* four in each cell, angular, dotted.

The only species in *M. velutina*, described above. Jussieu suspects it to be of the same genus as *Dombeya* and *Affinia* of Cavanilles, both united under the latter name by Schreber. Our plant is *Dombeya velutina*, Willd. Sp. Pl. v. 3. 726. (*Pentapetes velutina*; Vahl. Symb. v. 1. 49.) We have already objected to this *Dombeya* in describing the true one. See *Dombeya*.

MELHUA, or MELLUAH, in *Geography*, a town of Syria, in the desert; 20 miles S.E. of Aleppo.

MELIA, in *Botany*, a name adopted by Linnæus for this tree, apparently because its leaves resemble those of the *Az*, which is doubtless the true *Melia* of the ancient Greeks. Linn. Gen. 211. Schreb. 286. Willd. Sp. Pl. v. 3. 558. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 39. Juss. 265. Lamarek Illustr. t. 352. Cavan. Diff. 363. (*Azedarach*; Tournef. t. 387.)—Class and order; *Decandria Monogynia*. Nat. Ord. *Tribilata*, Linn. *Meliz*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, very small, five-toothed, erect, obtuse. *Cor.* Petals five, linear-lanceolate, spreading, long. Nectary cylindrical, of one leaf, the length of the corolla, with a ten-toothed mouth. *Stam.* Filaments ten, very small, situated within the apex of the nectary; anthers oblong, not protruding beyond it. *Pist.* Germen conical; style cylindrical, the length of the nectary; stigma capitate, with five, conniving valves. *Peric.* Drupa globose, soft. *Seed* a roundish, five-furrowed, five-celled nut.

Ess. Ch. Calyx five-toothed. Petals five. Nectary cylindrical, toothed at its mouth, bearing the anthers. Drupa a nut of five cells.

1. *M. Azedarach*. Common Bead-tree, or Pride of China.—Linn. Sp. Pl. 550. Sims in Bot. Mag. t. 1066. Sm. Ins. of Georgia, v. 2. t. 90.—Leaves bipinnate; leaflets smooth, about five. Native of Syria, and common in Spain. Cultivated, in 1656, by Mr. John Tradescant jun. It flowers from June to August. This beautiful tree grows to a large size in warm countries, and is much branched. *Leaflets* ovate, notched, pointed, green above, paler beneath. *Flowers* lateral, in long, loose panicles. Petals white, streaked with pink. *Fruit* oblong, the size of a cherry, of a pale yellow when ripe.—The pulp which surrounds the nut is poisonous, and “in the southern parts of Europe, the nuts are threaded for beads to assist the devotion of good Catholics, for which purpose they are peculiarly suited, having a natural perforation through the centre; hence the tree has been called *arbor sancta*, and by the Spaniards *arbol parayso*.” Sims.

2. *M. sempervirens*. Evergreen Bead-tree. Swartz. Prod. 67. Ind. Occ. v. 2. 737. (*M. Azedarach* β; Linn. Sp. Pl. 550. *Azadirachta indica*, &c.; Com. Hort. Amst. v. 1. 147. t. 76.)—Leaves bipinnate; leaflets somewhat rugose, generally about seven.—A native of the East and West Indies, in which latter country it is called Indian lilac. In separating this from the last species, we have the authority of Swartz, who says that the whole plant is considerably smaller, that the leaflets are of a brighter green, seldom more than seven, somewhat wrinkled, more deeply and unequally serrated and pointed. In addition to these marks of distinction its foliage is not deciduous. The author of the Botanical Magazine has not thought proper to disunite them, but we do not think his reasons conclusive.

3. *M. Azadirachta*. Ash-leaved Indian Bead-tree. Linn. Sp. Pl. 550. Cavan. Diff. t. 208. (*Aria Bepou*; Rheed. Hort. Mal. v. 4. t. 52.)—Leaves pinnate.—A na-

tive of the East. In India, flowering in June and July.—The stem of this tree is large and thick. The wood of a pale yellow; the bark of a dark purple, and very bitter. *Leaves* composed of five or six pairs of oblong, pointed leaflets, terminated by an odd one. These are opposite or alternate, on long footstalks, smelling disagreeably. *Flowers* small, white, lateral, in long, branching panicles. *Fruit* oval, the size of small olives, green, turning yellow, and purple when ripe; its pulp abounds with an acrid and bitter oil, some of which was sent by Dr. Roxburgh to the President of the Linnæan society in 1792, with the character of an excellent vermifuge.

4. *M. dubia*. Cavan. Diff. 364.—Leaves bipinnate, leaflets broadly lanceolate, acute, serrated, the terminal one larger.—Sent by M. Sonnerat to Lamarek from the East Indies.—All that we know of this species is from Cavanilles, who says that he saw a single specimen of it in Lamarek's herbarium without any name, but that he easily discovered it belonged either to *Trichilia* or *Melia*, and that he referred it to the latter genus from its fruit. The flowers resemble those of *M. Azadirachta*.

5. *M. composita*. Willd. n. 5.—Leaves pinnate; lower leaflets ternate, on stalks. Calyx and corolla downy.—A native also of the East Indies.—At the end of Willdenow's description of this species, he says, that *M. dubia* of Cavanilles seems very nearly allied to it.—It occurs nowhere but in the above quoted author, upon whose sole authority we adopt it. The pubescence of the calyx, and outer side of the petals, seems to be the great mark of distinction. The fruit is unknown.

MELIA, in *Gardening*, comprises plants of the deciduous and evergreen exotic tree kinds, of which the species cultivated are; the common bead-tree (*M. azedarach*); the evergreen bead-tree (*M. sempervirens*); and the Indian evergreen bead-tree (*M. azadirachta*.)

Method of Culture.—These different plants are all capable of being increased by seeds, which in the first sort are obtained from abroad, and should be sown in pots of light rich earth in the spring, plunging them in a hot-bed of tanners' bark or dung, under frame and glasses, giving frequent waterings, and fresh air, when the plants are come up, being fully exposed in a moderate shade, during the summer, and placed under a frame in the autumn, &c. to have the free air all winter in open weather, and be sheltered from frost.

But in the following March they should be planted in separate small pots, plunged in a bark-bed, &c. Though this last is not absolutely necessary, yet when practised, it greatly facilitates their rooting and early growth.

After they have been managed in this way for three or four years, and shifted occasionally into larger pots; some of the strongest and most woody plants may be planted out in the full ground under a warm wall, or in a dry sheltered part of the shrubbery. The proper season for this work is the first fortnight in April. And some plants should likewise be placed in pots, to have the management of greenhouse exotic plants, lest those in the open ground should be destroyed by the frost during the winter season.

The seeds in the second and third sorts, should be sown in pots, and plunged in the bark-bed, and managed nearly as the first sort; but, as being much more tender, must be always kept in pots, and plunged in the tan-bed in the store during their early growth; afterwards, when they have acquired considerable size and strength, they may be placed in the open air for a month or two in the heat of summer, but the rest of the year be kept in the hot-house; managing them as other woody exotic stove plants.

It may be noticed that the last sort is not common in the gardens.

In regard to the first sort, it is proper for shrubberies and other parts in warm situations, as well as for the green-house, and the others for stove collections, in mixture with the more tender plants.

MELIA Terra, in *Natural History*, a name given by some authors to the *melinum*, or white earth of the island of Melos, used among the ancients in painting; but in the works of Dioscorides and Galen signifying a substance of a very different kind; the *melinum* of the painters having been a marle, and the *melia terra* of the physicians a tripela.

The terra melia of Dioscorides, and the ancient physicians, is a dry loofe, and harsh earth, found in masses of different size, and lodged among the looser strata of other matter, never making a stratum of itself. It is very firm and hard, of a pale greyish-white or light ash-colour, very heavy, of a loofe, open, and spongy texture, and of a rough uneven, and dusty surface. It adheres slightly to the tongue, and does not stain the hand, and leaves a dust after the handling, which is so harsh as to make a grating noise, when the fingers are afterwards rubbed together. It makes no effervescence with acids. It is found in all the islands of the Archipelago, and was used by the ancients for the same purposes with the pumices.

MELIÆ, in *Botany*, one of Jussieu's Natural Orders of plants, the 71st in his system, or eleventh of his thirteenth class, derives its name from the most familiar genus among them; see *MELIA*. For the characters of the thirteenth class see *GERANIA* and *GUTTIFERÆ*. The following are the characters of *Melia*.

Calyx of one leaf, divided either down to the base, or only at the apex. *Petals* four or five, with broad claws, for the most part cohering at the bottom. *Stamens* of a definite number, either as many as the petals, or more generally double that number, their filaments united into a tube or cup, toothed at its summit, the teeth either bearing the anthers, or overtopping them when attached to their lower part, at the inside. *Germen* single; with a single style; the stigma simple, or, more rarely, divided. *Fruit* either pulpy, or more generally capsular, of many cells, each containing one or two seeds, the valves equal in number to the cells, with partitions from the middle of each valve. The *stem* is shrubby or arboresecent, with alternate branches. *Leaves* alternate, without stipulas, simple or compound.

The first section, with simple leaves, consists of *Canella* of Browne, Swartz and Schreber (*Winterania* of Linnæus and Jussieu), *Symphonia*, *Tinus*, *Geruma* of Forskall (see that article), *Aitonia*, *Quivissa* of Commerçon, and *Turraa*.

The second, with compound leaves, comprises *Ozophyllum* of Schreber (*Ticorea* of Aublet), *Sandoricum* of Rumphius, Schreber and Jussieu, *Portesia* of Jussieu, *Trichilia*, *Elcaja* of Forskall, *Guarea*, *Ekebergia*, *Melia* and *Leca*, which last is also *Aquilicia* of Linnæus. See *LEEA*.

A third section is subjoined by Jussieu, of genera akin to *Melia*. These are *Savietenia* and *Cedrela*. They differ widely from the proper genera of the order in their fruit, which is in both of them a woody capsule of five valves, splitting from the base, and containing numerous, imbricated, compressed, winged seeds.

The order in question is by no means one of the most natural in its learned author's system; at least with respect to the affinities of some of the genera which he has referred to it.

MELIANTHUS, from μέλι, *honey*, and ανθος, *a flower*, so named from the abundance of honey which flows from *M. major* in particular, for, as Linnæus remarks, if that

species be shaken whilst in flower, it distils a shower of nectar. Jussieu tells us that *Meliantbus* is allied to *Tropæolum* in the hood of the calyx, and situation of the petals and stamens; but that it is more like *Didamnum* in habit, fruit, and albumen of the seed. He well remarks however that it is very distinct from either of those genera, on which subject there cannot be the least question. We are told that the Linnæan botanists at Paris used sarcastically to remark that *Meliantbus* was not admitted into the public garden there, because no plausible place could be found for it in the system of the Jussieu.—Linn. Gen. 328. Schreb. 430. Willd. Sp. Pl. v. 3. 402. Mart. Mill. Dict. v. 3. Art. Hort. Kew. ed. 1. v. 2. 367. Tournef. t. 245. Juss. 297. Lamarck Illustr. t. 552.—Class and order, *Didynamia Angiosperma*. Nat. Ord. *Corydalis*, Linn. *Rutaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, large, coloured, cloven into five, unequal segments, the two upper ones oblong, erect, the lowest one very short, bag-shaped, swelling downwards, the intermediate two opposite, interior, lanceolate. *Cor.* Petals four, linear-lanceolate, reflexed at their tips, spreading in a parallel manner, turned outwards, forming a lower lip (as the calyx does an upper one) connected in the centre by their sides. Nectary of one leaf, situated within the lowest segment of the calyx, and adhering with it to the receptacle, very short, compressed at the sides, cut at the margin, and turned downwards at the back. *Stam.* Filaments four, awl-shaped, erect, the length of the calyx, the two lower ones a little shorter; anthers oblong, heart-shaped, four-celled in front. *Pist.* Germen superior, quadrangular, gibbous, four-toothed; style erect, awl-shaped, in length and position like the stamens, stigma cloven into four segments, of which the upper one is the largest. *Peric.* Capsule quadrangular, four-lobed, with acute, distant angles; the cells inflated, their partitions open in the centre to admit the receptacle of the seeds, the valves bursting between the angles. *Seeds* four, somewhat globose, adhering to the centre of the capsule.

Ess. Ch. *Calyx* of five leaves; the lower one gibbous. *Petals* four. Nectary beneath the lowest petal. Capsule four-celled.

1. *M. major*. Greater Honey-flower. Linn. Sp. Pl. 892. (*M. africanus*; Herm. Lugd. t. 415.)—Stipulas foliary, adhering to the leaf-stalk.—Discovered by Hermann at the Cape in the year 1672. It flowers in greenhouses from May to July.—*Root* perennial, woody, spreading. *Stems* numerous, four or five feet high, herbaceous towards the top. *Leaves* pinnate, embracing the stem, greyish, composed of about three or four pairs of ovate, deeply-toothed leaflets, three or four inches long, with an odd one; a leafy, jagged border or wing running along the mid-rib connects them at their base. *Flowers* in a longish spike; springing from between the leaves towards the top of the stalks, of a brown or chocolate colour.

2. *M. minor*. Lesser Honey-flower. Linn. Sp. Pl. 892? Curt. Mag. t. 301.—Stipulas in pairs, but separate. Clusters axillary, elongated. Bractæas linear, tapering.—Native of the Cape, and cultivated in 1708 by the dukes of Beaufort.—*Stems* four or five feet high, branched, soft, round, woody. *Leaves* about half as large as in the preceding, green on the upper side, whitish beneath. *Flowers* six or eight in a cluster, very ornamental, variegated with green, yellow and red or pink.—Mr. Curtis observes that the foliage when bruised has an unpleasant smell; that the secreted honey or nectar does not flow so copiously from this as from the last which is more common, but that it exhibits rather an unusual phenomenon, being retained in the lower part of the blossom, and of a dark brown colour.

3. *M. comofus*. Tufted Honey-flower. Willd. n. 3. (*M. africanus minor foetidus*; Comm. Rar. t. 4.)—Stipulas distinct. Clusters below the leaves. Flowers alternate. Bractles heart-shaped. Leaves hairy above.—A native also of the Cape. Stem upright, branched, four feet high, round. Leaves pinnate, consisting of about five pairs of linear, deeply toothed, soft leaflets with an odd one, hoary underneath. Flowers in pendent clusters, on short stalks, of a yellow colour.

MELIANTHUS, in *Gardening*, comprehends plants of the perennial exotic kind, of which the species cultivated are, the great honey-flower (*M. major*); and the small honey-flower, (*M. minor*.)

Method of Culture.—These two species of plants may be increased by suckers from the roots and cuttings of the young stalks or branches. The first sort is, however, best raised by planting the suckers, or side-shoots, any time in the spring or summer seasons, choosing such as are furnished with root fibres, in pots, or the places where they are to remain, which, after they are planted and have taken root, require little further care, but to keep them clean from weeds. The cuttings may be planted during any of the summer months, due water and shade being given. When they have taken root they should be planted out where they are to remain, or in separate pots, to be managed as green-house plants.

But the second sort is raised with more difficulty, and chiefly from cuttings, which should be planted upon an old hot-bed, the heat of which is over, and covered close with bell or hand-glasses to exclude the air. When they have taken root they may be planted out in pots, and sheltered in the winter under a frame for a year or two, till they are become strong, after which they may be set out in a warm border, and be managed in the same manner as the first sort. And they succeed best in a dry soil and warm situation; but some plants should always be kept in pots and treated as greenhouse plants, lest those in the open ground be destroyed by severe froils.

All of them afford ornament and variety in the borders and clumps, as well as among other plants in greenhouse collections

MELIBCEA, in *Ancient Geography*, a town of Greece, in the part of Thessaly called Magnesia, about the precise situation of which authors differ. Strabo places it in a gulf, on the eastern coast, between mount Ossa to the N. and mount Pelion, somewhat farther from the coast, lying from N.W. to S.E.

MELIBCEUS MOUNTS, a mountain of Germany, which, according to Cæsar (Bell. Gall. l. vi. c. 1.) formed a separation between the Cherusci and Suevi. It was part of those mountains which covered the forest Bacenis.—Also, a mountain of Italy.

MELICA, in *Botany*, a name supposed by Ambrosinus to be corrupted, either from *Miliaca*, which might express the likeness of the grass so called, to *Milium*; or from *Melinis*, the name of some sort of *Panicum*, which it also resembles in the aspect and distribution of the blossoms.—Linn. Gen. 34. Schreb. 48. Willd. Sp. Pl. v. 1. 381. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 91. Ait. Hort. Kew. ed. 2. v. 1. 152. Juss. 31. Lamarck Illustr. t. 44. Gært. t. 80.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* A glume of two ovate, concave, nearly equal valves, containing two flowers. *Cor.* of two ovate awnless valves, one of which is concave, the other flat and smaller. A turbinate stalked body, consisting of two abortive florets, stands between the two perfect ones. Nectary

of one fleshy horizontal leaf, surrounding the germen. *Stam.* Filaments three, capillary, thickened and united at their base, as long as the flower; anthers oblong, forked at each extremity. *Pist.* Germen superior, obovate, turbinate; styles two, bristle-shaped, spreading, naked at their base; stigmas oblong, feathery. *Peric.* none, except the corolla, which is not united to the seed. *Seed* one, ovate, with a longitudinal furrow at the upper side.

Obf. The stalked body between the florets is considered by Linnæus as affording an essential character. This consists of the abrupt rudiments of two other florets, placed in an alternate order, their glumes convolute and pellucid. To this Schrader adds that the stamens of the real florets are dilated and combined at their base, and that the nectary is of a single leaf.

Ess. Ch. Calyx of two valves, containing usually two florets, with the rudiment of more between them. Corolla of two valves, unconnected with the seed.

An elegant genus of grasses, of which Willdenow has thirteen species, three of them British. To these we add two gathered by Dr. Sibthorp in Greece, a third from America, and a fourth from the East Indies. The habit of the whole genus, well marked in some species, is not so uniform throughout the whole as could be wished. Neither is the number of perfect or of abortive florets constant in all.

1. *M. ciliata*. Fringed Melic-grass. Linn. Sp. Pl. 97. Sm. Fl. Græc. Sibth. v. 1. 54. t. 70. (Græmen montanum, avenæ femine; Clus. Hist. v. 2. 219.)—The outer petal of the lower floret fringed.—Native of dry stony ground in the south of Europe. With us it is sometimes kept in gardens for the sake of its long white plumpy spiked panicles. The root is perennial, tufted and knotty. Stems two or three feet high, erect, round, smooth, stiff, bearing several narrow rigid leaves. Panicle terminal, solitary, erect, close and cylindrical, from two to six inches long. Calyx containing only one perfect, and one abortive, floret. The glumes are membranous and whitish. Stamens long. Fringe of the corolla long, dense, and very remarkable.

2. *M. gigantea*. Gigantic Melic-grass. Thunb. Prod. 21. (Aira villosa; Linn. Suppl. 109.)—“Corolla hairy, awned. Panicle whorled. Stem erect.”—Found by Thunberg at the Cape of Good Hope. The root is crowned with ovate-oblong hairy scales. Stem smooth. Leaves flat, tapering, with frequently shaggy sheaths. Panicle terminal, a foot long. Florets two, large, rusty; one of them smaller, and rather imperfect. Corolla hairy, with a short, straight, terminal awn.

3. *M. geniculata*. Bent-stalked Melic-grass. Thunb. Prod. 21.—“Corolla hairy. Panicle compact. Stem decumbent.”—Native of the Cape.

4. *M. decumbens*. Decumbent Melic-grass. Thunb. Prod. 21.—“Corolla hairy. Flowers racemose, drooping. Stem decumbent.”—From the same country. This must not be confounded with *M. decumbens* of Weber, which is *Fesluca decumbens* of Linnæus, *Poa* of Fl. Brit. 107.

5. *M. racemosa*. Racemose Melic-grass. Thunb. Prod. 21.—“Corolla hairy. Clusters drooping. Stem erect.”—From the Cape. We have seen no specimens of the last four species.

6. *M. minuta*. Slender Melic-grass. Linn. Mant. 32. Willd. n. 10. (*M. pyramidalis*; Desfont. Atlant. v. 1. 73. *M. nutans*; Cavan. Ic. v. 2. 58. t. 175. f. 2?)—Stem branched. Leaves setaceous. Petals beardless. Panicle simple, drooping.—Native of Italy, Spain, Greece and Cyprus.—This is an extremely slender smooth grass, scarcely a foot high. The stems are in our specimens, as Linnæus describes them, very much branched. Cavanilles

MELICA.

says they are always simple. *Leaves* extremely narrow, perfectly setaceous when dry, from the inflexion of the edges; the long sheath crowned by a membranous *stipula*. *Panicle*, or rather *cluster*, simple, of a very few drooping flowers. The *calyx* contains two perfect florets, and the stalked rudiments of one or two others. All the *glumes* are obtuse and ribbed; the *corolla* minutely downy, but not fringed or bearded.

7. *M. saxatilis*. Rock Melic-grafs. Sm. in Prod. Fl. Græc. Sibth. v. 1. 51. Fl. Græc. t. 71. (*M. aspera*; Desfont. Atlant. v. 1. 71? Gramen avenaceum saxatile; paniculâ sparsâ, locustis latioribus candicantibus et nitidis; Tourn. Inst. 524?)—Stem simple. Petals beardless. Panicle close, directed one way. Flowers drooping. *Stipula* elongated.—Frequent on rising ground in the islands of the Archipelago. It has the habit of the last, but is much larger in every part, and the *stems* are simple, *panicle* of a much greater number of *flowers*, with sharper *glumes*. The *panicle* agrees with that of the British *M. nutans*, hereafter mentioned, but the *foliage* is narrower, and the *stipula* more elongated than in that species. There is some reason to suspect the synonym of Cavanilles, which we have cited for the foregoing, may belong to this; but no stress can be laid on his delineations of the minutest parts.

8. *M. nutans*. Mountain Melic-grafs. Linn. Sp. Pl. 98. Curt. Lond. fasc. 6. t. 4. Engl. Bot. t. 1059. Knapp. t. 42. Mart. Rust. t. 65. (*M. montana*; Hudf. 37.)—Petals beardless. Panicle compact, leaning one way, nearly simple. Flowers drooping. Calyx two-flowered. Leaves flat.—Found in mountainous woods, chiefly in the north of Europe. With us it is confined to Westmoreland and the north-west part of Yorkshire, where it flowers in the early part of summer. The *root* is fibrous and perennial. *Stems* several, above a foot high, leafy, slender and naked above, with rough angles. *Leaves* lanceolate, flat, rough-edged, with a long rough sheath, and a very short jagged *stipula*. *Panicle* long, erect or slightly incurved, almost always simple, of many elegant purplish pendulous *flowers*, leaning one way. *Florets* two, with the unequal rudiments of two more. *Glumes* bluntish, with a white membranous termination. The *nectary* in this species answers to Schreber's description, but scarcely, we fear, in all.

9. *M. uniflora*. Wood Melic-grafs. Retz. Obf. fasc. 1. 10. Curt. Lond. fasc. 5. t. 10. Engl. Bot. t. 1058. Knapp. t. 41. Mart. Rust. t. 64. (*M. Lobelii*; Villars Dauph. v. 1. 89. t. 3. *M. nutans*; Hudf. 37.)—Petals beardless. Panicle branched, leaning one way. Flowers erect. Calyx single-flowered. Leaves flat.—Common in groves and bushy places in England and most parts of Europe, flowering in May and June, when its little red tumid flowers, trembling upon the divaricated wiry stalks of the panicle, make a very pretty appearance. The *root* is fibrous and perennial. *Stems* simple, a foot and half high, slender. *Leaves* flat and broadish, thin, bright green, rough at the back and edges, with a downy sheath and short variously-shaped *stipula*. *Panicle* of not many flowers; its lower branches two together. The single fertile *floret* is oval, tumid, with ribbed green *glumes*; the barren one likewise solitary, on a thick inflexed stalk.

10. *M. major*. Greater Melic-grafs. Sm. Prod. Fl. Græc. Sibth. v. 1. 51. (*M. n.* 31; Gmel. Sib. v. 1. 99. t. 19. f. 1.)—Petals beardless. Panicle spreading; with branches in pairs. Flowers drooping. Stem simple. Leaves involute and pungent.—Native of Greece, France, and Siberia, in mountainous places. There is some reason to suspect this species to be what Dr. Sibthorp took for *M. nutans*, and put down as such in his lists of Greek plants,

the latter not being found in his herbarium, nor this noticed by any other appellation. The plants however are very distinct. The *major* has a branched panicle, more like the *uniflora*, but the *calyx* contains from two to four florets, besides an abortive one, their *corolla* mostly bristly at the back. The *leaves* are flat when growing, but rolled in when dry, with a sharp rigid point. We believe this has been called *M. amethystina* by the abbè Pourret.

11. *M. ramifl.* Branched Cape Melic-grafs. Thunb. Prod. 21.—“Petals smooth, beardless. Panicle compact. Stem branched.”—Gathered by Thunberg, at the Cape of Good Hope.

12. *M. capensis*. Spreading Cape Melic-grafs. Thunb. Prod. 21.—“Petals smooth, beardless. Panicle widely spreading. Leaves nearly thread-shaped.”—From the same country. We have seen neither of these last, but their characters mark them as very distinct.

13. *M. papilionacea*. Fly Melic-grafs. Linn. Mant. 31. Willd. n. 12. (*M. brasiliensis*; Arduin. Spec. 2. 17. t. 6. f. 1, 2.)—Panicle close. Outer valve of the calyx very large, obovate, coloured. Outer petals with toothed ribs, somewhat hairy.—The seeds of this curious grass were sent from Brazil to Arduino, who raised them at Padua in 1756, and thinking it might form a new genus, as appears by his specimen, sent it to Linnæus, who justly referred it to *Melica*. Commerçon gathered the same at Monte Video. The *stems* are eighteen inches high, simple, erect. *Leaves* broadish, somewhat involute in drying, their sheaths crowned by a long cloven *stipula*. *Panicle* branched, but compact. *Flowers* erect, remarkable for the large purple outer glume of their *calyx*, which embraces the whole of the spikelet, the inner glume being elevated on the stalk within, much narrower and more rigid, like the *corolla*, whose outer glumes have very strong, tuberculated, and somewhat hairy, ribs. The *florets* are two with one or two abortive ones.

14. *M. altissima*. Tall Melic-grafs. Linn. Sp. Pl. 98. Hoff. Gram. Austr. v. 2. 8. t. 9. Ehrh. Calam. 71. (*M. n.* 30. Gmel. Sib. v. 1. 98. t. 20.)—Panicle close, many-flowered. Calyx-glumes obovate, nearly equal, rather shorter than the florets. Outer petals roughish, beardless. Leaves lanceolate, broad.—Native of Siberia. A tall and very handsome grass, with flat *leaves* half an inch in breadth, and a very long, upright, close, branched *panicle*, compound of innumerable crowded purple *flowers*, turned to one side. The above specific character distinguishes it from the last, which it much resembles at first sight.

15. *M. glabra*. Smooth American Melic-grafs. Michaux Boreal-Amer. v. 1. 62. (*M. altissima* et *mutica*; Walt. Carol. 78? Michaux. Gramen avenaceum, locustis rarioribus muticis, virginianum majus; Morif. v. 3. 216. sect. 8. t. 7. f. 51.)—Panicle widely spreading, with branches in pairs. Flowers erect. Calyx-glumes elliptical, nearly equal, rather shorter than the florets. Petals smooth, beardless. Leaves linear.—Native of North America, from Virginia to Florida. Michaux. Linnæus referred the synonym of Morison to his *altissima*, having probably never seen the present species, which differs from that in its narrower *leaves*, spreading *panicle*, and smooth *flowers*. The *stem* is two or three feet high. Willdenow, who cites this as a variety of the last, still expresses his opinion of its being undoubtedly a different species.

16. *M. cærulea*. Purple Melic-grafs. Linn. Mant. 2. 325. Ehrh. Calam. 91. Curt. Lond. fasc. 5. t. 11. Engl. Bot. t. 750. Knapp. t. 40. (*Aira cærulea*; Linn. Sp. Pl. 95. Hudf. 33. Fl. Dán. t. 239.)—Panicle close, much branched. Flowers erect, cylindrical. Calyx-glumes much shorter than the florets. Petals acute, angular, smooth and beardless

beardless—Native of various parts of Europe, generally on the most barren sandy moors, or inundated heaths, flowering in August. This is a very coarse rigid useless grass, varying greatly in height and luxuriance according to the soil. Its habit is reed-like. *Leaves* taper-pointed and pungent, involute in drying, of a glaucous aspect, broad and sheathing at the base, with hairs in the place of a *stipula*. *Panicle* erect, cleft, repeatedly branched, consisting of numerous, small, upright *flowers*, of a bluish-purple hue, pale when growing in the shade. *Calyx* of two unequal ovate, acute valves. *Florets* four, elongated, much exceeding the calyx, acute, angular rather than ribbed, smooth and beardless, the two lower ones only complete and fertile. *Anthers* violet, almost black. The habit of this is very dissimilar to all the foregoing, and its flowers in particular more resemble the next.

17. *M. diandra*. Broad-leaved Diandrous Melic-grass. Roxb. MSS.—Panicle corymbose, of numerous, slender, many-flowered branches. *Flowers* erect, ovate. Glumes all sharp-pointed, keeled, smooth. *Leaves* ovato-lanceolate, reticulated.—Native of Calcutta. This has the habit of *Arundo Phragmites*. The stem is clothed with several alternate, broad, lanceolate, acute leaves, somewhat ovate at their base, with long, fringed, close sheaths. They have rough edges, and many ribs, connected by transverse reticulations. The panicle is level-topped, composed of numerous, slender, close, racemose branches. *Flowers* purplish, shining, smooth, rather smaller, as well as more compressed, than in the last, all their glumes very sharp-pointed. By the name we presume there are but two *flamens*. The inner *petal* seems to be coarsely fringed, at least in the upper and imperfect floret.

M. Falx, Linn. Suppl. 109, is referred by Thunberg to *Cynofurus*, see *C. Falcatu*, sp. 4. He is followed by Willdenow, and the habit as well as characters of this very curious grass strongly justify the measure.

MELICA is also a word used by the ancients as the name of a food of a refrigerating and moistening quality. It seems to have been a kind of *oxygala*; for Galen, when he directs persons of a hot habit to use a refrigerating diet, among other aliments of that kind, directs the eating of melica, which, he says, is prepared of milk. Constantine, in his book of agriculture, mentions melica, and says it was made by pouring milk into an earthen vessel, first well impregnated with boiling hot vinegar, by means of which there was a separation of the milk into whey and curd.

MELICE'RIA, or MELICÉRTOLA, in *Surgery*, a small encysted tumour, the contents of which are of the consistence of honey.

MELICE'RIS, (from *μελι*, honey, and *κηρος*, wax), an encysted tumour, filled with matter, that has the appearance and consistence of honey. See TUMOUR.

MELICHRUS, in *Botany*, from *μελιχρος*, honey-coloured, alluding, we presume, to the colour of the flowers; especially as the masculine gender is adopted in the specific names. Otherwise the latter would have been, as usual, feminine, *μελιχρα*, or *herba*, being understood.—Brown. Prod. Nov. Holl. v. 1. 539.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Epacridæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of many leaves, erect, permanent; the five innermost longest, equal, lanceolate, concave. *Cor.* of one petal, wheel-shaped, or pitcher-shaped, in five equal segments, bearded half way, and with five clusters of glands near its base. Nectary a glandular, nearly entire, cup, surrounding the base of the germen. *Stam.* Filaments five, thread-shaped, equal, inserted into the base of the corolla; anthers incumbent, oblong, bursting lengthwise,

slightly projecting. *Pist.* Germen superior, roundish; style columnar; stigma capitate. *Peric.* Drupa nearly dry, with a hard shell. *Nut* of five cells. *Seed* solitary?

Eff. Ch. Outer calyx of many leaves. Corolla five-cleft, wheel or pitcher-shaped, bearded half way, with five clusters of glands near the base. Drupa dry, of five cells.

This genus consists of two species of small shrubs, which are procumbent, or nearly so, with lanceolate leaves. The flowers are axillary, solitary, erect.

1. *M. rotatus*. Br. (*Vintenatia procumbens*; Cavan. Ic. v. 4. 28. t. 349. f. 1.)—Corolla wheel-shaped. Calyx hairy. Leaves nearly linear, hairy on both sides and at the edges.—Native of New South Wales, as well as of the tropical part of New Holland. The stem is much branched, procumbent. Branches clothed with several rows of imbricated, linear-lanceolate, acute, entire leaves, about an inch long, somewhat glaucous, clothed and fringed with soft hairs, and striated with numerous ribs. Flowers numerous, axillary, solitary, sessile. Calyx loosely covered with long, soft, white hairs. Segments of the corolla acute, broad at the base; Cavanilles represents them much too narrow; each is bearded with long hairs from beyond the middle to the point. There appears to be more of a tube than properly belongs to a wheel-shaped corolla, but our specimens are not sufficient to determine that point.

2. *M. urceolatus*. Br.—Corolla pitcher-shaped. Calyx smooth. Leaves lanceolate, taper-pointed, minutely toothed.—Gathered near Port Jackson by Mr. Ferdinand Bauer.

The other species of *Vintenatia*, *humifusa*, Cavan. Ic. v. 4. 28. t. 348, is referred by Mr. Brown to a distinct genus, *Astroloma*, Prod. Nov. Holl. v. 1. 538, in which the tube of the corolla is inflated, and twice the length of the calyx; its limb short, spreading, bearded. These differences are by no means strikingly indicated in Cavanilles' figures, nor do they there appear to us sufficient to divide plants in other respects so nearly alike. We can indeed judge but imperfectly from dried specimens, or from such delineations. Neither can we account for the spelling of the name, which was intended to commemorate the late M. Ventenat.

MELICOCCA, from *μελι*, honey, and *κοκκος*, a berry, so named by Dr. Patrick Browne from the sweetness or mellowness of its fruit.—The Genip Tree.—Browne Jam. 210. Jacq. Amer. 108. Linn. Gen. 188. Schreb. 254. Willd. Sp. Pl. v. 2. 330. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 350. Swartz Obs. 144. Juss. 248. Lamarck Illustr. t. 306. Gærtner. t. 42.—Class and order, *Obandria Monogynia*. Nat. Ord. *Tribilata*, Linn. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four, ovate, concave, obtuse, spreading leaves. *Cor.* Petals four, oblong, equal, reflexed between the calyx-leaves. *Stam.* Filaments eight, awl-shaped, erect, short; anthers oblong, erect. *Pist.* Germen superior, ovate, nearly the length of the corolla; style very short; stigma large, rather peltate, extended at each side, oblique. *Peric.* Drupa covered with a tough skin, roundish, obtusely pointed. *Seed* a leathery, roundish, smooth nut.

Obs. In Gærtner's description of *Melicocca* the *Pericarp* is said to be an ovate, pointed, leathery, thickish Berry, of one cell. The seeds solitary (rarely two or three), ovate, furrowed on one side, coated with a glutinous pulp.

Eff. Ch. Calyx deeply four-cleft. Petals four, reflexed between the calyx-leaves. Stigma shield-like. Drupa with a tough coat.

1. *M. bijuga*. Genip Tree, or Honey-berry. Linn. Sp. Pl. 495. Jacq. Amer. t. 72. (*Nux americana*, foliis aiatis bifidis; Comm. Hort. v. 1. 183. t. 94.)—A native of South America and cultivated in the East Indies. Introduced into this

this country in 1778 by Dr. Thomas Clarke. We learn from Browne's History of Jamaica that this tree was brought to that island from Surinam. He calls it Genip tree from the Dutch *Knippen*. The Spaniards term it *Monos*. Jacquin mentions it as growing wild about Carthage, and commonly cultivated at Curaçao. The stem of this tree rises to nearly twenty feet in height, and has numerous spreading branches. Leaves abruptly pinnate, on round, elongated, or rather compressed stalks, consisting of two pair of nearly sessile, ovate leaflets, acuminate at both ends, entire, nerved, smooth, bright green. Flowers in terminal, compound clusters of a yellow colour. Fruit about twice as large as a nutmeg, containing a sweet, acid, gelatinous substance like the yolk of an egg.

"Jacquin was informed at Curaçao that this genus was diacious, but Swartz ascertained it to be polygamous, one tree bearing perfect flowers, another only male ones; the latter is most common and bears the finest flowers; they expand in April and the fruit ripens about Midsummer."

MELICOPE, a name constructed by Forster, from μέλι, honey, and κοπή, an incision, the nectary being composed of a series of notched glands. Forst. Gen. t. 28. Schreb. 257. Willd. Sp. Pl. v. 2. 346. Mart. Mill. Dict. v. 3. Juss. 429. append. 453. Lamarck Dict. v. 4. 60. Illustr. t. 294. (Entoganum; Banks and Soland. MSS. Gært. t. 68.)—Class and order, *Oständria Monogynia*.—Nat. Ord. *Rutaceae*?

Gen. Ch. Cal. Perianth inferior, of one leaf, in four deep, equal, roundish segments, permanent. Cor. Petals four, equal, ovate-oblong, with a little blunt point, keeled, broad at the base, slightly spreading. Nectary of four large cloven glands, encompassing the base of the germen. Stam. Filaments eight, awl-shaped, equal, simple, smooth, shorter than the petals, inserted into the receptacle on the outside of the nectary; anthers terminal, erect, oblong, somewhat heart-shaped, simple, of two cells. Pist. Germen superior, ovate, four-lobed; style quadrangular, short; stigma dilated, quadrangular, umbilicated. Peric. Capsules four, elliptical, compressed, spreading, of one cell, opening at the upper margin. Seeds solitary, compressed, smooth, stalked.

Eff. Ch. Calyx in four deep segments. Petals four. Nectary of four cloven glands round the germen. Stamens simple. Stigma dilated. Capsules four, single-seeded.

1. *M. ternata*. Forst. Prod. 28. (Entoganum lævigatum; Gært. v. 1. 331.)—Gathered by Forster in New Zealand. The only known species. A shrub, with smooth, round, leafy branches; the young ones somewhat quadrangular. Leaves opposite, stalked, ternate; leaflets an inch or inch and a half long, obovate, bluntly pointed, very obscurely and irregularly crenate, rather thickened or bordered at the margin, tapering at the base, single-ribbed, with a few oblique forked veins, quite smooth, of a pale green when dry, full of small, pellucid, resinous dots; the terminal leaflet larger than the rest. Common footstalk about an inch long, linear, channelled, smooth. The lower leaves on each branch are simple, and smaller. Stipulas none. Flower-stalks axillary, solitary, shorter than the leaves, forked, or perhaps somewhat corymbose, smooth, slightly angular, with a pair of minute, concave bractæ at each subdivision. Whenever any of the stalks fall off, a broad pale peltate scar is left behind on the branch. Flowers about a quarter of an inch in diameter, white or yellowish, each on a quadrangular partial stalk, a quarter of an inch long, dilated upwards under the calyx. Capsules spreading in four directions, somewhat leathery, smooth, each a quarter of an inch long.

Of this very little-known shrub we have seen but one mutilated specimen, given by Forster to Linnæus. Nothing is

said by the author of the genus, any more than by Solander or Gærtner, to indicate its affinity to any other, nor could Jussieu form even a conjecture on the subject. The shape, and resinous dots, of the leaves, as well as the pallid hue which they, like the other parts, assume in drying, and even the aspect of the flowers, whose petals are full of resinous dots, all seem to indicate the natural order of *Aurantia*. But these characters, except perhaps the pale colour, equally belong to the *Rutaceae*, at least to those genera which are subjoined by Jussieu to that natural order, and of which *Diopsia* is the type; and the fruit strongly confirms the propriety of referring *Melicope* to them. With these Jussieu was but slightly acquainted. There are numerous genera of this tribe in New Holland (see *CORRÆA*, *CROWEA*, *ERIOSTEMON*); as well as *Boronia*, Sm. Tracts 287. t. 4—7, and *Tetratheca*, Sm. Exot. Bot. t. 20—22. The inflorescence of the genus before us, as far as can be discovered from our bad specimen, seems very nearly that of *Boronia pinnata*, Andr. Repof. t. 58. Its simple filaments and anthers, and, according to Gærtner's description, the want of an arillus to the seeds, are circumstances in which it differs from *Boronia* and most of its allies. The flavour of the dried leaves is a little bitter, scarcely aromatic. S.

MELICUCCA, in *Geography*, a town of Naples, in Calabria Ultra; 10 miles W.S.W. of Oppido.

MELICYTUS, in *Botany*, so named by Forster, from μέλι, honey, and κύτος, a cavity or cell, alluding to the five oblong bodies, hollowed out at their summits, which he conceived to be nectaries bearing the anthers. Forst. Gen. t. 62. Schreb. 685. Mart. Mill. Dict. v. 3. Juss. 428. Lamarck Dict. v. 4. 59. Illustr. t. 812. Gært. t. 44. Class and order, *Diocia Pentandria*. Nat. Ord. *Euphorbiæ*?

Gen. Ch. Male, Cal. Perianth very short, with five teeth. Cor. Petals five, equal, ovate, acute, widely spreading, longer than the calyx. Nectary of five club-shaped bodies, hollowed out at the top, erect, bearing the stamens at their inside. Stam. Filaments none, except the nectaries be so considered; anthers five, roundish-ovate, with four furrows in front, attached lengthwise to the inner side of the nectaries, and extending slightly beyond them.

Female, Cal. and Cor. as in the male. Nectary of five triangular acute scales, shorter than the calyx, surrounding the germen closely at its base. Pist. Germen ovate; style none; stigma of four or five small, flat, rounded lobes. Peric. Capsule pulpy, globose, smooth, coriaceous, of one cell, with four or five valves. Seeds about five, convex on one side, angular on the other, lodged in pulp.

Eff. Ch. Male, Calyx with five teeth. Petals five. Nectary of five hollow-tipped bodies, bearing the stamens.

Female, Cal. and Cor. as in the male. Nectary of five scales round the germen. Stigma sessile, four or five-lobed. Capsule pulpy, of one cell and five valves. Seeds five.

1. *M. ramiflorus*. Forst. Prod. 70.—Native of the neighbourhood of Queen Charlotte's Sound, New Zealand, flowering there in November. A shrub, or tree, with round, smooth, leafy branches. Leaves deciduous, scattered, on short smooth footstalks, elliptic-lanceolate or obovate, obtuse, bluntly serrated, smooth on both sides, with one rib and numerous interbranching reticulated veins, each leaf an inch and a half or two inches long, and nearly one broad. Flower-stalks several together, from scattered lateral or axillary buds, each about a quarter of an inch long, swelling upwards, simple, smooth, bearing about the middle a minute fringed concave bractæ, single-flowered. Flowers very minute, whitish.

Jussieu knew not where to place this genus in his natural orders, but was led by its artificial characters, as it seems,

to suppose it akin to *Astronium* of Jacquin and Linnæus. Gartner having the fruit, which Forster knew nothing of, more happily perceived its relationship to *Kiggelaria*. (See that article, and *ASTRONIUM*.) This relationship has induced us to refer *Melilotus* to the *Euphorbia* of the great French botanist, notwithstanding the presence of petals, which that natural order, it seems, ought to be without. We cannot however be too far led by hypothesis as to deny real petals to *Kiggelaria*.

MELIDES, in *Geography*, a town of Portugal, in the province of Estremadura; 21 miles S. of Setúval.

MELILITE. This scarce mineral substance has hitherto been found only in minute but very regular cubic or parallelepipedic crystals: they are of the size of a millet seed, of a yellow colour, and externally covered by a brownish or gold yellow crust of iron ochre. Their hardness is sufficient to scratch steel.

The melilite melts before the blowpipe, without effervescence, into a transparent solid glass of a greenish colour. Its powder forms a transparent jelly with nitric acid. It is not pyro-electric.

By these characters this microscopic mineral is sufficiently distinguishable from mesotype, stilbite, chabasie, and analcime, to which it bears some distant resemblance.

The cubic crystals of the melilite pass into the cuneiform octahedron.

These small crystals were discovered by M. Fleurieu de Bellevue in the fissures of a black, pretty compact lava, known under the name of *silex romano*, found at Capo di Bove, near Rome. They are accompanied by small, white, transparent, acicular crystals, which appear to belong to sommitte or nepheline. Brongn.

MELILLA, or MELELA, in *Geography*, a town of Africa, in the kingdom of Fez, situated on the coast of the Mediterranean, and belonging to the Spaniards. It was probably founded by the Carthaginians, and seems to have derived its name from the honey produced in its environs. The town is strongly fortified and surrounded by the sea. The only communication with the main land, inhabited by the Moors, is by a draw-bridge. It was abandoned by the Goths when the Arabs invaded the country, and being deserted by the Moors, was seized on by the Spaniards about the beginning of the 15th century. This town has large magazines and cisterns for preserving the water. The number of inhabitants is estimated at 2000; 140 miles E of Tetuan. N. lat. 35° 24'. W. long. 2° 54'.

MELILLI, a town of Sicily, situated on mount Hybla, famous for its excellent honey, to which it owes its name; as well as also to the fertility of the adjacent territory, or the sugar-canes once cultivated there, but now abandoned.

MELILOBUS, in *Botany*. (from *μῆλις*, honey, and *λοβός*, a pod, or legume, alluding to the sweet pulp in which the seeds are lodged,) the original name given by Mitchell to the *Gleditsia* of Clayton and Linnæus, and undoubtedly a very expressive one. It is much to be wished that such should always have a preference; and that no genus should ever be consecrated to any botanist, till an expressive name, of Greek or Latin derivation, had first been sought in vain. But alas! this is like wishing for honesty and disinterestedness in those who elect, and those who are elected.

MELILOT, a species of trefoil, or *trifolium*; which see. (See MELILOTUS.) This plant grows wild in most parts of Europe, in corn-fields, pastures, and by way-sides. Among bread-corn it is a troublesome weed; and ripening about the same time with the corn, is often ground with it, being difficult to separate from it: in such a case it spoils the bread,

or whatever the flour is used for, by giving it a strong taste, like the plaster made from it.

Melilot is scarcely ever given internally; but used externally, it was formerly esteemed emollient and digestive, and was employed as an ingredient in cataplasms, fomentations, and blister-plasters; but it is now laid aside as being rather acid and irritating than emollient. The flowers have been recommended by some in infusion, in the manner of those of chamomile, as a remedy for the fluxus albus. It formerly gave the name to one of the official plasters, which received from the melilot a green colour and an unpleasant smell, without any addition to its efficacy.

MELILOTUS, *μολιότος* of Dioscorides, appears to be the *Trifolium Melilotus-officinale* of Linnæus, which Dr. Sibthorp found growing wild, in low moist situations, in Attica and different parts of Greece. This ingenious and learned traveller suspected the other kind, which is mentioned by the above Greek writer as of a yellower colour and weaker scent, and growing about Nola in Campania, might be *T. Melilotus-italica*, which is found on the dry ground of Mount Hymettus, near Athens. Dr. Sibthorp observed the figure in the famous ancient manuscript at Vienna, to be evidently intended for one of these species.

MELIN, in *Geography*, a town of Croatia; 12 miles S.S.W. of Varasdin.

MELINDA, a kingdom of Africa, situated near the coast of the Indian sea. This country is for the most part fertile, producing almost all the necessaries of life, except wheat and rice, for want of which, those who cannot purchase them are supplied with potatoes, which are here large and plentiful. They abound with other roots and fruits, and with melons of excellent quality. Citrons here are abundant, and agreeably perfume the air during the greatest part of the year. They have also plenty of venison, game, oxen, sheep, geese, and other poultry; and a breed of sheep, whose tails weigh in general between twenty and thirty pounds. The men are black, swarthy, tawny, and white, and the women chiefly of an olive colour; their dress is elegant, consisting of fine silks, girt with rich gold or silver girdles, collars, and bracelets, and their heads are covered with veils. The men wear a kind of turban; and in other respects their dress consists of a piece of cotton wrapped round the middle, and reaching below the knees, the other parts of the body being naked. Those of the meaner class, and such as live in the interior of the country, wear little else besides a piece of cloth about their middle, except their shield and military weapons, which are the bow and arrows, the scymetar, and the javelin. Their religion is chiefly Mahometan; with a mixture of idolaters; and their government is monarchical, the king being treated with great respect and veneration by his subjects: and accompanied with attendants, who present him with incense and perfumes, whenever he goes abroad, and ladies who pay their homage to him with songs and several kinds of musical instruments. The prince of this country was formerly tributary to the Portuguese; but they are now obliged to purchase, by annual presents, permission to trade, and to search for gold. Adjoining to Melinda are five other kingdoms, to which the connection and influence of the Portuguese extend. The natives, besides their commerce with the Portuguese, carry on some trade with their own vessels, in which they frequent the Red sea, and Arabian ports; and they sometimes traverse the Indian seas, as far as Cambaya, in the territories of the great Mogul. On the other hand, the Arabians and Indians bring goods to Melinda: but the whole trade, which is little inferior to that of Mozambique, is ultimately transacted with the Portuguese.

tuguefe. The articles brought to Melinda are gold from Sofala; as well as ivory, copper, quicksilver, all forts of filks and cottons from Europe and the East Indies, together with spices, rice, and other grain.

MELINDA, the capital of the above-described kingdom, pleasantly situated on a beautiful plain near the coast of the Indian sea, and furrounded by fine gardens and orchards, producing all forts of fruit-trees, especially citrons and oranges. The houfes are built of square stone, many of them being constructed in a magnificent style, and all richly furnished, for the stated residence of rich merchants, and the occasional resort of foreigners, who carry on an extensive commerce in gold, copper, quicksilver, ivory, wax, and drugs, in exchange for silk, cottons, linen cloths, corn, and other commodities. The harbour is difficult of access, on account of rocks and shelves that intercept the approach to it, and obligé vessels to come to anchorage at some distance from it. The warehoufes at Melinda supply the country with European goods to a great distance within land, where they procure vast quantities of ivory. This city was wholly built by the Portuguese, and is said to contain 30,000 Portuguese, besides natives; and includes seventeen Christian churches, together with other religious houfes. S. lat. 3° 5'. E long. 42° 40'.

MELINDA, one of the Querimba islands, in the Indian sea. S. lat. 10° 30'.

MELINGEN, a town of Switzerland, on the Rufs; 43 miles N.E. of Berne. N. lat. 47° 10'. E. long. 8° 15'.

MELINUM, in *Natural History*, the name of an earth, famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the colours with which alone they performed all their works.

It is a fine white marly earth, of a very compact texture, yet remarkably light; a sort of texture which must render any earth fit for the painter's use, that is of a proper colour. It is frequently found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth, but not glossy surface; is very soft to the touch, adheres firmly to the tongue, is easily broken between the fingers, and stains the skin in handling. It melts readily in the mouth, and is perfectly fine, leaving not the least grittiness between the teeth. Thrown into water, it makes a great bubbling and loud hissing noise, and moulders away into a fine powder. It does not ferment with acids, and suffers no change in the fire. These are the characters by which the melinum of the ancients is distinguished from all the other white earths. It is still found in the same place from whence the painters of old had it, which is that from whence it has its name, the island of Milo, called Melos by the Greeks, and is common in most of the adjacent islands. It has been of late tried here as a paint, and is found not to make so bright a white as the other substances now in use among the painters, but seems not liable, like them, to turn yellow; and if so, would be worth the consideration of persons in the colour-trade, especially as it may be had in any quantities for carriage.

MELINUS COLOR, *Μελινον χρωμα*, in *Antiquity*, a colour often mentioned in speaking of the habits of players. It was a reddish-yellow, of the colour of ripe apples, in Greek called *μηλα*, and their colour *μηλοειδες χρωμα*.

MELIPILLA, in *Geography*, a town of South America, and capital of a jurisdiction in the kingdom of Chili; 42 miles S.E. of Valparaiso. S. lat. 33° 28'. W. long. 70° 7'.

MELIPU, a river of Ceylon, which runs into the sea near Matara.

MELIS, a town of Germany, in the principality of Gotha; 16 miles S. of Gotha.

MELISANA, a town of Italy, in the country of Friuli; 6 miles S. of Palma Nuova.

MELISEY, a town of France, in the department of the Upper Saone, and chief place of a canton, in the district of Lure. The place contains 1499, and the canton 10,130 inhabitants, on a territory of 187½ kilometres, in 12 communes.

MELISMATICO STYLE. See STYLE.

MELISSA, in *Botany*, from *μηλισσα*, the Greek name of a bee; or rather, as that name itself, like the ancient proper names *Melissa* and *Melissus*, also originated from *μηλι*, *honey*, because of the abundant and excellent honey of the flowers of this herb, for which bees are said greatly to frequent them.—Balm.—Linn. Gen. 298. Schreb. 394. Willd. Sp. Pl. v. 3. 146. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 416. Juss. 115. Tourn. t. 92. Lamarck Dict. v. 4. 76. Illustr. t. 512. (Horminum; Linn. Gen. 299. Juss. 116. Lamarck Dict. v. 3. 136. Illustr. t. 515.)—Class and order, *Didymia Gynnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, nearly bell-shaped, rather dry and scariose, somewhat gaping, angular, striated, permanent, its mouth two-lipped; upper lip three-toothed, bent backwards, flat; lower shorter, sharpish, deeply cloven. Cor. of one petal, ringent; tube cylindrical; mouth gaping; upper lip shortest, erect, vaulted, roundish, cloven; lower three-cleft, the middle segment largest and heart-shaped. Stam. Filaments four, awl-shaped, two of them the length of the corolla, two but half so long; anthers small, cohering in pairs. Pisl. Germen four-cleft; style thread-shaped, the length of the corolla, curved with the stamens under the upper lip of the corolla; stigma slender, cloven, reflexed. Peric. none, except the enlarged, but otherwise unaltered calyx. Seeds in the bottom of the calyx, four, ovate.

Ess. Ch. Calyx scariose, flattish on the upper side; its upper lip with three nearly level-pointed teeth. Upper lip of the corolla somewhat vaulted, cloven; middle lobé of the lower lip heart-shaped.

1. *M. officinalis*. Common Garden Balm. Linn. Sp. Pl. 827. Sm. Prod. Fl. Græc. Sibth. v. 1. 423. Stokes Mat. Med. v. 2. 365. Woodv. Med. Bot. t. 147. (Melissa; Ger. em. 689. Apiastrum five Melissa; Matth. Valgr. v. 2. 181.)—Whorls halved. Bractæas oblong, stalked. Leaves ovate, acute, serrated.—Native of the mountains of Geneva, Savoy, and Italy. Dr. Sibthorp found it in shady woods upon Mount Parnassus, where it is still called *μηλισσόχορτον*, or Balm-plant, which confirms the general opinion of its being the *μηλισσοφυλλον* of Dioscorides, who mentions the lemon-like scent for which this herb is so remarkable, and on account of which it is so generally used to make a grateful cooling infusion for persons in fevers. In this scent it much agrees with the more powerful *Verbena triphylla*, brought from Peru by the unfortunate DOMBEY, see his life in its proper place. The root of this *Melissa* is fibrous and perennial. Stems several, two or three feet high, leafy, somewhat branched, acutely quadrangular, hairy and harsh to the touch. Leaves opposite, stalked, ovate, or very slightly heart-shaped, serrated, somewhat hairy, strongly veined, an inch and half long. Flowers axillary, in halved whorls, leaning toward one side; their stalks downy, accompanied by small, oval, generally sessile bractæas. Calyx hairy. Corolla twice as long, white or pale-purplish.

2. *M. altissima*. Tall Greek Balm. Sibth. in Prodr. Fl. Græc. v. 1. 423.—Whorls halved, stalked. Bractæas stalked.

stalked. Leaves heart-shaped, sharply crenate.—Common in shady situations in Greece, especially under hedges, as well as in Crete. *Sibthorp*. This was suspected by Dr. Sibthorp to be the third *καλαμίνθη* of Dioscorides, but that point is scarcely to be settled with any probability. Neither are we fully satisfied of our present plant being specifically distinct from the first. By the specimens and figure, which last is destined for *t. 579* of the *Flora Græca*, it appears to be a taller and larger herb, with rather more heart-shaped leaves, and the whorls as well as bractæes are elevated on more evident stalks. The flower is represented white, with a pale pink upper lip; the lower lip hairy on the upper side near its base, its middle lobe broadest, but by no means heart-shaped.

3. *M. grandiflora*. Great-flowered Balm. Linn. Sp. Pl. 827. Curt. Mag. t. 208. (Calamentha flore magno; Riv. Monop. Irr. t. 46. f. 1. C. montana præstantior; Germ. 687.)—Flower-stalks axillary, forked, longer than the footstalks. Bractæes lanceolate, sessile. Leaves ovate, serrated.—Native of hilly ground in Greece, Italy, and Germany. Gerard cultivated this species here in 1566, and it may still be frequently seen in gardens, being, as Curtius observes, suitable for the decoration of rock-work. It thrives best in dry gravelly ground, and is perennial, flowering throughout the summer. Root fibrous. Stems about a foot high, weak and spreading. Leaves ovate, hairy. Flowers from three to seven on each long axillary stalk, with several small sessile bractæes. Corolla large, light crimson, with a white streak, and spots on the lower lip. The whole plant has a much more powerful scent than *M. officinalis*, without any of the lemon flavour.

4. *M. pyrenaica*. Pyrenean Balm. Jacq Hort. Vind. v. 2. 86. t. 183. (*M. pyrenaica*, caule brevî, plantaginis folio; Tourn. Inst. 193. Magn. Hort. 133. t. 17. Horminum pyrenaicum; Linn. Sp. Pl. 831.)—Stem leafless. Flowers whorled, turned to one side. Leaves oblong, bluntly toothed.—Native of the highest mountains among the Pyrenees, in the Tyrol and Carniola. We have seen it in no garden, but Jacquin cultivated this plant at Vienna. He was led by Scopoli to refer it to *Melissa*, instead of making it a distinct genus, as Linnæus had done. The root is long, woody, black, and perennial, flowering about the third year from the sowing of the seed, in June. Leaves several, all radical, oblong or somewhat ovate, veiny, smooth, strongly and bluntly toothed, decurrent at the base, on long stalks. Flower-stalks solitary, about a foot high, bearing several pairs of opposite, ovate, entire bractæes, and in the upper part numerous bracteated whorls of simply-stalked flowers leaning to one side. The Corolla is dark blue, about an inch long, handsome, more bell-shaped than in the foregoing, with shorter lips in rounded segments.

Such are all the genuine *Melissæ* known to us. The *M. Calamintha*, *Nepeta*, *cretica* and *fruticosa* of Linnæus appear to us by their habit, as well as by the hairs which close the mouth of the calyx, to belong to *Thymus*, to which genus the two first are referred in the *Flora Britanica*. It happened however that Willdenow did not receive this last-mentioned work, till he had written his *Sp. Pl.* as far as *Tetradynamia*, and as the *Hort. Kew.* generally follows him, these species continue there as they were. Indeed the subject is not without difficulty, as *M. officinalis* has some distant hairs in the mouth of the calyx; but its reflexed upper lip, with three teeth of equal height, is unlike that of the four species above named, though, we confess, too similar in that respect to some kinds of *Thymus*. The middle segment of the lower lip of the corolla, supposed to be

heart-shaped in *Melissa* and entire in *Thymus*, we find as little to be depended on as any of the above marks.

MELISSA, in *Gardening*, comprehends plants of the hardy herbaceous, fibrous-rooted perennial kind, of which the species cultivated are, the officinal, or common garden balm or balm (*M. officinalis*); the great-flowered balm (*M. grandiflora*); the Cretan balm (*M. cretica*); and the shrubby balm (*M. fruticosa*): as to these two last supposed species, see the last article.

The first sort varies occasionally with variegated leaves, and with the stalks slender, the leaves much shorter, the whole plant hairy, and of a strong disagreeable odour, the flowers in whorls, sitting pretty close to the branches, and smaller than those of the common sort; and has the name of Roman balm.

In the second species there are varieties with white flowers, with red flowers, and with variegated leaves; but they are all inferior to the purple

Method of Culture.—The two first sorts may be readily increased by parting the roots, and planting them out in the early autumn, as October, time enough for the offsets to be established before the winter frosts come on. They should be divided into small pieces, with three or four buds to each, and the first sort planted two feet a-part, in beds of common garden earth, and the second sort in the borders or other parts singly, in larger offset slips. The only culture they afterwards require is to keep them clean from weeds, and to cut off the decayed stalks annually in autumn, digging or stirring the ground between the plants in the common kind very well.

The third species may be raised by sowing the seeds in the autumn or spring, but where the seeds are permitted to scatter, there will be a sufficient supply of young plants without any further trouble.

And the fourth species may also be increased by seeds sown in the spring on beds or in pots, or by cuttings planted in the same manner, in any of the summer months, and shaded from the sun. They frequently live through the winter in warm borders; but it is always proper to keep a plant or two in pots, sheltered under a frame during that season, to prevent accidents.

In respect to the first sort, it is useful for various domestic purposes, and the others ornamental, in the borders, clumps, and other parts, as well as affording variety among potted plants in many cases.

MELISSA Officinalis, *Common Balm*, in the *Materia Medica*. The herb, in its recent state, has a weak, roughish, aromatic taste, and a pleasant smell, somewhat of the lemon kind: and hence this species has been denominated "*Melissa odore citri*." On distilling the fresh herb with water, it impregnates the first runnings pretty strongly with its grateful flavour: and when large quantities are employed in this way, there separates and rises to the surface of the aqueous fluid a small portion of essential oil, in colour yellowish, and of a very fragrant smell. Balm was formerly esteemed of great use, in all complaints supposed to proceed from a disordered state of the nervous system, and it was very generally recommended in melancholic and hypochondriacal affections, so that, in the opinion of Paracelsus, the "*primum ens Melissæ*" promised a complete renovation of man. Hoffmann and Boerhaave inclined to the opinion of the Arab physicians, and deemed it an efficacious remedy. S. Paulli and others speak of its effects as an emmenagogue: but neither this nor any other medicinal power is now attributed to balm. As tea, however, it makes a grateful diluent drink in fevers, and in this way it is commonly used, either by itself or acidulated with lemons. The essential oil probably possesses no qualities dif-

ferent from many other aromatics and cordials. Lewis and Woodville.

MELISSA, in *Geography*, a town of Naples, in Calabria Citra; 4 miles N. of Strongoli.

MELISSOPHYLLUM, in *Botany*. See MELITIS.

MELISSUS, in *Biography*, a philosopher of Samos, of the Eleatic sect, who flourished about the eighty-fourth Olympiad, or the year 440 B.C. He was a disciple of Parmenides, to whose doctrines he closely adhered. As a public man, he was conversant with affairs of the state, and acquired great influence among his countrymen, who had a high veneration for his talents and virtues. Being appointed by them to the command of a fleet, he obtained a great naval victory over the Athenians. As a philosopher, he maintained that the principle of all things is one and immutable, or that whatever exists is one being; that this one being includes all things, and is infinite, without beginning or end; that there is neither vacuum nor motion in the universe, nor any such thing as production or decay, that the changes which it seems to suffer, are only illusions of our senses, and mere appearances; and that we ought not to lay down any thing positively concerning the gods, since our knowledge of them is so uncertain. Themistocles is said to have been of the number of his pupils. Enfield's Hist. Phil.

MELISTAURUM, in *Botany*, so called by Forster, from μέλι, honey, and σταυρός, a stake, or a row of sharp pales, the nectary bearing a resemblance to a circular fence of that kind. This author declares the genus to belong to *Polygamia Dioecia*, and professes to describe a male flower only, having never seen the hermaphrodite ones. How he ascertained the existence of such, without having seen them, in a plant known to himself alone, does not appear. In his *Prodrômus*, p. 93, this is ranged among the obscure plants, of which he had seen imperfect specimens only, by the name of *Melistaurum distichum*, and said to be a native of New Caledonia. The male flower is figured in his *Genera*, t. 72, and thus described.

“*Cal.* none, unless the corolla be taken for such. *Cor.* minute, in five deep, roundish, concave, spreading segments. Nectary bell-shaped, abrupt, inserted into the corolla, bearing the stamens on its margin. *Stam.* Filaments twenty, inserted into the edge of the nectary, alternately awl-shaped, with roundish anthers, and of a thicker shape, hairy at the top, without anthers. *Pist.* Germen thickish, in the centre of the flower; style cylindrical, short; stigma blunt. *Peric.* and *Seeds* unknown, as well as the hermaphrodite flowers.”
Forster.

Every reader must perceive this to be the description of an hermaphrodite flower; so that we apprehend some misapplication of terms. However this may be, the description and figure are sufficient to justify Jussieu, who in his *Genera*, p. 438, refers Forster's plant to his own *Anavinga*, Lamarck Illustr. t. 355, which is *Casearia*, Schreb. Gen. 298, nearly allied to the *Samyda* of Linnaeus. See ANAVINGA and CASEARIA.

MELITA, in *Ancient Geography*, an island in the Mediterranean, concerning which geographers have entertained different opinions. Ptolemy places it very near to Africa. Silius Italicus gives it the epithet of “Lanigera” on account of its wool. Cicero speaks of a temple of Juno, which was in this island, situated near a town of the same name. As it was upon an island of this name that St. Paul was shipwrecked, in his voyage to Rome, after his appeal to Cæsar (see Acts, chap. xxvii. and xxviii.), the situation of this island has been the subject of curious and diligent investigation. But no person has employed more labour and

more learning in the research than Mr. Bryant. In the history, we find, that having been tossed for some time in the Adria, they were at last cast upon the island called Melite. The only question is, which is the sea, called Adria or Adriatic; and what island can be found in that sea under this name. The Adriatic sea is that large gulf which lies between Italy and the ancient Illyria, and retains its name to this day. And as to the island we are seeking, there was one in that sea called “Melite,” which is mentioned under that name by the best geographical writers. It appears from ancient authorities, that Melita was an Illyrian island in the Adriatic sea; and that it lay between Cocyra Nigra and the main land, very near the river Naro and the isthmus above it. It was called by the ancients Melite, Melitene, and Melitassa; at this day it is denominated Meleda, and by the Sclavonians, Mlekt, and is in the jurisdiction of Ragusa. Nevertheless it has been the common opinion, that the Melita, now called Malta, was the true place of the apostle's shipwreck; and the natives have a tradition of long standing to support this notion. Mr. Bryant, however, undertakes to prove, that this could not be the island mentioned by the writer of the book of Acts. But in doing this he contends with a host of learning and criticism; Grotius, Cluver, Beza, Bochart, and Bentley. In order to support this opinion, it is necessary for them to prove that Malta is an Adriatic island. This Bochart has much laboured to do; depending upon the authority of the poets, and a few of the later historians, who have extended the Adriatic to the coast of Africa. Polybius, Diodorus, Strabo, and Pliny, give a very different account of this matter. Mr. Bryant, after having fairly and fully stated the arguments of Bochart in favour of Malta, in his own words, undertakes to produce incontestible proof that Malta was not the place mentioned by the sacred historian, and that Melita Illyrica was. It must be allowed that, by the aid of the most approved geographers and historians, he has produced very strong, and to us satisfactory evidence, that the Adriatic sea was comprehended within the great Illyrian gulf, and never reached farther. Strabo expressly determines its extent by two fixed boundaries, that cannot be mistaken; it was included between Italy and the opposite continent. “Where then,” says our author, “was St. Paul shipwrecked? Certainly between Italy and Illyria, that is, the opposite continent. Is Malta to be found in this situation? It is far off, in a sea that has no affinity, no connection with those coasts. But the other Melita, taken notice of by Scylax, Agathemerus, and Pliny, is situated in the Adria, agreeable to the apostle's account; therefore, Melita Illyrica is certainly the island there mentioned.” Mr. Bryant strengthens his other arguments by adverting to the character of the natives, who are described as Βαρβαροι, barbarians. This character could not consistently be applied to the inhabitants of Melita Africana (Malta), which was first colonized by Phœnicians, and afterwards inhabited successively by Carthaginians, Greeks, and Romans. “Who will be so hardy as to denominate any of these nations barbarous? They were each of them renowned for arts, of great power and wealth, and of particular elegance and refinement. As the ancestry was good, the posterity did not fall off. The testimony of Diodorus Siculus (Hist. Bibl. l. v.) will sufficiently vindicate them from the charge of being barbarous. We have an account of some remains of antiquity in this island that will serve to guide our judgment concerning this people. The temples of Juno and Hercules appear to have been very magnificent, and of great extent: and the coins that were originally struck there are said to be of no ordinary cast. Nor can it be said

that those even of the lower class were rude and savage; because from them St. Paul experienced nothing but civility. But if we take a view of Melita Illyrica, the scene will be changed, and the appellation will be found to be more applicable. The character of the Illyrians, near whom this island was situated, is represented as barbarous beyond measure. Modern travellers report of Malta that it harbours no serpents; a blessing, we are told, bequeathed to the island by St. Paul at his departure. If this be true of Malta, what is allowed as a tell of the apostle's having been upon the island, is a proof to me, says our author, that he never was there. As there are no serpents now, my conclusion is, that there never were any; and consequently it could not be the place where St. Paul exhibited the miracle. For other particulars we must refer to Mr. Bryant himself. Bryant's *Observations and Inquiries*, &c. 1767, 4to.

MELITENE, MELEDNI, a country of Asia, in Armenia Minor, which extended to the right of the Euphrates, and was traversed by the river Meles.—Also, a town of Cappadocia, to the S.E., upon a stream which discharged itself into the river Meles.—Also, a country of Asia, in Cappadocia, occupying the S.E. part of it.

MELITENSIS TERRA, *Earth of Malta*, in the *Materia Medica*, an earth of which there are two very different kinds, the one of the genus of boles, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use: but both being brought from the same place, are confusedly called by the same name.

The Maltese bole, which is what we use now, is a fine earth, of a close compact texture, very heavy; when dug it is of a very pure white, but it is apt to contract a yellowness in drying, and become of a cream colour. It is of a very smooth and shining surface, scarcely at all stains the skin in handling, adheres strongly to the tongue, and melts into a butter-like substance in the mouth. It makes no effervescence with aquafortis, or any other acid menstruum, and suffers no change of colour in the fire. Hill. For the character of boles, see BOLES. The Maltese marle, which is the terra Melitensis of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and when exposed to the weather, soon falls into fine soft powder; but when preserved and dried, it becomes a loose light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into water it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstrooms.

Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals, but with how much justice we cannot say. The other has supplied its place in the German shops, and is used there as a cordial, a sudorific, and astringent. For the character of marles, see MARLE.

MELITIA, in *Geography*, a town of European Turkey, in Thessaly; 24 miles S. of Larissa.

MELITITES, Μελίτιτες, in *Natural History*, an indurated clay, of a yellowish colour, but in many respects approaching to the nature of the moroethus or French chalk: which, when pulverized, yields with water a milky liquor, of a taste somewhat like honey: whence it takes its name.

It is a smooth substance, of a compact texture and great weight, of a fine, even, glossy surface, smooth and soft to the touch, does not adhere to the tongue, nor stain the fingers; but drawn along a rough surface, leaves a fine slender

white line, and staved into very thin pieces, has some degree of transparency. It does not ferment with acids, and burns to a pure white.

It is found in mines of metals, and seems to partake pretty much of the nature of lead; having a sweetness somewhat like that of the galactite, but much fainter. It only differs from the galactite, in that it is milder to the taste. (See GALACTITE.) The ancients used it in inflammations of the eyes, and to dry ulcers.

They also applied it externally in ulcers, and gave it inwardly as a soporific to people who were to suffer pain, supposing it would make them less sensible of it. It is at present very common in Italy, and probably in many other places, but is not known or regarded.

MELITITES Lapis, a name given by some authors to some of the rounder species of echinite, from their resembling an apple in their shape.

MELITO, in *Biography*, an ancient Christian father, who flourished in the second century, was bishop of Sardis. Some moderns have supposed him the same as the angel of the church of Sardis, to whom the epistle in the book of Revelation was directed, but the most judicious critics have abandoned this idea. He travelled into Palestine for the purpose of ascertaining the number of books of the Old Testament, and he is the first Christian writer who has given us a catalogue of those books, which agrees with that of the Jews, excepting that it does not contain the book of Esther. Melito was in the number of those fathers who wrote in defence of the Christian faith, and addressed an apology to the emperor Marcus Antoninus in behalf of the persecuted Christians, of which a fragment is preserved by Eusebius. In this piece he intreats the emperor to examine the accusations which were preferred against the Christians, and to put an end to their persecutions and sufferings, by revoking the edict that he had published against them. He represented to him, "that so far was the Roman empire from having been injured or weakened by Christianity, that it was the more firmly established since the introduction of that religion into it." He boldly stated that the Christian religion had been persecuted only by wicked emperors, such as Nero and Domitian: and that, therefore, they naturally indulged the hope, that from his known clemency and goodness they should receive the same protection which they had enjoyed under the reign of Adrian. The date of this apology is fixed by Eusebius to 170, but Lardner and some others, from internal evidence, give it the date of 175 or 177. Melito was author of various treatises, the titles of which may be seen in the works of Eusebius, but of these only a few fragments remain. From the title of one of those pieces, "Concerning the Revelation of John," critics have inferred that he esteemed the book of Revelation of canonical authority, and to have been written by the apostle John. We have no account of Melito's death, except what is gathered from a letter of Polycrates to Victor, bishop of Rome, which proves it took place before the election of that pontiff, in the year 192. Lardner. Gen. Biog.

MELITO, in *Geography*, a small town and bishop's see of Naples, in Calabria Ultra, several miles S. of Monte Leone.

MELITOPOL, a town of Russia, in the province of Tauris, situated on a lake about 12 miles from the sea of Azof. N. lat. 46° 12'. E. long. 35° 10'.

MELITTIS, in *Botany*, from μελίτις, which in the attic dialect is the name of a bee; so that this word is, in fact, equivalent to *Melissa*, and was adopted by Linnæus therefore for the *Balsam*.—Linn. Gen. 299. Schreb. 395. Willd. Sp. Pl. v. 3. 157. Mart. Mill. Dict. v. 3. Sm.

Fl. Brit. 643. Ait. Hort. Kew. ed. 2. v. 3. 421. Juss. 116. Lamarck Dict. v. 4. 80. Illustr. t. 513.—Class and order, *Didynamia Gymnosperma*. Nat. Ord. *Verticillata*, Linn. *Labiate*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, round, straight, its mouth two-lipped; *upper lip* longest, acute; *lower* shortest, cloven, acute, its segments gaping. *Cor.* of one petal, ringent; *tube* much narrower than the calyx; mouth not much wider; *upper lip* erect, roundish, undivided; *lower* spreading, three-cleft, obtuse, its middle segment largest, flat, undivided, crenate. *Stam.* Filaments four, awl-shaped, sheltered by the upper lip, the two intermediate ones shorter than the outer ones; anthers cohering in pairs, forming a cross, cloven, obtuse. *Pist.* Germen obtuse, four-cleft, hairy; style thread-shaped, the length and situation of the stamens; stigma cloven, acute. *Peric.* none, except the unchanged calyx. *Seeds* four, in the bottom of the calyx.

Obf. The segments of the calyx differ in number in the different species.

Ess. Ch. Calyx unequal, much wider than the tube of the corolla. Upper lip of the corolla flat; lower three-lobed, crenate. Anthers forming a cross.

1. *M. Melissophyllum*. Reddish Bastard-Balm. Linn. Sp. Pl. 832. Engl. Bot. t. 577. Jacq. Austr. t. 26. (*Melissophyllum*; Rivin. Monop. Irr. t. 21. f. 2. *Melissa* Fuchsii; Camer. Hort. t. 30.)—Calyx three-lobed, nearly smooth.—Native of rather mountainous woods and thickets in Germany, Switzerland, France, Greece, and the south-west extremity of England, flowering in the beginning of summer. The root is fibrous and perennial. *Stems* herbaceous, erect, simple, square, leafy, hairy, about eighteen inches high. *Leaves* opposite, stalked, ovate, serrated, hairy, full two inches long and one broad; paler and rather polished beneath. *Flowers* axillary, about three on each side, mostly turned one way, on simple reddish round stalks. *Calyx* purplish, with hairy ribs, ample, three-lobed; the upper lobe or lip longest, acute, often notched or toothed at each side; lower lip in two vertical, equal, pointed or notched, side-lobes. *Corolla* large and handsome, thrice the length of the calyx, externally flesh-coloured, internally whitish, the lip marked with a divided crimson spot, and a few dots on its principal segment, and more or less of a stain on its two lateral lobes. The whole herb has, when fresh, rather an offensive smell; when dried it acquires the scent of new hay, like woodruff, which is also the case with the next. Some of the old authors mistook this *Melittis*, or the following, for they did not always distinguish the two, for the *μελισσοφυλλον* of Dioscorides; but that is evidently rather our *Melissa officinalis*, and as far as can be concluded from the synonym of *Apiastrum*, the *Melissophyllum* of Pliny. Haller therefore is to blame in citing the Roman author, to support his own preference of this last-mentioned name, to that adopted by Linnæus, for the genus before us.

2. *M. grandiflora*. Purple and White Bastard-Balm. Engl. Bot. t. 636. (*M. Melissophyllum*; Curt. Lond. fasc. 6. t. 39. Mill. Illustr. t. 52. *Melissophyllum*; Rivin. Monop. Irr. t. 21. f. 1. *M. adulterinum*; Fuchs. Hist. 497. fig. 498, verum.)—Calyx in four equal lobes, nearly smooth.—Native of woods in Hungary and Switzerland, as well as in Devonshire and Cornwall, flowering early in the summer. Linnæus, Haller, and their pupils for the most part, have confounded this with the foregoing, from which it differs essentially in the calyx, whose lobes are four, all lateral, none vertical, for the most part entire, though sometimes notched. The corolla is larger than the other species, white, with a pale tinge of yellow or cream colour in its up-

per part, the middle segment of its lower lip purple with a white margin. The general habit form and scent of the two plants agree, but this is rather the most ornamental. Clusius distinguished them in his *Hist. v. 2. 37*, as did after him Johnson in Ger. em. 690. The figure in Fuchsius marked *Melissophyllum verum*, is evidently intended for our present plant, the calyx being very clearly defined; but his account can only belong to the Garden Balm, *Melissa officinalis*, as the lemon scent is particularly noticed. It seems therefore that the cuts of these two very dissimilar plants have been transposed by his printer, a mistake hitherto unnoticed. Hence Fuchsius is very erroneously quoted by Vaillant, Haller, and others, as making this *Melittis* the true *Melissa*, or *μελισσοφυλλον*.

3. *M. japonica*. Japan Bastard-Balm. Thunb. Tr. of Linn. Soc. v. 2. 338. Willd. n. 2. (*M. Melissophyllum*, Thunb. Jap. 248.)—Calyx hairy. Leaves alternate, ovate, obtuse, unequally serrated.—Native, as it is presumed, of Japan, though Thunberg saw only one plant, cultivated in a pot, in the island of Nipon, in his journey towards Jeddo, flowering in May and June. The Japanese called it *Sjurowo*. Stem erect, villous, simple, a span high. Leaves alternate, stalked, ovate, obtuse, unequally and doubly serrated, villous, spreading, a finger's length. Footstalks the length of the nail. Flowers axillary, solitary, each on a hairy stalk, an inch long. Calyx rough with bristles, drooping. Thunb.

The leaves being alternate, is so improbable in this genus, that we cannot but suspect a mistake in that particular, or in the generic characters of the plant. We know nothing of this species but what Thunberg has given above.

MELITTIS, in Gardening, comprehends a plant of the flowery perennial kind, of which the species cultivated is, the ballard balm (*M. melissophyllum*).

In this plant there is much honey secreted, from a gland that encircles the base of the germ; it is of course a favourite plant with bees.

And there is a variety smaller in all respects, with the leaves ovate and heart-shaped, the flowers not so large, and usually of a pale red, but sometimes white, which is a native of Switzerland, and other similar situations.

Method of Culture.—Plants of this sort are capable of being increased by parting the roots and planting them out early in the autumn, where they are to remain; but the roots should not be parted oftener than every third year. When seeds can be procured, they may also be raised by sowing them in the early spring, where they are to remain. The plants succeed best in a loamy soil and eastern aspect, where they can be had.

They are capable of affording ornament in the borders and other parts of pleasure-grounds and gardens.

MELIUS INQUIRENDUM, in Law, a writ which lieth for a second inquiry to be made of what lands and tenements a man died seized, where partiality is suspected upon the writ called *diem clausit extremum*.

A "melius inquirendum" shall be awarded out of B.R. where a coroner is guilty of corrupt practices, directed to special commissioners. 1 Vent. 181.

MELIZZANO, in Geography, a town of Naples, in Lavora; 15 miles E. of Capua.

MELKOVATE, a town of Bulgaria; 52 miles S. of Viddin.

MELKSHAM, a considerable market-town in the hundred of Melksham and county of Wilts, England; is pleasantly situated on the river Avon, at the distance of 23 miles from Bath, and 96 from London. In ancient times it is said to have been a place of considerable note by the

the authors of the *Magna Britannia*, who assert that the Conqueror established a court of royal jurisdiction here. Edward I., according to the same authority, had likewise a forest in this neighbourhood, which was joined to that of Chippenham, and committed to the custody of Matthew Fitz-John, who was governor of the castle of Devizes. But if thus important in early times it seems to have greatly decayed before the age of Leland, as neither he, nor his successor Camden, so much as mention it, though the former was undoubtedly in this part of the county. Of late years, however, it has again risen to some degree of consequence by the influence of trade. For a considerable period Melksham has been celebrated for its manufacture of superfine cloths and cassimere. The buildings of this town are in general constructed of freestone, possessing, individually, an appearance of much neatness, but the streets are irregular and narrow. The church, of which the living is a vicarage in the gift of the dean and chapter of Salisbury, is a spacious edifice, with a handsome tower in the centre. Here are likewise meeting-houses for dissenters of different denominations, particularly Independents and Baptists. Methodists are less numerous than in most other towns of the same extent in England, though they have increased considerably of late years. According to the parliamentary returns of 1801, the number of inhabitants in the whole parish was estimated at 4030 persons, 1864 males, and 2166 females, of whom 1299 were engaged in trade, and 370 in agriculture. The proportion of poor is very great, owing to the manufactories which have again begun to decline, and will probably soon leave the town entirely, as has already taken place with regard to Corsham. Since the introduction of the new process in the cloth manufacture, Melksham has lost the advantages it was formerly supposed to possess in respect of situation on the banks of the Avon. The petty sessions for Melksham and Tinhead division are held here. The market is on every alternate Monday. A branch of the Wilts and Berkshire canal comes close up to the town, and communicates with Bath and Bristol. About two miles west of Melksham is Shaw-hill-house, the seat of R. Heathcote, esq. *Magna Britannia*, Wiltshire. *Britton's Beauties of Wiltshire*.

MELL ISLANDS, a cluster of small islands, near the W. coast of Scotland. N. lat. 58° 15'. W. long. 4° 57'.

MELLABA, a town of Africa, in the country of Barca. N. lat. 31° 5'. E. long. 23° 44'.

MELLARIA, in *Ancient Geography*, *Fuentes Orxuna*, a town of Hispania, in Bætica, at the foot of the mountains, and S.W. of Sifapa; which was a considerable place, and is mentioned in the Itinerary of Antonine.—Also, a town of Hispania, in Bætica (now *Tarifa*), situated towards the south on a strait, famous for its salt-works and for its commerce in salted provisions. According to the Itinerary of Antonine, it was 12 miles towards the W. from *Portus Albus*.

MELLATS, in *Chemistry*, are combinations of an acid called the mellitic with certain bases. See MELLITIC Acid.

MELLE, in *Geography*, a town of France, and principal place of a district in the department of the Two Sevres; 13 miles S.E. of Niort. The place contains 1741, and the canton 7782 inhabitants, on a territory of 165 kilometres, in 13 communes. N. lat. 46° 13'. W. long. 0° 4'.—Also, a town of Westphalia, in the bishopric of Osna-bruck; 11 miles S.E. of Vorden.

MELLEGETTA, MELEGETTA, or *Milleguetta*, in *Botany*, the African name, if we mistake not, of the Grains of Paradise, *Amomum Grana Paradisi* of Linnæus; see AMOMUM, sp. 15. See also GRAIN-Coast, where this word is

spelt *Malaguetta*, and supposed to be of Portuguese origin. It is likewise the Spanish name of the same drug, and, wherever it may have originated, is now in common use amongst the black natives of Sierra Leone. From thence we obtained, many years ago, by the kindness of Dr. Adam Afzelius, specimens of these grains in their native husk or capsule, a thing heretofore unknown among collectors of *Materia Medica* in England. We received also, at the same time, specimens of the plant, which is a genuine *Amomum*, according to Mr. Roscoe's able elucidation of the Linnæan order of *Scitamineæ*, see Tr. of Linn. Soc. v. 8. 351. t. 20. f. 11; and is now growing, in many of the English floras, from seeds brought over by Dr. Afzelius; but we have never heard of its flowering. The new edition of *Art. Hort. Kew.* does not contain this species, but it is admitted into the catalogue of the Cambridge garden by Mr. Donn, we believe with perfect propriety. As no authentic characters or descriptions of this plant have appeared, and its synonyms are altogether confused, even in the best writers, we shall attempt to clear up the whole of its history.

AMOMUM *Grana Paradisi*, Grains of Paradise. (True Melligetia Pepper. *Afzelius*.) Linn. Sp. Pl. 2. Berg. Mat. Med. v. 1. 3. (A. n. 3; Linn. Mat. Med. 2, with an erroneous character. *Grana Paradisi officin*; Dale Pharmac. 277; Bauh. Pin. 413; both with many wrong synonyms. Melligetia; Cord. Hist. 195. Meleguetta; Bauh. Prod. 158. Lobel. Advers. 445.)—Stalk simple. Bractæes numerous, closely imbricated. Leaves crowded, ovato-lanceolate, pointed. Capsule oblong, bluntly triangular, minutely hispid. Seeds roundish.—Native of Guinea, about Sierra Leone, from whence the seeds were brought very soon after the discovery of that country by European navigators. The root is perennial, woody, creeping horizontally. Stems erect, simple, slender, three feet high, leafy, but destitute of flowers. Leaves numerous, crowded, two-ranked, alternate, a span long and an inch broad, lanceolate, or slightly ovate, with a long taper point, entire, smooth, single-ribbed, striated with innumerable oblique veins. Their flavour is slightly aromatic, after having been dried twenty years. Footstalks sheathing, linear, very long, smooth, striated. Flower-stalks radical, solitary, an inch or two in length, ascending, clothed with numerous, close, sheathing bractæes, all abrupt, ribbed, somewhat hairy and fringed; the lower ones very short; the upper gradually much larger. Of the parts of the flower nothing can be made out from our specimens. Capsule an inch and half long, half an inch in diameter, oblong, bluntly triangular, scarcely ovate, beaked, of a dark reddish-brown, ribbed, coriaceous, rough with minute deciduous bristly hairs. When broken it is very powerfully aromatic, even after being kept twenty years, with a peculiar pepper-like flavour, rather too strong to be agreeable. Seeds numerous, enveloped in membranes formed of the dried pulp, roundish or somewhat angular, of a shining golden brown, minutely rough or granulated, extremely aromatic, hot, and acrid.

Of this plant or its capsule we have in vain sought for a figure in any book within our reach. The old authors confounded with it the *Cardamomum majus*, of which a figure may be found in Camerarius's *Epitome* 11. f. 1. Tabern. Kreuterb. 1319. Matth. Valgr. v. 1. 25. Ger. em. 1542, the largest kind. Bauh. Hist. v. 2. 204. This is *Amomum angustifolium* of Sonnerat's *Voyage aux Indes*, v. 2. 242. t. 137, found in marshy ground in Madagascar. The habit of this species is not unlike what we have described; but the capsule, (of which old authors mistake the base for the summit, and therefore compare it to a fig,) is very different, being

being ovate, flattened at one side, striated, but smooth, nearly twice the size of the above. Seeds larger than the former, but otherwise not very unlike in appearance, though totally different in their flavour, which much resembles that of the small East Indian Cardamom, and has none of that vehemently hot acrid taste, for which the Grains of Paradise are remarkable.

Gærtner has mistaken for the Mellegetta Pepper another very different species of *Amomum*, for which genus he perversely retains the name *Zingiber*. This is figured in his t. 12, by the name of *Z. Melegueta*, and is remarkable for the large and copious bractæas, each two inches long, encompassing the capsule. The latter is nearly as long, ovate, with a corrugated beak. Seeds ovate or nearly globular, partly angular, smooth and polished, lead-coloured, livid, or glaucous, with a strong umbilicated scar at their base, surrounded with a whitish rather tumid margin. Professor Afzelius has favoured us with some seeds which answer very well to this description, except in being twice as large as Gærtner represents them. But this is not an unfrequent error with him. Of the capsule, or plant producing these seeds, we have no information.

Another species, nearly akin to this of Gærtner, (and which we should almost have taken for his plant, were it not for the seeds just mentioned, considered as such by our friend Afzelius,) is described in Clusius, (*Exot.* 38. fig. 14.) of which we have one capsule, with seeds. The author describes this as bearing four capsules together at the top of the stalk, encompassed with short bractæas at the base, not long ones as in Gærtner. The capsules are two inches in length, ovate with a long beak, slightly triangular, cartilaginous rather than leathery, striated, smooth, reddish-brown. Seeds ovate inclining to cylindrical, dark brown, exquisitely smooth and shining, with a light brown corrugated and notched margin surrounding the scar. They are but slightly aromatic. Clusius seems to have received from Madagascar the true *Cardamomum majus*, *Amomum angustifolium* of Sonnerat mentioned above, which he rightly distinguishes from the Mellegetta Pepper, and seems to imply that it is also distinct from his fig. 14, of which there can be no doubt.

By the above remarks it appears that the species of this genus are very imperfectly known. We have, besides, specimens of some that are not at all described. It is highly desirable that botanical travellers should pay particular attention to this tribe, the seeds of several of which are important articles of commerce, and not useless in medicine. The botanical history of none of the Cardamoms was properly known to Linnæus, and that of the *Cardamomum medium*, *Zingiber Ensifol* of Gærtner, is still entirely in the dark. By the inflorescence we presume it of Dr. Maton's genus *Elettaria*, Tr. of Linn. Soc. v. 10. 254. S.

MELLI, or LAMLEM, in *Geography*, a country of Africa, bounded on the N. by Cashna, on the E. by Wangara, on the S. by Guinea, from which it is separated by mountains, and on the W. by Gago; 500 miles in length from E. to W., and from 150 to 200 in breadth. N. lat. $11^{\circ} 30'$ to 15° . E. long. $5^{\circ} 30'$ to $14^{\circ} 50'$.

MELLID, a town of Spain, in Galicia; 20 miles E. of Compostella.

MELLIFAVIUM, (from *mel* and *favus*, a honey-comb,) in *Surgery*. See MELICERIS.

MELLITE; *Honig-stein*, Wern.; *Honey-stone*, Jamefon; *Mellite*, Häüy, Broch. Brongn.; *Mellitite*, Kirw.

This mineral, which, by most mineralogists, is classed with the inflammable substances, was mistaken, by Born and other writers, for a crystallized variety of amber, till Werner and

Laumont, and principally Klaproth, determined its true nature, which is totally different from that of any other mineral substance we are acquainted with.

Its colour is honey-yellow, of more or less purity and intensity, passing into wax and sometimes into straw and greyish-yellow.

It is seldom found massive and in detached grains; generally crystallized.

The primitive form of the crystals is an octohedron with common base perfectly square; the inclination of each face of the four-sided pyramid, on its corresponding face in the other pyramid, is, according to Häüy, = $93^{\circ} 22'$. This primitive crystal (*Mellitite primitif*, Häüy, pl. 62. f. 12.) occurs more frequently than the following modifications.

1. The primitive octohedron having all the solid angles of the base replaced by quadrilateral planes, which, when they meet, form a rhomboidal dodecahedron, which is, however, different from the garnet dodecahedron in the measurement of its angles. (*Mellitite dodicaëdre*, Häüy, ib. fig. 14.)

2. The primitive octohedron, with the solid angles of the base as well as those of the summit of the pyramids, each replaced by a quadrilateral plane, the surface of which is sometimes more or less convex or curvilinear. (*Mellitite époincé*, Häüy, ib. fig. 13.)

The crystals, which are small and very small, are generally singly dispersed, sometimes grouped together; their surfaces are smooth and shining, seldom rough, and, as it were, corroded.

Internally it is splendid; lustre intermediate between vitreous and resinous.

Fracture perfectly conchoidal; the fragments are indeminately angular, and pretty sharp-edged.

It is seldom found perfectly transparent; oftener translucent and opaque, and possesses a very distinct double refraction.

It is soft; more so than amber. Brittle. Easily frangible, and yields a yellowish-grey powder. Specific gravity 1.550, Klapr., 1.5858, Häüy, 1.666 Abich. The purer crystals become slightly electric by friction.

Exposed to the flame of a candle, or on a burning coal, it first becomes opaque, and white spotted with black, which soon gives way to a pure white. No smoke, flame, or odour are perceived during this process. Projected on melted nitre no real detonation takes place, but only a slight scintillation; and the earthy part remains mixed with the nitre.

It is entirely soluble in nitric acid without heat, and the fragments remain translucent; in muriatic acid, on the other hand, the fragments become more or less opaque.

Abich and Lampadius have given analyses of mellite, which are completely superseded by those performed by Klaproth, according to which this substance is composed of

Alumine	-	-	16
Mellitic acid	-	-	46
Water of crystallization	-	-	38

100 Kl. Beitr. ii. p. 134.

This analysis has been confirmed by Vauquelin in *Ann. de Ch.* vol. xxxvi. p. 203.

This substance has been hitherto found only at Artern, in Thuringia, on a bed of bituminous wood and brown coal, accompanied by small crystals of native sulphur, which by the inattentive observer might be easily mistaken for the straw-yellow variety of mellite. Langenbogen in the Saal circle has been mentioned as another locality of this mineral, as likewise Switzerland, where it is said to have been found with slaggy asphaltum.

MELLITIC ACID, in *Chemistry*, is a product obtained

tained from the mineral called mellite, or honey-stone. It was discovered by Klaproth in the year 1799 (Beiträge, tom. iii. p. 114.); and the existence of it was shortly afterwards confirmed by the researches of Vauquelin (Annales de Chimie, tom. xxxvi. p. 291.) To procure this acid, it is merely necessary to boil the mellite, reduced to powder, in about seventy times its weight of water. The alumine with which it is combined in its native state, is by this process precipitated, and after filtering the solution, and evaporating it to a sufficient degree, the acid appears in a state of tolerable purity. It may be still contaminated with the presence of a little earthy matter; but, by exposing it to the action of alcohol, this will be detached, and it may then be obtained crystallized under the form of needles, or short prisms. In Vauquelin's analysis, the substance under enquiry was procured by adding the pulverized mellite to a solution of carbonate of potash; carbonic acid being evolved, and the mellitic acid uniting to the alkali. Nitric acid was afterwards presented to take up the alkaline base, and the mellitic acid separated, in the course of a few hours, in short prismatic crystals. Thus crystallized, this acid has a brownish-yellow tinge; its taste is slightly sour, accompanied with bitterness; and it is but sparingly soluble in water. Exposed to heat, it is easily decomposed, and emits a dense smoke which has no odour. With the alkalies, earths, and metallic oxyds, it enters into combination, and forms a class of salts, which, in conformity with the principles of the present chemical nomenclature, are denominated *mellats*. The properties of these, however, have been but very imperfectly examined. Mellat of potash crystallizes in prisms, which apparently differ from those of the acid in being longer. The form of mellat of soda is a cube, or three-sided table. The union of mellitic acid with ammonia yields fine transparent six-sided prisms, which become opaque on exposure to the air. Barytes, strontian, and lime, form insoluble compounds; as also does alumine. Solutions of silver, lead, and mercury afford each a white precipitate; but from iron a yellow compound is deposited. This acid, in many of its properties, bears a very near resemblance to the oxalic; but, in others, it exhibits a sufficient difference to forbid our considering them identical. The products it affords when decomposed by heat, are pretty much like those yielded by the vegetable acids. This species of analysis, however, has been, hitherto, so rude and unsatisfactory, that no very accurate comparison can be grounded upon the evidence which it supplies. The acute researches of M. M. Gay Lussac and Thenard have, in a very eminent degree, removed this defect; and we may shortly hope, aided by the light which their genius has diffused over these subjects, to find vegetable chemistry equally demonstrative and certain in its operations with the most accurate branches of experimental science. See *Recherches Physico-Chimiques par Gay Lussac et Thenard*, tom. ii.

MELLO-MESQUITELA, in *Geography*, a town of Portugal, in the province of Beira; 12 miles W. of Guarda.

MELLOON, or MELONE, a town of the Birman empire, on the W. side of the Ava, rich in temples, but in no other respect distinguished. N. lat. 20° 10'. E. long. 96° 9'.

MELLOOR, a town of Hindoostan, in Madura; 12 miles N.E. of Madura.

MELLOUNOSH, a town of Africa, on the E. coast of Tunis; 20 miles S.E. of Jemme.

MELLYPOUR, a town of Hindoostan, in Bahar; 38 miles W.S.W. of Boglipoor.

MELMOTH, WILLIAM, in *Biography*, an eminent and learned pleader at the bar, and member of Lincoln's Inn, was born in 1666. He became a member of that honourable society, and, in conjunction with Mr. Peere Williams, published Vernon's "Reports," under an order of the court of Chancery. It appears that he had an intention of printing his own Reports, and even advertised them as actually preparing for the press. They have not, however, made their appearance. But the work by which he is best known, and for which he will be very long remembered, is entitled "The Great Importance of a Religious Life." This little tract has gone through many editions; more than 40,000 copies were circulated in the course of twenty years, independently of other large impressions that have been taken off, as well for sale as for charitable purposes: and while this article was writing, several copies of a new edition of this valuable tract came into the hands of the writer, from a friend who has undertaken the office of editor, with the view of circulating it among persons into whose hands it would, without his exertions, scarcely have come: and with the hope, that by omitting certain expressions in controverted theology, "the work might recommend itself to a numerous and additional body of rational disciples of our common master." It is a singular circumstance, that the author of this treatise, so much read and highly applauded, should not have been known till the fact was revealed by his son. It was commonly attributed to the first earl of Egmont, to whom it had been given by Mr. Walpole in his Catalogue. Mr. Melmoth died on the 6th of April 1743, and was buried under the cloister of Lincoln's-Inn chapel. His character has been drawn by his son, the subject of the next article, in the following words: "The author's life was one uniform exemplar of those precepts which, with so generous a zeal, and such an elegant and affecting simplicity of style, he endeavours to recommend to general practice. He possessed by temper every moral virtue; by religion every Christian grace. He had a humanity that melted at every distress; a charity which not only thought no evil, but suspected none. He exercised his profession with a skill and integrity which nothing could equal, but the disinterested motive that animated his labours, or the amiable modesty which accompanied all his virtues. He employed his industry, not to gratify his own desires; no man indulged himself less: not to accumulate useless wealth, no man more disdained so unworthy a pursuit: it was for the decent advancement of his family, for the generous assistance of his friends, for the ready relief of the indigent. How often did he exert his distinguished abilities, yet refused the reward of them, in defence of the widow, the fatherless, and him that had none to help him! In a word, few people have ever passed a more useful, not one a more blameless life; and his whole time was employed in doing good, or in meditating it." See preface to "The Great Importance of a Religious Life, &c." 1812. Also "Memoirs of a late eminent Advocate, &c." By William Melmoth, esq. 1796.

MELMOTH, WILLIAM, son of the above, was born in 1710, and first appeared as a writer about the year 1742, in a volume of "Letters" under the name of Fitzosborne, which have been much admired for the elegance of their language, and their just and liberal remarks on various topics, moral and literary. In 1747 he published "A Translation of the Letters of Pliny," in 2 vols. 8vo., which was regarded as one of the best versions of a Latin author that had appeared in our language. In 1753, he gave a translation of the "Letters of Cicero to several of his Friends, with Remarks," in 3 vols. He had previously

to this, written an answer to Mr. Bryant's attack, in his Treatise on the Truth of the Christian Religion, on his remarks on Trajan's Persecution of the Christians in Bithynia, which made a note to his translation of Pliny's Letters. He was the translator likewise of Cicero's treatises "De Amicitia" and "De Senectute," which were published in 1773 and 1777. These he enriched with remarks, literary and philological, which added much to their value. In the former he refuted lord Shaftsbury, who had imputed it as a defect to Christianity, that it gave no precepts in favour of friendship, and Soame Jenyns, who had represented that very omission as a proof of its divine origin. The concluding work of Mr. Melmoth was a tribute of filial affection, in the Memoirs of his father, of which we have already made use. After a long and respectable life passed in literary pursuits, and the practice of private virtue, Mr. Melmoth died at Bath, March 15, 1799, at the age of 89. He had been twice married; first to the daughter of the celebrated Dr. King, principal of St. Mary's-hall, Oxford, and secondly to Mrs. Ogle. "The author of 'The Pursuits of Literature,' says Mr. Melmoth, "is a happy example of the mild influence of learning on a cultivated mind; I mean that learning which is declared to be the aliment of youth, and the delight and consolation of declining years. Who would not envy this fortunate old man, his most finished translation and comment on Tully's Cato? Or rather, who would not rejoice in the refined and mellowed pleasure of so accomplished a gentleman, and so liberal a scholar?" *Gent. Mag.* Preface to Fitzosborne's Letters, 1805.

MELNERSENS, in *Geography*, a town of Westphalia, in the principality of Luneburg-Zelle; 16 miles S.E. of Zelle.

MELNIK, a town of Bohemia, in the circle of Boleflaw, at the conflux of the rivers Elbe and Moldau; 18 miles N. of Prague. N. lat. 50° 20'. E. long. 14° 40'.

MELO, in *Botany*, from *μηλον*, an apple, the Melon. See CUCUMIS.

MELOCACTUS, so called from *Melo*, a Melon, and *Cañus*, the Torch-thistle, because the whole plant resembles a large green deeply-furrowed melon. See CACTUS.

MELOCHIA, a name adopted by Dillenius from Prosper Alpinus. Sonnini says it is the Arabic appellation of *Corehorus olitorius*, a plant agreeing in many particulars of habit and properties with the genus in question. Linn. Gen. 348. Schreb. 454. Willd. Sp. Pl. v. 3. 600. Mart. Mill. Dict. v. 3. Juss. 274. Cavan. Diff. 318. Lamarek Dict. v. 4. 81. Illustr. t. 571. Gærtn. t. 113.—Class and order, *Monadelphia Pentandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cut half-way down into five, half-ovate, acute, permanent segments, and sometimes accompanied by an external unilateral calyx of three leaves. *Cor.* Petals five, inversely heart-shaped, large and spreading. *Stam.* Filaments five, awl-shaped, united at the base into a little cup embracing the germen; anthers simple. *Pist.* Germen superior, roundish; styles five, awl-shaped, erect, the length of the stamens, permanent; stigmas simple. *Peric.* Capsule roundish, or five-sided, of five cells and five acute valves, with double partitions contrary to the valves. *Seeds* either solitary or in pairs, roundish on one side, angular from compression at the other.

Ess. Ch. Calyx single or double. Petals five, spreading. Filaments awl-shaped. Styles five. Capsule of five cells. Seeds one or two in each cell.

A tropical, and principally West Indian genus of plants, for the most part shrubby, and agreeing with *Sida*, more than with any other of the same natural order, in habit

and appearance. The 14th edition of Syft. Veg. enumerates seven species; Willdenow has fourteen. The leaves in all are stalked, simple, scarcely lobed, unequally crenate or serrated, and of course alternate. *Flowers* various in size, situation, and colour. The following examples may suffice.

M. pyramidata. Linn. Sp. Pl. 943. Jacq. Hort. Vind. v. 1. 11. t. 30. Cavan. Diff. 319. t. 172. f. 1.—Flowers in lateral umbels. Capsule pyramidal, with five sharp-pointed angles. Leaves naked.—Native of Brasil and the Caribbee islands. It has long been known in the stoves of this country, but is kept rather as a curiosity than an ornament. The stem and branches are round, straight and wand-like. Leaves ovate, pointed, serrated, two or three inches long and one broad, smooth, with one rib, and many straight, parallel, oblique veins. Flowers small, purple, four or five together, in lateral hairy umbels.

M. concotenata. Linn. Sp. Pl. 944. Cavan. Diff. 322. t. 175. f. 2. (*Althæa indica*, *foliulis parvis*, &c.; Pluk. Phyt. t. 9. f. 5.)—Spikes terminal, crowded. Capsules globose. Leaves serrated, naked.—Native of both Indies. We have not met with it in any garden. The inflorescence, and very small flowers, distinguish this from the foregoing; and the globular capsules, about the size of peas, encompassed with the long linear segments of the calyx, and disposed in spikes, like beads, are peculiar.

M. odorata. Linn. Suppl. 302. Forst. Prod. 47. Cavan. Diff. 320. t. 173. f. 2.—Leaves ovate, somewhat heart-shaped, doubly serrated, naked. Corymbs axillary, many-flowered, downy, on long stalks.—Gathered by Forster in the islands of Tanna and Amsterdam. A very fine species, with broad ovate leaves, three or four inches long, doubly and coarsely serrated, naked but roughish to the touch. The very abundant large and handsome flowers, which we presume are fragrant, grow on long, corymbose, finely downy, axillary stalks. Calyx downy, globose, with long sharp segments. Petals much longer than the calyx, of what colour we know not.

M. lupulina. Swartz. Ind. Occ. v. 2. 1141.—Clusters compound, crowded, axillary, somewhat umbellate, hairy. Leaves ovate or heart-shaped, doubly serrated, soft and hairy beneath.—Native of Jamaica. Communicated to the younger Linnæus by sir Joseph Banks. The shape of the leaves is not unlike the last, but their under side is clothed with minute hairs, very soft to the touch. The permanent scarious calyx has a tawny hue and somewhat of the aspect of hops. Corolla small, white.

M. corchorifolia. Linn. Sp. Pl. 944. Dill. Elth. t. 176. f. 217.—Flowers in axillary sessile hairy heads. Leaves ovate, obscurely lobed, crenate, smooth.—Native of the East Indies. The leaves are about two inches long, very smooth. Flowers small, pale flesh-coloured, in small axillary heads.

MELODIA, Lat. and Ital., *Melodie*, Fr., *μελωδία*, Gr., from *μελος* and *ωδη*, *continuata sonorum connexio*; *Melody*, Eng.

To describe all the rules and prohibitions in framing melodies, would require a code of laws equal to an art of poetry.

Dr. Pepusch (Treatise on Harmony) gives a very short, but intelligible definition of melody; which, he says, "is the progression of sound proceeding from one note to another successively in a single part."

Rousseau is eloquent on the subject. Melody he defines, "the succession of sounds according to the laws of rhythm and modulation, so as to form musical phrases agreeable to the

the ear; vocal melody is called *chant* by the French, instrumental is called *symphonic*."

The Italians called melody *cantilena*; by the English it is termed air, tune, principal or treble part.

A series of sounds only becomes melody by being in some specific time, or measure, that is, by being arranged in regular proportions of time, called *bars*; which, however divided and subdivided into notes of different value, must be performed isochronally, that is, in equal time, and these bars have their laws likewise, and are governed by accents. See ACCENT and BAR.

Though melody is so necessary in the treble part of a composition, it is not necessary in the bass, at least of the same kind. A polyphonic composition is admired by masters when all the parts *sing*, that is, when each part has a series of notes that may be called melody; unless in fugues and imitations, it is not necessary that the inferior part should move in the same kind of notes as the principal. For as only thirds and sixths can move together in a regular ascent or descent in the same kind of notes diatonically, they soon tire, and manifest a want of resources in the composer. And though melody is admired and expected in the several parts, it is best when of a different character from the principal part.

It is in the following periods that the eloquence, feeling, refined taste, and enlarged views of Rousseau appear in this article.

"Melody," he says, "is founded on two different principles: considered in the relations which the sounds of a key bear to each other, it has its principle in harmony, as it is an harmonical analysis, which gives the degrees of the gamut, the chords of the key, and the laws of modulation, the only elements of melody. Upon this principle all the force of melody is confined to the flattering the ear with agreeable sounds, as the eye is flattered by an agreeable change of colours, without their representing by their mixture any particular object or design. But considered as an art of imitation, by which we can awaken different images in the mind, move the heart with different sentiments, excite and calm the passions, operate, in short, moral effects beyond the immediate empire of the senses, we must seek another principle; for no such effects as these can be derived from harmony.

"What then is the second principle? It is in nature as well as the first; but it can only be discovered by more subtle and penetrating observation, to which nature only gives birth, and which cannot be taught. It is instinctive, and often unknown to the possessor. This principle is the same as that which varies the tone of voice in speech, according to what we say, and what we feel in saying it. It is the accent of languages which determines the melody of every country; it is the accent which speaks in singing; and we speak with more or less energy, as the language has more or less accent. The language in which the accent is most marked, produces a melody the most lively and impassioned; and that which has little or no accent, can only suggest a languid and cold melody, without character and without expression. These are the true principles. When we quit them, and speak of the power of music over the human heart, we know not what we talk about. If music only paints by the power of melody, and derives from melody all its force, it follows that all music which does not *sing*, however harmonious it may be, is not an imitative music; for as it can neither move the affections nor paint with its fine chords, it soon tires the ear and leaves the heart cold. It follows, then, that in spite of the multiplicity of parts which harmony can furnish, and which is so often

Vol. XXIII.

abused, as soon as two melodies are heard at once, they mutually enfeeble and efface each other, however excellent they may be in themselves."

This is the language which the Chinese, and every people not accustomed to harmony, talk. See CHINESE Music.

Rousseau is a champion for melody, and M. Laborde for harmony; but we think now, as we did forty years ago, that melody and harmony are as imperfect when separate, as an animal formed by nature with two legs or two arms, is with one. In music, melody and harmony have each distinct and peculiar beauties; but after being heard together, nothing can compensate for their separation. Melody should be polished, and harmony purified; but it was one of the paradoxes of the ingenious Jean-Jacques, in asserting "that harmony was an imperfection, a Gothic and barbarous invention; only wanted by the gross and obtuse organs of northern regions."

Rhythm is as necessary to melody, as that the sounds should follow each other in a manner agreeable to the ear. Sounds of the same length can form no interesting melody; they must be broken into notes of different duration, must be phrased, and have some sense given them, as well as words in literature and grammar.

MELODIEUX, *Fr.* Melodious. This epithet is seldom applied with accuracy. A sweet-toned voice in speech or song may be called *melodious*; but to say that an air or tune, or a piece of music is melodious, is a pleonasm that borders on vulgarity: as these words themselves imply melody; therefore to say that an air or tune is melodious, is saying that melody is melodious.

MELODINUS, in *Botany*, is one of Forster's genera, derived from *μελον*, an *apple*, and *δινω*, to *entwine*, because the plant bears globular fruit resembling apples, and its stem is twisted or scandent.—Forst. Nov. Gen. 19. Linn. Suppl. 23. Schreb. 165. Willd. Sp. Pl. v. 1. 1274. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 74. Juss. 148. Lamarck Illustr. t. 179.—Class and order, *Pentstemonia Digynia*. Nat. Ord. *Contortæ*, Linn. *Spiceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, of one leaf, cloven into five, ovate segments, folding over each other at the margin. *Cor.* of one petal, valver-shaped; tube cylindrical, thrice as long as the calyx; limb flat, cloven into five, sickle-shaped, crenulated segments, twisted to the right, shorter than the tube. Nectary in the mouth of the tube, stellated, composed of five, cloven, lacerated segments. *Stam.* Filaments five, awl-shaped, very short, in the middle of the tube; anthers ovate. *Pist.* Germen superior, globose; style round, the length of the calyx, divisible into two parts; stigma conical, acute. *Peric.* Berry fleshy, globose, with a fleshy partition. *Seeds* numerous, ovate, or roundish, rather compressed, imbedded in pulp.

Ess. Ch. Corolla contorted, its mouth crowned with five cloven jagged valves. Berry globose, of two cells, with many seeds.

1. *M. scandens*. Climbing Melodinus. Linn. Suppl. 167. Forst. Prod. 20.—Gathered in New Caledonia by Forster, who sent it to Kew Garden in 1775. It is kept in the stove, but does not appear to have flowered. The stem is shrubby, climbing, with round, smooth, leafy branches. Leaves opposite, ovate-oblong, with a blunt point, entire, three or four inches long, thick-edged, smooth and shining, with one rib, and numerous, fine, reticulated veins; paler beneath. Footstalks very short and thick. Stipules none. Flowers terminal, numerous, in a dense downy panicle, with opposite stalks, and small, ovate bractæas. The corolla is externally downy, about half an inch long. Fruit

E e

the

the size of a small orange. The habit of this plant, and form of the flowers, are much like *Rauwolfia*, but the numerous seeds afford a sufficient mark of distinction.

MELODORUM, so named by Loureiro, from *mel*, honey, and *odorum*, fragrant, on account of the remarkable sweetness and fragrance of the fruit; as he himself informs us.—Loureir. Cochinch. 351.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Coccoluteae*, Linn. *Anona*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three short, acute, spreading, permanent leaves. *Cor.* Petals six, triangular, nearly equilateral, fleshy, inflexed and closed, in a double row, concealing the organs of impregnation. *Stam.* Filaments none; anthers numerous, oblong, club-shaped, affixed to a slightly convex receptacle. *Pist.* Germens ten, oblong, pressed together by the surrounding anthers; styles none; stigmas forming a circle, very short. *Peric.* Berries ten, ovate-oblong, rather cylindrical, rough, of one cell, with many seeds. *Seeds* compressed, imbedded in pulp.

Eff. Ch. Calyx of three leaves. Petals six, triangular, equilateral, closed. Berries numerous, oblong, many-seeded.

1. *M. fruticosum*. Cây Bô gie of the Cochinchinese.—Leaves lanceolate, smooth. Stem shrubby.—Native of bushy places in Cochinchina. *Stem* four feet high, erect, with spreading branches. *Leaves* alternate, lanceolate, entire, smooth, fragrant. *Flowers* scattered, solitary, yellowish-brown. *Berries* of the same colour, an inch and a half long, with many seeds, and a very small quantity of highly delicious pulp. A decoction of the leaves is used for removing obstructions.

2. *M. arborcum*. Cây Nhaoc of the same people.—Leaves oblong, downy. Stem arboreous.—Native of woods in Cochinchina. A large tree, with ascending branches. *Leaves* alternate, stalked, ovate-oblong, pointed, entire; downy beneath. *Flowers* scattered, solitary, whitish-green, fleshy, downy, on very short stalks. *Berries* numerous from each flower, not eatable. The timber is used for building.

These plants appear, by the above descriptions, to be very nearly allied to the genus *Uvaria*, to which indeed we should, without much hesitation, refer them. Willdenow has omitted them.

MELO-DRAMA, Lat., a drama written for music. In 1772, when a few persons in France began to perceive that it was possible for operas to be set to better music than that of Lulli and Rameau, an anonymous treatise was published at Paris, under the title of "Traité du Melo-drame, ou Reflexion sur la Musique dramatique," 8vo.

In 1765, a small tract was published by the chevalier de Chastellux, "On the Union of Poetry and Music;" and in 1772, the anonymous "Treatise on Musical Drama." The former had a correspondence with Metastasio on the subject of his book. The poet's answers to his letters are preserved in late editions of his works, and translations inserted in the memoirs of his life and writings published in 1796. In the tract of M. de Chastellux, he gives in his parallel between music and poetry, the *pas* to the former. In the treatise on the melo-drama, the preference is decidedly given to poetry; and music degraded into his menial servant, with no better employment than that of rendering the voice of declamation more audible than that of common speech.

These two writers were the precursors of the Gluckists and Piccininists at Paris. And the dispute is reduced to this simple question; Which, in an opera or musical drama, is to be the tyrant, and which the slave? Metastasio long since with reason and good taste determined in his dramas that no tyranny or slavery should subsist; but that the two filters should mutually assist each other. He gave all the business

of the fable to *recitative*, or musical declamation, and the embellishing sentiment to the *airs* in a recapitulation of the dialogue at the end of each scene.

Though the poetry of Metastasio's operas has always been admired as the best, and almost the only poetry truly lyrical in modern languages; yet it must be allowed that beautiful air, impassioned strains, picturesque music, grateful harmony, fine voices highly cultivated, and great vocal talents, have rendered operas more attractive and captivating than the poetry alone, with all its high polish and beautiful sentiments could have done. Metastasio in his latter days joined in the complaints of French reformers of the Italian operas, against fine music and fine singing. No such jealousy appears in his letters to Farinelli, or to any other correspondent, till he had ceased writing, when musical composition and vocal talents were much more admired and applauded than at present.

MELOE, in *Geography*, a small island in the Baltic; 14 miles E.N.E. of cape Lindesnes.

MELOE, the Blossom-cater, in *Natural History*, a genus of insects of the order Coleoptera; of which the character is antennæ moniliform; thorax roundish; head inflexed and gibbous; shells soft and flexile. This genus is separated into two divisions, *viz.* into those that have wings and those that have none, of which the latter is subdivided. There are, in the several divisions or sections, about 36 species: of these only four are common to our own country, the others are distributed over the globe.

Section A. The insects of this division have no wings, and their shells are abbreviated.

Species.

* **PROSCARABÆUS**. This species is entirely of a blue-black, or dark violet colour. It inhabits Europe, and is described and figured in Mr. Donovan's English Insects. Its trivial name is the "oil-beetle;" thorax narrower than the head; shells very short and oval; abdomen long; the female is thrice as large as the male. It is found very frequently in the spring of the year in our own fields and pastures creeping slowly, the body appearing to be so much distended with eggs as to cause the insect to move with great difficulty. When touched it exudes a yellowish moisture like oil from its pores, whence it derives its name, which was formerly celebrated for its supposed efficacy in the rheumatism, applied to the parts in the form of an embrocation. It has been likewise recommended as a remedy in hydrophobia.

* **VARIEGATUS**. This is of a dull green; thorax edged with red; shells punctured; inhabits Europe; the antennæ are purple; head and thorax dull green, edged with purplish red; the shells are short, very minutely punctured; body large, above variegated with red, green, and copper, beneath and legs purple.

MAJALIS. Dorsal segments of the abdomen red. It inhabits divers parts of Europe, and very much resembles the proscarabæus, and has been thought to be only a variety of it.

MARGINATA. Black; thorax and shells edged with ferruginous; it inhabits Italy; the shells are short, smooth, coriaceous; the abdomen and legs are black.

* **PUNCTATA**. Black; thorax and shells with minute punctures: inhabits England.

* **TECTA**. Blue-black; shells nearly as long as the abdomen; antennæ thicker in the middle: it inhabits Europe, is smaller than the proscarabæus, and differs in the structure of the antennæ, having the shells nearly as long as the abdomen.

Section B. Winged; shells as long as the abdomen; divided into

α. Jaw horny, bifid, containing 26 species, and constituting the tribe *Mylabris* of Fabricius; and

β. Jaw linear, entire; containing four species, which are comprized in the *Georoma* of Fabricius.

Species in subdivision α, Jaw horny, bifid.

FASCIATA. Black; shells with a yellow band in the middle. Is found in India; head black; eyes testaceous; thorax black, with a ferruginous spot on each side; wings hyaline, with ferruginous ribs and veins.

CINOREI. Black; the elytra yellow, marked with three black bands. It is a native of Asia and the eastern parts of Europe. It is used in medicine among the Chinese. The antennæ are sometimes yellow at the tips. Found on the cichorium or fucory, and varies much in the colour of the shells and disposition of the bands.

PURPURA. Black; tip of the shells testaceous, with a black spot; inhabits Barbary and is found among corn.

MARGINALIS. Black; shells with a ferruginous margin; inhabits Barbary, and, like the other, is found among the corn.

ALGERICA. This also is black; shells testaceous, immaculate: it is found in various parts of India.

CAPENSIS. Black; shells with six yellow spots, the first is curved: it inhabits the Cape of Good Hope.

HERMANNIÆ. Villous, black; shells with a yellow spot at the base and two indented yellow bands. It inhabits Guinea; resembles the cichorei, but is not half so large. The antennæ are black, ferruginous at the tip; head and thorax black with a few cinereous hairs.

PUNCTUM. Villous, black; shells with two bands, the first yellow with a black dot, the hinder one reddish. It inhabits Tranquebar.

DECEM-PUNCTATA. Black; shells testaceous, with five black dots: it is found in Italy.

QUADRI-PUNCTATA. Black; shells testaceous, with two black dots: inhabits Russia and resembles the last.

TRI-MACULATA. Black; shells yellow, with a brown band and common dot. It inhabits the East. The shells have a common brown spot in the middle, and a brown band behind which hardly reaches the outer margin.

ARGENTATA. Covered with silvery down; the shells have yellowish spots, most of them connected at the margin. It inhabits Senegal; the antennæ are ferruginous; the shells have a small yellowish spot at the base; three marginal ones and one near the tip all surrounded with a black ring; the tip is yellowish, having a small black dot in the middle; the legs are ferruginous.

AMERICANA. Black; thorax semi-circular; the shells have three yellow bands. It inhabits America. The tip of the antennæ is clavate.

INDICA. This species is black; the shells are yellowish, fulvous behind, with a black dot and three-lobed spot at the base, indented band in the middle and semi-lunar margin at the tip. It is found in India.

ELONGATA. Glossy-black; shells yellow varied with blue.

AUREA. Green-gold; shells fulvous.

ARCUATA. Black, hairy; shells with a curved yellow spot on the fore-part, and two waved yellow bands. Antennæ black, clavate at the tip.

BI-FASCIATA. Black, hairy; shells with a yellow round spot on the fore part and at the outer angle, and two yellow bands. It is found in India. Antennæ yellow; base of the shells piceous. The yellow spot at the angle of the shells is sometimes wanting.

TRIFASCIATA. Steel-blue, with a greenish silky gloss; shells grey, with two greenish-black bands, one of them common. It inhabits near the Caspian sea.

ARATA. Deep glossy black; shells with a yellow waved band towards the tip. It inhabits near the Caspian sea; the antennæ are clavate at the end; the legs secrete a kind of oil.

NYCDALEA. Black; shells red, a little shorter than the abdomen, distinct at the tip. It is found in Russia.

PENNSYLVANICA. This species is entirely black and opaque: it inhabits Pennsylvania in America.

CHIROPTERA. Black, subvillous; shells yellow: it inhabits France. The first joint of the antennæ is three times as large as the rest.

MELANURA. Shells yellow, with four black spots, the tip black; antennæ clavate: it inhabits Calabria.

OCHROPTERA. Black; shells saffron, black at the base, on each side before and behind the middle is a saffron dot, with a black interrupted band and tip.

BICOLOR. Black; shells yellow, with a black dot on each side at the base; the tip and band in the middle, which is broader at the edges, are black.

Species, in subdivision β, Jaw linear and entire.

SCHAEFFERI. Green; antennæ and legs entire. Inhabits Europe. Shanks and tarsi of the male dilated, appendaged.

VAILLI. Green; antennæ and legs black: an inhabitant of Barbary. Abdomen reddish at the base.

SCHREBERI. Green; antennæ, legs, and three segments of the abdomen, yellow.

GOVANI. Black; shells with a sanguineous band and tip.

The larvæ as well as the perfect insects of this genus feed on leaves.

The officinalis cantharis, or Spanish-fly, was till very lately supposed to be a meloe, and indeed is generally so arranged in our pharmacopeias; but more minute and accurate observations have shewn that it is a species of the *LYTTA* genus; which see.

MELOLONTHA, the name of a very peculiar sort of beetle, which is found in all parts of England, and in many other countries among trees and hedges. The French call them *banneton*, and we *cock-chafers*, *dorrs*, and by many other names. The name melolontha is as old as Aristotle, and is given this creature from its feeding on the blossoms of the crab or wild apple. We have, of late years, had great damages done by the grubs of these beetles working under ground; but in Ireland they have been used to come in swarms, in certain years, in the beetle state, and have been so terrible to that country, that the people have called them locusts.

The first time they are remembered by authors to have appeared in this vast abundance, in that country, was in the year 1688. They then appeared in the south-west part of the county of Galway; they appeared first upon the coast, and were brought by a south-west wind, a wind so common there, that it may almost be called the trade wind of Ireland; from the coast they soon spread over the inland parts of the country, and were seen every where in such numbers, as were scarcely to be conceived. They never stirred in the day time, but were seen covering the leaves and branches of trees and hedges, and in many places hanging down in prodigious clusters on one another's backs, in the manner of bees when they swarm. As soon as the sun set, they used to leave the hedges, &c. and take wing, gathering in bodies, and making a humming confused noise like that of drums at a distance. They sometimes formed bodies together, that

darkened the air for three or four miles square. They flew so low sometimes, that it was scarcely possible for a person going along to make his way through them; and by striking against the faces and necks of women and children, they did much mischief, every one leaving a mark behind it; and those of this sex or age, who had been among them, came home all over bruises.

This, however, was little to the mischief they did the fields; for though the middle of the summer was the season in which they came, they had in a few days eaten up all the leaves of the trees so completely, that they all looked as bare as in the depth of winter. The noise they made, while eating in vast numbers together, was like that of sawing timber. The gardens fared no better than the hedges, for they eat up leaves, young stalks, and fruit, and every thing that was green and soft there, and left only a parcel of naked sticks behind them. Many of the trees, thus stripped, wholly perished. Phil. Trans. N^o 234. See SCARABÆUS *Melolontha*.

MELOMELL, a word used by the ancients to express honey impregnated with quinces.

MELON, in *Gardening*, the common name of a well known plant, which is much employed in forcing-frames, &c. See CUCUMIS, and FORCING.

MELON-ground, the space or portion of ground in the kitchen-garden, or other place, which is appropriated to the culture of melons and other vegetables that require artificial heat. See GARDEN, and MELONARY.

MELON-thistle, the common name of a plant of the thistle kind. See CACTUS.

MELON, *Water*, or *Citrus*. See CUCURBITA.

MELONS, *Petrified*, a name given by the people who have written books of travels, &c. to certain stones found on mount Carmel. The monks who inhabit that mountain at this time, and who pretend to be the followers of Elias the prophet, tell a legendary story about these stones, which has given occasion to the name. They say that when Elias lived on that mount, a certain gardener passing by his cave with melons, the prophet asked one of them; but the fellow replying, that they were not melons, but stones that he carried, the prophet miraculously fulfilled the saying, and converted them into stones. Travellers who are fond of these stories were usually glad to pick up one of these sacred stones as they went on; and the monks have been careful enough to gather all they could find for the better opportunity of obliging their visitors; so that though they were once very common, they are now only to be had by the favour of these people.

Breynius is the only author who has given a good account of them; he says, that they are spheric or spheroidal stones, of various sizes, from that of a hen's egg to that of the largest melon, or even more than that. They are generally found bedded in a very hard sand-stone, of a greyish or ash-colour; but they come out whole on breaking the stone, and are of a smooth surface; a greyish colour, or sometimes a brownish ferruginous hue. When they are broken, there is always a cavity found in them, sometimes regular and even, sometimes very irregular, and generally proportioned to the bigness of the stone. This cavity is lined on both sides with minute crystals, which are very bright and pellucid, and have their points standing toward the centre of the cavity. This substance of the stone itself approaches to the nature of marble, of a yellowish colour, and capable of a good polish; when wrought looking very like the Florentine marble. This is a crust of about half an inch or an inch in thickness, according to the bigness of the stone, and sometimes this is covered with a paler-coloured crust, of the thickness of a

straw, which in some degree resembles the bark or rind of the fruit. These stones are truly a sort of concave natural nodules, of the nature of our hollow flints. They have had no fruit for their matrix, nor have ever had any of the ribs and furrows which the melon has, nor any mark of the stalk; and within they have neither the natural divisions of the melon, nor any thing resembling the seeds. It is not only the want of many parts absolutely essential to the fruit supposed to be petrified, which shews that opinion to be erroneous; but the course of nature, in petrifications in general, argues also greatly against it.

The things we meet with, in this state, are all of them such as are naturally hard, dry, and permanent, and none of the tender and succulent bodies, such as the melon, and the like fleshy fruits, which must necessarily rot in the water that conveys the stony matter, before it could at all enter their pores. And the stones are certainly analogous to those concave nodules of a ferruginous colour, in the cavities of which amethysts are produced; and to that genus of stones which Woodward calls concave crystalline balls, common in many parts of the world.

The fallacy of an extravagant opinion in regard to fossils of any particular form, is not peculiar to these stones, as witness the small shells petrified and found in Egypt, which from their flat and roundish shape, are said to be the lentiles, which the children of Israel eat when making the pyramids: the *cornua Ammonis*, which is the remains of a sea-shell, and yet is supposed to be a petrified serpent; the *nummi minerales*, which are the operculums of shell-fish, but are generally supposed by the vulgar, about the places where they are found, to be medals and coins petrified with lying in the earth, and many the like follies. Breyn. de Melon. Petr. Mont. Carm.

MELONARY, in *Gardening*, the portion of ground in the kitchen-garden principally allotted for the business of early and general hot-bed work, in the culture of melons and cucumbers as well as occasionally in other framing culture.

These compartments are mostly inclosed by some sort of fence, and are particularly convenient and useful, as in the practice of hot-bed culture there is unavoidably a considerable littering occasioned at times, by means of the necessary supplies of hot-dung, straw, litter, and other materials, both in the making of the beds and after-culture; which by this means being confined to a particular part, the whole is performed more conveniently, and without incommoding the economy of the other parts of the garden.

They are also very useful when properly chosen in the driest and warmest situations, in the advantage of having the hot-beds on dry ground, and sheltered from cutting winds, with the full benefit of the whole day's sun, as well as in being more secure. In considerable gardens, the places allotted for this use are sometimes of such extent, as to have the hot-houses, or forcing houses, and other appurtenances of that kind, where culture by artificial heat is required, near together, by which time and trouble is saved, and great advantage in other respects gained.

In the choice of a place for this purpose, some part of the warmest, best-sheltered, dry quarter of the garden, which is well defended from the northerly and north-easterly winds, not liable to inundation or the stagnation of water, and conveniently situated for bringing in dung, tan, earth, &c. should be fixed upon. And if, with these advantages, it lies rather a little higher or very gently sloping towards some lower part, it will be more proper, especially when towards the full sun from rising to setting, so as to admit of ranging the

the hot-beds longitudinally east and west, or as nearly in that direction as possible. See GARDEN.

With respect to the extent or dimensions, they must be according to the quantity of hot-bed framing required, as from two or three, to ten, twenty, or thirty frames, or more; and sometimes also for hot-bed ridges for hand-glasses in the same proportions. They may of course be from two or three to five or ten rods square, or to that of a quarter, or half an acre, or more; in which, besides the part immediately allotted for the hot-beds, it is convenient to have room for the previous preparation of the dung, &c. for earthing the hot-beds. And in respect to form the most eligible shape is that of a square, either an equal or an oblong square.

When enclosed, the fences may be six, seven, or eight feet high in the northerly or back part and five or six in front, the sides corresponding, though when extensive they may be nearly of equal height all around. And the internal part, or immediate place for the hot-beds, even when dry, should be a little elevated to throw off the falling wet of heavy rain, &c. and when unavoidably low, or liable to be wet in winter or spring, be raised, with some dry materials, considerably above the general level, that the hot-beds may stand dry, as well as to afford advantage in performing the business of cultivation.

The ground for the immediate place of the hot-beds may generally remain even or level; some, however, form shallow trenches the width and length of the intended hot-beds, as from six to twelve inches deep, and make the lower part of the bed in the trench; which, however, is more proper in a dry or somewhat elevated situation than in low or wet ground, as water is apt to settle in the bottom, and chill the beds, occasioning the heat to decline suddenly.

Besides, by having the hot-beds wholly above ground, there is a better opportunity of applying the occasional linings quite from the bottom upwards. By proper attention in the construction of the different parts of these grounds and in the building of the fences, they may also be rendered highly useful in raising various kinds of fruit, which could not otherwise be the case.

MELONGENA, in *Botany*, a word of Arabian origin, according to Ambrosinus, from whence the Italian *Melanzana* seems to have come, rather than from *Mala insana*, as is commonly supposed; the Egg Plant. This fruit is said to be much used for food among the Arabs. It is also, according to Matthioli, commonly eaten in Italy, being dressed in the form of fritters, with flour and oil, or butter, and seasoned with pepper and salt. That author gives *Melongenæ* as the vulgar Lombard name of the fruit, which he says is called by the Tuscans *Petranciani*. We cannot but suspect the Latin name *Mala insana*, Mad Apples, which this fruit does not appear in any manner to deserve, to have been a corruption of the Arabic or Italian appellation, rather than the reverse. See SOLANUM.

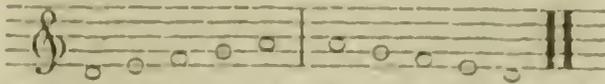

MELOPEPO, from *Melo*, a Melon, and *Pepo*, a Pompon, the name of various round kinds of Gourd. See CUCUMIS.

MELOPŒIA, Gr., *Melopœia*, Fr., a term in the music of the ancients, which implied the selection and arrangement of such sounds as were fit for song. The word is derived from *μελος*, *cantus*, *οικω*, *facio*, *tingo*, *fabrico*, *compono*, "to build the lofty rhyme."

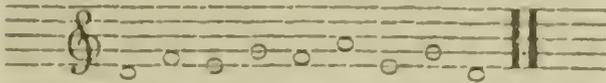

Melopœia had its particular rules, several of which are come down to us, and are still clear and intelligible: such as that an air, or piece of melody, should be composed in some particular genus, and be chiefly confined to the sounds of some certain mode. As to the succession, or order of

these sounds in the course of the air, that was in general confined to four kinds, which Euclid specifies in his Harmonic Introduction. These we shall endeavour to describe with exactness, as they may throw some light upon ancient melody.

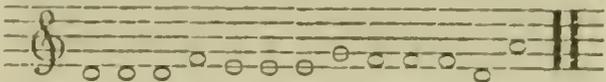

Euclid tells us, first, that sounds may move either ascending or descending regularly; as thus:

which was called *μεγαν*: secondly, by leaps of greater intervals than a second; thus,

which was called *πλοκε*, *interwoven*: thirdly, by repeating the same sound several times, which was called *πρισις*, *iteration*; as in singing these notes,

and fourthly, that sounds may be sustained in the same tone, which we call a *holding note*, and which the Greeks expressed by the word *τοση*.

There were many rules to be observed in moving by leaps, or disjunct degrees, the principal of which was to prefer, in general, consonant to dissonant intervals. It was likewise enjoined not to divide any two semitones into quarter tones, together, or two successive tones into semitones, nor were two major thirds to follow each other.

But these, and a great number of other rules laid down by Aristoxenus, with respect to the succession of intervals, were all derived from the genera, the rules for which were rules for melody. The diatonic genus of the ancients resembled our natural scale in every particular; and it is allowed by Aristoxenus even that three tones may succeed each other, ascending or descending, which is all that is allowed in our diatonic, except in minor keys, where we ascend to the octave of the key note by a sharp seventh, which the ancients seem never to have admitted.

A further detail or explanation of these rules would not make the matter much clearer; however, there are some particulars collected together in the first book of Aristides Quintilianus, that seem to merit attention.

He sets off by dividing Melopœia into three species, taken from the great and general system, which he names after the sounds called *hypate*, *mesè*, and *nete*; that is, lowest, middle, and highest; and these denominations resembled, with respect to melody, our distinctions of base, tenor, and treble.

With regard to modulation in melody, he has the same distinctions as Euclid for the several species, though he differs a little from him in his manner of defining them: but these differences are of small importance to us now; and indeed the authority of Euclid is so superior to that of Aristides Quintilianus, that nothing which can be cited from him would have weight sufficient to invalidate the testimony of so exact and respectable a writer.

However, the moral distinctions of Melopœia to be found in Aristides Quintilianus are so curious and fanciful, that we shall insert a few of them here.

He allows of three modes (*τροποι*) or styles of Melopœia: the *dithyrambic*, or bacchanal; the *nemic*, consecrated to Apollo;

Apollo; and the *tragic*; and acquaints us that the first of these modes employed the strings, or sounds, in the middle of the great system; the second, those at top; and the third, those at the bottom.

These modes had other subaltern modes that were dependent on them; such as the *erotic*, or amorous; the *comic*; and the *encomiastic*, used in panegyrics. All these being thought proper to excite or to calm certain passions, were, by our author, imagined to have had great influence upon the manners (*ἦθη*); and, with respect to this influence, Melopœia was divided into three kinds: first, the *syllabic*, or that which inspired the soft and tender passions, as well as the plaintive, or, as the term implies, such as affect and penetrate the heart; secondly, the *diastatic*, or that which was capable of exhilarating, by kindling joy, or inspiring courage, magnanimity, and sublime sentiments; thirdly, the *hesychastic*, which held the mean between the other two, that is, which could restore the mind to a state of tranquillity and moderation.

The first kind of Melopœia suited poetical subjects of love and gallantry, of complaint and lamentation; the second was reserved for tragic and heroic subjects; the third for hymns, panegyrics, and as a vehicle of exhortation and precept.

All these rules concerning the ancient Melopœia afford only general notions, which, to be rendered clear and intelligible, would require particular discussions, as well as illustrations by example; but the Greek writers on music have absolutely denied us that satisfaction, reserving, perhaps, when they published their works, all such minutiae for the lessons which they gave their scholars in private; for in no one of the seven treatises upon ancient music, collected and published by Meibomius, is a single air or passage of Greek melody come down to us; which is the more extraordinary, as there are few treatises upon modern music, without innumerable examples in notes, to illustrate the precepts they contain.

But whatever were the rules for arranging different sounds in such order as would flatter the ear in the most agreeable manner, it is easy to imagine that this regular disposition, and beautiful order of sounds, constituted nothing more than the mere body of melody, which could only be animated and vivified by the assistance of rhythm or measure. See *Music of the Greeks*.

MELORA, in *Geography*, a small island in the Mediterranean, near the coast of Etruria; 4 miles W. of Leghorn.

MELOS, in *Ancient Geography*, one of the Grecian islands, situated about 24 miles from cape Scyllæum, in the Peloponnesus, south-west of the isle of Siphnos, west of that of Sicinos, and east of the promontory of Malea, in Laconia. It was estimated at about 60 miles in compass, and, according to Pliny, it was almost round. This island, though small, made a very considerable figure in the flourishing ages of Greece. It enjoyed its liberty, says Thucydides, 700 years before the Peloponnesian war. The inhabitants were originally Lacedæmonians, and therefore, in the time of the war just mentioned, refused to join the Athenians, declaring that they would maintain a strict neutrality. They suffered severely for their attachment to Lacedæmon. All who were able to bear arms were put to the sword; the women and children were carried into Attica, and sold for slaves. The island being thus desolated, a new colony was sent thither from Athens. But not long after, Lyfander, the Lacedæmonian general, having obliged the Athenians, in their turn, to surrender at discretion, released the captive Melians, and restored them to their native coun-

try, after having expelled the Athenian colony. Melos afterwards experienced the common fate of the other islands of the Ægean sea, being reduced, with them, to a Roman province. This island abounded with iron mines, and was formerly famous for its wine and honey. The pastures and mineral waters of this island were also commended; and the alum of Melos was in great repute among the Romans, and preferred by them to that of any other country, except the Egyptian. See *MIL*.

MELOS and *Melodias*, which Meibomius has rendered by the Latin words, *modulatio* and *cantilena*, had no other signification than the change of sounds in singing, or, as we should call it, melody; and this is clear from a passage in Bacchius senior, where, in his Introduction to the Art of Music, by question and answer, it is asked, How many kinds of modulation there are? He answers, four; and these, he says, are *rising*, *falling*, *repeating* the same sound to different words, and *remaining upon*, or *holding out*, a musical tone. See *MELOPŒIA*.

MELOSIS, from *μολο*, a probe, in *Surgery*, the examination of a diseased part with a probe.

MELOT, JOHN BAPTIST, in *Biography*, a learned Frenchman, was born at Dijon in 1697, and died at Paris in 1760. He was librarian to the king, and wrote some papers in the "Memoirs of the Academy of Inscriptions," of which he was a member. He was also editor of *Jourville's Life of St. Louis*, with a glossary.

MELOTHRIA, in *Botany*, a name borrowed by Linnæus, in his *Hortus Cliffortianus*, from the *μυλωθρον* of Dioscorides, one of the synonyms of his *αμυλωθρον*, or White Vine, which is supposed to be the *Bryonia*, a plant of the same habit and natural order as the present. Linn. Gen. 24. Schreb. 32. Willd. Sp. Pl. v. 1. 189. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 78. Juss. 395. Lamarck Illustr. t. 28.—Class and order, *Triandria Monogynia*. Nat. Ord. *Cucurbitacea*, Linn. Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, bell-shaped, swelling, five-toothed, deciduous. Cor. of one petal, wheel-shaped; tube the length of the calyx, to which it is on every side united; limb flat, in five deep very blunt segments, dilated outwards. Stam. Filaments three, conical, inserted into the tube of the corolla, and equal to it in length; anthers of two roundish lobes, compressed. Pist. Germen almost entirely inferior, ovate-oblong, pointed; style cylindrical, the length of the stamens; stigmas three, thickish, oblong. Peric. Berry ovate-oblong, internally divided into three parts, without partitions. Seeds several, oblong, compressed.

Obf. Linnæus remarks that he once saw two flowers with stamens only.

Ess. Ch. Calyx bell-shaped, five-cleft. Corolla wheel-shaped, of one petal. Berry of three cells, with many seeds.

1. *M. pendula*. Pendulous Melothria, or American Bryonia. Linn. Sp. Pl. 49. (*Bryonia olivæ fructu rubro*, minor; Plum. Ic. 55. t. 66. f. 2. *Cucumis parva repens virginiana*, fructu minimo; Pink. Phyt. t. 85. f. 5.)—Native of North America and the West Indies. Root annual. Stem slender, branched, climbing by means of simple tendrils. Leaves heart-shaped, five-lobed, obscurely toothed, rough, on thick twisted stalks. Flower-stalks axillary, solitary, simple, capillary, about an inch long. Flowers small, yellow. Fruit red, the size and shape of a small olive. Jussieu says two of the filaments bear each two anthers, which is the case in *Bryonia*, to which genus this plant is certainly very nearly akin. Vahl having omitted the genus in its proper place, had perhaps a design of uniting it to *Bryonia*.

MELOTIS,

MELOTIS, a word used by the surgical writers to express a small probe, properly one intended to be used only to the ear.

MELOZZO, FRANCESCO, in *Biography*, an historical painter, who flourished about 1471. He is celebrated as being one of the first who introduced the fore-shortening of figures upon ceilings, so as to make them appear ascending or descending; and a picture of his, over the great altar in the church of the Apollon at Rome, which represents the ascension of our Saviour, is celebrated with the warmest praises. Vafari says, that the figure of Christ seems to pierce the roof. This work was painted for cardinal Riario, nephew of Nicholas V. about 1472; and when that chapel was repaired, it was cut out and placed in the Quirinal palace, where it is still seen with this epigraphic: "Opus Melotii Forotivensis, qui summo fornices pingendi artem vel prius invenit vel illustravit." Some heads of the apollons were likewise preserved in the Vatican: they are well turned, almost always fore-shortened, and wrought with great finish, diligence, and grace. It is to be lamented that so uncommon a genius has not met with an exact historian, who would have informed us of his preparatory studies. He is best known by the name of Melozzo da Forli.

MELPIGNANO, in *Geography*, a town of Naples, in Otranto; 9 miles W.N.W. of Otranto.

MELPILLY, a town of Hindoollan, in the Carnatic; 25 miles N. of Nellore.

MELPOMENE, the name of one of the nine Muses; who is represented with a mask, to denote her presiding over the stage; and distinguished from Thalia, the comic Muse, by greater dignity in her look, stature, and dress. Melpomene was supposed to preside over all melancholy subjects, as well as tragedy. See Horace, lib. i. od. 24. v. 4. lib. iii. od. 30. v. ult.

MELRICKSTADT, in *Geography*, a town of the duchy of Wurzburg, on the Streys; 19 miles N. of Schweinfurt. N. lat. 50° 27'. E. long. 10° 27'.

MELROSE, a considerable town, and a free borough of barony, situated on the banks of the river Tweed, in the shire of Roxburgh, Scotland. The river divides the town, which extends about a mile in length, into two parts. It is governed by a magistracy, elected annually by the burghesses; and, considering its inland position, may be regarded as a flourishing place. The whole parish, according to the parliamentary returns of 1801, contains 1355 houses, occupied by a population of 6947 inhabitants, viz. 3300 males and 3647 females. Of this number, 668 were reported as being employed in different branches of trade, but principally in the manufacture of linen and coarse woollens.

The parish of Melrose and its immediate neighbourhood are distinguished by numerous and splendid remains of antiquity. The abbey of Melrose is one of the most remarkable monastic structures in Scotland. Its original foundation probably took place towards the close of the sixth century. In the works of the venerable Bede, we have an account of the situation of the more ancient edifice, on the bank of the Tweed, as likewise of its abbots. This place was a celebrated school for learned and religious men, and seems to have continued to flourish till the reign of king David, by whom the new abbey was founded, in the year 1136. The former establishment was at Old Melrose, the name of which still serves to remind the inhabitants that they tread on ground rendered sacred by the piety of their ancestors. The foundation of the wall, which inclosed the ancient monastery and its precincts, can still be discovered, stretching

across a sort of promontory, formed by a curvature of the Tweed; but all vestiges of the buildings are entirely lost. It seems probable, therefore, that they were of little comparative magnitude, and might perhaps have been constructed only of wood, or other portable materials, as most of the churches of that age undoubtedly were. Of a similar description was the edifice erected by king David, which was rebuilt first in the thirteenth century, and again after the accession of Robert Bruce, who granted a revenue for its restoration. This last appears, from its ruins, to have been a truly magnificent and spacious structure. Indeed the size and workmanship of its columns, its symmetrical proportions, and the quality of the stone of which it is constructed, entitle it to rank among the most superb edifices which devotion or superstition has reared in Great Britain. From the charters granted to this monastery by different Scottish monarchs, its inmates appear to have been monks of the Cistercian order, and to have enjoyed a pre-eminence or species of jurisdiction over all their brethren in Scotland. Among the more distinguished of these monks was the celebrated St. Cuthbert, who entered as a monk under Boissil, about the year 601, and had the honour of founding the bishopric of Durham.

The church belonging to this abbey constitutes the most entire part of its ruins. It was built in the form of St. John's cross, and is dedicated to the Virgin Mary. The present extent of this building is 258 feet in length, and 137½ in breadth; its circumference measuring 943. That these are not the original dimensions, however, are evident from the state of the western division, the greater part of which has been destroyed, and that so completely, that it is impossible to determine to what distance it reached. Both the exterior and the interior of this edifice were formerly adorned with a variety of sculptured figures of men and animals. Many of the former, in particular, were destroyed in the reigns of Henry VIII., Edward VI., and Elizabeth, whose statesmen and warriors were no less egregious fanatics than the infuriated Scotch reformer John Knox, in whose time, likewise, this building sustained much additional injury. The niches in which they stood display much curious and beautiful workmanship. The tower, which rose from the middle of the cross or transept, was a noble piece of architecture. Part of it still remains, but the spire is entirely gone. The east window is most magnificent, and consists of four mullions with tracery, variously ornamented. On each side appear several elegant niches, and on the top is the figure of an old man, with a globe in his left hand, resting on his knee; and another of a young man on his right; both in sitting postures, with an open crown over their heads. Underneath this window, in the inside, stood the altar-piece. A great number of piscinas, niches, &c. excellently sculptured, are dispersed throughout the church. Many of the pillars are perfect and beautiful, and the embellishments upon them still seem as if newly executed; a decisive evidence of the excellence both of the stone and of the workmanship. Part of this church continues to be used for divine service.

The ruins yet standing, besides the church, consist chiefly of a part of the walls of the cloisters; the other buildings, of which there were many, being almost entirely levelled with the ground. All of these, together with the gardens, and other conveniences, were enclosed within a lofty wall, which extended about a mile in circuit. A large and elegant chapel formerly occupied the site of the present manse; and to the north of this house there has been lately discovered the foundation of a curious oratory, or private chapel, from
which

which was dug up a large cistern, formed from one stone, having a leaden pipe appended to it, for the conveyance of water.

At some distance to the south of this town are the three Eldon-hills, on the northernmost of which is a large Roman encampment, and below it are the remains of an extensive British fortress. Around this were several smaller forts, also of British origin, some of which the Romans appear to have converted into more defensible posts. Three entrenchments on these hills were connected by a very singular kind of military road, described by Mr. Kinghorn, who surveyed it in 1803, as being in general about 40 feet broad, but in some places 50, where the unevenness of the ground required such a breadth. On each side of this road is a ditch, from 12 to 28 feet wide, whence the earth is thrown up so as to form a mound on the exterior side. As this remains differs materially from all other Roman roads in this country, it seems probable that it has been the work of the Romanized Britons, during their contests with the Picts and Scots, after the departure of their enlightened conquerors, whose modes of warfare they would naturally endeavour to imitate. From the British fort on Eldon-hills to the fortrefs on Caldfheds-hill there likewise runs a fosse and rampart, which seems to have been carried through the distance between these fortresses as a defensible boundary. The great Roman road crosses the Tweed at the village of Galtonside, a little above Melrose. On the declivity of the hill, on which this village stands, are the remains of a spacious encampment. The stone wall around it is still tolerably entire. Half a mile to the east is another entrenchment, called Cheller-Knows, which was probably the most considerable station they possessed in this part of the country, being nearly three-quarters of a mile in circumference. Chalmer's Caledonia, vol. ii. 40. 1810. Beauties of Scotland. vol. ii. Sinclair's Statistical Account of Scotland.

MELSACK, a town of Prussia, in the province of Ermeland; 36 miles S.W. of Königsberg. N. lat. 54° 12'. E. long. 20 7'.

MELSO, a town of Italy, in Friuli; 9 miles N.W. of Udina.

MELT. See **MILT**.

MELTING-CONE, in *Affaying*, is a small vessel made of copper or brass, of a conic figure, and of a nicely polished surface within. Its use is to receive melted metals, and serve for their precipitation, which is effected, when two bodies melted together, and yet not mixing perfectly with one another in the fusion, separate in the cooling into two strata, on account of their different specific gravity. This precipitation might be made in the same vessel in which the fusion is performed; but then the melting-pot or crucible must be broken every time to get it out, whereas the conic shape, and polished surface of this vessel, makes it easily got out without violence. The shape of this vessel is also of another use in the operation; for by means of it, the heavy matter subsiding to a point, is formed into a perfect and separate regulus, even where the whole quantity, as is very frequently the case, has been but very small.

When the quantity of the melted matter is great, it is common to use, instead of this cone, a large brass or iron mortar, or any other conveniently shaped brass or iron vessel. It is necessary, when the cone is of brass, to be cautious that it be not made too hot; for the brittleness of that metal, when hot, makes it easily break, on the striking with any force on that occasion, to make the melted mass fall out.

These, and all other moulds for the receiving melted

metals, must always be well heated before the mass is poured into them, lest they should have contracted a moisture from the air, or have been wetted by accident; in which case the melted metal will be thrown out of them with great violence and danger. They ought also to be smeared over with tallow on their inside, that the regulus may be the more easily taken out of them, and the surface of the mould not corroded by the melted mass poured in.

If a very large quantity of a metal is, however, to be received into them, and especially if any thing sulphureous have place among it, this caution of tallowing the moulds does not prove sufficient; for the large quantity of the mass makes it continue hot so long, that this becomes but a slight defence to the surface of the mould. In this case the assayer has recourse to a lute, reduced to a thin pap with water, which being applied in form of a very thin crust, all over the inside of the cone, or mould, soon dries up, indeed, but always preserves the sides of the vessel from the corrosion of the mass. And this caution is found necessary, even when pure copper is melted alone, without any mixture of sulphur.

MELTING FIRE. See **FIRE**.

MELTING, *Surveyor of*. See **SURVEYOR**.

MELTON-MOWBRAY, in *Geography*, in ancient writings called Medeltune and Meltone, a small market-town, in the hundred of Framland, and county of Leicester, England, is situated in a vale on the banks of the river Eye, 15 miles from Leicester, and 104 from London. Connected with this town are three bridges over the rivers Eye and Seaford. These are repaired, and the streets preserved in good condition, with lamps, &c. from the rents arising out of the town estates. The church, which Leland calls "a faire paroche church, sumtime an hospital and cell to Lewis in Suffex," is a spacious structure, consisting of a nave, aisles, transepts, and chancel, with a tower in the centre, and a porch at the west end. The latter is a peculiar feature to the building, and has an elegant door-way, with an ogee arch. Above this porch is the large western window, comprising five lights, with four lofty mullions. The whole church is crowned with an embattled parapet, and at each angle is a crocketed pinnacle. The tower consists of two well-proportioned stories above the church. The poor of this town derive assistance from several charitable benefactions; among which are some public schools. So early as the reign of Henry III. we find these taken under the immediate patronage of that monarch. A free school for girls was established here in 1795. In the population report of the year 1801, Melton-Mowbray was stated to contain 348 houses and 1766 inhabitants. The market-day is Tuesday; and at every alternate market is generally a large show of cattle. Here are also three annual fairs, and a statute for hiring servants.

Among the more eminent natives of Melton were John de Kirkby, who was appointed keeper of the great seal in 1272, lord high treasurer in 1283, and bishop of Ely in 1286; William de Melton, successively lord high treasurer, lord chancellor, and archbishop of York, in the reigns of Edward II. and III.; John Henley, better known by the popular appellation of Orator Henley, who distinguished himself, about the middle of the last century, by his eccentric lectures. See **HENLEY**.

At Burton-Lazars, a hamlet to Melton, about two miles from the town, an hospital, for leprous brethren of the order of St. Augustine, was founded in the reign of king Stephen, by a general collection throughout England, but chiefly by the assistance of Roger de Mowbray. In adopt-
ing

ing this situation, the founders were probably influenced by a bath or spring, the waters of which were formerly in high estimation for the disorder called Leprosy, and are still said to afford considerable benefit to persons in heretofore complaints. A bathing room and drinking room were built here about the year 1765, for the accommodation of the athleted visitors. Nichols' History of Leicestershire, vol. 1. Beauties of England and Wales, vol. ix., by J. Britton.

MELTZ, a town of Bavaria; 10 miles N. of Bamberg.

MELVILLE, Sir JAMES, in *Biography*, a statesman and historian, was born at Hall-hill, in Fife-shire, in 1531. At the age of fourteen he entered the service of the queen-regent, and was appointed page to her daughter Mary, then wife to the dauphin of France. After passing some time in her service, she permitted him to enter into that of the comtable Montmorency, who sent him over to Scotland in 1559, in order that he might obtain a faithful account of the state of parties in that kingdom. Having remained several years in the employ of that nobleman, he visited the court of the elector palatine, who detained him three years in various negotiations with the German princes. He then passed through Italy and Switzerland, and returned to the elector's court, where he found a summons from Mary, who had now returned to take possession of the crown of her native country. He followed her to Scotland, in 1561, in the character of gentleman of the bed-chamber, and was employed by her confidentially in various important affairs till her imprisonment in Lochleven castle. He had been appointed one of her privy-counsellors, and was sent more than once to the court of Elizabeth. He maintained a correspondence in England in favour of Mary's succession to the crown of that kingdom, but upon the manifestation of her unhappy partiality for Bothwell, after her husband's murder, he ventured upon the strongest remonstrances with her. She not only disregarded these admonitions, but communicated them to Bothwell, in consequence of which the faithful Melvil was obliged, for some time, to absent himself from court. When Mary was detained a prisoner in England, she recommended her faithful servant to her son James VI., who consulted him and made use of his services till he acceded to the throne of England. He was ever the adviser of prudent and moderate measures, and retained the esteem of his royal master, who would willingly have taken him to England as one of his ministers. Melvil, however, thought himself too far advanced in years for so important a change in his habits, and he retired to his family seat, where he died in the year 1606. He left behind him in MS. an historical work, which came into the possession of his grandson, and was published in 1683, by Mr. George Scott, under the title of "Memoirs of Sir James Melvil of Hall-hill, containing an impartial account of the most remarkable affairs of state during the last age, not mentioned by other historians, more particularly relating to the kingdoms of England and Scotland, under the reigns of queen Elizabeth, Mary queen of Scots, and king James. In all which transactions the author was publicly concerned." To this work the reader is referred for more information relating to the author; and also to Robertson's History of Scotland. A brother of Sir James was also in the service of Mary, and is probably the Sir Andrew Melvil who was present at her death.

MELVIN-LOUGH, in *Geography*, a considerable lake of Ireland, between the counties of Fermanagh and Leitrim, from which a small river flows to the bay of Donegal.

MELUING, a town of Norway, in the diocese of Dronheim; 32 miles W.N.W. of Romsdal.

Vol. XXIII.

MELUN, a city of France, and principal place of the department of the Seine and Marne, of which it is the capital, situated on the Seine; before the revolution it contained one college and three parishes, two churches and two abbies. It carries on a trade with Flanders, coal, wool, wine, and cheese. The place contains 6124, and the two cantons, into which it is divided, 18,922 inhabitants, on a territory consisting of 87,400 acres, in 31 columns. N. lat. 48° 32' E. long. 41°.

MELYKUT, a town of Hungary; 16 miles E. of Buda.

MELYRIS, in *Natural History*, a genus of insects of the order Coleoptera; the generic character is, antennae entirely perforate; head inflexed under the thorax; thorax margined; lip clavate, emarginate; jaw one-toothed, pointed. There are three

Species.

VIRIDIS. Green; shells with three raised lines; it inhabits the Cape; antennae black; thorax reflexed at the edge, and grooved on the back, scutellum small and round; shells rough.

NIGER. Black; shells with three raised lines. A specimen of this species of the myelaris is in Sir Joseph Banks' museum. It is only about one-third the size of the last; thorax a little prominent before; the shells rough.

LINPARIS; Green; shell with three raised lines, and one on each side the thorax: it is about half the size of the viridis; thorax grooved, with a raised line on each side; lines on the shells crenate.

MELZEN, or MELZEN, in *Geography*, a town of Saxony, in Thuringia; six miles S. of Weissenfels.

MELZO, a town of Italy; 14 miles N.E. of Milan.

MEMAUN, a town of Persia, in Khorasan; 18 miles E.S.E. of Velazghard.

MEMBERS, in *Anatomy*, the exterior parts, arising from the trunk or body of an animal like the boughs from the trunk of a tree.

In which sense, members, *membra*, amount to much the same with limbs, *artus*: though some make a difference between the two: restraining members more immediately to the fleshy parts which cover the limbs, and artus to the bones and nerves. Physicians divide the body into three regions; the head, the breast, and the lower ventricle; and the extremities, which are the members. See EXTREMITIES.

MEMBER, in *Architecture*, denotes any part of a building; as a frieze, cornice, or the like.

MEMBER is sometimes also used for moulding.

MEMBER, in *Grammar*, is applied to the parts of a period, or sentence.

MEMBER is also used to denote some particular order or rank in a state or government: thus we say, member of a corporation, member of parliament, member of the council, &c.

MEMBERED, or MEMBERTD. in *Heraldry*, is when the beak, or legs, or feet of an eagle, griffin, or other bird, are of a different colour from the rest of the body.

MEMBIG, in *Geography*, a town of Syria, in the pachalic of Aleppo; 30 miles N. of Aleppo.

MEMBRANA, in *Anatomy*. See MEMBRANE.

MEMBRANA *Arachnoidea*, one of the coverings of the brain and medulla spinalis. See BRAIN.

MEMBRANA *Conjunctiva*, the mucous membrane lining the eye-lids; and covering the anterior surface of the eye. See EYE.

MEMBRANA *Decidua*, one of the coverings of the ovum. See EMBRYO.

MEMBRANA *Hyalidea*, the transparent covering of the vitreous humour of the eye. See EYE.

MEMBRANA *Mucosa*, the febraceous substance covering the membrana tympani in the fœtus. See EAR.

MEMBRANA *Nictitans*, a peculiar fold of the conjunctiva, which can be drawn across the front of the eye by means of two peculiar muscles connected with it. (See BIRDS, *Anatomy of*.) In quadrupeds a piece of cartilage is placed in a fold of the same kind, and the eye can be rolled behind it. See MAMMALIA, *Anatomy of*.

MEMBRANA *Pituitaria*, the mucous membrane lining the cavities of the nose. See NOSE.

MEMBRANA *Pupillaris*, an exceedingly thin production filling the aperture of the pupil in the fœtus. See EYE.

MEMBRANA *Ruyfchiana*, the internal surface of the choroid membrane of the eye. See EYE.

MEMBRANA *Tympani*, a membrane terminating the meatus auditorius externus, and forming the boundary between it and the cavity of the tympanum. See EAR.

MEMBRANE is a term applied to several parts of the body, which consist of thin sheets of animal substance, in which the thickness bears a very small proportion to the surface. This disposition is found in several tissues; the term, therefore, denotes a peculiarity of arrangement and form, and not of internal structure, and hence it includes parts differing from each other very widely in organisation, properties, and functions.

Membranes never have an insulated existence: they are disseminated among the other organs of the body, and concur in their formation; hence their history has generally been associated to that of the organs on which they are expanded. This is a convenient arrangement for purposes of description, but it occasions us to lose sight of the analogies between the particular membranes, and to neglect those general considerations, which form a very interesting part of the study of anatomy, which exhibit to us nature every where uniform in her proceedings, varying only in their results, sparing of the means which she employs, profuse in the effects obtained from them, modifying in a thousand ways some general principles, which, differently applied, preside over the animal economy, and are the sources of its innumerable phenomena. Haller has some general remarks on the membranes, but he establishes no demarcations between them. He describes them all as analogous in their texture, and having for their common basis the cellular organ, to which he says that they may all be easily reduced, principally by means of maceration. That this view is incorrect in many points, will appear from the sequel of the present article: how, indeed, can we expect the composition to be the same, when the conformation, the vital properties, and the functions are different?

Bichat is the anatomist to whom we are the most indebted for an elucidation of this subject. His "Traité des Membranes en general, et des diverses Membranes en particulier," Paris, an 8, contains a distribution of these organs into certain classes, a general account of each of these, and a particular description of the individual membrane. "When," says he, "we observe all the membranes in a general view, it seems that their classification must be very complicated, both on account of their great number, and their apparent variety. The extent of the different membranes, compared to that of the skin, cannot be less than in the proportion of eight to one: yet, perhaps, no two of them exactly agree in appearance. An examination of

their structure and functions quickly shews us that several come near to each other, and are distinguished only by their form." Bichat establishes two general divisions, viz. the simple and compound membranes: the latter are composed of two of the former united together, and exhibit a combination of the characters of each. He makes three classes of simple membranes. 1. The mucous, so named from the fluid, which moistens their surface. 2. The serous, characterised also by the particular fluid which covers them, and containing the membranes that line the several circumscribed cavities connected with the different viscera, and the smooth coverings of the joints, bursa mucosæ, &c. 3. The fibrous, moistened by no fluid, and distinguished by the fibres that enter into their composition.

From the union of these proceed the fibro-serous, sero-mucous, and fibro-mucous membranes.

There are moreover some, which either exist insulated, or are little known, and consequently cannot be brought under any classification.

The mucous membranes occupy the interior of the cavities, which communicate with the skin at the various openings of the latter on the surface of the body. Their number appears considerable on the first view of the subject; for the organs which they line are very numerous. The mouth, stomach, intestines, œsophagus, bladder, urethra, uterus, the ureters, all the excretory tubes, &c. &c. derive a part of their texture from these membranes. However, when we consider that they are every where continuous, that they arise by prolongations, one from the other, as we see them originally derived from the skin, their number must be very much reduced. In fact, when we regard them thus in a general view, as expanded over all the organs in which they are continuous, and not as insulated in each particular organ, they are reduced to two general surfaces, which may be named, from the various parts over which they are extended, the gastro-pulmonary, and the genito-urinary. The former is found in the head, neck, and abdomen: the latter in the abdomen, and more particularly in the pelvis.

There is one small insulated mucous surface, viz. that which enters the openings on the nipple, and lines the lactiferous ducts. As the observations on the others are applicable to this, we shall not examine it in detail.

The gastro-pulmonary surface enters the body by the mouth, the nose, and the front of the eye. 1. It lines the two first mentioned cavities, is continued from one of them into the excretory tubes of the parotid and submaxillary glands, and from the other into all the sinuses of the nose; it forms the conjunctiva, enters the puncta lacrymalia, lines the lacrymal sac and nasal duct, from which it is continued into the nose. 2. It descends into the pharynx, and penetrates through the Eustachian tube into the ear. 3. It goes into the larynx and trachea, and is expanded over all the air-tubes and vesicles of the lungs. 4. It lines the œsophagus and stomach. 5. It enters the duodenum, and furnishes two prolongations, one to the ductus choledochus, the hepatic duct and its numerous ramifications, the cystic duct and gall-bladder, the other to the pancreatic duct and its branches. 6. It is then continued into the small and large intestines, and lastly ends at the anus, where it is identified with the skin.

The second general mucous surface enters, in the male subject, at the urethra, and thence is expanded, on one side, over the bladder, ureters, pelvises, and calyces of the kidneys, the papillæ of the same organs and capillary tubes which open on their points; on the other it enters the excretory ducts of the prostate, the seminal ejaculatory tubes, vesiculæ

vesiculæ feminales, vasa deferentia, and the numerous intricate ducts which arise from them. In the female this membrane enters at the colon, extends over the urinary organs as in man, penetrates the vagina, and lines that canal as well as the uterus and the Fallopian tubes, at the apertures of which it is continuous with the peritoneum. This is the only example in the animal economy of a communication between mucous and serous surfaces.

The phrases of membranes entering cavities, being prolonged or extended from one part to another, &c. are not to be understood as indicating the progress of nature in the formation of parts, but merely as descriptive of the relations existing between the organs when fully formed. The membranes belonging to every part are formed independently in it, and not derived from any other.

The distinction of the two great divisions of the mucous system, and the connection of all the parts in each system are manifested, not only by anatomical researches, but also by pathological phenomena. In epidemic catarrhs one of these surfaces is often affected throughout, while the other escapes entirely; the gastro-pulmonary membrane is the seat of the disease in all its divisions, and the genito-urinary is completely unconcerned in the affection.

Irritation of any point often causes pain in some other part of the same surface; thus stone in the bladder produces uneasiness at the front end of the urethra, worms in the intestines cause itching of the nose, &c. But it is very uncommon for partial irritation of one membrane to affect the other: yet there are examples of such an occurrence, as in the bleeding from the lungs, which frequently supplies the place of menstruation, when it is interrupted accidentally.

The two mucous surfaces are united by means of the skin: the latter organ with the former may be regarded as a general and continuous membrane, covering the exterior surface of the body at all points, and prolonged in the interior over most of the important organs. Every mucous membrane has two surfaces; the one adhering to the neighbouring parts, the other free, in many cases villous, and always moistened with a mucous fluid.

The adhering surface corresponds almost universally to muscles, either of the animal or the organic life. The mouth, the pharynx, the whole alimentary canal, the bladder, a part of the urethra, &c. present a muscular stratum embracing the mucous membrane on the outside. This disposition agrees entirely with that of the skin in animals which have a panniculus carnosus: there are indeed many points of resemblance between these organs, which we have already observed to be continuous. It subjects the mucous membranes to habitual motions, which probably favour the secretion of their fluid and its subsequent excretion, as well as the various other functions of these organs. The muscular stratum is inserted into the close and dense tissue, named by Bichat the *tissu foumuqueux*, in which the strength of the organ resides, and which according to him decides and maintains the form of the part.

The free surface of the mucous membranes, habitually moistened by the fluid, from which their name is derived, presents three kinds of folds.

1. The first are composed by the muscular as well as the mucous coat; their situation is defined by a depression on the exterior surface of the organ, and they exist constantly whatever may be its state in respect to contraction or dilatation. The pylorus and valve of the colon are of this kind.

2. Others are formed in the mucous membrane only, are constantly seen, whether the part be full or empty, but are

rather less sensible in the latter state. They arise from the membrane being much more extensive than the surfaces to which it is applied, and being fold'd, compensate this difference. The valvula conniventes of the small intestine exemplify these very well. The cut edges of the muscular and serous coverings, as seen in a longitudinal section of the intestine, form straight lines, while that of the mucous surface is a very wavy line.

3. The last kind may be regarded in a manner as accidental, and is seen only when the organ is contracted; such are those of the stomach and large intestine. The cavity of the former, in particular, presents, in this state, very numerous and large folds, which may be compared, in some measure, so far as their appearance goes, to the cerebral convolutions. Distend it fully, and the surface becomes completely smooth. The exhaustion of the vital forces in individuals who die after lingering and debilitating diseases, occasions their stomachs to be frequently destitute of these folds, although they may be empty. But if the full stomach be cut longitudinally in a living animal, or in one recently killed, the contraction of the muscular coat will speedily produce the folds in a very marked degree. It follows from this circumstance, that the surface of the mucous membranes is nearly as extensive in the contracted as in the dilated state of the organs which they line. But all parts are not alike in this respect; the observation is true of the œsophagus, stomach, and large intestine; but it is not equally applicable to the urinary and gall-bladders.

The free surface of the mucous membrane is every where in contact with bodies heterogeneous to that of the animal; which are either introduced from without for various purposes, as in the alimentary canal and trachea, or derived from within, as in the excretory tubes of glands, all of which open on cavities lined by mucous membranes. Hence these membranes may be regarded as a kind of barriers, placed between our organs and extraneous substances, and protecting them from the noxious impressions of the latter, and serving the same purpose in the interior of the body, which the skin fulfils on the outside with regard to the objects that surround us, and are incessantly acting upon us.

The organisation and vital properties of the mucous system are accommodated to this habitual contact with foreign substances. Solid matters, as metals, stone, wood, &c. introduced into the interior of other parts, inevitably excite inflammation and suppuration by their simple contact; but they traverse the mucous system with impunity, provided their angles or asperities do not tear it; various things for example go through the alimentary canal, and are voided per anum, without having excited an uneasy feeling. Irritating fluids may be swallowed, or injected per anum, although they would produce abscesses, if conveyed into the cellular system.

On the other hand, this system may be exposed with impunity to external agents, where any part of it is protruded either through the natural, or through artificial apertures. This is exemplified in prolapsus of the uterus and rectum, of the intestine through an artificial anus, &c. In these instances the mucous surfaces seem to serve the office of integuments, and surrounding bodies hardly affect them more than they do the skin. The serous system, on the contrary, when exposed, as in the operation of hernia, &c. inevitably inflames. The cellular, muscular, nervous, and glandular tissues exhibit the same phenomenon.

Fistulous openings are every where surrounded by a callous substance, which defends the cellular and muscular tissues traversed by the fistula: an exposed mucous surface exhibits nothing of this kind, because its organisation sufficiently

protects it. The urinary and other fluids never escape through artificial canals excavated in the surrounding organs, without callosities being formed in the course of these canals; on the contrary, they traverse mucous surfaces with impunity. Cut an opening in a limb, and leave a tube in it; a callous canal will be formed round that tube. Leave a catheter in the urethra, and no alteration of structure is produced. "Let us conclude," says Bichat, "from all these considerations, that the mucous and cutaneous systems only are so organized as to support the contact of foreign bodies without being affected by their presence, or at least without feeling any further effect than an augmentation of secretion, which is not at all dangerous. These two systems then form two limits, an internal and an external one, between which are placed the organs, whose structure, or peculiar sensibility, incapacitates them from bearing the contact of extraneous bodies. The influence of the excitation produced by such bodies reaches no farther than these boundaries; the other organs feel nothing of it. We may conceive that the acute sensibility possessed by these systems acts as a kind of sentinel, placed by nature at the confines of the organic domain of the soul, to warn it of the approach of every thing hurtful."

There are two points to be considered in the organization of the proper tissue of the mucous system; *viz.* a more or less thick stratum making up its chief bulk, and which, from its analogy to the corion of the skin, may be called the mucous corion; and a number of small prominences surmounting the latter, and called villi or papillæ. The epidermis is considered with that of the skin, under the article INTEGUMENTS. It does not agree in any respect with the colouring substance of the skin, which is placed between the papillæ and the epidermis. In fact, we know that in the black, as well as in the white races, this tissue is of a bright red, derived from the blood-vessels.

Mucous Corion.—This important part of the mucous tissue, which regulates the thickness, form, and very nature of the organ, has a soft and spongy appearance; it appears at the first view like a thick pulp, covering the dense cellular tissue which lies under it. Its softness distinguishes it from the cutaneous corion, which indeed resembles it but little in its intimate nature. Its thickness varies very considerably; in the gums and palate it is thickest, and decreases successively in the following organs, *viz.* the nose and stomach, small intestine and gall-bladder, large intestine, urinary bladder, urethra, and the various excretory tubes. When cautiously removed in the latter, it appears transparent, like a serous membrane. It is thinnest in the sinuses of the head, and the cavity of the ear. The lining of the latter has been generally called periostrum by anatomists; but its continuity with the pituitary membrane through the Eustachian tube, the mucous fluid that habitually covers it, and every circumstance that we can observe of its appearance and texture, shew that it belongs to the mucous system; and its diseases agree with those of that system. Diseases produce great changes in its thickness; and distention or contraction of the organs to which it belongs have analogous effects. The degree of softness which it exhibits, is very different in different situations. In the nose, stomach, and intestines, it is like velvet, and the name of villous coat characterises it very well. At the origins of the system, as the mouth, nose, glans penis, &c. it is much more dense, so as to approximate in its nature to the cutaneous corion. In the latter situations it is the seat of variolous pustules, which are often seen on the tongue, palate, and cheeks, but never on the internal mucous surfaces. It becomes dry and very thin by exposure to the air, but preserves a certain degree of resistance. The

muscular and serous coats of an intestine are pliable when dried, while the mucous covering is rigid. It is transparent after desiccation, in organs where it is naturally pale, as in the rectum and bladder; it exhibits a darker tint in parts where it is redder, as in the stomach, and has even a blackish cast when much blood is accumulated in it by preceding inflammation. It putrifies with great facility, and acquires a very fetid odour: this is one reason why the abdomen of a dead body passes so soon into the putrid state. In this change it acquires a greyish colour, and as the subjacent cellular tissue decays much more slowly, it may be removed by very slight pressure in the form of a disorganized and fetid pulp. Gangrenic attacks it much less frequently than the cutaneous tissue; yet it occurs sometimes, as in putrid sore throat. It yields very speedily to maceration; quicker indeed than any organ, except the brain. It is converted into a reddish pulp, very different from that produced by putrefaction in the open air. Ebullition extracts from it a greenish froth, very different from that produced by the muscular and cellular tissues. Before the water begins to boil, it curls up, but in a less degree than other structures. In fact the tissue soughlike then contracts much more than it, so as to throw it into a recurved state. In the same way, the contraction of the serous and muscular strata of the stomach during life, being much greater than that of the mucous, produces the numerous folds of the latter. A concentrated acid has the same effect. After having been dried for a long time, it still is curled up when plunged into boiling water. The valvulæ conniventes of the intestine, which disappear on drying, are then reproduced. Long ebullition brings it to a dark grey colour; it is not rendered softer, but may be more easily torn. In this respect it is contrasted with the subjacent cellular stratum, which preserves its power of resistance much longer. It never has the gelatinous appearance, which the cutaneous corion, the fibrous organs, cartilages, and other structures which afford much gelatine, present on boiling. The action of acids reduces it into a pulp much more quickly than any other tissues. Caustics act on it more rapidly than on the skin, where the epidermis protects the corion. Nitric acid, taken into the alimentary canal, produces a whitish fear on the mucous surface, which, when death does not follow suddenly, is gradually detached in the form of a membrane. All mucous surfaces, and particularly those of the stomach and intestines, have the power of coagulating milk. That of the former still possesses this power after desiccation.

Mucous Papille.—The peculiar mode of sensibility enjoyed by the skin is usually ascribed to its papillary structure, which is not very readily demonstrable. The sensibility of mucous membranes, analogous, in many respects, to that of the skin, arises probably from the same kind of texture, which is here more readily discerned. The existence of papillæ cannot be doubted at the origins of the system, and at the commencement of the cavities, as on the tongue, the palate, the alæ nasi, glans penis, &c. The villousities with which the internal surfaces are every where covered, must be regarded as an analogous organization; and the existence of an analogous sensibility on these surfaces strengthens the opinion. A very different function has generally been assigned to these villi; they have been regarded in the alimentary canal, as destined to the exhalation of various fluids, the absorption of chyle, &c. Bichat considers it incorrect to ascribe to an organ so similar in all parts such a diversity of offices. He considers that the microscopical observations, on which is grounded the opinion that the villi absorb the chyle, do not deserve much confidence, as different observers give such different reports. And he cannot account
for

MEMBRANE.

for the villi of the pituitary membrane, urethra and bladder, unless on the supposition of their being connected with the sensibility of the parts. The delicacy of the objects renders their structure so obscure, and their investigation so difficult, that the question can hardly be decided by direct observation. Analogy and observation of the vital properties must guide us in forming an opinion.

The papillæ exhibit very numerous varieties; they are remarkably long on the tongue, small intestine, stomach, and gall-bladder; less distinct in the œsophagus, large intestine, urinary bladder, and the excretory tubes; the latter, in fact, are almost completely smooth on their mucous surface.

Besides blood-vessels, exhalants, and absorbents, which enter into the structure of this system, as into that of all others, it presents another common organ of a glandular nature, which is generally insulated, but here forms part of the system. The mucous glands probably exist throughout the system. Situated under the corion, or in its substance, they constantly pour out a mucilaginous fluid, which lubricates the free surface of the membrane, protecting it from the action of the bodies that come in contact with it, and facilitating their passage. They are very apparent in the trachea and bronchi, the œsophagus and intestines; they cannot be shewn in the urinary and gall-bladders, the uterus, the vesiculæ feminales, &c.: their existence in these organs can therefore only be inferred from the circumstance of a mucous fluid being produced analogous to what is found where the glands are manifest.

If we admit the force of this reasoning, and allow that identity of the secreted fluid proves identity of the secreting organ, we shall establish as a striking difference between the mucous and serous membranes, that the fluid of the former is produced by secretion, that of the latter by exhalation. Their size varies in different organs; they are largest in the lips, cheeks and palate. They generally have a rounded form, are dense in their texture, and surrounded by cellular substance, but contain very little of that substance in their interior. Little or nothing is known of their diseases. For further particulars, see GLAND.

A difficulty occurs in ascertaining the composition of mucous fluids, because they are formed in very small quantity in health, and are probably changed in their composition when increased in quantity in disease. They are generally insipid, colourless, and tenacious; but their colour, viscidinity, and odour, differ in different organs. For a further chemical account of them, see MUCUS.

Their use in the animal economy is obvious: they protect the mucous surfaces from the impressions of those heterogeneous substances, with which they are all in contact, by forming a stratum, which compensates for the extreme thinness or even the entire absence of epidermis. Hence they are more abundant where foreign matters lodge for some time, as in the alimentary canal, than where they only pass occasionally, as in the excretory tubes. For the same reason, they are poured out more abundantly where any foreign body of an unusual kind is left permanently in contact with a mucous surface, as a catheter in the urethra, a tube in the trachea, &c. In all these cases the effect must be referred to an irritation of the excretory orifices; for the body does not come in contact with the glands themselves.

By the secretion continually going on in the mucous membranes, they perform another important part in the animal economy. They are one of the great emunctories, by which the residue of nutrition is carried off, and, consequently, one of the principal agents in that habitual decomposition, which the solids of the living body are constantly undergoing. All

the mucous fluids are rejected from the body; that of the ureters, bladder, and urethra, with the urine; that of the alimentary canal with the feces, which are often very copious when nothing is taken in by the mouth; &c. If we consider that the two mucous surfaces, taken together, are of equal, if not greater extent than the skin, we shall deem their functions very important in this point of view. When these fluids have remained for some time in rather considerable quantity on their respective surfaces, a disagreeable sensation is produced, and leads to their expulsion in various ways. The air-passages are cleared by coughing; the stomach by vomiting, &c. Mucous membranes possess a great number of blood-vessels, and are hence distinguished by a remarkable redness, which however is not an uniform character. In the sinuses of the head, and the internal ear, they are whitish, and appear the more so, because their extreme thinness allows us to discern the bone, on which they are applied. In the bladder, the large intestine, and the excretory tubes, the colour is deeper, but still pale. In the stomach, small intestine, vagina, pituitary membrane, and mouth, the redness is strongly marked. It arises from a vascular network, the branches of which, after being ramified in the mucous corion, are expanded in a state of very minute division on the mucous surface. Their unsupported position makes them liable to rupture on the application of any force, as in the bronchi from coughing, in the ear and nose from blows on the head, &c. The passage of stones will produce bleeding from the ureters or bladder, and that of catheters from the urethra.

The superficial situation of these vessels enables us to judge by them of the state of the circulation; hence the lividity of the lips, nose, &c. in asphyxia.

Whether the quantity of blood in the mucous membranes be constantly the same, and particularly whether it varies in those organs, which are seen in very different states of contraction and dilatation, as the alimentary canal, are points concerning which we possess hitherto no means of judging.

The number of blood-vessels belonging to the mucous system, the fact that the blood is changed in respiration by exposure to the air through its containing vessels, and that it will also become red when placed in a bladder immersed in oxygen, led to an inquiry whether any change is produced by the air in the blood of mucous surfaces. Bichat could not discern any alteration from enclosing oxygen gas in a portion of intestine, or from making it pass backwards and forwards through a part of the canal.

This author conceives, that the red colour of the mucous is analogous to that of the muscular system, and derived from the colouring matter of the blood combined with the tissue of the part; except at the origins of these surfaces, where the cause of colour is principally in the blood contained in the vessels. Asphyxia does not affect the deeply-seated parts, so much as those which are superficial, and communicate with the skin; the latter become suddenly white in syncope, where the heart sends no more blood into the arteries. Repeated washings take away the red colour; and sudden whiteness is produced by immersion in boiling water or in acids. It is, on the contrary, increased to a remarkable degree of intensity in inflammations, on account of the increased quantity of blood accumulated in the capillary system.

It is a question, whether exhalation takes place on mucous surfaces: the analogy of the skin seems to indicate that it does. The pulmonary vapour, which is best seen when condensed by cold air, has been generally referred to the

exhalants

MEMBRANE.

exhalants of the air-passages; the gastric fluid, and fluid of the intestines, has been ascribed to the same source. It seems difficult to arrive at any certainty on such a point.

There is a great tendency in the exhalant vessels of the mucous organs to allow the passage of blood; hemorrhages without rupture are very frequent in them.

That absorption is carried on from mucous surfaces is proved by numerous familiar phenomena; *viz.* by the chyle and fluids taken up from the stomach and intestines; by the vapour of turpentine from the lungs; by the removal of the aqueous portions of the bile and urine, &c. This absorption is by no means constant and uninterrupted, as in the serous membranes; it exhibits numerous varieties according to the state of the vital powers of the part.

The origins of the mucous system, where the animal sensibility is clearly marked, and serves, as in the skin, to establish our relations with external bodies, possess cerebral nerves. In the pituitary and palatine membranes, the conjunctiva, the rectum, glans, prepuce, &c. this fact is evident; hardly any nervous twigs from the ganglia are seen in these situations. The latter, on the contrary, predominate in the intestines, the excretory tubes, the reservoirs of secreted fluids, &c. where the organic sensibility is more marked.

Properties of the Mucous System.—The extensibility and contractility of tissue are much less extensive in this system than they would appear to be on the first view, on account of the numerous folds which it presents in the hollow organs, when they are contracted. Yet these properties are very apparent under certain circumstances; the excretory tubes are often distended much beyond their natural size; the ureters sometimes are almost as large as an intestine, and the ductus choledochus and the pancreatic duct exhibit similar enlargements. The urethra and salivary ducts, on the contrary, do not readily yield to distention.

These properties are called into action very rapidly in the mucous system; the stomach, intestines, bladder, &c. pass in a moment from a dilated to a contracted state.

When mucous canals are no longer traversed by the fluids which are habitual to them, they remain permanently contracted, but are not obliterated on account of the presence of their mucous secretions. This fact may be observed in the intestinal canal in the case of artificial anus, in the urethra when the urine has run for a long time through the wound made in lithotomy, &c. Neither do they contract adhesions under inflammation, as is the case in serous cavities, and in the cellular tissue. The importance of this circumstance to the great functions of life is very obvious: the mucous cavities would be rendered useless if they were subject to the frequent adhesions which we observe in pleurisy, peritonitis, &c.

Vital Properties. 1. *Properties of the Animal Life.*—Like the integuments, mucous surfaces are constantly in contact with external bodies, and therefore require a sensibility, which may enable the mind to perceive the relations between us and those bodies, particularly at the origin of the surfaces. Hence the animal sensibility exists there in a very marked degree. In many places it is even superior to that of the skin, which possesses no feeling so lively as those produced by odours on the pituitary membrane, by favours on that of the mouth, on the vagina, urethra, and glans, at the moment of coition, &c. This sensibility, like that of the skin, is subject to the powerful influence of habit, which constantly tends to render our sensations less lively, and brings to a state of indifference the pleasure and pain which they produce. A catheter left in the urethra, produces at

first great pain; it becomes less and less troublesome, and is at last hardly felt. Pessaries in the vagina, tents in the rectum and other situations, &c. are further proofs of this fact. On this observation is grounded the possibility of keeping tubes in the trachea and œsophagus, for carrying on the functions of respiration and deglutition. This remarkable influence of habit is exerted only with respect to sensations produced by simple contact, and not such as are caused by actual injury, as cutting, tearing, &c.; hence it does not make the bladder less sensible to the excruciating pain of the stone, the nose to a polypus, or the trachea to a foreign body accidentally introduced. To this effect of habit we may probably refer in part the gradual diminution of the functions of the mucous system in old age. The active sensibility of the alimentary, biliary, urinary surfaces, &c. in the young subject, is the chief cause why the digestive and secretory phenomena succeed each other so rapidly: the same phenomena take place more slowly in an old person, from the sensibility being rendered more obtuse by the habit of contact.

The animal sensibility, which is acute at the origins of the mucous surfaces, as in the mouth, nose, glans penis, opening of the rectum, &c. is less marked in the more deeply-seated organs. In the former parts we always perceive the bodies that come in contact, but there is no such perception in the latter. Does this arise from the uniformity of the impression in the latter case affording no term of comparison? For each of these organs is brought into contact with one kind of substance only, while the others are exposed to a variety of excitations. In fact we perceive impressions made on the deeply-seated organs, when they are brought into contact with extraneous bodies; as when a catheter is introduced into the bladder, &c.

The sensibility of the mucous system is much increased in disease; acute catarrhs are very painful. We not only perceive the contact of bodies then, but find it very distressing. Yet the sensibility in these cases never rises to the point which it reaches in inflammations of the cellular, serous, fibrous, and other tissues.

The mucous system exhibits no animal contractility.

Properties of the Organic Life.—The organic sensibility and the insensible contractility are strongly marked in the mucous system. They are called into action by four different causes: 1, by the nutrition of the system; 2, by the absorption, which either takes place naturally, or accidentally; 3, by the exhalation; 4, by the continual secretion of the glands. These two properties are the primary causes of all these functions, the augmentation or diminution of which indicate their degree of activity. As numerous causes are constantly acting on the mucous surfaces, particularly at their origins, this degree is very frequently changing, as well as the functions which result from it.

The mucous system then differs from most others, in having its organic properties habitually more active, on account of the more numerous functions, over which they preside; and in having them change so frequently from variations in the excitation applied to them. In the bony, fibrous, cartilaginous, muscular, nervous, and other systems, these properties are only called into exercise by nutrition; and, on the other hand, no excitation can be applied to them; so that the properties remain permanently at the same degree.

From the preceding view, we cannot be surprised that the diseases, which particularly put in action the organic sensibility, and the insensible contractility, should be so frequent in the mucous organs. All the catarrhal affections,

whether

whether acute or chronic, the hæmorrhages, the various tumours, polypi, funguses, &c. all kinds of excoriation, ulcers, &c., which are seen in these organs, arise from the various alterations of which the organic properties are susceptible.

The mucous system does not seem to possess the sensible organic contractility; yet it sometimes exhibits phenomena, which seem to indicate something more than the insensible oscillations which compose the insensible organic contractility. The parotid duct sometimes throws out its contents to some distance from the mouth, although it seems entirely of a mucous structure, and has no muscular agent of impulsion at its origin. Perhaps the excretory ducts of the glands, which open on the deeply-seated mucous surfaces, exhibit the same phenomenon, which has been observed in some degree in the lactiferous tubes. These motions, analogous to those of the dartos, the cellular tissue, &c. seem to hold a middle place between those of tonicity and irritability.

The sympathies of the mucous system are very numerous.

Active Sympathies.—When any part of this system is inflamed or irritated in any manner, all the vital powers may be separately called into action in other systems. Sometimes the animal contractility is exerted; thus the muscles of respiration produce sneezing or cough, when the pituitary or bronchial membrane is irritated; or even when the surface of the stomach is affected. A general spasm is observed, when a foreign body lodges about the glottis. Stone in the bladder causes contraction of the cremaster. In other cases the animal sensibility is excited by affections of the mucous surfaces. Stone in the bladder produces itching of the glans penis. And a similar effect is produced in the nose by worms in the intestines.

The sensible organic contractility may be sympathetically excited by affections of the mucous system. The organic muscles generally contract from the excitation of a contiguous mucous surface. A stone in the pelvis of the kidney, or irritation of the uvula, produces vomiting. The action of the heart is accelerated when the seminal fluid is passing over the urethra.

Sympathy of the organic sensibility is exemplified in the furred tongue, connected with the affections of the stomach, in the hæmorrhages which supply the place of suppressed menstruation, in the diminution of the cutaneous transpiration observed by Sanctorius at the time of digestion, &c.

Passive Sympathies.—In various diseases, a sensation of burning heat is felt in the mouth, stomach, and intestines, although these parts do not seem to be actually hotter than is natural.

Cold bodies applied to the neighbouring skin stop bleeding from the nose and uterus. Most catarrhs seem to be produced by the action of cold on the skin. A cold atmosphere confines the functions of the skin, and occasions those of the mucous system to be proportionally extended. The pulmonary exhalation is more strongly marked, the internal secretions more abundant, digestion more rapid, and the appetite consequently more easily excited. In warm seasons and weather, on the contrary, the skin acts more powerfully, the secretions, particularly of the urine, are diminished, the digestive phenomena proceed slowly, and the appetite is recovered more difficultly. In scarlet fever the throat is remarkably affected. In the last stages of organic diseases of the viscera, as of the lungs, heart, liver, in cancers of the uterus, &c. the mucous membranes are usually affected: hence the colliquative diarrhœas so common in these cases.

Character of the Vital Properties.—In this system, as in the

skin, the vital properties are almost permanently in action, as it is constantly in contact with substances that affect it in some way or other. But they are not the same in all parts: they undergo, in each, particular modifications, arising probably from the differences of structure already pointed out, in the nature of the corion, the disposition of the papillæ, the distribution of the vessels and nerves, of the glands, &c. We see how widely the animal sensibility of the pituitary membrane differs from that of the mouth, how the urethra and glans are affected by the passage of the seminal fluid, which would make no impression on any other mucous surface. Each part bears a certain relation to the fluid which habitually covers it, and could not bear the contact of others without pain. The urine would excite the stomach, and the gastric juice the bladder; the bile, which remains quietly in the gall-bladder, would irritate the pituitary membrane, or vesiculae seminales.

From these varieties in the vital powers of the different divisions of the mucous system, we naturally derive the differences observed in the diseases affecting this system. To the same cause we must also refer the differences of the sympathies. Each part has a peculiar sympathetic action on other organs. Irritation of the pituitary membrane alone causes sneezing; that of the fauces, vomiting, &c.

Development of the Mucous System.—It is proportional, in general, to that of the organs to which it belongs, and is, therefore, earlier in the gastric apparatus, later in the pulmonary organs, and still more so in those of generation. The tissue is very delicate, and the papillæ hardly sensible in the fœtus. Its redness is not so clearly marked: less blood penetrates it, because the functions, of which it will at a future time be the seat, are either exerted feebly, or have not yet commenced. At this time the cutaneous system is in the opposite state with respect to the quantity of its blood. The mucous surfaces are often livid from the nature of the blood contained in their arteries. Its adhesions to the surrounding parts are weaker: hence it may be drawn out of the intestines in an entire piece.

At the time of birth respiration and digestion begin suddenly, and the secretions are increased: hence the mucous system exhibits a remarkable degree of activity. New substances come in contact with it, and stimulate it: red blood enters its vessels, augments its energy and sensibility, and renders it more fit to receive impressions. When the internal functions are once established in a state of activity, the mucous surfaces exhibit no further sudden changes. They act with considerable energy during the time of youth. Active hæmorrhages are frequent, as those of the nose, air-passages, and even of the stomach: yet, in general, they are not frequent in the organs below the diaphragm. They are much more common in men in the gastro-pulmonary, than in the genito-urinary surface: in women, on the contrary, who have a natural evacuation of blood from one part of the latter surface, they are most frequent in it: at the epocha of puberty, the development of the organs of generation in both sexes gives an increased activity to one part of the genito-urinary surface: but this is not accompanied with any debilitation of other parts, all of which, on the contrary, seem to acquire at this time a more energetic action. The mucous system becomes thicker and firmer in the years subsequent to puberty. Its vital energy still predominates for some time in the superior surfaces; but, as age advances, this predominance, as well as that of other organs, is transferred to the abdomen.

Numerous causes change the state of this system during life. It will hardly be found to exhibit the same colour, density,

MEMBRANE.

density, or external appearance in any two subjects. This may be seen in any particular surfaces, as that of the stomach for example.

The redness of the mucous system is clearly marked till the thirtieth year; beyond this time it changes. It receives less blood, grows more and more pale, and becomes more dense in the old subject. The remarkable soft and villous touch is no longer perceived. The vital powers grow languid; yet the mucous glands often separate their fluids abundantly, and even in increased quantity. Absorption takes place difficultly at this time from mucous surfaces, as from all others. The chyle is taken up more slowly; so that the digestion is longer, and contagious diseases are less readily taken.

The serous membranes consist of two kinds essentially distinct from each other. The first includes the pleura, pericardium, peritoneum, arachnoid, tunica vaginalis, and in general all the membranes of the great cavities. These are the proper *serous* membranes. The second comprehends the membranes that line the joints, and those which form the bursa mucosa, which may go by the common name of *synovial* membranes. These two kinds are joined in one class on account of their both possessing the external character of forming a bag without openings, of their being composed of cellular tissue, and being the seat of alternate exhalation and absorption. A strong line of demarcation is established by the different nature of the fluid that lubricates them, by the synovial membranes being exempted from the general dropsical affections of the serous, and of the cellular tissue, and *vice versa*.

The serous membranes generally cover the outside of those organs which are lined by mucous membranes, as the stomach, intestines, bladders, lungs, &c.; and it surrounds all those which are essential to life, as the brain, heart, gastric viscera, &c.

It does not form, like the mucous system, a surface every where continuous over the numerous organs to which it belongs; but its different divisions are insulated, and these are rather numerous. When taken altogether they surpass in extent the mucous surfaces. The particular membranes vary considerably in their extent, from the peritoneum, which is the largest, to the tunica vaginalis, which is the smallest. When taken altogether, they would form a surface greater than that of the skin.

Every serous membrane represents a bag without an opening, extended over the various organs which it includes, which may be either very numerous, as in the peritoneum, or single, as in the pericardium. It covers the organs in such a manner that they are not contained in its cavity, and that, if it were possible to dissect it completely off from them, it would form a perfect bag. In this respect it may be compared to the double night-cap, of which the part immediately covering the head is analogous to the serous membrane investing an organ, and the portion in which this is included represents the lining of the cavity in which the organ is contained. From this description, it will be readily understood, that the serous membranes do not open to allow a passage to the vessels or nerves which arrive at, or depart from, their respective organs, but that they are always reflected over them, accompanying them to the organ, and forming a sheath round them. This arrangement prevents the serum, which lubricates the serous cavities, from gaining admission into the neighbouring cellular substance, which it would do with great facility, particularly in dropses, if the serous membranes, like the fibrous, were perforated for the passage of vessels and nerves.

From the general idea which we have given of these membranes, it will be easily understood that each of them is composed of two parts, distinct although continuous; the one lining the internal surface of the cavity in which it is found, the other covering the organs belonging to the cavity. Thus, there is a pleura costalis and pulmonalis, a portion of peritoneum lining the abdominal parietes, and another covering the abdominal viscera, &c.

The imbricated end of the Fallopian tube offers the only example of a continuity between a serous and a mucous surface.

In every serous membrane there is a free surface, contiguous with itself at all points, and another adhering to the surrounding parts. The former is remarkable for its perfect smoothness and polish, which distinguishes this system and the following from all other membranes. All the organs, which have this polished surface, owe it to a serous covering: many have such a covering only on some part of their surface, and are rough elsewhere, as the bladder and liver.

The free surfaces of the serous membranes completely insulate the parts, over which they are expanded, from the surrounding organs, so as to form a kind of boundaries or barriers, if that term may be employed. Hence the great viscera, confined by their serous coverings, and suspended in the bags which they form, communicate with the adjacent parts only at the points where their vessels enter: in all other situations there is contiguity, but not continuity with the surrounding organs. This insulation of position coincides with the separate vitality of the organs. Each has its peculiar life, resulting from the particular modification of its vital forces, which establishes corresponding peculiarities in its circulation, nutrition, &c. No part feels, moves, or is nourished like another, unless it belong to the same system: every organ displays, on a small scale, the phenomena which appear on a larger plan in the animal economy: each takes from the circulating fluid the matter which suits its nature, prepares this matter, returns to the mass of the blood what is heterogeneous to it, and appropriates what can furnish it with the right nourishment: this, in fact, is digestion. Hence it is an important use of the serous membranes to contribute to this independence of the vital powers and functions of the organs. In the same way the serous coverings insulate the morbid affections of a part.

The smoothness of the free surface of the serous system facilitates the motions of the organs which it covers: the cellular substance is the principal means by which the movements of external parts are provided for, while these membranes are particularly designed for the internal organs.

This surface differs essentially from the corresponding one of mucous membranes, in the circumstance of its very frequently contracting adhesions. The pleura is hardly free from them in any subject: the peritoneum comes next, then the pericardium, the tunica vaginalis, and, lastly, the arachnoid, in which they are the most uncommon. They are seen under various forms. 1. The costal and pulmonary pleurae may be completely united so as to form apparently but one membrane. 2. They may be joined so loosely that very slight force is sufficient to detach them: the opposed surfaces, when detached, have lost their polish and smooth surface. 3. The two pleurae may be united by longer or shorter bands, having the same organisation, and the same highly polished surface, as the membranes which they join together. 4. The adhesion may be of a flocculent nature, and resembling cellular substance. 5. Depositions of coagulating lymph may join the two membranes: but these are foreign to the surfaces.

The external surfaces of serous membranes adhere in almost all cases to the surrounding organs: in a few instances these membranes are insulated on both sides. Yet, although they adhere to their respective organs, their organization is not connected with that of these parts. They sometimes, by turns, cover and leave uncovered the organ to which they belong: the broad ligaments of the uterus serve as a serous membrane to that viscus during pregnancy. The peritoneum lining an enormous hernial sac, has previously lined the abdomen. Since then the organs and the serous membranes can exist independently of each other, there is no reciprocal connection in their organization. The medium of union is cellular tissue, and not a vascular apparatus. The membrane may be, and generally is, affected independently of the organ, and *vice versa*: this is seen in the intestine in peritonitis and diarrhœa. Hence we may infer, that the organization and the life of the serous membranes are entirely independent of the organs which they surround. Yet, in some cases, they are inseparably attached to the subjacent parts, as the tunica vaginalis to the albuginea, and the arachnoid to the dura mater.

The smooth surface of every serous membrane is moistened with a fluid very similar to the serum of the blood. It is constantly poured out by the exhalants, and removed by the absorbents. It is a simple moisture in the natural state, and is dissolved in the air, and rises in the form of vapour from serous surfaces exposed in living or recently killed animals. It is more abundant in the dead subject, as it is increased by the fluids transuding through the blood-vessels after death; and its augmentation during life causes dropsies of the various cavities. In the first stage of inflammation the serous exhalants produce no fluid: as they remain thus preternaturally dry, and are very sensible, motion is highly painful. At this time adhesions are formed. If the affection continue, suppuration ensues, but the membranes are never ulcerated. Their tissue is thickened, and pus is poured out by their exhalants. This fluid varies in consistence from a milky serum to a complete and thick stratum of coagulating lymph, which adheres to the surface from which it has been exhaled.

The fluids of the serous system are plainly of an albuminous nature. One of these membranes plunged into boiling water is covered with a whitish stratum of concreted albumen. This substance predominates in the fluid of dropsies. The flocculent matters, which often float in such fluids, the new membranes, and the white substance, which sometimes gives them a milky appearance, are merely albumen in various states of consistence.

Organization of the Serous System.—It is characterized by a whitish shining colour, and a remarkable transparency: the thickness varies, but is never considerable in the natural state. It consists of a single layer, from the surface of which cellular strata may be removed, but which can never be divided into two or more portions. No pellicle is raised from it by the action of a blister.

The organic systems are formed, 1st, of common parts, as cellular membranes, blood-vessels, exhalants, absorbents, and nerves, which form the ground-work, or as it were the skeleton of the part; 2dly, of a peculiar substance deposited in this, as, for example, gelatine and phosphat of lime in the bones, fibrine in the muscles, &c. The organs, therefore, resemble each other in their common parts, and are distinguished by their peculiar tissues. The serous system seems to possess no peculiar tissue; it contains only the common parts. Cellular in its nature it differs from that system only in its form: the cells, instead of being separate and distinct, are here approximated and condensed.

The continual exhalation and absorption of lymph belong to both these tissues, and the phenomena of dropsy are common to them both: this identity of functions and effect leads us to infer an identity of nature. Maceration in water resolves these membranes into cellular tissue; and facile inflation under them produces a somewhat analogous effect. Cysts, hydatids, &c. are formed in both. Nothing of a fibrous nature is observed in serous membranes, nor in the cellular tissue; although fibres of some kind characterize the other organs.

These proofs of analogy, or even of identity of structure between the cellular tissue and serous membranes, are corroborated by the effects of various reagents, which are exactly similar in both cases. A serous membrane dried becomes transparent, does not turn yellow like the fibrous membranes, still remains flexible, and gradually returns to its former state when immersed in water. It putrifies much more slowly than the parts which it covers, and resists maceration for a very long time, as may be seen in the delicate membrane of the omentum. It is curled up by boiling water like the fibrous system, but furnishes much less gelatine, and does not turn yellow. The ordinary chemical agents operate in the same way on both parts.

When it putrifies in the open air, it does not turn green like the skin, but becomes dull and of a deep grey. When it sloughs during life, it is black; in the latter case it contains much blood, and hence the source of its dark colour. The peritoneum is almost the only instance in which this gangrene occurs.

Yet there are circumstances of difference that distinguish the serous and cellular systems. Their external appearance is not the same. In the cellular tissue there is nothing analogous to the slow inflammation, accompanied with the production of small tubercles, which particularly characterizes serous membranes, as milary eruptions characterize the skin, and aphthæ the mucous surfaces. The pus formed by the cellular organ is not the same as the fluid produced by serous surfaces.

The exhaling vessels which produce the fluid just described are easily demonstrated. Withdraw an intestine from the abdomen of a living animal; you see no vessels in the serous surface, but it has a rose-coloured tint from those which lie under it. If you irritate it, return it into the abdomen, and draw it out again after some hours, it exhibits a number of reddish streaks, which are the exhalant vessels; these could not be seen in the natural state from the transparency of their contents. Minute injections have a similar effect on the serous membranes, and the injected fluid is often thrown out on the surface, probably from the exhaling orifices.

A large portion of absorbents enters into the composition of serous membranes, which may probably be regarded as an intertexture of these vessels and exhalants, united by cellular tissue. The mouths of these absorbents can no more be directly demonstrated than those of the exhaling vessels; but phenomena very clearly prove their existence. They are seen in the dead subject loaded with fluids taken up from the cavities to which they belong, as in the different dropsies, or in effusions of blood. Coloured fluids thrown into the serous cavities are said to be absorbed; but Bichat says that the colouring matter is not taken up. During life they often carry off very large watery effusions in a short time.

Serous membranes contain very few blood-vessels in their natural state; so few, indeed, that Bichat almost doubts their existence. Numerous trunks run in the cellular tissue of their external surfaces, but these may be removed by dissection, without injuring the membranes. In the omentum

the existence of blood-vessels cannot be questioned; and in all cases they must be connected to the membranes through the medium of the exhalants.

Although the serous system is distinguished by certain general characters, the particular membranes differ considerably: each has its peculiar structure, suited to its situation and offices. The transparent arachnoid, yielding to the smallest force, is strongly contralled with the dense and strong peritoneum. Different parts of the same membrane are differently organised. The omentum is not like the rest of the peritoneum; and the two portions of the tunica vaginalis are very different. Hence we shall not be surprised at finding great varieties in the diseases of these membranes. Nothing is more common than inflammation of the pleura; that of the arachnoid is rare. The symptoms are different in inflammation of the pericardium, tunica vaginalis, and peritoneum; the Dropsies are very different, &c. Yet there is a common character in the affections, arising from analogy of organisation. The large serous collections, and the slow tubercular inflammation, belong especially to these membranes: the mode of adhesion is peculiar to them.

Properties of the Serous System.

1. *Properties arising from Organisation.*—The extensibility and contractility of tissue are less extensive in the serous membranes, than we might have supposed on the first view of the enormous dilatations which the organs covered by them occasionally exhibit, and of the facility with which they recover their original size. The folds of the membranes, which are particularly marked near organs susceptible of considerable variety in size, as in the abdomen, are separated as the organs enlarge, and contribute to their covering. Yet a considerable extension takes place in many cases, in the peritoneum in ascites, in the tunica vaginalis in hydrocele. The contractility is proportional: those membranes are restored to their original state when the distending fluids are removed. After very long extension they do not recover completely: the tunica vaginalis is flaccid when emptied, and the peritoneum in old dropsies.

2. *Vital Properties.*—Removed by their situation from the action of external bodies, the serous membranes do not enjoy, in their natural state, those properties which establish relations between such bodies and the living organs; they have no animal sensibility nor contractility. Hence they would not serve the office of integuments to the body, nor the purpose of lining the organs in the place of mucous membranes: they would give us in short no other sensation than that of an obscure and indistinct feeling. Living animals exhibit no signs of pain when these membranes are irritated. External bodies brought in contact with serous membranes excite inflammation in them: and this method is employed in surgery for producing artificial adhesions of their sides. When inflamed, animal sensibility is developed in them to a very high degree; these are among the most painful affections to which the body is subject.

This system does not possess the sensible organic contractility; but the insensible organic contractility, and the corresponding sensibility, are kept in permanent exercise by the exhalation and absorption habitual to this system, and by nutrition. The two latter properties predominate, and the morbid affections consist in alterations of them. Hence are derived acute and chronic inflammation, adhesions, effusions of various fluids, &c. It is these, also, which are called into action in sympathies; so that whether they are diseased idiopathically or sympathetically, serous membranes exhibit always a series of phenomena arising from an increased interior motion, or from a loss of power in the

exhaling and absorbing vessels, and in the proper tissue; while in the animal and organic muscular systems, the prevailing affections, marked in the one by convulsions and paralysis, in the other by irregular motions of irritability, do not indicate any such alteration of the tissue of the organ. Hence the latter systems, although frequently affected during life, present very few morbid changes after death, while the serous affords a vast field of observation to the morbid anatomist.

Sympathies.—The serous surfaces are often influenced by the affections of other organs. This is obvious in the organic diseases of the heart, lungs, liver, &c. which, although these parts are entirely unconnected in functions with the serous organs, are almost always accompanied, in their latter stages, with collections of fluid in the large cavities.

Development of the Serous System.—All the serous membranes are extremely thin in the fœtus; and the fluid which lubricates them is more unctuous, so that it seems to approach in its qualities to the synovia. Their growth corresponds to that of the organs which they cover. We cannot observe any marked change in their functions at the time of birth. For a considerable time they are extremely thin and transparent, but they afterwards grow thicker, and assume a dull colour.

This system remains unchanged for a long time in the adult. The different membranes in their affections follow the same laws as the organs which they surround: thus the serous surfaces of the chest are most frequently affected in young, and those of the abdomen in older subjects.

The membranes become more dense and firm, and adhere more strongly in old persons. Their powers become weakened, absorption is performed more languidly, and dropsies occur.

The *synovial* system presents two principal divisions; one belonging to the articulations, the other to the tendinous sheaths.

Synovial System of the Articulations.—The formation of the synovia has been very commonly ascribed to the masses of fat found in the neighbourhood of the articulations, and has been regarded as a species of secretion. These masses, which have been called synovial glands, consist apparently of a merely adipous texture, covered by the synovial membranes, and so placed as not to be subject to any considerable pressure in the motions of the joint. It was said, that the synovia was poured out by fringed processes projecting from their surfaces into the cavities of the joints. The following considerations will convince us that the synovia cannot be formed from this source. The bodies called synovial glands are not found in all the joints, and they do not exist in the sheaths of tendons. We can discover nothing in them but masses of fat: inflation or maceration demonstrates the cellular tissue belonging to them, and ebullition removes the fat, leaving nothing but collapsed cells like common cellular substance. They contain no trace of any glandular structure, nothing of that peculiar parenchyma, unknown in its nature, but remarkable in its structure, which distinguishes all glandular bodies. No excretory duct can be shewn in any of them. They do not exhibit in any case such diseased alterations as other glands display, but participate only in the general affections of the surrounding cellular tissue.

Another source has been assigned to this fluid in the transudation of the medullary substance of the bones through their extremities: this explanation is so mechanical, so unlike any vital process, and so inconsistent with all our views of the functions of the animal economy, that it is unnecessary to refute it formally.

We must then consider the synovia as produced by exhalation from the vessels of the membranes. In this point of view it may be compared to the serum of serous surfaces, to which it is analogous in its albuminous composition, in its function of lubricating the surface, on which it is deposited, in its increased deposition under certain circumstances, and in its being taken up from the cavities by absorption.

The synovia is a transparent and viscid fluid: it is tenacious, so as to be drawn out into strings when touched with the finger, and has a slippery unctuous feel, which renders it very fit for the purpose of lubricating the articular surfaces, and making them glide easily against each other in the motions of the joint. Its quantity is not uniform in all joints; in the ankle, hip, shoulder, elbow, &c. it is abundant; while its existence can hardly be observed in the sterno-clavicular, sterno-costal and collo-vertebral articulations. This difference does not arise from the smallness of the surfaces; for some small joints contain much synovia. The quantity is always the same in the same joint; it cannot be increased, like the serous fluids, by transudation after death, nor is it, like them, influenced sympathetically by affections of other organs. It never exhibits those changes in appearance, which are so frequent in the fluid of serous cavities, as the milky turbid state, the white flocculi, the false membrane of coagulating lymph.

The synovial membranes, which constantly deposit and absorb synovia, belong to the joints of the body in the same manner as the serous membranes do to the great cavities. Each of these organs is therefore to be regarded as an entire bag expanded over the parts which form the joint; that is, over the surfaces of the articular cartilages of the ligaments, and the masses of fat called synovial glands, and including the inter-articular ligaments, when such exist, in complete sheaths. The various organs composing joints owe to it their smooth, polished, and shining surface. We can conceive the possibility of removing it from them by dissection, in which case it would form a bag without any opening. All the organs, over which it is expanded, are on its external surface, as the different viscera are on the outside of their respective serous membranes.

A synovial membrane is found in all moveable articulations; indeed, its office is so essentially connected with the motion of the part, that it may be deemed a necessary constituent of these joints. A fibrous capsule belongs to very few joints; the hip and shoulder offer examples of it. These joints possess two very distinct coverings. The external is fibrous, and represents a bag open above and below: it embraces, by its two openings, the surfaces of the two bones, and is continued into their periosteum, the fibres of the two organs being interlaced. The other is the synovial membrane, lining the former, and separating from it at its attachment to the bones, to be reflected over the articular cartilages. To the former, if to any part, the term capsular ligament should be applied; it must lead to very incorrect notions to give this name to the synovial membrane, the structure and functions of which are so foreign to those of ligaments.

Other joints have no fibrous capsule; the ligamentous fibres, instead of assuming the membranous form, are collected into fasciculi. The internal layer, or that composed of the synovial membrane, exists here, as in the former joints, and has exactly the same disposition with respect to the capsule, which it forms round the joint, and its reflexion over the articular heads. In these joints, too, anatomists often call it the capsular ligament. It has the

same function in both kinds of articulation; that of secreting the synovia and confining it to the surface of the joint.

Simple inspection is sufficient to prove the existence of the synovial membrane in joints, where it exists alone, that is, not covered by a fibrous capsule. It can be very easily demonstrated in certain parts of other joints, as on the ligamentum teres, the synovial gland, and the neck of the femur in the hip, as well as where it is reflected from the fibrous capsule to the cartilaginous surfaces. On the surface of the fibrous capsule, and on the articular cartilages in all joints, its adhesion is so strong, that doubts may be entertained of its existence. It sometimes appears uncovered at some interval between the fibres of a capsule; and careful dissection, with maceration, enables us to detach it. The smooth surfaces of ligaments and cartilages can be owing only to a covering of this membrane, for those parts cannot derive that property from their own structure; articulations, which have no synovial membrane, have not this smooth surface, as the symphyses of the pelvis.

When a part passes through a joint, as the tendon of the biceps at the shoulder, the synovial membrane is reflected over it, so that there is no opening for the synovia to escape through.

As the form and office of the synovial strongly resemble those of the serous membranes, the organisation is also analogous. It is chiefly cellular, as we may prove by dissection, inflation, and maceration. Its external surface is every where covered by cellular tissue, which we find gradually more and more condensed as we approach the membrane. No kind of fibre can be distinguished in it. It has a degree of transparency when dissected out of a joint. In all points of its texture, in its exhalants and absorbents, it resembles the serous membranes.

Properties.—The extensibility and contractility of tissue are seen in the distention of joints in the hydroys articulari, and their subsequent return to their original size. The membranes admit, however, only of a gradual extension, and are torn by the sudden force applied in luxations.

Organic sensibility is the only vital property which they possess in the ordinary state; no sign of pain is produced, when they are exposed and irritated in living animals. Inflammation increases this sensibility and converts it into the animal kind; most excruciating pain is experienced from inflamed joints. The exhalation and absorption constantly carried on by these membranes, prove that they possess the insensible contractility.

These membranes are not affected by diseases of other organs. In acute diseases of important viscera, while the skin, the mucous surfaces, the cellular tissues, the nerves, &c. exhibit a greater or less sympathetic disturbance, the synovial membranes are completely quiet. In this respect they resemble the bony, cartilaginous, and fibrous systems.

Development of the Synovial System.—The membranes are proportionally large in the fœtus and child, because the articular surfaces are large; they are also very thin. There is nothing peculiar in the synovia. The membranes grow more dense, and less transparent, in the old subject, and produce less synovia: they acquire a rigidity, which is unfavourable to motion. But they do not become ossified.

Synovial membranes are sometimes accidentally developed. When the head of a bone is dislocated and not replaced, a smooth moist cyst is formed round it, by condensation of the surrounding cellular membrane, having very much of the appearance of a synovial membrane, and performing its office in facilitating the motions of the part.

Synovial System connected with the Tendons.—This entirely resembles

MEMBRANE.

resembles the preceding system in its nature, and differs from it only in situation: often indeed they are confounded together: thus those, which belong to the heads of the gastrocnemius, to the extensors of the knee and to the popliteus, are continuous with the joint of the knee, the same membrane belonging both to the articulation and to the tendon. Very few of these tendinous synovial membranes are found in the trunk, almost all of them occupy the limbs, in which they favour the motions of the tendons. They are found, 1, where a tendon turns over a bone at an angle, as at the passage of the peronei behind the outer ankle, and of the obturator internus over the ischium; 2, where a tendon glides against a bony surface without making any turn, as the tendo Achillis at the os calcis, the gluteus maximus at the great trochanter, &c.; 3, where a tendon plays in a fibrous sheath, as the flexors of the toes and fingers on the phalanges.

The synovial membranes of tendons, like those of the joints, form bags without any opening, expanded on one side over the tendons, and on the other over the organs with which the organs are in contact. From this disposition, and from the nature of the fluid with which they are lubricated, they have been called *burfæ mucosæ*, under which name they are generally described. It follows, that every tendinous synovial membrane must possess two surfaces, a smooth one, forming the interior of the bag, which is every where free and contiguous to itself, and an adherent one attached to the surrounding parts. The smooth surface is constantly moistened with a fluid of the same nature as the synovia of the joints, formed like it by exhalation, and not, as some have represented, by reddish fatty bodies placed on the outside of the membrane, which do not exist in general, and have no glandular texture when they do exist. This fluid in general is less abundant than in the joints; but the quantity varies in the different *burfæ*. It is sometimes increased in quantity, forming a species of dropsy, which is called a ganglion: this kind of tumour never exists in the fingers, because the fibrous sheaths which include the synovial membranes of their flexor tendons are unyielding. Often these ganglia are completely new formations, cysts developed in the cellular tissue.

The adherent surfaces of the membranes are fixed on one side to the tendons, to which they are closely attached, but not with equal firmness in all cases; it may be detached from the obturator internus, the psoas, &c., but in general it cannot be separated. On the other side it is fixed to the periosteum, which generally assumes the structure of fibro-cartilage. To this the membrane adheres as the articular synovial membranes do to the cartilages of their respective joints; that is, we cannot detach it, and shew it separately, but infer its existence from the polished surface of the part. Sometimes it is expanded over a fibrous capsule, instead of a bone. After covering the tendon, it is continued in some cases over a portion of the muscular fibres, as in the obturator internus. Where the membranes are reflected from the tendons to the surrounding organs, they are covered in general by a considerable quantity of cellular tissue: but in the case of tendons running in fibrous sheaths, they line those sheaths.

These membranes must obviously participate in the motions executed by the tendons, to which they belong: they will be drawn backwards and forwards as the tendon itself is moved.

The very various forms, which the bags of the tendinous synovial membranes present, may be reduced to two general modifications. The one kind are rounded bags, covering only one side of the respective tendons, having no internal

folds, and never surrounded by fibrous sheaths. The others, belonging particularly to the flexors of the toes and fingers, and to other tendons about the wrist and ankle, conhit in the first place of a cylindrical sac lining the canal, in which the tendon runs: it is then reflected over the tendon, which it covers on all sides, composing for it a complete sheath. This kind of membrane thus represents two cylindrical canals, one lining the bone and fibrous sheath, and the other covering the tendon, continuous with each other at the two ends, where the reflexion produces two cul-de-sacs. Folds are often seen in these, passing from one part of the membrane to the other: the synovial membranes of the digital flexors exhibit them.

Their organization is exactly analogous to that of the articular membranes. The structure is principally cellular, and distinguished by its softness: very few blood-vessels are seen, but the exhalants and absorbents prevail. The former become distended with blood under inflammation, and give to the membrane a more or less deep red tint. In this state synovia is not produced; and sometimes adhesions take place.

The vital properties, and those resulting from organization, seem not to differ from those of the preceding system. Like it, this is never affected sympathetically: all its diseases are local.

The obvious effect of these membranes is to facilitate the motions of the tendons over the bones and other parts in contact with them, by giving to the opposed surfaces a perfect polish, and lubricating them with a slippery fluid.

They are thin and delicate in the fetus and child, more dense and firm in the adult, and become rigid in old age: at the latter time they produce but little fluid, and are consequently dry. This state probably concurs with other causes in impairing the power of motion in the old subject.

Several of the *burfæ mucosæ* vary in different bodies. Sometimes this is only a mass of cellular tissue, in the place of that belonging to the gluteus maximus. These *burfæ* are always very dry when they exist, so that synovia can hardly be seen in them. They resemble, in that respect, the articular synovial membranes of the ribs, clavicles, &c.

Fibrous Membranes.—These comprehend the fasciæ of the limbs, &c., the periosteum and perichondrium, the dura mater, sclerotica, albuginea, the proper coverings of the kidneys, spleen, &c., the covering of the corpus cavernosum, &c.; all forming exterior investments of the organs to which they belong. These parts are not, like the stomach, intestines, lungs, bladder, &c., which are covered by serous membranes, subject to alternate enlargement and diminution: that would not suit the properties of fibrous organs. The membranes are moulded exactly to the form of the parts, and, with the exception of the dura mater, do not present the numerous folds seen in the serous membranes. Both their surfaces are adherent, in which they differ from the serous, mucous, and synovial membranes.

One of these surfaces, intimately connected to the organ, seems to send numerous processes into it. In the testes, corpus cavernosum penis, spleen, &c. are seen numerous fibres crossing in various directions, and attached to the fibrous membranes of these organs. On these, together with the membrane, the form of the part seems greatly to depend. Bony matter is thrown out in a rough and irregular form, when the periosteum no longer covers it: the figure of the testis is altered, when the albuginea is injured, &c. These fibres in the interior of the organs are not, however, of the same nature with the fibrous membranes: they cannot be deemed processes of those membranes. By boiling the corpus

pus cavernosum penis, or subjecting it to any other process, the interior spongy tissue and the outer fibrous covering always remain distinct in their appearance; there is no continuation of the one into the other.

The opposite surfaces of fibrous membranes are joined to the surrounding organs with various degrees of firmness, from the loose attachment of the corpus cavernosum to the close adhesion of the dura mater. In general, the fibrous membranes and other fibrous organs have a great tendency to adhere closely to the serous and mucous organs. The connection between the dura mater and arachnoid, the tunica albuginea and vaginalis, the fibrous capsules and the synovial membranes, shews this in the serous membranes. So intimate is the connection in these cases, that it is not possible to separate the parts by dissection in the adult. When fibrous and mucous surfaces meet together in an organ, they become completely confounded: this is seen in the pituitary membrane, in the membrane of the sinuses of the nose, in the ear, &c. In all these parts, the periosteum is not separable from the mucous surface. The vas deferens, the Fallopian tube, the ureter, seem to be fibro-mucous organs.

These membranes have, in general, a very close texture, and a remarkable thickness: they consist of a single layer. The dura mater seems to form an exception to this rule, by the folds which form the falx and the tentorium cerebelli; but we cannot point out two distinct layers in the membrane, except at the sinuses. They possess more vessels than all the other divisions of the fibrous system, and are perforated by numerous apertures for the passage of these vessels, which in general pass through them, in order to arrive at the organs which they cover. These openings, each of which is larger than the branch perforating it, distinguish the fibres from the serous membranes, which are always reflected, instead of being opened, for the purpose of admitting the vascular system into their respective organs. The description of the particular membranes will come under that of the organs to which they belong. We shall except the periosteum, which ought to be considered in a general way, both because it is a covering common to the whole bony system, and because it is a kind of connecting centre to all the organs of the fibrous system.

The *periosteum* surrounds all the bones in every part, except where they are covered by cartilage. It is hard, strong, of a greyish colour, remarkably thick in the early years of life, and proportionally thinner in the adult. The old anatomists conceived that it was prolonged from one bone to another, over the articulation, so as to constitute a continued bag for the whole skeleton. This is an incorrect notion. The periosteum is interlaced at the joints with the ligaments, which may thus be regarded as a medium of communication between the coverings of the different bones. It is in this way only that we can regard it as continuous over the whole skeleton. It does not exist in the crowns of the teeth, nor on the bony productions rising from the head in certain animals. It is feebly united to the bone in infancy, particularly at the middle of the long bones: the adhesion becomes strong in the adult; and is extremely firm in the old subject, in which the membrane is very thin. Numerous processes extend from this membrane into the bone: the number of these is much greater at the extremities of the long bones, and on the short bones, than at the middle of long, and over the surface of broad bones; all which we should have inferred, from observing the proportion of apertures in these situations. These prolongations accompany blood-vessels, and line the canals which penetrate the bones: they do not reach the medullary cavity, but are confined to the bony tissue, establishing relations between it and the

membrane from which they proceed. In consequence of this connection, the destruction of the periosteum is accompanied by the death of the corresponding part of the bone.

The relations of the periosteum to the surrounding organs are very various: in most cases the muscles lie on it, and are connected, according as they are capable of executing more or less considerable motions, by looser or closer cellular texture.

The direction of the fibres in this membrane is nearly analogous to that of the bones, particularly in the long and short ones; but it has not a radiated arrangement in the broad bones. They vary in length, and the superficial ones are the most extensive. Its vessels are derived from those of the neighbouring parts. Their ramifications form in the membrane a net-work, which injections shew very clearly, particularly in children: they are either lost in the membrane, or penetrate the tissue of the bone, or return into the neighbouring parts to form various anastomoses.

The periosteum receives the insertion of the tendons, ligaments, and aponeuroses. This attachment appears foreign to the bone in the child. If we detach the membrane, all these organs are brought away at the same time; but, as ossification extends to the internal plates of the periosteum, the fibrous organs seem identified with the bone in the adult.

In the fœtus it is soft, spongy, and containing much gelatinous fluid: it dissolves in water readily. Its fibres at this time are indistinct: they become more visible as age advances; the softness of the tissue is diminished, and its strength increased. The periosteum is extremely firm in the old subject: it resists ebullition almost as much as the ligaments. When the bones are boiled, it cracks in various parts, because its fibres are shortened and detached from the bone; but that which remains adherent is very difficultly converted into gelatine.

The functions of this membrane do not seem to be very satisfactorily ascertained. An opinion has been entertained that it serves to protect the bone from the pressure of the surrounding moveable organs, as the muscles and arteries. It has been supposed to be very much concerned in the formation of bone; but we cannot accede to this view of the matter. (See BONE.) It may form a kind of barrier, containing the progress of ossification within certain bounds. Bichat regards it as connected essentially with the functions of the fibrous organs attached to it. He considers that it is placed on the bony system, as a solid point of support, which enables it to bear the efforts of the various fibrous organs.

The *perichondrium* is a membrane surrounding the cartilages, except those belonging to the articulations, analogous in its structure and offices to the periosteum. It is thin and fibrous; less closely united to the organs, which it covers, than the periosteum, because they have fewer pores, and therefore receive fewer processes from the membrane: hence there is a less intimate connection between its life and that of the cartilage, than between that of the bone and the periosteum. Its blood-vessels are few. Bichat removed it from the thyroid cartilage of a dog, and no exfoliation followed.

For the vital properties of the fibrous membranes, the reader is referred to the article *FIBROUS SYSTEM*, where the subject is considered in a general point of view.

The compound Membranes.—The serous and fibrous membranes have a great tendency to adhere together, and exhibit this character wherever they are brought into opposition, as in the case of the arachnoid and dura mater, the tunica albuginea and vaginalis, the synovial membranes and fibrous capsules.

capsules of joints, &c. The two component parts of such membranes are so closely united, that it is impossible to separate them by dissection: however, they are clearly distinguished by their texture and properties.

The serous and mucous membranes are generally separated by a muscular stratum, as in the intestinal canal and bladder; and where they are not, as in the gall-bladder, the cellular substance belonging to the mucous is too copious to admit of the close adhesion necessary to form a compound membrane.

The fibrous and mucous membranes are in many cases consolidated together, as in the ureter, vas deferens, pituitary membrane, lining of the tympanum, &c. They are connected inseparably in these situations. In all, the mucous is the most important, as it is the seat of the functions of the part: the fibrous is accessory, and furnishes additional support and strength to the mucous.

There are several membranes, which do not come under the preceding classification: such are the fibrous coat of the arterial system (see HEART); the lining both of the arteries and veins (see HEART); that which lines the medullary canal of bones, and contains the marrow (see MEDULLARY System); the iris and choroid coat, and retina (see EYE); and the pia mater, see BRAIN.

MEMBRANE is a term also frequently applied in the English language to the cellular substance; *cellular membrane* therefore is exactly equivalent to the latter expression. A general account of this very important animal tissue is given under the head of *CELLULAR Substance*: we propose to consider it in a more extensive way in the present article, and particularly to exhibit the ingenious views of Bichat, as contained in the first volume of his "Anatomie Generale."

The cellular substance, surrounding the various organs of the body, forms at the same time a connecting medium which joins them together, and an intermediate structure which insulates them. It extends into the interior of the same organs, and is essentially concerned in their structure. We should regard it, first, in relation to the particular organs; and secondly, in a general manner, independently of other parts. In the first of these divisions we have to consider the cellular organ under two points of view: 1st, as composing & covering for each part; and 2dly, as forming one of the essential bases of its structure.

I. *Of the exterior Cellular Texture of each Organ.*—Some parts are covered on one surface only, as the skin, mucous and serous membranes, arteries, veins, and absorbents; while others are surrounded on all sides.

The corion of the skin contains, as we have shewn under the article INTEGUMENTS, a large quantity of cellular tissue, and anatomists have generally regarded it as formed by a condensation of this tissue. Besides this, a stratum of cellular substance, varying in quantity and density, lies under it in all parts of the body. At the median line the subcutaneous tissue is rather more dense than in other situations, and adheres more closely to the skin; this may be seen in the face, on the sternum of the linea alba, and over the spine. Bichat regards it as marking in an obscure way the symmetrical division which characterises the organs of the animal life; but we cannot insist much on it, as there are no traces in the neck. This author states that the air was confined to one side in some of his experiments on emphysema; but that it generally passed the line.

1. The subcutaneous tissue is remarkably dense under the scalp; it is loose and abundant in the face. By its laxity in the trunk it favours the motions of the large muscles in that situation. It is distributed almost uniformly in the limbs, except that it is dense in the palms and soles, where

consequently the skin is more closely united to the aponeuroses, and anasarous depositions are formed with difficulty. It is also more dense and close over the annular ligaments; and hence the constrictions which the limbs of children present in these situations, as the fat does not penetrate easily into cells so closely approximated.

The subcutaneous cellular tissue bestows on the skin its power of motion with respect to the organs that it covers; this is exemplified in the movements of the trunk and limbs, in the effects of external bodies brought in contact with the surface, in the cutaneous coverings acquired by large tumours, as hernia, farcocele, &c. at the expense of the surrounding parts. From the same cause arises the facility of motion in organs situated under the skin, as the muscles.

It contains a larger proportion of serous fluid than other parts of the cellular substance, and is more liable to preternatural accumulations of that fluid, probably on account of its greater laxity. If the skin and subjacent tissue be stripped from an anasarous lower extremity, it will appear very little larger than a healthy limb treated in the same way.

2. The mucous membranes have the same relations to the cellular substance as the skin, of which they are continuations, and to which their structure bears considerable analogy: the structure occupying their surface is called by Bichat *tissu solumneux*. It is much more compact and dense than the former, and the adhesion of the mucous system to the surrounding parts is consequently much more close. Hence it is difficult to separate the mucous membranes perfectly, and impossible to produce emphysema under them artificially. Air is never seen in this tissue in the most extensive natural emphysema, nor is water ever deposited in it in the most general anasarca. Indeed the hollow organs would have their functions destroyed by the obliteration of their canals, if the submucous were liable to the same distention as the subcutaneous tissue. This firmness in the former tissue enables it to serve as a point of attachment to the muscular fibres, which belongs to the stomach, intestines, bladder, &c.

3. The adherent surfaces of serous membranes are covered by cellular tissue, called by Bichat *tissu sousecreux*, which is in general loose and abundant. In some parts, however, the union is so close that no cellular substance can be discerned; as in the tunica vaginalis and albuginea, the arachnoid and dura mater, &c.: these constitute sero-fibrous membranes.

4. Arteries and veins are connected to the surrounding organs by a loose and easily lacerable cellular substance. (See the account of their structure in the article HEART.) The absorbing vessels are probably furnished with a corresponding covering; but their minuteness prevents us from ascertaining this point by direct investigation.

5. The various excretory tubes are surrounded by cellular tissue. All these have a mucous lining, which is covered by a dense and firm stratum of matter, differing in the different tubes, and the exact nature of which is probably not yet well understood. It seems doubtful whether we ought to assign this exterior covering to the cellular tissue. See GLAND

The organs of the body, except those which have been just mentioned, are surrounded on all sides by a more or less abundant cellular stratum, which insulates them, and interrupts those communications which would connect the vitality of one part to that of another in too intimate a manner, if their juxtaposition were immediate. The serous vapour and fat of the cells probably contribute to this insulation of vitality; but the essential difference, between the proper life of the cellular substance, and that of the organs which it incloses, renders that tissue very capable of fulfilling this

office, independently of the fluids which it contains. The confinement of diseases to particular organs is ascribed by Bichat to this insulation of their vitality. We meet every day with diseased organs covered by healthy serous membranes, with catarrhal mucous membranes surrounded by sound parts: the numerous cutaneous eruptions do not affect the subjacent organs, &c. On the other hand, diseases are very often communicated from one part to another. A phlegmonous inflammation involves all the surrounding parts: the rheumatic affection of a joint produces exterior swelling, and disease of the ligaments of the knee is accompanied by an analogous phenomenon. Nor are diseases alone communicated from one part to another: the effects of remedies often act in the same way, as for instance, blisters and poultices. If the cellular substance has any influence on these changes, how are we to account for results apparently so contradictory under similar circumstances? Will it not be more philosophical to confess that we are ignorant of the causes, by which the communication of diseases is influenced and modified, than to adopt, in the absence of all direct proof, a mode of explanation which so frequently fails? When Bichat tells us, in cases where disease is confined to one organ, that the cellular atmosphere, by possessing a different kind of vitality, prevents its propagation; and, in opposite instances, that this atmosphere becomes charged with emanations raised from the morbid part, or that its vital powers experience a change analogous to that which has affected the diseased organ, does this apparatus of words impart to us any farther knowledge than that of the simple fact, that morbid changes sometimes are, and sometimes are not, propagated from one organ to another?

The quantity of cellular tissue surrounding any organ bears a relation to the motions which it is capable of executing; and is more abundant in proportion as these motions are more extensive. Hence it is seen in considerable quantity about the large arterial trunks, the eye, the uterus, bladder, the large joints, as the hip and shoulder. By the extension and contraction of its cells it is very capable of accommodating the motions of the organs, particularly their dilatation and contraction. Parts, which enjoy extensive power of motion, and yet have but little cellular tissue on their surface, as the viscera, and the articular ends of bones, are surrounded by serous or synovial membranes. In many instances organs with very little motion are covered by an abundance of cellular tissue: the kidney, testis, thyroid gland, and pancreas are examples.

11. *The internal Cellular System of the Organs.*—After surrounding all parts, this system enters into their substance, and forms one of its principal elements. In those apparatuses, which are an assemblage of several systems, each is united to the surrounding ones by it; as the different coats of the stomach, intestines, bladder, &c. Again, it enters largely into the composition of the organic systems: it surrounds their vascular and nervous ramifications, and unites the various homogeneous parts that compose them. Thus, says Bichat, each portion of an organ has a covering, performing the same office with respect to it, that the general covering does to the whole organ; it forms an atmosphere, limiting and protecting the vitality of each fibre, or serving, (more readily on account of the greater juxtaposition) as a means of communication from one to the other.

This interior cellular tissue is only a means of union, and preserves all its own properties; it is insensible in the nerve, incapable of contraction in the muscle, and unconnected with secretion in the glands. It is often affected alone in an organ; hence the numerous tumours in the liver, which have the glandular tissue perfectly healthy.

The texture of many organs is so close that the cellular tissue is but little apparent, and its very existence has been denied. In tendons and fibrous membranes maceration renders it discernible: ebullition has a similar effect, by dissolving the gelatine which a part may contain. In all instances, even in bones and cartilages, the production of granulations, which are essentially of a cellular nature, demonstrates the existence of this tissue. The conversion of bones into a soft and fleshy state, and the production of fungous tumours in other systems, by rendering the tissue more loose, demonstrate the cellular substances.

Of the Cellular System considered independently of the Organs.—In the interior of the cranium this tissue seems to be almost deficient. Yet the pia mater is formed by it; and a small quantity of a very fine and perfectly transparent kind is seen where the nerves quit the surface of the brain. There is no possibility of demonstrating cellular tissue in the substance of the brain, unless perhaps by its fungous tumours. Through the optic foramina and the superior orbital fissures, the cellular substance of the cranium communicates with that of the orbit; through the holes of the cribriform plate with that of the nose; through the various apertures of the basis crani, and the numerous but minute pores about the sutures, with the corresponding external parts. It is more abundant, but still in comparatively small quantity, on the outside of the cranium, and communicates evidently with that of the face, particularly in front.

It is very abundant in all parts of the face: the orbits are filled with it; the hollows of the cheeks, bounded by the buccinator, masseter, and zygomatic muscles, contain it in large quantity, as well as all the parts about the tongue. The nose and its sinuses have a very small proportion. On its existence in greater or smaller quantity, the appearance of the countenance, with respect to fulness or sharpness, depends. The expression is regulated by the muscles. It communicates with that of the neck by its subcutaneous portion, by what accompanies the vessels, particularly in the triangular space lodging the parotid, and by the intervals of the muscles about the root of the tongue.

Very little is found in the vertebral canal, between the arachnoid and the medulla spinalis and its nerves: there is none between the arachnoid and dura mater. It is more copious on the outside of the latter, particularly towards the lower parts, where it is very loose. On the outside of the spine the muscles are very numerous and closely arranged, and the cellular tissue very sparing behind; it is copious on the front. It accompanies the carotids on the neck, the aorta and its large branches, the azygos, and the vena cava in the chest and neck. This disposition is very favourable to the formation and extension of depositions of pus.

The neck is a very muscular part, and contains much cellular tissue, besides what belongs to the spine, particularly on its sides, where the lymphatic glands are found. In this situation it communicates with that of the chest, by the superior opening of the latter cavity. It also communicates with the upper limbs above and below the clavicles.

The largest quantity of cellular tissue occupies the middle line of the chest: there is much of it in the mediastinum, about the pericardium, and the large vessels. In the parts occupied by the lungs, the quantity is considerably less. The communications between it and the abdominal cellular tissue take place, 1st, at the various openings of the diaphragm, particularly those which transmit the aorta and œsophagus, for the vena cava is too closely united to its opening to allow of such communication: 2^{dly}, through the intervals of the diaphragmatic fibres, particularly at the triangular space left between those attached to the xiphoid cartilage.

cartilage. There are communications from within outwards at the intervals of the intercostal muscles; but these are very trifling, and consequently the internal affections seldom have any influence on the external parts.

On the outside of the chest, the cellular tissue is abundant above; it encloses the mammary glands, and produces the elegantly rounded forms which charm us in the female; it contributes to the bold prominence which is the attribute and character of male strength. There is much of it under the pectoral muscles, but the quantity decreases very sensibly downwards.

The abdomen contains more cellular tissue than the chest. It is accumulated in large quantity about the large arterial and venous trunks, and accompanies them to their respective organs. It is also very abundant along the back of the peritoneum, particularly about the kidney, but much more sparing on the front and sides of the abdominal parietes. It communicates with that of the pelvis all round the peritoneum, and with that of the lower limbs at the inguinal canal, and more particularly at the crural arch. In the latter situation, the pus generally descends in lumbar abscesses.

The outside of the abdomen has the usual subcutaneous stratum, which is continuous with that of the pelvis and lower limbs. Between the abdominal muscles there is a moderate quantity. The outer and inner portions of cellular substance communicate through the muscles, particularly at the posterior and lateral regions: the fluid of lumbar abscesses sometimes takes this direction and presents in the loins.

Few parts have a more abundant distribution of cellular tissue than the pelvis; it is placed very copiously round the bladder, rectum, and uterus. The great dilatations of which the organs are susceptible, and the unyielding nature of the parietes of the pelvis, explain this arrangement. The nature of the abscesses, which occur about the anus, and the diffusion of urine from ruptures of the urethra, are modified by this structure. It communicates with that of the lower limbs by the ischiatic notch, the foramen ovale, and the arch of the pubes. The outside of the pelvis has also much cellular substance: it is most copious in front, about the generative organs, particularly in the labia and scrotum, and more abundant on the sides than behind.

Both in the upper and lower limbs the quantity of cellular tissue constantly decreases from above downwards. It is very considerable round the upper articulation of each: the hollow of the axilla is almost entirely filled with it; the bend of the thigh does not contain so much. There are large cellular intervals between the muscles of the arm and thigh. The elbow has much less than the ham, the deep hollow of which holds a large quantity. In the fore-arm and leg the muscles are more approximated, and the cellular strata consequently thinner. Towards the lower part of these two divisions of the limbs, it is still more diminished in quantity. Yet the sole contains much more than the palm. The difference in the extent of motion in the different parts of the limbs corresponds to this arrangement.

Concerning the general forms of the cellular tissue, the figure and permeability of the cells, and the serous fluid which lubricates them, we refer to the article *CELLULAR Substance*. We have only to remark here, that the capacity of the cells is extremely various. When distended with fat or serum, they are two, three, or four times as large as in the empty state. These variations in capacity produce the differences in the volume of the body in the states of embonpoint or emaciation, in which all the other parts, as nervous, tendinous, and muscular fibres; &c. remain unchanged, and the cellular tissue alone is altered.

When the cellular substance of a living animal, or of one recently killed, is exposed to cold air, a vapour arises from it, as it does from serous surfaces. This moisture seems just sufficient, in the natural state, to maintain the cells soft and pliant.

To the general observations on the fat, in the article *CELLULAR Substance*, we have a few remarks to add. Its proportion varies in the different organic systems. The arterial and venous tunics, the lymphatic glands, the brain and spinal marrow, contain none. There is always some in the intervals of the nervous fibres, as may be proved by drying them. Generally the muscular fibres of the animal life contain a tolerably large proportion; but those of the organic very little. Its place is supplied in the bones by the medullary structure. The cartilaginous, fibrous, and fibro-cartilaginous systems, are almost entirely destitute of it. Sometimes it is observable in the glandular system, as in the parotids, and about the pelvis of the kidney; but in other parts, as the liver, prostate, &c. no trace is discernible. The serous and cutaneous systems are surrounded by much fat, but contain none in their tissue: the same observation is true of the mucous also. The epidermis and hair have none. Thus we see that the organic systems in general contain very little fat: the organs themselves have but a small quantity between their different parts. In general there is hardly any between the coats of the stomach, intestines, bladder, &c.; between the periosteum and bone; the bone and cartilage, &c. It is accumulated principally in the intervals of the organs. In this point of view the cranium and face exhibit opposite arrangements; it is abundant in the latter, and deficient in the former, particularly on the inside. There is a tolerable quantity in the neck. Very little exists about the lungs, but much round the heart: and there is a large deposition on the outside about the breasts. In the abdomen, it lies principally behind, in the neighbourhood of the kidney, in the mesentery and epiploon: there is much in the pelvis about the bladder and rectum. It follows the same arrangement in the limbs as the cellular tissue, being more abundant at the upper parts, and about the large articulations, than in other situations.

All the fat in the child is concentrated under the skin: the omentum, and indeed the rest of the abdomen, contains none, except perhaps a few flocculi about the kidney. The chest contains hardly any more, and the intermuscular tissue is almost every where free from it. In the adult, the abdominal fat exceeds the proportion of the subcutaneous: the rounded contours, by which all the muscular forms are concealed in the early years, are rare at the latter period. These observations, however, concerning the proportions of fat, as connected with different ages, admit of frequent exceptions.

The fat is sometimes accumulated in an unnatural quantity: it constitutes in such cases a real disease. (See *CORPULENCE*.) The opposite circumstances to these, which produce this unnatural load of fat, cause emaciation.

The fat is almost always firm in the dead body, but it approaches more nearly to the liquid state during life: its condition, however, is not uniform in all parts, the subcutaneous being the most solid, and that of the omenta most fluid. It is not so fluid in the living body as exposure to heat renders it after death: its consistence indeed must depend on other causes than temperature, as it varies so much in different parts of the body under the same heat. It is whitish and very firm after death in young animals: hence there is a striking contrast between the solid feel of the skin in a young subject, and the yielding sensation which it offers in the adult. It is collected into small and more or less rounded granules

granules in the fetus; a remarkable and almost insulated globular portion, which can easily be drawn out entire, occupies the hollow between the masseter and buccinator muscles. It turns yellow as age advances, and acquires a different odour and taste: every one must have noticed the difference between that of veal and beef, and the distinction is not less strongly marked between that of a young and old person.

A yellowish, transparent, and semitranslucent substance, with a gelatinous aspect, is found about the hearts of those who have died from dropsy, phthisis, or other tedious debilitating diseases, and occupies the place of fat. It is also seen in other situations, but less frequently; and seems rather gelatinous than oily.

We have nothing to add to the remarks in the article *Cellular Substance*, concerning the mode in which the fat is formed; and we refer the reader to *FAT* for the history of its chemical properties.

Organization of the Cellular Substance.—The proper tissue, which composes the basis of this system, consists of a transparent web, disposed in plates of an uniform appearance, and so thin that they may be compared to soap bubbles; and of whitish filaments crossing these in various directions, and forming with them cells. This structure may be seen by taking a portion of the cellular matter of the serotum, extending it and observing it against the light. The filaments are approximated, and seem to touch each other when the part is left to itself; when it is distended, the intervals left between them are larger, and the intermediate laminae more distinct. Bichat conceives that the filaments are absorbents or exhalants, or made up by the union of the laminae, where they form cells. The plates are tolerably dense when the cellular tissue is contracted; when air is forcibly impelled among them, they are reduced into a kind of thin froth, in which we could hardly suppose that vital properties could reside.

In all parts where fat or serum is deposited, we see true cells, communicating together; and the great accumulations of such fluids are deposited in these cells. But the submucous tissue, and that which composes the outer coverings of arteries, veins, and excretory tubes, seems to be composed entirely of condensed and approximated fibres, without any plates, and consequently without any cells.

Composition of the Cellular Tissue.—Chemists have placed it in the class of white organs, or such as furnish a large quantity of gelatine. Solution of tan causes a considerable precipitate from water, in which it has boiled. Yet the effect of various agents on it is very different from what they produce on the fibrous, cutaneous, cartilaginous tissues, &c.

It is quickly dried in the air, but without assuming the yellow tint of the fibrous tissue; when plates of it are dried, it exactly resembles a serous membrane treated in the same manner. In this state it is perfectly flexible; it recovers its original appearance only in part, when immersed in water.

It yields to putrefaction less readily than most other tissues, than the glandular and muscular organs for example. This property is particularly observable in the submucous tissue, and in that which forms the outer covering of arteries and veins. The same observation may be made concerning maceration: the exterior tissue of arteries is hardly changed in three months; the subcutaneous, the intermuscular, and other parts of the system, yield more quickly. It resists longer when exposed alone, than in conjunction with parts which decay quickly; and this resistance is the more remarkable, since the nature of the tissue renders it

accessible to the action of water at all points. The latter circumstance must also render it more subject to the influence of ebullition; yet it does not yield quickly, and the exterior tissue of arteries, excretory tubes, &c. resists for a long time. The phenomena produced by boiling are analogous to those observed in other organs treated in the same way. It is not changed until a froth rises to the surface; it is then reduced in size, rendered firmer and elastic, and is curled up. After a certain time, as the boiling is continued, it becomes soft again, and is broken by the slightest force. The continued action of boiling water gradually melts it.

The gastric juice acts on it less quickly than on the muscular fibres.

Thus the cellular tissue seems to combine two opposite characters, softness and pliancy; by which it facilitates the motion of organs; and considerable resistance to the operation of various agents.

This tissue is distended with air in the bodies of the drowned, so that they float: probably the air is disengaged from organs containing a great deal of blood, as the muscles, glands, &c., and not from the cellular tissue. A similar phenomenon is observed in bodies buried under the earth, out of the contact of air; but it does not often take place in those left in the open air.

The blood-vessels of the cellular tissue are not numerous in the natural state. It is whitish, when observed in a living animal: large trunks pass through it to the neighbouring parts, and send off branches, which are lost in the tissue. After some exposure the number of these vessels is increased, as the red blood gains admission into the exhalants.

Successful minute injections have a similar effect in the dead body; they make it appear like a vascular network.

The exhalants are proved by the production of apparently new vessels where the part is exposed during life, and by the effect of injections; by the natural and the morbid depositions of serum and fat into the cells, &c. These vessels are very numerous in the present system: they are subservient to its nutrition, and to the habitual exhalation, of which it is the seat.

Absorbents cannot be shewn by actual inspection, nor by injection; but their existence is proved by phenomena: 1, by the natural and constant absorption of the serum and fat; 2, by the removal of unnatural accumulations of either of these fluids; 3, by the absorption of air in emphysema, or of fluids injected into the cells, &c. This system, indeed, seems to be a principal source of the absorbing vessels, at least of such as convey lymph. Some have considered it as formed exclusively of exhalants and lymphatics. Each cell is a reservoir, placed between the exhalants which terminate in it, and the absorbents which arise from it; we see the mouths of neither of these vessels: the cells are on a small scale what the serous cavities are on a larger.

Many nerves are seen going through the cellular tissue; but we do not know that any filaments terminate in it.

Properties of the Cellular System.

1. *Properties resulting from Organization.*—The extensibility of tissue is seen on a variety of occasions: all the motions of the body call it into exercise; the arm cannot be elevated without the cellular substance of the axilla being drawn out to twice or thrice its natural length, and the motions of the neck, the thigh, and indeed all other parts, present analogous phenomena in different degrees. Whenever any organ is drawn away from a contiguous one, the connecting tissue must be lengthened. In the distentions of the hollow viscera there is a similar

proccs. In the accumulations of serum or fat, of which this tissue is so frequently the seat, in the formation of tumours of all kinds, in the distentions of the abdomen or other cavities, the exercise of this property is clearly observed, and indeed is absolutely necessary to the production of the phenomena.

The different divisions of the system possess this property in very different degrees. The subcutaneous, the intermuscular, and that which covers serous membranes, enjoy it to a much greater extent than that which surrounds arteries, veins, and excretory tubes: from its indisposition to yield in the latter case arises the slow growth of aneurisms. Wherever laminae, and consequently cells are found, the extensibility can be brought suddenly into action: thus emphysema distends the whole body to an enormous degree in a very short time, and fractures and contusions are followed by very rapid and considerable tumefaction.

When the distending force is carried beyond a certain point, the tissue is first rendered very thin, and then broken. No natural motion can be carried to an extent sufficient to produce this effect; the tissue of the axilla may be distended three times as much as it is in the elevation of the arm, without any rupture. And this effect is still further prevented by the kind of locomotion which it admits; when forcibly drawn in any direction, it drags the neighbouring tissue, and thus can change its situation in some degree. Thus, in large swellings of the scrotum, the cellular substance of the abdomen, perineum, and thighs, is brought over the part.

Inflammation entirely destroys this property. In the induration accompanying cancerous affections the cellular tissue is actually rendered very brittle.

The contractility of tissue is observed, when the causes of extension cease to operate; as when a limb, after being extended, is restored to its former position, when fat, serum, or tumours are removed from the cellular substance, &c. If a wound be carried through the skin and cellular membrane, the edges are separated to a certain degree. This power exists in its greatest energy in youth, and is gradually weakened as old age advances. When a young man is emaciated, the skin is adapted closely to the organs, and preserves its tension: in an old person, on the contrary, the integuments are loose and flabby, because the subjacent tissue does not contract.

2. *Vital Properties.*—This tissue, in its ordinary state, does not possess animal sensibility; it may be cut, torn, or distended with gases without causing any pain, unless the nervous filaments passing through it should be accidentally irritated. In disease, on the contrary, the sensibility may be exalted to such a pitch, as to produce the most acute pain; for example, in phlegmonous inflammation.

The organic properties are very strongly marked in this system. The deposition and absorption of the fat and serum are performed under their influence. All substances are not in the same relation to the absorbing power. Blood, lymph, and milk, when introduced into the cellular substance, are taken up like the serum or fat. On the contrary, urine, bile, saliva, and other fluids designed to be expelled from the body, produce inflammation, and are not absorbed. Water and air artificially introduced are removed by the absorbents. Wine and other irritating fluids excite inflammation, and are expelled with the pus formed in consequence.

The cellular organ enjoys sensible organic contractility to a certain degree: this is evidenced in the corrugation of the scrotum from cold. It seems to be the first obscure rudiment of that power, which in a higher degree belongs to the muscular fibres.

The sympathies of the cellular with other systems are

very numerous, but cannot easily be appreciated, on account of its being so widely disseminated, and concurring in the structure of all the organs. In acute affections of a part, as the lungs, stomach, &c. abscesses often take place, and the critical suppurations seem to be a sympathetic phenomenon. Edema often comes on suddenly in acute diseases. But the influence of the principal viscera on the cellular tissue is particularly shewn in the alterations of their structure consequent on chronic disease. The slow affections of the heart and lungs, of the liver, stomach, spleen, uterus, &c. are attended in their latter stages by a more or less general anasarca. It seems now to be pretty generally agreed on, that the effusion in all these cases is symptomatic, and results from the influence of the affected organ on the cellular tissue. The very various conditions of the cellular substance in the dead subject, may be probably referred to the effect of the particular disease which has proved fatal.

It also acts upon other parts, when it is originally affected. Phlegmonous abscesses, when large, produce various affections of the brain, heart, liver, stomach, &c.

It is clear, from the preceding observations, that the vital forces exist in a very marked degree in the cellular system; in this respect it is very different from the white organs, such as the aponeuroses, tendons, cartilages, ligaments, &c. among which it has been ranked, and which are remarkable for the obscurity of their vital powers, and the slowness of their functions. Inflammation passes through its course with great rapidity in this system, and the fluid, which results from it, forms in its colour, consistence, and other properties, the standard by which we judge all kinds of pus. Yet that which comes from a bone, a muscle, a mucous membrane, &c. is equally good and laudable pus, as what is formed in a phlegmon.

Does the cellular tissue assume any peculiar vital modifications in the organs, of which it enters into the composition? This is not known.

However, these observations apply to it only in the intervals of parts, abstractedly from all combination of its structure with them.

We must not pass unnoticed the very marked difference between the generally diffused tissue made up of laminae and filaments, and that modification, consisting only of the filamentous part, which surrounds mucous surfaces, blood-vessels, and excretory tubes: the latter is very seldom the seat of inflammation or tumours. It very often places a boundary to the affections of the former, and thus protects the organ which it includes. The tissue surrounding the axillary or inguinal artery is often generally inflamed or ulcerated, and the vessel remains unaffected, &c.

The cellular tissue is distinguished from all others, by its reproductive properties, by its power of becoming elongated and growing, of forming what are called granulations, when it has been cut or divided in any way. Hence are explained the formation of cicatrices, tumours, cysts, &c. The reparation of injury, therefore, is chiefly confided to this tissue; and it goes on nearly alike in all parts, as all contain cellular substance: parts which have none of this never granulate.

Bichat states, that the granulations are small cellular vesicles, filled with a thick fatty (lardacée) substance, and not admitting distention by inflation of the surrounding tissue. They are developed separately and irregularly over the wound, unite at their bases, and thus form a kind of provisional membrane, which completely protects the subjacent parts from the contact of air, until the completion of cicatrization. The surface of this is tuberculated, and it differs in that respect only from a serous membrane. This explanation

nation of the process of cicatrification is confirmed by various considerations. Granulations are formed most readily, and wounds are healed most quickly, where the system is the most abundant; cicatrification proceeds slowly where the cellular tissue has been extensively removed. Maceration reduces all granulating surfaces to this common basis. The nature of granulations is every where the same, whatever organ, whether muscle, cartilage, skin, bone, ligament, &c. may have produced them. They null, therefore, be produced from a tissue common to all organs, and this is the cellular substance.

The red aspect of granulations has led to the opinion, that they are a vascular expansion; but the appearance admits of an easier solution. The cellular membrane is crowded with exhalant and absorbent vessels, into which the red blood passes under inflammation. As the granulations are cellular, and in a state of inflammation, they exhibit the redness of phlegmon or erysipelas, which depends, not upon the elongation of vessels, but simply on the transmission of red blood through those which ordinarily carry white. Thus, when the inflammation is passed, the membrane resumes its natural colour; and granulations, after the cicatrix is formed, are colourless, because the coloured blood has ceased to permeate them. How can we suppose red vessels to be generated in structures where they have no primitive existence? for tendons and cartilages granulate.

The process of nature is completely analogous in repairing the injuries of internal organs, as bones, cartilages, muscles, &c., where there is no exterior wound. The ends of a broken bone become inflamed, and covered with a cellular production. These granulations form a secretory or rather an exhalant organ, and first separate gelatine, which gives to the callus a cartilaginous nature, and afterwards calcareous phosphat, by which the bone is completed. In other organs the granulations separate in a similar way the peculiar nutritive matter of the organ; and the process does not seem to be at all different from that of ordinary nutrition. The granulations of an external wound exhale pus, which is excreted.

As suppuration proceeds, the white substance in the cells of the granulations is removed, the cells are contracted, the tubercular elevations disappear, and are replaced by a thin and smooth surface. It is thin, because the thickness of the granulations depended on the contents of the cells, which are now empty; and it is much less extensive than the original pellicle, because the contraction of the cells draws together in every direction the edges of the divided part. Thus the granular productions, which seemed to be so abundantly developed as amply to repair the loss of substance in the part, are reduced to a thin stratum constituting the cicatrix, of a reddish colour so long as the exhalants are full of blood, and afterwards whitish.

Fungous excrescences from wounds, and exuberant granulations of all kinds, are overgrowths of the cellular substance, exceeding the ordinary laws of cicatrification, which cannot be completed so long as they continue. The development of the cellular system is remarkably exhibited in tumours. The funguses of mucous membranes, as in the antrum, the mouth and uterus, polypi, and cancers, are all the produce of cellular tissue: that system forms their basis, on which a peculiar matter is deposited. It constitutes in short the general basis, or nutritive parenchyma, of all tumours; the formation of which exhibits phenomena exactly analogous to those of ordinary nutrition. All the organs of the body have the same parenchyma of nutrition, which is vascular and cellular; they differ in the nutritive matters deposited in it. In the same way all tumours are cellular, and their

distinctness are drawn from the matters deposited by that tissue, which differ according to the different modifications of its vital powers, produced by its peculiar alterations, of which it is the basis.

Cells have their origin in the cellular substance. Of this we have a proof in the striking similarity which they bear to serous membranes, which are essentially cellular. This analogy prevails throughout their construction, structure, vital properties, functions, and diseases.

Development of the Cellular Tissue—In the early periods of conception the fetus is a soft mucous mass, apparently homogeneous, in which the cellular tissue seems to prevail almost exclusively. Almost entirely fluid at first, it afterwards has the consistence of jelly, and then cellular substance is visible. The abundance of fluid is the cause of its peculiar appearance in the early periods: this fluid is viscous and unctuous, and prevents us from producing artificial emptyness. Nothing can exceed the delicacy of the plates and filaments which compose the cellular texture at this time.

Some time before birth, and during the years that follow it, the cellular fluid is constantly decreasing; the cells become more apparent, and the mass of the system diminished, because as the organs grow, their intervals are rendered narrower. Yet it predominates over the other systems for a long time; hence the roundness of form, the multiplicity and facility of movements in the child. The tissue is still extremely fine.

The vital powers of the system are strongly marked at this age; granulations are produced more readily, and pass through their periods more rapidly than at any other time; wounds are healed more quickly, and tumours are developed, and grow in a much shorter time; serous fluid is quickly removed from the cells.

The cellular tissue assumes a more dense and strong form in the adult, and is in smaller quantity in proportion to the organs; hence the prominences of the latter under the integuments, the energy of muscular forms, &c. Its quantity seems to vary in the different temperaments; and to be greater in the female than in the male.

It becomes still more compact and hard in the old subject; and contains less fluid; hence the dryness and rigidity of parts in old age, and the general diminution of bulk in the body. Its vital powers are diminished, and it no longer maintains the skin close upon the subjacent parts, but allows it to become folded. Bichat, *Traité des Membranes*; and his *Anatomie Générale*, tom. i.

MEMBRANE, *Nictitating*. See NICTITATING, and the preceding article.

MEMBRANES, in *Midwifery* and *Anatomy*, the coverings which surround the fetus while it is contained in the uterus; they are three in number, the decidua, chorion, and amnios. See EMBRYO.

MEME. *Que est Mem.* See QUE.

MEMECYLON, in *Botany*, a name adopted from Dioscorides, whose *μμεκκίλα* is a synonym for the fruit of the *Arbutus* or Strawberry-tree, his *κωμάρης*; and seems to be derived from *μωω*, to desire, or long for, in allusion to the tempting appearance of those berries. The Latin name of the same fruit, *unedo*, carries the idea a step further, implying that nobody would be tempted to eat more than one, because the flavour is by no means answerable to the appearance. Linnæus in his *Flora Zeylanica*, 57, first applied this name to the genus which now retains it, and which is of a shrubby and berry-bearing nature, but does not appear to have any other pretensions to this denomination. Mitchell chose it, with rather more propriety, but too late, for a small American plant, allied to *Arbutus*, which, as *Memecylon* was already pre-occupied, Linnæus called *EPIGEA*; see

MEMECYLON.

that article.—Linn. Gen. 191. Schreb. 258. Willd. Sp. Pl. v. 2. 347. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 355. Juss. 321. Lamarck Dict. v. 4. 88. Illustr. t. 284. Gærtn. t. 127 and t. 179.—Class and order, *Oëandria Monogynia*. Nat. Ord. *Onagrea*, Juss. or rather *Myrti*.

Gen. Ch. *Cal.* Perianth superior, of one leaf, undivided, bell-shaped, turbinate, entire, or obsoletely four-toothed, permanent; cup-like and sometimes furrowed within. *Cor.* Petals four, ovate, acute, equal, spreading, inserted into the rim of the calyx. *Stam.* Filaments eight, erect, awl-shaped, dilated and abrupt at the top; anthers simple, of two distinct lobes, attached to the edges of the dilated top of the filament. *Pist.* Germen inferior, turbinate, containing the rudiments of many seeds; style awl-shaped; stigma simple. *Peric.* Berry globose, crowned with the cylindrical calyx, of one cell. *Seeds* one, two or three, convex.

Eff. Ch. Calyx superior, turbinate, nearly entire. Petals four. Anthers on the edge of the dilated summit of the filaments. Berry crowned with the cylindrical calyx.

Obf. The corolla is said to be monopetalous in Willdenow and Hort. Kew. which is an error of the press in Linn. Syst. Veg. ed. 10, 12, 13 and 14, contradicting the character of four petals, rightly given at the head of the class.

1. *M. capitellatum*. Ceylon Memecylon. Linn. Sp. Pl. 497. Lamarck. fig. 1. (*M. foliis ovatis*; Linn. Zeyl. 57. *Cornus sylvestris*, foliis croceum colorem tingentibus, flosculis ad foliorum alas globosis; Burm. Zeyl. 76. t. 30. Walikaha; Herm. Mus. Zeyl. 4. Kasjavo-maram; Rheede Hort. Mal. v. 5. 37. t. 19.)—Leaves elliptic-ovate, obtuse, on short stalks. Umbels axillary, somewhat compound, on slender stalks, longer than those of the leaves.—Native of Ceylon, Malabar and the island of Mauritius. It is a moderate-sized tree, with many opposite branches, knotty or tumid under each subdivision. Every part is perfectly destitute of pubescence, which, as far as we can discover, is the case with the whole genus. *Leaves* on short thick *footstalks*, opposite, ovate, somewhat elliptical, and often roundish, blunt and generally emarginate, entire, as in the whole genus, about an inch long or more, and half as broad, coriaceous, single-ribbed, without veins; their upper side dark green and shining; under paler, yellow and opaque. *Umbels* axillary, more or less compound, their common stalk slender, obscurely quadrangular, its subdivisions partly racemose, but always more or less umbellate. *Flowers* green with a purple tinge in the petals. *Tops of the filaments* very broad. *Calyx* very slightly four-cleft, obtuse. *Style* thick, but twice the length of the calyx.

This is said by Hermann to supply the place of Saffron, in Ceylon, for dyeing. Linnæus confounded so many species under this one, at different times, that it is hard to say exactly which he really meant. Our's is the plant of Burmann, and of the generality of botanists, though not of the Linnæan herbarium. But in the present case the latter is of no authority, the specimen having been acquired after the publication of the *Species Plantarum*, and not even marked with any trivial name.

2. *M. ramiflorum*. Naked-flowering Memecylon. Lamarck Dict. v. 4. 88. (*M. tinctorium*; Willd. Sp. Pl. v. 2. 347. Koern. MSS. *Cornus zeylanica sylvestris altera*, korakaba dicta; Burm. Zeyl. 76. t. 31. Korakaha; Herm. Mus. Zeyl. 40.)—Leaves elliptical, obtuse, on shortish stalks, deciduous. Umbels from the defoliated part of the branches, aggregate, compound, stalked. Style capillary, four times as long as the petals.—Native of Ceylon, and other parts of the East Indies. Very like the last, except that the *leaves* are rather more oblong, *flowers* much more

copious, from the leafless part of the branches, and essentially distinguished by the great length, and slenderness, of their *style*. We cannot comply with Willdenow's change of Lamarck's most excellent name, for an unpublished one of Koenig's, which is at least as suitable to the first species, if not to every other. We have no doubt of Burmann's synonymy, though he describes but four stamens; as he commits the same error respecting the foregoing.

3. *M. ovatum*. Ovate Memecylon.—Leaves ovate, bluntly pointed, veiny, on longish stalks, deciduous. Umbels from the defoliated part of the branches, aggregate, stalked. Style thread-shaped, four times as long as the petals.—Native of the East Indies? It lies in the Linnæan herbarium for *Santalum album*; but the specimen is not an original one, and the real *Santalum album* is no other than *Sirium myrtifolium* of Linnæus; see Roxb. Coromand. v. 1. t. 2. The present species differs widely from the last in appearance, though nearly agreeing with it in several essential characters. The *footstalks* are above half an inch long; *leaves* near three inches, exactly ovate, with an elongated bluntish point; their upper side marked with many transverse parallel veins. *Flowers* small, numerous, with a very long style. The bottom of their *calyx*, above the *germen*, has eight elevated ribs, making as many furrows, which we find also in most of the species, as described by Linnæus.

4. *M. acuminatum*. Pointed Memecylon.—Leaves on short stalks, elliptical, pointed. Umbels axillary, stalked, in pairs, simple. Style about the length of the petals. We find a specimen of this, without name, or mention of its native country, in the herbarium of the younger Linnæus. Its *leaves* agree in size with the last, but are elliptical, tapering at each end, with a longish acute point, and no perceptible veins; their *footstalks* very short and thick. *Umbels* small and simple, axillary, and not from the naked parts of the branches, usually in pairs, each umbel of four or five flowers. *Style* rather above half the length of the former, straight.

5. *M. edule*. Eatable Memecylon. Roxb. Coromand. v. 1. 59. t. 82.—Leaves on short stalks, ovate, acute, veiny, deciduous. Umbels from the defoliated part of the branches, aggregate, stalked. Style the length of the petals.—Very common in every thicket on the coast of Coromandel, flowering in the beginning of the hot season. A small tree, with numerous branches. *Leaves* most like those of the third species, but less pointed, and on shorter stalks. *Flowers* purple, much like those of that species, except that Dr. Roxburgh represents the *style* as not longer than the *petals*. *Berries* the size of a black currant, purple, juicy, astringent, eaten by the natives, who call the plant *Alie*. The *calyx* is drawn with four very distinct lobes. We have seen no specimen, and much suspect this plant may be the same with our *ovatum*, n. 3; but as we find reason to presume the existence of more species than we have seen in sufficient perfection to define them, we think it best to keep these separate.

The specimen mentioned under the first species, as preserved in the Linnæan herbarium, very closely resembles Roxburgh's figure, as to *leaves* and *footstalks*, but the *flowers* are much larger, fewer, on thicker shorter stalks, and axillary. It is marked *Tamba bifa*, which we believe is a Malay name. Our materials are scarcely sufficient to distinguish this plant specifically from the *edule*. It is however most indubitably different from our *ovatum* and *acuminatum*.

6. *M. grande*. Large-leaved Memecylon. Retz. Obf. fasc. 4. 26. Willd. n. 3. (Nedum Schetti; Rheede Hort. Malab. v. 2. 21. t. 15?)—Leaves sessile, ovate, long-pointed. Flowers in dense, axillary, forked clusters.—

Sent

Sent by Mr Christopher Smith from Malacca. The *bracts* are round, knotty, smooth; purplish when young. *Leaves* nearly or quite sessile, crowded, four inches or more in length, one inch and a half wide, ovate at the base, tapering to a bluntish point, scarcely marked with any transverse veins; their substance very thick and cortaceous. *Flowers* larger than in any of the foregoing, purplish, in thick, dense, globose, axillary clusters. *Calyx* very obscurely four-toothed. Of the proportion of the *style* we cannot judge. The plant of the *Hortus Malabaricus* seems, by the description, to be this; but if so, the *flowers* are very badly drawn. We have seen no specimen from Koenig or Retzius, but we presume our plant to be the same as their's by the description.

7. *M. cordatum*. Heart-leaved Memeeylon. Lamarck Dict. v. 4. 89. fig. 2 Willd. n. 4.—Leaves sessile, heart-shaped, bluntish. Umbels axillary, stalked, compound—Brought by Commerfon from the ill. of Bourbon, where it is called *Bois de Mays*. There is a specimen in Sir J. Banks's herbarium, gathered in the Mauritius, by Aublet, who describes it as a tall and handsome tree, with a grey bark. The *leaves* of Commerfon's specimen before us are from one to two inches long, and one broad, obscurely veiny, more or less heart-shaped at the base. *Inflorescence* very different from the last, consisting of no great number of *flowers*, in a variously divided umbel, on a slender stalk, full half an inch long. *Calyx* much less distinctly four-cleft than in Lamarck's figure.

MEMEL, in *Geography*, a town of Prussian Lithuania, situated on the bay called "Curisch-Haff." On one side it has the Baltic; and on the other the Curisch-Haff; and it is also watered by the river Dange. Its harbour is deep, and has a good entrance, and has, not long ago, been improved by two moles, which extend above 50 rods into the Haff or bay. Memel lies under the guns of the fort, and is well inhabited, the number of houses being above 400. It has a German, Lithuanian, and Calvinist church. The burghers, who are divided into those of Altstadt, or the Old Town, and Frederickstadt, are employed in commerce, brewing, soap-boiling, agriculture, fishing, &c. Great quantities of flax, linseed, thread, and hemp, are annually exported from this town. It is well-fortified, and was formerly one of the Hanse towns; and it has now the establishments of a royal magazine, a salt-factory, and a post-office of considerable revenue; 72 miles N.N.E. of Königberg. N. lat. 55° 50'. E. long. 21° 25'.

MEMENE, a town of the island of Ceylon, near the E. coast; 86 miles E.S.E. of Candi.

MEMNISCA, a lake of Canada. N. lat. 52° 20'. W. long. 88° 50'.

MEMMINGEN, a town of Bavaria, on the Iller; which was imperial till the year 1804, when it was transferred, among other indemnities, to the elector of Bavaria. The inhabitants are chiefly Lutherans, but the principal church is possessed by them in common with the Roman Catholics. This town carries on a good trade with Switzerland, Italy, and other adjacent countries, in Bavarian salt, home-spun linen, hops, grain, and other goods. In 1805, it was taken by the French; 22 miles S.S.E. of Ulm. N. lat. 48° 3'. E. long. 10° 7'.

MEMNON, in *Biography*, a native of Rhodes, was a general in the service of the last Persian king, Darius, whom he served, with great fidelity, against Alexander the Great. When that conqueror had lauded in Asia, and was advancing up the country, Memnon advised him not to hazard a battle, but to lay waste the country before the invader. His counsel was rejected, and the battle of the Granicus, in the year 334 B.C. followed, in which Memnon, at the head of the

Greek mercenaries, displayed the greatest valour. After the defeat, he obtained, by his valour, the most honourable conditions, and was almost immediately afterwards created the high admiral of Darius, and governor of the Lower Asia. He had now the important command of the city of Halicarnassus, when it was besieged by Alexander, and employed every effort in his power to save it. The siege was continued a long time, and great numbers of the Macedonians lost their lives before the place. Memnon was generous as well as courageous, for when the fugitive Greek commanders, through hatred of Alexander, opposed the demand from the Macedonians of permission to bury their dead, he would not listen to their remonstrances, alleging that it was unworthy of a Greek to refuse the rite of burial even to an enemy. And hearing one of his soldiers abusing Alexander in gross and vulgar terms, he struck him with his javelin, saying "I hired you to fight Alexander, not to revile him." When he found the place no longer tenable, he threw a strong garrison into the citadel, and with his troops, and the inhabitants with their effects, embarked for the island of Cos. He then advised Darius to make a powerful diversion into Macedonia, as the only means of saving himself from destruction. Darius gave him full power to levy troops, and he exerted himself with so much vigour, that he reduced several of the Cyclades, and the islands of Chios and Lesbos, excepting Mitylene, the capital of the latter. While carrying on a siege against that city he died, and thus freed Alexander from the only foe of whom he stood in awe. Memnon had married Barsine, a Persian lady of high rank, who, with her children, remained at the court of Darius some time, till at length she fell under the power of the conqueror, who took her to his bed, and had a son by her. Univer. Hist.

MEMNON, a Greek historian, is thought to have flourished in the time of Augustus. He wrote a history of the affairs of Heraclea in Pontus, sixteen books of which were abridged by Photius. They came down to the death of an Heracleian ambassador to Julius Cæsar, then emperor. A Latin translation of his history was published at Oxford in 1597.

MEMNON, *Statue of*, a colossal figure of gigantic size, formed of very hard granite, which was found in a mutilated state, and lying on the earth, among the ruins of Thebes in Egypt. Diodorus Siculus (lib. i.) calls it Osmanduë; Strabo says (lib. xvii.), that it was called by the Egyptians Ismandes; but writers in general give it the name of Memnon. This colossus, according to Philostratus, represented a young man in the flower of his age, whose face was turned towards the rising sun; and when the solar rays fell upon it, it was said to speak, or to utter harmonious sounds. Strabo says, that he had been witness to this pretended miracle, which can be attributed to nothing but either the quality of the stone of which it was made, or to the imposture of the priests, or rather to some secret spring, which the learned Kircher, after Pausanias, (in Attic.) alleges to have been a kind of harpichord inclosed within the statue, whose strings being first slackened by the moisture of the night, and then distended by the heat of the sun, broke with a noise resembling that of the string of a violin when it breaks. Cambyles, who spared not the Egyptian ox Apis, having a mind to disclose this mystery, in which he suspected some trick of magic, broke the statue from the head to the middle of the body. Strabo, in his account of this statue, reports, that he and some friends, whilst they were surveying it, heard a certain sound, without being able to determine whether it came from the statue, or the base, or if it proceeded from any of the by-standers; for, he adds,
I would

MEMNON.

I would rather believe any thing else, than imagine that stones ranged in such and such a manner were capable of yielding such a sound. Pausanias informs us, that in his travels through Egypt, he saw the remains of this statue, which Cambyfes had broke. The lower part of the colossus, he says, was still upon its pedestal, but the rest of the body was thrown down to the ground, and every morning at the sun rising yielded the sound already mentioned. Pliny and Tacitus advance the same fact, but without having been witnesses to it: and Lucian informs us, that Demetrius went on purpose to Egypt, to see there the pyramids, and Memnon's statue, from which a voice proceeded at the rising of the sun. Of the fact that this statue uttered sounds, when the sun shone upon it, there can be no doubt; nor can it be difficult to account for the phenomenon. The priests of Thebes might have carried the mechanic art to such a degree of perfection as to be able to fabricate a speaking head, the springs of which were so arranged, that it should pronounce sounds at the rising of the sun. Cambyfes destroyed this wonderful mechanism, by overturning the upper part of the statue; and all the testimonies that are cited to the fact refer only to the trunk, which is now seen upon the pedestal. It is natural, therefore, to attribute the sound of the mutilated colossus to the artifices of the priests, who opposed this pretended miracle to the rise and progress of Christianity. Lucian in particular would have been glad to have availed himself of a phenomenon, which he speaks of with raillery, in this view of it. At all events, it is very certain, that since the commencement of the fourth century of the church, when the inhabitants of Egypt became Christians, no more has been said of the vocal statue, first called Memnon by Herodotus, but in the chronicle of Alexandria, and by the Egyptians themselves, Amenophis. In reply to those who inquire concerning the object which the priests had in view in framing this vocal statue, it has been said that they were in the habit of consecrating their secondary deities to the preservation of the records of their most important discoveries. Amenophis was formed with the same intention. To this purpose the ancients and Jablonski (De Memnon.) who has collected their testimonies with extreme attention, assure us that the seven vowels were consecrated to the seven planets, and that the statue of Amenophis repeated them at a certain epocha. Lucian introduces Eucrates on the stage, and makes him say, "In Egypt I have heard Memnon utter, not according to custom, an insignificant sound, but pronounce from his mouth an oracle in seven sounds." This passage, probably, is a mere pleasantry of Lucian, but it is founded on the general persuasion, that before Cambyfes broke this colossus, it pronounced the seven vowels. The Egyptians, as we learn from Macrobius (Somn. Scip.) regarded the spring equinox as the era of the creation, and to this period the attention of the learned and of the people was chiefly directed. Amoun, a symbolical divinity, was consecrated to it, and all the festivals they celebrated in his honour, related merely to this interesting period. It was at this period the astronomical year commenced; and from hence, according to the priests, the seven planets renewed their course, which they allegorically styled the celestial music. It was at this moment also that Amenophis pronounced the seven vowels which were the symbols of the planets, and which composed the terrestrial music. This famous statue may be called in sacred language the cousin of Osiris (Diod. Sic.) and the image of the sun, since it imitated on earth the office which this luminary performed in the heavens. The priests by making him repeat the seven sounds, of which all languages are formed, and which wonderfully paint our thoughts, were desirous of immortalizing the most beautiful of their dis-

coveries; a discovery which, according to Plato, could only be invented by a god, or by a divine mortal. Perhaps, also, the shadow of this lofty colossus served to mark the instant of the equinox. Its name at least composed of "Ame Nouphi," to tell good tidings, intimates somewhat of the kind, more especially when we consider that the sun, when he arrived at the equator, in his annual course, promised the Egyptians a cessation of the southerly winds, and the approach of the inundation, which made it an object of anxious attention.

There is no less variety of opinion among both ancients and moderns, concerning Memnon himself, than in relation to his statue. Upon the authority of Hesiod, who said that he was king of Thebes, the succeeding Greek authors adopted this opinion. Pausanias, Strabo, Diodorus mention it, and also Pindar and Ovid. M. Le Clerc has a singular opinion concerning this prince; he takes him for Harmon, or Ham, the son of Noah; and Vossius asserts that he was the same with Baaltis, a divinity of the Syrians, male and female, called by the Greeks *Aphrodité*, and represented under the form of a stone. Diodorus Siculus states, "that this prince, the son of Tithonus, led to Troy the Assyrian troops, under the reign of Teutamus, who was the 20th king from Ninus and Semiramis; the Assyrians at that time, *i. e.* more than a thousand years ago, possessing the empire of Asia; Priam, who was tributary to the kingdom of Teutamus, having applied to him for assistance in his pressing exigency, and having sent to him, under the conduct of Memnon, 10,000 Assyrians, and as many Persians, with 200 chariots." We shall close this article with a passage from the learned Huetius's Treatise concerning the Terrestrial Paradise (ch. 13.) which throws more light upon the history of Memnon than any thing that had been before said of him. "Memnon," says that learned prelate, "was the son of Tithonus and Aurora. Tithonus was the brother of Priam king of Troy, and to him is sometimes ascribed the founding of the city Sufa, the capital of Sufiana. From the name of Memnon his son, the citadel was denominated Memnonium, the palace and the walls Memnonian, and Sufa itself the city of Memnon, upon account of the veneration that was paid to him there; and in honour of him a temple was built, whither the Assyrians went and mourned for him, which is to be understood of the people of Sufiana. This is that Memnon who came to the assistance of the Trojans, from whom he derived his original, and who was slain by Achilles. When the Greeks feigned that he was the son of Aurora, they would have us to understand that he came from the east.—I know the history of Memnon is very perplexed, and very differently related. Most ancient authors tell us he was an Ethiopian; this error flows from their confounding Chus, which signifies Sufiana, with Chus which signifies the countries situated upon the borders of the Arabic gulf, I mean Ethiopia and Arabia.—What we are in reason to think concerning Memnon's expedition, may be gathered from Diodorus, and some others. The kingdom of Troas was in the dependence of the empire of Assyria. Tithonus, Priam's brother, who was master of that kingdom, went to the court of the king of Assyria, who gave him the government of Sufiana. There he married in his old age; and because his wife was from a country situated to the east of Greece and Troas, the Greeks, who turned all history into fiction, said he had married the Morning. Memnon and Emathion were the issue of this marriage: the war having after this arisen, Priam applied to Teutamus for assistance, or at least to some king of Assyria, who granted him twenty thousand men, and two hundred chariots of war. Diodorus says this supply consisted of ten thousand Ethiopians, and ten thousand

thoughtful Sufian, returned to the vulgar error, and confounding the Chus of Ethiopia with the Chus of Sufiana. To make the supply of more service, Pentamus gave the command thereof to Memnon, a young prince of the Trojan race, and who was therein concerned for the preservation of Troy. He kept Tithonus with himself upon a count of his age, which rendered him unfit for the expedition, and his prudence which qualified him for being member of his council. Memnon found resistance in his march. The Solyimi, who have been since called the Pisidians, would needs dispute the passage with him; but he defeated them and all that opposed him. He cleared the passage, repaired the ways, and by reason of that long and dangerous march, had the honour to communicate his name to that high way which was denominated Memnonian. He foiled the attacks of the Greeks before Troy with great valour; but at last was slain by Achilles. Various accounts are given of the place of his burial; for not to mention Philostratus, who will have it that he had no sepulchre, but that he was transformed into that miraculous stone, Troas, Phœnicia, and Sufiana contended together for him, and especially Ethiopia, though it has no other right to his burial any more than to his birth, but that which arises from the equivocation of the word Chus. But notwithstanding the obscurity that this equivocation has cast upon this history, Philostratus, George Syncellus, that is, the coadjutor to the church of Constantinople, and Suidas who had read and copied good authors, though often not very judiciously, have not been wanting to bear testimony to the truth; the first telling us that Memnon the Ethiopian, that is Amenophis, never came from Troy, and that he was wrongfully confounded with Memnon the Trojan, not comprehending how Memnon could have brought supply to the Trojans from so great a distance, nor even by what adventure Tithonus had gone and settled in Ethiopia, and came to be king thereof; the second, by distinguishing exactly Amenophis king of Thebes in Egypt, who is also titled Memnon, from the speaking statue of Memnon the son of Tithonus, whom he ranks among the kings of Assyria; and Suidas, by asserting that that Memnon was not an Ethiopian, but a Sufian. Pausanias, though of a very penetrating genius, has but half unravelled this confusion; saying that Memnon the Ethiopian came not from Ethiopia to Troy, but from Sufa. Eustathius, and the scholiast on Pindar, who goes by the name of Triclinius, write that Memnon and Emathion his brother were the only white men among those Ethiopians, though Virgil and others make Memnon black. This remark confirms my opinion; for though the poets and writers of romance have taken the liberty to feign that Andromeda and Charicleus were born white among the blacks, yet this is so singular in the ordinary course of nature, that there is much more reason to believe that Memnon was white, because in fact he was not an Ethiopian."

MEMOIRS, or MEMORIALS, a term now much in use for histories composed by persons who had some share or concern in the transactions they relate, or who were eyewitnesses of them; answering to what the Latins called *commentarii*.

The French are great dealers in this way of writing, and have an infinite number of books of memoirs, containing, for the generality, the lives, actions, intrigues, amours, &c. of the writers.

MEMOIRS also denote a journal of the acts and proceedings of a society; or a collection of the matters debated, transacted, &c. therein. Such are the Memoirs of the Royal Academy of Sciences, &c.

MEMORY, *memoria*, a power or faculty of the mind, which receives, retains, and recollects what, its creation requires, affects of things presented to the understanding.

Of all the faculties, there is none harder to account for, or that has perplexed philosophers more, than the memory. Some will have it a more or less, as the age, sex, &c. differ. Locke, in an "Essay concerning the Understanding of Memory," makes it to consist in a fluid, or ideas or images, formed occasionally by the mind, out of the finer parts of the brain, and disposed or held by its order.

Deseartes and his followers maintain, that the animal spirits, exciting a motion in the most delicate fibres of the brain, leave a kind of traces or bottles, which occasion our remembrance. Hence it happens, that by passing several times over the same things, the spirits becoming accustomed to the same passages, leave them open, and so make their way without any effort or labour; and in this consists the ease wherewith we recollect such ideas. Thus wine is found to sharpen the memory, because wine puts the animal spirits in motion, and agitates the fibres of the brain more briskly.

Father Malebranche expresses his notion of memory thus: "It being granted, that all our different perceptions are owing to changes happening in the fibres of the principal part of the brain, wherein the soul more immediately resides, the nature of the memory is obvious: for as the leaves of a tree, that have been folded for some time in a certain manner, preserve a facility of disposition to be folded again in the same manner; so the fibres of the brain, having once received certain impressions by the courses of the animal spirits, and by the action of objects, preserve, for some time, a facility to receive the same disposition. Now it is in this facility that memory consists; for we think the same things, when the brain receives the same impressions.

"Farther, as the animal spirits act sometimes more briskly, and sometimes more languidly, on the substance of the brain; and as sensible objects make much deeper, and more lasting impressions, than the imagination alone; it is easy, on this scheme, to conceive why we do not remember all things alike; why a thing, for instance, seen twice, is represented more vividly to the mind than another seen but once; and why things that have been seen, are usually remembered more distinctly, than those that have been only imagined, &c.

"Old men are defective in memory, and cannot learn any thing without much difficulty, because they want animal spirits to make new traces, and because the fibres of the brain are become too hard to receive, or too moist to retain, such impressions. For the same reason, those who learn with the greatest ease forget the soonest; in regard when the fibres are soft and flexible, objects make a slight impression, which the continual course of animal spirits easily wears off. On the contrary, the fibres of those who learn slowly, being less flexible, and less subject to be shaken, the traces are more deeply engraven, and last the longer. From all which observations it follows, that the memory is absolutely dependent on the body; being impaired or strengthened, according to the changes that befall the body; a fall, the transports of a fever, &c. being frequently found to erase or blot out all the traces, to bear away all the ideas, and to cause an universal forgetfulness."

The chief difficulty that embarrasses this doctrine of memory is to conceive how such an infinite number of things, as the head is stored with, should be ranged in so much order in the memory, as that the one should not efface the other; and how, in such a prodigious assemblage of traces impressed

MEMORY.

on the brain, the animal spirits should awake precisely those which the mind has occasion for.

Memory, according to Mr. Locke, is, as it were, the storehouse of our ideas. For the narrow mind of man not being capable of having many ideas under view and consideration at once, it was necessary to have a repository, in which to lay up those ideas which it may afterwards have use for. But our ideas being nothing but actual perceptions in the mind, which cease to be any thing when there is no perception of them; this laying up of our ideas in the repository of the memory, signifies no more than this, that the mind has a power, in many cases, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the assistance of this faculty, that we are said to have all those ideas in our understandings, which we can bring in sight, and make the objects of our thoughts, without the help of those sensible qualities which first imprinted them there.

Attention and repetition help much to the fixing of ideas in our memories: but those which make the deepest and most lasting impressions, are those which are accompanied with pleasure and pain. Ideas but once taken in and never again repeated, are soon lost; and those of colours in such as lost their sight when very young.

The memory of some men is tenacious even to a miracle; but yet there seems to be a constant decay of all our ideas, even of those which are struck deepest, and in minds the most retentive; so that if they be not sometimes renewed, the print wears out, and at last there remains nothing to be seen.

Those ideas that are often refreshed by a frequent return of the objects or actions that produce them, fix themselves best in the memory, and remain longest there: such are the original qualities of bodies, *viz.* solidity, extension, figure, motion, &c. and those that almost constantly affect us, as heat and cold.

In memory, the mind is oftentimes more than barely passive; for it often sets itself to work to search some hidden ideas; sometimes they start of their own accord; and sometimes tempestuous passions tumble them out of their cells. This faculty other animals seem to have to a great degree, as well as men, as appears by birds learning of tunes, and their endeavours to hit the notes right. For it seems impossible that they should endeavour to conform their voices (as it is plain they do) to notes whereof they have no idea. Essay concerning Hum. Und. book ii. chap. 10.

Dr. Hartley, agreeably to his mechanical theory of the human mind, defines memory to be that faculty by which traces of sensations and ideas recur, or are recalled, in the same order and proportion, accurately or nearly, as they were once presented: and he observes, that memory depends entirely or chiefly on the state of the brain, which is peculiarly conformable to his notion of vibrations. The rudiments of memory, he says, are laid in the perpetual recurrency of the same impressions, and clusters of impressions: and thus he endeavours to account for the peculiar imperfections of the memory in children and aged persons, as well as for other facts pertaining to the exercise of this faculty. Obs. on Man, vol. i. p. 374, &c.

Those who adopt Hartley's theory enumerate among other phenomena of memory such as the following: ideas of recollection are distinguished from sensations, chiefly by a difference in the vividness of the impressions, so that when from disease, or any cause, ideas become as vivid as sensations, they are mistaken for sensations, as in phrensy; and also by

the associates which accompany them. Ideas of memory are distinguished from reveries, chiefly by the readiness and strength of the associations by which they are cemented together; and recollected ideas are also distinguished from reveries by their connection with known facts, and by various methods of reasoning. Memory, it is also said, depends entirely or chiefly on the state of the brain. Hence diseases, concussions of the brain, and spirituous liquors impair it; and it generally returns again with the return of health. Memory also differs in different ages, inasmuch that children soon learn and soon forget; old people learn with difficulty, and remember best what they learned when young; and this, it is alleged, is agreeable to the theory of vibrations. Sensations, attended with great pleasure or pain, make a deep impression on the memory, which is probably owing to the vigorous vibrations which they excite. Sensible ideas gradually decay in the memory, if not refreshed by new sensations. Voluntary recollection is performed by calling up associated ideas, which by degrees introduce the idea in question. Some persons of weak judgment possess retentive memories; but there are limits beyond which the two powers of receiving and of retaining ideas cannot consist with each other. Memory is a faculty incessantly exercised while thought continues; nor is the mind wholly deprived of it, though it is often much impaired. The excellence of memory consists partly in its strength of retention, and partly in the quickness of recollection. All the faculties of the mind are dependent on the memory: and though some persons may have strong memories with weak judgment, no person can have a strong judgment whose memory is remarkably defective.

It is commonly supposed, says professor Dugald Stewart, (*ubi infra*) that genius is seldom united with a very tenacious memory. "So far, however," says this ingenious writer, "as my own observation has reached, I can scarcely recollect one person who possesses the former of these qualities, without a more than ordinary share of the latter. On a superficial view of the subject, indeed, the common opinion has some appearance of truth; for we are naturally led, in consequence of the topics about which conversation is usually employed, to estimate the extent of memory by the impression which trivial occurrences make upon it; and these in general escape the recollection of a man of ability, not because he is unable to retain them, but because he does not attend to them. It is probable, likewise, that accidental associations, founded on contiguity in time and place, may make but a slight impression on his mind. But it does not therefore follow, that his stock of facts is small. They are connected together in his memory by principles of association, different from those which prevail in ordinary minds, and they are on that very account the more useful; for as the associations are founded upon real connections among the ideas, (although they may be less conducive to the fluency, and perhaps to the wit of conversation,) they are of incomparably greater use in suggesting facts which are to serve as a foundation for reasoning or invention."—"Montaigne frequently complains in his writings of his want of memory: and he indeed gives many very extraordinary instances of his ignorance in some of the most ordinary topics of information. But it is obvious to any one who reads his works with attention, that this ignorance did not proceed from an original defect of memory, but from the singular or whimsical direction which his curiosity had taken at an early period of life."—"I can do nothing," says he, "without my memorandum book; and so great is my difficulty in remembering proper names, that I am forced to call

call my domestic servants by their offices. I am ignorant of the greater part of our coins in use; of the difference of one grain from another, both in the earth and in the granary: what use heaven is of in making bread, and why wine must stand some time in the vat before it ferments."—"Yet the same author appears evidently, from his writings, to have had his memory stored with an infinite variety of apophthegms and of historical passages, which had struck his imagination: and to have been familiarly acquainted, not only with the names, but with the absurd and exploded opinions of the ancient philosophers." The foregoing observations serve to account, in part, for the origin of the common opinion, that genius and memory are seldom united in great degrees in the same person; and it so appears, that some of the facts, on which that opinion is founded, do not justify such a conclusion. There are, however, other circumstances, that seem rather to indicate an inconsistency between extensive memory and original genius. "The species of memory which excites the greatest degree of admiration in the ordinary intercourse of society, is a memory for detached and insulated facts; and it is certain that those men who are possessed of it, are very seldom distinguished by the higher gifts of the mind, and such a species of memory is unfavourable to philosophical arrangement; because it in part supplies the place of arrangement." Dr. Pemberton informs us, that sir Isaac Newton was often at a loss when the conversation turned on his own discoveries; they probably made but a slight impression on his mind, and a consciousness of his inventive powers prevented him from taking much pains to treasure them up in his memory. He nevertheless, as Dr. Pemberton says, perfectly understood his own writings, though his memory was much decayed in the last years of his life. (See Preface to Pemberton's View of Newton's Philosophy.) "A man of original genius," says professor Stewart, "who is fond of exercising his reasoning powers anew on every point as it occurs to him, and who cannot submit to rehearse the ideas of others, or to repeat by rote the conclusions which he has deduced from previous reflexion, often appears to superficial observers to fall below the level of ordinary understandings; while another, destitute both of quickness and invention, is admired for that promptitude in his decisions, which arises from the inferiority of his intellectual abilities." Here we cannot forbear citing one of the aphorisms of lord Bacon: "Reading makes a full man, writing a correct man, and speaking a ready man." See also on this subject Watt's Improvement of the Mind, chap. xvii. or Works, vol. v. p. 275, &c.

Memory is a source of refined and permanent pleasure: painful recollections gradually subside within the limits of pleasure: and if time sufficient be allowed, by the power of association, all pain will be ultimately absorbed, and the pleasures of memory will be pure and unmixed with misery. See Rogers's Pleasures of Memory.

Memory, according to Dr. Reid, is an original faculty given us by the author of our being, of which we can give no account, but that we are so made. I believe most firmly, says this author, what I distinctly remember; but I can give no reason of this belief. It is the inspiration of the Almighty that gives me this understanding. Memory, he says, is always accompanied with the belief of that which we remember; and this belief we account real knowledge, no less certain than if it was grounded on demonstration. The testimony of witnesses, in causes of life and death, depends upon it, and all the knowledge of mankind, with regard to past events, is built on this foundation. Reid's Essays on the Intellectual Powers of Man, Ess. iii. ch. 1, 2, 7.

The word memory, says professor Donald Stewart, is not employed uniformly in the same sense; it is sometimes employed to express the capacity of retaining knowledge, and sometimes the power of recalling it to our thoughts, when we have occasion to apply it to use. When we speak of a retentive memory, we use it in the former sense; when of a ready memory, in the latter. The various particulars which compose our stock of knowledge sometimes recur to us spontaneously, or at least without any interference on our part; in other cases, they are recalled by an effort of our will. The former operation of the mind is denoted by Memory; the latter, though sometimes called by the same name, is more properly distinguished by the word Recollection. The operations of memory relate either to things and their relations, or to events. In the former case, thoughts which have been previously in the mind may recur to us, without suggesting the idea of the past, or of any modification of time whatever, as when I repeat over a poem which I have got by heart, or when I think of the features of an absent friend. In these cases, the operations of memory do not necessarily involve the idea of the past. But when I think of events, I not only recal to the mind the former objects of its thoughts, but I refer the event to a particular point of time; so that of every such act of memory, the idea of the past is a necessary concomitant. If it be inquired, to what it is owing that the memory retains some things in preference to others? our author replies, that this may be ascribed to two principles of our nature, upon which memory is dependent, and with which it is very intimately connected; these are *attention* and the *association of ideas*. Without attention, even the objects of our perceptions make no impression on the memory. (See Bacon, Nov. Org. lib. ii. aphor. 6.) This attention, though it be a voluntary act, requires experience to have it always under command. In the case of objects to which we have been taught to attend at an early period of life, or which are calculated to rouse the curiosity, or to affect any of our passions, the attention fixes itself upon them, as it were, spontaneously, and without any effort on our part, of which we are conscious. On the other hand, if an object does not interest some principle of our nature, we may examine it again and again, with a wish to treasure up the knowledge of it in the mind, without our being able to command that degree of attention which may lead us to recognise it the next time we see it. By this kind of reasoning we can account for a well-known fact, that objects are easily remembered which affect any of the passions. The passion assists the memory, not in consequence of any immediate connection between them, but as it presents, during the time it continues, a steady and exclusive object to the attention.

Our ingenious author proceeds to state the connection between memory and the association of ideas. This, he says, is so striking, as to have induced some to suppose, that the whole of its phenomena might be resolved into this principle. This the professor does not allow. "The association of ideas connects our thoughts with each other, so as to present them to the mind in a certain order; but it presupposes the existence of these thoughts in the mind; or, in other words, it presupposes a faculty of retaining the knowledge which we acquire. It involves also a power of recognizing, as former objects of attention, the thoughts that from time to time occur to us; a power which is not implied in that law of our nature, which is called the association of ideas."—"On the other hand, it is evident that, without the associating principle, the power of retaining our thoughts, and of recognizing them when they occur to us, would have

MEMORY.

been of little use; for the most important articles of our knowledge might have remained latent in the mind, even when those occasions presented themselves to which they are immediately applicable. In consequence of this law of our nature, not only are all our various ideas made to pass from time to time in review before us, and to offer themselves to our choice as subjects of meditation; but when an occasion occurs which calls for the aid of our past experience, the occasion itself recalls to us all the information upon the subject which that experience has accumulated." Our author observes, "that the various theories which have attempted to account for memory by traces or impressions in the sensorium, are obviously too unphilosophical to deserve a particular refutation." He adds, after some other appropriate remarks on this subject, "that the immediate dependence of this faculty on the state of the body, which is more remarkable than that of any other faculty whatever, (as appears from the effects produced on it by old age, disease, and intoxication,) is apt to strike those who have not been much conversant with these inquiries, as bestowing some plausibility on the theory which attempts to explain its phenomena on mechanical principles." Accordingly, it is recommended to medical writers to be at more pains than they have been at hitherto, in order to ascertain the various effects which are produced on the memory by disease and old age; effects which are widely diversified in different cases. "In some it would seem that the memory is impaired, in consequence of a diminution of the power of attention; in others, that the power of recollection is disturbed, in consequence of a derangement of that part of the constitution on which the association of ideas depends. The decay of memory, which is the common effect of age, seems to arise from the former of these causes."—"As far as the decay of memory, which old age brings along with it, is a necessary consequence of a physical change in the constitution, or a necessary consequence of a diminution of sensibility, it is the part of a wise man to submit cheerfully to the lot of his nature. But it is not unreasonable to think, that something may be done by our own efforts, to obviate the inconveniences which commonly result from it. If individuals, who, in the early part of life, have weak memories, are sometimes able to remedy this defect, by a greater attention to arrangement in their transactions, and to classification among their ideas, than is necessary to the bulk of mankind, might it not be possible, in the same way, to ward off, at least to a certain degree, the encroachments which time makes on this faculty? The few old men, who continue in the active scenes of life to the last moment, it has been often remarked, complain, in general, much less of a want of recollection than their contemporaries. This is undoubtedly owing partly to the effect which the pursuits of business must necessarily have in keeping alive the power of attention. But it is probably owing also to new habits of arrangement, which the mind gradually and insensibly forms from the experience of its growing infirmities."

The learned professor devotes a section of his excellent work to the illustration of the varieties of memory in different individuals. "As the great purpose," he says, "to which this faculty is subservient, is to enable us to collect, and to retain, for the future regulation of our conduct, the results of our past experience; it is evident that the degree of perfection which it attains in the case of different persons, must vary; first, with the facility of making the original acquisition; secondly, with the permanence of the acquisition; and, thirdly, with the quickness or readiness with which the individual is able, on particular occasions, to apply

it to use. The qualities of a good memory are, therefore, in the first place, to be susceptible; secondly, to be retentive; and, thirdly, to be ready." These three qualities are rarely united in the same person.

Our author has advanced some very ingenious and judicious observations on the difference between a *casual* and a *philosophical* memory. The bulk of mankind associate their ideas chiefly according to their most obvious relations, those, for example, of resemblance and analogy; and, above all, according to the casual relations arising from contiguity in time and place; whereas, in the mind of a philosopher, ideas are associated according to those relations which are brought to light in consequence of particular efforts of attention, with the relations of cause and effect, or of premises and conclusion. The advantage is greatly in favour of the philosopher; the arrangement he uses strengthens his memory, assists his invention, enables him to reason synthetically, and to correct his intellectual defects; but this kind of memory is not favourable to conversation. The man of casual memory is open to every impression, and readily accommodates his ideas to any circumstance which may occur. But the philosopher who thinks closely and reasons systematically, is deficient in ease and quickness, and is in danger of becoming tedious by long discourses. And as nothing appears weaker or more absurd than a theory partially stated, it frequently happens that men of ingenuity, by attempting it, sink in the vulgar apprehension, below the level of ordinary understandings. Professor Stewart, after pointing out in various particulars the difference between philosophical and casual memory, observes, that they constitute the most remarkable of all the varieties which the minds of different individuals, considered in respect of this faculty, present to our notice. He afterwards enumerates, in detail, and with appropriate illustration, several other varieties of a less striking nature. Stewart's *Elements of the Philosophy of the Human Mind*, chap. vi. § 1, 2, 3.

For the difference between memory and imagination; see IMAGINATION.

Aristotle distinguishes between memory and reminiscence. Memory is a kind of habit which is not always in exercise with regard to things we remember, but is ready to suggest them when there is occasion. The most perfect degree of this habit is, when the thing presents itself to our remembrance spontaneously, and without labour, as often as there is occasion. A second degree is, when the thing is forgot for a longer or shorter time, even when there is occasion to remember it, yet at last some incident brings it to mind without any search. A third degree is, when we cast about and search for what we would remember, and so at last find it out. It is this last which Aristotle calls reminiscence, as distinguished from memory. Reminiscence, therefore, includes a will to recollect something past, and a search after it. Aristotle says, that brutes have not reminiscence, which Dr. Reid thinks to be probable, but, says he, they have memory. Thus, a dog knows his master after long absence. A horse will trace back a road he has once gone as accurately as a man. Reid, *ubi supra*. See the preceding part of this article.

History furnishes us with several surprising instances of the retentive powers of the faculty of memory. Seneca says of himself, that, by the mere effort of his natural memory, he was able to repeat two thousand words upon once hearing them, each in its order; though they had no dependence or connection on each other. After which he mentions a friend of his, Portius Latro, who retained in his memory all the declamations he had ever spoken, and never
found

found his memory fail him, even in a single word. He also mentions Cynæa, ambassador to the Romans from king Pyrrhus, who, in one day, had so well learnt the names of his spectators, that the next he saluted the whole senate, and all the populace assembled, each by his name. Pliny says, that Cyrus knew every soldier in his army by name; and L. Scipio, all the people of Rome. Charmidas, or rather Carneades, when required, it is said, would repeat any volume found in the libraries as readily as if he were reading. Dr. Wallis tells us, that without the assistance of pen and ink, or any thing equivalent, he was able in the dark, by mere force of memory, to perform arithmetical operations, as multiplication, division, extraction of roots, &c. to forty places. Particularly, that, in February 1671-2, at the request of a foreigner (by night in bed) he proposed to himself a number of fifty-three places, and found its square root to twenty-seven places; and without ever writing down the number, dictated it from his memory, at his next visit, twenty days afterwards.

The perfection of memory consists in two things; readily to admit the impressions or images of things; and to preserve them from oblivion, that the understanding may have recourse to them, and employ them for such purposes, as reason shall direct. In order to assist and improve this faculty, every kind of intemperance and excess must be carefully avoided; and when we would commit any thing to memory, our first concern should be to understand it thoroughly; we should commit things to memory in a methodical and regular manner; writing down any thing is likewise a great advantage towards remembering it; a frequent review and careful repetition of the things that are learned will help to fix them in the memory, and likewise an abridgment of them in a narrow compass; conversation upon them with intelligent companions will also be found useful; care should likewise be taken not to overburden the memory: such seasons should be made choice of as are most proper for the exercise of this faculty, such are the evening and morning; and the most effectual way of gaining a good memory, is its constant and moderate exercise. Ward's Or. vol. ii. sect. 51. Rollin's Belles Lettres p. 208—216, sixth ed. Watts's Improvement of the Mind, ubi supra. Stewart's Elem. of the Philosophy of the Human Mind, ch. vi. sect. 3. 4, 5.

MEMORY, *Local*, or *Artificial*, is an art, or invention, by means of which the memory is supposed to be aided, strengthened, and enlarged.

This art seems to consist in nothing else but a certain method of coupling or associating the ideas of things to be remembered, with the ideas of other things, already disposed orderly in the mind, or that are before the eyes. It is of an old standing, having been practised by many of the ancient rhetoricians, under the denomination of "topical memory;" some of whom are said to have made use of paintings, images, and emblems, on this occasion; though others contented themselves with the parts, members, ornaments, furniture, and other circumstances of the place where they were to speak. Muretus tells us that a young man of Corsica pretending to do wonders this way, Muretus put him to the trial; and upon dictating to him two or three thousand words, some Greek, some Latin, some Barbarous; all without any relation to each other, and the greatest part without any meaning at all; the artist immediately, and without any hesitation, or the least stumbling or displacing, repeated them all, from first to last, in the same order wherein they had been dictated; and this done, beginning where he ended, he repeated them all backwards, from last to first. Adding, that this was but a slight essay of his memory; and that he

would undertake to repeat thirty-six thousand words in the same manner.

The truth is, this art seems better calculated for retaining things without any coherence or dependence on one another, as mere words or sounds, &c. than for things where reason or judgment are any way required.

Raim. Lully took so much pains with it, that it now goes by his name, being called *Lully's art*.

Many have been the attempts, in all ages, to assist the memory. Some have had recourse to medicine, such as Horstius, Marfilus Vicinus, Johnston and others. That good health, a good digestion, and a mind free from care, are helps in this respect, is an old observation. That attention, application, frequent recapitulation, are necessary, is known to every one. But whether, besides natural health and parts, and the exercise of our faculties, art may not give a farther assistance to memory, has been a question. Simonides is said to have been the first who found out the art of memory. His method was by a choice of *places* and *images*, as a repository of ideas; such, for instance, as a large house divided into several apartments, rooms, closets, &c. All these, and their order, were to be rendered extremely familiar to the imagination and memory. Then, whatever was to be remembered, was by some symbolical representation or another, as an anchor for navigation, to be connected with some part of the house, or other artificial repository, in a regular manner. Cicero and Quintilian give us some account of this method, and speak of it with respect. As far as it was the object of this species of artificial memory to assist an orator in recollecting the plan and arrangement of his discourse, the accounts which are given of it by the ancient rhetoricians are abundantly satisfactory. It appears, however, that its use was more extensive; and that it was so contrived, as to facilitate the recollection of a premeditated composition. In what manner this was done, it is not easy to conjecture from the imperfect explanations of the art, which have been transmitted to modern times. The reader may consult Cicero de Orat. lib. ii. cap. 87, 88. Rhetor. ad Herennium, lib. iii. cap. 16, &c. Quintil. Inst. Orat. lib. xi. cap. 2.

Several moderns have attempted improvements of artificial memory. There was a collection of various treatises of this kind published at Leipzig; this, and Bruxius's *Simonides Redivivus*, are commended by Morhof. Pafchius gives us some account also of several authors who have treated of this art. It is certainly of use in history and chronology. The chief artifice, in this respect, is to form an artificial word, the letters of which shall signify numbers. Hence a date or era may more easily be recapitulated and remembered than without such a contrivance. This invention is mentioned as a secret known to few, by Pafchius. It has been profecuted in England, by Dr. Grey, in his well-known work, entitled "*Memoria Technica*," by means of which a great mass of historical, chronological, and geographical knowledge is comprised in a set of verses, which the student is supposed to make familiar to himself as school-boys do the rules of grammar.

The method is this: to remember any thing in history, chronology, geography, &c. a word is formed, the beginning of which being the first syllable or syllables of the thing to be remembered, does, by frequent repetition, of course draw after it the latter parts, which is so contrived as to give the answer. Thus, in history, the deluge happened in the year before Christ 2348. This may be signified by the word *Dél étok*; *Dél* standing for deluge, and *étok* for 2348.

MEMORY.

How these words came to signify these things, or contribute to the remembering them, is now to be shewn.

The first thing to be done is to learn exactly the following series of vowels and consonants, which are to represent the numerical figures, so as to be able at pleasure to form a technical word, which shall stand for any number, or to resolve a word already formed into the number it stands for :

<i>a</i>	<i>e</i>	<i>i</i>	<i>o</i>	<i>u</i>	<i>au</i>	<i>oi</i>	<i>ei</i>	<i>ou</i>	<i>y</i>
1	2	3	4	5	6	7	8	9	0
<i>b</i>	<i>d</i>	<i>t</i>	<i>f</i>	<i>l</i>	<i>s</i>	<i>p</i>	<i>k</i>	<i>n</i>	<i>z</i>

Here *a* and *b* stand for 1, *e* and *d* for 2, *i* and *t* for 3, and so on. These letters are assigned arbitrarily to the respective figures, and may very easily be remembered. The first five vowels in order naturally represent 1, 2, 3, 4, 5. The diphthong *au*, being composed of *a*, 1, and *u*, 5, stands for 6; *oi* for 7, being composed of *o*, 4 and *i*, 3; *ou* for 9, being composed of *o*, 4 and *u*, 5; the diphthong *ei* will easily be remembered for 8 (eight), being the initials of the word. In like manner for the consonants, where the initials could conveniently be retained, they are made use of to signify the number, as *t* for 3, *f* for four, *s* for six, and *n* for 9. The rest were assigned without any particular reason, unless that possibly *p* may be more easily remembered for 7, or *septem*, *k* for 8, or *octo*, *d* for 2, or *duo*; *b* for 1, as being the first consonant, and *l* for 5, being the Roman letter for 50, than any others that could have been put in their places. It is farther to be observed, that *z* and *y* being made use of to represent the cypher, where many cyphers meet together, as 1000, 1000000, &c. instead of a repetition of *azyzyzy*, &c. let *g* stand for 100, *th* for a thousand, and *m* for a million. Thus *ag* will be 100, *ig* 300; *oag* 900, &c. *ath* 1000, *am* 1000000, *loun* 59000000, &c. Fractions may be set down in the following manner: let *r* signify the line separating the numerator and denominator, the first coming before the other after it; as *iro* $\frac{2}{3}$, *urp*, $\frac{5}{7}$, *pourag* $\frac{79}{100}$, &c. When the numerator is 1 or unit, it need not be expressed, but begin the fraction with *r*; as *re* $\frac{1}{2}$, *ri* $\frac{1}{3}$, *ro* $\frac{1}{4}$, &c. So in decimals, *rag* $\frac{1}{100}$, *ratb* $\frac{1}{1000}$.

This is the principal part of the method, which consists in expressing numbers by artificial words. The application to history and chronology is also performed by artificial words. This part of the art consists in making such a change in the ending of the name of a place, person, planet, coin, &c. without altering the beginning of it, as shall readily suggest the thing sought, at the same time that the beginning of the word, being preserved, shall be a leading or prompting syllable to the ending of it so changed. Thus in order to remember the years in which Cyrus, Alexander, and Julius Cæsar, founded their respective monarchies, the following words may be formed; for Cyrus, *Cyrats*; for Alexander, *Alexita*; for Julius Cæsar, *Julios*. *Uts* signifies, according to the powers assigned to the letters before mentioned, 536; *ita* is 331, and *os* is 46. Hence it will be easy to remember, that the empire of Cyrus was founded 536 years before Christ, that of Alexander 331, and that of Julius Cæsar, 46.

For the farther application of this method, we refer to the ingenious author's own account. We shall only add, that technical verses contribute much to the assistance of the memory, both as they generally contain a great deal in a little compass, and also because, being once learned, they are seldom or never forgot. The author before quoted has given us several specimens of such verses in history, chronology, geography, and astronomy, as also the Jewish, Grecian, and Roman coins, weights and measures, &c. He ad-

vises his reader to form the words and verses for his own use himself; as he perhaps will better remember them than those formed by the author.

Having given an account very much in detail of the most approved artifices that have been contrived for assisting the memory, our limits will not allow our specifying any of those modern methods for this purpose that have engaged popular attention; probably without much claim to originality, and which, as long as they are not explicitly divulged, may be more lucrative to those who teach than improving to those who are at the pains and expence of acquiring them. Every attempt, however, to improve this important faculty merits encouragement. See *MNEMONIC Tables*.

Concerning the utility of the system above stated, the ingenuity of which has been acknowledged, opposite opinions have been entertained. The prevailing opinion is, as professor Stewart conceives, against it; although it has been mentioned in terms of high approbation by some writers of eminence. Dr. Priestley, whose judgment in matters of this nature commands respect, has said of it (*Lectures on History*, p. 157), that "it is a method so easily learned, and which may be of so much use in recollecting dates when other methods are not at hand, that he thinks all persons of a liberal education inexcusable, who will not take the small degree of pains that is necessary to make themselves masters of it; or who think any thing mean, or unworthy of their notice, which is so useful and convenient." The learned professor, of whose observations we have so often availed ourselves, very justly remarks, that "in judging of the utility of this, or of any other contrivance of the same kind, to a particular person, a great deal must depend on the species of memory which he has received from nature, or has acquired in the course of his early education. Some men have an extraordinary facility in acquiring and retaining the most barbarous and the most insignificant verses; which another person would find as difficult to remember, as the geographical and chronological details of which it is the object of this art to relieve the memory. Allowing, therefore, the general utility of the art, no one method, perhaps, is entitled to an exclusive preference; as one contrivance may be best suited to the faculties of one person, and a very different one to those of another."—"One important objection applies to all of them, that they accustom the mind to associate ideas by accidental and arbitrary connections; and, therefore, how much soever they may contribute, in the course of conversation, to an ostentatious display of acquired knowledge, they are, perhaps, of little real service to us, when we are seriously engaged in the pursuit of truth. I own too, (says the professor,) I am very doubtful with respect to the utility of a great part of that information which they are commonly employed to impress upon the memory, and on which the generality of learned men are disposed to value themselves. It certainly is of no use, but in so far as it is subservient to the gratification of their vanity; and the acquisition of it consumes a great deal of time and attention, which might have been employed in extending the boundaries of human knowledge. To those, however, who are of a different opinion, such contrivances as Grey's may be extremely useful; and to all men they may be of service, in fixing in the memory those insulated and uninteresting particulars, which it is either necessary for them to be acquainted with, from their situation; or which custom has rendered, in the common opinion, essential branches of a liberal education."

As to Simonides's method, Quintilian says he will not deny it to be of some use; for instance, in repeating a multitude of

of words in the order they occur, and in things of this nature; but he thinks it of less use in getting by heart a continued oration, and in that respect rather an incumbrance. He himself advises, if the speech to be remembered be long, to get it by heart in parts, and those not very small. The partition ought chiefly to be made according to the different topics. He thinks it best to get things by heart tacitly, and if, the better to fix the attention, the words be pronounced, yet it should be in a low voice. Apt divisions help the memory greatly. But after all, the great art of memory is exercise; to get many things by heart, and daily, if possible. Nothing increases more by use, or suffers more by neglect, than the memory. At whatever age a man aims at the improvement of this faculty, he should patiently submit to the uneasy labour of repeating what he has read or written. Here, as in other cases, where habits are to be acquired, exercise should be increased by degrees. Quint. Inst. Orat. lib. xi. cap. 2. p. 989.

Lord Bacon enumerates several helps to memory, as order, artificial place, verse, whatever brings an intellectual thing to strike the senses, and those things which make an impression by means of a strong passion, as fear, surprize, &c. Those things also sink deepell, and dwell longest in the memory, which are impressed upon a clear mind unprejudiced either before or after the impression, as the things we learn in childhood, or think of just before going to sleep; as likewise the first time things are taken notice of.

A multitude of circumstances also, or, as it were, handles or holds to be taken, help the memory; as the making many breaks in writing, reading or repeating aloud; but as to this last, see Quintilian's opinion before mentioned. Those things which are expected, and raise the attention, stick better than such as pass slightly over the mind; whence if a man reads any writing twenty times over, he will not remember it so well, as if he read it but ten times with trying between whiles to repeat it, and consulting the copy where his memory failed. Bacon's Works abr. vol. ii. p. 475. See also vol. i. p. 135, 136. vol. iii. p. 176, and the article *MNEMONIC Tables*.

MEMORY, Weakness or Loss of, in *Medicine*, technically called *amnesia*, is a disease which appears to depend upon two opposite conditions of the brain; namely, upon a plethora or oppressed state of that organ, and upon an extreme debility of its vessels and languor of the circulation. Hence it arises from two different sets of causes, and is to be cured by two opposite modes of treatment. The first mentioned species of the disease is connected with the lethargic state preceding apoplectic attacks, or with the paralytic condition that often succeeds them: it arises also from local injury to the brain, occasioned by wounds and blows, which produce concussion or pressure upon the brain. The plan of treatment directed for these morbid states, and consisting chiefly of local evacuations, with low diet, will be necessary for the relief of these varieties of *amnesia*. But the second species, connected with a feeble circulation in the head, such as is said to arise from excessive indulgence of the venereal appetite, or to follow the continued use of spirituous liquors, where there is no plethora, requires the use of tonics and of opium; the exciting causes being also avoided. (See Sauvages Nosol. Method. Spec. 1. Amnesia à Venere. Spec. 7. A. à temulentia.) Where the disease results from old age, however, or from any organic changes, which may have taken place in the brain itself, a cure cannot of course be expected from any expedient.

MEMORY, Time of, in *Law*, has been long ago ascertained by the law to commence from the beginning of the reign of Richard I. (2 Inst. 238, 239.) This rule was adopted,

when by the statute of Westm. 1. (3 Edw. I. c. 39) the reign of Richard I. was made the time of limitation in a writ of right. But since by the statute 32 Hen. VIII. c. 2. this period (in a writ of right) hath been very rationally reduced to sixty years, it seems unnecessary that the date of legal prescription or memory should still continue to be reckoned from an era so very antiquated. See Litt. § 170. 34 Hen. VI. 37. 2 Roll. Ab. 269. pl. 16. See *MONUM.*

MEMORY Rocks, in *Geography*, a reef of rocks among the Bahama islands. N lat. 27 3. W. long 79 30'

MEMPHIS, in *Ancient Geography*, a large and populous city of Egypt, on the left side of the Nile. Concerning the epocha of its foundation and also of its destruction, as well as its precise situation, writers are not agreed. According to Diodorus Siculus it was seven leagues in circumference, and it contained magnificent temples and palaces. As to its position, Dr. Shaw says, that opposite to Cairo, on the banks of the Nile, which looks towards Libya, is the village of Gisa, where the ancient Memphis stood, the ruins of which are now covered and buried with earth. The authors of the Universal History adopt the opinion of Dr. Shaw, and represent Memphis as situated on the site now occupied by Gisa. According to Herodotus, Memphis was situated on the narrowest spot in Egypt, on the western bank of the Nile; a lake formed by the waters of the river surrounding it to the north and the west. But Strabo is more circumstantial in his details; and he says, that at 40 stadia, or 1½ league from Memphis, rises a stony hill, where a great number of pyramids are built. This situation, it is said, does not correspond with that of Gisa, which is three leagues from the nearest pyramids, and six from those of Sacæra. (See GIZÉ.) Pliny (N. H. l. vi.) says, that the three great pyramids, which are seen by navigators from all parts, are situated on a barren and stony hill, between Memphis and the Delta, one league from the Nile, two from Memphis, and near the village of Busris. Diodorus also places the pyramids 15 miles from Memphis. From these authorities we may infer, that as the pyramids are between Memphis and the Delta, and it is certain that Gisa or Gizé is between the pyramids and the Delta, Memphis could not have been situated on the spot where Gisa stands; or, in other words, Memphis, by Pliny's description, is two leagues to the southward of the pyramids, and Gisa being three leagues from them to the northward, it could not have been built on the ground occupied by Memphis. Moreover, the village of Busris still exists under the name of Busr, at a small distance from the pyramids; they are still a league from the river, and the small town of "Menph," formerly Memphis, is about two leagues to the southward of these monuments.

The foundation of this city is ascribed by Herodotus to Menes; and by Diodorus to Uchoreus, the eighth descendant of Osymandias. Some have proposed to reconcile these two accounts by attributing the commencement of the city to Menes, and its completion and aggrandizement to Uchoreus, who made it a royal city. The occasion of its having been erected is thus stated by Savary. After a king of Egypt had turned the course of the Nile, which lost itself in the sands of Libya, and the Delta was formed out of the mud deposited by its waters, canals were cut to drain the Lower Egypt. The monarchs who till that time had fixed their residence at Thebes, were desirous of coming nearer the mouth of the river, to enjoy a more temperate air, and to be more ready to defend the entrance of their empire. Accordingly they founded the city of Memphis, and strove to make it a rival worthy of the ancient capital. They adorned it,

as Strabo (lib. xvii.) informs us, with several temples, amongst which that of Vulcan attracted the attention of travellers, by the grandeur of the edifice and the richness of its ornaments. Another temple, no less an object of wonder, was dedicated to Serapis, the principal approach to which was adorned by prodigious sphinxes. Here was also a temple of Venus, which some have supposed to be the moon. In order to prevent the disaster which was likely to be occasioned by drifts of sand, the inundations of the river, and the attacks of an enemy, a long and lofty dyke was constructed towards the south; and on the west, it was defended by the king's palaces and a fortress erected on the mountain. On the east it was bounded by the Nile. Towards the north were lakes terminated by the plain of Mummies, and by the causeway which leads from Busris to the great pyramids. Thus situated, Memphis commanded the valley of Egypt, and communicated by canals with lake Mœris, and lake Mareotis. The citizen who inhabited it might travel from his own house all over Egypt in a boat; so that it became the centre of wealth, of commerce, and of the arts. The new capital, thus circumstanced, sunk Thebes and her 100 gates into oblivion; and the glory of Memphis lasted for many ages. It maintained its splendour till Cambyzes laid waste Egypt at the head of a formidable army. This ferocious conqueror destroyed, as far as he was able, her temples and her famous buildings; and, above all, he strove to extinguish the torch of the sciences, which the Egyptians, surrounded by waves and deserts, had lighted in their fertile valley. Memphis, however, retained so many traces of her magnificence as to be still the first city in the world. For upwards of 200 years she laboured to throw off the Persian yoke. Alexander, to whom she surrendered, amply revenged the outrages she had sustained. This conqueror, abandoning himself to a guilty delirium, removed, as Quintus Curtius informs us, within the walls of Persepolis, the horrors Cambyzes had committed at Thebes and Memphis. In process of time a city was founded which bore his name; and it was embellished by the Ptolemies, his successors. Alexandria became another Rome: the arts and sciences acquired reputation in this place: commerce also attracted hither wealth from various regions. Hence it happened, that Memphis was gradually depopulated by the migration of her inhabitants to the new and more favoured city. Under Augustus, however, it was still a great city, populous and full of strangers; though it then held the rank of only the second city of Egypt. Six hundred years after, it became the first conquest of the Arabs, who laid siege to its walls. The siege was long and bloody; but it was carried at length by storm, as Abulfeda informs us. Menf (Memphis), says this writer, is the ancient Mafr of Egypt. It is situated on the western bank of the Nile. Amrou, son of El Aas, having taken it by storm, rased it to the ground, and went to build the town of Fostat by order of Omar, son of Kettah, on the opposite side. At Menf are remarkable ruins, the remains of its ancient splendour, &c. Menf, he adds, is distant a short day's journey from Grand Cairo. The village of Menf, the sad remains of an immense city, is six leagues from Grand Cairo, on the western bank of the Nile. The lakes mentioned by Herodotus and Strabo have not entirely disappeared; one of them is near Saccara, with a wood of Acacia situated westward of Menf; the other is precisely north of it. (Savary's Letters on Egypt, vol. i.) Memphis gave name to a nome or canton of Egypt, situated on the west of the Nile, and called "Memphitis Nomos."

MEMPHITES, or *Lapis Memphiticus*, a sort of stone mentioned by Dioscorides, Pliny, and other natural his-

torians, supposed to be found in Egypt, not far from the city of Cairo, the ancient Memphis, whence its name.

The property it is famed for is, that being pulverized and smeared on any part of the body to be cut off, it deadens it so, as that the patient shall receive no pain, they say, from the operation.

MEMPHREMAGOG, in *Geography*, a lake which lies chiefly in the province of Canada, 40 miles in length from north to south, and two or three wide from east to west. The north line of Vermont state passes over the south part of the lake, in N. lat. 45°. This lake, which communicates by the river St. Francis with the river St. Lawrence, is the reservoir of three considerable streams, viz. Black, Bolton, and Clyde rivers, which rise in Vermont. The soil on its banks is rich, and the country round it is level.

MEMRAMCOOK RIVER, a river of America, which has been recommended as the most proper boundary between the province of North Brunswick and Nova Scotia. It lies a little to the eastward of Petitcodick, and pursues a north-easterly direction.

MEMRUMUS, in *Mythology*, a Phœnician deity, sprung from the race of giants, and the brother of Hypsaranus. The latter dwelt at Tyre, and invented the art of building cottages of reeds and rushes, and the papyrus; and his brother, with whom he quarrelled, taught men to clothe themselves with the skins of beasts. When an impetuous fire kindled a forest near Tyre, he took a tree, cut off its branches, and having launched it in the sea, made use of it for a ship. He also paid religious homage to two stones, which he had consecrated to the wind and fire, and poured out libations to them of the blood of certain animals. This, says Banier, is the second example of a worship paid to created beings; the sun having been the first object of idolatry. After the death of these two brothers, their children, says Sanchoniathon, consecrated to them misshapen pieces of wood and stone, which they adored, and instituted anniversary festivals to their honour. This is the first time we find religious worship performed to dead men.

MEN—*Midshipmen, Moot, Port, Quest, Sides, Twelve, Vestry* MEN. See the adjectives.

MEN, an abbreviation of the Italian adverb, *meno*, frequently used, in music, to announce a diminution; as *men forte*, less loud, &c.

MEN of *May*, in *Geography*, rocks near the north coast of Scotland; 5 miles E. from Dunnat Head. N. lat. 58° 3'. W. long. 3° 3'.

MENA, JUAN DE, in *Biography*, a Castilian poet of great celebrity, was born at Cordova about the year 1411. It was not till the age of twenty-three that he discovered any propensity towards literature; but then he made up for the time which he considered as having been lost, and betook himself most passionately to his studies, which he pursued first at Cordova, then at Salamanca, and afterwards at Rome. By his poetical talents he soon attracted a considerable degree of notice, and was patronized by several considerable persons, and by Juan II. This king, though far from respectable as to character or talents, was a lover of learning, and an encourager of it, and appointed Juan de Mena his chronicler, communicated to him materials for the history of his reign, and took delight in beholding the progress of his works. The history was never finished by de Mena; and he is chiefly known as a poet. The longest and most elaborate of his poems is entitled "El Labyrintho," commonly known by the title of "Las Trezientas," because it consists of three hundred stanzas. Mr. Southey, in the General Biography, has given a pretty full account of the plan and contents of this poem. It is said that the king ordered

dered him to add sixty-five stanzas to his poem, for this *raison*, that there might be just as many as there are days in the year. Of these, twenty-four are printed at the end of the poem. They contain some execrable flattery of Juan, and an orthodox address to the deity; the rest is declamation against the factious nobles. Juan de Mena was probably not the author of these. He has been greatly praised in this country, and has been said to unite the merits of Dante and Petrarca; but, according to Mr. Southey, the merits of Juan are exclusively what he may possess for his language: there is no glimpse of imagination, and scarcely a trace of feeling. De Mena was author of two other poems, entitled "La Coronacion," and "Tractado de Victorias y Virtudes." This last he left unfinished. There are many editions of these poems; the most complete are those of Senville in 1528, and of Antwerp in 1552. In the royal library at Madrid there is an unfinished abridgment of the Iliad, made by this author at the king's command. He died in 1456 at Tordelaguna, and was buried in the parochial church of that town. Gen. Biog.

MENA, in *Geography*, a town of Mexico, in the province of Nicaragua, on a river which runs into the lake of Nicaragua; 30 miles N.W. of St. Carlos.

MENA, in *Hindoo Mythology*, is the spouse of Himalaya, and mother of Parvati, in one of her terrestrial incarnations. The legend connected with this poetical fiction is very wild and fanciful. Himalaya, or the mansion of snow, is the Hindoo classical name of that vast chain of mountains that bounds India to the north, and embraces it with its eastern and western arms, both extending to the ocean: one named, in Sanscrit, Chandra-Sakra, or moon-crowned; and the other, which stretches westward to the mouths of the Indus, was called by the ancients Montes Parvati. The mountain Himalaya, being personified, is represented as a powerful monarch, bearing the moon as his crown, and being the source of all the good derivable from the many rivers that issue from him. These mountains were the resort of the god Siva; and his celestial consort having no children by him, became regenerated in the daughter of Himalaya and Mena, and was named Parvati, or mountain-born. In this incarnation, she, according to some legends, bore him two sons: Ganesa, the wisest of deities, the god of prudence and policy, always invoked at the beginning of every literary work; and Kartikeya, commander of the celestial armies. (See KARTIKEYA, SIVA, and PARVATI.) The name Himalaya is usually altered by European writers to Himmaleh; the range of mountains is otherwise called Hindookho. See these articles. See also MERA.

MENACES, in *Law*. See THREATS.

MENACHA, in *Geography*, a town of Arabia, in Yemen; 36 miles W.S.W. of Sanaa.

MENACHANITE, or MENAKANITE. See TITANIUM.

MENADON BAY, or *Panadon*, in *Geography*, a bay which lies two leagues from Port Balena, or Port Novo, on the coast of Cape Breton island, at the south part of the gulf of St. Lawrence, having the island of Seatair, formerly called Little Cape Breton, opposite to it.

MENAGE, GILLES, in *Biography*, a distinguished man of letters, was born at Angers in the year 1613, of which city his father was a king's advocate. Having completed his studies, he was admitted to the bar at Angers in 1632. He remained here but a short time, but went to Paris in the same year, where he pursued the legal profession, till he became disgusted with the chicanery connected with it, and adopted the ecclesiastical character, and thence gave himself up entirely to literary pursuits. He was soon distinguished among his contemporaries as a man of wit and erudition;

but by the usual freedom of his remarks on different characters with whom he associated, he was perpetually involved in quarrels. For some years he was an inmate in the house of cardinal de Retz; and when he quitted it, he took apartments in the cloister of Notre Dame, where he held weekly assemblies of the learned, to which he gave the title "Mercuriales." Menage was in easy circumstances. He had sold a small paternal estate for a life-annuity, enjoyed a considerable rent-charge upon two abbies, and obtained a royal pension, which, however, was paid but a short time. By these means he was enabled to cultivate literature in the way most agreeable to him, and to print some of his works at his own expence, which the booksellers would probably not have chosen to undertake. By a witty satire, entitled "Requête des Dictionnaires," he had precluded himself from an admission into the French academy, though it was afterwards a great object of his ambition. In the former part of his life he was distinguished by a prodigious memory; but in advanced age he experienced almost a total failure of that important faculty. Fortunately this defect was not permanent: he recovered it again, and recorded the grateful feelings of his heart in a Latin hymn to "Mnemosyne." He died at Paris in 1692, at the age of seventy-nine. His principal works are, 1. "Dictionnaire Etymologique, ou Origines de la Langue Françoise," first printed in 1650, and reprinted in 1750, with corrections and additions by M. Jault, in two volumes, folio: it is regarded as a work of much real value, though in the first editions there are numerous errors and absurd etymologies. 2. "Origines de la Langue Italienne;" in this he was assisted by several members of the academy of Della Crusca, of which he was an associate. 3. "Miscellanea," in quarto, being a collection of pieces in prose and verse, and in different languages. He also published an edition of Diogenes Laertius, with notes and illustrations; "Juris Civilis Amoenitates;" "Notes on the Poems of Malherbe;" "Histoire de Sable;" "Historia Mulierum Philosophorum," and several other pieces. Menage was an entertaining companion, by the variety of his knowledge, and the happy manner which he had of communicating it; but he was apt to be overbearing and opiniative. After his death, a "Menagiana" was compiled from notes of his conversation, anecdotes, remarks, &c. which has been several times reprinted. The last edition was published in 1715 by M. de la Monnoye, in four volumes, 12mo. Moreri.

In his admirable work, entitled "Dictionnaire Etymologique de la Langue Françoise," and in his "Origine della Lingua Italiana," curious inquirers after the musical language of the middle ages will find more information than in any other Lexicons or philosophical works with which we are acquainted, except in the Glossarium of Ducange.

MENAGE, *Fr.*, denotes a collection of animals; whence we have derived the word *menagery*.

MENAGE, in *Geography*, an island in the river Senegal.

MENAGIO, a town of Italy, in the department of the Lario; 15 miles N.N.E. of Como.

MENAI, a channel between the island of Anglesey and the county of Caernarvon.

MENAIIS, in *Botany*, perhaps from *μῆναι*, to stand undaunted against the attacks of an enemy, because this shrub is, as its specific name *topiaria* expresses, able to bear clipping, and plating into bowers. No explanation of the name having been given, we offer the best that occurs to us. Linn. Gen. 95. Schreb. 130. Willd. Sp. Pl. v. 1. 997. Loefl. It. 306. Juss. 128. Lamarek Dict. v. 4. 90.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifoliae*. Linn. *Borragineae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three lax, concave, small,

small, pointed, striated, permanent leaves. *Cor.* of one petal, falver-shaped; tube cylindrical, longer than the calyx; limb spreading, in five deep rounded segments. *Stam.* Filaments five, very short; anthers awl-shaped, in the mouth of the corolla. *Pist.* Germen superior, roundish, depressed; style thread-shaped, erect, the length of the tube; stigmas two, oblong, acute. *Peric.* Berry globose, of four cells. *Seeds* solitary, nearly ovate, acute at one end.

Eff. Ch. Corolla falver-shaped. Calyx of three leaves. Berry of four cells. Seeds solitary.

1. *M. topiaria.* Bower Menais. Linn. Sp. Pl. 251.—Native of South America. A *shrub*, with round, somewhat hairy stems. Leaves alternate, ovate, undivided, rough. We have seen no figure nor specimen of this plant. Linnæus mentions Aymen as the author of the genus. Justifieu suspects it not to be different from *Ehretia*, to which we have chiefly to object the three-leaved calyx. See *EHRETIA*.

MENAKA, the name of a semi-divine female, in the Puranic romances of the Hindoos, frequently alluded to in their writings and conversation, proverbially, as highly beautiful and fascinating. When the evil counsellor Indra, (see *INDRA*), jealous of the growing sanctity of the ascetic Viswamitra (which see), resolved to counteract his meritorious penance, he thought female blandishment the readiest mode of debauching the faint; and selected Menaka, as a promising instrument through whom to effect his unholy purpose. The moral legend is thus alluded to in the 50th section of the first book of the Ramayana. (See that article.) "When the sanctified ascetic Viswamitra, who had for thousands of years been engaged in the most rigid mortifications, beheld Menaka the Apsara, sent by Indra to debauch him, bathing, of surprising form, unparalleled in beauty, in appearance resembling Sri (see *SRI*), her clothes wetted by the stream, exhibiting her fascinating symmetry of frame; he, subdued by the arrows of Kandarpa (see *KANDARPA*), approached her; and five times five years, spent in dalliance with this seducing female, passed away like a moment. What!—exclaimed at length the reflecting sage,—my wisdom, my austerities, my firm resolution, all destroyed at once by a woman! Seduced by the crime in which Indra delights, am I stripped of the advantages arising from all my austerities!" In this manner we occasionally find sound morality inculcated by the wild fables of the Hindoos. If we object to the warmth of language sometimes observable in such writings, we should recollect that in fairness we ought not to estimate them by any standard of European criticism; but should advert to the usages of the people, the times, and the countries, for whom and wherein they were promulgated.

MENALD DEER, a species of the common fallow-deer, beautifully variegated.

MENAMAN, in *Geography*, a town of Asiatic Turkey, in Natolia, situated on the north coast of the gulf of Smyrna; 6 miles N.W. of Smyrna.

MENANDER, in *Biography*, the most celebrated of the Greek comic poets, was born at Athens in the year 342 B.C. He is considered as the person who introduced the new comedy, which refined upon the grossness and licence of the old, and banished living characters from the stage. He is represented as possessing every part of a perfect dramatic writer, *viz.* elegance of language, force and delicacy of sentiment, and the true and humorous delineation of character. He was so much the poet of nature, that the grammarian Aristophanes once exclaimed, "O Menander and Nature, which of you copied from the workmanship of the other!" Quintilian praises him for the strength and consistency displayed in the characters of his dramas. Ovid predicts that the fame of Menander would be immortal.

His fame extended as far as the Greek language; and we are informed by the elder Pliny, that the kings of Egypt and Macedonia gave him pressing invitations to their courts, and even offered fleets for his safe conveyance. He preferred, however, a life of freedom in his native city; yet he could not be accounted a moral philosopher. By Plutarch he is called "the chief priest of Love;" and Suidas gives him the character of one "mad after women." Phædrus paints him as paying his compliments to Demetrius Phalereus at Athens, perfumed all over, with a flowing garment, and advancing with an affected and languid step. He composed 108 comedies, eight of which obtained the theatrical prize. It is extraordinary that, of an author so much esteemed as Menander was, nothing has come down to our time except some fragments, chiefly of the sentimental kind, and generally of a gloomy and querulous tenour, which perhaps were characteristic only of the persons into whose mouth they were put: and what remains of him does not mark so strongly his own peculiar genius, as the taste of those selectors who have chosen his words to illustrate their own ideas. Thus, to the melancholy selector we owe the survival of the sad and peevish complaints on the many sorrows to which flesh is the natural heir. On the other hand, the strikingly moral passages with which his works abounded alone caught the attention of the fathers of the primitive church, who found in the Greek comedian a strain of piety so nearly approaching to their own faith and feelings, that all ideas of a preponderance of satire over moral precept must yield to evidence so irresistible as the approbation of Clemens Alexandrinus and Eusebius. It is from these two sources alone, the writings of the melancholy and pious man, that we are furnished with our specimens of Menander. Happy had it been for us and the world, had the gay and the witty finished the portrait of the bard, by transmitting to after-ages examples that would have enabled us to measure him by the standards of humour, sprightliness, and fancy. The superiority of the Grecian dramatist was felt and acknowledged by Roman imitators; and Cicero frequently reprobates the prevailing partiality of his countrymen for such foreign authors. Menander was drowned in the harbour of Piræus, in the year B.C. 293, at a period of his life when he had done enough to obtain immortality, and while the powers of his mind were unimpaired by age, and his genius sufficiently ardent to do still more. He is said to have thrown himself into the sea in a fit of jealousy, occasioned by his unfortunate competition with Philemon. He was vanquished, as Aulus Gellius asserts, by the superior interest rather than talents of his successful rival; and the same writer relates, that, meeting him shortly after the contest had been decided, he asked him, "If he did not blush at gaining the prize against him?" The fragments of Menander have been several times reprinted. The most complete edition is that of Le Clerc in 1709. To this, on account of many mistakes in prosody, Bentley, in 1713, gave his "Emendationes in Menandri et Philemonis Reliquias." Monthly Mag.

MENANDRIANS, in *Ecclesiastical History*, the most ancient branch of Gnostics; thus called from Menander their chief, said by some, without sufficient foundation, to have been a disciple of Simon Magus, and himself a reputed magician.

He taught, that no person could be saved, unless he were baptised in his name: and he conferred a particular sort of baptism, which would render those who received it immortal in the next world; exhibiting himself to the world, with the phrensy of a lunatic more than the founder of a sect, as a promised favour. For it appears by the testimonies of Irenæus, Justin, and Tertullian, that he pretended to be one of the

the Æons sent from the pleroma, or ecclesiastical region, to succour the souls that lay groaning under bodily oppression and servitude; and to maintain them against the violence and stratagems of the demons that hold the reins of empire in this sublunary world. As this doctrine was built upon the same foundation with that of Simon Magus, the ancient writers looked upon him as the instructor of Menander. See SIMONIANS.

MENAN-TAN, in *Geography*, a town of Siam; 6 miles N. of Portelon.

MENANGAEBOW, a kingdom of Sumatra, being the principal sovereignty of the island, which formerly comprehended the whole, and still receives a shadow of homage from the most powerful of the other kingdoms, that have sprung up from its ruins. This kingdom is the principal seat of empire of the Malays, and of the whole island. It lies near the centre, extending partly to the northward, but chiefly to the southward of the equinoctial, about 60 or 100 miles. The country is, generally speaking, a large plain, bounded by hills, clear of woods, and, comparatively, well cultivated. It has an easy communication with both sides of the island, lying nearer to the western coast, but having the advantage, to the east, of the large rivers Racan, Indergerce, Siak, Jambee, and even Palembang, with which it is said to have connection by means of a large lake, that gives source to the two last, as well as to the river of Cat-town on the opposite side. Colonies of Malays from Menangeabow are settled on several branches of Janbee river, or rather those small rivers which run into it. Here they collect large quantities of gold. The name of Menangeabow is said to be derived from the words "menarg," to win, and "carbow," a buffalo; from a story, which bears a very fabulous air, of a famous engagement on that spot between the buffalos and tigers, in which the former are reported to have gained a complete victory. The actual power and resources of the sultan are, at this day, scarcely superior to those of a common raja; yet he still asserts all his ancient rights and prerogatives, which are not disputed, as long as he refrains from attempting to carry them into force. His character is held in a sacred light, and the obscurity and air of mystery which surround his court, together with the influence of the Mahometan priests, who regard him as the head of their religion, keep up this veneration. This empire is allowed to be very ancient; though when the Europeans first made discoveries in these parts, it was in its decline. Like the other people of Sumatra, those of Menangeabow are entirely without records or annals. They are expert at writing in the Arabic character; but their literature amounts to nothing more than transcripts of the Koran, and "cabar," or historic tales, resembling our old romances, but having less ingenuity. They are famous for composing songs, called "pantoon," which spread throughout the island. The arts, in general, are carried among them to a greater degree of perfection than by the other natives of Sumatra. The Malays are the sole fabricators of the gold and silver *filagree*; which see. Menangeabow has also been celebrated for its considerable traffic in gold, lying in the midst of the mines, where it is chiefly produced. Much cloth is wrought in, and exported from it. Here also have been manufactured, from the earliest times, arms for their own use, and for the supply of the northern inhabitants of the island, who are the most warlike. Their guns are those pieces called matchlocks, nor is the improvement of springs and flints yet adopted by them; their barrels are well tempered, and of the justest bore. Powder is made by them in great quantity, but it is defective in strength. Besides guns, they have other arms, which

me, for the most part, weapons of a make between that of a scimitar and a knife. Their crosses are a species of dagger of a particular construction, and are worn by all descriptions of people. They have other implements of warfare, called "Ranjow," which are sharp-pointed blades of bamboo, of different lengths, stuck into the ground, in order to penetrate the naked feet or body of an enemy. They are made use of in cases of flight, to annoy and retard the pursuers, and planted in the path-ways, or among the long grass, by the vanquished party as they run. They are also disposed in the approaches to fortified divisions. Their wars are generally carried on rather in the way of ambuscade, and surprise of straggling parties, than open combat. The soldiers have no pay, but the plunder is thrown into a common fund, and divided.

The people of Menarg abow are all Mahometan, and in that respect distinguished from the other island inhabitants of the island. This country is looked upon as the supreme seat of that religion; and next to a voyage to Mecca, which some Sumatrans have undertaken, to have been at Menangeabow stamps a man learned and of superior sanctity. With the change of their religion, the people of this country altered their language, laws, custom, and manners. This was effected by the settlement of the Malays among them.

By late accounts it appears, that the kingdom of Menangeabow, even in its limited state, is rent into various sovereignties. Marsden's Sumatra.

MENAPII, in *Ancient Geography*, a people who, in the time of Cæsar, inhabited the banks of the Lower Rhine. They were bounded on the N. and E. by the Mosæ, and on the W. by the Scaldis. Their country corresponded to Brabant.

MENARD, LEON, in *Biography*, an historical writer, was born at Tarascon in 1700. It is imagined he was educated for the legal profession, though he certainly did not pursue it to any great extent, but devoted most of his time and talents to the study of history and antiquities. He obtained a place in the Academy of Inscriptions and Belles Lettres, and from that time passed his life chiefly at Paris, where he died in indigent circumstances in 1767. His principal works are, "A History of the Bishops of Nismes," in two vols. 12mo.: "L'Histoire civile ecclesiastique et litteraire de la Ville de Nismes," which consisted of seven volumes 4to., and was the product of many laborious years. In depth of research, and abundance of curious matter, this is said to be surpassed by few topographical works. As a relaxation from more serious labours, he composed a romance, entitled "Les Amours de Calisthene et d'Aristo-clie:" the scene is laid in Ancient Greece, and it consists in the delineation of Grecian manners, which subject is expressly treated on in another work of our author, entitled "Mœurs et Usages des Grecs," which was very much read, and proved honourable to his industry and learning. He next carried his researches into French history, and published, as the result of his labours, a collection of "Pieces fugitives pour servir a l'Histoire de la France," in three vols. 4to. Another, and probably his last publication, was entitled "A Refutation of the Arguments of Voltaire against the Authenticity of the Political Testament of Cardinal Richelieu." Gen. Biog.

MENARUOLO, in *Geography*, a town of Italy; 17 miles N.W. of Verona.

MENAS, Sr., an island in the Grecian Archipelago, about six miles in circumference. N. lat. 37° 33'. E. long. 26° 30'.

MENASSEH, BEN ISRAEL, in *Biography*, a celebrated rabbi, who flourished in the seventeenth century, was a na-

tive of Spain, and born very early in that century. His father, after having been cruelly tortured by the Spanish Inquisition, and stripped of his property, escaped into Holland with his wife and sons, of whom Ben Israel, the subject of this article, was one. Here he was placed under a learned preceptor, Isaac Ufeli, and pursued his studies with such diligence and success, that at the age of eighteen he was so deeply skilled in Hebrew and theology, that he was judged fully qualified to succeed his tutor as preacher and expounder of the Talmud in the synagogue of Amsterdam, a post which he occupied with high reputation for many years. He was not quite twenty-eight years of age, when he published in the Spanish language the first part of his work entitled "Conciliador:" of which was published a Latin version, in the following year, by Dionysius Vossius, entitled "Conciliator, sive de Convenientia Locorum S. Scripturæ, quæ pugnare inter se videntur, Opus ex Vetus et Recentioribus omnibus Rabbini magna Industria ac Fide congestum." This work shews that its author had a profound and intimate acquaintance with the Old Testament writings, and it procured for him the esteem and admiration of all the learned, as well Christians as Jews. It was recommended to the notice of biblical scholars by the learned Grotius.

Notwithstanding the learning and diligence of our rabbi, he found that the expences of a large and growing family could not be defrayed by the salary attached to his appointment, and engaged in the mercantile line of business; and he also set up a printing-press in his own house, at which he printed three editions of the Hebrew bible, and a number of other books. Under the protectorate of Cromwell, he came over to England, in order to solicit leave for the settlement of the Jews in this country. Here he met with a favourable reception from the protector and his parliament, and succeeded in obtaining greater and more important privileges for his nation than they had ever enjoyed before in this country, and in 1656 published an "Apology for the Jews," in the English language. This piece was afterwards published in the second volume of the collection of scarce and curious tracts entitled "The Phoenix," &c. Menasseh died at Amsterdam about the year 1659, and left a son, who inherited his printing-press, busily employed in printing some of his father's works. The rabbi was respected and esteemed as well for his moral virtues as for his great learning, and had been long in habits of correspondence and intercourse with some of the most learned men of his time, among whom were the Voffii, Episcopius, and Grotius. The following are his principal works independently of that already noticed: 1. An Edition of the Hebrew Bible, two vols. 4to.: 2. The Talmud corrected, with Notes: 3. De Resurrectione Mortuorum: and 4. Spes Israelis, dedicated to the parliament of England in the year 1650; it was originally published in Spanish, and afterwards translated into the Hebrew, German, and English, one object of which is to prove that the ten tribes are settled in America. He was author likewise of numerous other pieces. Moreri. Universal History.

MENAT, in *Geography*, a town of France, in the department of Puy-de-Dôme, and chief place of a canton, in the district of Riom; 24 miles N.N.W. of Riom. The place contains 1748, and the canton 10,014 inhabitants, on a territory of 180 kilometres, in 11 communes.

MENCKE, LEWIS OTHO, in *Biography*, was born in 1644, at Oldenburg, in Westphalia, of which city his father was a senator, and also in trade. After studying at and visiting several of the universities in Germany and Holland, he was appointed professor of moral philosophy at Leipzig in 1668,

He was, in the course of an active and well spent life, five times rector of the university, and occupied his post as professor till his death, in 1707. He was editor of several learned works, and was the planner of the periodical work called the Leipzig Journal, but better known by the name "Acta Eruditorum," of which, with the assistance of other learned men, he published thirty volumes. Moreri.

MENCKE, JOHN BURCHARD, son of the preceding, was born at Leipzig in 1674, and in 1699 we find him appointed to the professorship of history, an office in which he acquired a high reputation by his lectures. He was also historiographer and aulic counsellor to Frederic Augustus of Saxony, king of Poland; a member of the Academy of Berlin, and of the Royal Society of London. He died at Leipzig in 1732, leaving behind him several very learned and useful publications on historical and philosophical subjects. One of the most remarkable of these consisted of two Latin declamations, "De Charlataneria Eruditorum," which were translated into various languages. He had a large share in, and was the original projector of a German "Dictionary of Learned Men," but his chief undertaking was a collection of the German historians, under the title of "Scriptores rerum Germanicarum, speciatim Saxonicarum," in three volumes folio. He published an enlarged edition of Lenglet's "Methode pour etudier l'Histoire avec un Catalogue des principaux Historiens," and after the death of his father, he continued the Leipzig journal to thirty-three volumes more. Moreri.

MEND, in *Geography*, a town of Persia, in the province of Mekran, at the union of the Mekshid and the Nehenk, which hence take the name of Mend, and run into the Indian sea. The town is distant 40 miles S.W. from Kidge. N. lat. 25° 50'. E. long. 63° 30'.

MENDÆANS, in *Eccelesiastical History*. See HEMERO-BAPTISTS.

MENDAMA, in *Geography*, a town of the island of Ceylon; 18 miles N. of Candi.

MENDAVIA, a town of Spain, in Navarre; 8 miles E.S.E. of Viana.

MENDE, a town of France, and principal place of a district, in the department of the Lozère: situated on an eminence, near the Lot; before the revolution the see of a bishop; 49 miles W. of Privas. The place contains 5014, and the canton 10,610 inhabitants, on a territory of 305 kilometres, in ten communes. N. lat. 44° 31'. E. long. 3° 34'.

MENDELI, a fortified town of the Arabian Irak, on the frontiers of Persia; 50 miles N.E. of Bagdad. N. lat. 33° 54'. E. long. 45°.

MENDELSON, MOSES, in *Biography*, a Jewish philosopher, and elegant writer in the last century, was born at Dessau, in Anhalt, in the year 1729. His father was a schoolmaster, and undertook the education of his son. He was brought up to business, but devoted every hour he could claim as his own to literature, in which he greatly excelled, and obtained as a scholar a distinguished reputation; but it was, unfortunately, at the expence of his health. He was also destined to a state of extreme penury: at the age of fourteen, he travelled on foot to Berlin, where he lived in indigence and obscurity, and frequently in want of the necessaries of life. At length he got employment from a rabbi as a transcriber of MSS., who, at the same time that he afforded him the means of subsistence, liberally initiated him into the mysteries of the theology, the jurisprudence, and scholastic philosophy of the Jews. The study of philosophy and general literature became from this time his favourite pursuit, but the fervours of application to learning were by degrees alleviated and animated by the consolations

tions of literary friendship. He formed a strict intimacy with Israel Moses, a Polish Jew, who, without any advantages of education, had become an able, though self-taught, mathematician and naturalist. He very readily undertook the office of instructor of Mendelsohn, in subjects of which he was before ignorant, and taught him the Elements of Euclid from his own Hebrew version. "The singular spectacle of the two youthful rabbies, circumstanced as they were, sitting in the corner of retired streets, the one with a Hebrew Euclid, instructing the other, who was hereafter to be classed among the most eminent literati of his country, may instruct the young and the indigent, that the cold touch of poverty can never paralyse the sublime efforts of resolute genius." The intercourse between these young men was not of long duration, owing to the calumnies propagated against Israel Moses, which occasioned his expulsion from the communion of the orthodox; in consequence of this, he became the victim of a gloomy melancholy and despondence, which terminated in a premature death. His loss, which was a grievous affliction to Mendelsohn, was in some measure supplied by Dr. Kisch, a Jewish physician, by whose assistance he was enabled to attain a competent knowledge of the Latin language. In 1748 he became acquainted with another literary Jew, *viz.* Dr. Solomon Gumperts, by whose encouragement and assistance he attained a general knowledge of the living and modern languages, and particularly the English, by which he was enabled to read the great work of our immortal Locke in his own idiom, which he had before studied through the medium of the Latin language. About the same period he enrolled the celebrated Lessing among his friends, to whom he was likewise indebted for assistance in his literary pursuits. The scholar amply repaid the efforts of his instructor, and soon became his rival and his associate, and after his death the defender of his reputation, even at the expence of his own life: for when Lessing was charged with Atheism by M. Jacobi, a German writer, he roused all his powers in his justification, and entered so vehemently into the controversy, as to exhaust an already feeble and delicate frame: his whole nervous system became so completely deranged, that severe study, for a short time only, produced fainting fits. To avoid these, when he found them approaching, Mendelsohn would instantly abandon what he was about, and banish all thought from his mind. Being asked how he contrived to exult without thinking, and exercising the powers of reflection, he replied, "I retire to the window and count the tiles upon the roof of my neighbour's house." He died at the age of fifty-seven, highly respected and beloved by a numerous acquaintance, and by persons of very different opinions. When his remains were consigned to the grave, he received those honours from his nation which are commonly paid to their chief rabbies. As an author, the first piece was published in 1755, entitled "Jerusalem," in which he maintains that the Jews have a revealed law, but not a revealed religion, but that the religion of the Jewish nation is that of nature. His work entitled "Phædon, a Dialogue on the Immortality of the Soul," in the manner of Plato, gained him much honour: in this he presents the reader with all the arguments of modern philosophy, stated with great force and perspicuity, and recommended by the charms of elegant writing. From the reputation which he obtained by this masterly performance, he was entitled by various periodical writers the "Jewish Socrates." It was translated into French in 1773, and into the English in 1789. Among his other works, which are all creditable to his talents, he wrote "Philosophical Pieces;" "A Commentary on Part of the Old Testament;" "Letters on the Sensation of the Beautiful." Gen. Biog.

MENDEN, in *Geography*, a town of Westphalia; 47 miles N. E. of Cologne.

MENDES, or MYNDES, a town of Asiatic Turkey, in Natolia, in a bay of the Archipelago; anciently called "Myndus," 20 miles S. of Mileta. N. lat. 33° 5'. E. long. 27° 10'.

MENDES, in *Ancient Geography*, a town of Egypt, near the mouth of one of the eastern branches of the Nile, between Schennytus to the west, and Tanés to the east. The arm of the Nile on which it was seated was denominated the *Mendesian*. This ancient city was famous for its temples, and the indecency of the worship paid there to the ram. When the sacred animal dies, the Mendesian province solemnizes his death by a general mourning. Herodotus, lib. ii. *Euterpe*.

MENDES, in *Mythology*, an Egyptian deity, who was worshipped as the emblem of the sun. The Egyptians having discovered that they owed the fertility of their country to the influence of the sun, worshipped him under the name of Mendes, which signifies "very fruitful." Accordingly they consecrated the goat to him, as the most prolific of all animals. This animal was fed in the temple of Mendes, as the living image of the God whom he represented. The Greeks gave to Mendes the name of *Pan*; which see.

MENDESCAO, in *Geography*, a town of Naples, in Calabria Citra; 3 miles W. of Cosenza.

MENDEZ, MOSES, in *Biography*, an English poet and dramatic writer, who flourished in the last century, and died about the year 1758. He was of Jewish extraction, though he had abandoned the religion of his fathers. He was author of several poems in Doddsley's Collections.

MENDHAM, in *Geography*, a township of America, in Morris county, New Jersey; six miles W. of Morristown.

MENDICANTI, the title of one of the music schools at Venice for girls, known by the name of conservatorios. The maestro di capella of the hospital de Mendicanti, in 1770, was the worthy Bertoni, by whose favour we were admitted into the interior of this admirable seminary, to an extra concert of two hours, by the best vocal and instrumental performers of this hospital: it was really curious to see, as well as to hear every part of this excellent concert, performed by females, violins, tenors, basses, harpsichord, French horns, and even double basses; and there was a prioress, a person in years, who presided: the first violin was very well played by Antonia Cubli, of Greek extraction; the harpsichord sometimes by Francesca Rossi, maestra del coro, and sometimes by others: these young persons frequently change instruments. The singing was truly excellent in different styles; and the whole was very judiciously mixed; no two airs of a sort followed each other, and there seemed to be great decorum and good discipline observed in every particular; for these admirable performers, who are of different ages, all behaved with great propriety, and seemed to be well educated. It was here that the two celebrated female performers, the Archiapate, afterwards signora Guglielmi, and signora Maddalena Lombardini, afterwards madame Sirman, who received such great and just applause in England, had their musical instructions.

MENDICANTS, BEGGARS, a term applied to several orders of religious, who live on alms and go a begging from door to door.

The religious society distinguished by this appellation surpassed all the rest in the purity of its manners, the extent of its fame, the number of its privileges, and the multitude of its members. Its order was first established in the 13th century, and the members of it, by the tenor of

their institution, were to remain entirely destitute of all fixed revenues and possessions; though in process of time their number became a heavy tax upon the people. Innocent III. was the first of the popes who perceived the necessity of instituting such an order, and accordingly he gave such monastic societies, as made a profession of poverty, the most distinguishing marks of his protection and favour. They were also encouraged and patronized by the succeeding pontiffs, when experience had demonstrated their public and extensive usefulness. But when it became generally known, that they had such a peculiar place in the esteem and protection of the rulers of the church, their number grew to such an enormous and unwieldy multitude, and swarmed so prodigiously in all the European provinces, that they became a burthen, not only to the people, but to the church itself. The great inconvenience that arose from the excessive multiplication of the Mendicant orders was remedied by Gregory X. in a general council, which he assembled at Lyons, in 1272. For here all the religious orders, that had sprung up after the council held at Rome, in 1215, under the pontificate of Innocent III. were suppressed; and the extravagant multitude of Mendicants, as Gregory called them, was reduced to a smaller number, and confined to the four following societies or denominations, *viz.* the Dominicans, the Franciscans, the Carmelites, and the Augustines, or the hermits of St. Augustine.

As the pontiffs allowed these four Mendicant orders the liberty of travelling wherever they thought proper, of conversing with persons of every rank, of instructing the youth and multitude wherever they went; and as these monks exhibited, in their outward appearance and manner of life, more striking marks of gravity and holiness than were observable in the other monastic societies, they arose all at once to the very summit of fame, and were regarded with the utmost esteem and veneration through all the countries of Europe. The enthusiastic attachment to these sanctimonious beggars went so far, that, as we learn from the most authentic records, several cities were divided, or cantoned, into four parts, with a view to these four orders; the first part being assigned to the Dominicans, the second to the Franciscans, the third to the Carmelites, and the fourth to the Augustinians. The people were unwilling to receive the sacrament from any other hands than those of the Mendicants, to whose churches they crowded to perform their devotions, while living, and were extremely desirous to deposit there also their remains, after death; nor did the influence and credit of the Mendicants end here; for we find in the history of this, and of the succeeding ages, that they were employed, not only in spiritual matters, but also in temporal and political affairs of the greatest consequence, in composing the differences of princes, concluding treaties of peace, concerting alliances, presiding in cabinet councils, governing courts, levying taxes, and other occupations, not only remote from, but absolutely inconsistent with, the monastic character and profession. However, the power of the Dominicans and Franciscans greatly surpassed that of the other two orders; inasmuch that these two orders were, before the Reformation, what the Jesuits have been since that happy and glorious period, the very soul of the hierarchy, the engines of the state, the secret springs of all the motions of the one and the other, and the authors and directors of every great and important event, both in the religious and political world. By very quick progression their pride and confidence arrived at such a pitch, that they had the presumption to declare publicly, that they had a divine impulse and commission to illustrate and maintain the religion of Jesus; they treated with the

utmost insolence and contempt all the different orders of the priesthood; they affirmed, without a blush, that the true method of obtaining salvation was revealed to them alone; proclaimed, with ostentation, the superior efficacy and virtue of their indulgences; and vaunted, beyond measure, their interest at the court of heaven, and their familiar connections with the Supreme Being, the Virgin Mary, and the saints in glory. By these impious wiles, they so deluded and captivated the miserable and blinded multitude, that they would not entrust any other but the Mendicants with the care of their souls. They retained their credit and influence to such a degree, towards the close of the 14th century, that great numbers of both sexes, some in health, others in a state of infirmity, and others at the point of death, earnestly desired to be admitted into the Mendicant order, which they looked upon as a sure and infallible method of rendering heaven propitious. Many made it an essential part of their last wills, that their bodies after death should be wrapped in old ragged Dominican or Franciscan habits, and interred among the Mendicants. For such were the barbarous superstition and wretched ignorance of this age, that people universally believed, they should readily obtain mercy from Christ, at the day of judgment, if they appeared before his tribunal associated with the Mendicant friars.

About this time, however, they fell under an universal odium; but being resolutely protected against all opposition, whether open or secret, by the popes, who regarded them as their best friends, and most effectual supports, they suffered little or nothing from the efforts of their numerous adversaries. In the 15th century, besides their arrogance, which was excessive, a quarrelsome and litigious spirit prevailed among them, and drew upon them justly the displeasure and indignation of many. By affording refuge, at this time, to the Beguins in their order, they became offensive to the bishops, and were hereby involved in difficulties and perplexities of various kinds. They lost their credit in the 16th century by their ruttic impudence, their ridiculous superstitions, their ignorance, cruelty, and brutish manners. They discovered the most barbarous aversion to the arts and sciences, and expressed a like abhorrence of certain eminent and learned men, who endeavoured to open the paths of science to the pursuits of the studious youth, recommended the culture of the mind, and attacked the barbarism of the age in their writings and discourse. Their general character, together with other circumstances, concurred to render a reformation desirable, and to accomplish this happy event. Mosheim's *Ecl. Hist.* vol. iii. passim.

Among the number of Mendicants are also ranked the Capuchins, Recollects, Minims, and others, who are branches or derivations from the former.

MENDING, in *Agriculture*, a term used to signify the improving of land by means of manure.

MENDIP HILLS, in *Geography*, a range of hills, in the county of Somerset, near the city of Wells; celebrated for mines of lead and coals.

MENDLING, a town of Austria, on a river of the same name, which runs into the Salza, near Keisling, in Stiria; the town is 15 miles distant S.S.E. from Bavarian Waidhoven.

MENDOCINO CAPE, a cape of North America, on the coast of New Albion; off the cape lie some rocky islets and sunken rocks, about a league from the shore. This cape is rendered remarkable by being the highest on the sea-shore of this part of New Albion. The mountains behind it are elevated and break into separate hills, rising abruptly

abruptly and divided by many deep chasms. On both the hills and chasms are some few dwarf trees. The general surface exhibits vegetables of a dull green colour, inter-ferted with perpendicular strata of red earth or clay. N. lat. 40° 40'. E. long. 135° 53'.

MENDOLCIA, a town of Naples, in Calabria Citra; three miles W. of Bovio.

MENDON, a post-town of America, in Worcester county, Massachusetts; 37 miles S.W. of Boston. The township, called "Quaupungua" by the Indians, was incorporated in 1667, and contains two congregational parishes, a society of Friends, and 1608 inhabitants. On the S. it is bounded by the state of Rhode Island; and it is watered by the Charles and Mills rivers, and other streams, which turn several mills.

MENDOW, a town of Hindoostan, in Guzerat; 33 miles E. of Amedabad.

MENDOZA, DON INIGO LOPEZ DE, SENOR DE UREA Y BVRVITAGO, first marques de Santoluna, and Conde del Real de Manzanares, in *Biography*, was born in August 1398; he married in 1418 Dona Catalina de Figueroa, and died in 1458. During the reign of Juan II. his courage was conspicuous, and his prudence still more so, as he aggrandized himself without injuring his reputation. He is mentioned not only as a contributor to the literature of his own country, but as an early patron of it. His works are as follow: 1. Maxims of morality in verse, written by desire of Juan II. for the instruction of his son Henrique. This book has passed through ten editions at least, and is still reckoned one of the rarest in that language. 2. Proverbs which old women repeat by the fire-side: this is supposed to be the oldest collection of proverbs in any modern language. 3. A letter addressed to D. Pedro, son of the Infante D. Pedro of Portugal. This letter, which the marques sent with a collection of his own poems, is regarded as one of the most valuable documents for the literary history of Spain, as containing an account of all the Spanish poets, whose works the writer had either seen or heard of. Besides these, many of the marques' poems are in the "Cancionero General," and others in MSS.: among them is a poem upon the "Creation," consisting of 333 stanzas, in the same metre as the "Trezientas" of MENA, which see. He first introduced the sonnet into Spanish poetry.

MENDOZA, D. DIEGO HURTADO DE, son of Lopez de Mendoza, first marques de Mondejar, was born at Granada about 1505, and there, during his childhood, he acquired a practical knowledge of Arabic, which he continued to cultivate through life. He studied the Greek language very successfully at Salamanca, and was a soldier in the Italian wars. While engaged in the military service, he spent every winter, while the troops were inactive and in quarters, at Rome, or Padua, or some other Italian university, where he could enjoy and profit by the society of learned men. He was employed as ambassador by Charles V. in the most important transaction of his whole reign, at the council of Trent, at Venice, and at the papal court. At Venice he exerted himself to recover Greek MSS. He obtained many of the writings of St. Basil the Great, and of Gregory Nazianzen, the works of Cyril of Alexandria, and the more valuable remains of Archimedes, of Hero and of Applan: all these, with copies also of cardinal Bessarion's and of other collections, he left to the Escurial library. Don Diego was superseded at Rome in 1551 to satisfy the papal court. He continued some years one of Philip's counsellors, but was at length banished from his court. He retired to Granada, and there upon the spot composed his history of the war against the Moriscoes:

he has amused himself with literature during the remainder of his life. In 1574 he obtained leave to return to Madrid, and died in a few days after his arrival. None of his works were published during his lifetime. In 1615 a volume of his poems was collected by J. D. Hidalgo, the king's chaplain, who suppressed the coarse and lascivious poems, which were numerous. His history of the Moriscoes was published the same year by Luis Tribullus; part of the third book having been lost, was supplied by the count de Portalegre, D. Joan de Silva. It has been reprinted several times, and is reckoned the very best specimen of historical composition in the Spanish language. The story of Lazzarillo de Tormes, which has been translated into almost every European tongue, is attributed to this author as a youthful work, written at Salamanca. Others impute it to Juan de Ortega. Gen. Biog.

MENDOZA, PETER GONZALEZ DE, a Spanish cardinal, and archbishop of Toledo, was born in 1428. He acquired his high preferments in the church by his talents as a statesman. Pope Sixtus IV. made him cardinal. He died in 1495: as a literary man he is said to have translated the Iliad and Æneid, also Sallust, into the Spanish. Another person of the same name, an Augustine friar, was sent by the king of Spain as ambassador to the emperor of China in 1584. After obtaining several instances of preferment, he was appointed, in 1608, bishop of Popayan in the West Indies. He is known as an author by a history of China, written in the Spanish language. Moreri.

MENDOZA, in *Geography*, a jurisdiction of Chili, in South America, subject to the vice-royalty of Buenos Ayres. It has a town of the same name, which lies on the E. side of the Cordilleras, about 50 leagues from Santiago. It is situated on a plain, adorned with gardens, and supplied with water by means of canals. The town contains about 100 families, half Spaniards and half Indians, together with a college founded by the Jesuits, a parochial church, and three convents. This jurisdiction comprehends also the towns of St. Juan de la Frontera, on the E. of the Cordilleras, and about 30 leagues N. of Mendoza, and St. Louis de Loyola, about 50 miles E. of Mendoza; the latter is small, but has a parish church, a Dominican convent, and a college founded by the Jesuits. S. lat. 33° 25'. W. long. 69° 47'.

MENDOZA, a river which rises in the Cordilleras of the Andes; over which is a natural bridge of rocks, from the vaults of which hang icicles, formed of the water as it drops from the rocks. The bridge is broad enough to admit of three or four carts abreast. Near it is another bridge, called the bridge of the Incas, betwixt two rocks, and elevated a great height from the river.

MENDRA, a small island in the Indian sea, near the coast of Africa. S. lat. 2° 15'.

MENDRAH, a town of Fezzan, in a district or province of the same name, nearly S. from Mourzouk, and distant from it about 60 miles. Although much of the land is a continued level of hard and barren soil, the quantity of "Troua," a species of fossil alkali that floats on the surface, or settles on the banks of its numerous smoking lakes, has given it a higher importance than that of the most fertile districts. Of this valuable produce, great quantities are annually brought by the merchants of Fezzan to Tripoli, from whence it is shipped for Turkey and Tunis, and the dominions of the emperor of Morocco. The people of the latter employ it as an ingredient in the dye of the leather, for which they are famous, and in that of the woollen caps that are worn by the Arabs and the Moors as the basis

of their turbans. Proceedings of the African Association, &c. 1790.

MENDRISIO, or **MENDRIS**, a small well-built market-town of Italy, in the department of the Verbano, late the capital of a small bailiwick of the same name, lying between the lakes of Como and Lugano, which is extremely fertile, and contains 19 parishes, and about 16,000 inhabitants. The town is about 26 miles N.N.W. of Milan, and 7 miles from Como. N. lat. $45^{\circ} 45'$. E. long. $9^{\circ} 0'$.

MENDURAGU, a town of Russia, in the government of Viburg, on the borders of Finland; 48 miles W.N.W. of Velmanstrand.

MENEDEMUS, in *Biography*, a Greek philosopher, who flourished towards the close of the fourth century before Christ, was a native of Eretria, in the island of Eubœa. He was of the *ELIAC School* (which see), which he afterwards transferred to his native city, and gave it the name of *Eretrian*. Menedemus, though nobly descended, was obliged, through poverty, to submit to a mechanical employment, either as tent-maker or mason. He formed an early intimacy with Asclepiades, who was a fellow-labourer with him in his humble occupation. Having minds more adapted to study than manual labour, they resolved to devote themselves to the pursuit of philosophy. For this purpose, they left their native country, and went to Athens, where Plato presided in the academy. (See *ASCLEPIADES*.) In his own school at Eretria he neglected those forms which were commonly observed in places of this kind, and allowed his hearers and disciples to attend him in whatever posture they pleased, standing, walking, or sitting. At first Menedemus was received by the Eretrians with great contempt; and, on account of the vehemence with which he disputed, obtained the appellations of "Cur" and "Madman." But he afterwards rose into high esteem, and was entrusted with a public office, to which was annexed an annual stipend of 200 talents. He discharged the trust with fidelity and reputation, but accepted only of a fourth part of the salary attached to the appointment. He was sent upon several embassies to Ptolemy, Lyfander, and Demetrius, and rendered his countrymen essential services, by obtaining a diminution of their tribute, and rescuing them from other burdens. Antigonus entertained a personal respect for him, and professed himself one of his disciples. His intimacy with this prince created a suspicion among his countrymen, that he had a secret intention to betray their city into his hands. To save himself he fled to Antigonus, and soon after died, in the eighty-fourth year of his age. It is thought he precipitated his end by abstaining from food for several days, being oppressed with grief, as well on account of the ingratitude of his countrymen, as on his disappointment in not being able to prevail on Antigonus to restore the lost liberties of his country. Menedemus possessed great talents as a philosopher and disputant. He declared his opinions with freedom, inveighed with severity against the vices of others, and, by the purity of his own manners, commanded universal respect. He observed the strictest moderation in the manner of his living. His entertainments, which were frequented by many philosophers and men of distinction, were simple and frugal, consisting chiefly of vegetables. Enfield's Hist. vol. i.

MENEDEMUS, a Cynic philosopher, was a native of Lampascus, who lived during the reign of Antigonus, king of Macedon. At this period, the peculiarities of the Cynic sect had been carried to an absurd and ridiculous extreme. In Menedemus, the spirit of the sect was degenerated to downright madness: at first, its members being no more than severe public monitors, commanded attention and

respect, but their freedom in censuring had degenerated into scurrility, and the conduct of Menedemus surpassed, in folly and extravagance, every thing that had gone before him. He appeared in public dressed in a black cloak, with an Arcadian cap upon his head, on which were drawn the figures of the twelve signs of the zodiac, with tragic buskins on his legs, with a long beard, and with an ashen staff in his hand, exclaiming, that he was a spirit returned from the infernal regions to admonish and reform the world. Enfield's Hist. Phil.

MENEHOULD, *Str.*, in *Geography*, a town of France, and principal place of a district, in the department of the Marne. The place contains 3394, and the canton 12,820 inhabitants, on a territory of $437\frac{1}{2}$ kilometres, in 30 communes. The town is situated in a morass between two rocks, on the highest of which is a castle; 22 miles E.N.E. of Chalons. N. lat. $49^{\circ} 5'$. E. long. $4^{\circ} 55'$.

MENEJRE, a town of Arabia, in Yemen; 34 miles S.E. of Lobeia.

MENELAUS, in *Biography*, king of Sparta, famous in ancient history for the share which he took in the Trojan war, was son of Atreus, king of Argos, and brother of Agamemnon. He married Helen, the daughter of Tyn-darus, king of Sparta, and in her right succeeded to the crown of that country. According to the best account of the origin of the Trojan war, Paris, son of Priam, induced by the fame of Helen's beauty, paid a visit to the court of Menelaus, where he was most hospitably received. During his stay, Menelaus was obliged to take a voyage to Crete, and Paris made use of this opportunity to carry off Helen, together with all the treasure and rich moveables he could lay his hands upon. This injury was made a common cause by the petty kings of Greece, who, with a powerful army under the command of Agamemnon, laid siege to Troy. Menelaus was present as a leader of the confederates. In the tenth year of the Trojan war, Helen obtained the forgiveness and favour of Menelaus, by introducing him with Ulysses, the night that the city was reduced to ashes, into the chamber of Deiphobus, whom she had married after the death of Paris. This perfidious conduct totally reconciled her to her first husband, and she returned with him to Sparta, where Telemachus is represented in the *Odyssey* as finding them living in peace and prosperity. Menelaus is said to have been succeeded in this kingdom by two illegitimate sons, who were expelled by Orestes, son of Agamemnon. The palace which Menelaus once inhabited was entire in the days of Pausanias, as well as the temple which had been raised to his memory by the people of Sparta. Homer. Univer. Hist.

MENELAUS, a celebrated mathematician, who flourished under the reign of the emperor Trajan, was of Grecian extraction, but a native of Alexandria. He is called by Ptolemy a geometrician, as having made astronomical observations at Rome in the year 98 of the Christian era. He is supposed to have been the Menelaus referred to by Plutarch in his dialogue "De Facie quæ in orbe Lunæ apparet." He was author of three books "On Spherics," which have come down to the present times through the medium of the Arabic language. A Latin version of this work was published at Paris by father Merfenne, in 1664, with corrections, restorations, and additional illustrative propositions. Gen. Biog.

MENELAUS, called also *Menelaites*, in *Ancient Geography*, a town of Egypt, and capital of a nome called *Menelaites* by Pliny. According to Strabo, Menelaus is not far from the nome of Nitria.—Also, a town of Africa, in Marmarica,

rica, placed by Ptolemy in the interior of the country between Leuceæ and Gaphara

MENECLAUS, in *Geography*, a town of Africa, in Barca; 105 miles E.S.E. of Cureu. N. lat. 32° 10'. E. long. 23° 10'.

MENENIUS, in *Biography*. See *AGrippa*.

MENERANDRE, in *Geography*, a river on the S. coast of Madagascar, which runs into the sea, S. lat. 25° 5'. E. long. 42° 24'.

MENERBES, a town of France, in the department of the Mouths of the Rhone; 9 miles S.W. of Apt.

MENEROLA, a town of Genoa; 5 miles S.W. of Spezza.

MENES, in *Biography*, the founder of the Egyptian empire, was born at This, a town of Thebais, in Upper Egypt. He is supposed to have reigned 117 years after the birth of Phaleg, son of Heber, which was the year of the dispersion of the people throughout the earth. He built the town of Memphis, and in the prosecution of his work stopped the course of the Nile near it, by constructing a causeway several miles broad, and caused it to run through the mountains. By his ability and popularity he was deified after his death. He had three sons, who ruled after him, *viz.* Athotis, who ruled at This and Thebes; Curudes, who founded the kingdom of Heliopolis, afterwards the kingdom of Diospoli; and Necherophes, who reigned at Memphis.

MENESTREL, a musician, whose name and employment have been recorded by Pithon in his "History of the second Race of Kings of France," who tells us, that it was during the reign of Pepin that the chapel royal was established at Paris, under a music-master named Menestrel; which, perhaps, may have been the origin of the name of Menestrel, or Minstrel, being given, in after times, to musicians in general. Pepin died in 768.

MENESTRELS were the singers, and *Menestriers* the instrumental performers in France, who, in the time of king Robert, formed themselves into a society of musicians, in imitation of the ancient bards; they composed and executed the music to the poetry of the *trouvères, troubadours*, or *romancers*, who composed poems in rhyme. Others were called *jongleurs*, and *chantores* or *menestrels*.

In a tariff of St. Louis to regulate the toll at the entrance into Paris, it is said that the *jongleurs* should be excused paying the toll, upon condition that they sung a song, (hence, perhaps, the proverb of paying for any thing with a *song*), or made their monkeys dance, (whence, probably, the French have derived another proverb, "payer en monnoie de singe.")

MENESTRIER, JOHN BAPTIST LE, in *Biography*, an able antiquary, was born at Dijon in 1564. He obtained some considerable offices at court, but is particularly known by a work entitled "Medailles, Monnoies, et Monumens antiques d'Imperatrices Romaines." This was published in 1625; the author died in 1634, and in 1642 a posthumous work was given to the world by his friends, under the title of "Medailles illustres des anciens Empereurs et Imperatrices de Rome." Neither of these works is in much esteem by modern medallists.

Among the curious works of this ingenious Jesuit, his treatises on representations in music, and on ballets, or stage-dances, ancient and modern, should be consulted by those who read, as well as those who write histories of music and dancing: as the information they contain is original, and such as no other books can supply.

John Baptist le Menestrier, the learned antiquary of Dijon, who died in 1634, was an ancestor of the ecclesiastic,

and had the same singular passion for science and curious inquiries. He wrote on medals, coins, ancient monuments, on the Roman empresses, &c. Being buried in the church of St. Medard, in Dijon, the following extraordinary epitaph was formerly legible on his tomb-stone:

"Cy git Jean le Menestrier,
L'an de sa vie soixante-dix
Il mit le pied dans l'estrier,
Pour s'en aller en Paradis."

"Here John le Menestrier was put,
At threescore years and ten, precise;
Who then in stirrup placed his foot,
To go full speed to Paradise."

MENESTRIER, CLAUDE LE, also of Dijon, and a contemporary of the preceding, was likewise attached to the study of antiquity, and became keeper of the Barberini Museum. He is author of "Symbolica Dianæ Ephesiz Statua explicata," 4to. published in 1657. Moreri.

MENESTRIER, CLAUDE FRANCIS, a Jesuit known by his works on heraldry, &c. was born at Lyons in 1631. He entered, at an early age, into the society of the Jesuits, where he acquired a great knowledge of the ancient languages, and of literature in general. As he advanced in life, he devoted himself chiefly to the study of history, with all that relates to family distinctions, and the monuments of antiquity. He travelled into most of the countries of Europe, and by the knowledge which he acquired, he was enabled to make a figure in theological disputations, and in pulpit oratory. He was, however, particularly famous for his talents in planning and arranging all kinds of festive exhibitions, sacred and profane, from the entry of a prince to the canonisation of a saint. In his designs, devices, and inscriptions, his invention was inexhaustible. He had a great acuteness in decyphering old and mutilated inscriptions, blazoning coats-of-arms, explaining paintings and sculptures, and in all operations of antiquarian science. He died in 1705, at the age of seventy-four. The principal works of this author were, 1. "Histoire Civile ou Consulaire de la Ville de Lyon;" "Eloge Historique de la même Ville;" "L'Histoire du Regne de Louis le Grand par les Medailles, Emblemes, Devises, &c.;" "Methode du Blason;" "La Philosophie des Images;" besides these, however, he wrote a number of smaller pieces on similar topics. Moreri.

MENETOU-SALON, in *Geography*, a town of France, in the department of the Cher, and chief place of a canton, in the district of Bourges; 9 miles N. of Bourges. The place contains 3277, and the canton 10,873 inhabitants, on a territory of 367½ kilometres, in 11 communes.

MENETOUS, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Romorantin; 8 miles S.E. of Romorantin. The place contains 824, and the canton 4794 inhabitants, on a territory of 240 kilometres, in 10 communes.

MENEZES, in *Biography*. This is the name of the Condes de la Ericeira, a noble house in Portugal, in which the love of literature, united with considerable talents, continued to be hereditary for many generations. In the General Biography, the most celebrated persons are mentioned, with their principal works, in one article. To this we shall be indebted for the following account. The first of the family distinguished for literary talents was Don Diego, who, in 1628, published "Vida de D. Henriquede Menezes Governador de la India," 4to. Madrid. The second distinguished person was Don Fernando, whose chief publications were,

were, 1. "Historiarum Lusitanarum libri decem ab anno 1640, usque ad annum 1656." 2. "Historia de Tangere," folio, Lisboa, 1732. 3. "Vida de el Rey D. Joam I." His brother, son-in-law, and heir, Don Luiz, published a still more valuable work than any of the foregoing, under the title of "Historia de Portugal Restaurado." The wife of Don Luiz kept up the credit and fame of the family as an author, and it has been said of her, that "she wrote not with the quill of an eagle, for of such there are many;—but with the quill of a Phoenix, of which there is but one." This lady, as we have hinted, belonged to the family by blood, as well as marriage, having married her father's brother. Don Francisco Xavier, the son of this marriage, left behind him forty-four works, of which the most known and celebrated is the "Henriqueida, Poema Heroico, em doze Cantos," 1741. The Conde, Don Henrique, founder of the royal house of Portugal, is the hero of the piece. It appears that the author of this work, at the age of eight, was member of one academy, which seems by its title to have been designed for extemporary speaking; and, when a little older, was admitted into another, of which, at twenty, he was president. This, says his biographer, was the age of academies in Portugal: he was secretary and protector of the Portuguese, and censor and director of the royal one; a member of the Arcadians of Rome, and of our own Royal Society. He had as correspondents the most learned men in the different nations of Europe. He says in his preface, that the knowledge which he has of Greek is not sufficient for him to understand Homer well, a proof how little that language was cultivated in his country, when the most learned man in it would make such a declaration: in other respects, this preface discovers a range of poetical reading which few have equalled, and none, perhaps, exceeded. The poem itself is not worse than its French name-fake, though its faults are of a different character. He was blind when he wrote it, and died before it was published. This truly estimable man was the munificent patron of letters. He increased the family library with 600 MSS., and 20,000 volumes.

"This vein was not yet exhausted; Don Luiz, the fifth Conde, wrote commentaries of his own administration in India, corrections, and a supplement to Bluteau's Portuguese dictionary, and also to Moreri. He completed the catalogue of the library which his predecessor had begun: it was one of the noblest which any private family ever collected together, but it has been dispersed, and I (Mr. Southey), who write, have purchased some volumes from its wreck at the stalls in London. Portuguese literature is deeply indebted to this noble house. Individuals have succeeded better, but no family has ever done so much." Gen. Biog.

MENF, in *Geography*. See MEMPHIS.

MENFRICI, a town of Sicily, in the valley of Mazara, containing about 2700 inhabitants; 9 miles N.W. of Sacca.

MENFUS KEDDUS, a town of Abyssinia; 60 miles S.S.E. of Siré.

MENGEN, a town of Wurtemberg, insulated in the county of Scheer; 33 miles S.W. of Ulm. N. lat. 48° 3'. E. long. 9° 23'.

MENGENGUT, a town of Prussia, in the province of Oberland; 12 miles E. of Osterrod.

MENGERINGHAUSEN, a town of Germany, in the county of Waldeck; 24 miles W.N.W. of Cassel.

MENGERSDORF, a town of Germany, in the principality of Culmbach; 13 miles S. of Culmbach.

MENGER-S-KIRCHEN, a town of Germany, in the county of Nassau-Dillenburg; 7 miles S.W. of Dillenburg.

MENGESTA SEMAIAT, a town of Abyssinia; 165 miles S. of Gondar.

MENGOLI, PETER, in *Biography*, was an able Italian mathematician in the 17th century, concerning the place and time of whose birth there is no trace. He studied mathematics under Cavalieri, to whom the Italians ascribe the invention of the first principles of the infinitesimal calculus. Mengoli was appointed professor of "Mechanics," in the college of nobles at Bologna, and acquired high reputation by the success with which he filled that post. His principal works are, "Geometriae Speciosae Elementa;" "Novae Quadraturae Arithmeticae, seu de additione Fractionum;" "Via regia ad Mathematicas ornata;" "Refrazione e paralasse Solare;" "Speculationi de Musica;" "Arithmeticae rationalis Elementa;" "Arithmetica realis." Moreri.

His "Speculationi di Musica," a desultory and fanciful work, was published at Bologna, 1670. An account of this treatise was given in the *Phil. Transf.* vol. viii. N° c. p. 6104. seemingly by Birchensha, who, at the close of the article, has not forgotten himself, or his own interest. The speculations contained in Mengoli's work are some of them specious and ingenious; but the philosophy of sound has been so much more scientifically and clearly treated since its publication, that the difficulty of finding the book is no great impediment to the advancement of music. He was still living in 1678.

MENGRAVILLA, in *Geography*, a town of Spain, in Old Castile, famous for its mines of salt: near Avila.

MENGS, ANTHONY RAPHAEL, in *Biography*, was born on the 12th of March, 1728, at Aulitz, in Bohemia. His father, whose name was Ismael, was a miniature and enamel painter, and dedicated his son to the art from his birth: hence he had him christened after the names of *Anthony Allegri da Correggio*, and *Raphael d'Urbino*. His first studies were of course under the eye of his father, who from his earliest childhood obliged him to labour with his pencil; and as soon as possible gave him information of geometry and chemistry, in which sciences he became the most intelligent artist in Europe. Seeing that his son pursued his studies with a reflective mind, Ismael justly concluded, that it would be right at once to introduce him to the fountain head of the art, and lay before him the purest models for his study; and, therefore, at the early age of 12, he took him to Rome, and there introduced him to the works of M. Angelo, Raphael, &c. &c. Young Mengs was so far advanced in the art as to be capable of relishing the superior productions now laid open before him; prints and drawings from which he had long been accustomed to copy: and was eagerly desirous of persevering in the laudable desire of imitating them. At first, his father confined him to drawing in crayons from the Laocoon, the Torso, and the works of M. Angelo; and afterwards from those of Raphael. This most excellent system of education he himself thwarted, by enacting too much and too minute an imitation, and too long confinement to that alone; at a time when, if the vivid fancy of youth had been permitted to indulge itself, Mengs might have imbibed the spirit which animates, which governs the compositions of those great labours which were before him, instead of dwelling on the surface, and forgetting the object of the whole; which is, or should always be, the prime end in view in all studies made upon the works of others. That he was capable of all this fully appears by what he did, particularly by his future reasonings (which are published) upon the works of the principal painters; and that he did not do it effectually, equally appears by his paintings; which possess more of the character of the lines and composition observable in the works of Raphael, who was his favourite, than his just perception

of point and interest in a story, and the true pathos with which he selected incidents, and gave expression and grace to his figures.

It was only for three years that his father, who was extremely tyrannical and arbitrary, allowed him to stay at Rome, at the end of which time, probably being anxious to turn his son's talents to account, he obliged him to return with him to Dresden, where all this excellent preparation was defaced, by our artist being employed to paint portraits in crayons; by which, however, he became known to, and employed by, the king of Poland, who made him his cabinet painter, gave him a house and a pension, without any other obligation, than to give him the preference of those works he might perform, and for which he would pay the full price.

With this good fortune he returned to Rome to prosecute his studies; at first copying, but at length beginning to compose his own pictures. About this time he married a young lady of a respectable family, Margarita Guazzi, and was in hopes of being permitted finally and fully to establish himself in Rome; but his father, at the end of four years, again, in 1749, forced him to return to Dresden, and in pursuance of his arbitrary feeling quarrelled with him, seized his whole property, and turned him out of doors.

His talents were now his only safeguard and support, and, to the honour of the king, proved truly so. His majesty patronized him, gave him a house and a carriage, appointed him his first painter, and doubled his pension, without any obligation, and permitted him again to visit Rome.

His first work there was a copy of the school of Athens by Raphael, for the earl of Northumberland, which is now at Northumberland House. The failure of affairs at the court of Saxony and Poland, which happened soon after, caused a stoppage of his pension, threw Mengs upon the world, and induced him to accept many commissions for pictures; the principal one of which, a fresco ceiling in the church of the Augustines, dedicated to St. Eusebius, acquired him great reputation, and some employment of the like nature in the villa Albani; where he painted in fresco Apollo, and the Muses on Parnassus.

Some pictures which Mengs had executed acquired him the favourable regard of the king of Naples, who, upon becoming king of Spain under the title of Charles III., sent for him to Madrid, offering him a ship of war to convey him, a salary of 2000 doubloons, a house, a carriage, and to defray all the expences attending his professional labours. This munificent offer was readily accepted, and Mengs arrived in Spain in October 1761. The king received him with great kindness, and continued the same attention to him all the while he remained in that country, which was several years. He executed a great number of pictures both in fresco and in oil, which were highly admired and applauded by the court, but were criticised by some, as being too cold and phlegmatic in their style and expression.

Excess of study, and disgust at the harsh conduct of some of his contemporaries, affected his health; and being deprived of the benefit of domestic enjoyment, having sent his family to Rome, he fell into dependancy, and a decline approaching, his life was despaired of, when he obtained permission to return to Rome, still enjoying his pension as first painter to the king.

His health and spirits were soon re-established in his favourite residence, and he was employed by Clement XIV. to paint in the Vatican; particularly in the cabinet where the ancient papirii were preserved. He prolonged his stay in Italy as long as he could, though advised

by his friend the chevalier d'Azara, the Spanish minister at Rome, that his return to Spain was looked for by the king, by whose command he was at last obliged to go there again. He took part of his family with him, and remained there two years and a little more, painting many things, and again becoming exhausted and ill, too ill to prosecute his labours, his majesty left him at full liberty to return, with his pension of 3000 scudi, and 1000 more to divide in dowry among his daughters.

He had not been long in Rome when he lost his wife, which severe affliction entirely changed his mind and manners, and rendered him morose and unhappy, a scourge to himself and those around him. His old disease returned upon him, and in a short time afterwards he paid the debt of nature, having only attained the age of 51.

If the name and qualifications of Mengs had not been so extravagantly exalted by his friend and commentator Azara, and by Winkelmann, it is most likely his memory would have been in more esteem with the world than it now is. But when they resorted, in speaking of his talents, to such a degree of absurdity, as to place him above all competitors, either ancient or modern; to speak of him as the man for whom it was reserved to unite all the excellencies of art, criticism is excited, and a more scrupulous and less prejudiced examination induced, which bellows upon our artist a far less exalted rank among those great men with whom he has been compared, and even to whom he has been preferred, than his partial and prejudiced friends allotted to him. He certainly was the most ingenious professor they were acquainted with. His long and laborious researches into the more obscure matters relating to art, and his careful and even enthusiastic examination of the works of the ancients, and consequent knowledge of them, rendered him in their eyes, who do not appear to have had so much taste as enthusiasm, a kind of demi-god. But it is not researches and knowledge of this nature which make the artist; they will indeed assist him with principles and materials, they will prevent compositions, and fill vacant spaces upon a canvas, or on a wall, with something agreeable to, or imposing upon, the eye; but if the soul be wanting, if the true perception of that which alone stimulates the feeling heart and understanding mind, impress not its energy upon the observer, the artist is but a mechanic, whose studies happen to have fallen into a more side-long track than those of the generality; or at most he may be saluted with the title of the man of science, never in comparison with the truly great artists will he merit their distinguishing appellation.

These remarks are justly applicable to Mengs, who, though a very ingenious and extraordinary man, is but a tame and rather uninteresting artist. Mr. Cumberland, in his memoirs of painters in Spain, has given a very excellent and just critique upon his merits, which we will here transcribe. He was excited to it by a remark of Mengs upon the discourses of sir J. Reynolds, in which that artist observes, that "those discourses would lead youth into error, because they abandon them to superficial principles, the only ones known to the author." After some little petulance exhibited in the former part of his answer to this remark, Mr. Cumberland says, "that Mengs was an artist that had seen much and invented little; that he dispenses neither life nor death to his figures, excites no terror, rouses no passions, and risks no slights; that, by studying to avoid particular defects, he incurs general ones, and paints with tameness and servility; that the contracted scale and idea of miniature painting to which he was brought up, is to be traced in all or most of his compositions, in which a finished delicacy of pencil ex-

hibits the hand of the artist, but gives no emanation of the soul of a master; if it is beauty, it does not warm; if it is sorrow, it excites no pity." The picture of our Saviour's appearing to Mary Magdalen in the garden, known by the name of *The Noli me tangere*, which is in the chapel of All Souls' college, Oxford, will enable our readers to judge how far these remarks are founded in truth.

As a critic, Mengs has a more fair claim to attention. He certainly entertained sublime ideas of the capabilities of art, and therefore inspires them in the minds of his readers. There is, however, too great a mixture of metaphysics and subtle disquisition in his writings, to be generally useful. His explanations of beauty and taste are extremely vague. The former is built entirely upon the Platonic system of the beauty of goodness. On this, however, he proposes material selection from various objects of the same kind, to produce the beautiful of each species, and this choice he completely confounds with taste. Notwithstanding these defects, his writings convey much useful matter, and present many important points, for the consideration of an artist; as they embrace all the essential principles of the art of painting. They were published after the death of Mengs, by his friend the chevalier d'Azara; who also mentions that all the technical parts of Winkelmann's history of the arts are written by Mengs.

MENHAIA, in *Geography*, a town of Fez, in the province of Chaus, inhabited by Arabs.

MENHUSS, a town of Africa, in the country of Barca; 160 miles S.W. of Tolomata.

MENIAL SERVANTS. See SERVANTS.

MENIAN COLUMN. See COLUMN.

MENIE', in *Geography*. See MINIET.

MENIF, or MENUF, a town of Egypt, and chief place of a district; 28 miles N. of Cairo.

MENIGOUTTE, a town of France, in the department of the Two Seves, and chief place of a canton, in the district of Parthenay; 11 miles S.S.E. of Parthenay. The place contains 880, and the canton 7101 inhabitants, on a territory of 240 kilometres, in 10 communes.

MENIL, a town of the Arabian Irak, on the Tigris; 110 miles S.E. of Bagdad.

MENILITE; *Menilit*, Wern.; *Leber-Opal*, Karst.; *Quarz-résinite menilite*, Häüy.

The colour of this fossil, on the planes of fracture, is between chestnut and liver-brown, passing into hair-brown, and into greyish-yellow; externally the brown variety possesses a blueish tarnish, owing to closely adhering particles of the matrix in which it is found.

It occurs in knob-shaped or tubercle imbedded masses, and in amorphous tuberculated pieces, with rough dull surface.

Internally it is glistening, passing into shining; lustre sometimes resinous.

Longitudinal fracture coarse splintery, passing into flat conchoidal; transversal fracture flat conchoidal, more or less in a parallel direction; fragments indeterminate angular and sharp-edged, translucent on the edges. It yields a greyish-white streak.

Not very hard; hardness that of the semiopal; brittle, easily frangible. Spec. grav. 2.185, Klapr.; 2.162, Jordan.

It is infusible before the blowpipe, but becomes of a lighter colour, opaque, and flawed. With borax it fuses slowly, and with some ebullition. According to Klapproth's

analysis of the menilite, a hundred parts are composed of

Silica	-	-	-	85.50
Argil	-	-	-	1.00
Lime	-	-	-	0.50
Oxyd of iron	-	-	-	0.50
Water and carbonaceous matter				11.00
				98.50

It is found near Paris, the darker variety at Menil-Montant, the lighter or greyish at Argenteuil; at both places under a thick bed of clay, in a particular kind of slate, called *Klebschiefer* by Werner, or *adhesive slate*. According to Häüy it also occurs on the banks of the Maas. A blackish-green fossil, agreeing in most of its characters with menilite, and likewise in being found imbedded in adhesive slate, is met with at Zamuto, in the district of Semplin, in Hungary.

This fossil was first referred by Werner to the semiopal; and Karsten still enumerates it as a particular subspecies of opal, under the name of liver-opal, derived from its colour.

MENIMAN, in *Geography*, a town of Asiatic Turkey, in Natolia, from which Smyrna draws its chief supply of fruits and provisions.

MENIN, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. This town consists of little more than one street, with one parish church, situated on the Lys; and yet it has been the subject of many contests and vicissitudes during various wars. The place contains 4911, and the canton 17,769 inhabitants, on a territory of 100 kilometres, in seven communes. N. lat. 50° 48'. E. long. 3° 5'.

MENING, in *Botany*, a name given by the people of Guinea to a plant of the *resinous* or *palma Christi* kind, which they use in medicine: they dry and powder the leaves, and then give them to be snuffed up the nostrils, to cure all sorts of stuffings or stoppages in the head. Its leaves resemble those of the finch and ivy, and are hairy; whence Petiver has named it *ricinus Guineensis hederæ quinquefolia Virginianæ facie foliis hirsutis*. It is not known to grow any where in America. Philof. Trans. N° 232.

MENINGE, in *Ancient Geography*, an island of Africa. Plutarch, in Mario, says that Marius landed on the island of Meninge, and that from thence he passed to Carthage. This island is called by Ptolemy Lothophagites, in which were two towns, viz. Gerrapolis and Meninge.

MENINGEA ARTERIA, in *Anatomy*, a branch of the internal maxillary artery distributed upon the dura mater. See ARTERY.

MENINGES, from *μνινξ*, a *membrane*; a term sometimes employed in speaking of the membranes of the brain.

MENINGOPHYLAX, from *μνινξ*, a *membrane*, and *φυλασσω*, to *guard*, an instrument in use amongst the ancient surgeons for protecting the dura mater and brain from injury, in their mode of trepanning. It was somewhat like the lenticular, only its blade was completely round, without any edge, and it ended, like this other instrument, in a lentiform cup.

MENINSKI, or MENIN, FRANCIS, in *Biography*, a considerable oriental scholar, was born at Lorraine in 1623. Of the early part of his life we have no account, but he studied at Rome, and being particularly attached to the acquisition of the Eastern languages, when about the age of thirty he accompanied the Polish ambassador to Constantinople, and there applied so assiduously to the study of the Turkish tongue, that in a very short time he was made first interpreter to the Polish embassy at the Porte; and afterwards

was raised to the office of ambassador plenipotentiary to that court. Hence he was naturalized in Poland, and added the termination *ski* to the family name of *Menius*. In 1661 he accepted the post of interpreter of the Oriental languages at the court of Vienna, and accompanied the imperial ambassador to the Porte. In 1669 he visited the holy Sepulchre at Jerusalem, and was created a knight of that order. His services were so much approved, that on his return to Vienna he was appointed one of the emperor's council of war, as well as first interpreter. He died in 1698. As an author, the great work of Meniuski was his "Thesaurus Linguarum Orientalium," published at Vienna in 1680, in four volumes folio. Of these the fourth was entirely destroyed by the falling of a bomb upon the author's house during the siege of Vienna by the Turks, which obliged him to recompose it. The other volumes were greatly injured at the same time, which rendered the work extremely scarce and dear. A new edition of it with improvements was begun at Vienna in the year 1780. The Turkish, Persian, and Arabian grammars contained in the "Thesaurus," were republished in two volumes quarto, 1756.

MENIPEAN, *Satira MENIPEA*, a kind of satire consisting of prose and verse intermixed.

It is thus called from Menippus, a Cynic philosopher, who delighted in composing satirical letters, &c. In imitation of him, Varro also wrote satires under the title of "Satira Menippæ;" whence this sort of composition is also denominated *Varronian satire*.

Among the moderns, there is a famous piece under this title, first published in 1594, against the chiefs of the league, called also the "Catholicon" of Spain. It is esteemed a master-piece for the time.

MENISCIUM, in *Botany*, so called by Schreber, the author of the genus, from *μηνίσκος*, a *crefcant*, in allusion to the shape of the fructification. Schreb. Gen. 757. Swartz. Syn. Fil. 19. Sprengel Crypt. 93. t. 3. f. 20. Cavan. Leccion. 548. Mart. Mill. Dict. v. 3. Lamarck Dict. v. 4. 93. Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*, Linn. Juss.

Gen. Ch. *Capsules* annulated, in small, single, curved lines, nearly parallel to each other, and situated transversely, in regular series, betwixt the veins of the frond. *Involucrum* none.

Eff. Ch. Fructification in a series of small, transverse, crescent-shaped lines, between the veins of the frond. *Involucrum* none.

1. *M. triphyllum*. Swartz. n. 1. Sprengel as above.—Frond three-leaved. Native of China and the East Indies. Sprengel represents the frond as about five inches long, smooth, consisting of one large, terminal, oblong, pointed, entire leaflet, and a pair of much smaller, opposite, sessile ones, a little below it. Each of the leaflets is furnished with a midrib, and numerous transverse, oblique, parallel veins, connected by fine, regular, decussating lines of fructification.

2. *M. reticulatum*. Sw. n. 2. (*Polypodium reticulatum*; Linn. Sp. Pl. 1549. *Aplenium forbifolium*; Jacq. Coll. v. 2. 106. t. 3. f. 2. *Filix latifolia non ramosa, nigris tuberculis pulverulenta*; Plum. Amer. 6. t. 9. *Lingua cervina, nigris tuberculis pulverulenta*; Plum. Fil. 92 t. 110.)—Frond pinnate; leaflets undivided.—Native of the West Indies. We have it from St. Kitt's. Plumier found it very abundantly in ascending the mountain called *de la Calabasse*, in Martinico. This is a very large and handsome fern, about four feet high; the stalks smooth and shining, dark brown, or black. *Leaflets* numerous, about a span long, and above

an inch wide, almost sessile, alternate, but all near the base, tapering to a sharp narrow point; the margin slightly crenate, or wavy. The whole under-side is covered with *fructification*, in curved lines, more answering to the form of a crescent than those of the former species. Sprengel compares Linnæus without reason for making this fern a *Polypodium*; for the latter, having never seen a specimen of fructification, necessarily trusted to Plumier, whose fronds, less faithful than usual, as well as his description, abundantly justify Lamarck.

3. *M. proliferum*. Sw. n. 3. (*Hemionitis prolifera*; Retz. Obs. falc. 6. 38.)—Frond pinnate; leaflets lanceolate, crenate, with axillary smaller leaflets. Sent by Koenig from the East Indies. It is described as a large decumbent fern, with alternate, sessile, lanceolate, crenate leaflets, about half a foot long, abrupt at their base. From these are produced, at their origin, other axillary fronds or branches, a foot and half long, often in pairs, whose leaflets are exactly like the former, but much smaller, and the stalk has a knot at the part whence they originate. Fructification in decussating irregular lines, so as sometimes to give the character of a *Polypodium*, sometimes of an *Aerostichum*.

4. *M. cristatum*. Lamarck Dict. v. 4. 94.—"Frond pinnate; leaflets nearly opposite, lanceolate, pointed; the lower ones pinnatifid, with obtuse finely toothed segments"—Native of Martinico. Fronds about a foot and a half high, or more, with numerous falcate leaflets, of a delicate texture, about four inches long, and near an inch broad. The margin is cut throughout into rounded lobes or segments, finely toothed at their edge. Fructification copious, in curved lines.

Swartz enumerates this among his doubtful species; we do not distinctly see for what reason.

5. *M. ferratum* Cavan. Leccion. 548.—"Frond pinnate; leaflets alternate, lanceolate, serrated."—Native of the Havannah. Fronds above two feet high, shining. Leaflets five inches long, the lower ones an inch broad; all sharp-pointed, finely toothed. Fructification in curved parallel lines.

This also is reckoned by Swartz among the species which merit further inquiry; as well as a *Meniscium* from Cayenne, of which nothing is given but the generic character by Richard in the *Actes de la Société d'Hist. Nat. de Paris*, v. 1. 114.

Although *Meniscium* is, as yet, known to consist of but few species, it has all the characters of a very natural genus, nearly resembling *Hemionitis* indeed in character, but dissimilar in habit.

MENISCUS, in *Optics*, a glass or lens, concave on one side, and convex on the other; sometimes also called *lunula*. See **LENS**, and **OPTIC GLASS**.

In a meniscus, if the diameter of the convexity be equal to that of the concavity, a ray, falling parallel to the axis, will continue parallel thereto after refraction.

Such a meniscus, therefore, will neither collect nor disperse the rays; and is therefore of no use in dioptries.

To find the focus of a meniscus, the rule is, as the difference of the semidiameters of the convexity and concavity is to the semidiameter of the convexity, so is the diameter of the concavity to the distance of the focus from the meniscus. Hence, if the semidiameter of the concavity be triple the semidiameter of the convexity, the distance of the focus from the meniscus will be equal to the semidiameter; and therefore the meniscus will be equivalent to a lens equally convex on either side.

Again, if the semidiameter of the concavity be double that of the convexity, the distance of the focus will be equal

to the diameter; and therefore the meniscus will be equivalent to a plano-convex lens.

If the semidiameter of the concavity be quintuple that of the convexity, the meniscus will be equivalent to a sphere. The semidiameter, therefore, of the convexity being given, that of the concavity required to remove the focus to any given distance from the meniscus, is easily found.

MENISPERMA, in *Botany*, the seventy-seventh natural order in Jussieu's system, the seventeenth of his thirteenth class, named from the principal genus belonging to it; see the next article. For the characters of the class, see **GERANIA**. The order is defined as follows:

Calyx of a definite number of leaves. *Petals* of a definite number, opposite to the calyx; with an equal number of scales, in some of the genera, at the inside of the petals and opposite to them. *Stamens* of a definite number, equal to that of the petals, and opposite to them. *Germens* several, with as many styles and stigmas. *Fruits* as many, either pulpy or capsular, kidney-shaped, each containing one seed, of their own shape; many of them however are frequently abortive, one only coming to perfection. *Embryo* flat, small, with thin lobes, situated at the top of the fleshy albumen, which is much more incurved than itself. *Stem* shrubby, mostly farmentose. *Leaves* alternate, simple, without stipulas. *Flowers* axillary or terminal, often in aggregate spikes or clusters, each collection attended by a single bractea; they often become dioecious by imperfection of the respective organs of impregnation.

The genera enumerated by Jussieu are *Cissampelos*; *Menispermum*; *Leaba* of Forskall, perhaps not different from it; *Epibaterium* of Forster; and *Abuta* of Aublet.

The opposite situation, with respect to each other, of the calyx, petals, and stamens, brings this order near that of the *Berberides*; but the germen of the latter is simple, with many seeds, their albumen straight, surrounding the whole embryo, which is longer than in the *Menisperma*, and their anthers are differently formed, being very peculiar, and opening by revolute valves, in the *Berberides*. Their habits moreover are very unlike.

MENISPERMUM received its name, composed of $\mu\eta\sigma\eta\sigma$, the *moon*, and $\sigma\pi\epsilon\rho\mu\alpha$, *seed*, from Tournefort, in the *Memoires de l'Acad. des Sciences* for 1705; in allusion to the crescent-like form of the seed. Linn. Gen. 530. Schreb. 700. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 411. Juss. 285. Michaux Boreal-Amer. v. 2. 241. Lamarck Dict. v. 4. 94. Illustr. t. 824. Gærtn. t. 46. and t. 70. Class and order, *Dioecia Dodecandria*. Nat. Ord. *Sarmentacea*, Linn. *Menisperma*, Juss.

Gen. Ch. Male, *Cal.* Perianth of two short linear leaves. *Cor.* Outer petals four, ovate, spreading, equal; inner eight, smaller, inversely heart-shaped, concave, four of them in an inner row and broader. *Stam.* Filaments 16, cylindrical, rather longer than the corolla; anthers terminal, very short, bluntly four-lobed.

Female, *Cal.* and *Cor.* as in the male. *Stam.* Filaments eight, like the male, but with pellucid abortive anthers. *Pist.* Germens two or three, superior, stalked, ovate, incurved, approaching each other; styles solitary, very short, recurved; stigmas eloven, obtuse. *Peric.* Berries two or three, roundish-kidney-shaped, of one cell. *Seeds* solitary, large, kidney-shaped.

Obs. By the accounts of authors, the number of the different parts of fructification either differs in different species, or varies in the same: The above characters are taken from *M. canadense*.

Ess. Ch. Male, Outer petals four, inner eight. Stamens sixteen.

Female, Petals as in the male. Eight imperfect stamens. Berries two or three, single-seeded.

A genus of twining, perennial, often shrubby, plants, altogether strangers to Europe, but found in North America, Arabia and Japan, as well as in the East and West Indies. The *roots* of some are large and solid, worthy of inquiry as to their medicinal powers. *Leaves* alternate, stalked, simple, generally undivided, entire, and more or less downy, of a heart-shaped or ovate figure, without stipulas. *Flowers* small, racemose, axillary, inconspicuous, of a green, whitish, yellowish, or lurid hue. *Berries* dark, the size of small peas, in some cases narcotic. The species are not very correctly understood, and it is probable many more exist than botanists have ascertained. The fourteenth edition of Syst. Veg. enumerates eleven. The volume of Willdenow which comprehends this genus is not yet come to our hands. We shall therefore only mention some of the most remarkable species.

M. canadense. Canadian Moon-feed. Linn. Sp. Pl. 1468. Mill. Illustr. t. 93. (*Hedera monophylla, convolvuli foliis, virginiana*; Pluk. Phyt. t. 36. f. 2)—Leaves peltate, heart-shaped, rounded and angular. Clusters compound, drooping.—Native of North America—"from Canada to Carolina." Michaux. *Stem* somewhat shrubby, twining contrary to the sun's course, (*Miller*,) round, smooth, leafy, slightly branched. *Leaves* on long stalks, generally broader than long, peltate a little way from the base, either simply cordate and undivided, or more or less deeply lobed, the lobes either rounded or angular; the upper side dark green, nearly smooth; under glaucous, a little hairy at the ribs and numerous veins. *Panicles* in pairs, shorter than the leaves, drooping. *Flowers* greenish-white. *Berries*, according to Clayton, black.—This plant is preserved in some botanic gardens, but has little beauty to recommend it to general favour.

M. virginicum. Virginian Moon-feed. Linn. Sp. Pl. 1468. (*M. folio hederaceo*; Dill. Elth. v. 2. 223. t. 178. f. 219.) Upper leaves ovate, undivided; lower three-lobed and wavy. Clusters simple, solitary, erect.—Native of Virginia. Linnaeus appears not to have known this species. The specimen in his herbarium, from whence the specific character was taken, is only the foregoing. Dillenius has well figured and described the real *virginicum*, as having *leaves* much resembling ivy, the upper ones being ovate and undivided; the lower lobed and angular. The latter especially are somewhat downy. None of them are peltate. The *flowers* are whitish, in upright, simple, much smaller clusters. *Berries* black. Michaux does not mention this in his *Flora*. It is said to be cultivated in the Cambridge garden, flowering in July.

M. carolinum. Carolina Moon-feed. Linn. Sp. Pl. 1468. Michaux Boreal-Amer. v. 2. 242.—Leaves heart-shaped, downy beneath. Clusters cymose.—Native of Carolina, Linn. also of Georgia and Florida. Michaux. This has the *leaves* heart-shaped, undivided, roughish above, soft and downy beneath. *Clusters* nearly as long as the leaves, cymose, hairy, of numerous small *flowers*. Michaux says the *berries* are red; otherwise we should have a suspicion that his plant was the *virginicum*.

M. Cocculus. Indian-berry Moon-feed. Linn. Sp. Pl. 1468. (*Cocculæ officinarum*; Bauh. Pin. 511. Cocci; Ger. em. 1548. Tubabaccifera; Rumph. Amb. v. 5. 35. t. 22.)—Leaves heart-shaped, pointed, somewhat downy beneath. Clusters compound, from the naked woody stem. *Berries* nearly globular. Native of Ceylon and Malabar. This has a very woody, branched and twisted *stem*, from whence the *flowers* proceed, in compound clusters. The branches

branches are leafy. *Leaves* large, a span long, heart-shaped, pointed; dark green above; downy beneath; on long twisted *footstalks*. *Berries* purplish-black, as big as a black currant; but they come to us dried, and of a much smaller size. They are used in India for catching fish, which they intoxicate if thrown into the water. Their use for this purpose is, we believe, prohibited in England; nor is it easy to account for the copious importation of these berries as an article of trade, unless they serve to adulterate fermented liquors, as is often reported! (See *Cocculus* and *Cissampelos*.) We apprehend that Poiret, quoted in the last article, has confounded two very distinct plants. We have from the East Indies, by the name of *Menispermum orbiculatum*, as well as from the Mauritius, specimens which answer exactly to his description of the female *Cissampelos Cocculus*; but their axillary simple *clusters*, and large heart-shaped *bracteas*, to say nothing of their rounder *leaves*, mark them as sufficiently distinct from the above shrub of Rumphius. Perhaps the berries of several Indian plants, of this family, may have the same intoxicating quality, and be used indiscriminately.

MENISPERMUM, in *Gardening*, contains plants of the hardy climbing kind, of which the species cultivated are, the Canadian moon-feed (*M. canadense*); the Virginian moon-feed (*M. virginicum*); and the Carolina moon-feed (*M. carolinum*.)

Method of Culture.—The two first sorts are easily propagated by laying down the branches in the autumn season, and when the layers have made good roots, in the following autumn they may be separated and planted out where they are to remain. As their branches are weak and slender, they require support; and when planted near trees thrive better than in an open situation.

And the third sort may be increased by parting the roots, and planting them out in the spring, a little before the plants begin to shoot, in warm situations where the soil is light, as in strong retentive land the roots are apt to rot. When planted close to a wall exposed to the south or west, their stalks may be fastened against the wall to prevent their trailing upon the ground; in which situations the plants frequently flower. They should have a little shelter in severe frost, in order to preserve their stalks.

All these plants affords ornament and variety in the shrubberies and other parts of pleasure grounds.

MENITZ, in *Geography*, a town of Moravia, in the circle of Brunn; nine miles S.S.E. of Brunn.

MENKIN, a town of Asiatic Turkey, in Natolia; 36 miles N.E. of Boli.

MENMEN, a town of Asiatic Turkey, in Natolia; 18 miles N.W. of Smyrna.

MENNO, in *Biography*. See the following article.

MENNONITES, in *Ecclesiastical History*, a sect in the United Provinces, in most respects the same with those in other places called Anabaptists.

They had their rise in 1536, when Menno Simon, a native of Friesland, who had been a Romish priest, and a notorious profligate, resigned his rank and office in the Romish church, and publicly embraced the communion of the Anabaptists.

Menno was born at Witmarsum, a village in the neighbourhood of Boifwert, in Friesland, in the year 1505, and died in 1561, in the duchy of Holstein, at the country seat of a certain nobleman, not far from the city of Oldesloe, who, moved with compassion by a view of the perils to which Menno was exposed, and the snares that were daily laid for his ruin, took him, with certain of his associates, into his protection, and gave him an asylum. The

writings of Menno, which are almost all composed in the Dutch language, were published in folio, at Amsterdam, in the year 1651. About the year 1537, Menno was earnestly solicited by many of the sect with which he connected himself, to assume, among them, the rank and functions of a public teacher; and as he looked upon the persons who made this proposal, to be exempt from the fanatical phrenzy of their brethren at Munster (though, according to other accounts, they were originally of the same stamp, only rendered somewhat wiser by their sufferings), he yielded to their intreaties. From this period to the end of his life he travelled from one country to another, with his wife and children, exercising his ministry, under pressures and calamities of various kinds, that succeeded each other without interruption, and constantly exposed to the danger of falling a victim to the severity of the laws. East and West Friesland, together with the province of Groningen, were first visited by this zealous apostle of the Anabaptists; from thence he directed his course into Holland, Guelderland, Brabant, and Westphalia, continued it through the German provinces that lie on the coasts of the Baltic sea, and penetrated so far as Livonia. In all these places his ministerial labours were attended with remarkable success, and added to his sect a prodigious number of followers. Hence he is deservedly considered as the common chief of almost all the Anabaptists, and the parent of the sect that still subsists under that denomination. Menno was a man of genius, and directed by a very sound judgment; he possessed a natural and persuasive eloquence, and such a degree of learning as made him pass for an oracle in the estimation of the multitude. He appears, moreover, to have been a man of probity, of a meek and tractable spirit, gentle in his manners, pliable and obsequious in his commerce with persons of all ranks and characters, and extremely zealous in promoting practical religion and virtue, which he recommended by his example, as well as by his precepts. The plan of doctrine and discipline drawn up by Menno was of a much more mild and moderate nature than that of the furious and fanatical Anabaptists, whose tumultuous proceedings have been recited under that article, but somewhat more severe, though more clear and consistent than the doctrine of the wiser branches of that sect, who aimed at nothing more than the restoration of the Christian church to its primitive purity. Accordingly, he condemned the plan of ecclesiastical discipline, that was founded on the prospect of a new kingdom, to be miraculously established by Jesus Christ on the ruins of civil government and the destruction of human rulers, and which had been the fatal and pestilential source of such dreadful commotions, such execrable rebellions, and such enormous crimes. He declared, publicly, his dislike of that doctrine which pointed out the approach of a marvellous reformation in the church by the means of a new and extraordinary effusion of the Holy Spirit. He expressed his abhorrence of the licentious tenets which several of the Anabaptists had maintained, with respect to the lawfulness of polygamy and divorce, and, finally, considered as unworthy of toleration, those fanatics who were of opinion that the Holy Ghost continued to descend into the minds of many chosen believers, in as extraordinary a manner as he did at the first establishment of the Christian church, and that he testified this peculiar presence to several of the faithful, by miracles, predictions, dreams, and visions of various kinds. He retained, indeed, the doctrines commonly received among the Anabaptists, in relation to the baptism of infants, the millennium, or thousand years reign of Christ upon earth, the exclusion of magistrates from the Christian church, the abolition of war, and the prohibition of oaths enjoined by our

Saviour, and the vanity as well as the pernicious effects of human science. But while Menno retained these doctrines in a general sense, he explained and modified them in such a manner, as made them resemble the religious tenets that were universally received in the Protestant churches; and this rendered them agreeable to many, and made them appear inoffensive even to numbers who had no inclination to embrace them. It however so happened, that the nature of the doctrines considered in themselves, the eloquence of Menno, which set them off to such advantage, and the circumstances of the times, gave a high degree of credit to the religious system of this famous teacher among the Anabaptists, so that it made a rapid progress in that sect. And thus it was in consequence of the ministry of Menno, that the different sorts of Anabaptists agreed together in excluding from their communion the fanatics that dishonoured it, and in renouncing all tenets that were detrimental to the authority of civil government; and, by an unexpected coalition, formed themselves into one community.

Though the Mennonites usually pass for a sect of Anabaptists, yet M. Herman Schyu, a Mennonite minister, who has published their history and apology, maintains, that they are not Anabaptists, either in principle or by origin. However, nothing can be more certain than this fact, viz. that the first Mennonite congregations were composed of the different sorts of Anabaptists, of those who had been always inoffensive and upright, and of those who, before their conversion by the ministry of Menno, had been seditious fanatics; besides, it is alleged that the Mennonites do actually retain, at this day, some of those opinions and doctrines, which led the seditious and turbulent Anabaptists of old to the commission of so many and such enormous crimes: such particularly is the doctrine concerning the nature of Christ's kingdom, or of the church of the New Testament, though modified in such a manner as to have lost its noxious qualities, and to be no longer pernicious in its influence.

The Mennonites are subdivided into several sects; whereof the two principal are the Flandrians, or Flemingians, and the Waterlandians. The opinions, says Mosheim, that are held in common by the Mennonites, seem to be all derived from this fundamental principle, that the kingdom which Christ established upon earth is a visible church or community, into which the holy and just alone are to be admitted, and which is consequently exempt from all those institutions and rules of discipline, that have been invented by human wisdom, for the correction and reformation of the wicked. This principle, indeed, was avowed by the ancient Mennonites, but it is now almost wholly renounced; nevertheless, from this ancient doctrine, many of the religious opinions, that distinguish the Mennonites from all other Christian communities, seem to be derived: in consequence of this doctrine, they admit none to the sacrament of baptism, but persons that are come to the full use of their reason; they neither admit civil rulers into their communion, nor allow any other members to perform the functions of magistracy; they deny the lawfulness of repelling force by force, and consider war, in all its shapes, as unchristian and unjust; they entertain the utmost aversion to the execution of justice, and more especially to capital punishments; and they also refuse to confirm their testimony by an oath. The particular sentiments that divided the more considerable societies of the Mennonites are the following; the rigid Mennonites, called the Flemingians, maintain with various degrees of rigour, the opinions of their founder Menno, as to the human nature of Christ, alleging that it was produced in the womb of the Virgin, by the creating power of the Holy Ghost; the obligation that binds us to wash the feet

of strangers, in consequence of our Saviour's command; the necessity of excommunicating and avoiding, as one would do the plague, not only avowed sinners, but also all those who depart, even in some light instances pertaining to dress, &c. from the simplicity of their ancestors; the contempt due to human learning, and other matters of less moment. However, this austere system declines, and the rigid Mennonites are gradually approaching towards the opinions and discipline of the more moderate Waterlandians.

The first settlement of the Mennonites, in the United Provinces, was granted them by William, prince of Orange, towards the close of the sixteenth century; but it was not before the following century, that their liberty and tranquillity were fixed upon solid foundations, when, by a confession of faith, published in the year 1626, they cleared themselves from the imputation of those pernicious and detestable errors that had been laid to their charge. In order to appease their intestine discords, a considerable part of the Anabaptists of Flanders, Germany, and Friesland, concluded their debates in a conference held at Amsterdam, in the year 1630, and entered into the bonds of fraternal communion, each reserving to themselves a liberty of retaining certain opinions. This association was renewed and confirmed by new resolutions, in the year 1649; in consequence of which the rigorous laws of Menno and his successors were, in various respects, mitigated and corrected. Mosheim's Eccl. Hist.

MENOCHIO, JACOPO, in *Biography*, a learned Italian jurist, was born at Pavia, where he was probably educated, and was elected, in 1555, to the professorship of civil law in its university. Five years afterwards he accepted an invitation from Emanuel Philibert, duke of Savoy, to the newly erected university of Mondovi. In 1566, he removed to Padua, and became professor there, first of common law, and afterwards of civil law. In 1589, he was recalled by the senate of Milan to Pavia, and was, at length, elected a senator of Milan, and president of the extraordinary magistracy. He died in the city in 1607. He was a voluminous writer on subjects connected with his profession, some of which are still referred to by lawyers, particularly his treatises "De conjecturis ultimum Voluntatum," and "De tacitis et ambiguis conventionibus." These are held in high estimation, and their author was unquestionably reckoned the first doctor in civil and canon law of the age in which he lived.

MENOCHIO, JOHN STEPHEN, a learned Jesuit, who flourished in the former part of the seventeenth century, son of the preceding, was born at Pavia in 1576. At the age of seventeen he entered the society of Jesus, where he distinguished himself by his industry and talents, and was, at the close of his academical course, selected to fill the chair of professor: he was afterwards raised to the most honourable posts belonging to the society, in the colleges and provinces of Italy. He died at Rome in 1656. His principal works are, 1. "Hieropoliticon, seu Institutiones Politicæ à Sacris Scripturis depromptæ;" 2. "De Republica Hebræorum;" 3. "Institutiones Economicæ ex Sacris Literis depromptæ;" 4. "Brevis Explicatio sensus Literalis totius Scripturæ." The best edition of the last mentioned work was edited by father Tournemine in 1719, in 2 vols. folio: it was accompanied with a number of valuable treatises and dissertations on biblical subjects. This father wrote "A History of Christ," and six volumes of "Dissertations," chiefly intended to elucidate the holy scriptures. Moreri.

MENOLOGY, MENOLOGIUM, from *μην*, month, and *λογος*, discourse, in the Greek church, is much the same with *martyrology*, or *calendar*, in the Latin.

The Greek menologium is divided into the several months in the year; and contains an abridgment of the lives of the saints, with a bare commemoration of the names of such whose lives were never written. The Greeks have various menologies; and the Romans tax them with inserting divers heretics, in their menologies, as saints. Baillet treats of them at large.

MENORRHAGIA, in *Medicine*, an excessive discharge of the menses in women.

The flow of the menses is considered as excessive, when it recurs more frequently, when it continues longer, or when, during the ordinary continuance, it is more abundant, than is usual with the same person at other times, and more especially when it gives rise to a train of symptoms, indicative of a general diminution of the constitutional strength. But as most women are liable to some inequality with respect to the period, the duration, and the quantity of the catamenia; so it is only when these deviations are excessive, or permanent, so as to induce a manifest deterioration of the health, that they are to be deemed morbid. The affections of the other functions of the body, therefore, are considered by Dr. Cullen as the chief test of the excessive discharge in individuals respectively. When a larger flow than usual, he says, of the menses has been preceded by headache, giddiness, or dyspœa, and has been ushered in by a cold stage, and is attended with much pain of the back and loins, with a frequent pulse, heat and thirl, it may then be considered as preternaturally large. (Cullen, First Lines, par. 971.) The symptoms which inordinate menstruation leaves behind, however, are the most decided proofs of its morbid influence. For after a repetition of the copious discharges, the patient exhibits many symptoms of debility: the face becomes pale, and, if the loss of blood have been profuse, of a remarkably fallow or yellowish-white complexion, which has been aptly termed exsanguine, or bloodless; the pulse is weak and small, and rather more frequent than natural; an unusual lassitude is felt, and great debility on attempting to use exercise; the breathing is hurried by slight exertions; and the back becomes painful from continuance in an erect posture, in consequence of the feebleness of the muscles which support it: towards evening, likewise, the feet are somewhat enlarged by œdematous swelling. Other marks of debility, too, often appear; especially loss of appetite, with pain of the stomach, flatulence, and other symptoms of indigestion; frequent tendency to syncope or fainting; palpitation of the heart; and a weakness of mind, which becomes liable to strong emotions from slight causes, particularly when suddenly applied. From the local debility, produced in the parts from which the excessive discharge proceeds, there is also frequently a mucous discharge, or leucorrhœa, succeeding the menorrhagia; and, in many cases, when the debility has been much augmented by a recurrence of the disorder, there is a regular alternation of the one and the other; the leucorrhœa always appearing on the cessation of the menorrhagia, and continuing until the latter again returns; or, in a word, becoming habitual. See **LEUCORRHŒA**.

We shall not here enter into any theoretical discussion of the nature of the menstrual hæmorrhagy. It will be sufficient to state, that it is generally of what is called the active kind, and that it is accompanied by some degree of febrile *nifus* throughout the circulating system. The menorrhagia has hence been considered as depending, either upon the preternatural increase of the hæmorrhagic effort of the vessels of the uterus, or upon a preternatural laxity of the extremities of the uterine arteries, the hæmorrhagic effort remaining as in the natural state. Cullen, loc. cit.

The *existing causes* of menorrhagia may, therefore, be included under the following heads: 1st Those which increase the plethoric state of the uterine vessels; such as a full nutritious diet, much strong liquor, and especially when taken to the length of frequent intoxication, or combined with a sedentary life. There is much less of menorrhagia among the females of the lower class, in the country, who use a moderate diet, and take regular exercise, than among the ladies of the higher class, who live high, and use little active exercise, and particularly among those who take wine freely, though not to excess. And when young women have been weakened by this hæmorrhage, their matron-friends have too often recourse to more wine, and fuller diet, to restore the strength. This is even done in the pregnant state, to prevent abortions, when the opposite system should be adopted, with a view of diminishing both local and general plethora. 2^{dly}. All causes which determine the blood more copiously and forcibly into the uterine vessels, tend of course to bring on menorrhagia. Such are violent strainings of the whole body, from particular exertions of the muscular strength; violent shocks from falls; severe blows or contusions on the lower belly; violent passions of the mind; and violent exercise, especially in dancing. For in the last mentioned instance, the combination of the muscular exertion with the erect posture tends materially to direct the current of blood to the uterus: and hence the exercise of dancing has sometimes been found an effectual remedy for obstructed menstruation. 3^{dly}. Whatever irritates particularly the vessels of the uterus, may induce menorrhagia; as excess in venery, or the exercise of it during the time of menstruation; a coëive habit of body, giving occasion to violent straining at stool; cold applied to the feet. 4^{thly}. Whatever may have forcibly overstrained the extremities of the uterine vessels, and left them consequently in a weakened and relaxed state: such as frequent abortions, and tedious difficult labours, which give rise to excessive discharge; likewise frequent pregnancy, without nursing, which often not only deranges the general health, but occasions such a derangement of the uterine system, as leads to the production of frequent abortion, terminating in the constant occurrence of menorrhagia and leucorrhœa in alternate succession. And, lastly, all causes inducing a general laxity of the habit, such as living much in hot chambers, drinking much of warm relaxing liquors, as tea and coffee; or, on the other hand, the inability of procuring more substantial diet, combined with watching, fatigue, anxiety of mind, and other causes of constitutional debility, which often give rise to the constant alternations of menorrhagia and leucorrhœa in women of the lower classes.

The *treatment* of menorrhagia must necessarily differ according to the different causes of the disease, and the different states of constitution under which it occurs. In all instances, however, it is of the first importance to avoid the immediate causes of the malady, where these are obvious, and can be shunned; for in this way the returns of the disease may be often entirely warded off, and the health be fully restored, without recourse to medicine.

When this has not been done, and a copious menstrual discharge has come on, it will require the same kind of treatment as other active hæmorrhagies; especially if the patient be of a moderately strong habit; namely, such means as tend to allay inordinate action of the blood-vessels. One of the most important of these means is the application of *cold*, or, more correctly speaking, the abstraction of the stimulus of heat. With this view the apartment should be kept cool, the bed clothes should be light, and the beds not too soft; cold drink should be taken, as freely as the former

former habits of the patient will allow; and even cold applications should be made, as near to the bleeding vessels as may be, by applying wet cloths to the pudendum and round the loins. At the same time it is extremely important for the patient to remain entirely at rest, and that in the horizontal posture; to avoid the quickened circulation, which exertion produces, and the influence of gravitation upon the unsupported vessels in the erect position. The diet should likewise be light and cooling, all stimulants being discarded; and the bowels should be kept open by gentle laxatives, that occasion little stimulus; such as the neutral salts, castor oil, manna, sulphur, &c. Or the lower bowels may be emptied by clysters, which, if used cold, will have the double effect of removing the irritation of feces, and also of refrigerating the uterus, by the contiguity of these parts.

It now and then happens that menorrhagia occurs in robust women, and is accompanied with quickness and some hardness of the pulse, with severe pains in the back resembling those of parturition, and other febrile symptoms. In these cases it is sometimes advisable to diminish the general action of the vascular system by bleeding from the arm, such a practice, however, is not often necessary; for there are few cases, in which the refrigerating plan above mentioned, if pursued with attention and diligence, will not tend to moderate the discharge.

On the other hand, when the menorrhagia arises from an apparent relaxation of the vessels of the uterus, although the practice of depletion must not be adopted, yet all the sources of irritation must be shunned with equal care: for, under such circumstances, the general irritability, or susceptibility of excitement, is usually much increased, and less active stimuli produce a greater effect. The menorrhagia may be presumed to arise from such a relaxed state of the uterine vessels, from the general debility and laxity of the patient's habit, indicated by paleness of complexion, thin and flabby state of the muscular flesh, languor, and incapability of exertion; as well as from a knowledge of her previous state of indisposition, of her mode of life, and of the immediate exciting causes; and particularly from the circumstance, that, in the intervals of menstruation, she is subject to leucorrhœa. Quietness and the horizontal posture are still more requisite in this than in the former case. And as there is often much general irritation combined with this condition of the habit, small doses of an opiate may be employed, with considerable benefit, in moderating the discharge. In the case of a plethoric habit, however, opiates would tend to produce an aggravation of the complaint by their stimulus, and therefore must be employed with caution. Astringent medicines must be resorted to, in the case of menorrhagia from relaxation, such as alum, the sulphuric acid, and some of the preparations of iron. The astringent operation of these, however, when given internally, is not always very active: the chalybeates, especially the muriated tincture of iron, are, on the whole, the most efficacious. The astringents may be employed externally, that is, may be applied locally, as washes, with advantage. These astringent and tonic medicines, however, are administered perhaps with more decided benefit, in the intervals of menstruation, when they act rather as preventives, than as directly curative, by strengthening the whole system; and tend also to remove the leucorrhœa, which so often exists at those times. Cold bathing, chalybeate medicines, the metallic salts, cinchona and other bitters, together with exercise, especially in a carriage, are all serviceable in this view, during the intervals: and all the remedies recommended in the case of *Leucorrhœa*, (see that article,) al-

though some of them are too stimulant to be exhibited during the occurrence of menorrhagia from debility, may be resorted to with benefit in the intervals. The patients should also use a good nutritious diet at the same time. And it may be added, that these remedies should be employed in menorrhagia, from whatever causes it may have been originally produced, if the disease have already induced a considerable degree of debility in the body. See Cullen, First Lines, par. 966—974. Hamilton on Female Complaints.

MENOSTEY, in *Geography*, a town of France, in the department of the Jura; four miles E.S.E. of Auxerre.

MENOTTE, a river of Cambodia, which runs into the gulf of Siam, N. lat. $11^{\circ} 32'$. E. long. $101^{\circ} 30'$.

MENOUGAT, a town of Asiatic Turkey, in Caramania; 20 miles N. of Alanieli.

MENOUX, ST., a town of France, in the department of the Allier; seven miles W. of Moulins.

MENS, a town of France, in the department of the Isère, and chief place of a canton, in the district of Grenoble; 22 miles S. of Grenoble. The place contains 1883, and the canton 6516 inhabitants, on a territory of 242½ kilio metres, in ten communes.

MENSA *et Thoro*, *Divorce à*. See *DIVORCE*.

MENSÆ DOMESTICUS. See *DOMESTICUS*.

MENSALIA, MENSALS, such parsonages or livings as were formerly united to the tables of religious houses; and therefore by canonists called *mensal* benefices. See *PARSONAGE* and *BENEFICE*.

MENSARII, among the Romans, officers appointed to manage the public treasury, being sometimes three, and sometimes five in number.

MENSES, in *Physiology*, the monthly discharge from the uterus of the female subject. See *GENERATION*, under the head of *Physiology of the Female Organs*.

MENSES, *Suppression of*, in *Medicine*, or *Amenorrhœa* in the language of the nosologists, an interruption to the monthly discharge of women.

The interruption of the menstrual flux has been considered by physicians of two kinds; namely, the one, when the menses do not begin to flow at that period of life at which they usually appear, which has been called the *retention* (or *emanatio mensium*); and the other, when, at a subsequent age, and after they have repeatedly taken place, they cease to return (independently of pregnancy) at their usual periods, which has been called the *suppression* of the menses (*suppressio mensium*.) See Cullen, *Nosol. Method. Gen.* cxxvi.

The first of these species of amenorrhœa, the *retention* of the menses, occurs of course in girls about the age of puberty, and is accompanied by a number of symptoms, indicative of great general languor of the whole habit; but it is most commonly marked especially by an extraordinary paleness of the complexion, often with some degree of yellow, or even of a greenish hue, from which the appellation of *green-sickness*, or technically *chlorosis*, has been given to the disease. It is true, indeed, that this appearance of the complexion is not always present, where there is a *retention* of the catamenia; but the general train of symptoms varies little, and the same plan of treatment is requisite under most of the varieties of the complaint; we shall, therefore, not repeat here the detail of the symptoms, or of the methods of cure, which we have described at great length under the article *CHLOROSIS*; which see.

The *suppression* of the menstrual flux, then, after it has been for some time established in its regular course, will be the subject of the few following observations. Every interruption

interruption of the discharge, after it has once taken place, is not to be considered as a case of suppression; for, at its first appearance, it is not always immediately established with perfect regularity; and, therefore, an early interruption, especially when accompanied with the chlorotic symptoms, may be deemed a case of *retention*. On the other hand, the discharge may, at any period of life, be suppressed, when great general debility is induced by any cause; and it commonly is thus interrupted, when any great chronic affection occurs, to enfeeble the powers of life. In such cases, the suppression is merely symptomatic of those other affections, and does not itself become an object of medical treatment.

Most of the instances of idiopathic suppression of the catamenia, in this country, are occasioned by, or at least are ascribed to, the action of *cold*, which is believed to produce a constriction of the extreme vessels of the uterus, and thus to occasion a resistance to the flow of blood through them. The influence of fear, and other depressing passions, is supposed to produce a similar effect. The suppression seldom continues long, before it is accompanied by various symptoms or disorders in different parts of the body; partly, perhaps, originating from an irregular determination of blood into other organs, in consequence of the phlogistic condition occasioned by the suppression of the customary discharge; and partly from the great general sympathy of the whole nervous system, and of several organs in particular, with the condition of the uterus. From the first of these causes arise hæmorrhages from various parts; as from the nose, lungs, stomach, &c. when the menses are suppressed; as well as violent head-ache, acute pains in the chest, &c.; and, at the same time, from the nervous sympathy, various hysterical and other nervous affections occur, often to a formidable extent. The convulsions of hysteria, thus produced, are sometimes indeed more violent even than those of epilepsy; the colic pains, with costiveness, the *globus* in the throat, the violent flatulence, and other symptoms of dyspepsia, become often exceedingly tormenting.

Where the suppression of the catamenia is obviously idiopathic, and productive of these symptoms secondarily, the principal indication of cure appears to be to remove the obstructed state of the circulation in the vessels of the uterus. In very strong and robust habits, where, together with acute local pains, there is a great tendency to hæmorrhage, and a febrile or inflammatory disposition also manifests itself, even blood-letting may be resorted to with benefit in the commencement, to lessen the constrictive action of the blood-vessels in general; and in such cases, free purgation, together with the antiphlogistic regimen, will likewise be requisite. In the great majority of instances, however, the detraction of blood is unnecessary. A beneficial change is often produced upon the action of the uterine vessels, by local remedies; such especially as warm bathing, directed to the region of the uterus, by means of the semicupium, or of fomentation; the pedilavium; or emollient glysters, which, from the contiguity of the large intestine to the uterus, operate as an internal fomentation. In cases where the suppression is accompanied with great pain about the uterine region, but without fever, an anodyne glyster, combining the effects of fomentation with those of an opiate, is sometimes extremely beneficial. Dr. Gregory used to mention, in his lectures at Edinburgh, that an anodyne enema, administered at night, had sometimes brought back the catamenia before morning. Such applications, indeed, appear to be particularly efficacious, when there is an obvious attempt, as it were, in the constitution to effect the discharge. For, as Dr. Cullen has remarked, it commonly

happens, in the cases of suppressed catamenia, that though the discharge does not actually appear at the usual periods, there are often, at those periods, some marks of an effort, having a tendency to produce the discharge; it is, therefore, at those times especially, when the efforts of the system concur, that we ought to resort to the remedies for curing a suppression. These concurring efforts are indicated by the existence of pain in the loins, with a sense of fulness in the region of the uterus, and other symptoms which usually indicate the approach, or accompany the flow of the catamenia in the healthy condition.

The cases in which the menses flow after longer intervals, and in less quantity than usual, are proximate to the cases of actual suppression; and when they are attended with any of the disorders of the system before alluded to, they are to be treated by the same remedies as the cases of entire suppression. See Cullen, First Lines, par. 1007—1012.

The partial impediment to the flow of the menses, which is accompanied with considerable pain, (the *Amenorrhœa difficilis*, spec. 3. of Cullen,) has been treated of under the more common appellation, *Dysmenorrhœa*; which see.

MENSGUT, in *Geography*, a town of Prussia, in the province of Oberland; eight miles N. of Ortelzburg.

MENSHIE, or MEDCHIE, a town of Egypt; five miles N. of Girgê. The markets of this town are always well supplied, because the boats that are bound to the N. of Egypt, are accustomed to put in here for a stock of provisions. A conserve of wheat is sold here, which is highly valued in the country. It is composed of corn steeped in water for two days, then dried in the sun, and boiled to the thickness of a jelly: the paste thus prepared is called "chede" dew: it is sweet and nutritive. Menshié is decorated with a large mosque. "Ptolemais Hermei," or Hermes, so called because the symbolical deity Mercury was worshipped there, a large and populous city, formerly stood south of this spot and near it. A few scattered ruins, and a stone-dike to confine the waters of the river, are the only remains which Menshié preserves of its ancient splendour. Sonnini.

MENSIS. See MONTH.

MENSIS *Chymicus*. See MENSTRUUM.

MENSIS *Vetitus*. See FENCE-Month.

MENSOORIA, in *Geography*, a castle of the empire of Morocco, eight leagues from Rabat, in the province of Temfena, or Tremecen, built in the 12th century, by Jacob Almanzor, to afford an asylum to travellers during the night; the inhabitants of the surrounding country being a mischievous and thieving people.

MENSORES, among the Romans, harbingers or officers, whose business it was to go and fix upon lodgings for the emperor, when he took a journey to any of the provinces. Their office was also to mark out encampments, and assign every regiment its post.

MENSORES also signified land-surveyors, architects, or appraisers of houses and public buildings. Those likewise who distributed the provisions in the army, were called *mensores frumentarii*; and servants who waited at table had the appellation of *mensores*.

MENSORES was likewise the title of officers among the Romans appointed to receive the provisions brought to the city by sea, and to see them carefully laid up and preserved in public granaries, of which there were great numbers.

MENSTRUAL, or MENSTRUOUS, a term in *Medicine*, applied to the blood which flows from women in their ordinary monthly purgations. See MENSES.

MENSTRUAL *Epactis*. See EPACT.

MENSTRUAL *Longitude of the Moon*. See ARGUMENT.

MENSTRUATION, EXCESSIVE. See MENORRHAGIA.

MENSTRUATION, *Painful*. See DYSMENORRHEA.

MENSTRUUM, SOLVENT, or DISSOLVENT, in *Chemistry*, any liquor that will dissolve, that is, separate the parts of hard bodies

The term takes its rise from this, that some chemists pretend the complete dissolution of a mixed body cannot be effected in less than forty days; which period they call a *philosophical month*. See SOLVENT, and also SOLUTION.

MENSTRUUM, *Universal*. See ALKALIST.

MENSTRUUM, in *Pharmacy*, chiefly denotes a body that will extract the virtues of ingredients by infusion, decoction, or the like. See EXTRACT, INFUSION, and DECOCTION.

MENSURATION is that branch of mathematics which is employed in ascertaining the extension, solidities, and capacities of bodies; and in consequence of its very extensive application to the various purposes of life, it may be considered as one of the most useful and important of all the mathematical sciences: in fact, mensuration, or geometry, which were anciently nearly synonymous terms, seem to have been the root whence all the other exact sciences, with the exception of arithmetic, have derived their origin.

As soon as men began to form themselves into society, and direct their attention towards the cultivation of the earth, it became necessary to have some means of distinguishing one person's allotment from another, both as to position and quantity; as it did to enumerate the number of their flocks and herds; and hence, in all probability, the former gave rise to the science of mensuration, as the latter did to that of arithmetic; and though we may easily imagine that each of them remained for ages in a rude uncultivated state, yet it is from this period that we must date their commencement; and therefore, to state the precise time when they were discovered, or by whom they were first introduced, would be to trace out the origin of society itself: on this head, therefore, we shall barely observe that in all probability they first arose from the humblest efforts of unassisted genius, called forth by the great mother of invention, Necessity; and that they have since grown up by slow and imperceptible degrees, till they have at length acquired the dignity of the most perfect sciences; as the acorn which is first accidentally sown in a field, is in due course of time converted into the majestic oak.

But notwithstanding we cannot attribute the invention of the science of mensuration to any particular person, or nation, yet we may discover it in an infant state, rising as it were into a scientific form amongst the ancient Egyptians; and hence the honour of the discovery has frequently been given to this people, and to the circumstance of the overflowing of the Nile.

It is, however, to the Greeks that we must consider ourselves indebted for having first embodied the leading principles of this art into a regular system. Euclid's Elements of Geometry were probably first wholly directed to this subject, and many of those beautiful and elegant geometrical properties, which are so much and so justly admired, it is not unlikely arose out of simple investigations directed solely to the theory and practical application of mensuration. These collateral properties, when once discovered, soon gave rise to others of a similar kind, and thus geometry, which was first instituted for a particular and limited purpose, became itself an independent and important science, which has perhaps done more towards harmonizing and expanding the human faculties, than all the other sciences united.

But notwithstanding the perfection which Euclid attained in geometry, the theory of mensuration was not in his time advanced beyond what related to right-lined figures, and

this, so far as regards surfaces, might all be reduced to that of measuring a triangle; for as all right-lined figures may be reduced to a number of trilaterals, it was only necessary to know how to measure these, in order to find the surface of any other figure whatever bounded only by right lines. The mensuration of solid bodies, however, was of a more varied and complex nature, and gave this celebrated geometrician a greater scope for the exercise of his superior talents, and still confining himself to bodies bounded by right-lined plane superficies, he was able to perform all that can be done even at this day. With regard to curvilinear figures, he attempted only the circle and the sphere, and if he did not succeed in those, he failed only where there was no possibility of success; but the ratio that such surfaces and solids have to each other he accurately determined.

After Euclid, Archimedes took up the theory of mensuration, and carried it to a much greater extent. He first found the area of a curvilinear space, unless indeed we except the lunules of Hippocrates, which required no other aid than that of the geometrical elements. Archimedes found the area of the parabola to be two-thirds of its circumscribing rectangle, which, with the exception above stated, was the first instance of the quadrature of a curvilinear space. The conic sections were at this time but lately introduced into geometry, and they did not fail to attract the particular attention of this celebrated mathematician, who discovered many of their very curious properties and analogies. He likewise determined the ratio of spheres, spheroids, and conoids, to their circumscribing cylinders, and has left us his attempt at the quadrature of the circle. He demonstrated that the area of a circle is equal to the area of a right-angled triangle, of which one of its sides about the right angle is equal to the radius, and the other equal to the circumference, and thus reduced the quadrature of the circle to that of determining the ratio of the circumference to the diameter, a problem which has engaged the particular attention of the most celebrated mathematicians of all ages, but which remains at present, and in all probability ever will remain, the desideratum of geometricians, and at the same time a convincing and humiliating proof of the limited powers of the human mind.

But notwithstanding Archimedes failed in establishing the real quadrature of the circle, it is to him we are indebted for the first approximation towards it. He found the ratio between the diameter of a circle, and the periphery of a circumscribed polygon of 96 sides, to be less than 7 to 22, or less than 1 to $3\frac{1}{7}$; but the ratio between the diameter, and periphery of an inscribed polygon of the same number of sides, he found to be greater than 1 to $3\frac{1}{7}$; whence, *à fortiori*, the diameter of a circle is to its circumference in a less ratio than 1 to $3\frac{1}{7}$, or less than 7 to 22. Having thus established this approximate ratio between the circumference and diameter, that of the area of the circle to its circumscribed square, is found to be nearly as 11 to 14. Archimedes, however, makes the latter the leading proposition. These, it is true, are but rude approximations, compared with those that have been since discovered, but considering the state of science at this period, particularly of arithmetic, we cannot but admire the genius and perseverance of the man, who, notwithstanding the difficulties that were opposed to him, succeeded in deducing this result, which may be considered as having led the way to the other more accurate approximations which followed, most of which, till the invention of fluxions, were obtained upon similar principles to those employed by this eminent geometrician.

Archimedes also determined the relation between the circle and ellipse, as well as that of their similar parts; besides

MENSURATION.

which figures he has left us a treatise on the spiral, a description of which will be given under that article. See SPERAL.

Some advances were successively made in geometry and mensuration, though but little novelty was introduced into the mode of investigation till the time of Cavalieri. Till his time the regular figures circumscribed about the circle, as well as those inscribed, were always considered as being limited both as to the number of their sides, and the length of each. He first introduced the idea of a circle being a polygon of an infinite number of sides, each of which was of course indefinitely small; solids were supposed to be made up of an infinite number of sections indefinitely thin, &c. This was called the doctrine of indivisibles, which was very general in its application to a variety of difficult problems, and by means of it many new and interesting properties were discovered; but it unfortunately wanted that distinguishing characteristic which places geometry so pre-eminent amongst the other exact sciences. In pure elementary geometry we proceed from step to step, with such order and logical precision, that not the slightest doubt can rest upon the mind with regard to any result deduced from those principles; but in the new method of considering the subject, the greatest possible care was necessary in order to avoid error, and frequently this was not sufficient to guard against erroneous conclusions. But the facility and generality which it possessed, when compared with any other method then discovered, led many eminent mathematicians to adopt its principles, and of these Huygens, Dr. Wallis, and James Gregory, were the most conspicuous, being all very fortunate in their application of the theory of indivisibles. Huygens, in particular, must always be admired for his solid, accurate, and masterly performances in this branch of geometry. The theory of indivisibles was however disapproved of by many mathematicians, and particularly by Newton, who, amongst his numerous and brilliant discoveries, has given us that of the method of fluxions, the excellency and generality of

which immediately superseded that of indivisibles, and revived some hopes of squaring the circle, and accordingly its quadrature was again attempted with the greatest eagerness. The quadrature of a space and the rectification of a curve, was now reduced to that of finding the fluent of a given fluxion; but still the problem was found to be incapable of a general solution in finite terms. The fluxion of every fluent was found to be always algebraical, but the converse proposition, viz. of finding the fluent of a given fluxion, could only be effected in particular cases, and amongst these exceptions, to the great disappointment and regret of geometers, was included the case of the circle, with regard to all the forms of fluxions under which it could be obtained.

At length all hopes of accurately squaring the circle, and some other curves being abandoned, mathematicians began to apply themselves to finding the most convenient series for approximating towards their true lengths and quadratures; and the theory of mensuration now began to make rapid progress towards perfection. Many of the rules, however, were given in the Transactions of learned societies, or in separate and detached works, till at length Dr. Hutton formed them into a complete treatise, entitled "A Treatise on Mensuration," in which the several rules are all demonstrated, and some new ones introduced. Mr. Bonnycastle also published a very complete work on this subject, entitled "An Introduction to Mensuration." These may be considered as standard works, and the only ones of importance in our language, though there are others on the same subject, as Hawney's and Robertson's, the latter of which only requires the demonstrations of the several rules, which are omitted, in order to render it also a very useful and valuable performance.

To the above slight sketch of the history and progress of this science, we shall annex a synopsis of the principal rules, drawn from the works above mentioned, which will be found very useful as a reference in a variety of cases.

SYNOPSIS OF THE PRINCIPAL RULES OF MENSURATION.

TRIANGLES.

Let a, b, c represent the three sides of the triangle, A, B, C the angles opposite to those sides respectively; p the perpendicular falling upon the base b ; then,

1. The area = $\frac{1}{2} p b$
2. — = $\frac{1}{2} a b \sin C = \frac{1}{2} a c \sin B = \frac{1}{2} b c \sin A$.

Make $a + b + c = s$; then,

3. The area = $\sqrt{\left\{ \frac{1}{2} s \left(\frac{1}{2} s - a \right) \left(\frac{1}{2} s - b \right) \left(\frac{1}{2} s - c \right) \right\}}$
4. Log. area = $\frac{1}{2} \left\{ \log. \frac{1}{2} s + \log. \left(\frac{1}{2} s - a \right) + \log. \left(\frac{1}{2} s - b \right) + \log. \left(\frac{1}{2} s - c \right) \right\}$.

TRAPEZIUMS.

Let a, b, c, d , represent the four sides, a and c, b and d , being those which are opposite to each other, δ and δ' the two diagonals, M the angle formed by their intersection, also p, p' , the perpendiculars falling from two opposite angles on the diagonal δ ; then,

1. The area = $\frac{1}{2} \delta (p + p')$
2. — = $\frac{1}{2} \delta \delta' \sin M$

3. The area = $\left\{ (a^2 + c^2) \wedge (b^2 + d^2) \right\} \tan. M$.

If the trapezium be inscribable in a circle,

4. The area = $\sqrt{\left\{ (s - a) (s - b) (s - c) (s - d) \right\}}$
5. — = $(ab + cd) \sin. N$.

where N is the angle contained by a and b , or by c and d .

If a and c , or b and d , be parallel, and p their perpendicular distance, then,

6. The area = $\frac{1}{2} p (c + a)$, or $\frac{1}{2} p (b + d)$.

REGULAR POLYGONS.

Let s represent one of the equal sides, n the number of sides, p the perpendicular falling from the centre of the polygons upon one of the sides; then,

1. The area = $\frac{1}{2} p s n$
2. — = $n p^2 \tan. \frac{360^\circ}{2n}$
3. — = $\frac{1}{2} n s^2 \cotan. \frac{360^\circ}{2n}$

This last general formula resolves itself into the following particular ones, viz.

M m 2

4. Trigon

MENSURATION.

	Sides.	Area		
4. Trigon	3	—	$s^2 \times$	0.4330127
5. Tetragon	4	—	$s^2 \times$	1.0000000
6. Pentagon	5	—	$s^2 \times$	1.7204774
7. Hexagon	6	—	$s^2 \times$	2.5980762
8. Heptagon	7	—	$s^2 \times$	3.6399124
9. Octagon	8	—	$s^2 \times$	4.8284271
10. Nonagon	9	—	$s^2 \times$	6.1818242
11. Decagon	10	—	$s^2 \times$	7.6942688
12. Undecagon	11	—	$s^2 \times$	9.3656399
13. Dodecagon	12	—	$s^2 \times$	11.1961524

CIRCLE.

Let r represent the radius, d the diameter, c the circumference, and a the area; then,

1. The area = $\frac{1}{4} c d$
2. — = $d^2 \times .7854$
3. — = $c^2 \times .07958$
4. The circumference = $d \times 3.14159$

If we make $3.14159 = p$, we have the following relation of the above quantities; viz.

1. — , $d = \frac{c}{p} = \frac{4a}{c} = 2 \sqrt{\frac{a}{p}}$
2. — $c = p d = \frac{4a}{d} = 2 \sqrt{p a}$
3. — $a = \frac{p d^2}{4} = \frac{c^2}{4p} = \frac{d c}{4}$
4. — $p = \frac{c}{d} = \frac{4a}{d^2} = \frac{c^2}{4a}$

CIRCULAR ARCS.

The former notation remaining, let s represent the sine, and v the versed sine of the half arc; also let m represent the measure of the arc in degrees, minutes, &c. then,

1. The arc = $r m \times .0174533$.

$$2. \text{ The arc} = \begin{cases} 2 \sqrt{d v} \times \left\{ 1 + \frac{v}{2.3 d} + \frac{3 v^2}{2.4 5 d^2} + \frac{3.5 v^3}{2.4 6.7 d^3} + \&c. \right\} \text{ or,} \\ 2 d \sqrt{q} + \frac{q}{2.3} A + \frac{3^2 q}{4.5} B + \frac{5^2 q}{6.7} C + \frac{7^2 q}{8.9} D \end{cases}$$

where $q = \frac{v}{d}$; and A, B, C, &c. are the 1st, 2d, 3d, &c. terms.

$$3. \text{ The arc} = \begin{cases} 2 s \times \left\{ 1 + \frac{s^2}{3.3 r^2} + \frac{3 s^4}{5.2.4 r^4} + \frac{3.5 s^6}{7.2.4 r^6}, \&c. \right\} \text{ or,} \\ 2 s + \frac{q}{2.3} A + \frac{3^2 q}{4.5} B + \frac{5^2 q}{6.7} C + \frac{7^2 q}{8.9} D, \&c. \end{cases}$$

where $q = \frac{s^2}{r^2}$; and A, B, C, D, &c. the preceding terms.

To which may be added the following approximations:

4. The arc = $2 d \sqrt{\frac{3 v}{3 d - v}}$ nearly.
5. — = $2 \times \left\{ 5 d \sqrt{\frac{5 v}{5 d - 3 v}} + 4 \sqrt{d v} \right\}$ nearly.
6. — = $\frac{8 c' - C'}{3}$ nearly.

where C' is the chord of the whole arc, and c' the chord of half the arc.

CIRCULAR SECTORS.

Let l represent the length of the arc of the sector, and m its measure in degrees, minutes, &c.; then,

1. Area of sector = $\frac{1}{2} r l$
2. — = $.7854 d^2 \times \frac{m}{360}$

CIRCULAR SEGMENTS.

If A' represent the area of the circular sector, and C' the chord of the arc; then,

1. Area of segment = $A' - \frac{1}{2} C' (r - v)$.
2. Area = $\begin{cases} 2 v \sqrt{d v} \times \left\{ \frac{2}{3} - \frac{v}{5 d} - \frac{v^2}{28 d^2} - \frac{v^3}{72 d^3} - \&c. \right\} \text{ or,} \\ 2 \sqrt{d v} \times \left\{ \frac{2}{3} - \frac{3 v}{5.2 d} A - \frac{5 v}{7.4 d} B - \frac{7.3 v}{9.6 d} C - \frac{9.5 v}{11.8 d} D \right\} \end{cases}$

A, B, C, &c. being the preceding terms.

$$3. \text{ Area} = \frac{1}{3} v \sqrt{v V} + \frac{5}{5} V A - \frac{1}{7} V B + \frac{3}{9} V C - \frac{5}{11} V D, \&c. \text{ where } V = (d - v).$$

$$4. \text{ Area} = 2 r c'' - \frac{1}{2.3} q^2 A - \frac{1.3}{4.5} q^2 B - \frac{3.5}{6.7} q^2 C, \&c. \text{ where } c'' \text{ represents the cosine of half the arc, and } q = \frac{c''}{r}, A, B, C, \&c. \text{ being the preceding terms.}$$

To which may be added the following approximations, viz.

5. Area = $\frac{2}{3} \left\{ \sqrt{(d v - v^2)} + \frac{2}{3} \sqrt{d v} \right\}$ nearly.
6. Area = $\frac{2}{3} v (d v - \frac{2}{3} v^2)$ nearly.
7. Area = $\frac{1}{10} v (C' + \frac{2}{3} c)$ nearly.
8. Area = $\frac{2}{3} v \sqrt{(\frac{1}{4} C'^2 + \frac{2}{3} v)}$ nearly.
9. Area = $d^2 \times$ tabular number answering to $\frac{v}{d}$, in the table of circular segments.

Note.—The area of circular zones will be found by finding the difference of the two segments; and the area of circular rings, by finding the difference of the areas of the two circles.

MENSURATION.

Or by making D and d the diameters, then

1c. Area of the ring = $(D + d) (D - d) \times .7854$.

ELLIPTIC

Let t represent the semi-transverse axis, c the semi-conjugate, x any absciss, y the corresponding ordinate, and ρ the parameter; then will these quantities have the following relations, *viz.*

1. Ordinate (y) = $\frac{c}{t} \sqrt{(2tx - x^2)}$
2. Absciss (x) = $t + \frac{t}{c} \sqrt{(c^2 - y^2)}$
3. Conjugate (c) = $\frac{ty}{\sqrt{(2tx - x^2)}}$
4. Transverse (t) = $\frac{c^2 x}{y^2} \times \left\{ c \mp \sqrt{(c^2 - y^2)} \right\}$
5. Parameter (ρ) = $\frac{c^2}{t}$.

The same formulæ obtain for any pair of conjugate diameters.

Make $1 - \frac{c^2}{t^2} = m$; then,

1. Elliptic circum. = $C \times \left\{ 1 + \frac{m}{2} - \frac{3m^2}{2 \cdot 4^2} - \frac{3 \cdot 5 m^3}{2 \cdot 4 \cdot 6^2} - \frac{3 \cdot 5 \cdot 7 m^4}{2 \cdot 4 \cdot 6 \cdot 8^2}, \&c. \right\}$ where C is the circumference of the circumscribing circle.

2. Elliptic circum. = $(t + c) \times 3.1416$ nearly.

3. ——— = $3.1416 \times \sqrt{2(t^2 + c^2)}$ nearer.

4. ——— = $\frac{1}{2} \left\{ 3 \sqrt{2(t^2 + c^2)} - \frac{6t + \rho}{4} \right\} \times 3.1416$ still nearer.

5. Elliptic circum. = $\frac{1}{2} \left\{ 5 \sqrt{2(t^2 + c^2)} - \frac{35t + 7\rho}{8} + \frac{\rho^2 c^2}{16t^2} \right\} \times 3.1416$.

6. Elliptic circum. = $\frac{1}{2} \left\{ t + c + \sqrt{2(t^2 + c^2)} \right\} \times 3.1416$.

7. Elliptic area = $3.14159 \times t c$.

8. ——— = $3.14159 \times t c \times \sin.$ angle of intersection, in which last expression t and c are any pair of semi-conjugate diameters.

ELLIPTIC ARCS.

Let t represent still the semi-transverse, c the semi-conjugate, and z the distance of the ordinate from the centre; then the arc bounded by the ordinate, and the parallel axis, will be

1. Elliptic arc = $z \left\{ 1 + \frac{c^2}{6t^2} z^2 + \frac{4t^2 c^2 - c^4}{40t^4} z^4 + \frac{8t^4 c^2 - 4t^2 c^4 + c^6}{112t^6} z^6, \&c. \right\}$

Make $\frac{t^2 - c^2}{t^2} = q$; then,

2. Elliptic arc = $z \sqrt{\frac{t^2 - \frac{1}{3} q z^2}{t^2 - \frac{1}{3} q z^2}}$ nearly.

3. ——— = $\frac{1}{2} \left\{ q z \sqrt{\frac{t^2 - \frac{1}{3} q z^2}{t^2 - \frac{1}{3} q z^2}} - \left(1 + \frac{c^2 z^2}{6t^2} \right) 4 z \right\}$

4. Elliptic arc = $\frac{15\rho C + (17C - 21\rho)y}{15\rho C + (9C - 21\rho)y}$ nearly, C being the whole axis, where the arc is 180° ; and ρ, x , and y the corresponding parameter, absciss, and ordinate.

ELLIPTIC SEGMENTS.

Find the area of the circular segment described on that axis to which the base of the segment is perpendicular, and call it A ; then,

1. As this axis : the other axis :: A : the elliptic segment, make the height of the segment = b , and vertical axis of the ellipse = v , also put $\frac{b}{v} = q$; then,

2. Elliptic seg. = $t c \times$ tabular number answering to q in a table of circular segments.

PARABOLA.

Make any absciss = x , ordinate = y , parameter = ρ , and area = a ; then will these quantities have the following relations, *viz.*

1. Parameter (ρ) = $\frac{y^2}{x}$
2. Absciss (x) = $\frac{y^2}{\rho}$
3. Ordinate (y) = $\sqrt{\rho x}$
4. Area contained between x, y , and the curve } (a) = $\frac{2}{3} x y$.

PARABOLIC ARCS

Make $\frac{2y}{\rho} = g$, and $\sqrt{(1 + g^2)} = s$; then,

1. Parabolic arc = $\frac{1}{2} \rho \cdot \left\{ g s + \text{hyp. log. } (g + s) \right\}$
2. Parabolic arc = $\left\{ \begin{aligned} &2y \left(1 + \frac{g^2}{2 \cdot 3} - \frac{g^4}{2 \cdot 4 \cdot 5} + \frac{3g^6}{2 \cdot 4 \cdot 6 \cdot 7} \right. \\ &\quad \left. - \frac{3 \cdot 5 g^8}{2 \cdot 4 \cdot 6 \cdot 8 \cdot 9}, \&c. \right\} \\ &2y \left(1 + \frac{g^2}{2 \cdot 3} A - \frac{1 \cdot 3 g^4}{4 \cdot 5} B + \right. \\ &\quad \left. \frac{3 \cdot 5 g^6}{6 \cdot 7} C - \frac{5 \cdot 7 g^8}{8 \cdot 9} D, \&c. \right\} \end{aligned}$

where A, B, C , &c. represent the preceding terms. To which may be added the following approximations:

3. Parabolic arc = $2 \sqrt{(y^2 + \frac{1}{3} x^3)}$ nearly.
4. ——— = $\frac{2}{3} \left\{ \sqrt{(y^2 + \frac{1}{3} x^3)} - \frac{y^2 + \frac{1}{3} x^3}{\frac{1}{4} y} \right\}$ nearly.

PARABOLIC FRUSTUM, OR ZONE.

Let D and d represent the two ends, and a the perpendicular distance between them; then,

1. Area of zone = $\frac{2}{3} a \times \frac{D^3 - d^3}{D^2 - d^2}$

When $d = 0$, the area becomes $\frac{2}{3} a D$.

HYPERBOLA.

Let t = the semi-transverse diameter, c = the semi-conjugate, x any absciss, and y its corresponding ordinate; then will these quantities have the following relations, *viz.*

1. Ordinate (y) = $\frac{c}{t} \sqrt{(2tx + x^2)}$

2. Absciss

MENSURATION.

2. Abfcifs - $(x) = t \pm \frac{t}{2c} \sqrt{(c^2 + y^2)}$

3. Conjugate $(c) = \frac{ty}{\sqrt{(2tx + x^2)}}$

4. Diameter - $(t) = \frac{cx}{y} \left\{ \sqrt{(c^2 + y^2)} \pm c \right\}$

Making $\frac{t^2 + c^2}{c^2} = q$, and hyp. log. $\frac{y + \sqrt{(c^2 + y^2)}}{c}$

= A.

Also, $\frac{1}{2} \left\{ y \sqrt{(c^2 + y^2)} - c^2 A \right\} = B.$

$\frac{1}{4} \left\{ y^3 \sqrt{(c^2 + y^2)} - 3c^2 B \right\} = C.$

$\frac{1}{6} \left\{ y^5 \sqrt{(c^2 + y^2)} - 5c^2 C \right\} = D.$

&c. &c. &c.

HYPERBOLIC ARCS.

Let t and c be any femi-diameter and its conjugate as before; and y the ordinate which limits the arc to be measured from the vertex; then,

The length of the arc contained between the vertex and ordinate will be,

1. Arc = $c \times \left\{ A + \frac{q}{2} B - \frac{q^2}{2 \cdot 4} C + \frac{3q^3}{2 \cdot 4 \cdot 6} D - \frac{3 \cdot 5 q^4}{2 \cdot 4 \cdot 6 \cdot 8} E, \&c. \right\}$

2. Arc = $y \times \left\{ 1 + \frac{t^2 y^2}{6c^2} - \frac{(t^4 + 4t^2 c^2) y^4}{40c^4} + \frac{(t^6 + 4t^4 c^2 + 8t^2 c^4) y^6}{112c^6} - \frac{(5t^8 + 24t^6 c^2 + 48t^4 c^4 + 64t^2 c^6) y^8}{1152c^8}, \&c. \right\}$

3. Arc = $y \left\{ 1 + \frac{t^2 y^2}{6c^2} A - \frac{t^2 + 4c^2}{c^2} \cdot \frac{3y^3}{20} B + \frac{t^4 + 4t^2 c^2 + 8c^4}{t^2 + 4c^2} \cdot \frac{5y^5}{14c^4} C - \frac{5t^6 + 24t^4 c^2 + 48t^2 c^4 + 64c^6}{t^4 + 4t^2 c^2 + 8c^4} \cdot \frac{7y^7}{72c^4} D \&c. \right\}$

To which may be added the following approximation :

4. Arc = $\frac{120c^2 t + (19t^2 + 21c^2) \cdot 4x}{120c^2 t + (9t^2 + 21c^2) \cdot 4x} + y$, nearly.

HYPERBOLIC SEGMENTS.

Let t and c still represent the femi-diameter and its conjugate, x an abfcifs, $2y$ the double ordinate, which cuts off the segment, and z its distance from the centre; then,

1. Hyp. area = $zy - tc \times \text{hyp. log. of } \frac{ty + cz}{tc}$.

Making $\frac{x}{2t+x} = q$, we have

2. Hyp. area = $2xy \left\{ \frac{1}{3} - \frac{q}{1 \cdot 3 \cdot 5} - \frac{q^2}{3 \cdot 5 \cdot 7} - \frac{q^3}{5 \cdot 7 \cdot 9} \right.$

— &c. $\left. \right\}$

3. Hyp. area = $2xy \left\{ \frac{1}{3} - \frac{1}{5} A q - \frac{1}{7} B q - \frac{1}{9} C q \right.$

— &c. $\left. \right\}$

where A, B, C, &c. represent the preceding terms. To which may be added the following approximations, viz.

4. Hyp. area = $\frac{4cx}{15t} \left\{ 4 \sqrt{(2tx + \frac{3}{4}x^2)} + \sqrt{2tx} \right\}$ nearly.

5. Hyp. area = $\frac{4cx}{75t} \left\{ 21 \sqrt{(2tx + \frac{5}{7}x^2)} + 4 \sqrt{2tx} \right\}$ nearly.

HYPERBOLIC FRUSTUM, OR ZONE.

The same notation remaining as above, let z be the distance of a second double ordinate $2Y$; then,

1. The area of zone contained between $2y$ and $2Y$ - $\left\{ \begin{array}{l} ZY - zy - tc \times \text{hyp. log.} \\ \frac{tY + cZ}{ty + cz} \end{array} \right.$

PRISMS and CYLINDERS.

Let p represent the perimeter of the base, a its area, and b the height or perpendicular altitude; then,

1. Surface = $pb + 2a$

2. Solidity = ab .

PYRAMIDS and CONES.

Let p , a , and b , represent, as above, the perimeter, area and altitude; then,

1. Surface = $\frac{1}{2}pb + a$

2. Solidity = $\frac{1}{3}ab$.

The latter rule obtains also in oblique cones and pyramids.

FRUSTUMS of CONES and PYRAMIDS.

Let A and a represent the areas of the two ends, P and p their perimeters, and b the altitude of the body; then,

1. Surface = $\frac{1}{2}b(P + p) + (A + a)$

2. Solidity = $\frac{1}{3}b(A + a) + \frac{1}{3}b(\sqrt{Aa})$.

If the ends are circles, or regular polygons, by putting D and d for the diameters, and C and c for the circumferences in the former case; also S and s for the sides of the polygon in the latter, and T for the tabular number answering to any particular polygon; then,

4. Solidity of frust. cone = $\frac{1}{3}b(D^2 + Dd + d^2) \cdot 7854$.

5. ——— frust. cone = $\frac{1}{3}b(C^2 + Cc + c^2) \cdot 07958$.

6. ——— frust. pyra. = $\frac{1}{3}b(S^2 + Ss + s^2) T$.

PRISMOID.

Let A and a represent the areas of the two ends, a the area

MENSURATION.

area of the middle section, and l the length of the solid; then,

1. Solidity = $\frac{1}{6} l (\Lambda + 4a + a)$.

WEDGE.

Make L the length of the base, l the length of the edge, b the breadth of the base, and h the height of the wedge; then,

1. Solidity = $\frac{1}{6} h b (L + l)$.

CYLINDRIC UNGULA.

When the plane passes through the base of the cylinder.

Make the altitude = H , the base = b , $\frac{1}{2}$ arc of base = a , the sine, cosine, and versed sine of $\frac{1}{2}$ arc = s , c , and v , and diameter of cylindrical base = d ; then,

1. Curve surf. ungula = $\frac{(ds - ac) H}{v}$

2. Solidity ungula = $\frac{(s - bc) H}{v}$.

When the cutting plane does not pass through the base.

Put, in addition to the above notation, h for the least height of the ungula, H still representing the greater height; then,

1. Curve surface = $\frac{1}{2} (H + h) \times 3.1416 d$

2. Solidity = $\frac{1}{6} (H + h) \times .7854 d^2$

3. ——— = $\frac{1}{2} (H + h) \times .07958 c^2$

where c is the circumference of the cylinder.

CONIC UNGULA.

When the cutting plane passes through the opposite ends of the frustum.

Make the diameter of the greater end = D , of the less end = d , and altitude = h ; then,

1. Solidity gt. hoof = $\frac{D - d \cdot D d}{D - d} \times .2618 D h$

2. ——— lt. hoof = $\frac{D \sqrt{D d - d^2}}{D - d} \times .2618 D h$

3. Differ. of hoofs = $\frac{(D_1 - d)^2}{D - d} \times .2618 h$.

SPHERE, OR GLOBE.

Let d represent the diameter, c the circumference, s the surface, and S the solidity of the sphere; then,

1. Surface (s) = $c d$
2. ——— (s) = $3.1416 d^2$
3. ——— (s) = $.3183 c^2$
4. Solidity (S) = $\frac{1}{6} s d$
5. ——— (S) = $.01688 c^3$
6. ——— (S) = $.5236 d^3$.

SPHERICAL SEGMENTS AND ZONES.

The same notation remaining, let r represent the radius of the base of the segment, and h its height; then,

1. Surface of seg. = $3.1416 d h$
2. Solidity of seg. = $.5236 h (3 r^2 + h^2)$
3. ——— = $.5236 h (3 d - 2 h)$.

For the zone, put R and r for the two radii of its ends, and h its altitude; then,

4. Surface of zone = $3.1416 d h$
5. Solidity = $1.5708 h (R^2 + r^2 + \frac{1}{3} h^2)$.

CIRCULAR SPINDLE.

Put l = $\frac{1}{2}$ length of the spindle, m = $\frac{1}{2}$ its middle diameter, a the length of the generating arc, and Λ the area of generating segment.

Make $\frac{l + m^2}{s m} = r$; then,

1. Surface of spindle = $2 \left\{ l r - a (r - m) \right\} \times 3.1416$

2. Solidity = $4 \left\{ l^3 - \frac{1}{2} \Lambda (r - m) \right\} \times 3.1416$

For the middle zone of a circular spindle, make L = $\frac{1}{2}$ the length of the spindle, l = $\frac{1}{2}$ the length of the zone, Λ the generating area, r and m being the same as above; then

3. Solidity of zone = $2 \left\{ (L - \frac{1}{2} l) l - \Lambda (r - m) \right\} \times 3.1416$

THE REGULAR BODIES.

Let S represent the side or edge of one of the equal faces; then,

1. Tetraedron { Surf. = $s^2 \times 1.73205 = s^2 \sqrt{3}$
Solid. = $s^3 \times 0.11785 = \frac{1}{12} s^3 \sqrt{2}$

2. Hexaedron { Surf. = $s^2 \times 6.00000 = 6 s^2$
Solid. = $s^3 \times 1.00000 = s^3$

3. Octaedron { Surf. = $s^2 \times 3.46410 = 2 s^2 \sqrt{3}$
Solid. = $s^3 \times 0.47140 = \frac{1}{6} s^3 \sqrt{2}$

4. Dodecaedron { Surf. = $s^2 \times 20.64578 = 15 s^2$
Solid. = $s^3 \times 7.66312 = 5 s^3$

5. Icofaedron { Surf. = $s^2 \times 8.66025 = 5 s^2 \sqrt{3}$
Solid. = $s^3 \times 2.18169 = \frac{1}{2} s^3$

SPHEROID.

Let f denote the fixed axis, and r the revolving axis; then making $3.1416 = p$, and $\frac{f^2 s r^2}{f^2} = q$; we have

1. Solidity = $\frac{1}{6} f r^2 p$

2. Surface = $f r p \left\{ 1 \mp \frac{\Lambda q}{2.3} - \frac{3 B q}{4.5} \mp \frac{3.5 C q}{6.7} \right.$

$\left. - \frac{5.7 D q}{8.9}, \&c. \right\}$ the upper sign having place in the oblong spheroid, and the lower sign in the oblate spheroid.

If, also, we make $\frac{r}{f} = z$, $\sqrt{1 - z^2} = s$, m = the measure in degrees of the arc whose sine is s ; likewise

$P = 0.1745329 m$ in the oblong spheroid,

$P = 2.30285 \log. (s + z)$ in the oblate spheroid; then

3. Surface = $\frac{P f + r s}{2 s} \times 3.1416 r$.

FRUSTUMS OF SPHEROIDS.

Let f represent the fixed axis, and r the revolving one; $3.1416 = p$, $\frac{f^2 s r^2}{f^2} = q$; h the height of the frustum,

$\frac{4 q h^2}{f^2} = z$; then the frustum being cut off by two planes

perpendicular to the fixed axis, one of those planes passing through the centre of the spheroid, we shall have

1. Surface = $p r h \left\{ 1 \pm \frac{\Lambda z}{2.3} - \frac{3 B z}{4.5} \pm \frac{3.5 C z}{6.7} \right.$

MENSURATION.

$\frac{5.7Dz}{8.9}$, &c. } where A, B, C, &c. are the preceding

terms, and the upper or under sign is to be used, according as it is the oblate or oblong spheroid.

For the solidity, make the diameter of the greater end = D, of the less end = d; then

2. Solidity = $\frac{1}{12} (2D^2 + d^2) b \times 3.1416$.

If the frustum be cut off by planes, one of which passes through the fixed axis, and the other parallel to it; then putting T the transverse axis, and C the conjugate of the greater end; and t and c for those of the less end;

3. Solidity = $\frac{1}{12} (2TC + tc) b \times 3.1416$.

Note — For the whole middle frustum the above results must be doubled.

SEGMENTS of SPHEROIDS.

Let f denote the fixed axis; r the revolving axis; b the height of the segment; then

1. When the base is parallel to the revolving axis.

Solidity = $\frac{r^2}{f^2} (3f \text{ vers } 2b) b^2 \times .5236$.

2. When the base is perpendicular to the revolving axis.

Solidity = $\frac{r^2}{f^2} (3r \text{ vers } 2b) b^2 \times .5236$

ELLIPTIC SPINDLES.

Put the perpendicular axis of the ellipse = a; the parallel axis = b; length of the spindle = l; distance of the centre of the spindle and ellipse = C; and area of the generating segment = A; then

1. Solidity = $1.57078 \times \left\{ \frac{a^2 l^3}{3 b^2} - 4 c A \right\}$

2. Solidity = $\frac{2}{3} l \times .7854 \left\{ D^2 - 4c \left(\frac{3A}{l} - D \right) \right\}$

where D is the greatest diameter of the spindle.

PARABOLOID.

Let y represent the ordinate or semi-diameter of the base; x the altitude of the solid; $3.1416 = p$; then

1. Surface = $\frac{2 p y}{12 x^2} \left\{ (y^2 + 4 x^2)^{\frac{3}{2}} - y^3 \right\}$

2. Solidity = $\frac{1}{2} p y^2 x$.

FRUSTUMS of PARABOLOIDS.

Let D denote the greater diameter, d the less; P the parameter; and b the height of the frustum; then

1. Surface = $\frac{(P^2 + D)^{\frac{3}{2}} - (P^2 + d)^{\frac{3}{2}}}{P} \times \frac{1}{2} p$

where $p = 3.1416$.

2. Solidity = $.3927 b (D^2 + d^2)$.

These formulæ only obtain when the base of the frustum is perpendicular to the axis of the solid. For an oblique segment, multiply the base by half the altitude for the content.

PARABOLIC SPINDLE.

Let m denote the middle diameter, and l the length of the spindle; then

1. Solidity = $.418879 l m^2$

For the solidity of the middle frustum.

Let d denote the diameter of the end, then the former notation remaining,

1. Solidity = $.05236 l (8 m^2 + 3 d^2 + 4 d m)$.

HYPERBOLOID.

Let a and c represent the semi-axes of the generating hyperbola; v the distance of its base from the centre.

Also let $A = \frac{a^2}{v(a^2 + c^2)}$ be the semi-transverse of

another hyperbola, whose semi-conjugate is c, the same with that of the former.

Then find by the proper formula, the area of the frustum of this latter hyperbola, whose ends are distant from the centre by v and a; multiply this area by 3.1416 for the surface; that is

1. Surface = $p \times \left\{ v Y - a y - A C \cdot \text{hyp. log. of} \right.$

$\left. \frac{A y + c v}{A y + a c} \right\}$, where $p = 3.1416$, Y and y the ordinates of the latter hyperbola:

2. Solidity = $\frac{1}{2} \text{par.}^2 \times \frac{t + \frac{1}{2} a}{t + a}$

where a = altitude, r = radius of the base, t the transverse axis, and $p = 3.1416$.

3. Solidity = $\frac{r^2 + d^2}{6} \times a p$

where d is the diameter, in the middle between the base and vertex.

FRUSTUMS of HYPERBOLOIDS.

Let D and d denote the semi-diameters of the two ends, a the altitude, t and c the transverse and conjugate axes, $p = 3.1416$; then

1. Solidity = $\frac{1}{2} p a \left\{ D^2 + d^2 - \frac{c^2 a^2}{3 t^2} \right\}$

2. Solidity = $\frac{1}{2} p a \left\{ D^2 + 4 d^2 + d \right\}$

where d is the middle diameter.

HYPERBOLIC SPINDLE.

Let A = the generating area, D the greatest diameter, L the length of the spindle, $p = 3.1416$; then

1. Solidity $\frac{1}{2} p \left\{ \frac{(L^2 + D^2)}{D} A - \frac{1}{3} L^3 \right\}$

2. Solidity $\frac{1}{2} p L \left\{ D^2 + \frac{(3A - LD)}{L} 4C \right\}$

where C is the central distances.

To the preceding formulæ it will be proper to annex the following table of the area of circular segments, which will be found very convenient in various problems relating to the circle and ellipse; and with this addition, the foregoing formulæ will be found to contain all that is essentially necessary for measuring any plane or solid, with the exception of some of the higher curves, which could not be conveniently reduced into a similar form. In those cases where logarithms, sines, tangents, &c. are necessary, see LOGARITHMS, SINES, &c.

MENSURATION.

TABLE of Circular Segments to Radius $\frac{1}{2}$.

MENSURATION.

Let us now, before we conclude this article, give a few examples in order to illustrate the use of the preceding formulae; in doing which we shall only select a few of the most difficult cases, the others being so extremely obvious, that no hesitation or doubt can possibly arise in their application.

Example 1.—The three sides of a triangle are 790, 1000, and 864: required the area.

By formula 4, for triangles, we have

$$\text{Log. area} = \frac{1}{2} \left\{ \begin{array}{l} \log. \frac{1}{2}s + \log. (\frac{1}{2}s - a) + \log. (\frac{1}{2}s - b) \\ + \log. (\frac{1}{2}s - c) \end{array} \right\}$$

Now $790 = a$
 $1000 = b$
 $864 = c$

$2)2654 = s$

$1327 = \frac{1}{2}s$	$\log. 1327 = 3.122871$
$537 = (\frac{1}{2}s - a)$	$\log. 537 = 2.729974$
$327 = (\frac{1}{2}s - b)$	$\log. 327 = 2.514548$
$463 = (\frac{1}{2}s - c)$	$\log. 463 = 2.665581$

$2)11.032974$

The area = $328474 = 5.516487$

Example 2.—The two diagonals of a trapezium are 30 and 40, and their angle of intersection 48° : required the area.

By formula 2, the area = $\frac{1}{2} d d' \sin. M'$.

$\frac{1}{2} d d' = \frac{1}{2} (30 \times 40) = \frac{1200}{2}$
 $\sin. 48^\circ = .743145$

The area = 445.887000

Example 3.—Required the length of a circular arc, whose chord is 6, and radius 9.

By formula 2, for circular arcs.

The area = $2 d \sqrt{q} + \frac{q}{2.3} A + \frac{3^2 q}{4.5} B + \frac{5^2 q}{6.7} C, \&c.$

where $q = \frac{v}{d}$; v being the versed sine, and d the diameter.

By the property of the circle we readily find the versed sine, $v = 9 - 6 \sqrt{2} = .51471862$, and $.51471862 \div 18 = .02859548$.

Whence $A = 2 d \sqrt{q} = 6.087672$

$B = \frac{q}{2.3} A = 29013$

$C = \frac{3^2 q}{4.5} B = 373$

$D = \frac{5^2 q}{6.7} C = 6$

$6.117064 = \text{arc as required.}$

Or, by using formula 3, we have

$\text{arc} = 2s + \frac{q}{2.3} A + \frac{3^2 q}{4.5} B + \frac{5^2 q}{6.7} C + \frac{7^2 q}{8.9} D, \&c.$

where s is the sine of the half arc = 3, and $q = \frac{s^2}{r^2} = \frac{9}{81} = \frac{1}{9}$
 $= \frac{1}{9} = 0.111111, \&c.$

Whence $A = 2s = 6.00000$

$B = \frac{q}{2.3} A = 0.111111$

$C = \frac{3^2 q}{4.5} B = 0.055555$

$D = \frac{5^2 q}{6.7} C = 0.00367$

$E = \frac{7^2 q}{8.9} D = 0.00028$

$F = \frac{9^2 q}{10.11} = 0.00002$

The required arc = 6.11063

Example 4.—Required the area of that circular segment, of which the diameter is 52, and the height or versed sine 2.

By formula 2, for circular segments.

Area = $2 \sqrt{d v} \times \left\{ \frac{2}{3} - \frac{3v}{5.2d} A - \frac{5v}{7.4d} B - \frac{7.3v}{9.6d} C \&c. \right\}$; where v is the versed sine = 2, and the diameter = 52.

$+ A = \frac{4v \sqrt{d v}}{3} = \frac{2}{3} \sqrt{104} = 27.1947707$

$- B = \frac{3v}{5.2d} A = \frac{3}{10.26} A = 0.3137858$

$- C = \frac{5v}{7.4d} B = \frac{5}{7.4 \cdot 29} B = 0.0021551$

$- D = \frac{7.3v}{9.6d} C = \frac{7}{3.6 \cdot 26} C = 0.0000322$

$- E = \frac{9.5v}{11.8d} D = \frac{9.5}{11.8 \cdot 26} D = 0.0000007$

Negative terms = -0.3159738
 Area of segment = 26.8787969

But the readiest method of finding the area of circular segment is by formula 9; where the area = $d^2 \times$ by tabular number corresponding to $\frac{v}{d}$.

In the present examples $\frac{v}{d} = \frac{2}{52} = \frac{1}{26} = .038 \frac{6}{13}$, the corresponding tabular number by preceding table = $.009940$ and $.009940 \times 52^2 = 26.878$, the area required.

This method, however, can only be practised in cases where great accuracy is not required, unless the table of segments be very extensive, such as that given by Hutton in his Mensuration.

Note.—In those cases where the quotient is not found exactly in the column of heights, or versed sines, as in the example above, a proportional part must be found for the fractional part of the number; viz. as 1 is to the difference between the two areas corresponding to the two versed sines, between

MENSURATION.

between which the given number lies; so is the fractional part of that number to a fourth proportional, which shall be added to the least area, or subtracted from the greater.

Example 5.—Required the periphery of an ellipse, the diameters of which are 24 and 18.

By formula 1, for the ellipse.

$$\text{Periphery} = C \times \left\{ 1 + \frac{m}{2^2} - \frac{3m^2}{2^2 \cdot 4^2} + \frac{3 \cdot 5m^3}{2^2 \cdot 4^2 \cdot 6^2} - \right.$$

1st term	1	=		+ 1.00000
2d term A =	$\frac{m}{2^2}$	=	$\frac{m}{4}$	= - .10938
3d term B =	$\frac{3m^2}{2^2 \cdot 4^2}$	=	$\frac{3m}{4^2}$	A = - .00897
4th term C =	$\frac{3 \cdot 5m^3}{2^2 \cdot 4^2 \cdot 6^2}$	=	$\frac{3 \cdot 5m}{6^2}$	B = - .00164
5th term D =	$\frac{3^2 \cdot 5^2 \cdot 7m^4}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2}$	=	$\frac{5 \cdot 7m}{8^2}$	C = - .00039
6th term E =	$\frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9m^5}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2}$	=	$\frac{7 \cdot 9m}{10^2}$	D = - .00011
7th term F =	$\frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 \cdot 11m^6}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2}$	=	$\frac{9 \cdot 11m}{12^2}$	E = - .00003
8th term G =	$\frac{3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 \cdot 11^2 \cdot 13m^7}{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \cdot 10^2 \cdot 12^2 \cdot 14^2}$	=	$\frac{11 \cdot 13m}{14^2}$	F = - .00001

Negative terms	= .12053
First term	= 1.00000
	.87947

whence .87947 × 24 × 3.1416 = 66.31056, the length of the curve required.

Example 6.—Required the length of the curve of a parabola, cut off by a double ordinate to the arc, whose length is as 12, the absciss being 2.

By formula 1, for parabolic arcs.

$$\text{Parabolic arc} = \frac{1}{2} p \left\{ q s + \text{hyp. log. } (q + s) \right\}$$

where p is the parameter = $\frac{y^2}{x} = \frac{b^2}{2} = 18$, $q = \frac{2y}{p} = \frac{1}{3}$, and $s = \sqrt{(1 + q^2)} = \sqrt{(1 + \frac{1}{9})} = 1.018504$, whence the required arc =

By formula 1, for hyperbolic arcs.

$$\text{Arc} = c \times \left\{ A + \frac{q}{2} B - \frac{q^2}{2 \cdot 4} C + \frac{3q^3}{2 \cdot 4 \cdot 6} D - \frac{3 \cdot 5q^4}{2 \cdot 4 \cdot 6 \cdot 8} E +, \&c. \right\}$$

$$\text{where } \frac{c^2 + y^2}{c^2} = q = \frac{80^2 + 60^2}{60^2} = 1\frac{1}{2}$$

$$A = \text{hyp. log. } \frac{y + \sqrt{(c^2 + y^2)}}{c} = 3274501$$

$$B = \frac{1}{2} \left\{ y \sqrt{(c^2 + y^2)} - c^2 A \right\} = 10.76133$$

$$C = \frac{1}{4} \left\{ y^3 \sqrt{(c^2 + y^2)} - 3c^2 B \right\} = 641.796405$$

$$D = \frac{1}{8} \left\{ y^5 \sqrt{(c^2 + y^2)} - 5c^2 C \right\} = 45698.7933$$

E =

$$9 \times \left\{ \frac{1}{2} \times 1.2018504 + \text{hyp. log. } 1.8675170 \right\}$$

$$\text{Now hyp. log. } 1.867517 = .6251449$$

$$\frac{1}{2} \times 1.2018504 = .6012336$$

$$\hline 1.4263785$$

$$\text{Multiplier } \hline 9$$

$$\text{Parabolic arc } \hline - 12.8374065$$

Example 7.—Required the length of an hyperbolic arc, beginning at the vertex, the transverse diameter being 80, conjugate 60, and ordinate 10.

MENSURATION.

$$E = \frac{1}{3} \left\{ y^2 \sqrt{e^2 + y^2} - 7 e^2 D \right\} = 3540529 \cdot 3125$$

Hence +	A = .327450	-	$\frac{q^2}{2 \cdot 4}$	C = .000764
	+ $\frac{q}{2}$ B = .016607	-	$\frac{3 \cdot 5 q^3}{2 \cdot 4 \cdot 6 \cdot 8}$	E = .000012
	+ $\frac{3 q^2}{2 \cdot 4 \cdot 6}$ D = .000084		&c.	= &c.
	Sum + .344141			Sum - .000776

therefore difference $.343365 \times 30 = 10.30095$, the arc required.

Example 8.—Required the solidity of a conic frustum of which the altitude is 16, and two diameters 20 and 30.

By formula 4, for conic frustums.

$$\text{Solidity} = \frac{1}{3} p \left\{ D^2 + D d + d^2 \right\} \times .7854$$

where $D = 30$, $d = 20$, and $h = 16$.

Now $30^2 + 30 \cdot 20 + 20^2 = 1900$

therefore $\frac{16}{3} \times 1900 \times .7854 = 7625.38$, the solidity required.

Example 9.—Required the surface and solidity of the five regular bodies, the linear side of each being 2.

By the formula for the regular bodies.

Tetraedron	{	Surface = $1.73205 \times 4 = 6.92820$	
	{	Solidity = $0.11785 \times 8 = .94280$	
Hexaedron	{	Surface = $6.00000 \times 4 = 24.00000$	
	{	Solidity = $1.00000 \times 8 = 8.00000$	
Octaedron	{	Surface = $3.46410 \times 4 = 14.65640$	
	{	Solidity = $0.47140 \times 8 = 3.77120$	
Dodecaedron	{	Surface = $20.64578 \times 4 = 82.58312$	
	{	Solidity = $7.66312 \times 8 = 61.30496$	
Icofaedron	{	Surface = $8.66025 \times 4 = 34.64100$	
	{	Solidity = $2.18169 \times 8 = 17.45352$	

These examples will be sufficient for illustrating the use of the preceding formulæ, and for rendering their application to any other problems perfectly simple and obvious. Neither the limits of this article, nor the nature of the work, would allow of our entering upon their investigation; the reader, therefore, who is desirous of information on this head, is referred to the works of Dr. Hutton and Mr. Bonnycastle, above-mentioned.

MENSURATION of Altitudes, Distances, &c. See ALTITUDE and DISTANCE.

MENSURATION of Land. See SURVEYING.

MENSURATION of Timber, or Timber Measure, is the method employed by artificers in measuring trees, joists, beams, &c.: and as these always fall under one or other of the regular solids which have been already treated of in the preceding article, it would seem unnecessary to repeat here any rules for the mensuration of timber: but the fact is, that an erroneous rule has been adopted by persons concerned in this line of business, which common practice has so established, that it is rather to be wished than expected it should be replaced by some other, either perfectly true, or approaching towards the truth; for, according to the present rule, a tree frequently contains $\frac{1}{4}$ th more or less timber than it is estimated at, which, at the modern price of that article, is a matter of some importance, and merits the attention of

the timber grower, as well as the merchant. Government has, in some instances, come forward to fix a standard of measure, as in corn, coals, land, &c.; and as old prejudices can never be so successfully combated, as by the authority of enlightened legislators, it is to be hoped that we may some day find this, and other topics of a similar nature, become the subject of parliamentary investigation. We will, in the following pages, shew the great inaccuracy attending the present method, but, in the first place, it will be proper to state the rule as it is at present employed by all persons concerned in the buying or selling of timber.

GENERAL RULE.

Multiply the square of the mean quarter girt, or quarter circumference, by the length of the tree, for the contents; which, when the dimensions are taken in feet, will be also feet; and this divided by 50, the number of feet in a load, will give the number of loads.

Note—1. If the piece of timber is of the same girt throughout, the girt any where taken is the mean girt.

2. If the tree tapers regularly from one end to the other, the girt taken in the middle is accounted the mean girt; or take half the sum of the girts at the two ends for the same.

3. But if the tree do not taper regularly, but is unequal, being thick in some places and small in others; it is customary to take several different dimensions, the sum of which, divided by the number of them, is accounted the mean girt. But when the tree is very irregular, it is best to divide it into several lengths, and to find the content of each separately.

4. That part of a tree, or of the branches, whose quarter girt is less than half a foot, is not accounted timber.

5. It is usual to make a certain allowance in girting a tree for the thickness of the bark, which is generally one inch to every foot in the girt. This practice, however, is unreasonable, and ought to be discouraged. Elm timber is the only kind in which any allowance is necessary, and even in this, one inch out of the whole girt is quite sufficient.

As an example in the preceding rule: let it be required to find the content of a tree, the length of which is 9 feet 6 inches; and quarter girt 3 feet 6 inches.

Such is the rule commonly used by persons concerned in buying and selling of timber, on which we intend to make a few remarks, in order to point out its inaccuracy, which is not so generally known as it ought to be. Suppose, for instance, we take a balk 24 feet long, and a foot square throughout, and, consequently, its solidity 24 feet. Now if this piece of timber be slit exactly in two, from end to end, making each piece 6 inches, or $\frac{1}{2}$ a foot broad, and 12 inches, or a foot thick, it is evident that the true solidity of each piece will be 12 feet. But by the quarter girt method they would amount to much more: for the false quarter girt being equal to half the sum of the breadth and thickness, in this case will be 9 inches, or $\frac{3}{4}$ of a foot; the square of which is $\frac{9}{16}$, and therefore $\frac{9}{16} \times 24 = 13\frac{1}{2}$ feet for the solidity of each part, making the two pieces together 27 feet, instead of 24, which is the true content.

Again, suppose this balk to be so cut, that the breadth of the one piece may be only 4 inches, or $\frac{1}{3}$ of a foot; and that of the other 8 inches, or $\frac{2}{3}$ of a foot. Here the true content of the less piece will be 8 feet, and that of the greater 16 feet. But proceeding by the other method, we have the quarter girt of the less piece $\frac{2}{3}$ of a foot, and of the other piece $\frac{4}{3}$ of a foot. Whence the content of the less piece will be found $= \frac{4}{9} \times 24 = 10\frac{2}{3}$ feet, instead of 8 feet; and the content of the greater piece will be $16\frac{2}{3}$ feet, instead of 16; making the sum of the two $27\frac{1}{3}$ feet, instead of 24 feet. Farther, if the less piece be cut only two inches broad, and consequently the greater 10 inches, the true content of the less piece would be 4 feet, and that of the greater 20 feet. Whereas by the other method, the quarter girt of the less piece would be 7 inches, or $\frac{7}{12}$ of a foot; and $\frac{49}{144} \times 24 = 8\frac{1}{3}$ feet, instead of 4 feet, for the content; and by the same method, the content of the greater piece would be $20\frac{1}{3}$ feet, instead of 20, and their sum $28\frac{1}{3}$ feet, instead of 24.

Hence it is obvious, that the greater the proportion is between the breadth and the depth, the greater will be the error, by using the false method; and the sum of the two parts, by the same method, is greater, as the difference of the same two parts is greater; and, consequently, the sum is least when the two parts are equal to each other; or when the balk is cut equally in two; and finally, when the sides of a piece of timber differ not above an inch or two from each other, the quarter girt may be used without any very sensible error. To avoid, therefore, this inconsistency in the result, the following method should be employed, *viz.* Multiply the length, breadth, and depth continually together, and the product will be the true content in all cases of this kind.

With regard to round timber the error is of a different kind. We have seen in the preceding article, that the area of a circle is found by squaring the circumference, and multiplying that square by .07958, and, therefore, if a quarter of the circumference is used, we must multiply its square by $.07958 \times 16 = 1.27328$.

Hence, to find the true content of a piece of cylindrical timber, we ought to multiply the square of the quarter girt by the constant number 1.27328, and that product by

the length, instead of which the constant multiplier is omitted, and consequently the solidity is returned about 25 parts less than it is. But as the utmost accuracy is not necessary in those cases, the following rule might be used, which is as simple as can be desired, *viz.* Multiply the square of $\frac{1}{4}$ of the mean girt by double the length for the content, which is not far from the truth.

Another error to which timber measure is always subject, is the way in which the mean girt is assumed in tapering trees, which, as we have before stated, is done either by taking the girt in the middle, or half the sum of the extreme girts, both of which are equally false, so obviously so, that a tree of certain dimensions will measure more after a part of it has been cut off, than it did before. This being the case, it will not be amiss to shew the extreme inaccuracy of the method, and the folly in persisting in it, by the solution of the following problems, which have been taken from Dr. Hutton's Mensuration.

PROBLEM I.

To find where a tapering timber must be cut, so that the two parts, measured separately, shall measure the most possible, and be greater than if it were cut in any other two parts, and greater than the whole.

Put G = the greatest girt, g = the least girt, x = the girt at the section, z = the length of the part to be cut off, and L the whole length of the timber. Then by similar figures $L : z :: G - g : x - g$; hence $x = \frac{Gz - gz}{L} + g$; but $(g + x)^2 z + (G + x)^2 (L - z)$ is to be a *maximum*; which being put into fluxions, and reduced, gives $z = \frac{1}{2} L$.

Therefore, a tree being cut exactly in the middle, the two parts will measure more than if it were cut in any other two parts, and more than the whole tree. If a tree, of which the greater girt is 12 feet, and less girt 2 feet, and length 32 feet, be thus cut in two parts, the measure of the two parts will exceed the measure of the whole tree by 18 feet.

PROBLEM II.

To find where a tree must be cut, so that the part next the greater end may measure the greatest possible.

Here, by using the same notation as in the last problem, we have also $x = \frac{Gz - gz}{L} + g$, and $(G + x)^2 (L - x)$ a *maximum*; which, put into fluxions as before, gives $z = \frac{G - 3g}{G - g} + \frac{1}{2} L$.

Therefore, from the greater girt subtract the less girt, and that difference divided by the difference of the girts, and multiplied by $\frac{1}{2}$ of the whole length, will be the length to be cut off.

PROBLEM III.

To find where a tree must be cut, so that the part next the greater end may measure the same as the whole tree before it was cut.

Using still the same notation, and writing besides s for the sum of the two girts, and d for their difference; we shall have $s^2 L = (L - z)(G + x)^2$, or substituting, instead of x , its value $\frac{Gz - gz}{L} + g$, or $\frac{dz}{L} + g$, we obtain

$$z = \frac{L}{2d} + \left\{ \sqrt{(4s^2 + d) - 2s + d} \right\}$$

which

which length being cut off, the remaining part will measure the same as the whole tree.

These results, which are the necessary consequence of the preceding rules, are so obviously erroneous and inconsistent, that they speak for themselves, and therefore require no farther comment.

MENTAL, something that relates, or is restrained, to the operation of the understanding.

Thus, a mental prayer is such a one as is made merely in the mind, without pronouncing one word of it.

Mental reservations are the refuge of hypocrites. See RESERVATION.

MENTAL Derangement. Under this head may be comprehended a variety of terms, which have been employed to designate certain affections of the mind, or, as they have been called, disorders of the intellect. In the preliminary part of this investigation, it is highly important to understand fully the force and meaning of the words, which are intended to establish these different significations; and also to discover the contrivances of language, which have served to characterize the phenomena of disordered understanding. That the mind has no language peculiar to itself, seems to be an admitted axiom; because all the terms which are applied to it have their origin in the physical circumstances which surround us. The mental operations, which are supposed to be extensive, have not furnished any terms, (as the result of such internal operations,) which we did not previously possess, and which we have been compelled to borrow from the objects and impressions of the material world.

Although authors have generally divided mental derangement into *mania* and *melancholia*, according to the system of the Greeks; yet most nations have adopted peculiar expressions, to signify the form or degree of derangement of intellect. The term *derangement*, which we have taken immediately from the French, and which means out of *rank*, or *order*, is metaphorically applied to the mind, to denote that its ideas are out of the rank, or order, generally preserved by intelligent beings. *Delirium*, employed by the Romans, had its origin from the process of ploughing: for when the oxen deviated from the line to be pursued, they were said to be *de lira*, out of the track; and this figure was transferred to the deviations of the human intellect, when it erred from the established course. *Insane*, *insanus*, means merely *unfound*. The Greek *μανία* was probably from their verb *μαίνομαι*, *I rage*; *μελανχολία*, from *μελας*, *black*, and *χολή*, *bile*; black bile being supposed the cause of this disease. In the opinion of Cicero, (*Disputat. Tusculan.* lib. iii. c. 5.) the Roman terms, which marked the disorders of the intellect, were more appropriate than those employed by the Greeks. "Multoque melius hæc notata sunt verbis Latinis, quam Græcis: quod aliis quoque multis locis reperietur. Sed id alias: nunc, quod instat. Totum igitur id quod quaerimus, quid et quale sit, verbi vis ipsa declarat. Eos enim sanos quoniam intelligi necesse est, quorum mens motu, quasi morbo, perturbata nullo sit; qui contra affecti sunt, hos insanos appellari necesse est. Itaque nihil melius, quam quod est in consuetudine sermonis Latini; cum *exisse ex potestate* dicimus eos, qui effrenati feruntur aut libidine aut iracundia: quamquam ipsa iracundia libidinis est pars: sic enim definitur, *iracundia ulciscendi libido*. Qui igitur *exisse ex potestate* dicuntur; idcirco dicuntur, quia non sunt in potestate mentis: cui regnum totius animi a natura tributum est. Græci autem *μανίαν* unde appellant, non facile dixerim. Eam tamen ipsam distinguimus nos melius, quam illi; hanc enim insaniam, quæ juncta stultitiæ patet latius, a furore disjungimus: Græci volunt illi quidem, sed parum valent verbo: quem nos furem, *μελανχολίαν* illi vocant.

Quasi vero atra bili solum mens, ac non sæpe vel iracundia graviore, vel timore, vel dolore moveatur! quo genere Athamantem, Alemæonem, Ajacem, Orestem furere dicimus. Qui ita sit affectus, cum dominum esse rerum suarum vetat duodecim tabulæ." The supposed regulation of the intellect, in certain states, by the influence of the moon, has produced the term *lunatic*; which word still prevails in all legal proceedings relative to the insane. The vulgar opinion, that in madness the mind was broken into fragments, has given rise to the terms *crazy* (*ecrasé*, Fr.), *cracked*, and *shatter-brained*. The word *mad* has been derived by Mr. Haslam ("Observations on Madness and Melancholy") from the Gothic *mod*, which signifies *rage*. He observes, "It is true, we have now converted the *o* into *a*, and write the word *mad*; but *mod* was anciently employed." Of the similarity between violent anger and madness, the observation has been general. Cicero says, "An est quicquam similis insanix quam ira? quam bene Ennius initium dixit insanix." (*Disp. Tusc.*) Dr. Beddoes (*Hygeia*, N^o 12.) observes, that "*mad* is one of those words which means almost every thing and nothing. At first, it was, *I imagine*, applied to the transports of rage; and when men were civilized enough to be capable of insanity, their insanity, I presume, must have been of the frantic sort; because, in the untutored, intense feelings seem regularly to carry a boisterous expression."

Authors, who have treated on the subject of mental derangement, have commonly been desirous of affording a definition: they have endeavoured to compress into a few words, or a short sentence, the prominent and discriminating phenomena of insanity, and thus to establish an essential character of the disorder. However meritorious their labours, their success has been by no means proportionate to their exertions. They have all fundamentally differed; and to enumerate their attempts is only to record their failures. Dr. Mead conjectures, "that this disease consists entirely in the strength of imagination." "Insanity," says Dr. Cullen, "consists in such false conceptions of the relations of things as lead to irrational emotions or actions. Melancholy is partial insanity, without indigestion; mania is universal insanity." Dr. Ferriar, adopting the generally accepted division of insanity into mania and melancholia, conceives, in mania, *false perception*, and consequently confusion of ideas, to be a leading circumstance. Melancholia he supposes to consist in *intensity of idea*, which is a contrary state to false perception. Dr. Arnold observes, that "insanity, as well as delirium, may be considered as divisible into two kinds; one of which may be called *ideal*, and the other *notional* insanity.

"*Ideal* insanity is that state of mind, in which a person imagines he sees, hears, or otherwise perceives, or converses with, persons or things, which either have no external existence to his senses at the time; or have no such external existence, as they are then conceived to have; or if he perceives external objects as they really exist, has yet erroneous and absurd ideas of his own form, and other sensible qualities:—such a state of mind continuing for a considerable time, and being unaccompanied with any violent or adequate degree of fever.

"*Notional* insanity is that state of mind, in which a person sees, hears, or otherwise perceives external objects, as they really exist, as objects of sense; yet conceives such notions of the powers, properties, designs, state, destination, importance, manner of existence, or the like, of things and persons, of himself and others, as appear obviously, and often grossly erroneous, or unreasonable to the common sense of the sober and judicious part of mankind. It is of considerable

considerable duration; it never accompanied with any great degree of fever, and very often with no fever at all."

Mr. Hallam, in the first edition of his work (*Observations on Insanity*), defined insanity to be "an incorrect association of familiar ideas, which is independent of the prejudices of education, and is always accompanied with implicit belief, and generally with either violent or depressing passions." But the same author, in his second edition, has omitted this definition, and seems to be convinced that, instead of endeavouring to discover an infallible definition of madness, which he believes will be found impossible, (as it is an attempt to comprise in a few words the wide range and untable character of this Proteus-disorder,) much greater advantage would be obtained, if the circumstances could be precisely defined, under which it is justifiable to deprive a human being of his liberty.

Symptoms.—The approaches of insanity have been variously related by different writers. The late Dr. John Monro, in a pointed and elegant reply to Dr. Battie's *Treatise on Madness*, has remarked, that "high spirits, as they are generally termed, are the first symptoms of this kind of disorder: these excite a man to take a larger quantity of wine than usual; (for those who have fallen under my observation, in this particular, have been naturally very sober;) and the person thus affected, from being abtemperious, reserved, and modest, shall become quite the contrary; drink freely, talk boldly, obscenely, swear, sit up till midnight, sleep little, rise suddenly from bed, go out a hunting, return again immediately, set all his servants to work, and employ five times the number that is necessary: in short, every thing he says or does betrays the most violent agitation of mind, which it is not in his power to correct; and yet, in the midst of all this hurry, he will not misplace one word, or give the least reason for any one to think he imagines things to exist that really do not, or that they appear to him different from what they do to other people. They who see him but seldom, admire his vivacity, are pleased with his sallies of wit, and the sagacity of his remarks: nay, his own family are with difficulty persuaded to take proper care of him, until it becomes absolutely necessary, from the apparent ruin of his health and fortune."

In many instances, pain of the head and throbbing of its arteries precede an attack of insanity: sometimes giddiness and confused vision are complained of, as precursory symptoms. Those who have been several times disordered are now and then sensible of the return of their malady. Some have described the attack as highly delightful; and of this pleasurable feeling, a curious instance is recorded in the *Bibliothèque Britannique*, by a recovered lunatic, who had been a patient of the late Dr. Willis. "I always expected with impatience the accession of the paroxysms, since I enjoyed, during their presence, a high degree of pleasure. They lasted ten or twelve hours. Every thing appeared easy to me. No obstacles presented themselves either in theory or practice. My memory acquired, all of a sudden, a singular degree of perfection: long passages of Latin authors occurred to my mind. In general, I have great difficulty in finding rhythmical terminations; but then I could write in verse with as much facility as in prose. I was cunning, malicious, and fertile in all kinds of expedients." Some have described a sense of working in the head, and also in the intestines, as if they were in a state of fermentation. Others observe that they do not seem to possess their natural feelings; and they all agree that they become confused, from the sudden and rapid intrusion of unconnected thoughts.

Mr. Hallam, whose situation in Bethlem Hospital affords

abundant opportunities of observing this disorder, has thus related the commencement of madness and melancholy. "On the approach of mania, they first become uneasy, are incapable of confining their attention, and neglect any employment to which they have been accustomed. They get but little sleep; they are loquacious, and disposed to harangue, and decide promptly and positively upon every subject that may be started. Soon after, they are divested of all restraint, in the declaration of their opinions of those with whom they are acquainted. Their friendships are expressed with fervency and extravagance; their enmities with intolerance and disgust. They now become impatient of contradiction, and learn reproof. For supposed injuries, they are inclined to quarrel and fight with those about them. They have all the appearance of persons inebriated; and those, who are unacquainted with the symptoms of approaching mania, generally suppose them to be in a state of intoxication. At length suspicion creeps upon the mind, they are aware of plots which had never been contrived, and detect motives that were never entertained. At last, the succession of ideas is too rapid to be examined; the mind becomes crowded with thoughts, and confusion ensues. Those under the influence of the depressing passions will exhibit a different train of symptoms. The countenance wears an anxious and gloomy aspect; and they are little disposed to speak. They retire from the company of those with whom they formerly associated; seclude themselves in obscure places, or lie in bed the greater part of their time. Frequently, they will keep their eyes fixed to some object for hours together, or continue them an equal time 'bent on vacancy.' They next become fearful, and conceive a thousand fancies: often recur to some immoral act which they have committed, or imagine themselves guilty of crimes which they never perpetrated; believe that God has abandoned them, and with trembling await his punishment. Frequently they become desperate, and endeavour by their own hands to terminate an existence, which appears to be an afflicting and hateful incumbrance."

The mental characteristics of this disorder involve all those aberrations from intellectual soundness, and moral rectitude, which render man a worthless, and frequently a dangerous associate to the community. A degree of cunning, inscrutable by ordinary persons, and not always to be penetrated by those who have acquired extensive experience of the insane, constitutes a leading feature in mental derangement. Whenever they have meditated their own destruction, or intended mischief to others, the accomplishment of the deed has often been the only notice of the intention; and the pride, which usually accompanies this malady, has frequently induced these unhappy sufferers to haunt the persons of those distinguished by rank and elevated in office.

The bodily marks which distinguish the insane, are, a peculiar cast of countenance, familiar to, and recognizable by those versed in this disease; a quick, oftentimes protruded and glistening eye; coldness of the hands and feet; and a capability of sustaining cold with impunity. But Dr. Pinel, physician to the *Bicêtre* at Paris, conceives this exception from the effects of severe cold to be by no means general, and instances the frequent occurrence of mortified extremities during winter; and others of much experience are of the same opinion. Obstinate constipation has been mentioned as an unvarying attendant on madness; but the best informed writers regard it merely as an occasional symptom, prevailing only when general insensibility is the consequence of pressure on the brain. In deranged persons, the ear is the organ of sense most affected;

MENTAL DERANGEMENT.

fects; *tinnitus aurium* and deafness being found very generally to prevail: whereas blindness, or deprivations of the smell and taste, have been seldom noticed. Mr. Haslam has exclusively observed, in some cases, a relaxation of the scalp; by which it may be wrinkled, or rather gathered up by the hand to a considerable degree: it more generally occurs on the posterior part; is not noticed in the early stages of the disease, but after a raving paroxysm of more continuance.

Appearances on Dissection.—From the testimonies of Chiarugi in Italy, Greding in Germany, and from Mr. Haslam's work, diseased appearances of the brain and its membranes have been detected in those who have died insane. But there may exist many alterations in the structure of these parts, too minute for the eye to observe, and which can never be brought in view by the scalpel. Although Dr. Pinel denies the disorganization of the brain in madness as peculiar to that disease; yet he admits, that the same appearances are found, as occur in those who have died from epilepsy, apoplexy, fever, and convulsions. These morbid appearances consist in excessive determination of blood to the brain, with enlargement of its vessels, and effusion of fluids into its cavities. In many instances the substance of the brain has possessed an increased degree of firmness, and, according to the late Mr. John Hunter, has been found so tough, as to have some elasticity. Dr. Baillie has also remarked, that "when these changes take place in the brain, the mind is at the same time deranged; there is either mania or lethargy; or the person is much subject to convulsive paroxysms." In other cases the brain was of a preternaturally soft consistence. Gangrene of the brain has sometimes occurred, but more frequently in the warmer climates, as may be seen by consulting Chiarugi. The membranes of the brain have been found variously altered from their healthy state: the tunica arachnoidea has become thickened, and rendered more or less opaque. The pia mater is often inflamed, and turgid with blood, and not unfrequently an extravasated blotch appears on some part of this tunic. Effusion of a watery fluid between the membranes of the brain is a very common occurrence, and likewise into its ventricles, which have been consequently enlarged to a surprising extent. Ossifications have been detected, but principally on the dura mater.

Causes.—In the investigation of the causes of mental derangement, there is obviously much uncertainty; our knowledge of the human mind is too limited to affirm that particular states of the intellect will be the necessary result of certain circumstances preceding. Those who have attentively considered this subject have divided the causes of insanity into *physical* and *moral*. Under the head of *physical* causes, hereditary disposition has been stated very generally to prevail; whereby the offspring of an insane parent, or parents, will most probably become similarly affected; but, whether this transmission depend more especially on the male, or female, has not yet been certainly determined. Injuries to the head from external violence; frequent intoxication, particularly when produced by fermented liquors which have undergone the process of distillation; fever, during the course of which delirium has particularly prevailed; mercurial medicines, largely exhibited, and continued for a considerable time, without due precautions; paralytic affections (but these are very frequently the consequence as well as the cause of mental derangement); the suppression of periodical or occasional discharges and secretions; and, in some instances, the retropulsion of cutaneous eruptions; are the ordinary physical causes to which insanity has been ascribed.

The *moral* causes include those emotions which are con-

ceived to originate from the mind itself, and which, from their excess, tend to distort the natural feelings, or, from their repeated accessions, and unrestrained indulgence, at length overthrow the barriers of reason and established opinion. Such are the gusts of violent anger, and the protracted indulgence of grief; the terror impressed by erroneous views of religion; the degradation of pride; disappointment in love; and sudden fright.

Although mental derangement has been observed in persons of all habits and complexions, yet there is doubtless a temperament which particularly disposes to insanity: and there are also certain modes of education, and employment of the faculties, which conduce to their derangement. According to Mr. Haslam's statement, out of 265 patients in Bethlem Hospital, 205 were found to be of a swarthy complexion, with dark or black hair; the remaining 60 were of a fair skin; with light, brown, or red hair. Dr. Pinel, on examining the registers of the Bicêtre, says, that he found inscribed a great many monks and priests, as also a considerable number of country people, who had been driven beside themselves by horrid pictures of futurity; several artists, as sculptors, painters, and musicians; some versifiers, in extacies with their own productions; a pretty considerable number of advocates and attorneys; but there does not appear the name of a single person accustomed to the habitual exercise of his intellectual faculties; not one naturalist, or natural philosopher of ability; no chemist nor geometrician.

The *prognosis*, or means of ascertaining the probable event of mental derangement, is founded on the experience of those practitioners who have particularly attended to the treatment of this disorder. It is, however, to be lamented, that very few of those persons, who have been best qualified to afford information, have transmitted to the world the result of their practice. Much valuable knowledge may therefore be presumed to have perished. In the year 1758 Dr. Battie, the physician to St. Luke's Hospital, justly observed in his "Treatise on Madness," that "among the many good reasons, offered to the public for establishing another hospital for the reception of lunatics, one, and that not the least considerable, was the introducing more gentlemen of the faculty to the study and practice of one of the most important branches of physic." In England, females are more subject to insanity than men; but abroad, the case is believed to be reversed. From 1748 to 1794, a period of 46 years, there were admitted into Bethlem Hospital 4832 women, and 4042 men. Dr. Chiarugi of Florence, who, during four years, saw in the hospitals of St. Dorothea and St. Bonifacio 1157 lunatics, states the proportion of deranged males, as exceeding that of females by one-fifth. Females recover from mental derangement in a greater proportion than men: of the above mentioned 4832 women, 1402 were discharged cured; of the 4042 men, 1155 recovered.

As insanity frequently supervenes on parturition, women, becoming deranged from such cause, recover in a very large proportion. During ten years, 80 patients of this description were admitted into Bethlem Hospital, 50 of whom perfectly recovered. When females become worse at the period of menstruation, or have their catamena in profuse or deficient quantities, such occurrences may be considered unfavourable.

The chance of recovery is greater when the patient is attacked with mania, than when affected with melancholia. When the maniacal and melancholic states alternate, the hope of recovery is diminished. A greater number of patients are observed to recover, when the mental derangement

MENTAL DERANGEMENT.

ment has been produced from remote *physical* causes, than when it has arisen from causes of a *moral* nature.

It appears from the united testimonies of Dr. Pinel and Mr. Hallam, that a greater number of insane patients have been admitted into the Bicêtre, and Bethlem Hospital, from the age of 30 to 40, than during any other equal period of life; and from the statement of the latter, it may be inferred, that the disease is less frequently cured when it attacks persons of an advanced age. The following statement comprises the number of patients admitted into Bethlem Hospital from 1784 to 1794. The first column marks the age; the second the number admitted; the third poses the number cured; the fourth those who were discharged not cured.

Age between.	Number admitted.	Number discharged cured.	Number discharged uncured.
10 and 20	113	78	35
20 — 30	488	200	288
30 — 40	537	180	347
40 — 50	362	87	275
50 — 60	143	25	118
60 — 70	31	4	27

It is also calculated, that the chance of cure is diminished, in proportion to the length of time which the disorder has continued.

Where mental derangement is complicated with palsy or epilepsy, or where the natural powers of the mind become enfeebled during its continuance, there is but little hope of the patient's recovery. The insanity, which is often excited by the impression of religious terror,—by those gloomy views of futurity, and that constant dread of divine vengeance which false notions on this subject usually inspire,—has seldom a favourable termination. When the derangement has acquired a systematic character, it becomes very difficult to remove: in this state, incidents the most unconnected are easily reconciled, and become fondly involved with the prevailing delusion.

The *Cure* of mental derangement may properly be divided into *management* and *medicine*: for it appears to be the opinion of those who have most successfully treated this disorder, that the proper controul and subjection of the patient to salutary and established rules are of equal importance with the prescription of remedies.

By the common consent of foreigners, the English are supposed particularly to excel in the moral management of this disorder. It is, however, to be regretted, that general directions only can be given on this subject: the precise adaptation of these principles to individual cases, must depend on the skill, address, and experience of the practitioner.

Insane persons are most advantageously treated when removed from home, and from the interference of their immediate relations and friends. While they remain in their own houses, it is nearly impossible to divest them of the authority which they had been accustomed to maintain; and the salutary regulations of the superintendent are frequently rendered useless, by the mistaken indulgence of their family connections. A system of regularity should be established in their actions; and restraint should instantly be imposed on disobedience. As the deranged person should be taught to view the superintendent of his conduct with respect, the latter should be careful to deserve it by vigilant firmness, and steady decorum. The confidence of the maniac can never be reposed in ignorance and mismanagement, nor can his esteem be imparted to unfeeling and tyrannical assumption. Although it is proper to curb the extravagant follies of the

VOL. XXIII.

patient; yet no advantage appears to be derived from an endeavour to convince him by argument; the less frequently the subjects of his delusion are referred to, the more easily he becomes managed. When the insane are convalescent, the occasional visits of their friends are attended with manifest advantage: such intercourse brightens the prospects of future life, and often acts as a stimulus to self-restraint. But in certain states of the disorder, where pride, malevolence, and cunning, form the leading features of derangement, the ill-timed admission of friends has been signally prejudicial: it has tended to unfix the authority of the superintendent, and introduced a train of afflictions which has aggravated the malady. Of the beneficial effects of mild and humane treatment in this disorder, Mr. Hallam says, "Speaking of the effects of management on an extensive scale, I can truly declare, that by gentleness of manner, and kindness of treatment, I have seldom failed to obtain the confidence and conciliate the esteem of insane persons; and have succeeded by these means in procuring from them respect and obedience. There are certainly some patients who are not to be trusted, and in whom malevolence forms the prominent feature of their character: such persons should always be kept under a certain restraint, but this is not incompatible with kindness and humanity."

Deception on the part of the medical superintendent should never be resorted to. The late Dr. John Monro emphatically observes, "The physician should never deceive them in any thing, but more particularly with regard to their distemper; yet as they are generally conscious of it themselves, they acquire a kind of reverence for those who know it, and by letting them see that he is thoroughly acquainted with their complaint, he may very often gain such an ascendant over them, that they will readily follow his directions." Formerly coercion was employed with a degree of severity, that amounted to vindictive punishment: recourse was had to the whip, and stripes were actually inflicted by medical direction. The more rational and humane treatment of modern practitioners, has induced them to employ coercion only as a protecting restraint; to guard the patient from doing mischief to himself, or offering violence to others; and for this purpose the straight-waistcoat is usually sufficient.

Medicine.—An enumeration of all the remedies which have been proposed, and strongly recommended for the cure of mental derangement, would extend this article to an unprofitable length. The ancient physicians principally confided in a species of hellebore, which was cultivated with the greatest attention, prepared with the utmost care, and exhibited under particular cautions; but concerning these matters there was unfortunately much diversity of opinion. Considering the various and opposite states of mental derangement, a rational mind would scarcely expect any particular drug to possess powers adequate to the restoration of reason. If insanity be a disease of the *mind itself*, corporeal remedies can be of little utility; if an affection of the brain, and nervous system, no particular medicine can be supposed capable of restoring the various lesions, which anatomical investigation has detected.

When the experience of eminent practitioners is at variance; when remedies, which have been extolled for their virtues and successful operation by one medical writer, have been asserted by another to be impotent and unprosperous, the subject of cure becomes entangled with insuperable difficulties. Modern practitioners are nearly agreed, that at the commencement of this disorder, *bleeding* may be employed with advantage; and drawing blood by cupping-glasses has been usually preferred. Little difference of opinion has pre-

vailed concerning the utility of *cathartics*: some practitioners have, however, preferred particular articles of this tribe, as elaterium, calomel, jalap, &c.; while others have succeeded with the milder purgatives, as fenna, and the solutions of neutral salts, with the addition of a small quantity of the antimonium tartarizatum. As recovery is often preceded by a spontaneous diarrhœa, purgative medicines may be esteemed, under a judicious exhibition, of signal utility in most cases of mental derangement.

Emetics.—Practitioners are much divided in opinion respecting the propriety of administering vomits as a remedy for insanity. The late Dr. John Monro thought “the evacuation by vomiting infinitely preferable to any other.” Dr. Cox is equally partial to emetics as a cure for mental derangement. Mr. Haslam, however, entertains an unfavourable opinion of them: he states that, in some instances, paralytic affections have supervened within a few hours after the exhibition of an emetic; more especially when the patient has been of a full habit, and has had the appearance of an increased determination to the head. Perhaps in melancholia, emetics may be more generally advantageous; and in furious mania, the same remedies may be employed merely in nauseating doses, to prevent the severe convulsion of vomiting.

Opium has seldom procured sleep, when given in the furious state of insanity. Notwithstanding the encomium of this remedy by Bernard Heute, the respectable testimonies of Dr. Ferriar and others have not induced any expectation of benefit from its employment. Dr. Chiarugi deposes to the sedative effect of a watery solution of opium, applied to the internal membrane of the nose with a camel’s-hair pencil. Of the remaining tribe of narcotic remedies we have little that is satisfactory on record.

Digitalis, though strongly recommended by some, has produced no benefit in the hands of others. Dr. Ferriar expressly states, “that he has given this remedy, even to nauseating doses; but with no advantage. It never suspended the appearances of insanity for a moment.”

Camphor has been much extolled for its virtues in mental derangement; but Dr. Ferriar and Mr. Haslam, who gave it in large doses, did not experience any considerable benefit from the employment of this remedy. Dr. Laughter mentions nine cases of insanity cured by camphor; but in these instances it was combined with vinegar. Dr. Leopold Avenbrugger, in a curious tract entitled “*Experimentum noscens de remedio specifico, sub signo specifico in mania virorum*,” Vienna, 1772, has spoken still more highly of the specific virtues of camphor in this disease. *Blisters* have had their advocates; but it seems to be the opinion of those whose experience has been most extensive, that they succeed better when put to the lower extremities, than applied directly to the head. Issues and setons may in many cases be used with advantage; but they should be allowed to discharge for a considerable time; as their beneficial effects are not immediately apparent.

In some instances the *warm bath* has mitigated the fury of the patient, and in melancholia the use of the *cold bath* has been thought advantageous.

It appears to be a radical defect in almost all the institutions for the insane, that no plan for the *employment* of the patients has been hitherto adopted. Many difficulties certainly occur, as to the nature of the labour in which they ought to be engaged; but a judicious contrivance might surmount them, and appropriate a salutary exercise and amusement to the different classes of the insane.

MENTCHIKOF, ALEXANDER, in *Biography*, a statesman and general under the czar Peter I., was the son of

peasants who were the vassals of the monastery of Cosmopol. At the age of thirteen he went to Moscow to obtain the means of subsistence, and was taken into the service of a pastrycook, who employed him to vend his goods by crying them about the streets of that then celebrated city, now, alas, [Oct. 1812,] desolated by the madness of war. The czar happened one day to hear him, and being struck with the pleasant song which he annexed to his cry, entered into conversation, and, in the end, ordered him to come to court, where he was at first placed in a very low station, but his talents were discoverable in the midst of all disadvantages, and it was seen he had a wonderful facility in acquiring several languages. The czar took him to serve about his person, and he was from that time gradually advanced to the highest employments, till at length he became one of the most successful generals in the Russian army. When Peter went on his travels for improvement, he took Mentchikof for his companion, and, in 1706, he was created a prince of the German empire, and was, after this, frequently employed on occasions of ceremony to personate the czar, who chose rather to appear as a private person in his train. He was victorious over the Swedes, in the war against Charles XII., and had the command of the left wing of the Russians at the decisive battle of Pultowa, in the year 1709. His situation enabled him to acquire great wealth, but in 1715 he was called to an account for certain abuses of the administration, and fell under the censure of his sovereign. He was afterwards restored to his favour, and even placed at the head of the council of regency, when Peter set out on his expedition to Persia. He greatly contributed to the succession of the empress Catherine at the death of Peter, and upon her demise he took measures to insure the crown to Peter Alexievitch, on condition that he should espouse his eldest daughter. The accession took place in 1727, and Peter was betrothed to his intended bride. Mentchikof now assumed all the arrogance of uncontrollable sway, which in a very short time occasioned an order for his arrest: this was followed by a decree of banishment. It was intended to confine him to his own estate; he imprudently left the capital with a splendid train, which his enemies construed into marks of contempt for the emperor, who readily dispatched an order to carry him prisoner to Siberia. The place of his confinement was Berefok, on the rude and desolate banks of the Oby. His wife, who had been delicately brought up, wept herself blind, and expired in the course of her journey. His own mind soon accommodated itself to his situation. He cultivated a small farm, and, by industry and frugality, saved enough from his daily pittance, of ten rubles, to build a wooden church, in the erection of which he assisted with his own hands. He died in November 1729, little more than two years from the time of his banishment. Univer. Hist.

MENTHA, in *Botany*, an ancient Latin word, mostly written *Menta*, adopted from the Greeks, whose *μινθῆ* is synonymous with their *ῥόδισμος*; the latter being most generally used; see Dioscorides, book 3. chap. 41. The nymph Mintha, a favourite of Pluto, is fabled to have been changed by Proserpine into this herb, as incidentally mentioned by Ovid; *Metam.* book 10. 729.—*Mint*.—Linn. *Gen.* 291. Schreb. 387. Willd. *Sp. Pl.* v. 3. 74. Mart. *Mill. Dict.* v. 3. Sm. *Fl. Brit.* 609. *Tr. of Linn. Soc.* v. 5. 171. *Prodr. Fl. Græc.* Sibth. v. 1. 402. Brown. *Prod. Nov.* Holl. v. 1. 505. Ait. *Hort. Kew.* ed. 2. v. 3. 387. Juss. 113. *Tourn.* t. 89. Lamarck *Dict.* v. 4. 102. *Illustr.* t. 503.—Class and order, *Didymia Gymnospermia*. *Nat. Ord. Verticillatae*, Linn. *Labiatae*, Juss.

Gen.

MENTHA.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, erect, with five nearly equal teeth, permanent. *Cor.* of one petal, erect, tubular, somewhat longer than the calyx; limb in four deep, nearly equal, segments, the uppermost only being rather the broadest, and cloven. *Stam.* Filaments four, awl-shaped, erect, distant, the two nearest ones longest; anthers roundish. *Pist.* Germen superior, four-cleft; style thread-shaped, erect, longer than the corolla; stigma in two divaricated divisions. *Peric.* none, except the permanent straight calyx. *Seeds* four, small, generally abortive.

Ess. Ch. Calyx five-cleft, nearly equal. Corolla nearly equal, four-cleft; its broadest segment cloven. Stamens erect, distant.

This is one of the most natural genera possible; well marked in habit and characters. The herbage, and even the flowers, abound with resinous dots, the seat of an essential oil, on which the warm and aromatic qualities of these plants depend. Their flavour is different in the different species, and variable in the same, but on the whole almost peculiar to the genus. The following characters apply to the species in general. *Root* creeping, perennial. *Stems* square, branched, leafy. *Leaves* opposite, simple, undivided, generally serrated. *Flowers* in stalked many-flowered whorls, which are either axillary, capitate, or spiked. *Calyx* striated, or ribbed, rather dilated upward, almost regular, either naked, or clothed more or less completely with simple hairs, whose direction differs in different species, but is very constant in the same. Very rarely this part is covered with soft downy pubescence. *Corolla* funnel-shaped, purplish. *Stamens* inserted into its tube; when perfect generally longer than the limb. *Herbage* generally more or less hairy.

Mentha is principally an European and British genus. There are however some American and even East Indian species. Those of our own country have always been found extremely difficult to determine. Neither the shape of the leaves, general pubescence, length of the stamens, nor even the inflorescence, all which have been resorted to by botanists, has been found constant or certain. The writer of this article first proposed a mode of distinction, founded on the pubescence of the calyx and flower-stalks, and its various direction. By this clue all the British species are settled in the Transactions of the Linn. Soc. and Fl. Brit. above quoted, and we shall here apply it to the exotic ones. For want of having received information of this mode of discrimination, Willdenow has greatly failed in his view of the species. The same may, in some measure, be said of Mr. Sole of Bath, who published, in 1798, a Botanical Arrangement of the British Mints, in folio, with 24 plates; a work nevertheless of much original observation, and more correct as to species than most that had preceded it; though no attention is paid by his draughtsman to the pubescence of the calyx, in which respect no dependence whatever can be placed on his figures.

1. *M. auricularia*. Ear Mint. Linn. Mant. 81. Mat. Med. ed. 4. 169. Dale Pharmac. 160. Stokes Mat. Med. v. 3. 310. (*M. fetida*; Burm. Ind. 126. *Majana fetida*; Rumph. Amboin. v. 6. 41. t. 16. f. 2.)—Spikes tapering, close, hairy. Leaves ovate, coarsely serrated; hairy and green on both sides. Bractees ovate.—Native of the East Indies. We have it from China, as well as from Java. The stem is densely clothed with long, shaggy, tawny, horizontal hairs. Leaves on very short hairy stalks, ovate or somewhat oblong, bluntish, coarsely and unequally serrated, from one to two inches in length, various in breadth; bright green above, and clothed with numerous, scattered, silky hairs; a very little paler beneath, finely dotted, not at all hoary, the

ribs and veins extremely hairy. Spikes solitary, terminal, an inch or two long, tapering, close and interrupted; each whorl accompanied by a pair of opposite, ovate, fringed bractees, each pair crossing the next. Flowers crowded, small, nearly sessile. Calyx bell-shaped, spreading, with five broad blunt teeth, which are fringed with numerous hairs, the rest of the calyx being smooth and even, besprinkled with shining glandular dots. Corolla twice as long as the calyx, somewhat hairy. Stamens a little prominent.—This herb is celebrated as a powerful remedy for deafness. We have already mentioned, see HYDROPS, that Linnæus confounded it, at one time, with our second species of that genus, than which few plants can be more distinct.

2. *M. quadrifolia*. Downy Four-leaved Mint. Rottl. MSS.—Leaves linear-lanceolate, serrated, downy on both sides; those of the stem four in a whorl. Spikes cylindrical, very long, close, hairy. Bractees linear-lanceolate.—Sent by Dr. Rottler from Madras. The whole plant is clothed with dense velvet-like down. Stem nearly round, with whorled branches. The leaves on the latter are opposite only; those of the stem four in each whorl; all narrow, bluntish, with shallow serratures. Spikes terminal, solitary, cylindrical, very close, the principal one about six inches long, those of the branches much smaller. Bractees lanceolate, or linear, minutely hispid. Flowers innumerable, crowded. Calyx bell-shaped, even, most hairy in its upper part, especially about the teeth. Corolla hairy. Stamens and style prominent.—We are much inclined to suspect this may be the *Stoechada-mentha*, Linn. Zeyl. 194, *Mentha zeylanica camphorata hirsuta*, Burm. Zeyl. 157; but the descriptions of the inflorescence, in these works, do not accord with our plant; the spikes or heads being there implied, if not positively said, to be short, whereas in our specimen they are remarkably long.

3. *M. verticillata*. Smooth Whorl-leaved Mint. Rottl. MSS.—Leaves linear-lanceolate, serrated, smooth, all whorled. Spikes solitary, cylindrical, somewhat interrupted. Calyx longer than the bractees, with blunt, spreading, very hairy teeth.—Sent by Dr. Rottler from Madras. The herbage is nearly smooth. Stem striated, almost round, tumid above and below each joint, with whorled branches and leaves. The latter are linear, tapering at each end, furnished with shallow distant serratures. Spikes terminal, solitary, cylindrical, from one to two inches long; their whorls tumid and slightly interrupted, with short concealed bractees. Calyx funnel-shaped, clothed in its upper half with copious short dense hairs; the teeth obtuse and widely spreading; the inside smooth. Corolla very small, whitish, hairy. Only one seed seems to come to perfection, and this is large, globose and smooth.

4. *M. stellata*. Stellated Cluster-spiked Mint. Lour. Cochin. 361. *Rau ngu hoang* of the Cochinchinese.—Leaves oblong, obtuse, serrated, smooth, four in a whorl. Spikes clustered, oblong.—Found by Loureiro in moist uncultivated ground in Cochinchina. Stem a foot high, with four furrows. Leaves stellated, four in a whorl. Flowers minute, pale violet. Calyx erect, with sharp teeth. Stamens surrounded about the middle with long hairs. Seeds four, roundish.—We know nothing of this species but from the author quoted. The clustered spikes mark it as distinct from the last.

5. *M. incana*. Hoary Slender-spiked Mint. Sole MSS. Donn. Cant. ed. 5. 142. (*M. chalepensis*; Mill. Dict. ed. 8. n. 10. *Menthatrum chalepense angulifolium*, raro florens; Boerh. Lugd.-Bat. ed. 2. v. 1. 185.)—Leaves ovate-oblong, serrated, nearly sessile, very soft and downy on both sides. Spikes solitary, very slender.—Native of Aleppo.

MENTHA.

Hardy in our gardens, but it rarely flowers, unless, as Miller says, it be confined in a pot. The *stem* is square, a yard high, purplish, minutely hairy, roughish to the touch, leafy, with numerous opposite branches. *Leaves* from one to two inches long, nearly or quite sessile, ovate-oblong, or somewhat elliptical, acute, finely and sharply serrated, entirely clothed with fine, short, dense, hoary pubescence. The *flowers* we have never seen. This species seems nearest akin to the *sylvestris*.

6. *M. sylvestris*. Horse Mint. Linn. Sp. Pl. 804. Engl. Bot. t. 686. Fl. Dan. t. 484. (*M. villosa*; Sole Menth. t. 1 and 2. *M. rotundifolia*; Sole Menth. t. 4. Menthastrum; Ger. em. 684 Riv. Monop. Irr. t. 51. f. 1. Camer. Epit. 479. Fuchs. Hist. 292. *M. hortensis fecunda*; ibid 298.)—*Leaves* acute, with tooth-like serratures, chiefly downy beneath. Spikes hairy, slightly interrupted. Bractees awl-shaped.—Native of waste ground, in rather moist situations, throughout Europe, flowering, like most of the genus, towards autumn. The *stem* is from two to four feet high, square, shaggy with hairs pointing downwards. *Leaves* sessile, of a grey and hoary aspect, whitish underneath, with a strong disagreeable scent for the most part, though some German and Swiss varieties are said to be agreeably fragrant. Their shape varies greatly, from oblong, or ovate, to a very broad, almost orbicular, figure, as may be seen by the different figures above cited. The *spikes*, solitary at the end of every branch, are thick, various in length, consisting of crowded, many-flowered, hairy whorls, with long, linear, acute, hairy bractees, the lowermost of which are broadest. *Flower-stalks* covered with closely deflexed hairs. *Calyx* all over hairy, with long sharp teeth. *Corolla* pale lilac, hairy, twice as long as the calyx. *Stamens* occasionally longer or shorter than the corolla, generally the latter.

We have from Switzerland, under the name of *M. suavis* of Hoffmann, a narrow sharp-leaved variety of this; and from Pyrmont, one with broad ovate leaves, as *M. gratissima* of Ehrhart, see Hoffm. Germ. for 1791. 203; both have very hoary spikes. We presume the latter is the identical *M. suaveolens*, Ehrh. Beitr. fasc. 7. 149, but the synonyms there given all belong to the real *rotundifolia*, than which nothing can less deserve the name of *suaveolens*. Willdenow quotes Ehrhart, with doubt, but rightly, under his own *nemorosa*, which is merely the ovate variety of *sylvestris*. The *gratissima* of Willdenow is a repetition of the same.

7. *M. niliaca*. Egyptian Mint. Jacq. Hort. Vind. v. 3. 46. t. 87.—*Leaves* ovate, acute, serrated, hairy on both sides; paler beneath. Spikes clustered. Stamens much longer than the corolla, smooth.—Native of Egypt. As Vahl and Willdenow adopt this species, and we have seen no specimen, we would not presume to refer it absolutely to the last, but we are much persuaded that it is a mere variety. Jacquin describes the *leaves* as villous, though green on both sides; Vahl says they are, in the wild plant, soft and hoary. The length of the *stamens*, though striking, is by no means to be relied on for a specific character.

8. *M. glabrata*. Smooth Spiked Mint. Willd. n. 6. Vahl. Symb. v. 3. 75. (*M. kalirina*; Forsk. Egypt-Arab; 213.)—"Leaves stalked, ovate-lanceolate, serrated, smooth. Flowers in whorled clusters."—Found by Forskall about Cairo in Egypt. The whole *plant* is said to be smooth. *Leaves* half an inch (we presume) in breadth, dotted beneath. *Cluster*, or *spike*, terminal of course. *Whorls* with rine umbellate flowers at each side. *Bractees* linear, the length of the whorls. *Stamens* shorter, and *style* longer, than the corolla.—Our account is taken from Willdenow, who copies Vahl. The latter examined Forskall's specimen.

9. *M. rotundifolia*. Round-leaved Mint. Linn. Sp. Pl. 805. Engl. Bot. t. 446. (*M. crispa*; Linn. Sp. Pl. ed. 1. 576. *M. sylvestris*; Sole Menth. t. 3. Menthastrum anglicum; Riv. Monop. Irr. t. 51. f. 2. *M. niveum* anglicum; Ger. em. 684.)—*Leaves* elliptical, obtuse, rugged, crenate, villous beneath. Spikes interrupted, somewhat hairy. Bractees lanceolate.—Native of Germany, Switzerland, and England, in waste marshy ground. With us it is rather rare. In a variegated state, as described by Gerarde, it often occurs in gardens, and is sometimes almost entirely white, like blanchéd endive. This, which Mr. Sole unaccountably mistook for the *sylvestris*, is totally distinct from every variety of that species. The invariably short, roundish, convex, and obtuse *leaves*, rugose, of a dark grass green, (not grey or hoary,) above; strongly reticulated with very hairy veins, but not hoary, beneath; and the very peculiar strong smell, and viscosity, of the whole plant, mark it with sufficient precision. The *spikes* are often clustered or panicked, more or less interrupted. *Bractees* ovate, sharp-pointed, prominent. *Flower-stalks* clothed with deflexed hairs. *Calyx* short, bell-shaped, hairy all over, with long, sharp, coloured teeth. *Corolla* much like that of *sylvestris*. *Stamens*, as far as we have observed, always longer than the petal.

Mr. Sole greatly commends this mint for its stimulating refreshing virtues, to which we can readily give credit, on account of its powerful scent, well compared by that writer to a mixture of volatile salt of amber, camphor, and mint. He found it of great use in *chlorosis*, and not without some effect in epilepsy. He mistakes however in thinking it the "true *Menthastrum*, or Wild Horse Mint, of the shops." That plant of Dale's *Pharmacologia*, 159, our best authority, is certainly the *sylvestris*; described above. The *Mentha sylvestris* of Dale, as well as of Sole, is our *rotundifolia* here described. This is the more important to be observed, as the plants are probably very different in qualities.

10. *M. viridis*. Spear Mint. Linn. Sp. Pl. 804. Engl. Bot. t. 2424. Woodv. Med. Bot. t. 170. Sole Menth. t. 5. (*M. romana*; Ger. em. 680.)—*Leaves* sessile, lanceolate, acute, naked. Spikes interrupted. Bractees bristle-shaped, more or less hairy, as well as the teeth of the calyx.—Native of moist meadows, in various parts of Europe. In gardens it is sufficiently well known, by the names of Spear Mint, and Mackerell Mint, and is the *Mentha*, simply so called, of the shops, the first species in Dale's *Pharmacologia*; being the only kind, except Peppermint next mentioned, retained in the most recent London *Pharmacopœia*.—There are however several remarkable varieties of this species, wild in England, whose flavours and qualities differ from the best or cultivated kind; though the latter is also a native of the southern parts of our island. The *stems* are two or three feet high, erect, smooth, with sharp angles, branched, often purplish. *Leaves* sessile, lanceolate, acute, sharply serrated, or in some cases toothed, smooth, except an occasional hairiness beneath. They are strongly veined, and in the varieties just alluded to, they are considerably rugose, as well as of a broader and shorter figure. In an exotic variety, whose history is given in Trans. of the Linn. Soc. v. 5. 187, 188, and from which the description of Miller's *rubra*, n. 9, of his 8th edition, was made, the *leaves* are broadly ovate, with long wavy teeth, almost like *M. crispa*, hereafter mentioned. The *spikes* are always more or less interrupted, tapering. *Bractees* awl-shaped, very slender at the point, keeled, roughish, sometimes three-cleft, the lower and larger ones mostly assuming an ovate form. *Flower-stalks* always smooth, round and shining. *Calyx* ribbed,

ribbed, tapering at the base, and equally smooth and naked in that part, but the teeth are fringed, more or less conspicuously, even in the garden variety, and very copiously in the more common wild ones, with hoary hairs. The *corolla* is smooth. *Stems* various in length.

This species may be known, in all cases, from the *sylovestris*, with which some of its varieties have often been confounded, by the invariably smoothness of its *flower-stalks* and base of the *calyx*. The varieties with shorter rugose *leaves*, and most hairy *calyx-teeth*, have the most strong and disagreeable flavours, and are not fit for the uses of the table. Another variety has been sent us by the Rev. Dr. Muhlenberg, from Pennsylvania, of a diminutive stature, with ovate *leaves*, not an inch long at the utmost, but in every essential character agreeing with the above.

11. *M. piperita*. Pepper Mint. Sm. Fl. Brit. n. 4. Engl. Bot. t. 687. Hudf. 251. Woody. Med. Bot. t. 169. Sole Menth. t. 7, 8, and 24. Ehrh. Pl. Off. 216. Willd. n. 13. (*M. spicis brevioribus et habitioribus, foliis Menthae fuscæ, sapore fervido piperis*; Raii Syn. 234. t. 10. f. 2.)—Leaves stalked, ovate, smoothish. Spikes obtuse, interrupted in their lower part. Calyx very smooth at the base.—Native of watery places in various parts of England, but it seems not to have been found wild any where else. In gardens it is every where cultivated, for the sake of its valuable medicinal properties, which are of a stimulating or stomaehic kind, and exist in great perfection in the essential oil and distilled water. It appears by the Linnæan herbarium, and we think also by the Mat. Med. of Bergius, 516, though his description unfortunately omits what would absolutely decide the question, that the Pepper Mint cultivated in Sweden is not our's, but a high-flavoured variety of *M. hirsuta*, which, even in the old Linnæan specimen, still retains the taste of real Pepper Mint. Its *calyx* is entirely clothed with ascending hairs, the *flower-stalks* with deflexed ones, the essential characters of *M. hirsuta*; whereas the *piperita* has the *calyx-teeth* only hairy, the lower part of the *calyx*, and that of the *stalks*, being always remarkably smooth and polished. Hence it appears why Linnæus reckoned his *piperita* among the capitate species. Our's is truly spiked, though the spikes vary in length, and are usually blunter than in the *sylovestris* and *rotundifolia*. Mr. Sole's plates well display the two extremes, but we can easily trace one variety into the other.

The *stem* of *M. piperita* is generally two or three feet high, purplish, with some scattered deflexed hairs, and numerous opposite branches. *Leaves* on stalks of a moderate length, ovate, acute, more or less elongated, and varying from one to three inches in length, sharply serrated; dark green and nearly smooth above; paler beneath, with many, parallel, whitish or purplish, hairy veins. The *spikes* are thick, with lanceolate, fringed, long-pointed *bractæas*; one or two of their lower whorls often very distant. *Flower-stalks* sometimes a little hairy in their upper part. *Calyx* as above described, its teeth sharp, mostly purple. *Corolla* purplish, smooth, longer than the *stamens*.—The flavour of the whole herb is pungent, highly aromatic, leaving a coolness in the mouth, like camphor, and finally a disagreeable bitterness. We have gathered, truly wild, in the romantic dale of Bonfall, near Matlock, the precise Pepper Mint of the gardens, in its highest perfection, with elongated spikes; which is of rare occurrence in a wild state.

12. *M. crispata*. Curled Mint. Linn. Sp. Pl. 805. Berg. Mat. Med. 513. Ehrh. Pl. Off. 206. Riv. Monop. Irr. t. 50. (*M. n. 230*; Hall. Hist. v. 1. 100. *M. crispata danica*; Morif. sect. 11. t. 6. f. 5.)—Leaves sessile, heart-shaped, wavy, strongly toothed. Spikes capitate, blunt.

Teeth of the calyx, and top of the flower-stalks slightly hairy. Native of Siberia, according to Linnæus. Haller considered it as merely the weed of gardens in Switzerland. With us it is only seen in a cultivated state, and that but rarely. The *stems* are three or four feet high, rather bluntly quadrangular, clothed with a few hairs curved downward, but little branched, leafy. *Leaves* numerous, nearly or quite sessile, heart-shaped, somewhat pointed, short and very broad, wavy and plaited, with very strong, twisted, crowded, acute, marginal teeth; nearly smooth above; slightly hairy beneath; the veins all radiating, as it were, from the lower part of the midrib. *Spikes* usually short, capitate, and very blunt; sometimes more elongated and tapering, as in the plate of Rivinus. *Bractæas* broad, recurved. *Flower-stalks* smooth, except a roughness, or slight hairiness, at the very summit. *Calyx* ribbed, tumid at the base, contracted a little higher up, smooth, except a few marginal hairs on the long and sharp teeth. *Corolla* smooth, purplish, rather longer than the *stamens*.—This is most akin in foliage to the exotic variety of *M. viridis* above-mentioned; nor do their *calyces* or *flower-stalks* much differ. We are by no means certain that it ought not likewise to be considered as a form of *viridis*. The original *crispata* of Sp. Pl. ed. 1, is no other than *rotundifolia*, which is also the *crispata* of Jacquin. As the specimen came from Siberia, it seems to have caused Linnæus to attribute that *habitat* to the species, which thus proves erroneous. Roth says the true *crispata*, which by his description he seems to understand, is found in watery places near Rübeland in Hercynia.—*M. dentata*, Willd. n. 15, seems by his own suggestion, as well as the description, to be a whorled variety of this.

13. *M. odorata*. Bergamot Mint. Sm. Fl. Brit. n. 5. Engl. Bot. t. 1025. Sole Menth. t. 9. (*M. citrata*; Ehrh. Beitr. fasc. 7. 150. Willd. n. 13. *M. rubra*; Mill. Dict. ed. 8. n. 9, with a false description, as mentioned under *M. viridis*.)—Leaves stalked, heart-shaped, naked on both sides. Spikes capitate, very blunt. Calyx and flower-stalks perfectly smooth.—Native of watery places in Cheshire and North Wales. Sole. Willdenow thinks it may possibly be wild in the Palatinate. In gardens it is often preserved, for the sake of its fine scent, resembling that of the Bergamot Orange, being more powerful than *Monarda didyma*. The whole *herb* often assumes a dark purplish hue, in which it agrees with *piperita*; but it differs from all the Mints known to us, at least all that otherwise approach it, in being perfectly destitute of hairiness throughout. The *leaves* are broad, short, and heart-shaped. *Inflorescence* more truly capitate than in any variety of the Pepper Mint, and agreeing with the capitate state of *M. hirsuta*, n. 14, from which the uniformly smooth *flower-stalks* and *calyx* always keep it very distinct.

14. *M. hirsuta*. Hairy Mint. Sm. Fl. Brit. 616. α, with short round terminal heads. *M. hirsuta*; Linn. Mant. 81. Sm. Tr. of L. Soc. v. 5. 193. Hudf. ed. 1. 223. Engl. Bot. t. 447. (*M. aquatica*; Hudf. 252, α and β. Sole Menth. t. 10, 11. *M. aquatica*, five *Sisymbrium*; Raii Syn. 233. Ger. em. 684. *M. palustris spicata*; Riv. Monop. Irr. t. 49. *M. Sisymbrium dicta hirsuta, glomerulis ac foliis minoribus ac rotundioribus*; Dill. in Raii Syn. 233. t. 10. f. 1. *M. piperita*; Linn. Sp. Pl. 805. Berg. Mat. Med. 516. *Origanum vulgare*; Fl. Dan. t. 638!) β, with a more elongated terminal head, or blunt spike. *M. hirsuta* δ and ε. Fl. Brit. 617. (*M. palustris*; Sole Menth. t. 6. *M. paludosa*; ibid. t. 22. *Menthastris aquatica* genus *hirsutum, spicâ latiore*; Bauh. Hist. v. 3. p. 2. 222. Raii Syn. 234. *M. minus*; Ger. em. 685.)

MENTHA.

γ , with whorled flowers. *M. hirsuta* ζ -9; Fl. Brit. 17. (*M. fativa*; Linn. Sp. Pl. 805, excluding the synonyms. Sm. Tr. of L. Soc. v. 5. 109. Engl. Bot. t. 448. *M. rivalis* β , γ , and δ ; Sole Menth. 45.)
