PARENT, ANTHONY, in *Biography*, was born at Paris in the year 1666. Great care was taken of his education, and at a very early period he discovered a strong propensity to the study of mathematics. At the age of fourteen, he accidentally met with a dodecahedron, upon every face of which was delineated a sun-dial, excepting the lowest, upon which it stood. Struck with the curiosity of these dials, he attempted to imitate them, and was led from the practice to investigate the theory, and in a short time he wrote a treatise upon "Gnomonics," which, though said to be extremely rude and unpolished, had the merit of being his own invention, as was a work on "Geometry," which he wrote about the same time. At the earnest desire of his relations, he entered upon the study of the law, as a profession for his life, but he no sooner completed his studies in that faculty, than he betook himself, with increased ardour, to those pursuits which accorded best with his genius and inclination. He attended very diligently the lectures of M. de la Hire and M. Sauveur, and as soon as he felt himself capable of teaching others, he took pupils; and fortification being a branch of study which the war had brought into particular notice, he was called upon frequently to teach the principles of that science. After some time, he began to entertain scruples about undertaking to teach a subject of which he had no practical knowledge, and communicated them to Sauveur, through whose interest he made two campaigns with the marquis d'Alegre, during which he had many opportunities to inform himself with respect to every species of knowledge on the subject. Upon his return to the metropolis, he spent his time in a continual application to the study of natural philosophy, and all the branches of the mathematics, both speculative and practical, to which he added that of anatomy, botany, and chemistry. His great talents, and indefatigable industry, enabled him to surmount the difficulties attendant on the acquisition of any science. In 1699, M. Fillau des Billetes having been admitted a member of the Academy of Sciences at Paris, with the title of their academician, nominated M. Parent for his *élève*, who particularly excelled in that branch of knowledge. It was soon discovered that he directed his attention to all the subjects that came before the academy, and that he was competent to the investigation of every topic which was recommended to their notice. His temper was however very bad, and he exposed himself to many disputes, which he carried on in a very acrimonious manner, and which was the cause, together with the want of perspicuity in his compositions, of the very limited circulation of his various pieces. In the year 1716, the king abolished the class of élèves, and on this occasion he made M. Parent an adjunct, or assistant member of the class of geometry. He lived, however, but a short time to enjoy the honour, being in the same year cut off by the small-pox, when he was about fifty years of age. Although he was of a very irritable disposition, he is said to have possessed great goodness of heart, and though his means were extremely limited, he devoted much of his income to acts of beneficence. He was author of a work entitled "Elements of Mechanics and Natural Philosophy." "Mathematical and

Physical Researches," a sort of journal, which first appeared in 1705, and which in 1712 was greatly enlarged, and published in three vols. 4to.; and "A Treatise on Arithmetic." Besides these, he was author of a great number of papers in the different French "Journals," and in the volumes of the "Memoirs of the Academy of Sciences," from the year 1700 to 1714, and he left behind him in manuscript many works of considerable research; among these were some complete treatises on divers branches of mathematics, and a work containing proofs of the divinity of Jesus Christ, in four parts. Moreri.

PARENT, in *Geography*, a town of Prussia, in Pomerelia: 10 miles N. of Marienburg.

PARENTALIA, in *Antiquity*, funeral obsequies: or the last duties paid by children to their deceased parents.

PARENTALIA is also used for a sacrifice or solemn service offered annually to the manes of the dead.

PARENTELA—*De parentela se tollere*, in *Ancient Customs*, signified a renunciation of one's kindred and family.

This was done in open court, before the judge, and in the presence of twelve men, who made oath, they believed it was done for a just cause.

We read of it in the laws of Henry I. After such abjuration, the person was incapable of inheriting any thing from any of his relations, &c.

PARENTHESIS, *παρενθεσις*, formed of *παρ*, *inter*, between, and *θεσις*, *position*, q. d. *putting between*, in *Grammar*, intercalary words inserted in a discourse, which interrupt the sense or thread, but which seem necessary for the fuller understanding of the subject. The politest of our modern writers avoid all parentheses, as keeping the mind in suspense, embarrassing it, and rendering the discourse less clear, uniform, and agreeable. Long and frequent parentheses are intolerable, especially in verse, which they ever render dull and languid, and like to prose.

The proper characteristic of a parenthesis is, that it may be either taken in, or left out, the sense and grammar remaining entire.

In speaking, parentheses are to be pronounced in a different tone; and in writing they are inclosed between brackets, (), to distinguish them from the rest of the discourse.

The character itself, whereby they are distinguished, is also called a parenthesis. See PARENBOLE.

PARENTIS-*de-Born*, in *Geography*, a town of France, in the department of the Landes, and chief place of a canton, in the district of Mont-de-Marsan; 33 miles N. of Tartas. The place contains 1440, and the canton 4213 inhabitants, on a territory of 632½ kilometres, in six communes.

PARENZA, a sea-port town of Istria, and see of a bishop. The town is well built on a rock, and has a harbour for large vessels; 35 miles S. of Trieste. N. lat. 45° 18'. E. long. 13° 40'.

PAREOLA, in *Ornithology*, a species of *Pipra*; which see.

PARER, in the *Manege*, a term formerly used as a command to stop, but now exploded; all the riding-masters, when they have a mind the scholar should stop the horse, calling out *hola*. See STOP.

PARERE, in *Commerce*, an Italian term, which signifies the advice or counsel of a merchant, or negotiant; because such a person, being consulted on any point, introduces his answer, in Italian, with *mi pare*, i. e. *I think, it seems to me*.

The method of negotiating, especially that of bills of exchange, being borrowed from the Italians, most trading cities, especially Lyons, retain the use of *pareres*; which

are the advices or opinions of merchants and negociants, and which serve as acts before notaries, when given by authority of a judge conservator, or at a particular consultation, for maintaining the right of the consulter.

M. Savary has an excellent treatise intitled, "Parere, on Avis et Conseils sur les plus importantes Matieres du Commerce;" containing the resolution of the most difficult questions relating to bankrupts and failures, bills of exchange, orders without date, or expression of value, bank-signings, renewing of bills of exchange, those drawn or accepted by women in behalf of their husbands, or during the minority of the drawer, &c.

PARERGA, *παρηγοια*, a term sometimes used in architecture, for additions, or appendages, made by way of ornament to a principal work.

It is sometimes also used in painting, for little pieces, or compartments, on the sides, or in the corners, of the principal pieces.

PARRES CURTIS, or *Pares Curie*, peers of the court, an appellation which, in all the feudal institutions, both here and on the continent, distinguished the vassals of the inferior lords, who were bound by their fealty to attend their domestic courts baron (which were instituted in every manor, or barony, for doing speedy and effectual justice to all the tenants), in order as well to answer such complaints as might be alleged against themselves, as to form a jury or homage for the trial of their fellow tenants.

PARE'SIS, from *παρηγυμι*, to relax, in *Surgery*, a palsy of the bladder, attended either with retention of the urine, or involuntary discharge of it.

PARE SSEUX, in *Zoology*, a name given by Gautier to the *BRADYPUS tridactylus*; which see.

PARETONIUM, in *Natural History*, the name of an earth anciently found on the shores of Egypt, Cyrene, and the island of Crete; and used by the ancients in painting.

It had its name either from a part of Egypt, near which it was gathered, or from the name of a town in that kingdom, where it was usually sold.

Vitruvius is of the first opinion, and Volaterrus of the other. Of late we have been taught to think it lost; but it is still common on most of the shores of the islands of the Archipelago, though not observed or regarded; and is truly a very heavy and tough clay, of a fine white colour, found in masses of different sizes, generally as soft as the softer clays within the strata; and, by rolling about on the beach in this state, it gathers up the sand, small shells, and other foulnesses we always find about it. It is most probable, that there are strata of it fine and pure in the cliffs there, and that the sea washes off masses of them in storms and high tides, which are what we find.

PARERAH, in *Geography*, a town of Hindoostan, in Oude; 8 miles N. of Bahraitch.

PARFAIT, FRANCIS, in *Biography*, was born at Paris in 1698, of a distinguished family, and died in 1753. His works are, 1. "A General History of the French Theatre," in 15 vols. 2. "A History of the ancient Italian Theatre," in two vols. 3. "A Dictionary of Theatres," in 7 vols. 4. Several dramatic pieces that were never acted.

PARGAS, in *Geography*, a small island in the gulf of Finland, near the coast of Sweden, with a town. N. lat. 60° 19'. E. long. 22° 7'.

PARGET, in *Natural History*, a name given to the several kinds of gypsum or plaster-stone, which, when slightly calcined, make what is called *plaster of Paris*, used in casting statues, in stuccoing floors and cieling, and on many other like occasions.

The word parget, though generally understood of all the

gypsums, is, however, by the workman principally applied to the two species which make up the first genus of that class, called by Dr. Hill the *pholides*. These are the Montmartre kind, and that of Derbyshire. See PHOLIS.

PARGETING, in *Building*, is used for the plaistering of walls; sometimes for the plaster itself.

Pargeting is of various kinds: as, 1. White lime and hair mortar laid on bare walls. 2. On bare laths, as in partitioning, and plain cieling. 3. Rendering the insides of walls, or doubling partition-walls. 4. Rough-casting on hearth-laths. 5. Plastering on brick-work, with finishing mortar, in imitation of stone-work; and the like upon hearth-laths.

PARGOIRE, St., in *Geography*, a town of France, in the department of the Herault; 14 miles S.S.E. of Lodeve.

PARGOW, a town of Hindoostan, in the circar of Gohud; 9 miles S.S.W. of Kooch.

PARHAM, a town of the island of Antigua, and legal port of entry; 5 miles W. of St. John's.

PARHELIUM, or PARHELION, formed from *παρηλα*, near, and *ἡλιος*, sun, in *Physiology*, a mock sun or meteor, being a part of the heavens strongly illuminated by the image of the sun, and appearing like another sun, but often coloured and drawn out to a considerable length, in the form of a tail.

The parhelia usually accompany the coronæ, or luminous circles, and are placed in the same circumference, and at the same height. Their colours resemble those of the rainbow; the red and yellow are on the side towards the sun, and the blue and violet on the other. Though there are coronæ sometimes seen entire, without any parhelia; and sometimes parhelia without coronæ.

The apparent size of parhelia is the same as that of the true sun; but they are not always round, nor always so bright as the sun; and when several appear, some are more bright than others. They are tinged externally with colours like the rainbow, and many of them have a long fiery tail opposite to the sun, but paler towards the extremity. Some parhelia have been observed with two, and others with three tails. These tails appear for the most part in a white horizontal circle, which generally passes through all the parhelia; and if it were entire, would go through the centre of the sun. Sometimes there are arcs of lesser circles, concentric to this, touching those coloured circles which surround the sun. They are also tinged with colours, and contain other parhelia. Parhelia are generally situated in the intersections of circles; but Cassini says, that those which he saw in 1683, were on the outside of the coloured circle, though the tails were in the circle that was parallel to the horizon. M. Æpinus apprehends, that parhelia with elliptical coronæ are more frequent in the northern regions, and those with circular ones in the southern. They have been visible for one, two, three, and four hours together; and in North America they are said to continue some days, and to be visible from sun-rise to sun-set. When the parhelia disappear, it sometimes rains, or there falls snow in the form of oblong spiculæ, as Maraldi, Weidler, Krafft, and others, have observed; and because the air in North America abounds with such frozen spiculæ, which are even visible to the eye, according to Ellis and Middleton, such particles have been thought to be the cause of all coronæ and parhelia.

Parhelia are sometimes double, triple, &c.

Aristotle observes, that two were seen in Bosphorus from morning to evening, though, in general, he observes, they are not seen, except when the sun is near the horizon.

Pliny

PARHELIUM.

Pliny relates under what confuls this phenomenon was ever seen at Rome.

In the year 1629, was seen at Rome, by Scheiner, a parhelion of four suns, and the same number was seen by M. Muschenbroeck at Utrecht; Gassendi says, that in 1635 and 1636, he often saw one mock sun; in 1661, Hevelius observed at Dantzic one of seven suns; and in 1666, another was seen at Arles, of six.

Phenomena of this kind have also been observed by M. de la Hire at Paris, in 1689, and by M. Cassini, in 1693; by Mr. Grey, in 1700; by Halley, in 1702; and Maraldi, in 1721.

The Roman phenomenon observed by Scheiner, is represented *Plate XVII. Optics, fig. 8*, in which A is the place of the observer, B his zenith, C the true sun, A B a plane passing through the observer's eye, the true sun, and the zenith. About the sun C, there appeared two concentric rings, not complete, but diversified with colours. The lesser of them, D E F, was fuller, and more perfect; and though it was open from D to F, yet those ends were perpetually endeavouring to unite, and sometimes they did so. The outer of these rings was much fainter, so as scarcely to be discernible. It had, however, a variety of colours, but was very inconstant. The third circle, K L M N, was very large, and all over white passing through, the middle of the sun, and every where parallel to the horizon. At first this circle was entire; but towards the end of the appearance it was weak and ragged, so as hardly to be perceived from M towards N.

In the intersection of this circle, and the outward iris G K I, there broke out two parhelia, or mock suns, N and K, not quite perfect; K being rather weak, but N shone brighter and stronger. The brightness of the middle of them was something like that of the sun, but towards the edges they were tinged with colours, like those of the rainbow, and they were uneven and ragged. The parhelion N was a little wavering, and sent out a spiked tail N P, of a colour somewhat fiery, the length of which was continually changing.

The parhelia at L and M, in the horizontal ring, were not so bright as the former, but were rounder, and white, like the circle in which they were placed. The parhelion N disappeared before K; and while M grew fainter, K grew brighter, and vanished the last of all.

It is to be observed, farther, that the orders of the colours in the circles D E F, G K N, was the same as in the common halos, namely, red next the sun; and the diameter of the inner circle was also about 45 degrees; which is the usual size of a halo.

Aristotle (*Meteor. cap. 3.*) was of opinion, that rainbows, halos, and mock suns, were all occasioned by the reflection of the sun beams in different circumstances, by which an imperfect image of his body was produced, the colour only being exhibited, and not his proper figure. The image, he says, is not single, as in a mirror; for each drop of rain is too small to reflect a visible image; but the conjunction of all the images is visible.

M. Mariotte accounts for the appearance of parhelia from an infinity of little particles of ice floating in the air, which multiply the image of the sun, either by refracting or breaking his rays, and thus making him appear where he is not; or by reflecting them, and serving as mirrors.

The known laws of reflection and refraction have given a handle for geometrizing on these phenomena; and M. Mariotte has determined the precise figure of the little icicles, and their situation in the air, the size of the coronæ, or cir-

cles, which accompany the parhelia, and the colours with which they are painted, by a geometrical calculus.

The hypothesis of Descartes, to account for that horizontal circle in which mock suns appear, has less probability than any of his conjectures. He supposes that a great quantity of frozen vapours, crowded together by contrary winds, form a prodigious cylinder, which reflects the light that falls from it on all sides, so as to exhibit that lucid appearance in all the surrounding clouds. M. Huygens, on applying his attention to these appearances, was soon sensible that they could not arise from such globules as formed the halos; yet since parhelia are always attended with halos, he was satisfied that their causes must be much alike. Considering, then, what other figures hail-stones might possibly have, besides a spherical one, he could find no other so simple as that of a cylinder; and, indeed, he had often observed, that snow did consist of several slender oblong particles, mixed with those of other shapes; and seeing that small globules were sufficient for the production of halos, he imagined that a great number of small cylinders, floating in the air, might produce similar appearances. He also remembered that Descartes had taken notice of certain small columns, or cylinders, which he had seen lying on the ground, the extremities of which were bounded with flat stars, consisting of six rays or points.

The large and white horizontal circle, in the Roman phenomenon, M. Huygens supposed to be produced by the reflection of the sun's rays from the outsidés of the upright cylinders; since, when the sun shines upon a great number of such cylinders, suspended in the air, a white circle must necessarily appear to pass through the sun, parallel to the horizon, and of the same breadth with that of the sun. This he shews very distinctly by a large figure of a cylinder, and by pointing out the progress of the sun's rays reflected from it. For every point of the sun's vertical diameter, as well as his centre, will illuminate a circle of cylinders, of the same apparent height as the illuminating point. It is observable that no thick clouds are seen in the air when these circles appear, but only such as are very thin, and scarcely visible. For in most of these observations the sky is said to have been very clear and serene, which very well agrees with this hypothesis; since these minute cylinders must constitute a very thin cloud, uniformly extended; through which the sun, and even the blue colour of the sky, may be seen.

M. Huygens supposes that the parhelia at K and N, (*fig. 8.*) are produced by the same upright cylinders which produce the great white circle; but not in the same manner as that was caused, *viz.* by simple reflection, but by means of two refractions, exactly in the same manner as halos are produced; the centre of the cylinder being snow, and the outer part ice. The interval between these parhelia, he says, will be greater, as the cylinder of snow is thicker in proportion to the whole cylinder; and because the sun appears brightest through those cylinders which are on the outsidés of the arch K N; and as this brightness decays gradually to a certain distance, it exhibits the appearance of a parhelion, with a tail always tending towards the white circle, and making it brighter as far as it extends. The tail N P, of the parhelion at N, is drawn out of this circle; but this was a mistake, as Hevelius observes; and though it is not said that the parhelion at K had any tail, yet it is plain that a certain part of the white circle was its tail, though but a dull one; because this parhelion is said to have been fainter than the other; and it appears, by the observations of Hevelius, and his own, that these parhelia, or mock suns, as well as paraselenæ, or mock moons, always have

PARHELIUM.

have tails. Lastly, the extraordinary brightness of these parhelia, which was said to rival that of the sun, he supposed, might easily be accounted for, by considering that every cylinder shines through its whole length; whereas, the round grains in the halo, or the rainbow, emit but little light; so that the cylinder may probably afford more light than ten of those round grains; and if there be great plenty of cylinders in the air, it is no wonder that those images of the sun should appear so bright.

He then proceeds to demonstrate his hypothesis, by an accurate consideration of the refraction of the rays of light through the sides of such cylinders as have been described; and he investigates the distance at which the parhelia must appear from the sun; shewing that it is so much the greater, as the internal cylinder of snow is thicker in proportion to the whole cylinder; and that this distance must become greater as the sun rises higher; and he subjoins a table of these distances, in proportion to any given altitude of the sun; from which it appears, that if a sufficient number of cylinders be placed one above another, (some of which are melted more and some less,) besides the collateral parhelia next the sun, two or more may appear farther from him, but still in the same white circle, which was also confirmed by the observations of Hevelius in 1661, and of Scheiner in 1630. It appears also, from the same tables, that while the cylinders remain in the same situation, as the sun rises higher the intervals between him and the two parhelia will increase, which was the very thing which he himself had observed. But a greater alteration of these intervals may happen, if the cylinders be more melted; and from hence might arise that very remarkable phenomenon, which is said to have appeared in the time of Augustus, when three suns were seen at the same time, all of which were soon contracted into one; which, he observes, would be effected by the warmth of the air melting the snow in the cylinders; by which means both the parhelia would draw nearer to the sun, till they coincided with it; at which time all the cylinders would be melted, and changed into round drops.

In the next place, our author proceeds to explain the cause of that corona in the Roman phenomenon, of which the sun is the centre. And here his former hypothesis concerning halos, he acknowledges, will not answer the purpose. For though, when small cylinders are produced in the air, it is probable that half-thawed globules are lodged there at the same time, for the production of coronas; yet it is difficult to conceive how they can be thawed in so exact a proportion, as to produce a corona that shall pass precisely through those very parhelia.

Neither, as he observes, can this appearance be produced by cylinders obliquely situated, but only by the round ends of upright cylinders. And to suppose the above-mentioned cylinders to be always terminated by plain bases, he says, is by no means agreeable to nature; for, since their tops and bottoms will be thawed, as well as their sides, and to the same degree quite round, the water at their extremities will necessarily assume a round figure; so that not only those upright cylinders which lie on each side of the sun, and produce the collateral parhelia, will transmit his rays to the eye; but also those that lie quite round beyond him, to a certain distance, which will, therefore, produce a corona.

To verify this hypothesis by experiment, he ordered a glass cylinder to be made with round ends; and, inclosing it in an opaque body of the same shape, he found that it did, in reality, refract the light in such a manner as would produce this appearance. Considering, therefore, the necessity there is for the cylinders being of this particular shape, in order that the rays, passing through their extremities, may

produce coloured circles, he did not doubt, but that these circles are those very coronas. Otherwise some irregular and ill-shaped circles would be seen.

Hevelius had remarked, that the circle which passes through the parhelia, frequently appears fainter above and below, and brightest next the parhelia. The reason of this M. Huygens thought to be very plain from his glass cylinder, since the rays which passed through the round tops and bottoms of them produced only a small round image of the sun, as round grains do; whereas those which passed towards the ends of the cylindrical surfaces, where they just began to turn round, were formed into a broader and brighter pencil, like those which produce the parhelia; and this must make the corona grow gradually brighter and brighter towards the parhelia, both above and below, and to be more intensely coloured.

Having explained the cause of this corona, he proceeds to account for the two parhelia L and M, which appeared in the back part of the great white circle. And these, he thought, were produced, not by the reflection, but by the refraction of the sun's rays in the upright cylinders. The inner opaque cylinders, he observes, are so far from contributing to the production of these parhelia, that they sometimes hinder their appearance. But yet this inner cylinder of snow is absolutely necessary, whether the outward shell that contains it be made of water or of ice; for, without the snow, the watery cylinders would be immediately changed into round drops, and the whole cylinders could not be ice, because then they could not be every where transparent, without supposing them to have been quite liquid before they were frozen, which is inconsistent with a cylindrical figure.

He then shews, that these back parhelia must be in the large white circle; and determines, geometrically, that the distance between them must be sixty degrees. Indeed, in Scheiner's scheme, the distance of these parhelia exceeds ninety degrees; but it was neither measured, nor estimated; nor, indeed, so much as mentioned, and therefore M. Huygens does not doubt but that it is drawn much too large. In the Roman phenomenon these parhelia are said to have been white, whereas, according to this hypothesis, they ought to have been coloured. M. Huygens supposes that the whiteness arose from the weakness of their light; on which account halos sometimes appear white, and sometimes also the lateral parhelia, as appears by the accurate observations of Keckelius. But that these back parhelia do sometimes appear coloured, is evident from the account we have of one in Mat. Paris's history; in which we are told, that, besides the true sun, four mock suns appeared red, in a great circle, of the colour of crystal. That two of these were back parhelia, is evident from the figure, though it may be faulty in other respects.

The scarcity of cylinders, M. Huygens supposes, may be the reason that, in many observations, these parhelia have not appeared, though the white circle was plain enough to be seen. But there is another circumstance which may hinder their appearance, *viz.* the inner cylinders of the back part of the white circle being too thick in proportion to the water that surrounds them. For then the rays, which should produce the parhelia, will be stopped; and he found, by calculation, that when the sun is twenty-five degrees high, if the diameter of the opaque cylinder bear a greater proportion to that of the whole, than 590 to 1000, no back parhelia can appear.

That the back parhelia in the Roman phenomenon appeared rounder than the lateral ones, M. Huygens supposes to arise from this circumstance, that though some cylinders

cylinders in the arc LM, which lie not far from L and M, do send some refracted rays to the eye, yet they are not so numerous as those which come from the cylinders at L and M; and, therefore, that these parhelia can have no tails that are far extended, like the lateral ones. Besides, the refractions through the cylinders that produced the back parhelia are more regular; for the rays are not confined in their course by the opaque cylinders within, but receive their directions from the refractions at the most exact figure and polish of the outward watery surface of the cylinders. For the dark cylinders within, not being exactly equal to one another, are the cause of the irregular and inconstant shape of the lateral parhelia. The reason of the fluctuating motion of the tail of the parhelion N, he supposes to be, that sometimes fewer, and sometimes more cylinders were carried into that place; which also accounts for the corona DEF being sometimes entire, and sometimes open below, and that the parhelion K grew brighter while N grew duller. The phenomenon observed in 1661 by Hevelius, exhibited in *fig. 9*, seems to comprise all the real varieties of this most magnificent spectacle, parts of which have often been seen separately. The greatest difference between this appearance and that at Rome, consists in the arcs QGR and THS, which are convex towards the sun, and which Huygens accounts for by cylinders lying in a horizontal situation. The parhelia in these inverted arcs, he says, are nothing more than the brightest parts of them; and therefore they never appear quite distinct, nor much brighter than the adjoining parts of the arcs. Accordingly, Hevelius, in all his observations of this kind, took notice, that they appeared rather dull, heavy, and faint; and he was not sure whether there was a parhelion at H, or not. The reason why the middle part of the arc should appear a little distinct from the rest, he supposed to be this, that though there be great plenty of horizontal cylinders in the air, yet they may be so short, as to have but little of a cylindrical surface, or perhaps may be like oblong spheroids. Besides, it is perfectly agreeable to the observations of Hevelius, that the higher the sun or moon, and consequently the more the coronas are elevated above the horizon, the flatter these inverted arcs appear. It is confessed by M. Huygens, that the upper parts of these arcs are represented by Hevelius as being much less than his calculations require them to be; but he imagines that the sight of the observer was imposed upon, by the arcs being so much elevated above the horizon; in consequence of which they would appear to be parts of much lesser circles than they really are.

M. Muschenbroeck says, that nothing has been advanced concerning the cause of parhelia, more probable than the hypothesis of M. Huygens, except that frozen cylinders or spiculæ are always found transparent, and are never opaque at the centre. The coloured arcs that accompany parhelia, he thinks, to be not at all different from the common coronæ, so that if there be a quantity of icy spiculæ in a thin fog, the whole of this appearance will be produced, the coronæ being formed in the fog, and the parhelia in the spiculæ. See Huygen's Dissertation on this subject in Smith's Optics, book i. chap. 11. See also Priestley's Hist. of Light, &c. p. 613, &c. and Muschenbroeck's Introduction, &c. vol. ii. p. 1038, &c. quarto.

PARHOMOLOGÿ, *παρρομολογία*, in *Rhetoric*, a figure wherein a part is yielded to the opponent, and the rest denied: thus, "Sume hoc ab iudicibus nostrâ voluntate: nomen illi propiorem cognatum quam te fuisse, concedimus: officia tua nonnulla in illum exitisse, stipendia vos unâ secisse

aliquamdiu nemo negat; fed quid contra testamentum dicis, in quo scriptus hic est." See CONCESSION.

PARIA, or NEW ANDALUSIA, in *Geography*, a province of South America, in the government of Caraccas, formerly a part of Spanish Guiana, situated E. of Cumara, on the N. coast of the continent of South America. Between it and the island of Trinidad is a large bay, called the "Gulf of Paria;" 80 miles long, and from 30 to 40 broad.

PARIA, a town of South America, and capital of a district in the viceroyalty of Buenos Ayres, commencing 210 miles N.W. of that city, and about 120 miles in extent. The air is so cold, that the country produces little grain, but this deficiency is compensated by its abundance of all kinds of cattle: the cheefe that is made here, from the milk both of sheep and cows, is in high estimation, and sent into every part of Peru. Here are also some silver mines; 18 miles S. of Oruro. S. lat. 18° 50'. W. long. 68° 20'.

PARIAN CHRONICLE. This venerable relic of Grecian literature is occasionally called, Marmor Chronicon, Marmor Chronologicum, Parium Chronicon, Marmor Epocharum, Stela Epocharum, or the Arundel Marble. (See ARUNDELIAN MARBLES.) It was, in its perfect state, a square tablet of coarse marble, five inches thick; and when Selden first inspected it, measured three feet seven inches, by two feet seven. The upper part was then imperfect, the lower corner on the right hand having been broken off, which reduced that side of the marble to two feet eleven inches. On this stone were engraved some of the principal events in the history of ancient Greece, forming a compendium of chronology during a series of 1318 years, which commenced with the reign of Cecrops, the first king of Athens, B. C. 1582, and ended with the archonship of Diognetus.

It originally contained about one hundred lines, each consisting, on an average, of sixteen words, or one hundred and thirty letters; so that the whole might have been comprised in six octavo pages. This venerable monument of antiquity was purchased, with many others, by Mr. W. Petty, who was employed by the earl of Arundel, in the year 1624, for the purpose of collecting marbles, books, statues, and other curiosities, in Italy, Greece, and Asia Minor. It appears to have been dug up in the island of Paros, and was purchased at Smyrna. When brought to England in 1627, it was placed in the gardens belonging to Arundel-House, the site of which is now occupied by Arundel, Norfolk, Surry, and Howard-streets in the Strand. The next morning, it was examined, with eager curiosity, by some of the most distinguished literati of that time. These were sir R. Cotton, Selden, Patrick Young, and Richard James. After much labour it was decyphered, and a copy of it published by the learned Selden in the year 1628, accompanied with a Latin translation and commentary.

During the civil wars, and the subsequent usurpation of Cromwell, this rare monument of ancient literature was unfortunately broken into smaller fragments, and almost entirely defaced. The upper part, containing nearly half the original tablet, is said to have been used in repairing a chimney-piece, or hearth, in Arundel-House; but luckily the inscription, or at least as much of it as could be made out, was preserved in the copy, which Selden had previously taken and published. In the year 1667 the remaining fragments were presented by the Hon. Henry Howard, grandson of the first collector, to the university of Oxford, and deposited in the public schools, where they still remain.

The genuineness of this valuable relic of antiquity was universally acknowledged throughout all Europe, as soon

PARIAN CHRONICLE.

as its contents were made known: its authority has been considered as equal, if not superior, to any other, and writers of the first eminence have derived the greatest advantage from it in their historical and chronological researches. It was not till the year 1788, that its authenticity was impeached by a man of considerable learning and industry, in an elaborate volume, called "A Dissertation on the Authenticity of the Parian Chronicle." The author was the Rev. John Robertson, who founded his doubts and objections on the following considerations:

1. The characters have no certain, or unequivocal marks of antiquity.
2. It is not probable that the Chronicle was engraved for private use.
3. It does not appear to have been engraved by public authority.
4. The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece.
5. This chronicle is not once mentioned by any writer of antiquity.
6. Some of the facts seem to have been taken from authors of a later date.
7. Parachronisms appear in some of the epochs, which we can scarcely suppose a Greek chronologer, in the 129th Olympiad, would be liable to commit.
8. The history of the discovery of the marbles is obscure and unsatisfactory; and
9. The literary world has been frequently imposed upon by spurious books and inscriptions; and therefore we should be extremely cautious with regard to what we receive under the venerable name of antiquity.

These observations are made the subject of separate chapters and disquisitions, and are illustrated with an appearance of much candour and extensive erudition; and, for a short time, the credit of the Parian Chronicle was shaken in the public opinion: but early in the following year, a vindication of it was undertaken by a writer of equal learning and certainly of superior judgment. This was the Rev. J. Hewlett, B. D. who is well known to the public as the author of three volumes of sermons, that have been much approved, and as the editor of a classical and elaborate edition of the bible, with a comment and notes, which will afford very important and useful instruction to every person who wishes to acquaint himself with the sacred writings.

Other writers followed Mr. Hewlett on the same side; but their arguments had for the most part been anticipated by him, or illustrated with additional learning and sagacity of criticism. It would exceed our limits to enter minutely into this controversy; but our readers may expect to have the summary arguments of the vindication laid before them in the correspondent order of the dissertator's doubts and objections.

With respect to the first, it is truly said, that mere characters can have no certain, or unequivocal marks of antiquity; but that those of the Parian Chronicle bear a general resemblance to such as appear on the coins of that age, and the most genuine monuments of antiquity, without being a slavish imitation of any; and that a singular mode of notation is adopted, which is explained only in an obscure tract of Herodian; but which occurs in no other author.

With respect to the second observation, it is remarked, that there is no improbability in supposing the Parian Chronicle to have been engraved by a private person. Monuments on different subjects have been engraved and erected by individuals; such are the Apotheosis of Homer; the Tabula Iliaca; and, particularly, the Marble Tables discovered at Palestrina, on which Verrius Flaccus had a corrected calendarium engraved.

As to the third remark, it is only necessary to observe, with Mr. Hewlett, it does not appear that the Parian Chronicle was *not* engraved by public authority, and that, in either case, its authenticity cannot be affected by the present supposition.

In answer to the fourth, it is shown that the Greek and Roman writers, for a long time after the date of this work, do not complain of their having *no* chronological account of the affairs of ancient Greece: they only complain, that there was not any *authentic* and *consistent* chronology of those ages; a complaint which still exists.

In reply to the fifth article, Mr. Hewlett observes, that though this Chronicle is not mentioned by any writer of antiquity, yet there are abundant reasons to prove, that the ancients could have no motive, or fair opportunity, for mentioning it. The remains of ancient literature, in which any notice of a small chronological tablet could be expected, are extremely few and imperfect; besides, it was not the practice of the ancient writers, as we learn from Pliny and others, to quote authorities, with any accuracy; and no writer who flourished before the Christian era, would appeal to so short a compendium of chronology as the Parian Chronicle was, cut on stone, and erected in the little island of Paros, when he could refer to the voluminous collections of Timæus Siculus, Eratosthenes, Apollodorus, Julius Africanus, and others. Much stress has been laid on the omission of Archilochus, who was a native of Paros, in a chronological monument, that was evidently calculated to mark and record the progress of literature and science: but professor Wagner has shown, that the name of the Parian satirist ought to have been inserted under the proper epocha, where the commentators have arbitrarily filled up the lacunæ on the marble with an event of no importance. Vide Epoch. P. 34.

With regard to the sixth assertion of the dissertator, it is confidently affirmed, after a minute and critical investigation of the subject, that there are no facts in the Parian Chronicle, which seem to have been taken from authors of a later date.

On the seventh, the result of Mr. Hewlett's disquisition is, that if there really are parachronisms in some of the epochs, the authorities opposed to the Parian Chronicle are extremely doubtful; and that the circumstance of its differing from the few remaining authors of antiquity, in some particulars, is rather an internal proof of its authenticity. After all, no one in vindicating the genuineness of this venerable relic of Grecian literature, ever dreamed of proving its infallibility, any more than that of any other chronologist.

In answer to the eighth objection, it is remarked, that the history of the discovery of the Parian Chronicle, upon the whole, is not unsatisfactory, or obscure; since the commentators, critics, and historians, who have had occasion to mention it, and who had a clear idea of what it was, agree as to the time and place of its discovery, and with regard to the person who procured it. And though we are not precisely informed of the sum which was paid for it, (because it formed a part of a collection,) nor are furnished with a full account of the particular circumstances under which it was purchased; yet this must necessarily have proceeded from the negligence and inadvertence, and not the ignorance, or doubts, of the first editor. It is sufficient, that no just ground of fraud, or suspicion, attaches to any of the parties in the whole of the transaction.

With respect to the ninth remark, it is said, that though the literary world has frequently been imposed on by spurious books and inscriptions, yet spurious books apply not to the

present question; and as to inscriptions, there is nothing to be found in the whole history of impostures, that bears the least resemblance in point of learning, labour, and expence, to the Parian Chronicle.

In addition to these remarks, let it be observed, says Mr. Hewlett, that very few men, since the revival of learning, have been capable of executing such a literary monument as the Parian Chronicle. Of these few, not many, it is hoped, would have had the baseness to attempt it; and others might have been justly withheld from doing it, by the labour of the undertaking, and the danger of detection; since it would require three months to cut the characters only; and, in executing such a project, it is scarcely possible, that many persons should not be privy to it, and that the author should not be guilty of some error, or meet with some untoward circumstance, that would have betrayed the imposition to such a man as Mr. Petty, who purchased it, and who is represented by Selden, Dr. Chandler, and others, as a person of the greatest judgment and discernment, and no less distinguished for his learning.

Farther, on the supposition of its being a forgery, it does not appear that the impostor received any adequate compensation for his trouble; and, as no ostensible author was held forth, the vanity of learning could not be gratified, for a moment, by the excellence of imitation, or any successful competition with works of departed genius; motives which appear to have been general with the impostors of antiquity, and no less prevalent among those of modern times. Besides, it is not at all probable, that the fabricator of such an inscription would have broken it to pieces and defaced it, in the manner that it was when Mr. Petty purchased it, unless, like the rest of his fraternity, he had contrived some prudent means of being the restorer of his own monument, and the interpreter of his own mysteries.

Such are the mere heads of the arguments advanced by the learned and successful vindicator of this valuable monument of ancient literature; arguments which are illustrated and enforced with varied and extensive erudition, and great diligence of research, combined with much critical acumen, that is displayed in detecting fallacies, exposing errors, and refuting objections. It is remarkable, that on the appearance of this masterly vindication, the controversy almost instantly ceased; and the respectable author of it has had the satisfaction of seeing the Parian Chronicle re-established on the same solid basis, on which it had always rested from the time of its first discovery.

Parian Marble. See MARBLE.

PARIANA, in *Botany*, a name of Aublet's, which, as Professor Martyn remarks, seems to have been suggested by the flowers growing in pairs upon the spike. *Aubl. Guian. v. 2. 876. Schreb. 650. Willd. Sp. Pl. v. 4. 492. Mart. Mill. Dict. v. 3. Juss. 34. Lamarck Dict. v. 5. 13. Illustr. t. 776.*—Class and order, *Monoclea Polyanthia*. *Nat. Ord. Gramina*.

Gen. Ch. Male, *Cal.* Glume of two short acute valves, containing a single floret. *Cor.* of two ovate acute valves, larger than the calyx; one of them narrower than the other. *Stam.* Filaments about forty, capillary, inserted into the base of the corolla; anthers linear.

Female, solitary in the same whorl, *Cal.* Glume of two ovate, concave, acute valves, containing a single floret. *Cor.* of two acute valves, hairy at the summit, smaller than the calyx. *Pist.* Germen superior, triangular; style long, hairy; stigmas two, villous. *Peric.* none, except the permanent corolla. *Seed* solitary, triangular, invested with the glumes.

Eff. Ch. Male, Calyx of two valves. Corolla of two

larger valves. Stamens forty, inserted into the base of the corolla.

Female, Calyx of two valves. Corolla of two smaller valves. Style hairy. Stigmas two. Seed one, triangular.

1. *P. campestris.* *Aubl. Guian. 877. t. 337.*—Gathered by Aublet in woods and by way-sides in Cayenne, flowering in January. The root is perennial. Stems several, reedy, a foot or two in height, simple, knotty, leafy. Leaves solitary at each joint, ovals, broad, pointed, entire, many-ribbed, smooth; paler beneath; sheaths long, striated, closely enveloping the stem, bearded at the summit with copious long reddish hairs, and contracted suddenly below the leaf, into a sort of slender, short footstalk, accompanied by a pair of membranous fringed stipules. Spike terminal, solitary, erect, about two inches long, dense, whorled, each whorl consisting of two pair of male flowers, with a solitary one, and a single female flower in the centre between them. The great number of stamens is very extraordinary in the natural order of grasses, to which this plant belongs.

PARIA-TUBA, in *Geography*, a town of Brazil, in the government of Para, on the river Amazons; 35 miles S.W. of Pauxis.

PARIDSONG, or *PHARI*, a strong town and mountain of Bootan, on the borders of Thibet; 40 miles N.W. of Tassifudon. N. lat. 28°. E. long. 89° 13'. The fortress of Phari is a strong stone building, situated on high ground; and on the N. and W. sides of it is an extensive suburb; on the S. is a large basin of water; and on the E. a bank of earth projected to a considerable distance, and falling with an easy slope from a level with the rampart into the plain. The valley of Phari is very extensive, being not less than ten miles long and four broad, surrounded on all sides with rocky hills. At the foot of the rocks, on the west border of the plain, is a large brook, flowing towards the south, called "Mahatchieu," which is said to have a passage, through the hills of Nipal, into Bengal. This is the station of Phari Lama, a dependant of Teshoo Loomboo, who is here a little potentate, being superintendent of a goombah, or monastery, and governor of a most extensive range of rocks and deserts, which yield verdure only in the mildest season of the year, when his neighbourhood is frequented by large herds of the long-haired, bushy-tailed cattle. From his character and station, he has great influence among the herdsmen. The musk-deer, which produce a valuable article of revenue, abound in the vicinity of these mountains. The musk-deer are deemed the property of the state, and hunted only by the permission of government; and of course a great part of the musk, which is a secretion formed in a little bag, or tumour, resembling a wen, situated at the navel, and found only in the males, passes through the hands of its agents. It is liable to much adulteration; but that which bears the regent's seal may be regarded as genuine. The musk-deer, in the language of Thibet, is called "La;" and the vascular covering of the musk, "Lacha." Turner's Tibet.

PARIESOVATZ, a town of Croatia; 15 miles S. of Bibacs.

PARIETALIA OSSA, in *Anatomy*, two bones of the cranium. See CRANIUM.

PARIETARIA, in *Botany*, so named from *paries*, a wall, in allusion to the place of growth of the most common species, which is uniformly on old ruins, or mouldering, flint walls. *Linn. Gen. 544. Schreb. 724. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 189. Ait. Hort. Kew. ed. 1. v. 3. 429. Tournef. t. 289. Juss. 404. Lamarck Dict. v. 5. 13. Illustr. t. 853. Gært. t. 119.*—Class and order, *Polygamia Monoclea*, *Linn. and Schreb. Tetrandria Monogynia*, *Smith. Nat. Ord. Scabridæ*, *Linn. Urtica*, *Juss.*

Gen.

PARIETARIA.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, four-cleft, flat, obtuse, half the size of the involucre. *Cor.* none. *Stam.* Filaments four, awl-shaped, longer than the flowering perianth, elastic, permanent; anthers twin. *Pist.* Germen superior, ovate; style thread-shaped, coloured; stigma pencil-shaped, capitate. *Peric.* none, except the elongated, enlarged, bell-shaped perianth, whose mouth is closed by the inflexed segments. *Seed* solitary, ovate, polished.

Obs. The class *Polygamia* having been much curtailed by Dr. Smith, we have followed him in removing this genus to *Tetrandria*. It may be remarked however that some of the flowers are female, and in these the calyx undergoes no change.

Ess. Ch. Calyx four-cleft, inferior. Corolla none. Stamens elastic. Seed solitary, inclosed by the elongated calyx.

1. *P. indica*. Indian Pellitory. Linn. Mant. 128. Syft. Veg. ed. 14. 908. (*Cratægonum majus*; Rumph. Amboin. v. 6. book 10. 25. t. 10?)—Leaves lanceolate. Stem erect.—Native of India. The appearance of this species is very similar to the following one, but the whole herb is more naked. *Leaves* with much longer points, three-nerved and naked. *Flowers* in smaller heads. *Bractæas* awl-shaped, not ovate. *Styles* longer. *Fruit* sessile, furrowed. Linnæus once took the plant of Rumphius above quoted for a *Spermacoce*, but the description of the seed seems to prove it a *Parietaria*, though the opposite, nearly sessile leaves make us rather suppose that this synonym belongs to *P. zeylanica*, which is now, as well as *P. microphylla*, referred to *Urtica*.

2. *P. officinalis*. Pellitory of the Wall. Linn. Sp. Pl. 1492. Engl. Bot. t. 879. Curt. Lond. fasc. 4. t. 63. Fl. Dan. t. 521. (Ἐλξίον; Diof.)—Leaves lanceolate-ovate, without lateral ribs at the base. Segments of the involucre ovate. Stem ascending.—Native of Britain, on mouldering walls, chiefly in sheltered places, being rather impatient of cold; common in the south of Europe. It flowers abundantly through the summer and autumn. *Root* perennial. *Stem* branched, spreading, reddish, shining, leafy, juicy. *Leaves* alternate, elliptic-lanceolate, oblique, pointed, pale beneath, the lateral nerves all springing from the main rib considerably above the base of the leaf, in which it especially differs from *judaica* and *indica*. Each *involucre* is cut into seven ovate segments, and contains three fertile flowers; the central one female. The elastic *stamens*, which spring from the *calyx* forcibly when touched, scatter the pollen by that means all around.

The mucilaginous qualities of this plant have led some writers on the *Materia Medica*, to regard it as an emollient, but in this respect it is inferior to the Mallow tribe. Curtis remarks, on the authority of Aurelius Victor, that Constantine bestowed on the emperor Trajan the name of *Parietarius*, because his statues and his inscriptions, like that herb, were found on all the walls of Rome. Bradley recommends the Pellitory to be laid on the corn in granaries, for the purpose of driving away that destructive insect the weevil.

3. *P. judaica*. Basil-leaved Pellitory. Linn. Sp. Pl. 1492. Villars. Dauph. v. 2. 346. (*P. minor*, *ocymi folio*; Tourn. Inst. 509. Bocc. Sic. 47. t. 24. f. A.)—Leaves ovate. Stems ascending.—Native of Italy, France, Switzerland, Greece, and Palestine. Very similar in habit to the last, but different in having shorter *stalks*, and smaller, oval *leaves*. *Flowers* in rather smaller clusters.

4. *P. lusitanica*. Chickweed-leaved Pellitory. Linn. Sp. Pl. 1492. (*P. lusitanica annua minima*; Tourn. Inst. 509. *P. ficula alfinæ folio*; Bocc. Sic. 47. t. 24. f. B.)—Leaves ovate, obtuse. Stems thread-shaped, striated, even,

procumbent.—Native of Spain and Portugal. Introduced at Kew in 1771, by M. Richard, where it flowers in July. *Root* annual, according to Tournefort, though Boecone says it differs only from the last, and *officinalis*, in the *leaves*, which are very much smaller, and of the form and size of Chickweed.

5. *P. urticifolia*. Nettle-leaved Pellitory. Linn. Suppl. 434. Syft. Veg. ed. 14. 908.—Leaves opposite, stalked, ovate, ferrated, veiny, downy. Flowers axillary.—Found by Commerçon in the Island of Bourbon, hanging from the rocks, in repeatedly branched leafy tufts. *Leaves* hardly an inch long, alternate, stalked, ovate, rough, strongly ferrated, with an elongated blunt point. *Flowers* small, in minute axillary panicles.

6. *P. cretica*. Cretan Pellitory. Linn. Sp. Pl. 1492. Sm. Prodr. Fl. Græc. v. 1. 106. Fl. Græc. t. 154. (*P. cretica minor*, *capsulis feminum alatis*; Tourn. Cor. 38.)—Leaves nearly ovate. Involucre when in fruit lateral, two-lipped, tubular at the base; outer lip very large.—Found originally by Tournefort, and afterwards by Dr. Sibthorp, on the rocks of Crete and Cimoli. Time of flowering not recorded. *Root* perennial? fibrous, simple at the upper part, round. *Stems* numerous, very diffuse, a span long, branched, round, hairy, reddish, leafy. *Branches* short, alternate. *Leaves* alternate, stalked, ovate or roundish, obtuse, entire, veiny, hairy, dark-green; dotted with minute tubercles on the upper side. *Stalks* half as long as the leaves, hairy. *Flowers* axillary, sessile, three together, the middle one female.

7. *P. capensis*. Cape Pellitory. Thunb. Prodr. 31.—Leaves opposite, ovate, ferrated. Branches diffuse.—Native of the Cape, and adopted entirely on the authority of Thunberg's Prodomus. We are not acquainted with either a figure or description of this species.

8. *P. debilis*. Slender Pellitory. Forst. Prodr. n. 387.—Leaves alternate, stalked, ovate, quite entire, rather hairy. *Stalks* axillary, three-flowered. Stem nearly upright.—Native of New Zealand. Forster.

9. *P. cochinchinensis*. Cochinchina Pellitory. Loureir. Cochinch. 654.—Leaves ovate, three-nerved, hairy. Stem tufted, diffuse.—Native of China and Cochinchina, in neglected gardens. *Root* perennial. *Stem* herbaceous, a foot and half high, slender. *Leaves* opposite, entire, small, hairy. *Flowers* axillary, whorled, in little heads. Loureiro says that the natives use this plant to put at the mouths of vessels containing salt provisions, for that it attracts such vermin as would otherwise destroy the salted meat, or fish. It is also esteemed an emollient, refrigerant, and diuretic herb.

10. *P. arborea*. Tree Pellitory. L'Herit. in Journ. de Rozier. v. 33. 55. Ait. Hort. Kew. ed. 1. v. 3. 429. (*Urtica arborea*; Linn. Suppl. 417. L'Herit. Stirp. Nov. 39. t. 20.)—Leaves elliptical, pointed, slightly three-nerved. Stem arboreous.—Native of the Canary Islands, whence it was sent to Kew by M. F. Masson in 1779. It flowers from February to May. *Root* woody, branched, fibrous, reddish. *Stem* shrubby, five or six feet high, upright, round, branched, ash-coloured. *Branches* villous; red when young with hoary hairs. *Leaves* alternate, spreading, entire, veiny, bright green, soft and downy; rather paler beneath; the younger ones much wrinkled. *Flowers* in terminal panicles, composed of simple, axillary, erect, villous spikes. L'Heritier originally made this species an *Urtica*, but, upon further examination, referred it to the present genus.

PARIETARIA, in *Gardening*, contains a plant of the
P p 2 shrubby

shrubby kind for the greenhouse, of which the species cultivated is tree pellitory (*P. arborea*.)

Method of Culture.—This plant may be increased by planting cuttings of the young shoots in the summer season, watering them occasionally till they have stricken root. When the plants are well rooted, they may be removed with balls about their roots into separate pots, and have the constant protection of the greenhouse, in which they afford variety.

PARIETES is often used, in anatomical descriptions, to denote the sides or walls of a cavity; thus we speak of the parietes of the chest or abdomen, &c.

PARIGNE' L'EVEQUE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans; nine miles S.E. of Le Mans. The place contains 2636, and the canton 14,712 inhabitants, on a territory of 310 kilometres, in 12 communes.

PARILIUM, in *Botany*, Gærtn. v. 1. 234. t. 51. f. 1, appears to have received that appellation because the capsule consists of two equal parts, clapped close together, in an advanced state easily separable from each other. So the garments of the Romans made of a double stuff, were called *pariia*, from *par*, a pair. The genus thus denominated nevertheless retains the name of *Nyctanthes*, and its history is curious. The only species known is the *Arbor tristis*, which Linnæus forced into his original *Nyctanthes*, notwithstanding its capsular fruit; that genus, as at first constituted, having a berry, and differing from *Jasminum* only in having eight instead of five segments to its corolla. (See *JASMINUM* and *NYCTANTHES*.) He afterwards so entirely forgot the plant, having no specimen in his herbarium, that when he subsequently received one, he described it afresh in his Mantissa, by the name of *Scabrita triflora*, which was somehow changed in the Syst. Veg. to *S. scabra*. He was the more readily led into this error, by finding four stamens in the flowers; so that he placed *Scabrita* in his class *Tetrandria*. This character seems to be variable, for the plant is described with two stamens in the Hortus Malabaricus, which nobody has contradicted. But it has been found proper to remove all the berry-bearing species of *Nyctanthes* to *Jasminum*, there being no certainty in the number of segments in the corolla, which in the common *J. officinale* vary from four to six, and in others are five, six, seven, or eight. When the Linnæan herbarium arrived in England, *Scabrita*, which had always been a mystery, proved, on inspection, the identical *Arbor tristis*, for which the generic name of *Nyctanthes* is peculiarly appropriate. Even Jussieu, to whom Vahl had, rather surreptitiously as on many other occasions, communicated this intelligence, thought proper to let that name so remain, establishing a new genus, under the title of *Mogorium*, for the Jasmines with eight segments to the corolla; which however has not been adopted. (See *MOGORIUM*.) Vahl in his Enum. Plant. v. 1. 25, has acceded to the decision of Banks and Solander on this point.

PARILLA, in *Geography*, a town of South America, in the province of Panama; 70 miles N.W. of Panama.—Also, a town of Peru; 50 miles S. of Truxillo.

PARILOVA, a town of Russia, in the government of Irkutsk, on the Angara; 68 miles N. of Balaganfok.

PARIMA, called also *Paranapitima*, or the *White sea*, a lake of South America, in Spanish Guiana, is represented by La Cruz, as more than 100 British miles in length, by 50 in breadth. Its extent, and even its existence, have been doubted, as it was the noted feat of the city *El Dorado*, (which see,) the streets of which were paved with gold; a fable, which seems to have arisen from a rock of talc reflecting, like a mirror, the golden rays of the sun. N. lat.

3° 40'. W. long. 45° 20'.—Also, a large river, likewise called the Rio Blenco, which has its source in the above-mentioned lake, and which joins the river Negro, and great river Maranon.

PARIMA, *Mountains of*. See **ANDES**.

PARINA CAUCHA, or *Cocha*, or *Cocas*, a town of Peru, and capital of a jurisdiction in the bishopric of Guamanga, fertile in cattle, corn, and fruit, but receiving its principal riches from its silver and gold mines.

PARINARIUM, in *Botany*, Juss. 342, a name formed by that author from the *Parinari* of Aublet, v. 1. 514. See **PETROCARYA**; also **MAMPATA** and **NEOU**.

PARING and BURNING, in *Agriculture*, the process of paring off the surface of lands in the state of grass, in order to convert them into tillage, by means of fire. It is a practice for the most part employed on rough coarse grounds that are over-run with strong plants of the grass, moss, or heath kinds, and on some mossy or peaty lands.

The author of a late practical work states, that “the practice of bringing land into a suitable condition for the growth of grain or other crops by means of fire, by paring and burning the surface or sward, is probably a method of cultivation that was adopted at a very early period. It is a process by which various changes are produced in the materials of the soils on which it is employed; some of which would seem to lessen rather than improve their fertility, while others have obviously the power of promoting and augmenting it in a very considerable degree.” And that “the action of the fire during the time of the combustion, especially when carried to a great height, by forcing off and dispelling much of the moisture and elastic principles that they contain, as well as by reducing the proportions of vegetable and animal matters, which may be mixed and incorporated with them, must have the effect of producing some degree of deterioration; while, by its conversion of the fresh vegetable products, as the different kinds of coarse plants and grasses, into ashes of an alkaline, saline nature, which process has the property of quickly rendering the portions of vegetable materials which may remain, proper for supplying the nutrition of plants; and by combining oxygen with the argillaceous, earthy, or other particles contained in them, in such a manner as to be easily parted with during the incipient stages of vegetation, great advantage and improvement must unquestionably in many cases be produced. It would seem to be chiefly on the former principle, that the crops are generally found to be so abundant after land has undergone this process; as the saline substance contained in the ashes, though frequently small in quantity, by bringing such parts of the soils as were not before in a fit state for the purpose of being applied to the support of vegetables, suddenly into that situation in which they may be taken up by the absorbent roots of the plants, a vast immediate fertility may be given, but which must soon have the effect of exhausting the ground, if grass or some other kind of green crops be not cultivated in due rotation upon it. That some effect of this sort takes place in such cases, is shewn by the general experience of the most correct practical agricultors.” But besides this, there is also another way “in which the saline or other matters thus formed may be conducive to the purposes of vegetation, which is, by the great stimulus which it is known to afford to the roots of growing plants, by which they may be induced to take up a larger proportion of nutrient matters from the soils on which they grow. And on lands prepared in this manner, especially where they are of the clayey kinds, it is probable, that in some instances so much oxygen may be combined, by means of the fire, with the particles of clay, as, in particular situations and circumstances,

circumstances, to render it capable of forming nitrous acid ; as is the case with imperfectly-baked bricks, according to Dr. Darwin, which, where lime is made use of at the same time with the ashes, may constitute a sort of calcareous nitre ; a substance which experiment has shewn to be highly favourable to the process of vegetation."

Further, that "in the method of cultivating lands, by means of paring and burning the surface, such losses or deteriorations of soil as may be sustained, must evidently be produced by the quantity of vegetable or animal materials, which may have been consumed or dispersed in the state of carbonic acid or other aerial forms ; as it is sufficiently known, that not a particle of the real earthy matter of the land can be destroyed or carried away by the process ; it being left in most cases where the business has been properly performed, probably in a much more mellow and friable condition, than it was before the commencement of the operation, and perhaps more suited to the absorption of elastic principles from the surrounding atmosphere." It has, however, been stated by the earl of Dundonald, that "the disadvantage in respect to vegetable matter, is nineteen parts out of twenty ; but the above author suggests that, as he has not informed us what is the degree of loss of such matter by this process, where it is incorporated in the state of soil, or the nature of the experiment from which his conclusion was drawn, we are at liberty to believe, that in this mode of preparation it is not by any means so great, whatever it may be where the vegetable matters are themselves simply submitted to the action of the fire ; especially as in the trials which he has made by burning such soils as contained a large proportion of vegetable materials, so as nearly to resemble that of garden mould, consequently, having considerably more than is usually met with in the lands that are subjected to the operations of paring and burning, it has not been nearly in such a proportion even under a high degree of heat, which ought in every case to be as much as possible avoided." It is further conceived by the noble author, "that as it is only from the ashes of fresh or growing vegetables that saline matters, such as fixed alkaline salts, can be procured, none being produced from the burning of dead or decayed vegetable substances, the proportion of alkaline or other saline matters obtained by the process is so small, that if the utility or advantage of the practice depended materially upon them, it would be more economical to purchase them." "Experience has, however, shewn, the first writer observes, that whatever may be the proportion of saline matter which is formed in this way, a great deal depends upon the ashes which are produced ; as it has been found by those who have been largely engaged in the practice of this husbandry, that on those parts where the ashes were spread out upon the land as soon as the process was finished, the crops were highly luxuriant and productive ; while on those where they had been from necessity taken away, they were very mean and inferior, not being worth more than from an eighth to a tenth of the value of the others."

In respect to the nature of the saline substances that are formed during the process of paring and burning, they have been found to be fixed vegetable alkali, and vitriolated tartar : in the latter case, the alkali of the consumed vegetable matters uniting with the sulphuric or vitriolic acid, which is frequently found to exist in some state of combination or other in soils. These substances have been found, by the experiments of Dr. Home, to be capable of promoting the growth of vegetables in a considerable degree.

And in addition to these modes, in which the practice of paring and burning may be beneficially employed in the cultivation of land, there are some others which seem of a more

mechanical nature ; such as its reducing the various kinds of coarse vegetable productions, as heath, furze, different sorts of dwarf shrubby plants, tough bent grasses, rushes, and many other aquatics, into such a powdery carbonaceous slate, as that, by the ready action of other substances upon them when thus reduced in the soils, they may become useful in promoting the growth of proper kinds of vegetables ; but which, without undergoing this process, could not, by any means, from their great elasticity, and almost indestructible properties, be prevented, for a very considerable length of time at least, from rendering the ground too light and porous for growing any sort of grain crops. And the state and condition of the soils, in so far as respects their textures, as already suggested, must likewise, in many cases, be greatly improved, being, by such means, when properly performed, rendered much more mellow and powdery, and thereby more proper for the admission of the fibrous roots of the growing plants, as well as more capable of minutely dividing the particles of the manures, of whatever kind they may be, that are afterwards applied to them, and consequently of affording a more full and equable supply of nourishment to the crops that may be cultivated. And from the process radically destroying, in most instances, when well performed, all sorts of plants of the weed kind that may have established themselves in the soils which are subjected to the operation, the lands are left perfectly clean, and therefore in the most proper situation for affording the whole of the nutritious properties which they contain to the support of the crops that may be grown upon them.

From this view of the manner in which this process may contribute to the improvement of land, the nature of the products that are formed by it, and the effects which they produce on the soils, it would appear to be a mode of cultivation more adapted to some sorts of land than others ; as where they are light or thin, and there is much vegetable matter accumulated within the soil, whether from the decay of successive crops or different sorts of plants, for a great length of time, or the repeated applications of manures, without their having much sward or coarse vegetable products, such as have been mentioned, growing upon the surface, it may do harm, especially when a great degree of heat is not carefully guarded against, and judicious modes of cropping introduced, by lessening the quantity of useful vegetable matter which they contain, without supplying any thing as a compensation. But where they are more stiff and heavy, and there is a thick matted sward, disposed to the production of moss, or covered with any sort of rough sward plants, whether of the grass or other kinds ; it must, when cautiously practised, be a highly beneficial, and perhaps, in many cases, an indispensable mode of cultivation ; not only by rendering them more open and porous in their textures, and reducing the coarse vegetable mass into that sort of form in which it can be readily turned down and incorporated with the earthy materials, but also by supplying a portion of saline or other matter, that may operate still further in promoting their fertility and productiveness. These are considered as the effects of the process, and the cases in which it should be made use of, or rejected, as is fully shewn by the experience of the most exact and careful practical farmers. Mr. Donaldson, an intelligent inquirer, who seems to have paid great attention to the effects of the different modes of practice that are employed in different districts in the cultivation of land, it is remarked, he observes, that such soils as are light and friable, are every where considered as unfit or improper for being treated by means of this process. And an experienced writer, who appears to have cautiously examined the nature and effects of the operation, assures us,

PARING.

he says, that he has many doubts about the propriety of extending the practice to such soils as have been already fertilized and brought into a proper state of tilth, by the application of manures.

It is suggested, that there is also another sort of soil on which the process of paring and burning must be practised with equal caution, or perhaps in some cases be wholly rejected, from the danger there is of its reducing the materials of which it is constituted in too great a degree. This is that of the peat or mossy kind. In this case, the author mentioned above supposes, it is not the plants which grow upon it, but the very substance itself, that served as a soil on which the plants grew, that is totally destroyed by incineration. This substance is, by burn-baking, amazingly diminished in quantity; and the little that remains, instead of soil, after this destructive process, is an inert earth, which is more unfit for the purposes of vegetation than any other that has ever fallen under his observation. There cannot, however, be any doubt but that, in some cases, mossy soils may be subjected to the process of paring and burning with much benefit to the cultivator, provided that it be performed with proper care and attention. And it is unquestionably practised in various districts without any injury being produced by the destruction of the materials that constitute such soils.

In cases where the soils are of the four, heavy, stiff, and fenny kinds, and where overgrown with such coarse vegetable productions as have been already mentioned, there cannot be the least doubt of the propriety of adopting such a method of practice in breaking them up and bringing them into a state of cultivation.

Mr. Young has well observed in his Calendar of Farming, in regard to the contradictory opinions held on this practice, that by one set it is pronounced, contrary to every principle, that it is a wasteful, extravagant operation, which dissipates what should be retained; annihilates oils and mucilage; calcines salts, and reduces fertile organic matter into ashes of very weak efficacy; that the vegetable particles which are brought into play at once, for the production of a single crop, by less desperate management might be husbanded to the support of many. On the contrary, the advocates for this management assert, that these objections are all founded on vain reasoning, and philosophical theory; that practice the most decided, and experience the most extended, pronounce it to be an admirable system; and that the mischiefs often quoted as flowing from it, are to be attributed merely to the abuse of the method, and by no means necessarily connected with it. And he must, without the least hesitation, declare, that the latter of these opinions is that to which he must subscribe. To trust to reasoning in matters of agriculture, is a most dangerous reliance. He shall leave others to detail their philosophical speculations, and rest what he has to offer solely on the practice, various and extensive, of numerous agriculturalists, and on the common husbandry of many spacious districts. These agree in declaring, and it is most particularly to be had in remembrance, for the enemies of the practice admit it, that by paring and burning you may command two or three good corn crops in succession. The fact cannot be denied; for whether you examine the peat of the Cambridge fens, or the shallow chalk soils of the downs and wolds of Hampshire, Gloucester, and the East Riding, it is known, that bad farmers do act thus absurdly. They get great crops, but they too often take them in succession, to the injury of the soil, though not to its ruin, unless that can be esteemed the ruin of land, which enables the tenant to pay a double rent for it. Such farmers have been in the habit of burning for wheat, and then taking two crops of spring corn; all good. Now, it might be asked, how is it

possible that that husbandry can have all the philosophical evils detailed above, of annihilation, dispersion, conversion, and destruction, which enables a soil, naturally poor and weak, to give two or three good crops of corn? Their argument evidently proves too much. The effect shews that there is a powerful cause or agent in burning, which they do not understand; which escapes from the retort of the chemist, and from the *rationale* of the theorist. That operation or manure which will give a good crop of wheat, will give a good crop of turnips or cabbages; and he, who having made this commencement for the food of sheep on the land, and knows not how to go on preserving the advantage he has gained, is a tyro in the art of husbandry. The farmers that are railed at, know it as well as their philosophical instructors; but avarice, united with the baneful effect of short, or no leases, make them practise against their judgments. It is maintained, that paring and burning will, on all soils, give turnips or cabbage; these fed on the land by sheep, will secure barley or oats, and seeds; the seeds fed with sheep, whether for a short or a longer duration, will secure another crop of corn adapted to the soil; and in this stage of the progress the soil will have gained much more than it has lost. To instance cases which he has seen, and to quote authorities for these assertions, would be tiresome. He could produce instances from more than half the counties of the kingdom in support of it.

But further, it has been often contended that burning lessens the soil. If this happens any where it must be in peat; yet in the fens in Cambridge, this husbandry has been repeated once in eight years for a century and a half, and the proofs of a loss of depth are extremely vague, in every instance he has met with, and hardly to be distinguished from that undoubted subsidence which takes place in drained bogs of every description. In all other soils the assertion may be safely and positively denied. He has calcined pared turf, not calcareous, after careful separation and weighing, and in a heat far exceeding what is ever given in densifying heaps, and on re-weighing, found the loss too minute to be attributed to any thing but loss of water intimately combined, but driven off by heat, and re-exposing the earth to the atmosphere, free from rain, found an increase rather than a diminution of weight. The vegetable particles only are reduced to ashes. These, in any method of putrefaction, would dissolve, and combining with water, be exhaled by heat, or absorbed by the vessels of plants. In ashes, these are in a more fixed state, relatively to the influence of the atmosphere. That plants feed on them, the great crops that succeed offer abundant proof. In conclusion, it is noticed that there are men who are timid in acknowledging truth, who admit the practice to be good, in poor soils, and in peat, and sedgey bottoms, but fear it on better land. Experiment is against them, for in Yorkshire, land of 20s. and 30s. an acre, has been thus broken up with great success; but in what manner do they reason? Rich soils are full of vegetable fibres. Then there will be the more ashes. These are in proportion to the organic matter. Peat, which these men admit to be burnt, is the richest soil in the world, and therefore burning the most universally practised on it. The soil itself is not reduced; if it was rich before burning, assuredly it will be rich after it. And in addition to these circumstances, is the capital one, of destroying insects, grubs, and weeds. These are apt to abound most in the richer soils, no reason for abstaining from this husbandry on such. He ventures therefore to conclude, that paring and burning, with a proper course of crops, is safe on any soil; and essentially necessary on some. He however well remarks, that very rich ones will do exceedingly well in many cases without it. This distinction,

PARING.

distinction, therefore, should be made. There is, in some cases, no necessity for it; there is in others.

It is observed in the twelfth volume of the Annals of Agriculture, that on inclosing the waste lands in the parish of Bows, in Yorkshire, large portions of the ground were subjected to the process of paring and burning; and the few persons who ploughed up the ground without previously employing this method, had reason to regret it. And it has been stated by a writer, in speaking of bringing into cultivation the chase lands in the county of Middlesex, that the impropriety of breaking up this kind of land, without paring and burning, is manifested in the neighbourhood of Beech-hill, where land, after twenty years inclosure and cultivation, is in a worse state than it was originally. Well would it be for the owners of such allotments, if they could now pare and burn it; but it has been ploughed, and not reducing more than what the vermin destroyed, laid down in so rough a state to grass, as to be incapable of being pared and burnt; the original wiry bent and dwarf shrubs are now growing in full vigour; and that on the inclosure of Stanwell, in the same county, the allotments on Hounslow-heath succeeded well under the perfect practice of paring and burning, and ill, where the turf was ploughed without the application of fire. In the former case the land was immediately fit for turnips, tares, barley, and clover: in the latter, the tough, wiry bent, heath, and dwarf furze, kept the land too light and spongy for any crop. Even rolling, he asserts, cannot keep it down, for its elasticity raises the soil soon after the roller has passed over it, and it is of to imperishable a nature, that it is likely to plague the farmer for many years. The difference between the two methods of breaking up rough ground, is more than the value of the freehold in favour of paring and burning, whereas the other proceeding leads to nothing but expence and disappointment. It is likewise added that paring and burning has more merit than any other manure, in its property of converting heath, furze, shrubs, and wiry bent, into coal, most fitly prepared for the food of plants; and that it will pulverize such a soil as much in two years as all other means can effect in twenty. And others contend, that on any sort of soil which has not before been reclaimed from a state of waste, and where furze, broom, brambles, ferns, rushes, &c. abound, these operations, when properly performed, are productive of the most beneficial consequences. That there is perhaps no other method that could be devised, so well adapted for preparing land in a state of nature, and incumbered with such productions, for valuable crops with expedition and certainty; and that, on this account, paring and burning might well be considered by Virgil, and other ancient writers, as a sure means of improvement. And that, in such cases, they are so at this period, may, it is thought, be proved by the concurring testimony of those to whose lot it falls to cultivate the common or waste lands in many of the new inclosed districts of the kingdom. It is further stated, that instances are frequently met with of great advantage, resulting from this mode of management; and that wherever land is rendered unfit for cultivation by the incumbrances that have been mentioned, the Devonshire mattock and the paring-spade may be used with the greatest propriety, and the best effects.

In the Agricultural Survey of Suffolk, it is stated, that in that district they could not cultivate without this capital assistant. It is scarcely possible, profitably, to bring boggy, moory, and peat soils, from a state of nature into cultivation, without the assistance of fire, which is the most effective destruction of the spontaneous growth, and never fails,

unless the men employed do not pare deep. However, of late years an opinion against it has prevailed much in some counties. Several of the nobility and gentry of very large estates have interdicted the practice, not allowing their tenants to pare and burn under any pretence whatever. The reason assigned for this conduct is an apprehension, that the depth of the soil decreases from it, that you burn *the land*, and reduce half an inch to half a line, a great evil when the land is perhaps only three or four inches deep on a lime-stone rock. But this reasoning, many very sensible and experienced farmers know to be false. They, on the contrary, urge the universal circumstance of no land ever being pared till it has acquired a turf, which with natural grasses will be from seven to twenty years, and with sainfoin the duration of the crop, which is from ten to twenty years; that it is not the *soil* which is burnt, but the bulbs of the plants, the roots and net-work of grass roots; the earth which is intermixed is not burnt, it is calcined but not reduced to ashes, all of which arise from bulbs and roots: hence the fact that the staple of the soil rarely suffers from paring and burning. If this reasoning be not true, whence the known fact that soils not four inches thick, and which have remained at the same thickness as long as the oldest man can remember, have yet been pared and burnt regularly four or five times in a century? and as the same husbandry is known by record to have been practised for ages in the same land, the staple must have left three inches every hundred years; in other words, it must have been totally gone long ago, and nothing but rock remained; all which is evidently false, the soil at this day being as thick as ever. We may hence conclude, what such farmers assert to be true, that the earth suffers no diminution, those roots and bulbs only being reduced to ashes, which in breaking up by the plough alone would rot away.

In speaking of the objections which have been made to this practice in fen districts, from the idea that it has the tendency of reducing the soil greatly, as is shewn by the sinking of drained lands that have been pared, the same writer adds, that it has been found that a series of ploughing and cropping stiffens, concentrates, and diminishes the lighter kinds of fen soils; and that the stratum of black peat earth, which on their first breaking up was considerably deeper than the plough ran, has been within the memory of the present occupiers, without any fresh paring or burning, so far reduced, that without taking more mould, or ploughing deeper than they formerly had been accustomed to do, they have not only passed the whole of the black peat stratum, but have ploughed up two or three inches of the clay beneath it; and that if it be granted, which will scarcely be denied, that the surface of the adjacent depastured fen lands, from the decay of vegetables, dung of animals, and the soil brought thither by the waters from the neighbouring high lands, has been continually, though slowly, increasing, there will then appear other reasons for their present different level than mere paring and burning. It is well known, that earth is not to be dissipated by combustion; it is more likely this appearance proceeds, in the first place, from the light peaty earth of a fen soil being gradually consolidated by alternate cultivation and pasturage, so as to sink below the level it formerly preserved in its uncultivated state; and in the next place, may it not proceed from the commons gradually rising higher by the accumulation of mud and soil deposited by the upland waters? All these facts, which obviously rest upon the foundation of practical experience, sufficiently demonstrate that little danger is to be apprehended from the destruction of the soil, when the process is properly performed, and a correct method of management pursued with the land.

PARING.

The effects of the process may, however, be examined a little further, as they stand in respect to the different sorts of soil.

Clayey Soils.—Mr. Young supposes that many appropriate reasons have not been brought against the practice on this sort of land; the only one that merits the least attention, is the assertion, that it converts what is properly soil, into pieces of infertile brick. The fact is not so, for every one that ever burnt clay for manure, knows that though there are many lumps of the substance which they allude to, yet, that the mass of the heaps consists of ashes, properly so called; but when the tenacity of this soil, which is one of its greatest evils, is considered, it will be found that bricks are an excellent addition to the soil, to loosen and open its stubborn adhesion. He has seen and examined carefully heaps of clay ashes, amounting to many hundreds of loads, that have been burnt and applied to great profit on this soil. By paring and burning you have, therefore, on it the common manure found in vegetable ashes, and you have in addition a substance which acts mechanically. Hitt, he says, who wrote from practice, and whose writings abound with many just observations, remarks: I recommend burning of the surface as the cheapest manure, and most effectual of any; for it not only adds salts to the soil, which the burning of grass-roots produces, but it opens part of the stratum of clay next the soil so much, that the roots of vegetables can afterwards feed therein; for when the turf of a piece of land has been burnt in heaps, at four or five yards apart, though all the ashes be taken away with some of the clay, and spread over the other parts of the land, yet neither corn nor turnips will grow so vigorously there, as on those places that were only opened by heat.

Also near Guilford, Mr. Birbeck has found this practice highly useful on clayey soils. After remarking that by the process, that portion of the turf, which contains from three-fourths to four-fifths of the undecayed fibres, is at once converted into a substance the most favourable to vegetation; he has had the most decisive proofs of the preference of paring and burning, to fallowing and to sowing on the fresh turf on both clays and loams, and that he has never had occasion to notice the impoverishment from the former, which he had suspected; on the contrary, the reverse has been so obvious, as to amount, in his judgment, to very strong evidence, if not demonstration. And he believes, that if the crops on equal quantities of land subjected to these different processes, were accurately weighed for two, or perhaps three years, it would be found that the produce of the pared and burnt land would exceed that of the fallowed, by more than the amount of the whole turf consumed.

Near Beverley in Yorkshire, Mr. Moss likewise gives an instance, within his own knowledge, of a farmer breaking up several closes of old sward, one of the best of which, about twelve acres, he ploughed out, and pared and burnt the rest. The first year he lost 100*l.*, the second 100*l.*, and the third 50*l.* for want of paring and burning; the whole loss 250*l.*, being more than 20*l.* per acre, at that time about two-thirds the value of the land. This was a fine sweet sward, and has not been superior since to the pared and burnt land, on account of cropping about twenty years.

And on poor clay near Horncastle, Mr. Elmhurst, after properly draining such as wanted it, pares an inch, or an inch and a half thick, about Lady-day, and gets it well burnt. So soon as all or a good part of the piece is burnt, he spreads all the ant-hills as level as possible upon the ground betwixt the ash-hills. He then has the ashes all evenly spread, and as soon as a tolerable rain comes, he has the

whole well harrowed, and ploughed shallow-furrow for turnips; and for the most part has had very good crops; which he always eats off with sheep. As the land is not broken up too deep, as soon as the turnips are eaten off, and the land is dry enough, he has it ploughed up again into small lands, about two inches and a half, not more than three deep; and with two more ploughings and harrowings in good time for sowing it with cole-seed, and then barley. He has often had more than six quarters per acre, and the next year from five to six quarters per acre of wheat, upon poor land by this process; and in various parts of the country, where he has for many years occupied such lands, paring and burning such sort of land is the very best practice that can be used, as it tends to the enriching of it, by the greatest quantity of manure that can be obtained.

Also on poor cold clay, the same thing has been experienced by Mr. Maxey, in Bedfordshire. Thirty years back he broke up a piece of sward of this description, one part of which he pared and burnt, another he ploughed with horses, and a common plough, ground sharp, as thin as it could be, which part he also burnt; the remaining part was fallowed the succeeding winter. The part that he had ploughed by horses, which was about five acres, abounding with ant-hills which consisted entirely of clay, he was under the necessity of burning in large heaps, whereby a large portion of the essence was destroyed. On this he had more ashes than could be used to advantage thereon, and from which, after spreading a double portion, he manured eight acres in an adjacent field. Now, were burning so prejudicial as has been represented, this piece must have been utterly ruined. The two pieces thus burnt were prepared for wheat, and in due season sown therewith; the other with oats, which was a very poor crop, owing in some measure to the grub and other insects, to which this kind of land is subject; and which in a great measure are destroyed by the preceding process; the wheat on both pieces was very fine, but that which was ploughed by hand was somewhat better, which he ascribed to the superior quality of the ashes, they being the product of the surface only, and burnt in small heaps. In the course of cropping that followed, the parts burnt were so much superior to the other, that he shall not exaggerate if he says, he had more profit from an acre of that burnt in three years, than in five from the other part. It is worthy of remark, that those spots where the large heaps were burnt, on which the whole surface or staple quite to the clay was consumed to ashes, yet by their situation not to that degree as was the bulk of the heaps, the fire not being so strong next to the ground, but so as to retain its essence, not only produced the most luxuriant crops at first, inasmuch that he has been under the necessity of mowing them down twice, and yet has had so much at harvest; but continued for a number of years superior to any part of the field. When he has manured this field, he has avoided laying any dung thereon, and yet it is at this time, after a lapse of thirty years, equal to any part of the land. This confirmed him many years back in the propriety of burning, as it is a demonstrative proof of its efficacy and advantage, and a full refutation of all the objections which he has heard advanced to that practice. The advantage in burning in many instances is much greater than he has described, as much depends upon the season. If it should prove a fine dry time, the turf may be burnt much more quickly, and in smaller heaps, whereby the quality is rendered far superior than it can be, in wet unfavourable seasons, when it cannot be burnt in such small quantities. He particularly recommends it to be burnt in as small quantities as the season will admit; if only scorched the

PARING.

the better. For the above reasons, he recommends paring by hand in preference to that by the plough. In further proof of the advantage of burning, he states a recent experiment of two neighbours in an adjacent parish where an inclosure took place five years back, at which time they had each a portion of waste or common laid to their allotments adjoining to each other of equal quality: the one who is the proprietor pared and burnt, and sowed in succession with cole-seed, barley wheat, wheat, barley: all of which were good crops. The land is at this time under winter tares, which he proposes feeding off with sheep, and sowing it with wheat again in the autumn. Although he cannot recommend such a course of cropping, yet he doubts not, as the prices of the produce have been, but that he will profit very much thereby; and that its own produce of dung will more than compensate the expence. The other farmer, who is a renter, (probably like the majority of renters, under some injudicious restraints laid down by some farmer's land *taster*), fallowed his land in the winter, sowed barley, oats, cole-seed, and barley, all of which were very poor crops. The former calculates that he has made a profit from fifteen to twenty pounds an acre more than the latter, and that his land is in a far superior state for any succeeding crop. It is objected that land which is burnt will not bear clover, the fallacy of which he has proved in many instances, having always found the clover on such land to be equal to that on land which is not burnt; but this he has also discovered, that no land of this description whilft new, either burnt or not, will bear clover to advantage; it must first go through a course of cropping of at least five or six years, when it will be of a better texture for that purpose.

Loamy Soils.—These are, Mr. Young says, especially when good, those upon which the practice has been most condemned; but here we have some experiments to recur to, which, in his estimation, set the matter in so clear a light, that nothing more is necessary than to recite them very shortly. Mr. Wilkes, of Measham, in Derbyshire, has for many years been in the practice of ploughing old rough pastures, the soil a stiffish loam, eight or nine inches deep, and burning the old furrow in heaps of thirty or forty bushels each, the fires lighted by a few coals, and coal-slack; the effect was very great, and the improvement immense and durable. Mr. Wilkes is of opinion, from the experience of many years, that even this burning, which is twenty times the depth of common paring, does not waste the soil in the least, but does no more than break the texture of stiff soils, expelling a great quantity of water; that by exposition to the atmosphere the land re-absorbs its water, and by the great immediate fertility, fills itself presently with more vegetable particles than it had before. Thirty years ago his father burnt at Oversea, exactly in the manner described, a field of ten acres, which was not then, and has not since been treated with any more favour than the fields adjoining, yet it has ever since retained a superiority. And the writer, in 1790, hollow-drained an old grass-field of four acres and a half, of cold, wet, poor loam, on a clay-marle bottom; the rent 9s. an acre, and not worth more in its then state, perhaps, than 7s. In 1791 he ploughed four acres of it four inches deep, which was the whole depth of the soil or surface, of different colour from the stratum beneath, between that surface and the clay-marle, and burnt the whole furrow of the part so ploughed. Having no coal-slack, and wood being dear, he made but four heaps in the field; the consequence was, the heat and degree of calcination were far beyond what is ever practised in common, and many persons who knew and approved of paring and burning in the common way, pronounced the field completely ruined. The ashes

were spread, and ploughed in with a shallow furrow, and turnip-seed sown, and very slightly bush-harrowed. The crop was very fine, worth, to sell for feeding on the land, at least 50s. an acre. The crop on the burnt part double to that of the half acre.

And after feeding them with sheep, the land was ploughed thrice, and sown with oats and grasses. The oats produced above seven quarters an acre, and the grass has ever since been much better worth 20s. an acre than it was worth 5s. before. The oats on the half acre were not threshed separately, but judged by those that viewed them to be much inferior to the rest. About half the field has been since dressed with earth and road fuggage, and once dunged slightly. It is remarkable, that in three years crested dog's tail, an excellent grass, common in the country, the feed heavy, and which, therefore, could not be carried by the wind, began to appear, and has been increasing ever since. There is at present no perceptible difference between the part burnt and the other not burnt; if any thing, the burnt is best. These two experiments prove, if any thing can, that paring and burning does not lessen the soil, in its most excessive application, and that it works a very great improvement on loams.

Likewise on stone-brash and light loams, near Bristol, the Rev. Mr. Swayne has experienced the advantage of this process; he, indeed, has remarked, in more instances than one, the beneficial effects of combustion, in promoting the growth of vegetables on red or yellow ferruginous clay or till, which have long been ranked among the most unfruitful of soils. It is that the mineral oil, with which these soils abound, and which in its natural state may be the cause of infertility, is by the action of the fire wholly dissipated, in the case of the clay being burnt red, and converted into carbonaceous matters, when that is burnt to a black cinder:—or, is this effect, he asks, produced chiefly from the mere admission of water owing to the alteration made by fire in the contexture of the clay? However he may be unable chemically to account for it, he is well assured of the fact.

But the following detail of a field pared and burnt, may possibly be thought of more consequence to the present inquiry, than the before-mentioned small and unfinished experiment. A small close of old grass lay of between two and three acres, the soil a lightish hazel loam, of about eight inches staple, upon a clay subsoil, underneath which, at the depth of two or three feet, several strata of stones, which will burn to brown lime, was let, in the year 1796, to a common labourer, for the term of five years, at the rate of five guineas *per acre per annum*, to be ploughed up for potatoes, or any other crop he might choose to raise. In the month of February the turf was pared with a breast-plough, and burnt in the month of March, the ashes then spread, and the ground immediately ploughed. In the months of April and May it was planted with potatoes. The summer being rainy, it was found that the potatoes had been planted too thick. The strength of the fresh ground manured with the burnt sward, caused them to run too much to haulm. However, fifty-six sacks of potatoes were dug from fifty perches of ground. The second year it was again planted, the greater part with potatoes, some part with wheat. The produce was not ascertained. After the potatoes were dug up, part of the ground, exactly half an acre, was sown with wheat in the beginning of December. The wheat was hoed in; that is, drills were opened with the potatoe-hoes, at about nine inches apart. When one drill was opened, the seeds were scattered therein as evenly as possible by hand, after the rate of about one bushel to an acre. In making a second drill, the earth hoed thereout covered the wheat sown in the first, and so on. The crop of wheat, owing to

the uncommonly wet season, run much to straw, but its produce was sixteen bushels, or after the rate of thirty-two bushels an acre; a very rare crop in that unpropitious season. The rest of the field was planted with potatoes: no account taken of their produce. The fourth season, two roods and a half were sown with wheat, the sort red lammas, in the same manner as in the former year: the produce nineteen bushels. A better crop, by fifteen bushels an acre, than any farmer's in the neighbourhood. The straw was purchased by the writer at two guineas and a half.

Sandy Soils.—In regard to sandy soils, it is remarked by Mr. Young, that Hitt, a practitioner of this husbandry, observes, that it improves sandy soils as much as any other; and he has seen some fields thus worked in Suffolk and in Cambridgeshire, and improved by it, though under a course of crops by no means admissible. There is not the least reason, from analogy, to doubt the effect on this, or indeed on any soil.

And in Suffolk, Mr. Baldock found vast advantage from the use of this mode of breaking up poor sandy soils on an extensive scale. In the course of twelve years, the land broken up in this manner has cost near 60*l.* *per* acre, but the produce which has been afforded has been fairly estimated at 120*l.* *per* acre in the same time.

Also, on this skinned warren land, near Spillsby, Lincolnshire, Mr. Kershaw has found this practice beneficial. In the year 1782, he entered upon a farm of nearly seven hundred acres of land, which had chiefly been in a warren, and was at that time of very small annual value. A considerable portion of this land was pared and burnt, and found to answer his most sanguine expectation. The crops were full as much more as from the land which was broken up and sown in the common course of husbandry. In order to prove this assertion, he mentions two or three circumstances of the process and conduct. At Michaelmas 1782, he entered on the largest part of the farm; he had, amongst other lands, a walk containing forty-five acres, valued to him by the quitting tenant, from that time till May-day 1783, at forty shillings. He mentions this to shew the poverty of the land, which was so thin skinned, that to have pared and burnt it was not practicable; he therefore, the year following, ploughed it up and sowed it with oats, the crop of which was scarcely worth the labour. The summer after, working it well, and getting it into good condition, he sowed it with cole, and it produced but a scanty crop. The spring following he laid thirty acres of it down with sainfoin, of which he had good crops for several years. When it was worn out, having a good deal of rough grass upon it, he pared and burnt it, and got a good crop of turnips, considering that it was a very dry season; after which, he sowed it with oats, and had a remarkably good crop for that kind of land, more than six quarters *per* acre. The year following he sowed it with turnips and cole, which were decent crops; ear them off at Michaelmas, and sowed the land with wheat. The middle of February he laid about three quarters of foot *per* acre, and the latter end of April laid it down with a stone of white clover, and two bushels of ryegrass *per* acre, and harrowed the seeds in upon the wheat; the latter yielded near a chaldron *per* acre, and a finer crop of seeds could not be seen. He has continued them ever since, and the land has kept three times the stock it was ever known to do before. This clearly shews the utility of paring and burning; in proof of which the thirty acres so cultivated, part of the forty-five valued at forty shillings, are now worth from six to eight shillings *per* acre, for the same period of time.

The other fifteen acres of the best land he worked in the

common way, without being able to get any turnips; the crops of corn were scanty, and the seeds did not afford more than a proportion of two-thirds for the feed of sheep. In the year 1791, he pared and burnt another piece of sainfoin, about eighteen acres; also a piece of grass seeds twenty-five acres, on both of which he had remarkably fine crops of turnips.

Likewise on poor, gravelly heath land, Mr. Wright, in Rutlandshire, has found this practice to answer perfectly. In March 1799, he began grubbing, paring, and burning a twenty-four acre piece of this heathy land: in June, sowed it with turnips, on one ploughing, not suffering the plough to exceed the depth of two inches, lest the ashes should be buried, and out of reach of the turnip to taste. As harrowing this tough sod would have made it lie worse instead of better, the seed was sown, and only bush-harrowed. The plants came up true and well; but, after hoeing, the places where the fires had been, grew, if possible, ten times as fast as those where there had been none, notwithstanding there were no ashes left on those spots. This shews the amazing fertility of fire, and is a lesson to him and all future burners, to make their heaps as small as possible, so as to enable the fires to cover as much of the surface as may be; for, if all the ashes be swept off, and even some of the surface pared off, it will still be superior to the ashes, as he fully experienced. Another advantage arises from making the heaps small, which is the quality of the ashes; the larger the heaps, the more intense the fire, and the centres of such heaps get too much burned, as may be seen by the redness of the ashes; those on the outside being perfectly black, and very little inferior to foot. This ground produced a most excellent quality of turnips (as indeed all burnt ground does), 2*l.* 10*s.* *per* acre. He afterwards sowed with barley on one ploughing, in March: a finer crop he never saw (quality of land considered); it was estimated at five quarters *per* acre, throughout the piece, but not yet threshed; clearing to him as much in one year (and consequently a proportionate benefit must accrue to the nation), as it would have done by pastureage, in its original state, in a century.

Chalky Soils.—Mr. Young observes, that in respect to these, we have a much more ample field of experience, for it has been, and is the common method of breaking up downs in every part of England. On the Cotswold hills, in Gloucestershire, it is the common husbandry, and often repeated. The sheep walks and warrens on the wolds of the east riding of York, and of Lincoln, have thus been brought most profitably into culture, though not with the attention in cropping that ought to have been given. In Hampshire and Wilts, the same husbandry prevails. In these counties he has been shewn lands that have been pronounced ruined by this husbandry. The cropping was bad, but still the rent had been doubled by the practice. It is stated in his Eastern Tour, that, in the west riding, colonel St. Ledger remarks, that if burning walled the soil, his lime-stone lands, only four inches deep, would have been gone long ago, as it had been pared and burnt for ages.

In Kent, he lets Mr. Boys speak for himself: who observes, that if any persons who condemn paring and burning should come into Kent this summer (1795), he can shew them several scores of acres of wheat, barley, oats, and sainfoin, now growing on land which has several times undergone that operation. The crops of sufficient value to buy the land at more than forty years' purchase, at a fairly estimated rent before the improvement. It is humbly presumed, that Messrs. Kent, Claridge, and Pearce, the great enemies of paring and burning, will not pronounce this land ruined by that execrable practice.

And

PARING.

And in the experience of Mr. Birbeck, near Guildford, in Surrey, on a chalky soil, two fields, making together about fifty acres, were laid down in an exhausted state. When they had acquired a turf, one received a summer's and winter's fallow, the other was pared and burnt; and both were sown with barley and seeds. The effect was strikingly in favour of the latter, both in the barley and seeds which followed.

And another field of the same quality, twenty-two acres, was pared by the plough in the spring of 1799; and about half of it was harrowed repeatedly during the summer: the wetness of the season prevented the burning; but as the turf was completely killed, and much broken by the harrow, this part of the field became a good fallow. The remainder, not being disturbed, set again; and, the following spring was nearly as green as before. In the succeeding summer, the operation of burning was thoroughly performed: where it had not been previously broken by the harrow, the entire turf, down to the chalk, was subjected to the fire; and in the other, though nearly decomposed by two years' fallowing, enough was burnt to produce a tolerable sprinkling of ashes, to stimulate vegetation, if that were their property. This field affords a fair opportunity of deciding betwixt the two modes of reducing old turf to tillage. He expected that, in this instance, the fallow would have taken the lead by the help of the ashes; but in the turnips now growing, the seeds are very much in favour of the pared and burnt land.

Peaty Soils.—Mr. Young states, that whatever variety of sentiments there are on this method, for other soils, here there can be none. The universal practice, from the flat fens of Cambridge to the swelling bogs of Ireland, the mountainous moors of the north of England, the rough fedy bottoms, in almost every part of the kingdom, when they are broken up by men of real practice and observation, are always done by paring and burning. Registered experiments of doing it by fallowing, are to be met with in various works. The Board's reports of the North Riding of York, and of Somerset, detail some; others are to be found in his Tours; and the result is either loss, or a profit so very inferior, that the question ought to be considered as settled and done with. Let it sleep for ever, except for the wrong-headed individuals who will, upon every question, arise in every age to contradict the common sense of mankind.

Paring.—In the method of performing the process there are some slight differences in the practice of different districts; and perhaps in managing this business, an attention to the nature of the lands may be as necessary as in other cases of husbandry: as it would seem that some, as those of the more clayey and heavy kinds, would be most benefited, by having the fire to come as much as possible into contact with the whole of the superficial parts of them, without being carried too far; as by that means they may be rendered more proper for the reception of the roots of vegetables, after being slightly ploughed, as well as more suitable for supplying nourishment to them; while in others, as those of the more light and thin descriptions, it might be most advantageous to merely consume the thin paring of sward after being piled up for the purpose; without permitting the fire to exert its influence upon the mould or soil immediately below, as in this way there would not probably be so much danger of injuring the staple by destroying the vegetable matters contained in such soils. Of course, that in the first of these modes of burning the sward, the sods or parings should be piled up as little as possible into heaps, the advantage of a suitable season being taken to apply the fire to them in the state in which they lie, or

are set at first after being cut up, or after a few only have been placed together, as happens in some instances, where they are, immediately after being cut, set on edge to dry, and placed in serpentine directions, in order to prevent them from falling over; but in the latter cases they should be formed or built up into little circular heaps or piles, somewhat in the form and size of the little cocks made in hay-fields, the sods being placed the grass-side downwards, in order to admit air; but the openings both at the bottoms and tops, after they have been fully set on fire by some combustible substance, such as straw, &c. are to be closed up, as well as those in other parts covered by an addition of sods; so as that the combustion may proceed in a slow, smothering manner, such as is practised in the making of charcoal. When the whole of the earth in each of the piles has been acted upon by the fire, the heaps may be suffered to extinguish themselves by slowly burning out.

And there is another method of practice of this kind, which is much in use in some districts, as in Devonshire and Cornwall, for breaking up and preparing grass lands for the reception of what have been termed fallow crops, which is that of skirting; in performing which, a part of the sward or surface is alternately left unturned, upon which the next thin furrow-slice is constantly turned, so that the swards of each come in contact, by which means the putrefactive fermentation is speedily excited, and the greatest part of the grassy vegetable matter converted into manure; what ultimately remains undestroyed being, after repeated cross-cuttings with the plough, and harrowings, all the mould or earthy matter having been previously well removed from the roots of the plants by shaking, collected into small heaps, (which is done either by the hand, or with iron-headed rakes, constructed for the purpose,) and burnt, the ashes being then spread evenly over the land. The operation, when managed in this way, is termed beat-burning, and would appear to be the most proper and useful on land, where the turf or sward is not very tough or matted together, and where there is little or no coarse vegetable products growing upon the surface of it.

In separating the sward from the surface of the soil, different implements are made use of in different parts of the island: that which was the most employed in the infancy of the art, was a kind of curved mattock or adze, about seven or eight inches in length, and five or six in breadth; and which, from its shape, would appear to have been better adapted for cutting up the roots of brush-wood, furze, broom, or other coarse shrubs, than for paring off the surface of a field free from such incumbrances. This instrument is, however, it is said, common in the south, western districts; and that, though it no doubt retains in a great measure the shape of the instruments first used for the purpose in that part of the country, when the lands were in very different state; yet the labourers, who are in the practice of using it, are able to pare off the sod with great dexterity and dispatch. But in other districts, where the sod is pared off by manual labour, the ordinary breast-spade, (in some places called the breast-plough, and in Scotland the slaughter-spade,) is mostly employed. The iron, or cutting part of this implement, is about eight or nine inches in length, and from ten to twelve inches in breadth, having frequently a kind of edge rising up a few inches at the right-hand side of the turf, next the unmoved sward. This instrument, which is formed with a fine edge, is forced forward by the strength of the arms of the person using it, and by pressing the breast against that part of the frame or shaft which is held in the hand. In working the tool,

PARING.

the labourer generally cuts the fods at about an inch or an inch and a half thick, and from ten to twelve inches broad; and when the spade has run under the fod to the length of about three feet, he throws it off by turning the instrument to one side, and proceeds in the same way, cutting and throwing over the fods, the whole length of the ridge. In this way of performing the operation, the labourers, by following each other with a slice of the fward or surface of the land, accomplish the business with much ease.

There is another implement that is sometimes used for paring the fod, which is the *horse-paring-plough*, and is made of different constructions, according to the circumstances of the ground to be pared. In the fenny districts on the eastern coasts, where paring and burning are practised on a large scale, they have ploughs constructed for the purpose of a particular form, but which vary from the common ploughs chiefly in the breadth and sharpness of the share or sock. They are admirably calculated for paring off the fward or fod of such grounds as are level, and where neither stones, brush-wood, ant-hills, nor other impediments obstruct their progress; but where such obstructions present themselves, the breast-spade, or common team-plough, with a small alteration of the share, will be found preferable, both in respect to the extent of ground that can be pared, and the superior manner in which the work in such cases can be performed. Ploughs, from their great expedition and regularity of performing the business, should always be made use of where the nature and situation of the land will admit them, in preference to such tools as require manual labour. In some of the western counties the common plough only is used. There the old grafs fields, when it is proposed to burn the fward, are rib or slob-furrowed about the beginning of winter; and being again cross-ploughed the following spring, the fods are collected and managed in the manner mentioned in speaking of skirting. In those cases the plough has, however, a wing turned up on the furrow-side of the plough-share, by which the furrow is cut any breadth required. The work is also sometimes done by means of the spade, mattock, and breast-plough, in such cases.

Mr. Young states, that in the fens of Cambridgeshire, upon a peat soil, free from large roots and stones, the work of paring is always done with a plough, which they make on purpose for the work, and which executes it in the completest manner that can be imagined. It turns off a furrow, from 12 to 16 or even 18 inches broad, and not more than an inch deep. The use of this admirable tool brings down the whole expence of paring, burning, and spreading the ashes, to 9s. or 10s. *per acre*. But upon those soils, when they have not been in a state of cultivation, such a plough would not work.

But in old meadows and pastures, this sort of work is done with the breast-plough, as it is called, which is pushed on by strength of body, the thighs being armed with wooden guards. It is hard work, and now commonly paid for, including burning and spreading, from 25s. to 40s. *per acre*. An inch, or an inch and a half, is the common depth; but some farmers prefer two inches, for the sake of more ashes. The thinner it is pared, the more certain the burning, should the weather prove unfavourable. Considerable tracts of heath and down-land, on a weak, thin, loamy sand, with a calcareous bottom, have, within the last five years, been thus broken upon Newmarket-Heath, at the expence of 36s. *per acre*, and immense crops the consequence. And the moors and mountains of the north of England, Wales, Devonshire, &c. when broken up for cultivation, are often,

and ought always to be reduced by this practice. It has long been common husbandry in those counties, and is, therefore, done cheaper, from 24s. to 30s. *per acre*. However, draining should precede it.

The months in which the greatest quantity of land is pared and burnt, are April, May, and June. The particular period must, however, always depend much on the state of the weather, the nature of the crop, and the farmer's convenience. When the east winds prevail, in February and March, this sort of business may sometimes be carried on. But for accomplishing the work with the greatest dispatch, and also with the least trouble and expence, a dry season is obviously the best. The prudent farmer should not embark in the undertaking, unless there be a reasonable probability of his accomplishing it while the weather keeps dry and favourable. The latter end of May, or the beginning of June, when the hurry of the spring seed time is over, in the more northern districts, when a number of hands can be most easily procured, may upon the whole be considered as the best and most convenient season; as at this period the green vegetable products are in their most succulent and full states, and of course may probably afford more saline matter; but in the more southern counties either a much earlier season must be taken, or the interval between the hay season and the harvest time must be fixed upon, the latter of which is, on the principle just stated, evidently the best, where the extent of ground to be burnt is not too large. In other seasons it would frequently be impossible to procure a sufficient number of hands for performing the business. In bringing waste lands into cultivation, where an extensive tract of ground is to undergo this process, the autumn may, in many cases, afford a convenient opportunity for the operation.

As the crops, that are sown after paring and burning, are various, and as the season for performing the process, in many cases, depends, in some measure, on their nature, it may be observed, that when rape or turnips, which are the most prevailing crops in such circumstances, are to be cultivated, the end of May or the beginning of June will be the most proper time: but if barley or oats are to be sown, the paring and burning must be completed as early in spring as the nature of the season will admit; and when lands are pared and burned as a preparation for a crop of wheat, July, or even the beginning of August, may, in favourable seasons, answer; but it is better to have the ground ready sooner if possible.

The depth to which lands of different qualities may be pared with the most advantage differs much; but as it can hardly be proper to pare light, thin, stapled soils, to the same depths as those of the more deep and heavy kinds, it should, in some degree, be regulated by their particular nature, and their differences in respect to depth and heaviness. Mr. Boys, however, who is in the habit of breaking up thin chalky soils, and such as have been in tillage this way, observes, that in Kent, where the method of paring most in use is with down-shares or breast-ploughs, they take off turfs as thick as the nature of the soil will admit, from half an inch to two inches; the thicker the better, provided there be a sufficient portion of vegetable matter contained within them to make them burn well. The most usual depths of paring are from about one to three inches.

Burning.—When the season is not very wet, the turfs will commonly be sufficiently dried in about a fortnight or three weeks, even without being turned; but in rainy weather they require a longer time, and must be turned more than

PARING.

than once to prevent their striking out roots and shoots, which might hinder them from burning. And that as soon as the turfs have fully undergone the process of burning, and are reduced to the state of ashes and a powdery earthy matter, the whole should, as soon as possible, be spread out over the land in as regular and equal a manner as the nature of the work will admit of; for, without great attention in this respect, great inequality in the crops may take place; besides, the soil will be made lighter in some places than in others, which may be disadvantageous in the same way. The spreading, where it can by any means be accomplished, should always be performed before any rain falls; as where this point is not attended to, a great loss may be sustained by the saline matters being carried down in a state of solution, and their beneficial effects in a great measure lost before the crops are in a condition to receive them. In order to secure the full influence of the ashes, the land is frequently slightly ploughed over immediately after the ashes are spread out. And Mr. Donaldson states, that those, who are more than ordinarily attentive in this respect, only rib or slob-furrow the field, so that the ashes may be got covered up with the greater expedition and dispatch. By this mode they cannot probably, however, be so equally mixed with the soil as by that of ploughing the whole field with a very slight furrow, so as just to cover them. It is remarked by Mr. Young, that in this business, the heaps should not be made large, twelve or fifteen bushels of ashes are large enough; twenty may be admitted, but if much larger, the turfs will be too much burned. This must, however, depend, in some measure, on the weather, for the worse that is, the larger the heaps must be. It will also depend on the thickness of paring. Thin flags will burn in smaller heaps than thick ones.

It is evident that the expence of the operation of paring and burning must vary according to the nature and situation of the land, the method in which it is performed, and the customs of the district in regard to the price of labour. On the thin sort of chalky soils it is stated by Mr. Boys, who is accustomed to have such land prepared by this means, that the expence for paring at a moderate thickness, where the land is not very stony, is twenty shillings *per* acre; for laying it up in heaps and burning, ten shillings; and for spreading the ashes, three shillings; and that a coat of manure is thus produced on the land of from eighty to one hundred and sixty cart loads *per* acre, for the trifling expence of thirty-three shillings. A hundred cart-loads of dung purchased from neighbouring towns and villages, at the distance of three miles from the land, would cost, carriage home included, ten times the price of down-harrowing, and yet would not improve the land more. But that, where the land is well covered with turf, it may be ploughed for burning about two inches deep, with a common plough, drawn by a pair of horses, early in the spring, and as soon as a drying wind sets in, the turf be laid in heaps, and burnt by labourers for one pound one shilling *per* acre, which will produce near two hundred cart loads.

In some fen districts, where the original surface is rough and unequal, from great tufts of rushes, &c. called haffocks, Mr. Young states, that some persons cut them with spades at the expence of five or ten shillings an acre, and others with the plough. Paths for the horses are in that case to be cut by hand, and the plough made on purpose, and called a-haffock plough, cuts laterally much beyond the line of its draught. But opinions are said to be in general, that the hand-work is the cheaper; in either case, the haffocks are dried, heaped, burnt, and the ashes spread. After this they go over it again with a very complete and effective tool,

called a fen-paring plough, the furrow of which is burnt: the expence of this business in different cases has been shewn above.

Cropping.—In the management of land by this process, it is necessary to attend to such a mode of cropping as will tend to its improvement, whatever may have been the manner or kind of soil in which the process was performed. Without a nice and exact attention in this respect, much injury may frequently be done, and an useful practice be brought into disrepute. Where the nature and situation of the land will admit of them, as in the lighter sorts of soils, the growing of turnip or rape crops, to be consumed on the ground, would seem to be most proper for the first year; then a white or grain crop, as oats, or wheat; after that turnips again, or, in some cases, peas, beans, or some sort of green crop, to be eaten off, if possible, by sheep; and lastly, a grain crop with grass feeds: but on the heavier sorts of lands, where the turnip husbandry cannot be so well introduced, cole, clover, and bean crops, may often be interposed between those of the grain kinds with the most propriety and advantage. And it would seem that the interposition of green crops ought on the whole to be more frequent in the former sorts of soil than in those of the latter, on account of their containing, in general, a less proportion of vegetable matter. It is often attended with great advantage to apply some sort of manure, such as lime, with the second crop of turnips in cases of these kinds. It has been observed by Mr. Young, that upon high moors, in undertaking new improvements, it may be of singular importance to gain straw. In that case, to sow cats upon the first burnt lands may be admitted, but in general it is much more correct to leave the ashes ploughed in for sowing turnips, upon all the land burnt in March, April, or May. This preparation is unexceptionable for potatoes, so that if this root be wanted, it may be planted in April on the land burnt in March.

It is stated to be the practice in some of the western districts, where the method of paring and burning is much practised, and in high estimation, that old sainfoin lays, and all such swards as are of a sufficient texture, are usually broken up in this way. Turnips are frequently the first crop; and from the freshness of the land, and the good effects of the ashes, a large crop is mostly produced. But as in those cases the time is too short to get the land in proper tilth for the succeeding crops of barley, grass feeds, and other similar crops, it is often adopted as a better method to sow wheat in the first instance on one ploughing; after which, from the ashes being still fresh in the ground, a crop of turnips may be as certainly depended on, and there is a sufficient length of time to get the land into a complete state of tilth. Mr. Young speaks of this as the best method, on account of the danger of grain crops being destroyed by the red worm, which abounds much in such layers. Wheat stubbles, of the more grassy kinds, which will produce a tolerable quantity of ashes, are also frequently pared and burnt for turnips with a considerable degree of success. In short, when this practice is properly followed up with the turnip and clover husbandry, its good effects cannot, it is conceived, be disputed in any respect. And in other districts cole-feed is sown on a shallow ploughing, and never harrowed. This is intended either for a crop of seed, or for sheep-food: in the latter case, it sells in some places for a guinea an acre; in the former, for two or three guineas. Oats are then sown; the crop is productive, and the land, if well laid down to grass, becomes good meadow. But the management in this respect is frequently, it is observed, very bad, only clover and ray-grass being sown, and after

PARING.

fix or seven years pared and burnt again; instead of which, if proper seeds were sown, the land would be ever after in a state of improvement. On this, Young remarks, that, one peculiar circumstance attending the breaking up of grass lands, whether old turf or sainfoin lays, in this manner, is the bringing them into order for turnips with only one ploughing; and it is a general and very just observation, both in the north and west of England, where this husbandry is most common, that turnips scarcely ever are known to fail on burnt lands: the fly on such is nearly unknown. Now any farmer must be sensible of the vast importance of thus bringing turf lands by only one ploughing to a turnip crop; much tillage is thus saved as well as a great expence, and the turnips are generally a crop that repays the expences of the operation with profit. In a word, this husbandry deserves the warmest praise.

An able writer states, that where there are poor, wet, cold, hungry pastures and neglected meadows, over-run and filled with all sorts of rubbish, and abounding with too few good plants to render their improvement easy without breaking up, that these should be pared and burnt; not to keep under the plough, to be exhausted and ruined, which is infallible, and the land left in a worse state beyond all comparison than it was before, but to be laid immediately to grass, that is, as soon as the course of husbandry necessary will admit. This, it is conceived, ought to be without variation, under any pretence whatever, in this course of crops: 1st. Pare and burn for turnips to be fed on the land with sheep: but in moist-bottomed lands, rape will often succeed better than turnips: and the sheep feed better with rape upon such lands. 2dly. Oats; and with these oats the grass seeds should be sown. The oats and the turnips, it is asserted, would more than pay all the expence of a previous hollow draining, should that be necessary; of the paring and burning, and every other charge; and the change, from a very bad pasture to a very fine one, would all be neat profit. The tenant, it is contended, would be greatly benefited, and the landlord find his estate improved, if let, as farms ought to be let, with an absolute exclusion of selling a lock of hay under any pretence whatever. And that this method is practised with great success in the fen land in Lincolnshire, the business being performed by means of the plough, and cole-seed afterwards sown. In some cases, horses and ploughs are found, and the labour put out, which, including a ploughing in order to turn in the ashes, is done at seven shillings an acre: the cole is fed with sheep, and is worth three pounds an acre; but the selling price forty to fifty shillings. Then oats, eight quarters an acre, and ten quarters have been had; then cole and oats again; being laid down with fourteen pounds of white clover, and one peck of ray grass, lets at twenty shillings. It is found to be a great and lasting improvement of the land. This is conceived to be a low estimate, from the land keeping five sheep an acre, from Lady-day to Michaelmas, and one and a half on the acre in the winter. Where then, it is inquired, is the supposed mischief of this practice?

And there are other sorts of lands, as dry, rough sheep-walks, covered with ling, furze, broom, &c. which should also be broken up in the same manner, but universally to be laid down again with the grasses suitable to the soil and to sheep. On weak, thin, staped land, two crops of corn, after paring and burning, may often be pernicious. Perhaps they might be well laid down without a single one, which would be a better method of management. It is also supposed by some able agricultors, that it would be better to take, in such cases, two or three successive crops of turnips, in order to completely eradicate all the seeds of

the ling, furze, and broom, before the land is laid down to grass, as otherwise these plants may appear with redoubled vigour. These observations seem just, and to be founded in good sense, reason, and experiment; they place the absurdity of indiscriminately condemning this mode of agricultural improvement in the clearest point of view; as the injury that may take place in some cases may be occasioned by an injudicious and improper method of cultivation. In Kent, Mr. Boys observes, that, of all the improvements in the cultivation of land that have hitherto been made use of in that district, this stands foremost; some of the very worst land having been made to produce excellent crops; and poor chalky downs, of scarcely any value in their original state, are by it made to produce good turnips and clover, and crops of corn often equal in value to double the fee simple of the land. Instead of the land being injured by the operation, as some theoretical writers have imagined, provided it be under a proper system of management and fairly dealt by, it is put into a progressive state of improvement from the time of its surface being burnt. It has frequently happened, that land after burning has been sown with corn four or five years in succession without being folded with sheep, or any part of its produce ever returned in manure; even charlock and other weeds have been suffered to remain, by which it has been annually burthened with a double crop: hence it has been left in an impoverished state, and the burning is unjustly condemned for the mischief done by the negligence and rapacity of the cultivator. Let the land, when burnt, be perfectly cleaned from charlock and other weeds, by growing turnips until the weeds are totally eradicated by hoeing, &c. Let the turnips be fed off the land, by sheep lying on the land day and night; then sow it with barley and clover: the latter to be fed off with sheep, folding them on the land for wheat. Lastly, return the straw produced upon the land in manure, mixed with clay or loam, or any other fresh earth that is near at hand, for a second Norfolk rotation, which may be repeated; or the land may be sown with sainfoin, to remain till a turf is formed fit for paring and burning again. This plan being pursued, the practice of burning the soil will not give any cause of complaint either to landlord or tenant. Theorists exclaim that by paring and burning, the staple of the land is reduced, and the soil is watted; which may be somewhat true: but all this is very immaterial, if fine crops of corn can be produced where none ever grew before, and the land at the same time be improved.

Mr. Young, in speaking of cropping repeatedly with white or grain crops after paring and burning, strongly remarks, that if a dung-hill were given to a bad farmer, and it was used on similar principles, it would almost equally exhaust the soil; yet who has found out that dunging land is bad husbandry? Paring and burning give a dung-hill also; it is bad management alone that converts it into an evil. Make it the preparation for grass, and all is safe. It has also been stated, that the practice of paring and burning is so advantageous in some cases, as to render lands, the produce of which was not worth two shillings and sixpence, in the course of four years capable of producing two valuable crops of corn, and as many turnips, and to be rented at twenty shillings *per* acre.

A very intelligent farmer, in the fifteenth volume of the Annals of Agriculture, has given the following statement of the expences and returns of breaking up fresh land of a stiff loamy quality by means of this process, and cropping it with oats and peas. The summer in this instance was lost for preparing the ground for a wheat crop. The crops are here charged with rent and taxes for two years.

I. *Oat Crop.*

	£	s.	d.
Rents <i>per</i> acre, two years poor rates, and road levy	1	4	0
Striking the bushes and levelling willocks	0	10	6
Paring and burning, and spreading the ashes	1	10	6
Once ploughing and harrowing	0	12	0
Seed oats four bushels, at 29s.	0	11	0
	<hr/>		
	4	8	0
	<hr/>		
Sold seven quarters of oats at 1 <i>l.</i> 1 <i>s.</i> 0 <i>d.</i> <i>per</i> quarter	7	7	0
Seeds and expences	4	8	0
	<hr/>		
Profit <i>per</i> acre	2	19	0

Straw not charged, but set against the expences of mowing and threshing, which it more than defrayed.

II. *Pea Crop.*

	£	s.	d.
Expences the same as for the oat crop, with the addition of 5 <i>s.</i> for four bushels of seed at 3 <i>s.</i>	4	3	0
Sold four quarters of peas at 32 <i>s.</i>	6	8	0
	<hr/>		
Profit	2	5	0

And from the ameliorating nature of pea crops, and the excellent state in which they leave the land for a crop of wheat, they will, it is supposed, be on the whole more advantageous than the oats.

In Yorkshire, the expences and profits on cold, mossy, old meadow land, with a north-east aspect, cultivated in this manner for turnips, as given in the same work by the writer of the Middlesex Survey, is this :

Expences and Profits.

	£	s.	d.
Paring, drying, and burning, with spreading the ashes, <i>per</i> acre	0	15	0
Ploughing once over and harrowing	0	8	0
Seed $\frac{3}{4}$ lb. and sowing with weeding, which in land thus prepared is but little required	0	1	0
Rent, tythe, taxes, and assessments	0	18	0
	<hr/>		
	2	2	0
	<hr/>		
Turnip crop plentiful, large sizes, about a foot distance, estimated in feeding stock by the acre at	5	0	0
Seeds and Expences	2	2	0
	<hr/>		
Profit <i>per</i> acre	2	18	0

It is noticed, that in that neighbourhood, the usual agistment price is sixpence a week for fattening wethers, and three-pence a week for hogs (lambs of the preceding year) to eat the broken turnips and shells left by the wethers.

These expences of the process of paring and burning are much too low for the present period.

In what respects the kind of grafs-seeds that may be proper after this operation, they must probably be different, according to the nature and quality of the soil. In the light forts of land, those kinds of grafses that cover the earth well may be most suitable. On chalky soil, sainfoin may frequently be employed. In the fenny forts of soil, marl-grafs with a little meadow fox-tail grafs, will often be found beneficial. And a small mixture of the finest ray-grafs, or darnel, is likewise found to answer well. Marl-grafs, though it has some resemblance to red clover, is materially different in its effects; the former being found unfriendly to all natural grafses, while the latter is quite the reverse. This is a fact that has been established by extensive experience. One other very material advantage resulting from the cultivation of marl-grafs, is, that neat cattle are not so liable to swell by eating it in moist weather, as they are with red clover. The heavy or clayey soils will in most cases require the largest proportion of grafs-seeds to be sown upon them, in laying them down after being prepared by the process of paring and burning.

In short, it may be concluded, that from the great ease and expedition with which all those coarse forts of land, which have been mentioned as proper for being broken up by this means, are rendered fit for the growth of crops of different kinds, such as those of grain, rape, turnips, &c. as well as from the very abundant produce which is generally the case after such preparation, that where proper attention is paid to the process, and the method and management afterwards, it must be highly beneficial, and probably the best that can be adopted. It has indeed been remarked, in the able Survey of the North Riding of Yorkshire, that when the husbandry that succeeds paring and burning is judicious, no mode of improvement can be compared with it; for it is *certain* to produce *great* crops of turnips and grain, and these are *certain* means of future fertility in the hands of a judicious farmer.

PARING-Plough, an implement of great utility in many cases, where the system of paring and burning is practised. At *figs.* 1 and 2 in the plates on ploughs, are two side views of a paring-plough, recommended by Mr. Young for rough land. It has the share six inches in width, by means of the pivot *a*, which screws into the holes *b*. It is said to be capable of performing its work in a good manner, where the fen paring-plough cannot stir at all. It is said to have been in use at Sheffield Place, the seat of lord Sheffield, thirty years ago; having been obtained from Cheshire, where it had been made use of on the farm of sir George Warren. See the preceding article.

PARING-Spade, a sort of spade which is made use of in paring land for burning, being made with a crooked handle, so as to be pushed forward in using by the breast. It is sometimes termed a breast-plough.

PARING the Hoves of Horses, in the *Manege*, a kind of operation in shoeing, performed on the feet of these animals, with the intention of adapting or suiting them to the shoes. The business is executed with a sort of edge tool, which is called a butteris, and is often done to the great injury and prejudice of their feet. As it is unquestionably the object in shoeing horses to preserve the hoof, as well as to defend the sole, it cannot, of course, be necessary to pare away what is wanted to be kept in a state of preservation. This is consequently a practice that should never be submitted to either with farm or other horses, except in cases where the horny sole is so very uneven, that the shoes cannot be otherwise made to bear equally upon the feet, which would take off

off from the requisite firmness of them. It may perhaps sometimes be proper in such instances as these, but in other cases it is highly absurd and mischievous, being not unfrequently the occasion of great injury and inconvenience to the animals. See HORSE and SHOING.

PARING the Sole, in shoeing horses, an improper operation which is too often performed on the horny parts of the feet of these animals in fixing the shoes upon them, and from which injury not unfrequently arises.

PARINO, in *Geography*, a town of Mexico, in the province of Culiacan; 42 miles E. of St. Miguel.

PARIPE, a town of Brasil, in the government of Bahia.

PARIPURA, a river of Brasil, which runs into the Atlantic, S. lat. $9^{\circ} 42'$. W. long. $35^{\circ} 26'$.

PARIS, MATTHEW, in *Biography*, an early English historian, was a monk of St. Albans, who flourished during the middle of the 13th century. He is described as a man of almost universal accomplishments; he was a mathematician, poet, orator, theologian, painter, and architect. He was employed to visit the monasteries and revive their decayed discipline, and without hesitation he censured what he found wrong in all orders of people. His principal work is his "*Historia Major*," which is a history of English affairs from the conquest to the 43d year of Henry III. It was published by archbishop Parker at London in 1571. It is supposed originally to have had a first part commencing with the creation, and coming down to William the Conqueror. It is reckoned a very valuable work, composed with exactness and much candour; and displaying great freedom in exposing the usurpations of the Roman see, upon the prerogatives of the English kings, on which account it incurs the censure of Baronius, who otherwise is inclined to give it great commendation. It was republished with additions, and the author's lives of the abbots of St. Albans, in 1606, by Dr. William Watts. Matthew Paris also composed a "*Historia Minor*," being an abridgment of the former, with additional circumstances. He wrote other works, which are lost or lie concealed in libraries.

PARIS, FRANCIS, generally known by the name of the *abbé Paris*, and rendered famous for a time by the impostures and delusions which were practised at his tomb, was the eldest son of a counsellor to the parliament, and born at Paris in the year 1690. His father wished to bring him up to the law, in order that he might have him for an assistant in his business, and that eventually he might become his successor, but he preferred embracing the ecclesiastical life, and was accordingly admitted to deacon's orders. Upon the death of his father, he renounced all claim to his patrimonial inheritance, in favour of a younger brother, and devoted himself to what he thought was a life of meritorious poverty. Having made trial of different places of solitude, he at length fixed upon a house in the suburb of St. Marcel, at Paris, where he spent his time in prayer, and the most rigorous acts of penance; hence he acquired a character for extraordinary sanctity with the superstitious populace, who thought such mortifications the very perfection of virtue. He died in 1727, at the age of thirty-seven. His brother erected a tomb to his memory in the cemetery of St. Medard, and so highly was his piety esteemed, that many persons who had, during his life, been edified by his instructions, went to visit his monument, and some pretended to be cured of their diseases on their approach to the grave. This induced others to do the same, and so great was the delusion, that government was under the necessity to order the cemetery to be closed up with lofty walls. Accounts were published of at least an hundred miracles said to have been wrought on the spot. The *abbé Paris* was author of a

"*Commentary on the Gospel of St. Matthew*," and "*An Explication of some of St. Paul's Epistles*."

PARIS, in *Geography*, the metropolis of France, is situated on a plain, through which the river Seine flows in a most pleasing and picturesque manner.

History and Extent.—Cæsar is the first historian who makes mention of this city. In the seventh book of his Commentaries, that conqueror relates that he sent his lieutenant Labienus towards Lutetia, which was the name given by the Gauls to the capital of the Parisii. It was then entirely contained within that island on the Seine, which, at the present day, is called l'Île du Palais; and in comparison with the capitals of the other provinces of Gaul, Lutetia was but a sorry village; its houses were small, of a round form, built of wood and earth, and covered with straw and reeds. When the Romans had conquered Lutetia, they embellished it with a palace, surrounded it by walls, and erected at the head of each of the two bridges leading to it, a fortress, one of which stood on the site of the prison called "Le Grand Châtelet;" and the other, on that of "Le Petit Châtelet." The Yonne, the Marne, and the Oise, being rivers which join the Seine, suggested the idea of establishing a trading company by water, in order to facilitate, by those channels, the circulation of warlike stores, and provisions. The merchants were called "Nautæ Parasiaci." The Romans also erected, near the bank of the Seine, a magnificent palace and aqueduct. This palace was called Thermæ, on account of its tepid baths. Julian, being charged to defend Gaul against the irruptions of the barbarians, took up his residence in these Thermæ in the year 360, two years before he was proclaimed emperor, in the square which was in the front of the palace. "I was," says he, in his work entitled "*Misopogon*," or *the Enemy of the Beard*, which, says Gibbon, still remains a singular monument of the repentment, the wit, the humanity, and the indiscretion of Julian, "in winter quarters in my dear Lutetia. Thus is named, in Gaul, the little capital of the Parisii." And by another ancient writer, it is described as an inconsiderable island, surrounded by walls, the foot of which is bathed by the river. The entrance to it, on each side, is by a wooden bridge. Towards the middle of the fifth century, this city passed from the dominion of the Romans to that of the Franks, and in 508, Clovis declared it the capital of his kingdom, and he contributed very much to the embellishment of it. Charlemagne founded in it a celebrated school, and in a short time after, another was established in the abbey of "St. Germain-des-Près." In the course of the ninth century, it was besieged and pillaged three times by the Normans. Philip Augustus surrounded Paris with walls, comprising in the enclosure a great number of small towns and hamlets in its vicinity. The undertaking occupied about twenty years, having been begun in 1190, and finished in 1211, and this monarch was the first who caused the streets to be paved. The wars with the English required new fortifications, and in the reigns of John, and Charles V., in the fourteenth century, ditches were dug, and the Bastile erected. Francis I., the restorer of literature and of the arts, neglected nothing that might conduce to the embellishment of this capital. He caused new streets to be made, many Gothic edifices to be pulled down, and was, in France, the first person who revived Greek architecture, the remains of which, buried by the hand of time, or mutilated by that of barbarians, being collected, began to improve the genius of celebrated artists, and in the sequel led to the production of many fine master-pieces of art. The successors of Francis executed a part of his projects, and

this extensive city imperceptibly lost its irregular and Gothic aspect. Henry IV. was the first of the kings of France who embellished Paris with regular squares, or open spaces, decorated with the different orders of architecture. Having nearly finished the Pont Neuf, he built the Place Royale, and also the Place Dauphiné. During the reign of this king several handsome streets were built and finished in a year. In the reign of Lewis XIV. Paris knew no limits. Its gates were converted into arcs of triumph, and its ditches, being filled up and planted with trees, became public promenades. Paris, however, was not the favoured city of this prince, for had he expended on it a fourth part of the money which he lavished on Versailles, it would have become the most astonishing city in Europe. It must however be admitted, that its great extent and population, magnificent edifices, celebrated national establishments of learning and science, rich libraries, curious cabinets, where lessons of knowledge and genius present themselves to those who have a taste for them, together with its theatres, and other places of public entertainment, have long rendered Paris deserving of the admiration of enlightened nations. Before the revolution, Paris contained 46 parish churches, and 20 others answering the same purpose, 11 abbeys, and 133 monasteries or convents of men and women, 13 colleges, 15 public seminaries, and 26 hospitals. To these must be added the three royal habitations, the Louvre, the Tuilleries, and the Luxembourg, also the Hotel des Invalides, the Palais Royal, and the Palais Bourbon. Since the revolution several of these buildings have been destroyed; almost all the monasteries and convents, together with the churches belonging to them, have been sold as national property, and either demolished for the sake of their materials, or converted to different uses.

Population.—The number of houses in Paris, many of which are from five to eight stories in height, has been estimated at upwards of 80,000, and by an official statement a few years since, the number of inhabitants, exclusive of foreigners, was about 630,000. During the last year of the republic, the number of males born at Paris was 9296; and that of females 9177, making the total number of births to be 18,473, of which 3644 were born out of wedlock, that is, nearly one in five. The number of persons who died in the same period was 10,446 males, and 10,301 females, making together 20,747, causing an annual decrease in the population of 2274. The number of marriages was 3826, and that of divorces 720, nearly two in eleven.

Divisions and Barrières.—Paris is divided into twelve mayoralties, each of which is presided over by a central officer of the municipal police. The faubourgs retain their ancient names, but those of many of the streets have been changed since the revolution. In proportion as the limits of the capital became extended, the real gates were removed, but they re-appeared under the name of *barrières*. These edifices, many of which were very costly, were constructed during the ministry of Calonne, under the direction of Ledoux, the architect, who has taken pleasure in varying their form and character. One represents an observatory; another, a chapel; some have the appearance of rusticated buildings; others of temples. There are about sixty of these barrières, which, during the revolution, were frequently shut to serve the purposes of party, and to favour the arrest of particular persons: they are now occupied by custom-house officers, whose business is to collect duties, and to watch that no contraband goods find their way into the city.

The Seine and Quarries.—The river Seine, to which we

have already referred, is justly esteemed one of the most beautiful in France; it is of a light sea-green hue, a singularity which adds to the effect of the noble bridges and quays. This colour is not observable before the junction of the Seine and Marne, where it may be clearly observed to belong to the latter stream, the Seine being of a brown or muddy appearance, while the green hue of the Marne continues unpolluted for a considerable space. Towards the north this plain is bounded by a semicircular range of gentle elevations, mostly composed of gypsum, or alabaster, which by combustion yields the noted *plaster of Paris*. This substance is much used in the construction of houses. The calcareous free-stone, with which the superior hotels are built, is drawn from quarries on the south of the city. The ancient quarries are without the southern bounds of the original city, in the form of catacombs, or narrow passages of great regularity.

Soil, Climate, and Streets.—The soil on which the city stands is various. On the south of the river it is calcareous free-stone, frequently intermixed with shells; while on the north, as far as the streets that rise in the skirts of Mont Martre, it consists of alluvial sand to a considerable depth, followed by the gypsum of Mont Martre. "It is," says Mr. Pinkerton, "a well-known singularity in geology, that the banks of the rivers are often composed of different substances, owing, probably, to some natural incoherence, which afforded an easier course for the water to penetrate." The fossil bones found at Mont Martre are, by Cuvier, supposed to belong universally to different species and sizes of an animal now extinct but approaching nearest to the tapir of America. And the sea-shells, some of them unknown at present in the Atlantic, discovered at Grignon, to the west of Versailles, in a bed of sand, under a layer of solid lime-stone, indicate changes in the globe which it is impossible to account for. The climate of Paris differs from that of London in the superior heat of the summer, which matures the grape in the open vineyard, a circumstance totally unknown in England. The general warmth of the year is much the same at Paris as at London, the superior cold of the winter balancing the heat of the summer. In the winter of 1802-3, the river Seine was frozen over during a fortnight, and the cold was intense. Pinkerton says, that he always thought that the environs of Mont Martre were colder than any other part of Paris, not only from the greater height of the situation, but from the proverbially cold nature of the alabaster. In Paris the streets are very narrow and crowded, yet even amidst the inconveniences arising from these circumstances, the superior magnificence of the houses and public buildings is very striking, especially to a person who, after a long residence at Paris, returns to London. While the latter is enveloped in clouds of smoke, none is perceivable at the former, except at the moment of lighting the fires in the morning; and a spectator from a neighbouring eminence is dazzled with the white splendour of the houses and towers. The Parisians have an universal prejudice against the use of coal, which they conceive to be very unhealthy, and hurtful to the lungs. The smoke of wood, though more prejudicial to the furniture, the colour of which it soon changes, is yet scarcely visible in the open air, while that of coal blackens the surrounding objects, as appears but too certainly from the dark hue of our London churches and other stone buildings. The Parisian edifices, on the contrary, are of such dazzling whiteness, that in the summer the eye is fatigued, and seeks for the repose of some milder colour.

Public Buildings.—It has often been made a question, whether Paris or London is to be reckoned the finer city; according,

ording, however, to a well-informed traveller, London is said to be the more imposing to the eye as a whole, but Paris will better bear dissection. The wide streets and broad foot pavements in London give a general impression of grandeur, but the public buildings that can be noticed as really fine ones are few. At Paris, while the city does not give an impression of grandeur as a whole, the objects which, taking it in detail, claim particular attention, are grand and numerous. There is nothing in London which can be compared to the quays at Paris along the Seine, from the Pont Neuf to the end of the town on the west, particularly the quay on the right bank; along which run, in succession, the Louvre, the great gallery of which joins it to the Thuilleries, the Thuilleries itself with the gardens, the Place de la Concorde, and the Champs Elysées. The origin of the Louvre, as well as the etymology of its name, is lost in the darkness of time. It existed under that name in the reign of Philip Augustus, who surrounded it with ditches and towers, and made it a fortress. The great tower of the Louvre, celebrated in history, was insulated, and built in the middle of the court. All the principal feudatories of the crown derived their tenure from this tower, and came hither to swear allegiance, and pay homage. It was likewise a prison previously prepared for them, if they violated their oaths. The Louvre received also from this enormous tower a melancholy and terrifying aspect, which rendered it not at all adapted to a royal residence. Charles V. endeavoured to enliven it, and made it commodious for those times. Several foreign monarchs successively lodged in it, such as Manuel, emperor of Constantinople; Sigismund, emperor of Germany; and the emperor Charles V. The large tower of the Louvre, which, at different periods, had served as a palace to the kings of France, as a prison to the great lords, and as a treasury to the state, was at length taken down in 1528. The part of the palace which at present is denominated the Old Louvre, was begun under Francis I., but was first inhabited by Charles IX., under whom it became the bloody theatre of treacheries and massacres, on the infamous St. Bartholomew's day, which time will never, and ought never, to efface from the memory of mankind, and which, till the merciless reign of Robespierre, were unexampled in the history of that country. In after-times this palace became the quiet and happy cradle of the arts and sciences, the school for talents, the arena for genius, and the asylum of artists and literati. The centre pavilion over the principal gate of the Old Louvre, was erected under the reign of Lewis XIII. from the designs of Mercier, as well as the angle of the left part of the building, parallel to that built by Henry II. The eight gigantic *cariatides* (see the article), which are to be seen there, were sculptured by Sarrafin. The several parts of this palace which were constructed under the reigns of Charles IX. and Henry III., partake of the taste of the times, in regard to the multiplicity of the ornaments; but the interior announces, by the majesty of its decorations, the refined taste of Lewis XIV. The part of the Louvre, which, with two sides of the old building, forms the perfect square about 400 feet in extent, called the New Louvre, consists in two double façades, which are still unfinished. The colonnade of the Louvre, which is the master-piece of French architecture, and the admiration of Europe, was built by Perrault. The façade of this colonnade, which is of the Corinthian order, is about 525 feet in length; it is divided into two peristyles, and three avant-corps. The principal gate is in the centre avant-corps, which is decorated with eight double columns, crowned by a pediment, whose cornices are composed of two stones only, each fifty-four feet in length by eight

in breadth, though no more than eighteen inches in thickness. They were taken from the quarries of Meudon, and formed but one single block, which was sawed in two. The other two avant-corps are ornamented with six pillars, and two columns of the same order, and disposed in the same manner. On the top, instead of a ridged roof, is a terrace, bordered by a stone balustrade, the pedestals of which are intended to bear trophies intermixed with vases. In front of this magnificent colonnade, a multitude of salesmen erect their stalls, and display their various articles. This contrast still speaks to the eye of the attentive observer. It is the image of all the rest,—grandeur and beggary side by side. The front to the river is handsome, but not to be compared to the other, and that is unfinished. The other two fronts are so encompassed by houses, that they are scarcely seen at all. The inside of the court, like the rest of the building, will be handsome, and extremely grand, if it be ever finished.

The great Gallery which joins the Louvre to the Thuilleries is more than 1200 feet long. The Palais des Thuilleries was so called, because a tile-kiln formerly stood on the site where it is erected. At that time, this part of Paris was not comprised within its walls, nothing was to be seen in the vicinity of the tile-kiln, but a few coppices and scattered habitations. The construction of this palace was begun in May 1564. At first, it consisted only of the large square pavilion in the centre of the two piles of building, which have each a terrace towards the garden, and of two pavilions, by which they are terminated. Henry IV. enlarged the original building, and in 1600 began the grand gallery which joins it to the Louvre. Lewis XIII. made some alterations in the palace, and in 1664, Lewis XIV. directed it to be finished, by making the additions and embellishments which have brought it to its present state. These deviations from the first plan have destroyed the proportions required by the strict rules of art; nevertheless the architecture, though variously blended, presents, at first sight, an *ensemble* which is magnificent and striking. The whole front of the palace consists of five pavilions, connected by four piles of building, standing on the same line, and extending for the space of more than 1000 feet. The first order of the three middle piles is Ionic, with encircled columns. The two adjoining pavilions are also ornamented with Ionic pillars; but fluted, and embellished with foliage from the third of their height to the summit. The second order of these two pavilions is Corinthian. The two piles of building, which come next, as well as the two pavilions of the wings, are of the Composite order, with fluted pillars. An iron palisade divides the court of the Thuilleries from the Caroufel; in this are three gateways, the two end ones of which are ornamented by the four celebrated bronze horses, supposed to have been the work of Lysippus, and which, previously to their occupying their present station, had successively ornamented the arch of Nero at Rome, the Hippodrome at Constantinople, and the church of St. Mark at Venice. The gardens of the Thuilleries are always open to the public, and are the principal promenade of this part of the town. Among the decorations of the gardens are many fine statues, bronzes, and casts. The Place de la Concorde, at the end of the gardens of the Thuilleries, between them and the Champs Elysées, is one of the finest spots in Paris. The Garde Meuble, which forms one side of the Place, is little inferior in beauty to the grand façade of the Louvre; the design of it seems indeed to have been taken from the latter building, only that in the Garde Meuble there is an arcade below the colonnade which is not the case in the Louvre; a street leading to the Boulevards divides the length

of this building. At the end of this street is seen the church of La Madeleine, begun some years ago upon a very beautiful design, but like many other fine buildings it is only half finished. Four very fine marble groups decorate the gates which lead from the gardens of the Thuilleries, and from the Champs Elysées to the Place de la Concorde. Those on each side the gates of the Thuilleries are Mercury and Fame; those to the Champs Elysées are wild horses broken by slaves.

Bridges.—Of all the bridges, says Sterne, it must be acknowledged that the grandest, the lightest, the longest, and the broadest, that ever joined land to land, is the Pont Neuf. The first stone of this bridge was laid by Henry III. in 1578, and the foundation of the piles was begun to be formed on the opposite side, when the troubles of the League forced the architect, De Cerceau, to withdraw to foreign countries. The work was not resumed till the reign of Henry IV.; it was finished in 1674. The length of the bridge is 1020 feet and its breadth 72 feet, which is sufficient to admit of five carriages passing abreast. It is formed of twelve arches, seven of which are on the side of the Louvre, and five on the side of the Quai des Augustines, extending over the two channels of the river, which is wider in this place, from their junction. In 1775 the parapets were repaired, and the foot-way lowered and narrowed. Soufflot, the architect of the Pantheon, availed himself of the opportunity to build, on the twenty half-moons which stand immediately above each pile, as many rotundas, in stone, to serve as shops. On the outside, above the arches, is a double cornice, which attracts the eye of the connoisseur in architecture, notwithstanding its mouldering state, on account of the *fleurons* in the antique style, and the heads of sylvas, dryads, and satyrs, which serve as supports to it, at the distance of two feet from each other. As the mole that forms a projection on this bridge, between the fifth and seventh arch, stands facing the Place Dauphine, which was built by Henry IV. it was chosen for erecting to him a statue, which was the first public monument of the kind that had been raised in honour of French kings. To the east of Pont Neuf the small islands in the middle of the Seine are connected to its banks by several bridges; to the west there are two; of these the first is the Pont National, formerly called the Pont Royal, from its having been built by Lewis XIV., and the expences defrayed out of the privy purse, to supply the place of one of wood, situated opposite to the Louvre, which was carried away by the ice in 1684. It is reckoned one of the most solid bridges in Paris, and, till the existence of the Pont de la Concorde, was the only one built across the river, without taking advantage of the islands. It stands on four piles, forming, with the two abutments, five elliptical arches of a handsome sweep. The span of the centre arch is seventy-two feet, that of the two adjoining sixty-six, and that of the two outer ones sixty. On each side is a raised pavement for foot passengers, in the middle there is breadth sufficient to admit of four carriages passing abreast. The north end of the Pont National faces the wing of the palace of the Thuilleries, distinguished by the name of the Pavillion de Flore. From the middle of this bridge the city is seen in a most striking point of view. Following the banks of the Seine towards the west we next come to the Pont de la Concorde, which was begun in 1787, and finished in 1790. It is 462 feet in length, by forty-eight in breadth. Like the Pont National it consists of five elliptical arches, the span of the centre arch is 96 feet, that of the collateral ones 87, and that of the two others near the abutments 68. Under one of the latter is a tracking-path for the facility of navigation.

Boulevards.—This is the name given to the promenades

with which Paris is, in part, surrounded, for an extent of more than 12,000 yards. They are distinguished by the names of the Old and New. The Old, or North Boulevards, commonly called Les Grands Boulevards, were begun in 1536, and intended to serve as fortifications against the English, who were ravaging Picardy, and threatening the capital. Hence the name Boulevard, which signifies a bulwark. The extent of the Old Boulevards is about 5000 yards: they were first planted in 1660, and are formed into three alleys by four rows of trees. The middle alley is appropriated to carriages and persons on horseback, and the two lateral ones are for foot passengers. The New Boulevards, situated to the south, were not finished till 1761: they are about 7000 yards in extent, and though laid out much in the same manner as the Old, there is little resemblance between them. Near the middle of the North Boulevards stand two edifices, which owe their erection to the vanity of Lewis XIV. In the gratification of that passion did he console himself for his numerous defeats and disappointments, and the age in which he lived being fertile in great men, his display of it was well seconded by their superior talents. Previously to his reign, Paris had several gates, some of which being taken down, arches of triumph, in imitation of those of the Romans, were erected in their stead, by Lewis the Great, in commemoration of his exploits. Such was the origin of Porte Saint Denis. The magnificence of the architecture of this building classifies it among the first public monuments in Paris. It consists of a triumphal arch, insulated in the manner of those of the ancients: it is 72 feet in diameter as well as in elevation, and was executed in the year 1672. On each side of the principal entrance rise two sculptured pyramids, charged with trophies of arms. Underneath each of the pyramids is a small collateral passage for persons on foot. The arch is ornamented with two bas reliefs: the one facing the city represents the passage of the Rhine; the other the capture of Maestricht. On arriving from Calais, you enter Paris by the Porte St. Denis; and it was by the Porte St. Denis that kings and queens made their public entry. On these occasions, the houses in all the streets through which they passed were decorated with silk hangings and tapestry, as far as the cathedral of Notre Dame. Scented waters perfumed the air in the form of jets d'eau, while wine and milk actually were made to flow from different public fountains. At a short distance from Porte St. Denis is Porte St. Martin, which was erected in 1764, as a triumphal arch, but it is not at all equal in magnificence to the other. It is pierced with three openings; the centre one is eighteen feet wide, and the two others nine. The whole structure, which is fifty-four feet both in height and breadth, is rusticated, and in the spandrels of the arch are four bas reliefs, which are crowned by an entablature of the Doric order, surmounted by an attic. The Porte St. Martin is the grand entrance into Paris from all parts of Flanders.

Public Libraries.—The most splendid of these collections has had different names according to the nature of the government. Under the kings it was the Royal Library; during the republic it was called the National Library; and it is now the Imperial Library. The building itself is very large, its length being more than 500 feet, and its breadth upwards of 120. The principal floor of the building which surrounds the large court is entirely filled with books, from the bottom to the ceiling. At the window, and in different parts of one of the wings, tables are placed for the accommodation of readers. The library is open every day from ten till two. In a small recess of one of the four sides of the library, is a group of about five feet in height,

PARIS.

and six in breadth, erected in the time of Lewis XIV. It represents Parnassus with Apollo and the Muses. There are likewise in the library some busts of celebrated French literati. This library traces its origin to a very remote era. Charles V. added about 900 volumes to a small collection left by his father John. This collection, placed in a tower of the Louvre, was called "La Tour de la Librairie," and was lighted every night by thirty small chandeliers and a silver lamp, so that students and the learned might be accommodated every hour. The library was after this dispersed; for in 1429, when Paris was in the hands of the English, under the command of the duke of Bedford, that nobleman bought the 150 volumes, of which it consisted, for 1200 livres. Lewis XI. collected the scattered remnants of this library, and profited by the resources which the invention of printing presented to him. Charles VIII. added to it what the conquests of Italy allowed him to collect. Lewis XII. enriched it with the library of Petrarch: Francis I. with Greek manuscripts; and Henry II. augmented it, in consequence of the decree of 1556, enjoining booksellers to furnish the royal libraries with a copy on vellum of every book published. Hence it became so large, that many years ago it was allowed to equal, if not to excel, every other collection extant. It is now much enriched by the spoils of Venice, Florence, and Rome. It consisted, fifteen years ago, of more than 300,000 volumes, and is divided into five departments. The first, containing the printed books, is on the first story. The second department comprises manuscripts, to the number of 80,000; of which 25,000 are in learned and foreign languages, and 30,000 on the history of France, chiefly from the reign of Lewis XI. The five great rooms on the second story contain the genealogies, and are filled with 5000 port-folios. The cabinet of medals is decorated with three large pictures, representing Thalia, Calliope, and Terpsichore. There are also three pictures representing Psyche, the inventrix of the flute, led by Hymen, and the three patrons of the Muses. The cabinet of antiques, situated on the third story, contains busts, vases, inscriptions, and instruments of sacrifices collected by the celebrated Caylus. Opposite to the entrance, various Egyptian antiquities meet the eye. At one end of the room are warlike instruments of different Indian nations. On the floor stands a large antique marble table. The walls are decorated with the shields of Scipio and Hannibal. In the middle of this cabinet of antiques is a long table, covered with Etrurian vases of superior beauty. On the third floor are two apartments, which contain Etrurian vases of extraordinary magnitude, a bathing vessel of porphyry, sacrificing knives, lamps, &c. Two rooms belonging to the library are filled with a collection of 5000 volumes of prints.

The library of the Arsenal is supposed to contain 75,000 volumes, and 6000 manuscripts. It formerly belonged to the count d'Artois, now forms part of the library at the Luxembourg, and contains many MSS. beautifully illuminated on vellum. The library of the Pantheon consists of 100,000 printed volumes, and 2000 MSS., and is decorated with different marble busts of French literati. The library of St. Victor was opened in 1652, and among its numerous MSS. is a collection of the proceedings against the celebrated Jeanne d'Arc. Besides these, all the public bodies have their respective libraries, to which access may be readily had by foreigners as well as natives.

Literary Institutions.—The National Institute is the principal of the learned societies of Paris. Its main object is to improve the arts by uninterrupted inquiries; by the examination of literary and scientific labours, and by corre-

spondence with foreign and learned societies. "It is impossible," says an American traveller, "for a foreigner and a student to be a week in the French capital, without having his imagination absolutely overpowered, and his enthusiasm wound up to the highest pitch, by the eclat which he sees attendant on science and literature, and the facilities which he finds open to him for the culture of all the branches of human knowledge. For besides the libraries, and other establishments already mentioned, all of which are accessible upon the easiest terms, there are innumerable gratuitous lectures read at the expence of government at all hours in the day: a garden of plants, and a museum of natural history, the most perfect in the arrangement, and the most ample in the materials, to be found in the world; and the branches of knowledge to which they relate are daily explained to all visitors, by men illustrious for their skill and their discoveries; public exhibitions to excite literary emulation, and national rewards to give spirit to literary industry." Of the National Institute (see INSTITUTE), his imperial majesty himself is a member, and the reputation of this learned body exceeds that of any other learned society in the world. This body is but an incorporation of the old academies of Paris, and is now divided into four distinct classes correspondent to those academies. The *first* class is that of the physical and mathematical sciences; the *second*, that of the literature of France, and of the French language; the *third*, that of history and ancient literature; and the *fourth*, that of the fine arts. The members, together with the foreign associates, amount to the number of two hundred. When a nomination is to take place, the class by which it is to be made selects two candidates, between whom the emperor makes choice. Each class has one public sitting annually; at this prizes are distributed, memoirs read, &c. The first class has a private sitting every Monday, from three o'clock until six in the evening, to which strangers are admitted when introduced by a member. The members receive an annuity from government of about fifty pounds. Most of them, however, and particularly those who belong to the first class, are invested with public employment, so as to be furnished with an easy subsistence. Upon some of them the highest honours of the state have been lavished. For some time after his accession to the government, Bonaparte found the Institute the most unmanageable of all the public associations of France. It was filled with men who had taken an active part in the revolution, and some of whom were enthusiastically devoted to the principles of freedom. His efforts to mould them to his purposes, and to render them completely subservient to the consolidation and increase of his power, were for a long time ineffectual. After employing the means of intimidation without success, he had recourse to a system of patronage and corruption, which he has found much more efficacious. The laborious *savans*, and the indigent literati, were converted into senators, counsellors of state, legislators, inspectors, and even ministers, and the majority of the whole body invested with the cross of the legion of honour. A complete victory over the Institute was of some importance to the views of Bonaparte, but of a most pernicious tendency with regard to the interests of freedom and sound literature. The subordinate classes of this body embrace, with few exceptions, those who are most deservedly eminent throughout the empire for their learning. The first class, as a scientific association, ranks higher than any other in the world. The public meetings of the National Institute are held in a very extensive and magnificent room. Both its sides are adorned by beautiful colonnades, and the ceiling is finely painted and decorated. Between the columns

lums are fourteen marble statues, highly finished, of the most celebrated persons whom France ever produced, *viz.* Conde, Tourville, Descartes, Bayard, Sully, Turenne, Daguesseau, L'Hopital, Rossuel, Duquesne, Catinat, Vauban, and Fenelon. At the ends are two sitting figures of Pascal and Rollin. In the antichamber are the statues of Moliere, Racine, Corneille, La Fontaine, and Montesquieu. The hall is extremely well lighted; the floors are covered with carpets, and tables are placed parallel to the four walls of the hall, at which the members of the Institute take their places. The president of the Institute is seated at the upper end of the hall; in the middle, and rather on one side of him, is a tribune, from whom, whatever is proposed is received by the president, who does not leave his chair. The place allotted for members is surrounded by a rail, between which and the walls there is, round the hall, a row of benches, where the spectators take their seats. Each class annually proposes two prize questions, and in these general meetings the answers are made public, and the premiums distributed. The united sections of painting, sculpture, and architecture elect the pupils, who, at the expence of the republic, are to travel to Rome, in order to study the fine arts. Twenty young men are elected by the Institute to travel in France, and in foreign countries, for the purpose of studying rural economy. Six members, also, of the Institute itself, are to travel at the public expence to collect information, and to acquire experience in the different sciences.

In the Museum of French monuments, the several subjects are distributed in different apartments; and by their arrangements they exhibit the state of statuary in France from the earliest periods to the present time. They are arranged according to their respective antiquity, each department containing specimens of a single century, which is numbered at the entrance; and receiving light through the windows of painted glass, executed during the same period. The Museum of Natural History consists of a botanic garden, of a library for natural history, of a menagerie, or collection of foreign animals, and of an amphitheatre, or lecture room. Professors deliver public lectures in rotation during the summer months.

Public Instruction.—After the suppression of the colleges and universities existing under the monarchy, the National Convention, by a decree of the 14th of January 1795, established Normal schools throughout the republic. Professors and teachers were appointed to them, and it was intended, that in these nurseries youth should be prepared for the higher schools, according to the new plan of instruction. However, in the course of a few months, these Normal schools were shut up, and primary, secondary, and central schools, were ordered to be established in every department. In the primary schools, reading, writing, and arithmetic formed the chief part of the instruction. Owing to various causes, the secondary schools were not established. In the central schools, the whole of the instruction was divided into three classes or sections. In the first are taught drawing, natural history, and ancient and modern languages. In the second, mathematics, physics, and chemistry. In the third, universal grammar, the fine arts, history, and legislation. In the first class, the pupils were to be received at the age of twelve; into the second, at fourteen; and into the third at sixteen. To each central school are attached a library, a botanic garden, and an apparatus for chemistry and experimental philosophy. The professors are examined and chosen by a jury of instruction, and that choice confirmed by the administration of the department. Besides these, there are special schools, in which are taught the useful

sciences, jurisprudence, medicine, and natural history. There are likewise schools appropriated to different professions, solely devoted to the public service, and which require particular knowledge in the arts and sciences. Hence they bear the name of "Schools for public Services." In order to be admitted into any of these schools, the candidates must prove themselves qualified by the preliminary instruction required in the examinations at the competition prescribed for each of them. The pupils of these schools receive a salary from the nation. At the head of them is the *Polytechnic School*, which is the grand nursery whence the pupils, after they have attained a sufficient degree of perfection, are transplanted into the other schools for public services. Next come the *Schools of Artillery*, of which there are eight in the places where the regiments of artillery are garrisoned. The pupils who are sent thither as officers, after having been examined, apply their knowledge to the arts; to the construction of works; and to the manœuvres of war dependent on artillery. Each school, in which the pupils must remain two years longer, is under the superintendance of a general of brigade of the corps. The school of military engineers, united to that of miners, is established at Metz. Its labours relate to the application of the theoretical knowledge which the pupils have imbibed at the Polytechnic school. The object of these labours is the construction of all sorts of works of fortification, mines and countermines, mock representations of sieges, attack and defence, the drawing of plans and military surveys, and all the details of the duty of engineers in fortified places, and in the field. The number of pupils is limited to twenty: they have the rank and pay of second lieutenants. They undergo a strict examination respecting the objects of instruction, which examination is entrusted to a jury, composed of the commander-in-chief of the school, a general or field officer of the corps, appointed every year by the minister at war, and one of the permanent examiners of the Polytechnic school. This jury forms the list of merit which regulates the order of promotion. The school of bridges and highways was founded, in 1787, by Trudaine, and continued under the direction of Perronet, chief engineer of the corps, till his death, in 1794. By his will he bequeathed to this school, for the instruction of the pupils, his library, his models, his manuscripts, and his port-folios. This school unites the dépôt, or repository of plans and models, canals and harbours, for trade. The number of pupils is fifty. They are taken from the Polytechnic school, and retain the salary which they received there. The instruction given to them chiefly consists in the application of the principles of physics and mathematics to the art of planning, and constructing works relative to roads, canals, and sea-ports, and the buildings belonging thereto; the means of execution; and the mode of forming plans and estimates of the works to be executed, and the order to be observed in keeping the accounts. The practical schools of mines are established, one at Geislautern, in the department of La Serre, and the other at Pefay, in the department of Mont Blanc. The director and professors form a committee for the working of the mines of Pefay, as well as for the instruction of the pupils. In consequence of the report of this committee, the council of mines, established at Paris, proposes to the government the measures necessary to be adopted. Twenty pupils, who have passed their examination at the Polytechnic school, are attached to the practical schools for the purpose of applying the theoretical part of their instruction. The school of Naval Engineers is for pupils who have been students, at least two years, in the Polytechnic school. The examination of the candidates takes place every year,

and the preference is given to those who excel in descriptive geometry, mechanics, and the other branches of knowledge appropriated to the first year's study at school. When the pupils have proved, in the repeated examinations which they must undergo, that they are sufficiently qualified, they are then sent to Brest, in order to apply the theory they have acquired to the different works carried on in that port, where they find both the example and the precept, and are taught every thing relative to the construction of ships of war and merchant vessels. The pupils admitted into it receive a salary of 1800 francs, or about 75*l.* *per annum.* The schools of mathematics and hydrography, established for the navy of the state, and the schools of hydrography destined for the merchant-service, bear the name of Schools of Navigation. Every year there is a competition for the admission of candidates for naval employment. The hydrographical examiner makes a general tour to the different ports, where he interrogates the pupils in arithmetic, algebra, geometry, statics, and navigation. According as they prove themselves worthy by their examinations, they are admitted to the rank of *aspirans de marine*, or midshipmen; captains of merchants'-ships for long voyages; masters of coasting vessels; pilots, &c. Besides these, there are special schools of painting and sculpture; of architecture, music, &c.

Hospitals and other charitable Institutions.—The civil hospitals in Paris form two distinct classes: the one comprehends the hospitals of the sick; the other, those for the indigent: the former are devoted to the relief of the afflicted, the latter serve as an asylum to children, to the infirm, and to the aged indigent. All persons who are not ill enough to be admitted of necessity into the hospital nearest to their residence, are obliged to present themselves to the Bureau Central d'Admissions. Here they are examined, and if there be occasion, they receive a ticket of admission for the hospital where their particular disorder is treated. At the head of the hospitals for the sick stands the Hôtel-Dieu. Formerly this was rather a charnel-house than an hospital. It was founded, as far back as the year 660, for the reception of the sick and maimed of both sexes, without any exception of persons. All of every country, and of every religion, were admitted without form or recommendation. Though it contained but 1200 beds, the number of patients very often exceeded 5000, and on the average it was never less than 2500. Till the year 1786, no steps were taken for enlarging the hospital, or providing elsewhere for those who could not be conveniently accommodated in it. The air of the neighbourhood was contaminated by the noisome exhalations continually arising from this abode of pestilence, and that which was breathed within the walls of the hospital was so contagious, as to turn a trifling complaint into a dangerous disorder, and a simple wound into a mortification. In 1785, the attention of the government being called to this serious evil by various memoirs, the Academy of Sciences was directed to investigate the truth of the bold assertions made in different publications. A report was made, and the hospital enlarged, so as to contain 2000 beds. Since the revolution, the improvements introduced into the interior government of the Hôtel-Dieu have been great and rapid. Each patient now has a bed to himself. Those attacked by contagious disorders are transferred to the Hospice St. Louis. Insane persons are no longer admitted; men, thus afflicted, are sent to a special hospital established at Charenton, and the women to Salpêtrière. At the Hôtel-Dieu every method has been put in practice to promote the circulation of air, and expel the noxious miasmata. In all the French hospitals, one ward, at least, is now

always kept empty. The moment it becomes so by the removal of the patients into another, the walls are lime-whitened, and the air is purified by the fumigation with some of the mineral acids, according to the plan first proposed by Guyton-Morveau. This operation is thus alternately performed in each ward in succession; that which has been the longest occupied being purified the first, and left empty till it is wanted. The number of hospitals in Paris has of late years been considerably augmented. They are all supported by government, and not, like those in England, by private benefactions. Sick children of both sexes are no longer admitted promiscuously into different hospitals; but are received into a special hospital, extremely well arranged, and in a fine airy situation beyond the Barrière des Sevres. Two institutions have been formed for the aged, infirm, and indigent, who pay on entrance a moderate sum. An hospital for gratuitous vaccination is open for the continual treatment of the cow-pox, and the distribution of the matter to all parts of France. In general, the charitable institutions in Paris have, within the last twenty years, undergone very considerable improvements. The male orphans admitted, to the number of two thousand, into the asylum formerly called La Pitie, used to remain idle, or employed only to follow in funeral processions, but are now kept at work, and are instructed in some useful trade. A new institution for female orphans has also been established. The palace of the Hospital des Enfants-Trouvés is supplied by an establishment on a large scale, called the Hospice de la Maternité, which is divided into two branches, each of which occupies a separate house. The one for foundlings, in the rue de la Bourbe, is intended for the reception of children abandoned by their parents. Here they are reared, if not sent into the country to be suckled. The other, in the rue d'Enfer, which may be regarded as the General Lying-in Hospital of Paris, is destined for the reception of pregnant women. From 1500 to 2000 are here delivered every year. No formality is required for the admission of new-born infants.

Marriages and Funerals.—The civil act of marriage is entered into at the office of the municipality. But this is not to be confounded with the contract drawn up by the notary, and containing the stipulations, clauses, and conditions. The former signifies merely that such a man and such a woman take each other for man and wife. There are but few, if any persons married, who do not repair from the municipality to the parish church, or go thither the next morning; the civil act being considered by individuals only as the ceremony of the betrothing; and till the priest has given the nuptial benediction, the relations take care, that the intended bride and bridegroom shall have no opportunity of anticipating the duties of marriage. At the church mass is said in a low voice, during which the priest, or rector, receives the promise of the wedded pair. With little exception the ceremony is the same for all. Those who pay well are married at the high altar; the rector addresses to them a speech, in which he exhorts them to live happily together; the beadles perform their duty, and the organist strikes up a voluntary. With regard to funerals, it depends on the relations to have the corpse presented at the parish-church; but there are many persons who dispense with this ceremony. The priest receives the corpse at the door of the church. It is carried thither in a *corbillard*. Each municipality has its own, and there are twelve municipalities in Paris. Some of them have adopted the Egyptian style, some the Greek, and others the Roman, for the fashion of their *corbillard*, according to the taste of the municipality which ordered its construction. It is drawn by two horses abreast, caparisoned somewhat

PARIS.

somewhat like those of our hearfes. An officer of the police, clothed in black, and holding a cane with an ivory head, walks before the corbillard or hearfe. Each corpse has its particular coffin furnished by the municipality. The relations follow on foot, or in carriages: few of them are in mourning, and still fewer wear a cloak. Before the revolution, the church-yards in Paris were not numerous, the burials being often in the churches themselves. That of the Innocents was the largest and most remarkable, a predilection for its presumed holiness having been adopted by the devout. Since the law ordaining that the dead should not be buried in churches, nor even in the city, only two church-yards are open for this populous capital. One serves for the southern half of the city, including Hôtel Dieu: the other, for the northern half, is in a small irregular vale, on the southern declivity of Mont Martre. The latter repository is not only in a picturesque situation, but variegated by the unevenness of the ground; it is surrounded by a wall of moulded clay, capped with flat tiles, to protect it from the weather, and supported by so many buttresses, that a stone wall would probably have been cheaper. On entering this place you see to the left a sandy elevation of the natural soil, declining towards the west. The coffin is let down on the edge of this declivity to a shelf at a small depth, and covered with a few shovels-full of sand. If the body come from an hospital, it is only enclosed in a sack, and borne by two men on a hand bier, over which two half hoops support a linen cloth. The rapidity with which burials are hastened deserves the severest reprobation, the bodies being kept at no time 24 hours, so that the death can scarcely be ascertained: the bodies are, however, exposed in the gateway of the hotel, with tapers and holy water, which is sprinkled over the coffin by devout visitants. Towards the right, or eastern part of Mont Martre, there is a little vale, planted with weeping willows and shrubs interspersed with tombs of stone. This part is reserved for those of a superior class: the epitaphs are elegant and concise.

Government and Police.—Of the several officers at the head of the government in Paris, one is denominated the *minister of justice*, who is charged with the printing and distribution of the laws, proclamations, and orders of the government; he corresponds with the various tribunals, and their commissaries; he submits to the councils of state the new questions which may arise relating to the administration of justice, and superintends its administration. The *minister of the home department* corresponds with the prefects of the departments. All acts relative to prisons, hospitals, roads, bridges, public works, canals, commerce, industry, agriculture, manufactures, arts, inventions, public schools, museums, and national festivals, are under his immediate direction. What particularly regards the government of the city of Paris is the department of the police, of which the minister or director, for it matters not the name he is called by, has a most arduous task. "He has not," says a close observer, "a moment that he can call his own; he is every day obliged to punish; he is afraid to give way to indulgence, because he does not know that he may not one day have to reproach himself with it. He is under the necessity of being severe, and of acting contrary to the inclination of his heart. Not a crime is committed, but he receives an exaggerated account of it. Not an accident happens but he must prescribe the remedy; he has but a moment to deliberate and act, and he must be equally fearful to abuse the power intrusted to him, and not to use it opportunely. Popular rumours, slighty conversations, theatrical factions, false alarms, every thing concerns him. He must be answerable for every thing; he must trace the robber, and the assassin,

for the magistrate appears blameable, if he has not found means to deliver him up quickly to justice. The time that his agents have employed in this capture will be calculated, and his honour requires that the interval between the crime and the imprisonment should be the shortest possible. What dreadful duties! What a laborious life! He must daily make up for the imperfection and tardiness of the civil laws, but he must, at the same time, use this rare privilege with extreme circumspection. The chief of the police is become a minister of importance; he has a secret and prodigious influence; he knows so many things, that he can do much good, or create a deal of mischief, because he has in his hand a multitude of threads, which he can entangle or disentangle at his pleasure; he strikes or he saves, he spreads darkness or light; his authority is as delicate as it is extensive. He exercises a despotic sway over the *mouchards*, or *spies*, who are found disobedient, or who make false reports; as for these wretches, they are of a class so vile, that the authority to which they have sold themselves, has necessarily an absolute right over their persons. This is not the case with those who are apprehended in the name of the police; they may have committed trifling faults, but are frequently detained without the sanction of any law. A few real advantages compensate for the irregular forms to which every one is subject, and, as an excuse for the arbitrary imprisonment of individuals, it is said 'there are an infinite number of irregularities which the slow and grave process of the tribunals can neither take cognizance of, nor put a stop to, nor foresee, nor punish. The audacious or subtle delinquent would triumph in the winding labyrinth of our civil laws. The laws of the police, more direct, watch him, press him, and surround him more closely. The abuse is contiguous to the benefit, I admit, but a great many private acts of violence, base and shameful crimes, are repressed by this vigilant and active force, which ought, nevertheless, to publish its code, and submit it to the inspection of enlightened citizens.' Could the minister of police communicate to the philosopher all he knows, all he learns, all he sees, and likewise impart to him certain secret things, of which he alone is well informed, there could be nothing so curious, and so instructive, under the pen of the philosopher. But this magistrate is like the great penitentiary; he hears every thing, relates nothing, and is not astonished at certain delinquencies in the same degree as another man. He is in a perpetual state of mistrust; and in the main he ought to possess such a character; for he ought to think nothing impossible, after the extraordinary lessons which he receives from men and things. The spies of the police are a regiment of inquisitive fellows, with this difference, that each individual belonging to it has a distinct dress, which he changes frequently every day, and nothing so quick, or so astonishing as these sorts of metamorphoses. The same spy who figures as a private gentleman in the morning, in the evening represents a priest; at one time he is a peaceable limb of the law; at another a swaggering bully. The next day, with a gold-headed cane in his hand, he will assume the department of a married man buried in calculations: the most singular disguises are familiar to him. In the course of twenty-four hours he is an officer of distinction, and a journeyman hair-dresser; a shorn apostle and a scullion. He visits the dress-ball, and the lowest sink of vice. At one time with a diamond ring on his finger, at another with the most filthy wig on his head; he almost changes his countenance as he does his apparel; he is all eyes, all ears, all legs; for he trots over the pavement of every quarter of the town. Sometimes, in the corner of a coffee-room, you would take him for a dull, stupid, tiresome fellow, snoring till supper

is ready; he has, however, seen and heard all that has passed. At another time he is an orator, and the first to make a bold speech; he courts you to open your mind; he interprets even your silence; and whether you speak to him or not, he knows what you think on any particular proceeding. Such was the universal instrument employed in the reign of Lewis XVI. for diving into secrets; and such unquestionably is the system now carried on for the same purpose. There may be variations in the manner, as there must be different characters to perform their parts, but the police is, at least, as strict as it ever was in the reigns of the most arbitrary monarchs, and the means pursued for the purpose as hostile to the rights and liberty of the subject."

PARIS, *Department of*, one of the new divisions of France, including the city of Paris and its immediate environs.

PARIS, a town of Prussia, in the province of Bartenland; eight miles N.N.E. of Raftenburg.

PARIS, a thriving post-town of America, in the state of New York, and county of Oneida, incorporated in 1792, and containing, in 1800, 4721 inhabitants. Iron ore is found in its vicinity, and the land is excellent. It has an academy and a parish church, and its progressive improvements are rapid.—Also, the county town of Bourbon county, in Kentucky; 18 miles N.E. of Lexington. It has a court-house and gaol, a Presbyterian church, and several mills in its vicinity. Its houses are principally constructed of brick and stone. The town is pleasant and thriving, and contains 377 inhabitants.—Also, a town of London county, Virginia; 59 miles from Washington.—Also, a town in Cumberland county, and state of Maine; containing 844 inhabitants.—Also, an island on the coast of South Carolina.

PARIS, in *Botany*, a name of very obscure etymology. Professor Martyn leaves it unexplained, as Tournefort and Linnæus had done before him, all of them either overlooking, or being dissatisfied with, the explanation of Ambrosinus, who, in his *Phytologia* 506, derives it "*a paritate foliorum*," from the uniformity or equality of the four leaves, which make, as it were, two pair, equally situated. Linn. Gen. 198. Schreb. 266. Willd. Sp. Pl. v. 2. 471. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 431. Ait. Hort. Kew. ed. 2. v. 2. 425. Juss. 42. Lamarck Illustr. t. 319. Gertr. t. 83. Class and order, *Oxandria Tetragynia*. Nat. Ord. *Sarmentaceæ*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, of four lanceolate, acute, spreading leaves, the length of the corolla. *Cor.* Petals four, spreading, awl-shaped, equal, permanent, similar to the calyx but narrower, and alternate with it. *Stam.* Filaments eight, awl-shaped, short below the anthers, which are long, united to the middle part of the filaments. *Pist.* Germen superior, roundish, with four blunt angles; styles four, spreading, shorter than the stamens; stigmas downy. *Peric.* Berry nearly globose, with four blunt angles, somewhat depressed, of four cells. *Seeds* several, globose, inserted in two rows, upon a central receptacle.

Eff. Ch. Calyx of four leaves. Petals four, narrower than the calyx. Berry superior, of four cells. Anthers united to the middle of the filaments.

1. *P. quadrifolia*. Common Herb Paris. Linn. Sp. Pl. 526. Encl. Bot. t. 7. Fl. Dan. t. 139. Redout. Liliac. t. 226. Bulliard t. 119. (Herba Paris; Ger. em. 405. Camer. Epit. 835. Matth. Valgr. v. 2. 439).—Leaves ovate, about four.—This singular plant, found in shady woods, chiefly in the northern or cooler countries of Europe, but not very commonly in any, has always attracted the notice of botanists, from the peculiarity of its habit. It flowers in May, and the berry is ripe in July. The root is perennial, creeping. Stem solitary, erect, a foot high, per-

fectly simple, round, smooth, naked, except at the very summit, where it bears a whorl of four spreading, nearly equal, ovate, broad, acute, entire, three-ribbed, veiny, smooth leaves, tapering at the base, of a dull green hue, and pliant texture, each of them about three inches long, increasing in size as the fruit ripens, after which the whole plant soon turns of a pale yellow and withers. Flower solitary, terminal, central, on an upright angular stalk, about half as long as the leaves. Calyx-leaves ribbed, of a lighter green than the foliage, each an inch long. Petals of the same colour and length, but much narrower. Stamens half the length of the calyx, ascending, green, with yellow anthers. Styles pale, downy. Berry purple. The leaves occasionally vary in number to three or five, Haller mentions six. Linnæus says the roots are emetic, but only half as powerful as *Ipecacuanha*.

2. *P. polyphylla*. Many-leaved Herb Paris.—Leaves lanceolate, eight or ten. Discovered by Dr. F. Buchanan, growing in woods near rivulets, in Upper Nepaul, where it is known by the name of *Dai Swa*. The root is creeping, but much thicker and more tuberous than the former. Stem a foot or more in height, brownish, thrice the thickness of the first species, crowned like that with a whorl of leaves, in a similar spreading position, but about twice as numerous, and much narrower, being elliptic-lanceolate, taper-pointed, triple-ribbed; each supported on a short purplish stalk. Flower-stalk much shorter than the former, but the flower is larger, of the same green colour. Its calyx-leaves and petals are usually five, with ten stamens, but sometimes only four, with eight stamens, or even three with six. The styles, as well as the cells of the germen, always agree in number with the petals, but the former are combined by a thick columnar base, which character, added to his not having seen the ripe fruit, caused Dr. Buchanan to doubt of the genus. The habit, and rest of the characters, however, leave no scruple in our mind; but it is very possible that what Linnæus, in the European species, calls styles, may be almost wholly stigmas, for they are downy all along their upper side, and the Nepaul plant will then be found to differ merely in having the style more elongated.

PARIS, *Herb, of Canada*. See TRILLIUM.

PARISCATTY, in *Geography*, a town of Hindooostan, in Oude; 25 miles E. of Goorachpour.

PARISH, the precinct, or territory, of a parochial church; or the circuit of ground within which the people belonging to any church, or under the care of one parson or vicar, do inhabit.

The word comes from the Latin *parochia*, of the Greek *παροικια*, habitation; compounded of *παρεα*, near, and *οικος*, house. Accordingly, Du-Cange observes, that the name *παροικια* was anciently given to the whole territory of a bishop, and derives it from neighbourhood; because the primitive Christians, not daring to assemble openly in cities, were forced to meet secretly in neighbouring houses.

In the ancient church, there was one large edifice in each city, for the people to meet in; and this they called *parochia*, parish. But the signification of the word was afterwards enlarged, and by parish was meant a diocese, or the extent of the jurisdiction of a bishop, consisting of several churches; unless we will suppose, as some do, that those bishops were only pastors of single churches.

Du Pin observes, that country parishes had not their origin before the fourth century; but that those of cities are more ancient. The city of Alexandria is said to have been the first that was divided into parishes. Baronius says, that in the time of pope Cornelius there were forty-six parishes in Rome.

How ancient the division of parishes is it is not easy to ascertain; for in the early ages of Christianity in this island parishes were unknown, or at least signified the same that a diocese does now. There was then no appropriation of ecclesiastical dues to any particular church; but every man was at liberty to contribute his tithes to whatever priest or church he pleased, provided only that he did it to some; or if he made no special appropriation thereof, they were paid into the hands of the bishop, whose duty it was to distribute them among the clergy, and for other pious purposes, according to his own discretion. (Seld of Tithes, 9. 4. 2 Inst. 646. Hob. 296.) Camden says England was divided into parishes by archbishop Honorius, about the year 630 or 636. Sir Henry Hobart maintains that parishes were first erected by the council of Lateran, held A. D. 1179. But Mr. Selden has shewn, that the clergy lived in common without any division of parishes, long after the time mentioned by Camden; and it appears from the Saxon laws, that parishes were in being long before the council of Lateran, in 1179. The distinction of parishes occurs in the laws of king Edgar, about the year 970. It seems pretty clear and certain, says judge Blackstone, (Com. vol. i. 113.) that the boundaries of parishes were originally ascertained by those of a manor or manors; because it very seldom happens, that a manor extends itself over more parishes than one, though there are often many manors in one parish. The lords, he adds, as Christianity spread itself, began to build churches upon their own demesnes or wastes, to accommodate their tenants in one or two adjoining lordships; and in order to have divine service regularly performed therein, obliged all their tenants to appropriate their tithes to the maintenance of the one officiating minister, instead of leaving them at liberty to distribute them among the clergy of the diocese in general; and this tract of land, the tithes of which were so appropriated, formed a distinct parish; and this will account for the frequent intermixture of parishes one with another. For if a lord had a parcel of land detached from the main of his estate, but not sufficient to form a parish of itself, it was natural for him to endow his newly-erected church with the tithes of such lands.

Extra-parochial wastes and marsh lands, when improved and drained, are by 17 Geo. II. cap. 37. to be assessed to all parochial rates in the parish next adjoining. For settling the bounds of parishes, see PERAMBULATION.

Camden reckons 9284 parishes in England. In a book made out by cardinal Wolsey in 1520 are reckoned 9407 parish churches. And Chamberlayne makes at present, 9913, and the number of parishes is now reckoned to be about 10,000. See CHURCH of England.

PARISH-PRIEST, the parson or minister who holds a parish as a benefice.

If the predial tithes be appropriated, the parson is called *rector*. If they be impropriated, he is called *vicar*.

PARISH-CLERK. In every parish the parson, vicar, &c. hath a parish-clerk under him, who is the lowest officer of the church. These were formerly clerks in orders, and their business at first was to officiate at the altar; for which they had a competent maintenance by offerings; but now they are laymen, and have certain fees with the parson on christenings, marriages, burials, &c. besides wages for their maintenance.

The law looks upon them as officers for life: and they are chosen by the minister of the parish, unless there is a custom for the parishioners or churchwardens to choose them; in which case the canon cannot abrogate such custom; and when chosen it is to be signified, and they are to be sworn

into their office by the archdeacon, for which the court of king's bench will grant a mandamus.

Parish clerks, after having been duly chosen and appointed, are usually licensed by the ordinary, and when they are licensed, they are sworn to obey the minister. The parish-clerk ought to be deprived by him that placed him in his office; and if he is unjustly deprived, a mandamus will lie to the church-wardens to restore him: for the law looks upon him as an officer for life, and one that hath a freehold in his place, and not as a servant: and therefore will not suffer the ecclesiastical court to deprive him, but only to correct him, for any misdemeanour, by ecclesiastical censures. 3 Roll's Abr. 234. Gibf. 214. God. 192.

PARISH-CLERKS, *Company of*. See COMPANY.

PARISI, in *Ancient Geography*, inhabitants of Britain, seated to the north of the Coritani, and occupying that district which is called Holderness, or as Mr. Camden imagines, the whole east riding of Yorkshire. The Parisi are supposed to have derived their name from the two British words "Paur Isa," which signify low pasture, and which are descriptive of the situation and use of their country. However this may be, it is evident that our Parisi never attained to any great degree of power or consequence, but were always subject to the authority, and followed the fate of their more powerful neighbours, the Brigantes. Their only town was "Pituaria," probably Patrington in Holderness.

PARISIAN ISLAND, in *Geography*, an island in lake Superior, near the S.E. coast. N. lat. 46° 30'. W. long. 85°.

PARISIS, a French money of account, formerly a real coin struck at Paris, at the same time with the Tournois, struck at Tours.

The Parisi exceeded the Tournois by one-fourth; so that the livre, or pound Parisi, was twenty-five sels; and the livre Tournois twenty. The sels and deniers Parisi, &c. were in proportion. See COIN.

PARISOT, in *Geography*, a town of France, in the department of the Aveyron; 10 miles S.W. of Villefranche.

PARISTHMIOTOMUS, from *παρισθμια*, the *tonfils*, and *τεμνω*, to cut, in *Surgery*, an instrument anciently employed for scarifying the tonsils.

PARITA, in *Geography*, a town of South America, in the province of Panama; 5 miles N. of Santos.

PARITEE-HOTUN, a town of Chinese Tartary. N. lat. 42° 28'. E. long 125° 16'.

PARIUM, in *Ancient Geography*, CAMANAR, a town situated in the Propontide, between Lampacus and Priapus. Its territory was fertile, and produced excellent wines, and it had a good port. This town was founded by the Milesians, the Erythræans, and the inhabitants of the isle of Paros, from which it took its name. Augustus established a colony in this place, and, like many others, it was governed by a senate or council composed of decurions. The worship of Apollo and Diana was transported from Adrastia to Parium, where a large and splendid altar was erected, the work of the celebrated Hermocreon. Strabo. Pliny also mentions a statue of Cupidon, belonging to this city, the production of Praxiteles, and not inferior in beauty to the Venus of Cnidus. Parium was ravaged in the year 267 by the Heruli, a German nation; but these barbarians were defeated and driven into their own country by the emperor Gallienus, in consequence of which a triumphal arch was erected; which arch consisted of three arcades, upon which the emperor appeared in a car drawn by two elephants, between two victories, which presented to him a crown

of laurel. When the government of proconsular Asia was divided into several provinces, Parium was comprised in the new province of the Hellespont, of which Cyzicus was the metropolis.

PARIVOA, in *Botany*, a name in Aublet, v. 2. 756, for one of those genera on which Schreber founded his DIMORPHIA; see that article, as well as PANZERA. As we have, after Willdenow's example, separated the latter, the *Parivoa* must remain under the denomination of *Dimorpha*, which however, by this division, loses its original meaning.

PARIYATEKA, is the Sanscrit name of a species of *nyctanthes*, and in the mythological legends of the Hindoos is a golden tree, yielding in its fruit whatever the heart can desire. It is fabled to have arisen from the ocean when churned by the gods and demons, as described under the article KURMAVATARA, and to have fallen to the lot of the demigod Indra, regent of the firmament, who hence, and from similar possessions, is called the lord of wealth. (See INDRA.) The name is commonly pronounced *parijat*, and it is often alluded to in the holy tales and fables of the Hindoos. Sometimes it is called *Lakshmi-vriksha*, the tree of Lakshmi, or wealth. This is a treatise on Hindoo music in the Persian language, probably a translation from the Sanscrit, named after this all-yielding tree *Pariyateka*.

PARK, PARCUS, a large inclosure, privileged for wild beasts of chase, either by the king's grant, or by prescription. Co. Litt. 233. 2 Inst. 159. 11 Rep. 36.

The word is originally Celtic; where it signifies an inclosure, or place shut up with walls.

Manwood defines a park a place of privilege for beasts of venery, or hunt, and other wild beasts of the forest, and of chase; *tam sylvestres, quam campestris*. A park differs from a forest, in that, as Compton observes, a subject may hold a park by prescription, or the king's grant; which he cannot with respect to a forest.

A park differs from a chase also; because a park must be inclosed; if it lie open, it is a good cause of seizing it into the king's hand, as a free chase may be, if it be inclosed. Nor can the owner have any action against such as hunt in his park if it lie open. See CHASE.

Du-Cange refers the invention of parks to king Henry I. of England, and the first park in England is said to have been that of Woodstock in Oxfordshire, made by him, which was walled round with stone, and seven miles in circumference: the royal example was first followed by Henry, earl of Warwick, to preserve his deer and other animals for hunting; after which the practice of park-making became general among persons of opulence. But Spelman shews it is much more ancient; and was in use among the Anglo-Saxons. Zosimus assures us also, that the ancient kings of Persia had parks.

The clergy of rank, at all times, had the privilege of hunting in their own parks and inclosures; and therefore, that they might not be prevented from following this favourite pastime, they took care to have such receptacles for game belonging to their parks. Accordingly, at the time of the Reformation, the see of Norwich, only, was in the possession of not less than thirteen parks, well stocked with deer and other animals for the chase.

No man can now erect a park without a license under the broad seal; for the common law does not encourage matters of pleasure, which bring no profit to the commonwealth. Wood's Inst. 207.

But there may be a park in reputation, erected without lawful warrant; and the owner of such park may bring his action against persons killing his deer. Ibid.

To a park three things are required. 1. A grant thereof.

2. Inclosures by pale, wall, or hedge. 3. Beasts of a park, such as buck, doe, &c. and where all the deer are destroyed, it shall no more be accounted a park, for a park consists of vert, venison, and inclosure; and if it is determined in any of them, it is a total disparking; and the king may by letters patent dissolve his park. Cro. Car. 59, 60.

Parks as well as chases are subject to the common law, and are not to be governed by the forest laws. 4 Inst. 314.

Offenders pulling down park-walls or pales, shall be liable to the same penalty as for killing deer, &c. by statute. See DEER-stealers.

A park ought to have three sorts of ground in it: 1. Mountainous and barren. 2. Hilly and yet fertile. And 3. Plains that are sufficiently fruitful. The mountainous part should be well covered with high woods over at least a third part of it. The downs and hilly part should have one-third part coppices and low woods; and the plains should be at least one-third part pasture ground, with some arable or corn land. There should be a river contrived to run through some part of it, and a spring or brook to go through a great part, and at length fall into the river.

These are the natural advantages to be wished in a park; but when they are wanting, they are to be supplied as far as may be by art, as by ponds to preserve rain water, to supply the place of rivers and springs, and proper plantations and exposures for the rest; only the person who is to make a park should know what the natural advantages are, that he may take in as many as he can. When ponds are to be made to supply the place of natural brooks and rivers, they should be made large enough: the extraordinary expence in this will be easily repaid, by breeding fish in them, and fowl may also be kept in plenty on them. The park should also be well stored with trees; oaks should not be wanting in it, but beech and chestnut are the quickest of growth, and are easy to be had: these, therefore, should be planted in considerable numbers. Apple-trees and plum-trees also should be planted, as generally thriving very well, and affording good food to the deer, &c.

The best inclosure for a park is a brick or stone wall; but as the expence of this is very great, it may be done by paling; the pales must, in this case, be of sound heart of oak; and so close planted, that no animal of prey can make its way in between them; and for a farther defence, a good quick-set hedge is very proper, and should be kept in good order. Some part of the mountain and high wood may conveniently be made a heronry, and some part of the middle may be a warren for hares and rabbits. Colts and horses may be bred at large in the park, and in the summer season it will be proper to have cows in the pasture-ground on the plains.

There should be at least five or six inclosures in the park, that the deer may be shut out or let in as occasion requires. In the coldest seasons, they should always be kept altogether in the high woods, where they have good shelter, and are to be fed constantly with provender by the keepers. In the summer such a number as are intended to be used may also be kept on the best ground, that they may thrive quicker than those intended only for store. Some artificial holes and caverns should also be made for the deer to retire into in the hot weather, as well as in the cold.

PARK, in *Gardening*, an inclosed piece or portion of ground, of a larger or smaller extent, which surrounds a mansion or residence, and which has commonly some sort of forest or other trees, planted or growing on it, for the purpose of beauty or ornament. Large parks mostly contain deer or other similar animals, and the more they have of this
wild

wild or forest scenery, the more natural and proper they appear.

It is supposed by Mr. Loudon, in his "Treatise on Country Residences," that parks should be of two kinds; those belonging to small houses, where regard should principally be had to the value of the pasture, and where the pasturing animals are horses, cattle, sheep, &c.; and those where grandeur of character is the main object.

In the former sort, the surface of the ground should be unbroken, but clothed and varied, or characterized chiefly by trees, unless a few shrubs of the lower growths be admitted near the residences, or the walks of the pleasure or more ornamental parts. The apparent extent of this kind of parks depends more upon the variety of the grounds, and the manner in which the trees and shrubs are planted, than upon the number of acres. A level or uniform surface, spotted by circular, oval, or even angular clumps, and surrounded by a compact serpentine belt, as at Duddington, and some other places, can never, it is supposed, appear extensive; but a very few acres of varied ground, sprinkled over with light groups, thorns, and hollies, appear boundless. In such a park, every step presents a new composition, arising from the varied herds of cattle intermingling with the trees, &c. and always changing their position: and as there is no permanent mark by which one scene can be distinguished from another, so as to know it again; a person might wander up and down the extent of a few acres for several days, without being able to say whether he was not traversing a park of several square miles. And this is the case in natural forests, as depending on the same principles.

In the latter kind of parks, nothing, it is believed, can contribute so highly to the necessary grandeur of effect, as the *wild, forest* style, of breaking the ground, and planting trees, shrubs, low growths of plants, furze, bramble, ferns, &c.; and shewing roots, decayed trunks, rocks, or stones, when they may appear with propriety, and as it were fortuitously. The grazing animals in this case should be principally deer, a few wild cattle, and horses. It is suggested, that as parks are the prominent features of all extensive residences, were this appearance of wildness and forest scenery given to them, words could not convey an adequate idea of the beauty and grandeur that would be communicated to them, and at the same time to the country at large. The materials by which this is chiefly to be effected are, as has been seen, the proper arrangement of *low scrubby growths, wild plants, and forest trees*. Nothing can however give an idea of what these effects might be, except looking at the finest ranges of forest scenery, few of which now exist in the country. In the New Forest, as well as that of Needwood, it is however supposed, that there are still select ranges or tracts, which the true admirers of nature will view with rapture or enthusiastic delight, and by the imitation of which, vast ornamental advantages might be made to the already beautiful parks of Donnington, Blenheim, and Croom, as well as all those esteemed the finest in the kingdom.

Some may suppose the utility of such parks thus to be injured. And so it would in some degree; but it is asked, is not beauty or grandeur of character one of the chief objects of such scenes? if not, why change the common character of the country, why make the interesting variety of corn-fields, farms, cottages, hedges, coppices, &c. give way to one dull rapid monotonous surface of green, as insipidly varied by trees; where one might wander an age without seeing any thing else than their naked stems and clump-like heads? Nothing, it is believed, can be grand or sublime, but as it soars above the common appearances of the like things. Now, says the writer, in a fertile and cultivated country,

what can be more truly uncommon with regard to the surface, than making it assume the wild irregularity and excesses of nature, leaving flocks and herds to roam at pleasure, and despising the teeming abundance of cultivation, and the grosser ideas of mere profit or use?

It is not, however, meant by this to affirm, that there would be much real difference in the annual profit of a park so laid out, when compared with one in the modern taste. What was not occupied with pasture would be covered with wood; which, whether as undergrowth, or timber produce, would be highly valuable, and often produces as much profit as either pasture or aration, and in many scenes is highly suitable for parks: besides the abundance of every kind of game which this would produce, as well as the encouragement it would give to different classes of beautiful singing-birds. It is added, that this being the case, and it being taken into view that deer are not grazed for pecuniary advantage, it cannot be seen that there would be any real disadvantage in point of profit by adopting the mode; and hence it is wished that it should in some degree be attended to, even in parks of the smallest size, where cattle and sheep are grazed. And it is farther suggested, that in this age of refinement and universal cultivation, wildness and native simplicity have charms which are highly interesting to all, except those engaged in the vortex of fashion.

PARK is also used for a moveable pallisade, set up in the fields to inclose sheep in to feed, and rest in, during the night.

The shepherds shift their park from time to time, to dung the ground, one part after another.

PARK is also used for a very large net, disposed on the brink of the sea, with only one hole, which looks towards the shore: and which becomes dry after the flood is gone off; so that the fish once got in have no way left to escape.

PARK, in *War*. PARK of *Artillery*, a post in a camp, out of cannon-shot of the enemy, and fortified to incamp the train of artillery, and to secure the magazines and ammunition, as well as the battalions of artillery, appointed for its service and defence. See ARTILLERY *Park*.

The figure of the park of artillery is commonly a parallelogram, unless the situation of the ground renders another necessary. The artillery is generally placed in the centre of the second line of encampment, and sometimes in the rear line, or corps of reserve. In both places the muzzles of the guns are in a line with the fronts of the serjeants' tents of the regiments of artillery and infantry. Some generals place the park about three hundred paces before the centre of the front line of the army: some place all the cannon and mortars in the front, together with their spare carriages; others are for dividing the equipage in brigades, and place the first in the front line, the second in the next, &c. But the most approved method, says Mr. Muller, *Artill.* p. 281, is to divide the artillery into brigades; and to place the guns of the first to the right of the front line, and their ammunition behind them; then those of the second brigade next to the first in the front, leaving five paces between them, and their ammunition behind them; and all the rest in the same order; the pontoons forming the last line. The artillery companies and miers are half encamped to the right, and the other half to the left of the park, with some of the lieutenants in the rear. At about twelve paces in the rear of the park, are encamped the civil list in one line; behind them, at the distance of thirty paces, is a line of the remaining lieutenants, and behind these the captains and commissaries, Opposite to the centre, and thirty paces behind the captain's line, is the major's tent; and behind this, at twenty paces,

the colonel's to the right, and the comptroller's to the left. Opposite to the centre, and fifty paces before the park, is placed the army guard; and opposite to the right wing, the artillery guard at the same distance. In the middle of the front, two light pieces are advanced at a distance of twenty paces, loaded with powder for the alarm guns, which are ready to be fired when required. To the right of the park are placed the artificers with their tools, materials, and baggage, in a line from the front to the rear. To the left of the park, the commissaries and their baggage; to the right of the artificers is encamped the first battalion of artillery, with their baggage and officers behind them; and to the left of the commissaries the second battalion in the same manner. The horses are placed behind the first battalion, except those of the picket in the rear of the park.

Every attack, at a siege, has its park of artillery.

PARK of Provisions, is a place in the camp, on the rear of every regiment, which is taken up by the sutlers, who follow the army with all sorts of provisions, and sell them to the soldiers.

PARK Bote, in our old *Writers*, signifies to be quit of inclosing a park or any part thereof. 4 Inst. 308.

PARKANY, in *Geography*, a town of Hungary, at the conflux of the rivers Gran and Danube; 2 miles N. of Gran.

PARKEL, a town of Hindoostan, in Golconda; 32 miles S.S.W. of Hydrabad.

PARKER, MATTHEW, in *Biography*, archbishop of Canterbury, was born at Norwich in 1504. He had the misfortune to lose his father when he was only twelve years of age; but his mother took care to place him under good masters, by whom he was well grounded in grammar-learning. In the year 1520 he was sent to Cambridge, and was entered of Corpus Christi college, of which house he was chosen a bible-clerk, or scholar, in the following year. Here he applied with great assiduity to his studies, and in 1523 was admitted to the degree of B.A. In 1527 he was ordained deacon, and afterwards priest; and in the same year he commenced M.A., and was chosen fellow of his college. When he was about 29 years of age, he preached his first sermon before the university; and almost immediately became a popular preacher in the neighbourhood of Cambridge. He had by this time imbibed the principles of the Reformation, and shewed so much zeal for them, that archbishop Cranmer granted him a licence to preach throughout his province. About this time he was sent for to court, and was made chaplain to queen Anne Boleyn, who appointed him, a short time before her death, to the particular charge of her daughter Elizabeth. About the year 1534 he was presented by the queen to the deanery of the college of Stoke, near Clare, in Suffolk, a preferment of small value in a pecuniary view, but affording him a pleasing place of retirement, when he chose to withdraw from the court, from which it was about 20 miles distance. Here he laboured to reform the Popish superstitious, and founded a grammar-school, for the instruction of youth in sound learning, and in the principles of the Christian religion. In 1537, after the death of queen Anne Boleyn, he was appointed one of Henry VIII.'s own chaplains; and in the following year he was created doctor of divinity. In 1541 he was installed prebendary in the cathedral church of Ely; and in 1542 he was presented by the chapter of Stoke to the rectory of Ashen, in Essex. He obtained other preferments in the church; and in 1544, on account of his high character and great learning, he was chosen master of Corpus Christi college, to which he afterwards became a liberal benefactor, and compiled for it a new body of statutes. In 1545 he was elected vice-chan-

cellor of the university of Cambridge; and in the same year he was presented by his college to the rectory of Landbeach, in Cambridgeshire. After the accession of king Edward VI. he married; and in 1549, being accidentally in Norfolk, during the time of Kett's rebellion, Dr. Parker had the resolution to go to the rebels' camp, where he preached to them under the oak of Reformation, exhorting them most earnestly to temperance, moderation, and submission to the king. In so doing, he run great risk of his life; but he fortunately escaped out of their hands. In 1551 Dr. Parker was included in a commission for correcting and punishing the Anabaptists; and about this time he preached a funeral sermon for Martin Bucer, regius professor of divinity, with whom he had been on terms of great intimacy. In 1552 Dr. Parker was presented by Edward VI. to a prebendary in the cathedral church of Lincoln, and also to the deanery of the same church. He had been nominated, previously to this, a chaplain to his majesty. Thus he lived in great reputation and affluence, during the reigns of Henry VIII. and Edward VI., and happy in the acquaintance and esteem of all the principal men of his time.

After the accession of queen Mary, Dr. Parker was deprived of all his preferments, and gladly withdrew into privacy. Great pains were taken to find out his retreat, but he eluded the machinations of his enemies; and on the death of the cruel and bigotted sovereign, he was by her successor preferred to the archbishopric of Canterbury, and was duly and regularly consecrated at Bow church; though the Papists, some years afterwards, propagated a report, that Parker had been consecrated at a tavern in Cheapside, which was proved most satisfactorily to be a calumny. Being thus constituted primate and metropolitan of the church of England, Dr. Parker endeavoured to fill the vacant sees with men of learning and distinguished piety, who were zealous for promoting the Reformation; and very soon after his own consecration, he consecrated, at Lambeth, Grindall, bishop of London, Cox, bishop of Ely, Sandys, bishop of Worcester, Jewel, bishop of Salisbury, and several others. He also extended his influence and his anxious concern for the Protestant interest to the kingdom of Ireland, sending over proper instructions to the archbishop of Dublin, for completing the work of reformation in the church of Ireland.

About this time archbishop Parker received a letter from Calvin, exhorting him to prevail with the queen to summon a general assembly of all the Protestant clergy, wheresoever dispersed, for the purpose of agreeing upon one common form of worship and of church government to be established, not only within her dominions, but also among the reformed and evangelical churches abroad. This letter was taken into consideration by the queen's council, who requested his grace to return thanks to Calvin for his proposals, but, at the same time to signify to him, that the church of England would still retain her episcopacy. It is not in our power, in this article, to notice all the attempts made by Elizabeth, in which the archbishop seems to have concurred, to introduce a uniformity of faith. In consequence of those proceedings against the Puritans, many churches in London, and in every part of the kingdom, were shut up for want of preachers. The sufferers under these persecutions, having been refused a hearing by the archbishop, and the other commissioners appointed by the queen, appealed to the public, and circulated various books and pamphlets in defence of their nonconformity. To some of these, answers were written, on the part of the bishops, either by themselves, or their chaplains; which were followed by replies from Puritans, whose tracts were eagerly sought after. In consequence

sequence of this, a decree was obtained from the star-chamber, prohibiting all books and pamphlets, in which any thing should be advanced against the queen's injunctions, and empowering the wardens of the stationers' company to search all suspected places for such books, and to bring the offenders before the ecclesiastical commissioners. This scandalous stretch of tyranny took place in the month of June, 1566. In the following year the archbishop founded three grammar-schools in Bennet-college; and two years afterwards, seven other schools, and two fellowships, in the same house. In 1568, a new folio edition of the English bible was published, chiefly under the inspection of archbishop Parker, with a preface written by him. It was commonly denominated the *bishops' bible*, on account of its having been revised and corrected principally by the bishops, from the translation published by Cranmer; and it was made use of in the churches, till the last translation took place in the reign of James I. One of the last acts in which the archbishop was employed was a metropolitan visitation of the diocese of Winchester, and in particular of the Isle of Wight, in 1575, in which he exercised such severities as exposed him to universal odium, and even induced the court to interfere and reverse his proceedings. He died in the month of May, 1575, when he was in the 71st year of his age, and was buried, with great magnificence and solemnity, in his own private chapel at Lambeth, under a tomb erected by himself, which remained there till 1648, when the tomb was pulled down, and the ashes of the prelate exposed to much insult. Some time after the restoration, they were decently re-interred in the place where the monument formerly stood, and another was now erected to his memory. Archbishop Parker has the honour to rank among the principal agents in exposing the superstitions of Popery, and in placing the Protestant religion on a permanent footing in England: he, however, sullied his reputation, by introducing into Protestantism much of the ecclesiastical pride and persecuting spirit of the church from which he separated. He was naturally of a warm temper, but, till his head was turned by his exaltation, he exhibited no instances of haughtiness or ill nature. He was to the last hospitable and charitable, and did many kind and benevolent things for private people, as well as for the public benefit. The regulation of his family was extremely laudable: he assigned all his domestics some particular employment, and suffered none to be idle. Those who were not occupied in learned pursuits, about the management of his revenues, or the affairs of his household, were variously employed; some in binding books, others in engraving, painting, transcribing manuscripts in fine hand-writing, drawing, or illuminating.

The archbishop was much attached to the study of British and Saxon antiquities, and he spared neither labour nor expense in collecting and preserving whatever manuscripts of this kind could be met with, of which a fatal havock and destruction had been made at the time of the dissolution of the monasteries. In 1563 he was the instrument of preserving two volumes of collections in folio, made by archbishop Cranmer. Whatever he was able to collect, he deposited in a library that he built for Corpus Christi college, in Cambridge. He published editions of four of our ancient English historians, *viz.* Matthew of Westminster, Matthew Paris, Thomas Walsingham, and Asser's Life of King Alfred. He also published "A Testimony of Antiquity, shewing the ancient Faith of the Church of England, touching the Sacrament of the Body and Blood of the Lord, here publicly preached, and also received, in the Saxons' Time, about seven hundred Years ago, being a Sermon translated out of Latin into Saxon by Ælfric, Abbot of St.

Albans, about the year 996, and appointed to be delivered to the People at Easter, before they should receive the Communion." Another considerable work of the archbishop contains the lives of his predecessors in the see of Canterbury, and is entitled "De Antiquitate Britannicæ Ecclesiæ, et Privilegiis Ecclesiæ Cantuariensis, cum Archiepiscopis ejusdem LXX, 1572." The materials for this performance were collected from ancient historians, by John Jofeline, secretary or chaplain to the prelate, who was himself the digester and compiler of it. The best edition of this work is that of 1729, illustrated with fine engravings. Biog. Brit. Neal's Hist. of Puritans.

PARKER, SAMUEL, an English bishop, son of John Parker, a serjeant at law under the protectorate of Oliver, and also after the restoration, was born at Northampton in 1640. He was educated in grammar-learning among the Puritans, at his native place; after which he was sent, in 1656, to the university of Oxford, where he was entered of Wadham college. Here he is said to have led a very strict and religious life. In 1659 or 1660 he was admitted to the degree of B.A. Although now a zealous Puritan, he became, at the restoration of Charles II., violently attached to the court, obtained preferment, and was, in 1667, appointed chaplain to Dr. Sheldon, archbishop of Canterbury. In 1670 he was nominated to the archdeaconry of Canterbury, and obtained several other benefices. In the reign of James II. he was made, for his fervility to the king's arbitrary measures, bishop of Oxford and privy counsellor. He was also constituted, by mandamus, president of Magdalen college, in violation of the privileges of that society. He was author of a number of works; and he left behind him, in manuscript, "A History of his own Times," in Latin, which was published in 1726, under the title of "Reverendi admodum in Christo Patris Samuelis Parkeri, &c. de Rebus sui Temporis Commentariorum Libri quatuor," of which two English versions afterwards appeared. He died in March, 1687-8, at the age of 48, unlamented and despised by good men. Bishop Burnet says, "he was a man of no judgment, and of as little virtue; and as to religion, rather impious. He was covetous and ambitious; and seemed to have no other sense of religion but as a political interest, and a subject of party and faction." Biog. Brit. Burnet's Hist.

PARKER'S Bay, in *Geography*, a bay on the south coast of Jamaica, south of Palmetto point.

PARKER'S Creek, a river of Maryland, which runs into the Chesapeake, N. lat. 38° 32'. W. long. 76° 39'.

PARKER'S Island, an island in the Chesapeake, near the coast of Maryland; 15 miles S. of Annapolis. N. lat. 38° 53'. W. long. 76° 41'.—Also, an island called *Ruskobegan*, in Lincoln county, and state of Maine, formed by the waters of Kennebeck river west, by the sea south, by Jeremysquan bay east, and by a small strait which divides it from Arouseag island north; so called from John Parker, who purchased it from the natives in 1650: part of it still remains to his posterity. It is in the township of Georgetown.

PARKER River, a river which takes its rise in Boxford, in the Massachusetts, and pursuing a variable course, at length wanders through the marshes, and enters Plum island sound by a mouth about a quarter of a mile wide. It is richly stored with fish, and is navigable for coasting vessels to the head of the tide, but obstructed by two bridges.

PARKGATE, or *the New Quay*, a sea-port and hamlet in the parish of Great Neiton, hundred of Wirral, and county-palatine of Chester, England, is situated on the north-eastern bank of the estuary of the river Dee, at the distance

distance of twelve miles from the county-town, and one hundred and ninety-three from London. This place has of late years become a convenient and fashionable bathing place, and is also celebrated as a station for the Irish packets, which sail from Dublin four times a week. The houses here are chiefly disposed in one long street stretching itself parallel with the river, and are mostly neat modern buildings of brick. The chief support of Parkgate arises from the custom of the passengers to and from Ireland, and from its celebrity as bathing-quarters. Beauties of England and Wales, by E. W. Bravley and John Britton, F.S.A.

PARKHURST, JOHN, in *Biography*, second son of John Parkhurst, esq. of Catesby in Northamptonshire, was born in June 1728. He was educated in grammar learning at Rugby school, in Warwickshire. Being intended for the church, he was entered of Clare-hall, in the university of Cambridge. Here he took his degrees of B. A. and M. A. in 1752, and was many years fellow of his college. Soon after he had entered into holy orders, by the death of his eldest brother he became heir to a very considerable estate, but neither then, nor at the death of his father, when he came into possession, did his accession of fortune produce any change in his manners or pursuits. He still continued to cultivate the studies becoming the clerical profession, paying particular attention to that of the original languages of the Jewish and Christian scriptures. He never obtained any preferment in the church, yet he took pleasure in the exercise of the clerical duty, and for a long time officiated in the capacity of curate, with exemplary zeal and diligence, but without any salary, in his own chapel at Catesby, which afterwards served as a parish church. When he became possessed of the right of presentation to a living, he considered church-patronage as a trust, rather than property, and instead of taking it himself, he bestowed it on a gentleman, known to him only by character, from no motive but a persuasion that he would faithfully discharge the duties of his office. In 1754 Mr. Parkhurst married a lady, by whom he had a daughter and two sons, and after her death he married a second time, by whom he had one daughter, who had a passion for classical learning, and who arrived at a degree of perfection in it, which is seldom met with among females. He was first known as an author in 1753, by publishing a "Friendly Address to the Rev. John Wesley;" his next work was "An Hebrew and English Lexicon, to which is added a Methodical Grammar, adapted to the use of Learners." This performance reflects much credit on his learning and patient enquiry, and may be recommended as affording valuable assistance to the biblical student in forming an acquaintance with the Hebrew scriptures. In 1778 a second edition of it was published with corrections and improvements, and a third was given to the public in 1792. The author had, however, in the mean time, published a "Greek and English Lexicon to the New Testament," to which was prefixed a plain and easy Greek grammar. A second edition of this work was published in 1794, and it was the intention of the author to give new editions of them in octavo, but he died before he could complete the business, and the task of editing them devolved on his younger daughter, the wife of the Rev. Joseph Thomas. Mr. Parkhurst departed this life, after a long and painful illness, in February 1797. Through his whole life he had been a most assiduous student; for many years it was his usual practice to rise at five o'clock, and in winter to light his own fire. He was attached to the works of Hutcheson, but was well acquainted with their defects as well as their excellencies. He was an ardent lover of the truth, and was not afraid to avow his sentiments. In forming his religious principles, he followed no guide but the

scriptures, the study of which was the business and the pleasure of his life. Mr. Parkhurst at one period of his life engaged in a controversy with Dr. Priestley respecting the divinity and pre-existence of Christ. He was naturally irritable, warm, and earnest in his resentments, but he effectually subdued this temper by an attention to the injunctions of religion, and passed through a long life in peace and harmony with all around him, respected by men of learning, beloved by his friends, and honoured by his family.

PARKI, in *Geography*, a town of Bengal; 32 miles N. of Ramgur.

PARKINSON, JOHN, in *Biography*, a celebrated old herbalist, of the latter part of the 16th century, and the first half of the 17th, was born in 1567, and bred up as a London apothecary. He is mentioned by his contemporaries as a man of eminence in his profession, and was at length appointed apothecary to king James I. King Charles I. afterwards conferred upon him the title of *Botanicus Regius Primarius*. A great share of his attention, during a long life, was devoted to the study of plants. He had a garden well stored with rarities, and he bestowed equal notice upon the curiosities of the flower-garden, in all their luxuriant Proteus-like varieties, and on the native productions of his own and other countries, embracing their literary history, as well as their practical investigation.

His first publication was his *Paradisus in Sole Paradisus terrestris, or a choice Garden of all sorts of Rare Flowers, &c.; to which is annexed a Kitchen Garden, &c.* This was printed at London, anno 1629, in a folio of 612 pages. A second edition, "much corrected and enlarged," appeared in 1656, after the decease of the author. Both editions are dedicated "to the Queen's most excellent Majesty," which could hardly have been, as Dr. Pulteney supposed, Queen Elizabeth; but rather the Queen of Charles I.; and it is to the honour of those who edited the new impression, in 1656, that this dedication was not then suppressed. About a thousand plants, either species or varieties, are described in this book, of which 780 are figured, in wood cuts, partly copied from Clusius and Lobel, partly original, but all of them coarse and stiff, though sometimes expressive. Numerous remarks are interspersed, respecting the botanical history or medical virtues of the plants, as well as their culture; but the latter subject is, for the most part, given in the introductory chapters, which display no small degree of intelligence and experience. This book affords a very correct and a very respectable idea of the gardens of our ancestors, at the time it was written, and has been considered, by the learned authors of the Hortus Kewensis, unequivocal authority as to the time when any particular species was introduced or cultivated among us. The florist and the kitchen gardener will find some productions recorded which have since disappeared, and though our kitchen gardens had not arrived at such luxuriant perfection or variety as they afterwards attained, in King William's days, and have since preserved, there is reason to think the science of horticulture declined considerably after the time of Parkinson, previous to its restoration at the end of the 17th century. As to the botanic garden, Dr. Pulteney remarks, from an investigation of the *Paradisus Terrestris*, that "intertropical productions had, at this period, been but sparingly imported. The real stove plants are very rare throughout the book. There are some American species, and particularly from Virginia, as being a part of that continent with which England had the most frequent intercourse. But the principal productions of the English gardens were exotic European, and Grecian plants, some Asiatic, and a few from the northern coasts of Africa."—It is no small praise to the work before us, that

the late Mr. Curtis held it in particular estimation. He always cites it in his Magazine with peculiar pleasure and respect, giving many a specimen of the old writer's amusing quaintness, whilst he enriches us with his information.

In 1640 our author published his principal work, the "*Theatrum Botanicum*, or Theatre of Plants, or an Herbal of large extent; &c." This is a ponderous folio of 1746 pages, with innumerable wooden cuts. This work and the Herbal of Gerarde were the two main pillars of Botany in England till the time of Ray, who indeed gave them fresh importance by his continual reference to their contents. These volumes were dispersed throughout the country, one or other, or both, being the inexhaustible resource of all who had any love for plants, or any interest in enquiring into their qualities. The benevolent country divine, the lady of the manor, the village doctor, and the humble herb-gatherer employed in the service of all the rest, consulted Gerarde or Parkinson, as they would have consulted their bibles, and with little less implicit confidence. Of these two writers it is justly observed that Parkinson was by far the most original and the most copious, but his cuts being of vastly inferior merit to those admirable ones, prepared for Conrad Gesner, with which Gerarde had the means of adorning his publication, the latter has greatly prevailed in popularity, as a book of reference. It is indeed chiefly for the figures that we now cite these works. Nice distinctions of species, or any discrimination between species and varieties, are not to be expected; still less, any ideas of classification or scientific arrangement, worthy a moment's consideration or comparison. Parkinson is much more original than Gerarde in his descriptions, and more particular in his indications of the places of growth; he is also very learned and critical in his synonymy, and, above all, in the medical part of his subject. Gerarde, though intelligent and industrious, was fundamentally a compiler, without always taking the pains to accommodate his text to the country in which he published, as we have already sufficiently noted; see GERARDE. It is not to be wondered at if these great works contain some hundreds of repetitions, when we consider how obscurely many plants had been described, or even figured, by previous authors; inasmuch that it was, in many cases, next to impossible to discover whether a given plant had been described before. Parkinson however is entitled to superior praise on this head, having taken all possible pains to avoid such mistakes, by his deep study of synonyms. Some papers of Lobel are said to have fallen into the hands of Parkinson, after the death of the former, which proved of use to his undertaking, but it does not appear that he implicitly confided in such, any more than in previously printed authorities, without a due investigation, and therefore they became in some measure his own.

The time of Parkinson's decease is not known, but he appears to have been living when his Herbal was published, in 1640, at which period he was, if Dr. Pulteney's date of his birth be correct, 73 years old. Nothing is recorded of his family. Some copies of his *Paradisus* have an engraved portrait of the author, done in his 62d year, and there is a small oval one in the title-page of his *Herbal*, or *Theatrum Botanicum*. Pulteney's Sketches of the progress of Botany in England. Haller Bibl. Bot. Parkinson's Works. S.

PARKINSONIA, in *Botany*, was dedicated to the memory of our laborious English herbalist, (see the last article.) by Plumier, who observes that his *Theatrum Botanicum* embraces a wider range of species, than any previous history of plants.—Plum. Gen. 25. t. 3. Linn. Gen. 206. Schreb. 277. Willd. Sp. Pl. v. 2. 513. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 24. Juss. 347. Lamarck Illustr.

t. 336.—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf; its base bell-shaped, shallow, permanent; border in five deep, ovate, acute, coloured, spreading, nearly equal, deciduous segments. *Cor.* Petals five, with claws, widely spreading, wavy, nearly equal; four of them ovate; the lowermost kidney-shaped, with a longer claw. *Stam.* Filaments ten, awl-shaped, rather declining, shorter than the corolla, villous in their lower part; anthers oblong, incumbent. *Pist.* Germen superior, long, cylindrical, declining; style thread-shaped, curved upwards, the length of the stamens; stigma obtuse. *Peric.* Legume very long, roundish, with numerous bead-like swellings, pointed. *Seeds* several, one in each tumid part of the legume, obovate, roundish, obtuse.

Ess. Ch. Calyx five-cleft; its segments deciduous. Petals four of them ovate; the fifth kidney-shaped. Style awl-shaped. Legume beaded, with many roundish seeds.

1. *P. aculeata*. Prickly Parkinsonia. Linn. Sp. Pl. 536. Hort. Cliff. 157. t. 13. Jacq. Amer. 121. t. 80. Walth. Hort. 36. t. 13.—Native of South America and the West Indies. Miller appears to have cultivated this plant in 1739, and it is often to be seen in stoves, but we never heard of its flowering in England. Jacquin describes it as a very elegant tree, about twelve feet high, with a green shining bark, turning brown and striated on the trunks of older individuals only. Wood white. Prickles solitary, awl-shaped, somewhat recurved, under the insertion of each leaf, about four lines long; on the older branches they are often three together, in which case the middlemost becomes much larger and stronger. Leaves alternate, with an axillary tuft of three, four, or five besides, pinnate, shining; the midrib about a foot long, flattened and linear; leaflets extremely numerous, minute, obovate, entire. Clusters axillary and terminal, lax, simple, smooth, each consisting of about ten sweet-smelling yellow flowers, about an inch or rather more in diameter, their kidney-shaped petal besprinkled with scarlet dots at the base. Leaves yellowish. Seeds variable in number, tumid, polished.

Jacquin says this shrub grows very quickly, flowering the first year after it is sown, and combining with the *Poinciana*, or Barbadoes Flower-fence, to make the most beautiful of all hedges. Dr. Swartz has it not in his *Prodromus* or *Flora*, so that it seems not to be a general West Indian plant.

PARKINSONIA, in *Gardening*, contains a plant of the exotic flowering tree kind, of which the species is the prickly Parkinsonia (*P. aculeata*). In Jamaica it is called the *Jerusalem thorn*. These trees perfume the air to a considerable distance; for which reason the inhabitants of the West Indies plant them about their houses.

Method of Culture.—It is capable of being increased here by sowing the seeds in pots filled with light rich mould, early in the spring season, plunging them in a hot-bed. When the plants have attained a few inches in growth, they should be carefully removed into other small pots, separately re-plunging them into the hot-bed, shading them till fresh rooted, when fresh air should be admitted according to the warmth of the season. The only method by which these plants have been kept with success through the winter, in this climate, has been by hardening them in July and August to bear the open air; and in September placing them on shelves in the dry stove, at the greatest distance from the fire, so that they may be in a very temperate state of warmth.

These plants afford ornament among other potted plants of the stove kind.

PARKON, in *Geography*, a town of Austrian Poland, in Galicia; 30 miles N.N.W. of Chelm.

PARKSTEIN, a town of Bavaria, in the principality of Sulzbach; 17 miles N.E. of Sulzbach.

PARLAGOW, a town of Hindooftan, in Candeish; five miles E. of Barawnay.

PARLASCA, a town of Italy, in the department of the Lario; five miles N. of Como.

PARLEY, formed of the French *parler*, to speak, talk, a conference with an enemy, &c.

Hence to beat or sound a parley, is to give a signal for the holding such a conference, by beat of drum, or sound of trumpet. See **CHAMADE**.

PARLIAMENT, **PARLIAMENTUM**, in England, a grand assembly, or convention, of the three estates of the kingdom, *viz.* lords spiritual, lords temporal, and commons, summoned to meet the king, to consult of matters relating to the commonweal; and particularly to enact, and repeal, laws.

The word *parliament*, *parlement*, or *colloquium*, as some of our historians translate it, is comparatively of modern date, derived from the French, and signifying the place where they met and conferred together. It was first applied to general assemblies of the state under Louis VII. of France, about the middle of the twelfth century. The first mention of it in our statute law is in the preamble to the statute of West. 1. 3 Edw. I. A. D. 1272. But long before the introduction of the Norman language into England, all matters of importance were debated and settled in the great councils of the realm; a practice which seems to have been universal among the northern nations, particularly the Germans: and carried by them into all the countries of Europe, which they overran at the dissolution of the Roman empire.

The two houses of parliament are the king's grand council.

Till the conquest, the great council, consisting only of the great men of the kingdom, was called *magnatum conventus*, and *prælatorum procerumque concilium*, *assisa generalis*, and sometimes *communitas regni Angliæ*. The Saxons, in their own tongue, called it *wittenagemote*, *i. e.* *assembly of the wise*; and it hath subsisted immemorially under these appellations and others, as *michel-synoth*, or *great council*; and *michel-gemote*, or *great meeting*.

We have instances of its assembling to order the affairs of the kingdom, to make new laws, and to amend the old, so early as the reign of Ina, king of the West Saxons, Offa, king of the Mercians, and Ethelbert, king of Kent, in the several realms of the heptarchy. And after their union, the Mirror informs us, that king Alfred ordained for a perpetual usage, that these councils should meet twice in the year, or oftener, if need be, to treat of the government of God's people: how they should keep themselves from sin, live in quiet, and receive right. Our succeeding Saxon and Danish monarchs held frequent councils of this sort, as appears from their respective codes of laws; the titles of which speak them to be enacted either by the king, with the advice of his *wittenagemote* or wise men, or by those sages with the advice of the king, or by them both together. These great councils were also, without doubt, held regularly under the first princes of the Norman line. Glanvil, who wrote in the reign of Henry II. speaking of the particular amount of an amercement in the sheriff's court, says, it had never yet been ascertained by the general assize, or assembly, but was left to the custom of particular countries. In Edward III.'s time, an act of parliament, made in the reign of William the Conqueror, was pleaded in the case of the abbey of St. Edmund's-bury, and judicially allowed by the court. Hence

it appears, that parliaments or general councils are coeval with the kingdom itself. Though the high antiquity of parliaments in this kingdom must be universally allowed, it does not so clearly appear how they were composed; and particularly whether the commons were summoned at all, or, if summoned, at what period they began to form a distinct assembly. Nevertheless it is generally agreed, that in the main the constitution of parliament, as it now stands, was marked out so long ago as the seventeenth year of king John, A. D. 1215, in the great charter granted by that prince, in which he promises to summon all archbishops, bishops, abbots, earls, and greater barons, personally; and all other tenants in chief under the crown, by the sheriff and bailiffs; to meet at a certain place, with forty days' notice, to assess aids and scutages when necessary. And this constitution has subsisted in fact at least from the year 1266 (49 Hen. III.), there being still extant writs of that date, to summon knights, citizens, and burghesses to parliament.

Sir Walter Raleigh, in his *Prerogative of Parliament*, thinks the commons were first called in the seventeenth of Hen. I. and Dr. Heylin fixes the time of their first admission to the reign of Henry II.

Indeed, sir Edward Coke, Dodderidge, Prynne, and others, have shewn, that the commons of England had always a share in the legislature, and a place in the great assemblies; though not on the present footing, as making a distinct house, and as composed of knights, citizens, and burghesses.

Parliaments are to be summoned, prorogued, and dissolved by the king alone: nor can a parliament begin without the king's presence, or that of his commissioners.

At first, new parliaments were called every year; by degrees their term grew longer. In the time of king Charles II. they were held a long time with great interruptions between them. Both which methods were found of such ill consequences, that in the beginning of the reign of king William an act was passed, whereby the term of all parliaments was restrained to three sessions, or three years; this was hence called the *Triennial act*. Since that, from other views, the period of parliaments is lengthened to seven years.

A parliament is called by the king's writ, or letter directed to each lord, commanding him to appear; and by other writs directed to the sheriffs of each county, to summon the people to elect two knights for each county, and one or two burghesses for each borough, &c.

This writ is issued out of chancery by advice of the privy council, at least forty days before it begins to sit. This right of summons is a branch of the royal prerogative; so that no parliament can be convened by its own authority, or by the authority of any, except the king alone. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor; for this revived parliament must have been originally summoned by the crown. Indeed, by statute 16 Car. I. c. 1. it was enacted, that if the king neglected to call a parliament for three years, the peers might assemble and issue out writs for choosing one; and, in case of neglect of the peers, the constituents might meet and elect one themselves. This act, however, was deemed injurious to the royal prerogative, and repealed by statute 16 Car. II. c. 1.

There are, it must be acknowledged, two capital exceptions to this rule, which were justifiable on a principle of necessity, that supercedes all law. The convention parliament, that reformed king Charles II. met above a month before his return; the lords by their own authority, and the commons

in pursuance of writs issued in the name of the keepers of the liberty of England by the authority of parliament; and this parliament sat full seven months after the restoration, and enacted many laws still in force. But the first thing done after the king's return, was to pass an act declaring this to be a good parliament, notwithstanding the defects of the king's writs. And it was thought farther necessary to confirm its acts in the next parliament, by 13 Car II. cap. 7. and cap. 14. The other exception occurs at the time of the revolution, A. D. 1688, when the lords and commons by their own authority, and upon the summons of the prince of Orange (afterwards king William), met in a convention, and disposed of the crown and kingdom. The throne at this time was vacant by the abdication of king James II. and it was declared by W. & M. stat. 1. cap. 1. that this convention was really the two houses of parliament, notwithstanding the want of writs, and other defects of form.

As the king only can convoke a parliament, he is bound to do this every year, or oftener, if need be. And by 16 Car. II. cap. 1. it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most: by 1 W. & M. stat. 2. cap. 2. it is declared to be one of the rights of the people, that for redress of all grievances, and for the amending, strengthening, and preserving the laws, parliaments ought to be held frequently; and this indefinite frequency is reduced to a certainty by 6 W. & M. cap. 2. which enacts, that a new parliament shall be called within three years, after the determination of the former.

As to the constituent parts of a parliament, these are the king, who sits there in his royal political capacity, and the three estates of the realm; the lords spiritual, the lords temporal, who sit together with the king in one house, and the commons, who sit by themselves in another. And the king, and these three estates together, form the great corporation or body politic of the kingdom, (4 Inst. 1, 2. stat. 1. Eliz. c. 3. Hale of Parl. 1.) of which the king is said to be *caput, principium, and finis*. (See KING.) For upon their coming together the king meets them, either in person, or by representation, without which there can be no beginning of a parliament; and he also alone has the power of dissolving them. 4 Inst. 6.

The spiritual lords consist of two archbishops and twenty-four bishops, who are supposed to hold certain ancient baronies under the king, in right of which they obtain their seats in the house of lords; where they intermix in their votes with the temporal lords, so that in every effectual sense they form one estate. (See ARCHBISHOP and BISHOP.) The lords temporal consist of all the peers of the realm, as dukes, marquises, earls, viscounts, and barons. Some of these sit by descent, as do all ancient peers; some by creation, as do all new made ones; others, since the union with Scotland, by election, which is the case of the sixteen peers, who represent the body of the Scotch nobility: and twenty-eight peers for Ireland, besides one archbishop and three bishops. Their number is indefinite, and may be increased at will by the power of the crown. See PEER.

The commons consist of all such men of any property in the kingdom as have not seats in the house of lords; every one of whom has a voice in parliament, either personally, or by his representative. See COMMONS.

The number of English representatives is five hundred and thirteen (*viz.* ninety-two knights of shires, fifty citizens for twenty-five cities, Ely sending none, and London four; three hundred and thirty-four burgesses for one hundred and sixty-seven boroughs, two each; five for five boroughs, one each; and twelve for twelve boroughs in Wales, Pem-

broke sending two, and Merioneth none; four for the two universities, and sixteen for the eight cinque ports), of Scots forty-five, and of Irish one hundred; so that the representatives of the united kingdom amount to 658. The consent of all these three parts is required to make any new law that shall bind the subject. Whatever is enacted for law by one, or by two only, of the three, is no statute, and no regard is due to it, except in matters relating to their own privileges. It is particularly enacted by statute 13 Car. II. c. 1. that if any person shall maliciously or advisedly affirm, that both, or either of the houses of parliament have any legislative authority without the king, such person shall incur all the penalties of a "præmunire."

The jurisdiction of parliament thus composed and considered as an aggregate body, is so transcendent, says sir Edward Coke (4 Inst. 36.), that it makes, enforces, enlarges, restrains, abrogates, repeals, revives, and expounds laws and statutes, concerning matters ecclesiastical, civil, criminal, martial, maritime, &c. And for making of laws, and in proceeding by bill, this supreme court is not confined either for causes or persons within any bounds; nor is it tied down to any certain rules or forms of law, in proceedings and determinations: the court of parliament hath power to judge in matters of law; and redress mischiefs and grievances that happen, especially such as have no ordinary remedy; to examine into the corruption of judges and magistrates, and illegal proceedings of other courts; to redress errors, and determine on petitions and appeals, &c. and from this high court there lies no appeal.

It can regulate or new model the succession to the crown; as in the reign of Henry VIII. and William III. It can alter the established religion of the land, as was done in the reigns of king Henry VIII. and his three children. It can change and create afresh even the constitution of the kingdom, and even of parliaments themselves, as was done by the act of union, and the several statutes for triennial and septennial elections. And, therefore, some have not scrupled to call its power, by too bold a figure, the omnipotence of parliament. It is therefore, as judge Blackstone observes, a matter most essential to the liberties of the kingdom, that such members be delegated to this important trust, as are most eminent for their probity, their fortitude, and their knowledge; for it was a known apophthegm of the great lord treasurer Burleigh, "that England could never be ruined but by a parliament;" and as sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in this kingdom, if by any means a misgovernment should any way fall upon it, the subjects of this kingdom are left without all manner of remedy. To the same purpose the president Montesquieu (we trust too hastily,) presages; that as Rome, Sparta, and Carthage, have lost their liberty and perished, so the constitution of England will in time lose its liberty and perish: it will perish, whenever the legislative power shall become more corrupt than the executive.

Affairs of parliament are to be determined by the parliament; and though the parliament err, it is not reverfible in any other court: and not only what is done in the house of commons, but what relates to the commons during the parliament, and sitting of the parliament, is no where else to be punished but by themselves, or a succeeding parliament. Every court of justice having laws and customs for its direction, the high court of parliament hath its own proper laws and customs, called the laws and customs of parliament; in-somuch that no judges ought to give any opinion of matters done in parliament, because they are not to be decided by

the common law : but the parliament, in their judicial capacity, are governed by the common and statute laws, as well as the courts in Westminster-hall.

The lords and commons in their respective houses have power of judicature, and so have both houses together : and in former times, both lords and commons sat together in one house of parliament. The king cannot take notice of any thing said to be done in the house of commons but by the report of the house ; and every member of the house of parliament has a judicial place, and can be no witness.

The house of lords is a distinct court of judicature from the commons, to several purposes ; they try criminal causes on impeachments of the commons, and have an original jurisdiction for the trial of peers upon indictments found by a grand jury : they also try causes upon appeals from the court of chancery, or upon writs of error to reverse judgments in the king's bench, &c. Also the house of commons is a distinct court to many purposes ; they examine the right of elections, expel their own members, and commit them to prison, and sometimes other persons, &c. And the book of the clerk of the house of commons is a record.

In order to prevent the mischief that might arise from reposing such extensive authority with incompetent persons, it is provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age. (7 & 8 W. III. cap. 25.) No member shall sit or vote in either house, till he hath, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, and subscribed and repeated the declaration against transubstantiation, and invocation of saints, and the sacrifice of the mass. (30 Car. II. stat. 2. 1 Geo. I. c. 13.) No alien, even though he be naturalized, shall be capable of being a member of either house of parliament. (12 & 13 W. III. c. 2.) As to the qualifications of members of the house of commons, besides the above qualifications, it is declared and required by the law of parliament or special statutes, that they must not be any of the twelve judges, because they sit in the lords house, nor of the clergy, because they sit in convocation, nor persons attainted of treason or felony, because they are unfit to sit any where : that sheriffs of counties, and mayors, and bailiffs of boroughs, are not eligible in their respective jurisdictions, as being returning officers : that no persons concerned in the management of any duties or taxes created since 1692, except the commissioners of the treasury, nor any of the officers following, *viz.* commissioners of prizes, transports, sick and wounded, wine licences, navy and victualling ; secretaries or receivers of prizes, comptrollers of the army accounts, agents for regiments, governors of plantations and their deputies, officers of Minorca or Gibraltar, officers of the excise and customs, clerks or deputies in the several offices of the treasury, exchequer, navy, victualling, admiralty, pay of the army or navy, secretaries of state, salt, stamps, appeals, wine licences, hackney-coaches, hawkers, and pedlars ; nor any persons that hold any new office under the crown, created since 1705, are capable of being elected members : that no person having a pension under the crown during pleasure, or for any term of years, is capable of being elected ; that if any member accepts an office under the crown, except an officer in the army or navy accepting a new commission, he vacates his seat, but is capable of being re-elected : and moreover, persons in particular circumstances have forfeited the right of choice, and have been declared ineligible for that parliament by a vote of the house of commons, or *for ever*, by an act of the legislature. By 22 Geo. III. c. 45. contractors are ineligible. It has been also required, in strictness, that all members should

be inhabitants of the places for which they are chosen, but this is altogether disregarded and repealed by 14 Geo. III. c. 53. For other qualifications, and for the qualifications of electors, see BURGESS and KNIGHTS of the Shire.

As for the method of proceeding in elections ; when the parliament is summoned, the lord chancellor (or if a vacancy happens during parliament, the speaker, by order of the house) sends his warrant to the clerk of the crown in chancery ; who issues out writs to the sheriff of every county, for the election of all the members to serve for that county, and every city and borough in it. Within three days after the receipt of this writ, the sheriff is to send his precept, under his seal, to the proper returning officers of the cities and boroughs, commanding them to elect their members : and the said returning officers are to proceed to election within eight days from the receipt of the precept, giving four days notice of the same ; and to return the persons chosen, together with the precept, to the sheriff. But elections of knights of the shire must be proceeded to by the sheriffs themselves in person, at the next county court, that shall happen after the delivery of the writ. If this court falls upon the day of delivering the writ, or within six days after, the sheriff may adjourn the court and election to some other time, not longer than sixteen days, nor shorter than ten ; but he cannot alter the usual place without consent of the candidates : and in all such cases, ten days public notice must be given of the time and place of election. In order to prevent all undue influence, as soon as the time and place of election, in counties or boroughs, are fixed, all soldiers quartered in the place are to remove at least one day before the election, to the distance of two miles or more ; and not to return till one day after the poll is ended. By vote of the house of commons, no lord of parliament, or lord lieutenant of a county, hath any right to interfere in the election of commoners ; and by statute, the lord warden of the cinque ports shall not recommend any members there. If any officer of the excise, customs, stamps, or other branches of the revenue presumes to intermeddle in elections, by persuading or dissuading any voter, he forfeits 100*l.* and is disabled to hold any office.

For the provisions against bribery, see BRIBERY.

On the day of election, the returning officer first takes an oath against bribery, and for the due execution of his office ; the candidates, also, if required, must swear to their qualifications ; and the electors, both in counties and boroughs, are compellable to take the oath of abjuration, and that against bribery and corruption. When the election is closed, the returning officer in boroughs returns his precept to the sheriff with the persons elected by the majority : and the sheriff returns the whole, together with the writ for the county, and the knights elected, to the clerk of the crown in chancery, before the day of meeting, if it be a new parliament ; or within fourteen days after the election, if it be an occasional vacancy ; under penalty of 500*l.* If the sheriff does not return such knights only as are duly elected, he forfeits, by the old statutes of Henry VI. 100*l.* ; and the returning officer in boroughs, for a like false return, 40*l.* ; and they are besides liable to an action, in which double damages shall be recovered, by the later statutes of king William : and any person bribing the returning officer shall also forfeit 300*l.* But the members returned by him are the sitting members, until the house of commons, upon petition, shall adjudge the return to be false and illegal.

The privileges of parliament are very large and indefinite : the chief of these are privilege of speech, of person, of their domestics, and of their lands and goods. Privilege of speech is declared to be one of the liberties of the people, and

and it is declared by statute 1 W. & M. stat. 2. cap. 2. that the freedom of speech and debates, and proceedings in parliament, ought not to be impeached or questioned, in any court or place out of parliament. And this freedom of speech is particularly demanded of the king in person, by the speaker of the house of commons, at the opening of every new parliament. So likewise are the other privileges, which are immunities as ancient as Edward the Confessor, and the old Gothic constitution. To assault by violence a member of either house, or his menial servants, is a high contempt of parliament, and there punished with the utmost severity: and there are also penalties annexed to it in the courts of law, by the statutes 5 Hen. IV. cap. 6. and 11 Hen. VI. cap. 11. Neither can any member of either house be arrested and taken into custody, unless for some indictable offence, without a breach of the privilege of parliament. But all other privileges, which derogate from the common law, in matters of civil right, are now at an end, save only as to the freedom of the member's person; which in a peer (by the privilege of peerage) is always inviolable, and in a commoner for forty days after every prorogation, and forty days before the next meeting; and this is commonly as long as the parliament subsists, it seldom being prorogued for more than four more days at a time.

As to all other privileges, which obstruct the ordinary course of justice, they were restrained by the statutes 12 W. III., 2 & 3 Ann. c. 18, and 11 Geo. II. c. 24, and are now totally abolished by the statute 10 Geo. III. c. 50, which enacts, that any suit may at any time be brought against any peer or member of parliament, their servants, or any other person entitled to privilege of parliament, which shall not be impeached or delayed by pretence of any such privilege; except that the person of a member of the house of commons shall not thereby be subjected to any arrest or imprisonment. Likewise, for the benefit of commerce, it is provided by statute 4 Geo. III. c. 33, that any trader, having privilege of parliament, may be served with legal process for any just debt to the amount of 100*l.*; and unless he makes satisfaction within two months, it shall be deemed an act of bankruptcy; so that commissions of bankruptcy may be issued against such privileged traders, in like manner as against any other. See farther, on this subject, under the article COMMONS.

As to the special privileges and claims of peers, we may observe, that, by the charter of the forest, confirmed in parliament 9 Hen. III. every lord, spiritual or temporal, summoned to parliament, and passing through the king's forests, may, both in going and returning, kill one or two of the king's deer without warrant. They have also a right to be attended by the judges of the court of king's bench and common pleas, and such of the barons of the exchequer as are of the degree of the coif, or have been made serjeants at law, and likewise by the masters of the court of chancery, for their advice in point of law, &c. The secretaries of state, the attorney and solicitor-general, and the rest of the king's learned counsel, being serjeants, were also used to attend the house of peers, and have, to this day, their regular writs of summons issued out at the beginning of every parliament: but as many of them have of late years been members of the house of commons, their attendance here is fallen into disuse. Every peer, by licence obtained from the king, may make another lord of parliament his proxy, to vote for him in his absence; which no member of the house of commons can do, because he is himself but a proxy for a multitude of other people. Each peer has also a right, by leave of the house, when a vote passes contrary to his sentiments, to enter his dissent on the journals of the house, with the reasons

for such dissent, which is usually styled his *protest*. All bills, likewise, that may in their consequences affect the rights of the peerage, are by custom of parliament to have their commencement in the house of peers, and to suffer no amendments or changes in the house of commons. Moreover, the statute 6 Ann. cap. 23. which regulates the election of the sixteen representative peers of North Britain, peculiarly relates to the house of lords.

The special privilege and right of the house of commons comprehend all grants of subsidies or parliamentary aids, which begin with them, and are first bestowed in their house. See MONEY Bills.

The place where the parliament meets is wherever the king pleases: of late it has been in the palace of Westminster, the lords and commons each in a distinct apartment. In the lords house the princes of the blood are placed in distinct seats; the great officers of state, dukes, marquises, and bishops, on benches, and the viscounts and barons on others across the house; all according to their order of creation, place, &c.

The commons sit promiscuously, forty members constituting a house; only the speaker has a chair at the upper end; and the clerk and his assistant at a table near him. See SPEAKER.

As to the Manner of debating and passing Bills in Parliament.—To bring a bill into the house, if relief sought by it is of a private nature, it is first necessary to prefer a petition; which must be presented by a member, and usually sets forth the grievance desired to be remedied. This petition, (when founded on facts that may be in their nature disputed) is referred to a committee of members, who examine the matter alleged, and accordingly report it to the house; and then (or otherwise upon the mere petition) leave is given to bring in the bill. In public matters the bill is brought in upon motion made to the house, without any petition at all. Formerly all bills were drawn in the form of petitions, which were entered upon the Parliament Rolls, with the king's answer thereunto subjoined; not in any settled form of words, but as the circumstances of the case required: and at the end of each parliament the judges drew them into the form of a statute, which was entered on the Statute Rolls. In the reign of Henry V., to prevent mistakes and abuses, the statutes were drawn up by the judges before the end of the parliament; and, in the reign of Henry VI., bills in the form of acts, according to the modern custom, were first introduced.

The persons directed to bring in the bill, present it in a competent time to the house, drawn out on paper, with a multitude of blanks, or void spaces, where any thing occurs that is dubious, or necessary to be settled by the parliament itself (such, especially, as the precise date of times, the nature and quantity of penalties, or of any sums of money to be raised); being indeed only the skeleton of the bill. In the house of lords, if the bill begins there, it is (when of a private nature) referred to two of the judges, to examine and report the state of the facts alleged, to see that all necessary parties consent, and to settle all points of technical propriety. This is read a first time, and at a convenient distance a second time; and after each reading the speaker opens to the house the substance of the bill, and puts the question, whether it shall proceed any farther.

The introduction of the bill may be originally opposed, as the bill itself may at either of the readings; and, if the opposition succeeds, the bill must be dropped for that session: as it must also, if opposed with success in any of the subsequent stages.

After the second reading it is committed, that is, referred

to a committee; which is either selected by the house in matters of small importance, or else, upon a bill of consequence, the house resolves itself into a committee of the whole house. A committee of the whole house is composed of every member; and, to form it, the speaker quits the chair (another member being appointed chairman), and may sit and debate as a private member. In these committees the bill is debated clause by clause, amendments made, the blanks filled up, and sometimes the bill entirely new modelled. After it has gone through the committee, the chairman reports it to the house with such amendments as the committee have made; and then the house reconsider the whole bill again, and the question is repeatedly put upon every clause and amendment. When the house have agreed or disagreed to the amendments of the committee, and sometimes added new amendments of their own, the bill is then ordered to be engrossed, or written in a strong gross hand, in one or more long rolls (or presses) of parchment sewed together. When this is finished, it is read a third time, and amendments are sometimes then made to it; and, if a new clause be added, it is done by tacking a separate piece of parchment to the bill, which is called a *rider*. The speaker then again opens the contents; and, holding it up in his hands, puts the question whether the bill shall pass. If this is agreed to, the title to it is then settled; which used to be a general one for all the acts passed in the session, till, in the fifth year of Henry VIII. distinct titles were introduced for each chapter. After this, one of the members is directed to carry it to the lords, and desire their concurrence; who, attended by several more, carries it to the bar of the house of peers, and there delivers it to their speaker, who comes down from his woolack to receive it.

It there passes through the same forms as in the other house (except engrossing, which is already done), and if rejected, no more notice is taken, but it passes *sub silentio*, to prevent unbecoming altercations. But, if it is agreed to, the lords send a message, by two masters in chancery, (or sometimes two of the judges,) that they have agreed to the same: and the bill remains with the lords, if they have made no amendment to it. But if any amendments are made, such amendments are sent down with the bill to receive the concurrence of the commons. If the commons disagree to the amendments, a conference usually follows between members deputed from each house; who for the most part settle and adjust the difference; but, if both houses remain inflexible, the bill is dropped. If the commons agree to the amendments, the bill is sent back to the lords, by one of the members, with a message to acquaint them therewith. The same forms are observed, *mutatis mutandis*, when the bill begins in the house of lords. But, when an act of grace or pardon is passed, it is first signed by his majesty, and then read once only in each of the houses, without any new engrossing or amendment. And when both houses have done with any bill, it always is deposited in the house of peers, to wait the royal assent; except in the case of a money-bill, which, after receiving the concurrence of the lords, is sent back to the house of commons.

The royal assent may be given two ways. 1. In person; when the king comes to the house of peers, in his crown and royal robes, and sending for the commons to the bar, the titles of all the bills that have passed both houses are read; and the king's answer is declared by the clerk of the parliament in Norman-French. If the king consents to a public bill, the clerk usually declares, "*le roy le veut; the king wills it so to be;*" if to a private bill, "*soit fait comme il est desiré; be it as it is desired.*" If the king refuses his assent, it is in the gentle language of "*le roy s'avisera; the king will*

advise upon it." When a money-bill, or bill of supply, is passed, it is carried up and presented to the king by the speaker of the house of commons; and the royal assent is thus expressed, "*le roy remercie ses loyal sujets, accepte leur benevolence, et aussi le veut; the king thanks his loyal subjects, accepts their benevolence, and wills it so to be.*"

In case of an act of grace, which originally proceeds from the crown, and has the royal assent in the first stage of it, the clerk of the parliament thus pronounces the gratitude of the subject; "*les prelates, seigneurs, et commons, en ce present parlement assemblees, au nom de tous vous autres sujets, remercient tres humblement votre majeste, et prient a Dieu vous donner en sante bone vie et longue; the prelates, lords, and commons, in this present parliament assembled, in the name of all your other subjects, most humbly thank your majesty, and pray to God to grant you in health and wealth long to live.*"

2. By the statute 33 Hen. VIII. cap. 21. the king may give his assent, by letters patent, under his great seal, signed with his hand, and notified, in his absence to both houses, assembled together in the high house. And when the bill has received the royal assent, in either of these ways, it is then, and not before, a statute or act of parliament: a copy of which is usually printed at the king's press, for the information of the whole land. See, on this article, Blackst. Com. book i. chap. 2.

PARLIAMENT, *Adjournment of*, is a continuance of the session from one day to another, as the word signifies, which is done by the authority of each house separately, every day, and sometimes for a fortnight or a month together; but the adjournment of one house is no adjournment of the other.

PARLIAMENT, *Dissolution of*, is the civil death of the parliament, which may be effected either by the king's will, expressed in person, or by representation, or by the demise of the crown; in which case it is enacted, by 7 & 8 Will. III. cap. 15. and 6 Anne, cap. 7. that the parliament in being shall continue for six months after the death of any king or queen, unless sooner prorogued or dissolved by the successor; and that if, at the time of the king's death, it stands adjourned or prorogued, it shall assemble immediately; and that, if no parliament is then in being, the members of the last parliament shall assemble, and he again a parliament; or, lastly, by length of time, which by 6 W. & M. cap. 2. was three years; but, by 1 Geo. I. stat. 2. cap. 38, is now seven years; so that the parliament must expire or die a natural death at the end of every seventh year.

PARLIAMENT, *Prorogation of*, is the continuance of it from one session to another. This is done by the royal authority, expressed either by the lord chancellor, in his majesty's presence, or by commission from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time: it not being a prorogation of the house of lords or commons, but of the parliament. The difference between a prorogation and an adjournment is obvious; the former puts an end to the session, and then such bills as are only begun, and not perfected, must be resumed *de novo* (if at all) in a subsequent session; whereas, after an adjournment, all things continue in the same state, and may be proceeded on without any fresh commencement.

PARLIAMENT-HOUSE, *Porter of*. See PORTER.

PARLIAMENT, *Rolls of*. See ROLLS.

PARLIAMENT, *Session of*. See SESSION.

PARLIAMENT is sometimes also used for other assemblies beside those of the states of the realm. Thus we read, that the abbot of Croyland was used to call parliaments of his monks, to consult of the affairs of the monastery. And, at this day, an assembly of the two temples, called to consult of their common affairs, is called a parliament.

PARLIAMENTS of France, according to the old constitution, were courts, or assemblies, established by the king to judge of the differences between particular persons, and to pronounce on appeals from sentences given by inferior judges.

There were twelve of these parliaments in France; that of Thoulouse, established in 1302; that of Dijon, in 1476; that of Grenoble, in 1453; that of Rouen, in 1499; that of Rennes, in Bretagne, in 1553; that of Bourdeaux, according to Du-Cange, in 1460; that of Aix, in 1501; that of Metz, in 1633; that of Pau, in Bearn, in 1519; that of Besançon, in 1422; that of Doway, in 1668; and that of Paris, about 1254.

The parliament of Paris was the principal, and that whose jurisdiction was of the greatest extent. This was the chief court of justice throughout the realm. It consisted of eight chambers; the grand chamber, where causes of audience were pleaded; the chamber of written law; the chamber of counsel; the Tournelle criminelle, for judging criminal affairs; the Tournelle civile, in aid of the grand chamber; and three chambers of inquests, where processes were adjudged in writing; besides these, there was also the chamber of vacations, and those of requests.

In 1771, the king thought fit to branch the parliament of Paris into six different parliaments, under the denomination of superior courts, each parliament having similar jurisdiction.

Under their second race of kings, this parliament, like that of England, was the king's council; it gave audience to ambassadors, and consulted of the affairs of war and government.

The king, like our's, at that time presided in them, without being at all master of their resolutions. But, in after-times, their authority was abridged; the kings having reserved the decision of the grand affairs of the public to their own councils; leaving none but private ones to the parliaments.

PARLIAMENT-Heel, in *Sea Language*, the situation of a ship, when she is made to stoop a little to one side, so as to clean the upper part of her bottom on the other side, and to cover it with a new composition; and afterwards to perform the same office on that part of the bottom which was first immersed. See *Boor-Topping*.

PARLIAMENTARIAN is a term used to denote those, who, in the time of the civil war, were attached to the parliament, in opposition to the royalists, devoted to the king.

PARLIAMENTUM INDOCTORUM, a denomination given to a parliament, held at Coventry, 6 Henry VI. whereunto, by special precept to the sheriffs of the several counties, no lawyer, or person skilled in the law, was to be called.

PARLIAMENTUM Infanum, was a parliament held at Oxford, anno 41 Henry III. thus called, say our chronicles, because the lords came with great retinues of armed men to it; and many things were violently transacted therein against the king's prerogative.

PARLIAMENTUM Diabolicum, was a parliament held at Coventry, 38 Henry VI. wherein Edward, earl of March (afterwards king,) and several others, were attainted. The acts passed herein were annulled by the succeeding parliament.

PARLIAMENTUM de la Bande, was a parliament in Edward II.'s time, whereto the barons came armed against the two Spencers, with coloured bands on their sleeves, for distinction.

PARLIE, in *Geography*, a town of Hindoostan, in Guzerat; six miles S. of Pernalla.

PARLOUR, PARLOIR, from the French *parler*, to talk, in nunneries, a little room or closet, where people talk to the nuns, through a kind of grated window.

Anciently there were also parlours in the convents of monks, where the novices used to converse together at the hours of recreation; but there were listening-places over, from whence the superiors could hear every thing they said. Such a one there still subsists in the abbey St. German de Prez.

In the order of Feuillans, the parlour is a little room open on all sides, placed at each end of the dormitory, where the monks talk together, it not being allowed them to speak in the dormitory.

PARMA, among *Antiquaries*, a kind of ancient buckler. Polybius describes the parma as very strong, round, three feet in diameter, and big enough to cover the whole body; yet Servius on the *Æneid*, and even Virgil himself, mention it as a light piece of armour, in comparison of the clypeus, though bigger than the pelta.

PARMA, or "*The Parmesan*," in *Geography*, a duchy of Italy, to which are united the territories of *Placentia* or *Picenza*, and *Guastalla*; which see respectively. This country is bounded on the N. by the river Po, separating it from the Cremonese and the Lodese, on the E. by the duchy of Modena, on the S. by Tuscany and Genoa, and on the W. by Genoa and the Pavese; about 40 miles from N. to S., and from 30 to 48 from E. to W. These conjoined territories were contended by the Lombards, and by the exarchs of Ravenna; and after many revolutions, became subject to the papal see; from the dominion of which they were transferred by pope Paul III. in the year 1545, to his natural son Pietro Aloysius, or Farnese, from whom that family sprung. This family becoming extinct in 1731, the duchies of Parma and Placentia, after some contest, were finally assigned to the Bourbon family in Spain. By the treaty of Luneville in 1801, the duke of Parma was nominated by the emperor and the French republic, to the throne of Tuscany, with the title of king of Etruria, of which he soon after took possession. The population of these duchies is computed at 300,000, and the revenue at 175,000*l*. Parma and Placentia have each of them an university. The soil of these territories is a rich sandy or gravelly loam, producing corn, olives, chestnuts, and various kinds of fruit. The pastures are excellent, and the cheese, called "*Parmesan*," has been long held in high estimation. The farms are small, and agriculture has been ill conducted, irrigation being little practised. The sheep are bad, yielding a wool like hair. The Bourbon family very much neglected the improvement of the country.

PARMA, the capital of the above duchy, is divided by the river of the same name, which rises in the south part of the duchy, and runs into the Po near Viadana, into three parts, that communicate with each other by two bridges. This city was founded by the Etrurians, taken by a tribe of Gauls, called the Boii, and, at length, colonized by the Romans. It is said to have suffered much from the licentious cruelty of Antony; and its sufferings on this occasion are pathetically deplored and immortalized by Cicero, in his 14th Philippic, the last tribute which he paid to Rome and to liberty. During the disastrous period that occurred between the reigns of Theodosius and Charlemagne, it was taken and retaken by the Goths and Romans, the Lombards and Greek exarchs, till it was given by Charlemagne to the holy see; and after a succession of ages and changes, it was at length bestowed by Paul III. on his son, Ottavio Farnese.

Farnese. In this family it remained till its extinction, in the middle of the last century, when it passed to a prince of Spain; and on the death of the last duke, was taken possession of by the French, and is now pining away under the influence of their domination. The city is large, populous, airy and clean, though it cannot boast of any very striking or regular building. It is surrounded by walls, flanked with bastions, and a ditch filled with water. On the south is the citadel, which is a regular pentagon, and reckoned the best in Italy. The roads that lead to Parma are in a line, and the streets are straight and broad, formed by well-built and painted houses, and meet in the centre, constituting a handsome square. The new palace was erected on the ruins of the old, and forms an irregular and huge mass of building. The theatre is represented as one of the most beautiful in Italy, and is said to contain upwards of 12,000 spectators, who, by the structure of the place, are capable of hearing the actor on the stage, without any elevation of voice. Here is also a smaller theatre, for the accommodation of the inhabitants. This city is the see of a bishop, suffragan of Bologna. Its university was founded in 1599, and its academy of sciences was instituted in 1601. It has five collegiate and 30 parish churches, besides the cathedral, many of which contain pictures by Correggio, and other eminent masters, and 40 convents. The cathedral is Saxon, but lined in the interior with Roman architecture: its dome is much admired, on account of Correggio's paintings. The baptistery is an octagon, in the same style with the cathedral, cased with marble, and ornamented with various arches and galleries. The Steccata is the most regular church in Parma, in the form of a Greek cross. The church of the Capuchins is only remarkable for being the burial-place of the celebrated Alexander Farnese. The arts and sciences have by no means been neglected in Parma. An university, two academies, schools of painting, &c. announce the application; and a long catalogue of great names might be produced, to prove the success of the Parmians in every literary pursuit. The dukes have for many years assumed the character of Mecænas, and, by their judicious encouragement, attracted men of talents, from other countries, to their territories. The public walks on the ramparts are very pleasing. The country round is well wooded, and the town and territory of Parma, on the whole, seemed to have been in a flourishing state till the entrance of the French army. Since that fatal period, its prosperity has been on the decline, its government unsettled, and its inhabitants impoverished and discontented. The contributions raised by the French amounted to five millions of French livres; a sum enormous for so small a territory, and equalling two years of its regular income. The chief trade of the place consists in stockings, and some other articles of silk manufacture. The printing press, established by Bodoni in 1765, has been distinguished for beautiful publications. The number of its inhabitants is not accurately ascertained; some reckoning them at 45,000, and others at 37,000; 32 miles S.W. of Mantua. N. lat. 44° 47'. E. long. 27° 52'.

Parma was a town of Gallia Cispadana, and possessed for a long time by the Boii. It appears to have subsisted for a considerable period, when, in 579, the Romans sent hither a colony under the consulates of Q. Fabius Labeo and Marcellus. In the reign of Augustus, this place assumed the appellation of "Colonia Julia Augusta." It suffered much during the wars of Antony.

PARMELIA, in Botany, so called, as Professor Acharius, the author of the name and of the genus, tells us, from *παρμηνη*, a sort of small shield, and *εἰλωτο*, to surround or inclose,

a genus of the natural order of LICHENES. (See that article, sect. 3. n. 16.) The learned writer, whose distribution of this tribe we have explained in that place, has judged it best to exclude the name of *Lichen*, as a generic appellation, retaining it for the whole natural order, which is perhaps the most commodious plan; otherwise, it should have remained with the genus before us, as being the most extensive in species, and the most comprehensive in character, of the whole. It is indeed so miscellaneous in habit, that we cannot but feel favourably disposed to any attempt at dividing it; and yet we can hardly accede to the very great multiplication of genera in Acharius's most recent work, the *Lichenographia universalis*; a book indeed so very scarce in this kingdom at present, that we have not been able to acquire or to study it. *Collema* however is so naturally distinct in habit and appearance, that no doubt can remain of the propriety of its separation. (See its character in the place above cited.) That of *Parmelia*, see Ach. Meth. 153, should therefore stand as follows.

Shields orbicular, horizontal, superficial, somewhat elevated, with a cartilaginous accessory border.

The disk is sometimes concave, oftener nearly flat, or indeed convex and hemispherical when far advanced in age, of a different substance and colour from the border, and without any border, or separate edge, of its own substance, in which last respect it differs from the Acharian genus *Lecidea*. The texture of the disk is tolerably firm, though occupied with innumerable vertical parallel cells, each containing about eight minute seeds, placed one above the other. Its external colour is different in different species, most generally brown or reddish, but always totally unlike that of the border; internally it is paler. By age the disk in many species becomes loosened, falling out, and leaving its border in the shape of a small cup, or rather saucer, as may be seen in *P. conspersa*, Ach. Meth. 205. In *P. subfusca*, 167, see Engl. Bot. t. 2109. a very extraordinary proliferous appearance is occasionally seen in the disk. The writer of this has suspected that, in *subfusca* especially, when impregnation fails, the disk does not acquire its proper colour.

The border is of the same colour and substance with the frond, from which it proceeds, being elevated more or less above the level of that part, and very generally, at least in the more leafy species, attached merely by a central stalk, though its circumference is flat, and clapped, often very closely, to the surface. In the crustaceous kinds the union of the parts is more considerable; in the more filamentous or branched ones it is merely central, by an elongated and obvious stalk. The extreme part of the border is more or less tumid and thick, either smooth or powdery, entire or crenate, rarely fringed or leafy, while the very edge itself is inflexed and even.

The frond is various and of many different shapes and appearances. When crustaceous, leprous, or tartareous, it is either uniform, and limited by a well-marked border, usually blackish; or it is loosely dispersed, without any distinct limitation, frequently in small portions or patches, and then, in many instances, finally disappears by age, leaving the bare and scattered shields, as if growing independently out of the stone or bark. In other cases the frond consists of lobed fragments, assuming a leafy imbricated aspect, and a cartilaginous texture; from which there is an insensible gradation to a truly leafy configuration, which is either membranous or coriaceous, dilated and lobed, or narrow and repeatedly branched, round or compressed, erect, horizontal, or pendulous: in all cases it readily imbibes moisture, and by that means becomes instantly soft, flexible, and

and vegetative, however dry, contracted and brittle before. The colour of the frond is commonly very different in its moist and flourishing state, to what it is when dry; being, in the latter condition usually pale and greyish, but assuming a beautiful green when moistened. Yet there are some species always of the same grey hue, whether wet or dry, which by that very circumstance are well distinguished from others. See *P. stellaris* and *asplasia*, Ach. Meth. 209.

The male fructification of *Parmelia* is supposed, rather than known, to consist of scattered powdery warts, mostly of a lighter colour than the frond, on whose surface or segments they are situated, burbling, as it were, from under the cuticle. They are conspicuous in *P. casta*, see Engl. Bot. t. 1052, and *physodes*, t. 126. There is perhaps much reason to suppose such efflorescences to be of the nature of buds, or *gemmæ*, by which the species may be increased. The great Hedwig however speaks of them, in the example last cited, as clearly anthers. (See his *Theoria*, 124. t. 31, and *Withering*, v. 1. 371. t. 16. f. 86, 87.) In that they are commonly found on a separate plant from the shields, a rare occurrence in this tribe. They are also in the species in question, as well as most others, by far most abundant when the shields, which are unquestionably the female parts of fructification, are sparingly produced; which is rather in favour of the opinion of their being buds. The same opinion is strengthened by a consideration of the plants constituting a supposed genus called *Lepraria*, which are propagated very copiously by such powdery granulations only; and yet a few of its species are known to bear sometimes, though very rarely indeed, proper shields, with the character either of a *Parmelia* or a *Lecidea*; and we are much inclined to presume they may all be capable, in favourable circumstances, of doing so. The parts of the shield, at the period when impregnation, in whatever mode, must take place, are so minute, homogeneous and obscure, that if we still remain in total ignorance of the flowers of Ferns, no wonder we are equally in the dark respecting Lichens.

PARMENALORE, in *Geography*, a town of Hindoostan, in Coimbatore; 15 miles S.W. of Errood.

PARMENIDES, in *Biography*, a celebrated Greek philosopher of the Eleatic sect, who flourished about 500 years before Christ, was a native of Elea, possessed a large patrimony, and lived in much splendour in his earliest years. He was distinguished in civil affairs, and is said to have drawn up for his fellow-citizens some excellent laws, to which their magistrates obliged them annually to swear obedience. He at length withdrew from the concerns of public life to the silence and leisure of the schools. He became the disciple and successor of Xenophanes, and is said to have attended upon the instructions of Anaximander. According to the testimony of Cebes, in his allegorical tale, our philosopher was distinguished as an eminent pattern of virtue. He wrote the doctrine of his school in verses, of which only a few fragments remain. Plato, in the dialogue which he denominated *Parmenides*, professed to represent his tenets, but confounded them with his own. He maintained that philosophy was twofold; that which follows the report of the senses, and that which is according to reason and truth. The former treats of the appearances of sensible objects; the latter considers the abstract nature of things, and inquires into the constitution of the universe. He maintained that the universe is one, improveable, eternal, and of a spherical form; that the earth is spherical, and placed in the centre, being exactly balanced by its distance from the heavens, so that there is no cause why it should

move one way rather than another. Parmenides adhered more closely to the Pythagorean doctrine than Xenophanes, the founder of the Eleatic sect; for while the latter considered the universe as possessing within itself a divine force, the former supposed the deity to be an informing principle, or intellectual fire diffused throughout the universe, but more especially residing in the extreme sphere of the world; on which account, he is metaphorically represented by this philosopher as a crown of light, inclosing within its circumference the celestial orb. Enfield's Hist. Phil.

PARMENIDES' *Philosophy*. See ELEATIC.

PARMENIO, in *Biography*, a distinguished Macedonian commander, who rose to great reputation under king Philip. That monarch is said to have pronounced him the only general he had ever met with. When Alexander invaded Asia, he was accompanied by Parmenio, who, after the victory of Granicus, gave the advice of venturing upon a naval engagement, and offered himself to serve on board the fleet. Alexander, however, regarding the sea as the proper element of the Persians and their allies, would not consent to the hazard. At the battle of Issus, Parmenio had the command of the left wing; and after that important victory, he was dispatched to Damascus, to take possession of the treasures of Darius, left in that city. In the decisive action of Arbela, Parmenio again commanded the left wing of the Macedonian army; while his two sons, Philotas and Nicanor, had separate commands on the right. During the battle he had to sustain the charge of the whole Persian cavalry, and was, at one time, reduced to such danger, that he sent for succour to Alexander, who was victorious in the centre. The prince arrived in time to rescue Parmenio, who thereupon took possession of the enemy's camp, while Alexander continued the pursuit of Darius in person. He next endeavoured, but in vain, to divert Alexander from the frantic design of burning the royal palace of Persepolis. The ruin of Parmenio was occasioned by the indelicacy of his own son Philotas, who, elated by his prince's favour, affected a pomp and splendour which might render him suspected of ambitious views. The discontents of the army, at the Persian manners assumed by Alexander, after the death of Darius, having produced a conspiracy against his life, Philotas, on its detection, was involved in the guilt, or at least in the accusation, and was put to the rack to force a confession. Unable to endure the torture, he named many accomplices, and among the rest his father. His criminality being supposed to be proved, he was put to death; but the life of Parmenio was at last taken away in a safe and treacherous manner. The persons employed in this infamous business, approaching the general as he was walking in his pleasure-grounds, presented him with a letter from the king, and another in which the hand of Philotas was counterfeited; and while he was intent upon reading them, they stabbed him with repeated wounds. His head was then cut off, and sent to Alexander, while his affectionate soldiers mournfully interred his body. Univer. Hist.

PARMENTIER, JOHN, a scientific French navigator, a native of Dieppe, was born in the year 1494. He was intended and educated for mercantile pursuits, but possessing a love of science, and spirit of enterprize, he acquired celebrity among his contemporaries. He was also esteemed as a poet, and wrote verses on different subjects, of which a collection was published in 1531, under the title of "Description nouvelle des Dignités de ce Monde, et de la Dignité de l'Homme, composée en Rithme François, et en Maniere d'Exhortation." This work is now extremely scarce, and very highly prized by collectors of curious and rare books; but it is chiefly valuable, as containing particulars concerning

concerning the author prefixed to it, from which the following is extracted. "From the year 1522 he had applied himself to the science of cosmography, and the study of the wonderful fluctuations of the sea. On these subjects he became profoundly skilled, as he was likewise in the science of astrology. He drew several maps and charts, both spherical and plane, which were of great service to navigators. He was worthy of the esteem of all men of learning, and capable, had his life been prolonged, of reflecting honour on his country, by his great enterprises. He was the first pilot who conducted ships to the coast of Brasil, the first Frenchman who discovered the Indies as far as the island of Sumatra, called Taprobane by the ancient cosmographers. It had been his intention to have proceeded as far as the Moluccas; and he frequently told me, says the editor, Pierre Crignon, that he was determined, after he should have returned to France, to seek a northern passage, and from thence to pursue his discoveries towards the south." This design was frustrated by his death, which took place in 1530, at the island of Sumatra, when he was only 36 years of age.

PARMESAN, *The*, in *Geography*. See PARMA.

PARMESAN is a name given to a cheese, much esteemed among the Italians, and made at Parmesan, whence it is conveyed to various parts of Europe.

The excellent pasture-grounds of this country are watered by the Po; and the cows, from whose milk this cheese is made, yield a great quantity of it. Of this cheese there are three sorts, the *fromaggio di forma*, about two palms in diameter, and seven or eight inches thick; and the *fromaggio di raviolo* and *di ribolini*, which are not so large. This cheese is of a saffron colour, and the best is kept three or four years. See LODESAN.

PARMIGIANO, IL, in *Biography*, was the cognomen of Francesco Mazzuoli, a painter of great and deserved renown, born at Parma in 1504. He was the pupil of his uncles Michele and Filippo, and at the early age of nineteen had attained very considerable celebrity; having made Correggio, who was then living, the object of his imitation. He then went to Rome, and taking with him some of his productions, was introduced by their renown to pope Clement VII. who highly honoured and esteemed him. In Rome he attached himself to the study of Michael Angelo and Raphael; and exhibited the loftiness of his mind, by composing a style for himself from the high qualities of those two great men, in conjunction with what he had learned of Correggio. In Rome, and under the immediate influence of this newly acquired gusto, he painted several pictures, and among them one which was bought by the marquis of Abercorn, of Mr. Dumo in Italy, for 1500*l.*, and resold by him in 1809 to Mr. Davis of Bristol, for 3000 guineas. It represents the Virgin seated in glory with a book in her hand, and the infant standing on the clouds, and leaning against her knee; in front is a figure of St. John kneeling upon one knee, pointing with one hand to the Virgin, and turning his face to the observer; and in the background, asleep, is a figure of St. Jerome, who is supposed to have seen this vision, and from which the picture takes its name. Vafari makes especial mention of it; and says, Parmigiano painted it for Donna Maria Bufolina of Citta di Castello, who intended to place it in the church of St. Salvatore del Lauro; in a chapel near the door. In the execution of it, Parmigiano had nearly lost his life; for notwithstanding the siege of Rome by the Colonnas, he continued painting upon it, and some Germans, intent upon plunder, entered his room while he was so engaged. The splendour of the work, however, fortunately so astonished and delighted them, that

though they spared in no excess, but robbed the palaces and churches of every thing they thought worth having; yet they protected the painter and honoured his abilities. He did not quite complete the picture, and soon after left the city; but not till the soldiers had obliged him to make for them a number of drawings in pen and ink. He was afterwards, in going to see some friends, made a prisoner by other soldiers, from whom he disengaged himself by paying money; and then his uncle, alarmed for his safety, removed him from Rome and sent him back to Parma. This grand picture was safely lodged in the convent of the Frati della Pace, where it remained in the refectory many years, and was then carried by Julio Bufolino to its original destination, the church at Citta di Castello.

In his return to his native place, Parmigiano stopped at Bologna; and there for a while he engaged himself in making those free and elegant etchings, with which the cognoscenti are so enamoured. He also painted several pictures there, and made a great number of drawings, and two portraits of Bonifacio Gozadino and his wife. Among the pictures was a large one for the monks of St. Margaret, of the Virgin, with several saints, which was very highly esteemed by the Caracci, and by Guido was preferred to the St. Cecilia of Raphael. He there also painted a portrait of Charles V. with a figure of fame crowning him with laurel, which he effected after seeing the emperor dining in public several times; and it so gratified his majesty that he wished to have it, but Parmigiano stating that it was not finished, it remained with him, and afterwards passed to the possession of the duke of Mantua.

He at length returned to his native city, and was immediately engaged to paint, in fresco, the vaulted ceiling of the church of Sta. Maria della Steccato; and in the lower part executed six figures; a Moses, three Sybils, and an Adam and Eve. Of which Mr. Barry, in a letter to Mr. Burke, says, "that they exhibit powers which, if fully displayed, might have exceeded either Raphael or M. Angelo." Unfortunately at this time, when Parmigiano ought to have pursued this great work, and have established his fame upon it, he turned aside to the alluring study of alchemy, and wasted his time and his fortune in vain attempts at transmutations; which only prevented him from exercising his abilities in a more certain mode of obtaining not only gold, but also glory. He died at the age of 36 or 7, in 1540-1.

"The ruling features of his style are elegance of form, grace of countenance, contrast in attitude, enchanting chiaroscuro, and blandishments of colour. When these are pure, he is inimitable: but his elegance is often stretched to excessive slenderness, and his grace deformed to affectation."

He was a learned designer: to his depth in design, we must ascribe that freedom of execution, those decided strokes of his pencil, which Albano calls divine, and which add grace to the finish of his pictures: they have not indeed all equal impact of colour, nor equal effect, though some, for the amorè with which they are conducted, have been ascribed to Correggio: such is the Cupid scooping his bow, with the two infants at his feet, one laughing, the other crying, of which, besides that in the Imperial gallery, there are several repetitions. "Such was the delight found in the study of the pictures of Parmigiano, that copies, and excellent ones too, are found all over Italy; and are not unfrequently sold here as originals. The one upon which we have dwelt so minutely above, the dream of St. Jerome, is of so high a class, that it may rank with the Peter Martyr of Titian, the Transfiguration of Raphael, and the St. Jerome of Dominichino. His cousin, Girolamo Mazzuolo, was his friend and pupil, and possessed so much skill in execution, that it is not impossible

possible that many pictures ascribed to Parmigiano are executed by this artist." He was more attached to the style of Correggio than Francisco; and seized its character with great felicity in the Nuptials of St. Catharine, in the church del Carmine. He excelled in perspective; and in the Last Supper in the refectory of S. Giovanni, placed and painted a colonnade with all the illusion of Pozzo. To the most harmonious chiaro-scuro, he added grandeur, variety, vivacity, in fresco. None of his fellow artists equalled him in copiousness, fertility, and execution; and to these perhaps we may ascribe the inequality perceptible in his works.

PARMILLIEU, in *Geography*, a town of France, in the department of the Isere; 24 miles E N E. of Lyons.

PARMONCA, a town of Peru, in the audience of Lima, near the sea; 35 miles N.N.W. of Guaura.

PARNAPIACABA, a river of Brazil, which runs into the Atlantic, S. lat. 24° 12'.

PARNASSA, a town of Hindoostan; 15 miles S.S.E. of Allahabad.

PARNASSIA, in *Botany*, well altered by Tournefort from the old name of Gramen Parnassi, which has been appropriated to this most curious and elegant plant, because it appears really to be what Dioscorides terms the Grass of Parnassus, *αγρυσις ἢ ἐν παρνασσῷ*. Not that it has any thing to do with the grasses, properly so called; but he describes it as "having ivy-like leaves, a white and pleasantly-scented flower, with small not ineffectual seed, five or six roots as thick as the finger, white and soft." This description sufficiently answers to our *Parnassia*, except that we know of no smell in the flowers. Some have taken *Convallaria bifolia* for what Dioscorides intended.—Linn. Gen. 151. Schreb. 204. Willd. Sp. Pl. v. 1. 1516. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 339. Prodr. Fl. Græc. Sibth. v. 1. 210. Ait. Hort. Kew. ed. 2. v. 2. 177. Juss. 245. Tourn. t. 127. Lamarck Illustr. t. 216. Gærtn. t. 60.—Class and order, *Pentandria Tetragynia*. Nat. Ord. *Campanaceæ*, Linn. MSS. *Capparides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five, deep, elliptic-oblong, spreading, permanent segments. *Cor.* Petals five, roundish, striated, concave, spreading. Nectaries five, opposite to the petals, each a roundish or oblong fleshy scale, fringed with from three to thirteen erect marginal stalks, bearing every one a small globe, shorter than the petals. *Stam.* Filaments five, awl-shaped, the length of the nectaries, separately inflexed for a time over the germen; anthers incumbent, depressed. *Pist.* Germen superior, ovate, large, sessile; style none, but an aperture in its place; stigmas four, obtuse, permanent, enlarged in the fruit. *Peric.* Capsule ovate, somewhat quadrangular, of one cell and four valves, the partitions from the centre of each valve, each bearing a furrowed parallel receptacle. *Seeds* several, oblong, ascending.

Eff. Ch. Calyx in five deep segments. Petals five. Nectaries five, fringed with stalked globules. Capsule of four valves, with many seeds.

1. *P. palustris*. Common Grass of Parnassus. Linn. Sp. Pl. 391. Engl. Bot. t. 82. Fl. Dan. t. 584. Mill. Illustr. t. 15. Sm. Intr. t. 13. f. 175. Dickf. H. Sicc. fasc. 7. 10. Ehrh. Pl. Off. 133. (Gramen Parnassi; Ger. em. 840.)—Leaves heart-shaped. Petals sessile, emarginate. Nectaries with numerous segments.—Native of boggy pastures throughout Europe, flowering in autumn. Dr. Sibthorp gathered it on the Bithynian Olympus, and there is every reason to believe it may grow on Parnassus, and other Grecian hills; whereas *Convallaria bifolia*, which some botanists suppose to be what Dioscorides meant, is not known to be a Grecian plant, but is rather confined to the northern parts of

Europe. The root of *P. palustris* is perennial, cylindrical and fleshy, throwing out many long fibres. *Stems* erect, near a span high, simple, angular, twisted, smooth, bearing one sessile leaf, and one flower. *Leaves* heart-shaped, entire, ribbed, smooth; the radical ones numerous, on stalks thrice their own length. *Flower* terminal, above an inch wide, white and singularly elegant. *Petals* marked with many parallel pellucid lines. *Nectaries* wedge-shaped, each bearing about thirteen globe-tipped bristles; the globes, like the anthers, pale yellow. The *stamens* are bent successively over the *stigmas* to impregnate them, retiring subsequently, as in *Saxifraga* and *Ruta*. Afterwards the *stigmas* are brought nearer together, closing the aperture of the *germen*; but the insertion of the *seeds* proves that the impregnation must take place through the usual parts, and not by the aperture.

2. *P. caroliniana*. Carolina Grass of Parnassus. Michaux Boreal. Amer. v. 1. 184. Ait. n. 2. Sims in Curt. Mag. t. 1459.—Leaves almost orbicular. Petals nearly sessile. Nectaries deeply three-cleft.—Discovered by M. Bosc on bogs in North Carolina. It was sent to Kew garden in 1802 (not 1782) by the late Mr. Masson, and is hardy in our climate, flowering in autumn. This has altogether the habit of the preceding, but is somewhat larger. The *leaves* are more orbicular. *Petals* more elliptical, entire, not emarginate, the lines green and very numerous, the whole of the petals of a greenish cast. *Nectaries* remarkably different, being deeply divided into three awl-shaped segments only, with a yellow ball upon each point. Mr. Aiton mentions this species as flowering in May and June; Dr. Sims from July to September.

3. *P. afarifolia*. Kidney-leaved Grass of Parnassus. Venten. Jard. de la Malmaison. t. 39.—Leaves kidney-shaped. Petals with claws. Nectaries oblong, with three terminal segments.—Native of bogs in North America, flowering in the latter part of summer. M. Ventenat described it from the collection at Malmaison. This differs from both the foregoing in having shorter or kidney-shaped *leaves*; *petals* furnished with considerable claws; *nectaries* of an elongated and linear form, divided at the upper part only, into three bristle-like segments, tipped with darker-coloured globules. The *petals* moreover seem to be smaller, and more rounded, than in the *caroliniana*; entire, and not, as in the *palustris*, emarginate. We have not heard of this, any more than the following, in the English gardens.

4. *P. fimbriata*. Fringe-flowered Grass of Parnassus. König in Ann. of Bot. v. 1. 391.—Leaves kidney-shaped. Petals fringed at the lower part, with entire claws. Nectaries palmate, with numerous segments.—Gathered by Mr. Archibald Menzies on mountains on the north-west coast of America. We are indebted to him for fine specimens, by which this species appears to agree with the last in habit, but the *flowers* are essentially different. The claws of the *petals* are smooth and entire, but the base of each petal itself is copiously fringed with fine long capillary segments. The *nectaries* are palmate, mostly resembling those of the first species, which they seem to approach in their number of segments, but those segments are of a much shorter proportion. The stem *leaf* is much nearer the flower than the root; the radical ones are remarkably hollowed out at their base, close to the lateral ribs, which are connected with one another by a common base, like the divisions of a pedate leaf, and have a very elegant appearance. The same thing is seen, though less remarkably, in *Aristolochia Clematitis*.

PARNASSUS, in *Ancient Geography* and *Mythology*, a mountain of Greece, in the Phocide, consecrated by the poets to the Muses, thence called Parnassides, to Apollo and to Bacchus. It was situated to the S.E. of the Crif-

fean gulf, and N.W. of the river Cephus. On this hill, though for the most part sterile, there were groves and small villages adapted to excite and inflame the poetic genius. It is described as having two summits, one called Hyampea, the other Phitorea, between which arises the Cæstalian fountain. The Greeks call this mountain Licaoura.

PARNASSUS was also a town of Asia, in Galatia, upon the route from Cæsarea to Ancyra, between Aspona and Nyssa, according to the Itinerary of Antonine.

PARNEL, in *Geography*, a town of Hindoostan, in Dowlatabad; 15 miles S.W. of Amednagur.

PARNELL, THOMAS, in *Biography*, an English poet, descended from an ancient family in Cheshire, was born at Dublin in the year 1679, and received his school education in that city, after which he was transferred to the college. He was admitted to the degree of M. A. in 1700, took deacon's orders in the same year, and was ordained priest three years afterwards. In 1705 he was presented to the archdeaconry of Clogher, and about the same time was married to a lady of great beauty and merit. From this period he began to make frequent excursions to England, in which the pleasanter part of his life was spent. He connected himself with the whigs, who were at that time in power, and was familiar with their most distinguished men of letters, as Addison, Congreve, and Steele. Towards the close of queen Anne's reign, Parnell, influenced, it was thought, by Swift, deserted his former friends, and joined in close union with that celebrated wit, and his associates, Pope, Gay, and Arbuthnot. Swift introduced him to lord-treasurer Harley, and with a dictatorial air insisted upon the treasurer going with his staff in his hand into the anti-chamber, where Parnell was waiting to welcome him. Parnell, however, never had any claim to a high rank in literature, nor was it possible he could render his friends much political service. He was a pleasant good tempered man, attached to his particular associates, and so much addicted to society, that he preferred what was indifferent to solitude. He was, at one period, an assiduous preacher in the London pulpits, hoping to rise into notice by the popularity of his talents, but the complete change in the administration by the death of queen Anne entirely destroyed his brilliant prospects in the church. By means of Swift's recommendation of him to the notice of archbishop King, he obtained a prebend and a valuable living. In 1712 he received a most severe shock, by the death of his beloved wife, from which he never recovered. The loss is said to have had such an effect upon his spirits, as to lead him into those habits of intemperance in wine which shortened his life, and his biographer, Dr. Goldsmith, represents him, in some measure, a martyr to conjugal fidelity. He died at Chelster, on his way to Ireland, in July 1717, in the 38th year of his age, and was buried, without any monumental record, in Trinity-church in that city. He was author of several pieces both in prose and verse. He wrote the *Life of Homer*, prefixed to Pope's *Iliad*, which, however, on account of the stiffness of the style, cost that poet much labour in the correction. It is as a poet that he is now exclusively known and valued. After his death, Pope made a selection of such of his pieces as he thought worth preserving, and published them in one volume octavo. They have since made a part of the body of approved English poetry. They are remarkable for ease, sprightliness, fancy, clearness of language, and melody of versification. Though not ranking among the noblest and most finished productions of the British muse, they claim a place among the most pleasing. Their sentiments are elegant, and their morality very pure. A volume of posthumous pieces was printed at

Dublin in 1758, the contents of which have been since added to the former in the collections of English poets. Dr. Johnson has thought it unnecessary to enquire into their authenticity, or canvass their merits: he expressly limits his commendations to the pieces published by Pope.

PARNES, in *Ancient Geography*, a mountain of Greece, in Attica, on which were a statue of Jupiter Parnetian in bronze, another of Jupiter and Serrelé, and another altar on which the adjacent inhabitants sacrificed to Jupiter, under the appellations of the *beneficent* and *rainy*, or *pluvius*. This mountain abounded with bears and wild boars.

PARNIPA, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 18° 10'.

PARNON, in *Ancient Geography*, a lofty mountain of the Argolide, on which were placed the Hermæan statues of Mercury, which, in the time of Pausanias, indicated the limits of Laconia, and of the territory of the Tægeates, a people of Arcadia.

PARNOPS, in *Natural History*, the name of a species of wasp, found very frequently in vineyards, and among the wine presses, especially in hot countries. It is distinguished from all the other wasps by the roundness of its body, which is not slender or flattened in the common way, but round and tumid.

PARO, or PAROGONG, or *Kinjipo*, in *Geography*, a town, castle, and palace, as well as valley of Bootan. The castle stands near the base of a very high mountain, in the form of an oblong square, fenced by walls and parapets, having one entrance over a bridge, that may be easily removed, and guarded by stone buildings, placed as a kind of out-post, in a triangular position upon the side of the mountain. This is the residence of the governor, and famous for the manufacture of idol deities and forging of arms, particularly of swords and daggers, and the bars of arrows. Paro boasts the only market in Bootan; and appears to be much frequented. The valley exceeds that of Tassifudon by almost a mile in width: it lies nearly N.W. and S.E., and the river intersects it irregularly, as it pursues its winding course. Paro lies 12 miles S.W. of Tassifudon. N. lat. 27° 43'. E. long. 89° 32'. Turner's Tibet.

PARO, a small island near the coast of Nicaragua, in Salinas bay. N. lat. 10° 3'. W. long. 85° 36'.

PARO *Hotun*, a town of Chinese Tartary; 288 miles N.N.E. of Peking. N. lat. 44° 2'. E. long. 118° 47'.

PAROCHETEUSIS, from *παρεα* and *οχησις*, from *οχησις*, a canal, a term used by Hippocrates, to express a derivation of the humours from one part, in order to the evacuating them by another not far distant. This is often a very happy turn for the cure of a disease.

PAROCHIAL, something belonging to a parish.

Every church is either cathedral, collegiate, or parochial. Cathedral is where there is a bishop's see, or seat, called *cathedra*. Collegiate consists either of regular clerks, professing some religious order; or of a dean and chapter. Parochial church is that instituted for the performing of divine service to the people who dwell within a certain compass of ground. See PARISH and EXTRA-PAROCHIAL.

PAROCHUS, among the Romans, one who provided mules, tents, and carriages, with all other necessaries, for the provincial magistrates in their journeys, as also for ambassadors. For, in the early times of the republic, they had their charges borne by the public, that the allies or provincials might not be burthened.

PARODICAL DEGREES, in an equation, the several regular terms in the quadratic, cubic, biquadratic, or other equation, the indices of whose powers ascend or descend orderly in an arithmetical progression.

Thus

Thus $Z^3 + Z^2M + Z^1r = S$ is a cubical equation where no term is wanting, but having all its parodic degrees, the indices of the terms regularly descending thus, 3, 2, 1, 0. Harris.

PARODY, PARODIA, formed from *παρῶς*, and *ὁδός*, *via*, *way*, as being trite, or passing among the people, a popular maxim, adage, or proverb.

PARODY, *παρωδία*, is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule, to another; or in turning a serious work into burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, or cadences.

The parody was first set on foot by the Greeks; from whom we borrow the name. It comes near to what some of our late writers call *travestly*.

Others have more accurately distinguished between a parody and burlesque: and they observe, that the change of a single word may parody a verse; or of a single letter a word. Thus, in the last case, Cato exposed the inconstant disposition of Marcus Fulvius Nobilior, by changing *Nobilior* into *Mobilior*.

Another kind of parody consists in the mere application of some known verse, or part of a verse, of a writer, without making any change in it, with a view to expose it.

A fourth instance is that of writing verses in the taste and style of authors, little approved.

The rules of parody regard the choice of a subject, and the manner of treating it. The subject should be a known and celebrated work: as to the manner, it should be by an exact imitation, and an intermixture of good-natured pleasantry. Mem. de l'Acad. Belles Lettres, tom. viii. p. 39. &c.

The French term it parodying an instrumental air when it is made vocal, by writing or adjusting words to it. In good compositions, the melody is made for the words; but in parodying an air, the words are set to the melody. In ballads, and songs of many stanzas to the same air, Rousseau observes, that all but the first are parodies, which is easily discovered by the liberties taken with the rhythm by the singers, and the want of musical knowledge in the poet.

PARCEMIA, *παρκεμία*, formed from *παρῶς* and *ὁμίον*, *way*; *quasi*, *παρὰ ὁμίον*, *justa viam*; i. e. *tritum*, a proverb; which see.

PAROL, PAROLE, in *Law*, is sometimes used in ancient writers for a plea in court.

PAROL *Conveyances*, are such as were formerly, in many instances, made by parol, or word of mouth only, without writing; but this occasioning a variety of frauds, the statute 29 Car. II. c. 3. enacts, that no lease estate or interest in lands, tenements, or hereditaments, made by livery of seisin, or by parol only (except leases, not exceeding three years from the making, and whereon the reserved rent is at least two-thirds of the real value,) shall be looked upon as of greater force than a lease or estate at will: nor shall any assignment, grant, or surrender of any interest in any freehold hereditaments be valid; unless in both cases the same be put in writing, and signed by the party granting, or his agent lawfully authorized, in writing.

PAROL *Demurrer*, is a privilege allowed to an infant who is sued concerning lands, which came to him by descent: and the court thereupon will give judgment, *Quod loquela predicta remaneat quousque*, the infant comes to the age of twenty-one years. And where the age is granted on parol demurrer, the writ doth not abate, but the plea is put *sine die*, until the infant is of full age; and then there shall be a resummons.

The granting of a parol demurrer is in favour of an in-

fant, and for his benefit, that he may not be prejudiced in his right, for want of well knowing his estate, &c. In many real actions, brought by or against an infant, under the age of twenty-one years, and also in actions of debt brought against him, as heir to any deceased ancestor, either party may suggest the nonage of the infant, and pray that the proceedings may be deferred till his full age: or (in our legal phrase,) that the infant may have his age, and that the *parol may demur*, that is, that the pleadings may be staid: and then they shall not proceed till his full age, unless it be apparent that he cannot be prejudiced thereby. (Finch. l. 360.) But by the statutes of Westm. 1. 3 Edw. I. c. 46. and of Gloucester 6 Edw. I. c. 2. in writs of entry *sur disseisin* in some particular cases, and in actions auncestrel brought by an infant, the parol shall not demur: otherwise he might be deforced of his whole property, and even want a maintenance till he came of age. So likewise in a writ of dower the heir shall not have his age; for it is necessary that the widow's claim be immediately determined, else she may want a present subsistence. (1 Roll. Abr. 137.) Nor shall an infant patron have it in a *quare impedit* (ibid. 138.), since the law holds it necessary and expedient, that the church be immediately filled.

PAROL *Evidence*. See EVIDENCE.

PAROL *Lease*, or *per Parol*, is a lease by word of mouth; thus called to distinguish it from one in writing. See LEASE.

PAROL *Pleadings*. See PLEADING.

PAROLE, in *War*, &c. When a prisoner of war is allowed to go into his own country, or to his own party, upon his word and promise to return at a time appointed, if not exchanged, he is said to be upon parole, i. e. upon his word.

PAROLE denotes also a word given out every day in orders by the commanding officer both in camp and garrison, in order to know friends from enemies.

PAROLE, *Pasi*. See PASS-PAROLE.

PAROLI, in *Gaming*, the double of what was laid at stake, before. Hence to offer the paroli, &c.

PAROLLES, Fr. the words of a song, an opera scene, or a cantata.

PARONE, in *Geography*, a town of Hindoostan, in the country of Nays; 32 miles S. of Calicut.

PARONOMASIA, *παρωνομασία*, formed from *παρῶς*, *near*, and *ὄνομα*, *name*, q. d. proximity or resemblance of two names, in *Rhetoric*, a pun, or figure, whereby words nearly alike in sound, but of very different senses, are affectedly or designedly used.

As, not *friends* but *fiends* were here. So Tully to Antony, *cum in gremio mimarum mentem & mentum deponeres*: and to Atticus, *consul ipse parvo animo & pravo, facie magis quam facitiis ridiculus*. And that of P. Chryfologus, *monachorum cellula jam non eremiticæ sed aromaticæ*. And, in another place, *hoc agant in cellis quod angeli in cælis*.

Among the Greeks the paronomasia was very familiar. Thus Herodotus, *παθημαίω, μαθημαίω, quæ nocent, docent*. And thus that inscription of Apollodorus, a celebrated painter, on one of his pieces.

Μομησέται τις μάλλον, η μιμησείται.

“It will be easier to deride, than to imitate.”

PARONYCHIA, in *Botany*, a name that has been applied to several plants, according as commentators were pleased to conjecture one or other of them to be the *παρωνυχία* of Dioscorides, a point which nobody could ascertain. He describes it as “a diminutive shrub, growing in stony places, and resembling purslane, but of more humble growth, though

the leaves are larger. The whole plant bruised is a remedy for whitlows and scald-heads." Matthiolus supposed the Wall-rue, *Asplenium Ruta-muraria*, to be what Dioscorides intended; but he cites other botanists who have thought *Mollugo tetraphylla* to be the plant in question; see Matth. Valgr. v. 2. 388, 389. Dodonæus, Lobel, and Gerarde took *Saxifraga iridiphytes* to be the true *Paronychia*. Clusius has called a species of *Illecebrum* by the name of *Paronychia hispanica*, and hence, rather by accident than for any particular reason, Linnæus has denominated that plant *Illecebrum Paronychia*. The most prevalent opinion has been, that some plant of the class *Tetradynamia* was intended by Dioscorides; though it is difficult to guess why this idea was adopted. Hence however the name of Whitlow-grass has remained with our *Draba verna*, which is reckoned, by several authors, one sort of *Paronychia* at least; and hence that English name has been extended to all the British species of *Draba*.

Tournefort has a genus under the name of *Paronychia*, of which the above-mentioned *Illecebrum* is his first species; see his t. 288. Gærtner follows him, v. 2. 218. t. 128, saying that amongst all the species of *Illecebrum* which he has met with, the *verticillatum* only answers to the Linnæan character, the rest belonging to *Achyranthes*, *Celsia*, or this genus *Paronychia*, either by reason of their stamens being united at the base, or the capsules destitute of valves, or splitting into two hemispheres. See ILLECEBRUM.

PARONYCHIA, from *παρρη* and *ονχ*, the nail, an abscess towards the extremity of the finger, more commonly known by the name of whitlow. See WHITLOW.

PARONYMA, in *Grammar*, are words which have some affinity in their etymology.

PAROPAMISUS, in *Ancient Geography*, a province of India, the eastern limit of which, in Alexander's arrangement of boundaries, was the river Cophenes. According to the ideas of Ptolemy it lay between the countries which the moderns name Khorasan and Cabul; and answers to the tract between Herat and Cabul. Alexandria was regarded as the capital. This province was separated from Bactria by the chain of mountains called "Paropamisus." See GAUR.

PARORCHIDIUM, from *παρρη* and *ορχις*, the testicle, the case in which the testicles do not descend into the scrotum, but remain within the ring of the external oblique muscle, or pass no farther than the groin. A little before birth, these bodies usually descend into the scrotum; but it sometimes happens that this occurrence is retarded by causes, with which we are not satisfactorily acquainted, and, in particular individuals, the testicles even continue within the abdomen during life. Mr. Pott remarks, that he knows not of any particular inconvenience arising from the detention of a testicle within the cavity of the belly; but its lodging in the groin exposes it to be hurt by accidents. When hurt, it may be mistaken for a different disease, and occasion very improper treatment. Besides these considerations, he adds, that there is no kind of disease to which the testicle is liable in its natural situation; but what may also affect it in any, or all its unnatural ones. In the first case, related by Mr. Pott, a testicle being detained in the groin of a young healthy seaman, who hurt the part by hitting it against a piece of timber, the tumour became extremely painful, and was mistaken for a bubonocoele, from which it might have been more readily distinguished by the following circumstances, had not the extreme tenderness of the injured testicle prevented any examination by the touch; and the very hard swelling of the scrotum precluded any certainty of a testicle being there, or not. Mr. Pott observes, that the tumour in the groin did not, like the bubonocoele, point obliquely from the ilium to-

wards the pubes, but lay across the groin, and when the scrotum became soft, no testicle could be felt; two striking circumstances to determine the nature of the case. In the earlier part of this young man's life, the detained testicle had been mistaken for a rupture, and a truss had been applied to it. In the second case, the testicle was detained in the groin; and the patient was also advised to wear a truss, which he could not bear from the pain it occasioned. At last, when the patient was infected with a gonorrhœa, this detained testicle inflamed, forming a hernia humoralis, unfortunately mistaken for a bubo. The tumour, however, was moveable, and the scrotum on that side contained no testicle; two circumstances of importance in the diagnosis. Each patient was cured by the remedies for inflammation of the testicles in their usual situation.

PAROS, in *Ancient and Modern Geography*, an island in the Grecian archipelago, and one of those anciently called "Cyclades," and situated S. of Delos, N. of Ios and Sicinos, W. of Naxos and very near it, and E. of that of Oliaros or Antiparos, from which latter it is separated by a narrow channel. It was known by various names among the ancients; it was called Minoa, because it was conquered by Minos, the renowned king of Crete; before that time, it was denominated Pactia; and since it has repeatedly changed its name, till it took, and at last retained, that of Paros, either from the name of the son of Jason, the argonaut, or of a certain Arcadian, son of Parrhasius. Although it was of small extent, not exceeding 36 miles in circumference, it formerly prided itself on its power and riches, which gave it great influence on the condition of the neighbouring islands. For these it was indebted to the activity of its commerce, and the culture of the arts; its excellent harbours were favourable to navigation and trade, and its quarries of beautiful marble inspired a taste for the arts, of which Phidias and Praxiteles, who were born in this island, eminently availed themselves. We may add that the valour of its inhabitants for a long time maintained its security and its liberty. The Parians, in the time of their prosperity, joined Darius in his expedition against Greece, and assisted him with a considerable squadron; but after the victory of Miltiades and Marathon, they were reduced to great straits by that general. After the battle of Salamis, Themistocles subjected them to Athens, and exacted from them large contributions by way of punishment for the succours they had given to the Persians. From the dominion of the Ptolemies of Egypt, to which the Cyclades were constrained to submit, Paros reverted to that of the Athenians, till their conquerors were expelled by Mithridates the Great. But when this prince was forced to submit to Sylla, Lucullus, and Pompey, Paros and the other Cyclades were reduced into a province by the Romans, together with Lydia, Phrygia, and Caria. Its population was considerable when it was subjected to the Ottoman empire by Barbarossa; but since that epoch it has suffered so much by the pillage of the Turks, by the despotism of the government, and by the stay which the squadron of the captain-pacha makes there every year; that its inhabitants have imperceptibly disappeared, and that at this day it presents scarcely any thing but uncultivated fields and villages partly destroyed. Its quarries of beautiful marble are abandoned and partly filled up with rubbish; so that the descendants of its celebrated artists, whom misery and slavery have degraded, are no longer acquainted with an art which constituted the glory of their country. At the beginning of the last century, the number of its inhabitants was estimated at 6000; but at the present day they are supposed not to exceed 2000. The European consuls have long since withdrawn from it; the Catholics

tholics have fled; and the Greeks who remain, idle and wretched, find themselves exposed every year to the oppression of the officers of the captain-pacha's Squadron, to the sword of the sailors, and to the rapacity of all. Although its extent is not so considerable as that of Naxos, it has in proportion a much greater quantity of lands fit for culture. Its mountains are less elevated, its rising grounds less arid, and its plains would be as fertile, if they were as well watered. A small town called "Paréchia" has replaced the ancient city of Paros, on the W. coast of the island, facing Antiparos; it presents no idea of it, except it be by the beautiful ruins, which are employed, without taste, in its construction. Similar fragments of magnificent monuments cover, in an useless manner, almost the whole territory of the island, and in those deserted remains, art would still discover objects worthy of its admiration. Off "Paréchia" the sea forms a bight, and a harbour whose entrance is difficult, on account of the shoals that obstruct it on the opposite coast. The harbour of Naussa, situated to the north, is one of the finest and most spacious in the archipelago. Here are still visible the batteries which the Russians had erected for defending its entrance, when, masters of the archipelago in their war before the last with the Turks, they had made Paros the depôt of their forces. In autumn this harbour is insalubrious, and also towards the end of the summer, on account of some marshes which are situated at the head of it. The Russian army suffered from them to such a degree, that it was obliged to quit the place, after having lost a great number of soldiers and sailors. There are three harbours on the E. side of the island; the first, called Port Santa Maria, towards the N. point, is sheltered by some islands from winds from the N. and S.; but it is open to the N.E., which prevents ships from frequenting it in winter. The harbour of Marmora lies in the middle. Near it is seen Fort San Antonio, in which Venieri, prince of the island, sustained for a long time all the efforts of Barbarossa. He gave up this important post only because the garrison were in want of every thing, and perishing with thirst and hunger. The harbour of Trio lies lower down, and it is, like the first, sheltered by some islands, but open to southerly winds. Here the captain-pacha remains at anchor every year upwards of a month, till the return of the galleys and small vessels which he dispatches to the neighbouring islands, in order to collect the impost to which they are subject. There is only one harbour to the westward, at the head of which the principal town, now a wretched village, is built. Vessels of burden anchor without, under shelter of some islets, as well as in the narrow channel that separates Paros from Antiparos. Marpefus, situated to the westward of the harbour of Marmora, is the most lofty mountain in the island; and it is this that furnished more particularly the marble for which Paros was so celebrated. Near an ancient quarry, about four miles from Paréchia, is still to be seen a basso-relievo, mentioned by Tournefort, cut in the rock, and containing 29 figures of nymphs and satyrs, dancing a kind of carol. The most valuable monuments of antiquity now extant, called the Oxford or Arundelian marbles, were constructed by a native of this island, whose name is unknown, but who, according to Usher, lived in the third century before the Christian era. (See *PARIAN Marble*.) The inhabitants of Paros and Antiparos supply themselves from the produce of the islands with wheat, barley, wine, sesamum, and some legumes. Cotton is the most considerable production, and the only one that enables the inhabitants to pay their impost, and to procure for themselves such commodities as they need. These two islands pay an impost somewhat more than 8000 piastres. Archi-

lochus the fatirist, was born at Paros, about 720 years B.C. N. lat. $37^{\circ} 4'$. E. long. $25^{\circ} 18'$.

PAROTID GLAND, *Parotis*, in *Anatomy*, from *παρω*, near, and *ως*, the ear, the largest of the salivary glands, situated in front of the ear. See *DEGLUTITION*.

PAROTID Duct, *Wounds and Fistule of*. See *WOUNDS of the FACE*, and *SALIVARY FISTULE*.

PAROTIDES, in *Medicine*; signifies the inflamed and tumid state of the parotid glands. An inflammation of these glands often occurs in persons of scrofulous constitution, without any very obvious exciting cause; but more commonly they are inflamed in consequence of irritation from the absorption of acrid matter, as in the case of excoriations about the face and ears, of scald head, &c.; or from sympathy with inflamed gums, or tooth-ache, especially in the lower jaw; or, lastly, from an extension of inflammation of the throat to them, as in the case of *Mumps*, or *CYNANCHE parotidæa*; which see. In scrofulous or debilitated habits, inflammation and suppuration of the parotids, as well as of other glands, are liable to occur at the close of acute fevers, of which they appear to be sometimes *critical*; but in other instances, especially when they follow severe attacks of measles, or small-pox, they are often extremely tedious in their progress, and difficult of cure, and seem to be indicative of a cachectic condition, left by these fevers. See *SCROFULA*.

PAROTIS, from *παρω* and *ως*, the ear, in *Surgery*, the parotid gland: also an inflammation, or abscess, of this part.

PAROXYSM, *παροξυσμος*, in *Medicine*, is the *fit*, *attack*, or *exacerbation* of a disease, that occurs at intervals, or has decided remissions or intermissions. It is applicable to all febrile, spasmodic, convulsive, painful, or otherwise violent diseases, whether the periods of remission be regular or irregular. Thus we speak of a paroxysm of ague, of gout, of colic, of epilepsy, of insanity, &c.

PARPAJAH, in *Geography*, a town on the N.E. coast of the island of Sumatra, on the river Camfer. N. lat. $0^{\circ} 15'$. W. long. $102^{\circ} 45'$.

PARPARSARAT, an island in the straits of Malacca, near the coast of Sumatra, about 50 miles in circumference. N. lat. $1^{\circ} 21'$. E. long. $102^{\circ} 15'$.

PARPOOLY, a town of Hindoostan, in Concan; 28 miles N.N.E. of Goa.

PARPOUR, a town of Bengal; 70 miles N.W. of Midnapour.—Also, a town of Bengal; 8 miles N. of Curuckpour.

PARR, THOMAS, in *Biography*, mentioned in this work on account of the great age to which he attained, a husbandman in Shropshire, was born about the year 1483. At the age of 120 he married a second wife, by whom he had a child. In the year 1635, he was brought to London by lord Arundel, and introduced at court to king Charles I. as a prodigy; but the change of air, and the new mode of living to which he was necessarily subject, occasioned his death in the same year.

PARRA, in *Geography*, a town of Persia, in the province of Segestán; 60 miles N. of Zareng.

PARRA, the Jacana, in *Ornithology*, a genus of birds of the order Grallæ. The generic character is; bill tapering somewhat obtuse; nostrils oval, in the middle of the bill; front covered with lobate caruncles; the wings are spinous. Sixteen species are enumerated by Gmelin, which are as follow.

Species.

PARRA.

Species.

DOMINICA, or St. Domingo Jacana; so called from its being found in that island, as also in the island whence it derives its specific name, and in almost all the warm parts of America. It is characterised by yellow and moderate claws. The bill is yellow; the caruncle lax, and of a pale yellow colour; the head and body above are of a pale yellow, beneath it is ochry, inclining to rosy.

LUDOVICIANA; Louisiana Jacana. The bill and caruncle are tawny; the crown is black; body above is grey-brown, beneath the colour of ochre. It is about eleven inches long, and is found in the country whence it takes its name. The quill-feathers are black, mixed with a little grey; the tail is of a pale yellow, tipped with black; the legs are red; claws are black.

CAYANENSIS; Cayenne Jacana. Legs reddish; hind-head brown, with a blackish crest. It inhabits Cayenne, feeds on insects, and is about eight inches and a half in length. The bill is red, tipped with black; front and chin black; middle of the crown cinereous; breast with a broad black band; belly and vent white; back greenish-purple; wings white without; tail from the base to the middle white, the rest black, the tip edged with white.

GOENSIS; Goa Jacana. Caruncle red; legs yellow; head, neck, wings, and middle of the tail black; body beneath white. It is found in or near Goa; and is about thirteen inches long. The bill is dusky; from the hind part of the eye a black streak runs through the sides of the neck as far as the breast; the back and wing-coverts reddish-brown, the greater ones white; the tail is white at the base, and tipped with brown.

SENEGALLA; Senegal Jacana. Claws moderately long, and the legs are red. It is found, as its name imports, near Senegal, and is twelve inches long. The bill is of a yellowish-green, tipped with black; the front is white; caruncle lax, and of a pale yellow; chin and throat black; lower part of the belly, tail-coverts, and greater wing-coverts, whitish; quill-feathers black, tipped with white. At the bend of the wings is a black spur: the tail, from the base to the middle, is whitish, the rest black, tipped with reddish; the rest of the body and head is of a grey-brown.

CHILENSIS; Chile Jacana. Claws moderately long; legs brown; hind-head sub-crested. It inhabits Chili, and is the size of a jay, but with longer legs. It feeds on worms and insects, is noisy, and defends itself by the spurs on its wings; it builds in the grass, and lays four tawny eggs, which are speckled with black. The bill is conical, and about two inches long, a little curved at the tip; the irides are yellowish; caruncle two-lobed and red; the neck, back, and fore-part of the wings are violet; throat and breast black; wings and a short tail brown; spurs on the wings yellowish, conical, bony, and about half an inch long.

JACANA; Chestnut Jacana. In this species the hind claws are very long; the legs are greenish. It inhabits the watery places in South America, and is ten inches long. The bill is about an inch and a quarter long, and is of an orange-colour; and on the forehead is a membranous flap, half an inch long, and nearly as broad. On each side of the head also is another of the same kind, about a quarter of an inch broad, and both together they furround the base of the bill. The head, throat, neck, breast, and under parts, are black; and sometimes mixed with white. The birds of this species are chiefly found in Brazil, Guiana, and Surinam; but they are not at all uncommon at St.

Domingo, where they frequent the marshy places, the sides of ponds and streams, and wade up to the thighs in water. They are also generally seen in pairs, and, when separated, call each other continually till they join again. They are very shy, and most common in the rainy seasons in May and November. They are at all times very noisy; their cry is sharp and shrill, and they may be heard a great way off. The flesh of this bird is accounted very good.

NIGRA; Black Jacana. Hind-claws very long; legs cinereous; head, neck, tail, and body above black. It inhabits Brazil, and is about the same size as the last. The bill is of a saffron colour; the front is rufous; the breast, belly, and vent brown; quill-feathers green, tipped with brown; the wing-spurs are yellow.

BRASILIENSIS; Brazilian Jacana. The hind-claws are very long; the body of a greenish black. It inhabits Brazil and Guiana. The size and manners very much resemble those of the chestnut jacana; it is gregarious, and feeds on fish and insects; the wing-spurs are yellow.

VRIDIS; Green Jacana. Hind-claws long, yellow; legs yellowish-green; body blackish-green. It inhabits Brazil, and is of the size of a pigeon. The bill is partly red, and partly yellow; the front is red; the head, neck, and breast are of a glossy-violet; the toes are very long.

VARIABILIS; Variable Jacana. Hind-claws long; legs blueish. This is also denominated the spur-winged water-hen, and is about nine inches long. The colour of the bill is of an orange-yellow. On the forehead is a flap of red skin; the crown of the head is brown, marked with spots of a darker colour; the hind part of the neck is much the same, but of a deeper dye. On the fore part of the wing is a yellow spur. The legs are furnished with long toes, as in all the others; the colour of which is of a blueish-ash. This species inhabits Brazil, and is said to be pretty common about Carthagena, and in other parts of South America.

LUZONIENSIS; Luzonian Jacana. Beneath white; toes long; legs black. This species is found in the marshy and maritime parts of the Manilla islands.

AFRICANA; African Jacana. This species is of a pale cinnamon; the toes are long; the legs greenish-black. It inhabits Africa, and is about nine inches and a half long.

SINENSIS; China Jacana. The toes of this are long; legs greenish; body of a claret colour. It is found in China, and is about twenty-one inches long.

CHAVARIA; Faithful Jacana. Toes long; legs tawny; hind-head crested. This is the most remarkable of all the species. The bill is of a dirty-white; upper mandible like that of the dung-hill cock; on both sides, at the base of the bill, is a red membrane extending to the temples, in the middle of which are the eyes; irides brown; hind-head with about twelve blackish feathers, three inches long, forming a pendent crest; the rest of the neck is covered with thick black down; the body is brown; the wings and tail blackish; it has two, and sometimes three wing-spurs, half an inch long; the belly is of a light black; the thighs are half bare; the toes so long as to entangle each other in walking. This species inhabits the rivers and inundated places near Carthagena in America; it feeds on herbs; its gait is slow; and it cannot run unless assisted by the wings, but flies easily and swiftly. When the skin is touched, a crackling is felt; the voice is clear and loud. The natives keep one of these tame to wander with the poultry, and defend them against birds of prey, which it does by means of the spurs on its wings. It never deserts the charge committed to its care, but brings them home at night. It will readily

readily suffer itself to be handled by grown persons; but not by children; it is about the size of a cock, and stands a foot and a half from the ground.

INDICA; Indian Jacana. Blackish-blue; back and wings brown; eye-brows white; a red spot at the gape of the mouth. It is found in many parts of India, among the marshes, and builds a floating nest. The bill is yellow, the base above is blueish; the legs are of a yellowish-brown.

PARRAL, in *Geography*, a town of Mexico, in the province of New Biscay, on a river which runs into the Conchos; 230 miles N. of Durango. N. lat. $28^{\circ} 10'$. W. long. $105^{\circ} 12'$.

PARRAMATTA, a settlement founded in New South Wales, near Port Jackson; 10 miles W. of Sydney Cove.

PARRAMPORE, one of the small islands in the Atlantic ocean, which line the E. coast of Northampton county, Virginia.

PARRAN, PERE, in *Biography*, published, in 1646, a treatise on theoretical and practical music, containing the rules and precepts of composition.

PARRAS, in *Geography*, a town of Mexico, in the province of Zacatecas; 90 miles N. of Zacatecas.

PARREL, (*Rigging*.) in a *Ship*, a sort of collar, by which the yards are fastened, at the slings or middle, to the masts, so that they may be hoisted or lowered with facility. There are four different sorts of parrels, one of which is formed of a single rope, having an eye spliced in each end; and the surface of the rope, between the eyes, is *seamed* with spynarn, or covered with leather. Its middle is passed round the slings of the yard, and fastened together on the aftside of the yards; and the two ends, which are equally long, are passed round the aftside of the mast; and one of them being brought under, and the other over the yard, the two eyes are lashed together on the forefide of the yard, whilst another lashing binds them together abast the mast, having every turn secured with a knot. Another sort is formed of two ropes which have an eye at one end; the other end, as a laniard, reeves through the upper hole of the rib, and through a truck alternately, sufficient to embrace the mast; the other hole likewise reeves through the lower hole in the rib, and so on. The eye in the lower rope of the parrel passes under the yard, and the upper rope over the yard, till both eyes meet on the forefide of the yard, and there *seized* together with spynarn. The other ends of the parrel-rope are passed round the yard, and the after part of the parrel alternately, till the latter is sufficiently secured to the former; and the whole of the turns are *marked* together with quarter-leizings, to confine them close in the cavity formed on the back of the ribs. The third sort, calculated to confine the jaws of a boom to the mast, is formed of a rope which reeves through several trucks without ribs. The fourth sort, called truss-parrels, are similar to the first, having tackles hooked to their lower ends, which lead upon deck; by which the yard may, as occasion requires, be slackened from the mast, or confined more closely thereto. The latter are peculiar to the lower yards, whereon they are very convenient. The second are used for topfial yards, and the first for top-gallant yards only.

PARRENNIN, DOMENIC, in *Biography*, a distinguished Jesuit missionary, was born in 1665, and in 1682 we find him entered among the Jesuits at Avignon, with the view of engaging in their missions. In 1698 he was sent to China. The reigning emperor was at that time favourable to the Christian missionaries, on account of the scientific improvements which they introduced into his dominions, and Parrennin had masters assigned to him for instructing him in the languages of the country, in which he acquired a proficiency

beyond that of any preceding European. The emperor, who was a thoughtful and learned man, frequently conversed with him on the history, manners, and politics of Europe, and on different sciences, with which he was desirous of becoming acquainted. The missionary was obliged to study hard, to satisfy the curiosity of the Chinese monarch, and he translated into the Tartarian language every thing which he found new and curious in geometry, astronomy, and anatomy, in the memoirs of the French Academy of Sciences, and in other works. During the space of twenty years he followed this emperor in his progresses through the different provinces of the empire, and for a still longer time he acted as interpreter for all European missionaries and ambassadors, who came into China, and as mediator in the disputes between the courts of Moscow and Pekin. He drew up many books in the Chinese and Tartarian languages, as well for the information of the emperor, as the instruction of the profelytes. He wrote a vast number of letters to correspondents in Europe, relative to the business of his mission, and to the manners, customs, sciences, and occurrences of China, which were printed in Du Halde's collection. Of these the most valuable are his letters to De Mairan. From the labours of this zealous missionary proceeded the maps of all the provinces of China, and of the Chinese Tartary, with which Du Halde's description of that empire is illustrated. Parrennin died at Pekin in 1741, and was honoured by the emperor Kien-Long with a public funeral. Moren.

PARREO, in *Geography*, a town of Hindoostan, in Bahar; 23 miles W.S.W. of Patna.

PARRET, a river of England, which rises on the borders of Dorsetshire, passes by Langport, Bridgewater, &c., and runs into the Bristol channel, about ten miles below the last town.

PARRHASIA, in *Ancient Geography*, a town of the Peloponnesus, in Arcadia: it is mentioned by Homer and Pliny; but not noticed by Pausanias nor Strabo, though they speak of a mountain and people under this appellation.

PARRHASII, a people of India, beyond the Ganges, mentioned by Quintus Curtius.—Also, a people who inhabited the S.W. part of Arcadia.

PARRHASIUS, AULUS JANUS, in *Biography*, the assumed name of Gianpaolo Parisio, was born in 1470. His father, Tommaso Parisio, a counsellor in the Neapolitan senate, would gladly have brought up the son to the same profession, but the young man had imbibed so decided a taste for literature, as to refuse to settle to business. The wars in the kingdom of Naples occasioned his removal to Rome, where his life was brought into danger by his attachment to two cardinals, who had incurred the displeasure of pope Alexander VI. He escaped to Milan, where he married a daughter of Demetrius Chalcondylas, and was appointed professor of eloquence in the university. This was about the year 1500, when he first appeared as an author, by publishing his commentaries upon Claudian's Rape of Proserpine. He soon obtained a very high reputation as a lecturer, and had the most distinguished people in the country as his auditors. His fame excited against him many enemies; he was charged with citing books that never had any existence, and he was accused of crimes of an infamous nature, which have been thought to have had no other foundation than the envy of his rivals. He retired to Vicenza, where he was elected to the chair of eloquence with a liberal salary. The wars excited by the league of Cambray obliged him to quit that country, and he returned to his native place, where

he laid the foundation of the Cofentine academy, which afterwards became very famous. He after this accepted of an invitation from Leo X. to occupy the chair of eloquence at Rome; scarcely, however, had he entered upon the duties of this office, when ill health obliged him to resign: he returned to Cofenza, where after passing many years in continual sufferings, he died in the year 1534. His works were published, collectively, by Henry Stephens in 1567, of which the principal is entitled "Liber de Rebus per Epistolam Quæsitis." This consists of a number of letters written to different learned men, containing explanations of passages in the ancient writers, and elucidations of points of antiquity, which display much erudition. There are also illustrations of Ovid's Heroical Epistles; of Horace's Art of Poetry; of Cicero's Oration for Milo, and various other tracts on classical subjects. The whole collection was reprinted in the first volume of Gruter's "Thesaurus Criticus." A new edition of the book "De Quæsitis," with additions from the author's manuscript, was given at Naples in 1771. Moreri.

PARRHESIA, in *Rhetoric*, a figure in which a person admonishes or reproves another with art and address, and in such circumstances as render it difficult to displease. See Revelation, chap. ii. 2—5.

PARRIAH, in *Geography*, a town of Hindoostan, in Bahar; 35 miles N. of Durbungah. N. lat. 26° 40'. E. long. 85° 52'.

PARRICIDE, PARRICIDA, or *Patricida*, in strictness, denotes the murder or murderer of a father: as matricide does of a mother. Though the word parricide is also ordinarily extended to both.

The Romans, for a long time, had no law against parricides; which was also the case at Athens; from an opinion, that nobody could be so wicked as to kill his parents. The Persians, according to Herodotus, entertained the same notion, when they adjudged all persons who had killed their reputed parents to be bastards. L. Otilius was the first who killed his father, five hundred years after Numa's death; and then the Pompeian law was made, which ordained, that the person convicted of this crime, after he had been first scourged till the blood came, should be tied up in a leathern sack, together with a dog, an ape, a cock, and a viper, and so thrown into the sea, or the next river. By the English laws, this crime is treated no otherwise than as simple murder, unless the child was also the servant of his parent. 1 Hal. P. C. 380.

PARRICIDE is also extended to the murder of any near relation, as a husband, wife, brother, sister, child, grandchild, uncle, &c. and even to that of great or sacred persons, though no way allied in blood, as a king, &c.

PARRIER, in *Geography*, a town of Hindoostan, in Oude; 35 miles S.W. of Lucknow.

PARRIDA, a small island in the Pacific ocean, near the coast of Veragua. N. lat. 7° 16'.

PARROAH, a town of the island of Ceylon; 50 miles W.S.W. of Trincomaly. N. lat. 8° 17'. E. long. 80° 34'.

PARROCEL, JOSEPH, in *Biography*, was born in Provence in 1648, and was the pupil of Bourgoigne, whose subjects and whose style he imitated, though not with so much fire and freedom of touch. He endeavoured to improve himself by a residence at Venice for some time, and did acquire somewhat of the tones of that school. His colouring is rich, deep, and fresh; and there is great bustle and animation in his designs; which were not always warlike, but sometimes of fancy, of history, and of portrait. He died

in 1704, leaving a son, Charles Parrocel, who successfully imitated the compositions and manner of his father, and who died in 1729, at the age of 52.

There was also a nephew of the name of Ignatius, who also painted battle-pieces in the same style, and who died in 1722.

PARROQUET, or PARRAKEET, in *Ornithology*. See PSITTACUS.

PARROT. See PSITTACUS.

PARROT Islands, in *Geography*, a cluster of islands in Dusky bay, New Zealand; 3 miles S.W. of Facile harbour.

PARROT'S Key, a small island in the Spanish main, near the Mosquito shore. N. lat. 12° 7'. W. long. 82° 56'.

PARR'S POINT, a cape on the N.E. coast of the island of St. Christopher.

PARRY, RICHARD, in *Biography*, a learned divine, was educated at Oxford, and in 1604 was made bishop of St. Asaph. He revised the first edition of the Welsh bible, which was published in 1620. Before his elevation to the episcopal dignity, he was master of Ruthin school, Denbighshire.

PARRY, JOHN, generally known by the appellation of the celebrated *blind harper*. He was the first among his contemporaries, who played either a lesson or a concerto on the treble Welsh harp, an instrument which had been long lost to the world, and owed its revival to the genius and diligence of this great performer. He died at Rhuabon, in Denbighshire, in 1782, about which time the pedal harp seems to have superseded all other harps on the continent, as well as in our island, so that it appears as if its resuscitation was for a very short period. Evans played on that truly British instrument at the oratorio in 1772, on which he accompanied "O had I Jubal's lyre."

PARRYING, in *Fencing*, the action of defending a man's self, or of staying off the thrusts, strokes, &c. offered him by another. See FENCING.

Good fencers push and parry at the same time.

The Spaniards parry with the poniard. The ancients parried with their bucklers.

PARSBERG, in *Geography*, a town of Bavaria, in the principality of Neuburg; 18 miles N.W. of Ratibon.

PARSCHINA, a town of Russia, in the government of Tobolsk, on the Niznei Tunguska. N. lat. 60° 40'. E. long. 106° 54'.

PARSHEPATNAM, a town of Hindoostan, in Marawar, on the coast; 6 miles N. of Tondy.

PARSLEY, in *Botany, Gardening*, and the *Materia Medica*. See APIUM.

PARSLEY, in *Agriculture*, a well known tap-rooted biennial plant. It is observed, in the twenty-second volume of the Annals of Agriculture, that Mr. Fleet of Hampshire, famous for curing the rot of sheep, cultivates it largely with success; he sows half a bushel to the acre, with a bushel of rye-grass, with spring corn; and he finds that it lasts in the ground till it is permitted to feed. He feeds it constantly, it being excellent for sheep, and when suffered to get a-head, pigs feed wonderfully upon it in the autumn. After September, it will not run to seed. When it was ploughed up, he obtained good oats. The land was poor, and the next round of the course, the clover was much the better for the parsley having been sown, or the clover omitted; for in a field half parsley, half clover, when the clover came again to be sown, it was excellent on the parsley half, but bad on the clover part. In laying down land to grass, Mr. Hoyte, in the fourth volume of Communications to the Board, advises the sowing with twelve pounds of white clover, two pounds

of red clover, two pecks of rye-grass, and two pounds of parsley to the acre, as the parsley stands two years, and by its diuretic qualities, prevents the sheep from dying of the red-water, which too luxuriant feeds are apt to produce.

And the following trial with this vegetable, is stated in the fifth volume of the Farmer's Magazine, printed at Edinburgh. A friend of mine, says the writer, having occasion to observe the partiality of black cattle for the garden parsley, and their preference of it, when growing, to almost any other green food, took it in his head to try how it would succeed in a field that he was going to sow down for pasture. He accordingly sowed two or three ridges with parsley-feed, and the rest of the field with clover and rye-grass. As soon as the field was ready for pasture, he led his cattle into it, and it was perfectly evident that they preferred that part which was sown with the parsley to any other part of the field, inasmuch that they never touched the rest while there was a single blade of parsley to be had. Horses were equally fond of it. He had not an opportunity to try sheep upon it; but the probability is, that they would, if possible, have been fonder of it, and thriven better, than any of the other two. This, therefore, seems worthy of a farther trial. We know that black cattle, sheep, horses, and indeed every other animal, always prefer that food (when they have it in their power to make a choice) that is most agreeable to them, and most conducive to their health. We know also that parsley is a most wholesome vegetable for the human species. It is a powerful antiseptic. If we were to reason from analogy, we should suppose that its beneficial properties should extend to the animal creation in general. As it is a biennial plant, it will answer well for fields that are to be laid down for pasture for a considerable while. Sheep in particular, being of a tender and delicate constitution, and especially subject to bowel complaints, its antiseptic quality may be of great use to correct these. The difficulty may be at first to get the seed in any considerable quantity: but that may soon be remedied, if the experiment be thought worth while. He would suppose that the ground upon which it is sown must be good, in good condition and clean, otherwise it will not have a fair trial.

It should probably be sown early in the spring, and be kept constantly close fed down with stock, where it is intended to be preserved in the ground any great length of time, as probably, by preventing its sending up seed-stems, this may be effected.

More experiments are wanting to fully ascertain the value of this vegetable in field culture; but it has been found very beneficial as a rabbit-food, and would constantly be raised as one of the most proper crops where these kinds of animals are kept. See RABBIT.

PARSLEY, *Piert*. See APHANES.

PARSLING, in *Ship-Building*. See PARCELLING.

PARSNEP, in *Botany, &c.* See PASTINACA.

PARSNEP, in *Agriculture*, the name of a tap-rooted plant, cultivated for the sake of the root. This sort of crop requires a rich, mellow, and deep soil, in order that the roots may have full room to thicken and run downwards. It is the garden parsnep that is made use of in the field culture, which has a long fleshy root much larger than the carrot, and equally sweet, nutritious, and juicy. And it has been

suggested, that from its being more hardy, it is probably better suited to the northern parts of the island than the carrot. Its easy culture, and the large produce which it is capable of affording, should render it more an object of the farmer.

Soil.—The soils most adapted to this sort of crop, are those of the rich, deep, friable, loamy or sandy kinds, in which the roots can get down to a great depth, and become large. It is observed by Mr. Young, that of all the roots which a farmer can cultivate, this is the most valuable; but it demands a better soil than any other crop he can put into the ground. If he has not land of an extraordinary quality, he had better not venture on the attempt. It loves a very rich, dry, putrid, sandy loam, worth 40s. or 50s. an acre, which should be ploughed as deep as possible about the end of the autumn, and left for the frosts to exert their influence upon. This fine deep pulverization of the land is effected in different ways in different districts. In some it is given by ploughing the ground with a light plough, which is regulated in the fore part by two wheels being fixed to it, one of which runs in the furrow, and the other on the unploughed land, the former being fourteen or fifteen inches higher than the latter, and which opens down and turns the mould to the depth of about five inches; after which, the furrow is dug down with a spade, so as to form a trench of about sixteen inches in depth, proceeding in the same way till the whole of the field is prepared; but the latter, which is by means of two ploughs of different kinds, one following in the same track after the other, is by much the most expeditious and economical.

But the light plough just described, answers very well in performing the first part of the operation; and in the second, one of the trench kind must be made use of, by which the mould is raised from the bottom of the furrow made by the first, and applied over the slice it had turned up. In this way the soil is not only broken up to a great depth, but the surface left in a fine state of mould. Where this sort of tillage is practised, the work is generally performed in the more dry sorts of land about the middle of February; and in those that are retentive of moisture, towards the latter end of March. The ground, after being thus exposed to the influence of the atmosphere for a week or a fortnight, is harrowed lightly over in order to render it fit for the seed. In some cases, however, a slight ploughing is given to the lands intended for this crop in September, the use of the other ploughs being had recourse to in January in the succeeding year. The principal object in this business is, that of loosening and rendering the soil mellow to as great a depth as can possibly be done.

But though the use of manure is not in general so necessary for this crop as some others, where the land is not in tolerably good heart, it should constantly be employed in such proportions as may be sufficient to render it rich. Well-rotted farm-yard dung is the best adapted to this crop, being turned into the soil by a light plough immediately before the time of putting the seed into the ground.

Seed.—In the cultivating of this sort of crop, great care should be taken to have good perfectly ripened seed, and which should always be made use of while perfectly fresh, old seed frequently either wholly failing, or coming up with great irregularity, or in a straggling manner.

In respect to the proportion of seed that may be employed, it must be different according to the nature of the soil and other circumstances; but in general about five pounds to the acre may be sufficient for the purpose.

As to the time of sowing, the most usual period is the early part of the spring, as soon as the frosts will admit of it; as

PARSNEP.

about the beginning or middle of February, or in the following month. It is, however, sometimes sown in the autumn of the preceding year, immediately after it has been ripened and collected from the plants, as about the beginning of September. And it is contended by some, that in this way the plants will appear more early in the following spring, and of course become large and strong before any weeds rise to injure them; and that as the plants are in little or no danger from the severity of the winter season, this is, on the whole, the most eligible period. Where the soil is, however, in a proper state of preparation, as there can be no apprehensions of their being inconvenienced by the growth of weeds, the former must be the most safe and convenient season for the purpose.

The most usual method of sowing the parsnep seed is in broadcast over the land, being afterwards covered in by means of a light harrow. It is probable that this sort of crop might be sown in rows, either by means of the drill machine, or by having small furrows made in the land, and sowing the seed over it in the broadcast method, afterwards lightly harrowing it into them. In this mode, by having the rows at sufficient distances, the crops might be kept more clean and at less expence than in the simple broadcast method. But in this way they have not been found to answer so well.

The author of Practical Agriculture states, that in districts where parsneps are much cultivated as a field crop, it is the common practice to have beans at the same time with them, either planted in single rows, at the distance of four feet and a half, and about eight or ten inches from each other, or double ones at the distance of twelve feet, and eighteen inches in the rows. In this manner two crops are obtained from the same piece of ground; but unless care be taken to remove the beans in good time, great injury may be done to the parsneps. As though there may have been much leaf and stem before the roots of these plants, begin to swell out and acquire their size towards August, the beans ought never to be suffered to remain longer than that period upon the ground.

After-culture.—The management of these crops, after they have been put into the ground, is, that they require to be kept perfectly clean and free from weeds during the early parts of their growth; frequent hoeing and weeding are, therefore, to be practised. Where cultivated in rows at sufficient distances, the intervals may be cleaned by the plough or horse-hoe. It is sometimes usual, where this sort of crop forms a part of field husbandry, to have recourse to the harrow before the process of hoeing or weeding is begun. This must be performed about the time the seeds first begins to germinate; as by harrowing too soon the weeds will not have risen, and if deferred too long, there may be danger of destroying the buds of the parsneps. This is supposed more necessary on the stiffer sorts of soil, as it renders them more easily weeded. The first weeding may be performed about the beginning or middle of May, according to the forwardness of the plants, being at this operation only partially thinned out where they appear to stand much too close together. The same operation is to be again performed about the beginning of July; when the plants must be carefully set out to the distance of six inches. This sort of work is executed either by means of a small fork with two prongs, or a kind of very small spade having a short handle; the labourer, in making use of it, kneels on one knee, and, holding it in his right hand, digs and turns the mould, while with his left he pulls up and removes the weeds. After this second weeding, nothing further is found requisite in the parsnep culture.

As this sort of root strikes downwards to a great depth, and of course draws much of its nourishment from below, it may with propriety be introduced after most sorts of fibrous-rooted crops. And there is little hazard in the cultivation of parsnep crops, except from the falling of too much rain immediately after sowing, by which the seed may be in danger of being washed away; or when dry weather succeeds, from the baking of the land rendering the plants incapable of pushing their roots sufficiently down. They are seldom injured by frosts or other causes during the winter season, or liable to be destroyed by any kind of insects or other vermin.

It is stated, that the produce of this sort of crop, when cultivated on a proper soil, and in a suitable manner, will, from the great size of the roots, be equal to, if not greater than, that of the carrot kind.

Application.—With regard to the methods of application of this root, they are much the same as that of the carrot. In the fattening of cattle it is found equal if not superior, performing the business with as much expedition, and affording meat of exquisite flavour, and a highly juicy quality. The animals eat it with much greediness. It is reckoned that thirty perches, where the crop is good, will be sufficient to fatten an ox of three or four years old when perfectly lean, in the course of three months. They are given in the proportion of about thirty pounds weight, morning, noon, and night; the large ones being slit in three or four pieces, and a little hay supplied in the intervals of those periods. And when given to milch-cows with a little hay in the winter season, the butter is found to be of as fine a colour, and as excellent a flavour as when feeding in the best pastures. Indeed the result of experiments has shewn, that not only in neat cattle, but in the fattening of hogs and poultry, the animals became fat much sooner, and are more bulky, than when fed with any other root or vegetable. And that, besides, the meat is more sweet and delicate. In these applications, in the trials of an experienced farmer in Surry, the results were these: he in the first place put up sixteen hogs to fatten upon them. The method he took in giving them to the hogs, was throwing the parsneps upon the ground whole. This he continued for about a month, when finding his hogs grow heavy, he observed they did not go on so well with them as at first. Upon this he boiled the parsneps, and made wash of them; thickening the wash with half a bushel of barley-meal every day. He gave it them in a trough, and continued this for two months, when he killed them, and found them to be very good meat; weighing from 28 to 33 stone per hog. One of them, being very large, weighed 58 stone. The neat value of his hogs, when killed, amounted to 52*l.* 17*s.* 4*d.* The whole expence of his barley-meal with which he thickened the wash, amounted to 3*l.* 18*s.* 9*d.*; of the firing to boil them, at 5*d.* per day, 1*l.* 10*s.*; of a boy to look after them for three months, at 6*d.* per day, 2*l.* 5*s.*; which sums added to the expences attending the parsneps, prime cost of the hogs, &c. amount in the whole to 35*l.*; so that his profit upon this article only, is 17*l.* 16*s.* 8*d.* which remains to be carried to the account of the parsneps. After his hogs were killed, he kept four dairy cows upon the remainder of the parsneps for three months, which at 1*s.* 6*d.* per week, amounted to 3*l.* 12*s.*; and this sum added to the 17*l.* 16*s.* 8*d.* before mentioned, makes the neat profit on the one acre of parsneps to be 21*l.* 8*s.* 7*d.* But he says, he must observe, that giving his dairy cows the parsneps, answered his purpose greatly, by increasing their milk, and making the butter much richer and finer than turnips or carrots, which he had given them long before; the manner in which he gave the parsneps was,

cutting

cutting them in pieces. On finding the parsneps agree with his hogs and cows so well last year, he now determined to give them to his horses; and having five that were making up for sale, he begun with giving them a very few the first week. He observed then that they agreed with them extremely well, and he therefore gave them a larger quantity, which made them thrive very fast, and determined him to continue giving them the parsneps, which saved him a great deal of hay, as he found they had occasion for very little of it. He kept them in this manner for ten weeks, when he sent them to Mr. Bever's repository, where they were sold for forty guineas each horse. The manner in which he gave them the parsneps was, cutting them in small pieces, and throwing them into the manger. He calculates the expence half a guinea *per* week, for the parsneps for each horse, which amounts to 26*l.* 5*s.* to be carried to the account of the parsneps for this year. And he adds, that at the same time he began fattening an ox, which cost him 4*l.* 10*s.* from the plough. He was thirteen weeks in fattening, and ate nothing but parsneps the whole time. He then sold him to Job Spratley, a butcher at Guildford, for 2*s.* 8*d.* *per* stone, weighing 102 stone 6*lb.*, which amounted to 13*l.* 4*s.* 4*d.*; exclusive of the above, he had within him 22 stone 6*lb.* of loose fat, which was more than ever was known to be taken out of a bullock of that weight in the town of Guildford, and it was remarked by many, that finer beef never was eaten. He mentions these particulars, in order to shew the great use of parsneps, as he is convinced by experience, they are preferable to carrots or turnips. But to proceed on in his account; the profit upon this bullock amounted to 9*l.* 4*s.* 4*d.* which he also carries to the account of the parsneps. And, the remainder of his parsneps he gave to seven dairy cows eleven weeks, at 1*s.* 6*d.* *per* week each, which amounts to 5*l.* 15*s.* 6*d.* So that the net profit (after deducting 6*l.* 12*s.* *per* acre for the necessary expences attending the parsneps, as *per* the calculation for last year) amounts to 28*l.* 10*s.*, besides a great many of the parsneps that he gave occasionally to his store hogs and cattle, which he valued at 3*l.* 10*s.* This statement fully shews the vast advantage of cultivating this sort of crop, where the farmer has a soil proper for their being grown upon.

It has been stated, that when chopped and used with dry cut meat, horses eat them freely, and are kept in good condition with them. Parsneps are also found an excellent, wholesome, and very nourishing food for cattle in other countries.

And in France they have been used to great advantage to fatten cattle. Hogs have no other food in winter, and bullocks and oxen thrive well upon it. Cows fed with parsneps give more milk than with any other winter fodder, and it yields better butter than the milk of cows nourished with any other substance. Horses fatten with this food; though some pretend that it renders them less mettlesome, and hurts their legs and eyes.

And cattle eat these roots raw at first, sliced lengthwise; and when they begin not to relish them, they are cut in pieces, put in a large copper, pressed down there, and boiled with only so much water as fills up the chafins between them. They then eat them very greedily, and continue to like them.

And in addition to their advantages in these ways, the tops afford a large portion of green food for these sorts of live stock, either by having them cut off when taken up, or by being consumed in the field. In the last method, the most proper period of having them eaten is at the period when they begin to shrink and get dry.

In respect to their being taken up and preserved, they

may be dug up with three-pronged forks in the beginning of the autumn season, as potatoes, and be packed up in dry sheds in the same manner.

On this plant it has been remarked by Mr. Young, that when the soils are suitable, the inducement to the cultivation is very strong, as they fatten bullocks, as well as oil cake, and are of great use with hogs. They have also the valuable property of preparing the land in an excellent manner for grain crops.

To save the seeds of this plant in the most advantageous way, some of the longest, straightest, and largest roots should be singled out and planted about two feet asunder, in a place where they will be defended from the strong south and west winds; for the stems of the parsneps generally grow to a great height, and are very apt to be broken by strong gusts of wind, if they are exposed thereto. The ground should also be kept clear from weeds; and if the season should prove dry, watering the plants moderately twice a-week will increase the quantity, and improve the quality of their seeds, which will be ripe about the end of August, or the beginning of September, when the heads should be carefully cut off, and spread upon a coarse cloth for two or three days to dry. The seeds should then be beaten off, and put up for use. But neither these nor carrot-seeds should be depended on after they are above a year old, as they seldom grow well.

PARSNEP, *Cow.* See HERACLEUM.

PARSNEP, *Prickly.* See ECHINOPHORA.

PARSNEP, *Water,* the name of a species of *Sium*; which see.

PARSOI, in *Geography*, a town of Hindooستان, in Baglana; 17 miles S.W. of Naderbar.

PARSON, *Persona ecclesiæ*, the rector or incumbent of a parish-church; who has full possession of all its rights.

He is said, by some, to be thus called by way of eminence; the revenues of a church being destined to maintain *magnam personam*; or, as some will have it, because he is bound by virtue of his office, in *propria persona servire Deo*; whence *impersonare*, in old charters, is to put in possession of a parsonage, &c. Or, according to others, because the original parsons, *personæ*, were, in reality, only dignitaries, and possessed benefices, which gave them some personal pre-eminences in the church or chapter, but no power. Or, lastly, according to others, because the parson, for his time, represents his church, being in himself a body corporate, and sustaineth the person thereof, as well in suing, as being sued, in any action touching the same.

Some distinguish between a rector and parson: the rector, say they, is where the vicarage is endowed; and the parson, *persona*, where the parsonage is without a vicarage: the distinction seems new and subtle. Bracton apparently uses rector and parson as synonymous terms.

For the difference between a parson and vicar, see VICAR. The method of becoming a parson or vicar is much the same. To both the following four requisites are indispensable: *viz.* *holy orders, presentation, institution, and induction*; which see respectively. There are many ways by which a parson or vicar may cease to be so: *viz.* by death, by cession in taking another benefice, by consecration, by resignation, and by deprivation. See CESSION, CONSECRATION, RESIGNATION, and DEPRIVATION.

Formerly, he who had a church by institution and induction, only for his own life, was called *parson mortal*: but any collegiate or conventual body, to whom the church was for ever appropriated, was called *parson immortal*.

Some, again, make a distinction between *parson* simply, and *parson impersonæ*, or impersonated.

Parson *impersonce* is the rector or incumbent in possession of a parish-church, whether presentative or inappropriate, and with whom the church is full: or a parson *impersonce* is a clerk presented, instituted, and inducted into a rectory, and, therefore, in complete possession.

Parson simply, they contend, is properly the patron, or he that has the right of a presentation: called *parson*, because, before the Lateran council, he had a right to the tythes, in respect of his liberality in erecting or endowing the church, *quasi sustineret personam ecclesie*.

It is certain, in the register of writs, *persona impersonata* is used for the rector of a benefice presentative: and, in Dyer, a dean and chapter are said to be *parsons impersonce* of a benefice appropriated to them. So that *personata* seems only changed into *impersonata*, in respect of the possession of the benefice. See Coke on Litt. fol. 300.

PARSON'S *Island*, in *Geography*, a small island near the coast of Maine. N. lat. 44° 36'. W. long. 67° 25'.

PARSON'S *Town*, a town of the state of North Carolina; 60 miles W. of Salisbury.—Also, a post-town of the King's county, Ireland, formerly called *Birr*; under which name an account of it has been already given in this work.

PARSONAGE, a rectory, or parish-church, endowed ordinarily with house, glebe, and tythe, for the maintenance of a minister, with cure of souls, within such parish.

There may also be a rectory or parsonage without any glebe land, except the church and church-yard; and without any tythes, or other fixed income, except an annual payment, or pound rate.

PARSONAGE, in its original, and, at this day, in other countries, is a benefice, which gives some prerogative, or pre-eminence in a church or chapter, but without any jurisdiction.

The ancient parsonages gave a little honour and dignity as to the person, but they gave no power; whence, apparently, the name, intimating the effect of the dignity to be refrained to the person, *persona, parson*.

Such are still the chantries in several churches, and the subchantries in others.

Some, as Oldrade, &c. extend the word parsonage to dignitary, and comprehend under it the archdeacons, deans, &c. in cathedrals; but this seems to be straining the sense of the word.

In effect, the canonists use the term very differently; some applying it to all who have any prerogative in the choir or chapter, over the other canons, either in options, suffrages, elections, or barely in place and procession; thus confounding it with dignity; while others apply it to simple rectors, &c.

PARSONS, JAMES, in *Biography*, a physician, anatomist, and antiquary, was born at Barnstable in 1705. His father being appointed a barrack-master in Ireland, he was taken over to that country while an infant, and received his early education at Dublin. Choosing medicine for his profession, he went to Paris for the purpose of cultivating that science, and attended the courses of all the eminent teachers of that metropolis. He afterwards visited some other continental schools, and received the degree of doctor of physic at Rheims, in 1736. He settled in London, and was employed by Dr. James Douglas as his anatomical assistant. His practice was directed principally in the oblique line, and his residence was in Red-Lion-square. In 1740, he was elected a fellow of the Royal Society, and he maintained an intimate connection with the most distinguished of its members. He was also a fellow of the Society of Antiquaries; and he corresponded with several of the most

learned and scientific men abroad. He was every where respected for his useful and extensive acquirements, and the goodness of his heart, and died much regretted in 1770.

Dr. Parsons left the following works. 1. "A Mechanical and Critical Enquiry into the Nature of Hermaphrodites," 8vo. 1741, which was principally a compilation. 2. "A Description of the Urinary Human Bladder, and the Parts belonging to it, with Figures," 1742, which was intended to disprove the reported utility of Mrs. Stephens' medicines for the stone. 3. "Philosophical Observations, on the Analogy between the Propagation of Animals and that of Vegetables," 8vo. 1752. As an antiquary, Dr. Parsons distinguished himself by an elaborate publication, entitled "Remains of Japhet; being historical enquiries into the affinity and origin of the European languages," 4to. 1767. This is a performance of great erudition and research; but the author, like most of the speculators upon these topics, is induced, by his zeal for establishing a system, to place too much confidence in fabulous traditions and dubious remains. He finds, in the inhabitants of the British isles, the lineal descendants of Gomer and Magog, with the vestiges of their primitive language. Besides these separate publications, Dr. Parsons was the author of several papers, printed in the *Philosophical Transactions*; viz. "Croonian Lectures on Muscular Motion," 1745, in which he considers the muscular fibres as tubes; "Human Physiognomy explained," in the Appendix to the *Philos. Transf.* for 1746; and several other papers on anatomical and physiological subjects, especially an account of the dissection of a rhinoceros, which is valuable, and illustrated by good figures. Gen. Biog.

PARSONS, ROBERT, a musician of the 16th century, born at Exeter, admitted early into the chapel royal, and afterwards appointed organist at Westminster Abbey. He was extremely dexterous in writing upon a plain song, moving in slow notes of equal value; but the building harmony upon an ancient ecclesiastical chant, was no more than written discant, which is still an exercise for young contrapuntists in the conservatories of Naples, and practised in Italy by all writers for the church. During the 16th century, many of our great harmonists displayed wonderful science and abilities in these laborious undertakings, and like some of the proud sovereigns, that were led in triumph by the ancient Romans, preserved an appearance at least of dignity and independence, even in chains. There are some excellent compositions by Parsons in the MSS. of Christ-church college, Oxford, particularly an "Ave Maria," and an "In Nomine."

PARSONSFIELD, in *Geography*, a post-town of America, in York county, in the province of Maine; 36 miles N.W. of Portland; incorporated in 1785, and containing 1350 inhabitants.

PARSONSIA, in *Botany*, received that appellation from Mr. R. Brown, in memory of James Parsons M.D. F.R.S. author of "A Microscopical Theatre of Seeds," published in 1745, in quarto, as well as of an octavo volume, entitled "Philosophical Observations on the Analogy between the Propagation of Animals and that of Vegetables," printed in 1752. He wrote numerous zoological papers, in the *Philosophical Transactions*, and died in 1770. (See his article.) Dr. P. Browne, in his *History of Jamaica*, 199, had already dedicated a plant to the same purpose; but that is *Lythrum Parsonsia* of Linnæus, and really belongs to Jacquin's genus of *Cuphea*. Brown in *Tr. of the Wern. Soc.* v. 1. 64. Prodr. Nov. Holl. v. 1. 464. Class and order, *Pentandria Monogynia*. Nat. Ord. *Contorta*, Linn. *Apocinea*, Juss. Br.

Eff. Ch. Corolla funnel-shaped, naked and pervious at the mouth; limb in five deep, recurved, equilateral segments. Stamens prominent. Filaments thread-shaped, inserted into the lower part of the tube. Anthers arrow-shaped, adhering to the middle of the stigma, their hinder lobes destitute of pollen. Germens two, sometimes but one, of two cells. Style one. Stigma dilated. Scales at the base of the germen five, either separate or united.

A genus of twining shrubs, with opposite leaves. Their flowers cymose, sometimes racemose, and either situated between the footstalks, or terminal. Mr. Brown proposes to divide them thus.

SECT. 1. *American species. Germen two. Follicles distinct.*

1. *P. corymbosa*. Corymbosa Parsonfia. (Echites corymbosa; Jacq. Amer. 34. t. 30. Linn. Syst. Nat. ed. 12. v. 2. 190. Willd. Sp. Pl. v. 1. 1240. Swartz. Obf. 105.)—Clusters corymbosa, terminal. Leaves elliptic-lanceolate, acute, smooth.—Native of mountainous places in Hispaniola, flowering in November. Stem shrubby, slender, climbing to the height of 20 feet, by twining round other plants. A white milky juice is discharged from every part, when wounded. Leaves opposite, stalked, two or three inches in length, hardly an inch broad, elliptic-oblong, acute, entire, smooth; shining above; pale beneath. Flowers numerous, purple, small, in terminal, compound, corymbosa, spreading reddish clusters. Follicles very long, horizontal, reflexed, roundish, obtuse.

2. *P. floribunda*. Many-flowered Parsonfia. (Echites floribunda; Swartz. Ind. Occ. v. 1. 534. Willd. Sp. Pl. v. 1. 1239.)—Clusters corymbosa, axillary. Leaves ovate, pointed with parallel ribs. Branches straightish.—Native of bushy places on the hills of Jamaica.—The branches of this are, according to Swartz, nearly erect, flexible, tough, and somewhat climbing among the surrounding bushes, but not twining; they are smooth, furrowed in the upper part, often reddish. Leaves stalked, opposite, ovate, with a short point, entire, furnished with numerous, parallel, but not prominent, nerves, which are wanting in the foregoing species; their substance is coriaceous and laurel-like; their surface smooth and shining, paler beneath. Clusters axillary, compound, corymbosa, shorter than the leaves. Flowers small, whitish.

3. *P. spicata*. Spiked Parsonfia. (Echites spicata; Jacq. Amer. 34. t. 29. Linn. Syst. Nat. ed. 12. v. 2. 190. Willd. Sp. Pl. v. 1. 1240.)—Spikes axillary, opposite, dense, much shorter than the leaves. Leaves ovate-oblong.—Gathered by Jacquin near Carthage, in close woods, where it twines round the loftiest trees, to the height of more than sixty feet. The stems are an inch in diameter, ornamented, here and there, with alternate, leafy branches, about eighteen inches long. Leaves six inches long, veiny, nearly smooth. Spikes an inch and a half long, dense, rarely divided, composed of numerous small white flowers, with scarcely any scent. Jacquin could never meet with the fruit, the flowers being all, as far as he could discover, in the course of many months, abortive. They are chiefly produced in July and August.

SECT. 2. *Australasian species. Germen of two cells. Follicles cohering lengthwise.*

4. *P. capsularis*. New Zealand Parsonfia. (Periphoca capsularis; Forst. Prodr. 20. Willd. Sp. Pl. v. 1. 1251.)—Clusters cymose, downy, many-flowered. Leaves obovate, emarginate, smooth.—Gathered by Forster in New Zealand.—His specimen before us does not answer to his specific character, the leaves being by no means lanceolate, but obovate, emarginate, an inch or inch and half long, entire, smooth on both sides, paler beneath. The stem is twining.

Young branches downy. Flowers numerous, in repeatedly branched, downy-stalked, lax, cymose clusters, or panicles, which terminate the short lateral leafy shoots. In size and general appearance the flowers resemble those of *P. corymbosa*, but of their colour we know nothing. The calyx is downy, as well as the outside of the corolla. We know not to what the specific name alludes.

5. *P. velutina*. Velvet-leaved Parsonfia. Br. n. 1.—“Cymes stalked, opposite. Leaves heart-shaped, ovate, acute or somewhat pointed, downy.”—Gathered by Mr. Brown in the tropical part of New Holland.

6. *P. mollis*. Soft-leaved Parsonfia. Br. n. 2.—“Cymes divided. Leaves lanceolate, pointed, downy and soft.”—From the same country.

7. *P. lanceolata*. Smooth-lanceolate-leaved Parsonfia. Br. n. 3.—“Cymes divided. Leaves lanceolate, pointed, smooth.”—Gathered, like the two last, in the tropical part of New Holland, by Mr. R. Brown, whose specific characters are all we know of the history of these three species. This genus is entirely a stranger at present in the gardens of England; and is, as its author remarks, but too nearly related to *Lyonsia*, see that article, from which it differs only in having distinct follicles, or at least merely cohering in some species, whereas in *Lyonsia* they are perfectly united into a cylindrical capsule, divided into two cells by a parallel distinct partition.

PART, PARS, a portion of some whole, considered as divided, or as divisible.

Quantity is divisible into an infinite number of parts, not equal parts, but proportional ones. Philosophy is divided into four parts; viz. logics, ethics, physics, and metaphysics.

The schoolmen usually distinguish parts into logical and physical.

PART, *Logical*, is that referring to some universal as its whole; in which sense, the species are parts of a genus; and individuals, or singulars, are parts of the species.

PART, *Physical*, is that which, though it enter the composition of a whole, may yet be considered apart, and under its own distinct idea; in which sense, a continuum is said to consist of parts.

Physical parts, again, are of two kinds, homogeneous and heterogeneous; the first are those of the same denomination with some other; the second of a different one. See HOMOGENEOUS, &c.

Parts, again, are distinguished into subjective, essential, and integrant.

PART, *Subjective* or *Potential*, is the same with logical part; viz. that contained in some universal whole, not in act, but only in power. As, man and horse are in animal: Peter and Paul are in man.

PART, *Essential*, is that whereby, with the concurrence of some other, an essential whole is constituted. Thus, the body and soul are essential parts of men.

PART, *Integrant*, or *Integral*, is that which is necessary to the integrity of the whole. As, a head is of a man, &c.

Anatomists divide the parts of a human body into containing and contained; similar and dissimilar; and the similar, again, into spermatic and sanguineous, &c.

PARTS, *Noble*, or *Essential*, are those absolutely necessary to life. As the heart, lungs, liver, brain, &c.

PARTS, *Natural*, or *Genital*, popularly called *privy parts*, are those ministering to generation.

The finest writings of physicians are those which treat of the use of the parts. Galen's works, “De Usu Partium,” afford infinite arguments of the being and wisdom of God.

Nature, we say, always discharges itself on the weak part, the diseased part, the part affected, &c.

PARTS, *Consent of*. See **CONSENT**.

In chemistry, bodies are said to be resolved into their minute parts, their component parts, &c.

That art is said to separate the homogeneous parts from the heterogeneous; and the volatile, subtile, sulphureous, mercurial, &c. parts from the fixed, crass, earthy, viscid, &c. parts.

PART, in *Geometry* and *Astronomy*, is applied to the divisions of lines and circles.

The semidiameter of the circle, called also the radius, and whole sine, is divided into a hundred thousand parts; and the circumference of the circle into three hundred and sixty parts or degrees, in which two divisions all the celestial computations are made.

PARTS, *Aliquant* and *Aliquot*. See the adjectives.

PART, *Proportional*, is a part or number agreeable and analogous to some other part or number: or a medium to find some number or part unknown by proportion and equality of reason.

PARTS, *Similar*, are those which are to one another as their wholes are to one another.

PART, *Organical*. See **ORGANICAL**.

PART, in *Music*, denotes a piece of the score or partition written by itself, for the convenience of the musician; or it is one or more of the successions of sounds which make the harmony, written apart.

Or, the parts are the sounds made by several persons singing or playing in a concert.

Music in parts was unknown to the ancients; they had but one part; all their harmony consisted in the succession of notes, none in the consonance.

There are four principal parts; the treble, bass, tenor, and counter-tenor.

Some compare the four parts in music, to the four elements: the bass, they say, represents the earth; the tenor, water; counter-tenor, air; and the treble, fire.

PART, in *Trigonometry*. In a rectangular spherical triangle, *ABC*, (*Plute I. Trigonometry, fig. 3.*) that part lying between two others, considered as extremes, is called, by some authors, the middle part. Thus, if *AB* and *BC* be the extreme parts, the angle *B* will be the middle part.

If the parts, considered as extremes, be contiguous to the middle part, and one of the extremes; those are called conjunct parts. Thus, if *B* be in the middle part, *AB* and *BC* will be in the conjunct parts.

If, between the extremes and the middle part, there lie another, besides a right angle; then the parts are said to be disjunct or separate; *e. g.* if *B* be the middle term, *AC* and *C* will be disjunct parts; because, between the middle part *B*, and the extreme *C*, there lies the hypotenuse *BC*, and between the middle part *B*, and the other extreme *AC*, besides the right angle, there lies the leg *AB*.

Those parts either joined to the middle part, or separated from it, are called lateral parts. See **CIRCULAR PARTS**, **TRIANGLE**, and **TRIGONOMETRY**.

PARTS of Speech, in *Grammar*, are all the sorts of words which enter the composition of discourse.

The grammarians usually admit of eight parts of speech; *viz.* noun, pronoun, verb, participle, adverb, conjunction, preposition, and interjection. See each in its proper place, **NOUN**, **PRONOUN**, &c.

PART of Fortune, in *Judiciary Astrology*, is the lunar horoscope; or the point wherein the moon is, at the time when the sun is in the ascending point of the cast.

The sun in the ascendant is supposed, according to this

science, to give life; and the moon dispenses the radical moisture, and is one of the causes of fortune. In horoscopes the part of fortune is represented by a circle divided by a cross.

PART, in the *Manege*. in French, *partir*, is used to signify the motion and action of a horse when put on at full-speed. From the horse's parting to his stop there are commonly two hundred paces of ground. To make your horse part with a good grace, you must put your bridle three fingers lower, and press gently with your heels, or only with the calves of your legs. See **ECHAPER**.

To PART again. See **REPART**.

PART Owners, those that are concerned in ship matters, and who have joint shares therein.

PART and Art, in *Law*. See **ART**.

PARTABPOUR, in *Geography*, a town of Bengal; 25 miles E. of Midnapour. N. lat. 22 21'. E. long. 87 50'. — Also, a town of Hindoostan, in Oude; 10 miles E. of Fyzabad.

PARTAPAH, a town of Hindoostan, in Bahar; 13 miles N. of Hajypour. N. lat. 25 54'. E. long. 85 28'.

PARTE, in *Italian Music*, implies the voice part of a song, or *la parte che canta*.

PARTE, *Ex*, in *Law*. See **EX**.

PARTENI, in *Geography*, a river of Natolia, which runs into the Black sea, near Amasieh.

PARTENKERCH, a town of Bavaria, in the bishopric of Freyting; 6 miles S. of Weilkaim.

PARTERRE, in *Gardening*, a spacious level spot of ground in the pleasure garden, divided into many little partitions of different figures and dimensions; by means of edgings or lines of dwarf-box, or by verges of grass turf, with fine gravel walks between, &c. These sorts of works were formerly in great estimation, and were commonly situated directly in the front of the house, generally the whole width, and sometimes more, extending proportionably in length: and where the intermixture of the figures is artfully disposed, they strike the eye very agreeably, and afford an ornamental effect at all seasons.

For the most part, the general figure of a parterre is an oblong or long square, about as long again as broad: a level open spot in some conspicuous part, as above, is mostly chosen for the purpose: first forming a long bed, or border of earth, all round for a boundary; the internal space within this border being then traced out into various little partitions, or inclosures, artfully disposed into different figures corresponding to one another, such as long squares, triangles, circles, various scroll-works, flourishes of embroidery, and various other devices; all of which are formed either by lines of dwarf-box, with intervening alleys and tracks of turf, sand, fine gravel, small shells, &c. as above, or formed sometimes entirely of verges of fine turf, disposed into wide or narrow compartments, as the figure may require: and sometimes they consist of box-edgings, and tracks of turf, together; the partitions, or beds of earth, formed by the tracks of box and turf, &c. being planted with some choice flowers; but no large plants to hide the form, as the regularity of it, in the artful distribution of the different figures, is intended as a decoration to the whole place long after the season of the flowers is over. Some prefer parterres composed entirely of turf and beds of earth, perfectly even, without any other figure than the long square, forming a border of earth all round, within which are spots of grass, and beds or borders of earth of different sizes, and sometimes parterres, with box-edgings, are formed into labyrinths, or mazes; and some are made to represent coats of arms with the proper supporters. All crowded designs, however,

however, lose their effect. But works of this sort are now almost wholly in disuse in this country: however, for the sake of variety, they may, on some occasions, still be admitted, though not immediately in the front of the house, but in some convenient place.

Parterres, therefore, vary in their forms, extents, and kinds from those of the common flower gardens to be met with in many parts of the country, or the remains of those old French parterres, which contained the shapes of family arms, animals, &c. cut in the trees, and shell-works of different sorts. Nuneham and Beaumont-hall have gardens of the first kind; and Wentworth-castle, and Leven's-park, furnish examples of the latter description.

It is noticed by Mr. Loudon, that in *ornamental* gardens and parterres of every kind, the soil should be unmanured, and rather poor than otherwise; but the situation and exposure should be good, and the surface of the ground beautifully varied. The extent of them must be in proportion to the nature of the place to which they belong. In general they need not be large. In almost every kind, a few trees and shrubs should be introduced, to remove from the general view the appearance of insipidity, and to break it into separate scenes; one of which alone should be seen at a time, that the extent of vision being circumscribed, the spectator may thus be induced to examine or admire the minute beauties of single objects, or small compositions. And it is observed, that where parterres are intermingled with lawns, those disgusting lines of separation at the edges of walks, or round groups and dug patches of flowers or shrubs, which abound every where, should not be introduced; the gravel of the walk, and the earth at the edges of the dug patches or groups, ought to be kept nearly on a level with the grass on the lawn. Where much culture is requisite in the groups, the line of separation should be delicate and graceful; and where this is not necessary, or not much attended to, both the lines of the walk, and the lines of the dug group, or patch, should blend and harmonize, and, in a natural easy manner, glide insensibly into each other. The most remarkable varieties of parterres are these.

1st. The general flower garden parterre, that should contain such a variety of beautiful trees, shrubs, and flowers, &c. as that a number of each will be in perfection every month of the year, particularly in the summer season. They should be placed in irregular groups and thickets, of different sizes, gliding into one another on smooth lawn, beautifully varied, and broken into small confined scenes by trees and shrubs of the most elegant sorts. And throughout the whole, smooth gravel walks should wind in a graceful and easy manner. In this kind of garden parterre, a greenhouse and stoves for exotic plants and trees may be placed. In the summer season, those plants which are reared in the greenhouse may be dispersed throughout the garden; and the pots being sunk in the earth, the plants will appear as natives; or they may be arranged in a situation by themselves, and retain their own character; and, during this season, the house may be filled with balsams, coxcombs, amaranths, and other tender annuals. And few elegant seats, both covered and uncovered, may also be introduced; but no grottos, urns, busts, or temples, which have all their proper places in ornamental scenery, but which, as has been formerly remarked, are unsuitable to this kind of scene.

2dly. The winter garden parterre, which should contain principally such trees, shrubs, plants, and other kinds of growing vegetables, as are in perfection, or retain their verdure, during this severe season; as most of the evergreen tribe; and several flowering plants, as aconite, Christmas-

rose, &c. and they should be *grouped* and arranged in the *natural* manner, a dry gravel walk being carried and conducted throughout the whole. In regard to situation, this sort of parterre should constantly be placed near to the mansion or residence, in order that it may be conveniently and comfortably approached in the winter months, and the conservatory should be occasionally placed in it.

3dly. The spring garden parterre, which should comprehend all those deciduous shrubs and trees which blossom or put forth leaves the most early in the spring, such as the almond, the mezereon, the fringe tree, and several others which possess the same qualities. Also all the early-blowing flowers, as well those of the bulbous, as the fibrous-rooted kinds, as the narcissus, crocus, iris, cowslip, auricula, hepatica, and many others. Here the walks should likewise be gravelled, and but very little, or no lawn at all, appear to the eye.

And it is proper that this sort of garden parterre should contain a house or other erection for heaths, auriculas, and other early-flowering plants. It should also be placed near to the former, and be connected with it and the mansion or residence by a comfortable gravel walk, that they may be approached at any season. The soils of both should be light and dry, the situations well exposed to the sun, and sheltered from the north and easterly blasts or storms.

4thly. The autumn garden parterre, which ought to comprise such a collection of ornamental plants and trees as may be in full perfection at this season of the year, as most sorts of annual flowers when late sown; many kinds of herbaceous plants, as the aster, solidago, and several others, as well as various trees and shrubs that continue a long time in perfection, as the honey-suckle, the rose, acacia, and some others.

5thly. The bulbous root parterre, which requires to be somewhat different in form and design from any of these. The general form in this sort should be as regular as possible. It may be a square, a circle, or an oval, divided into compartments, and each of these laid out into beds of three or four feet broad. In this sort may be grown the different varieties of tulips, hyacinths, ranunculuses, anemones, and other similar root plants, each being cultivated in its proper sort of soil or earth, and such a parterre may contain a stove or hot-house for the ixia and amaryllis tribe of plants, as well as for other similar bulbous exotics, and have near it the auricula and carnation shed.

6thly. The parterre garden may also be formed solely for the purpose of cultivating any particular family, genus, or species of shrubs or plants. In this way there may be a parterre garden of roses, of annual flowers, of pinks and carnations, of double flowering plants and trees, of variegated kinds only, and several others; also parterres of ferns, of grasses, and of the vegetables, natives of any particular country, as those of the Cape, America, Siberia, the Alps, or of any other part of the world.

Parterres may likewise exist in the forms of the ancient British flower gardens, the Chinese gardens, the Grecian, Roman, Italian, French, and Dutch gardens, as well as in those of the modern British flower gardens.

And they are not only pleasing and amusing in themselves, but when introduced in a pleasure ground, by their contrast with other scenes, and with one another, may add to the variety and interest of that kind of ornamental scenery.

PARTESTI, in *Geography*, a town of Bukovina; 18 miles W. of Sueseva.

PARTHA, a river of Saxony, which runs into the Pless, near Leipzig.

PARTHA, in *Mythology*, a name of the Phallic emblem, worshipped

worshipped by certain sects of Hindoos, and called by them *Linga*; see that article. The Part'ha is, we believe, a domestic idol, made of the usual conical form, with clay, and without any thing indecent in its appearance, for females to pay their daily adoration to. It is sometimes placed under a tree, and circumambulated a certain number of times daily, especially by barren females, in the hope of offspring. This ceremony is called *pradakshna*, and is described under that word.

PARTHENAY, CATHERINE, in *Biography*, heiress to the lordship of Soubise, was married, in 1568, to the baron de Pons, and afterwards, in 1575, to Renatus, viscount Rohan. The celebrated duke de Rohan, who so courageously defended the Protestant cause in France during the civil wars of Louis XIII. was her eldest son. Catherine, one of her daughters, has rendered her name illustrious by the following answer which she made to Henry IV. who solicited her favours: "I am too poor, sire, to be your wife, and too proud to be your mistress." She afterwards married the duke de Deux-Ponts. Catherine, the subject of this article, was at Rochelle at the time of its memorable siege, and when the place surrendered, she and her daughters were sent to the castle of Niort. She died in 1631, at the age of seventy-seven. She published poems in 1572, and likewise a tragedy, entitled "Holofernes," which was performed at Rochelle. She translated the precepts of Ilocrates to Demonicus into the French language. Bayle. Moreri.

PARTHENAY, in *Geography*, a town of France, and principal place of a district, in the department of the Two Seves, near the river Thoue. The place contains 3213, and the canton 6319 inhabitants, on a territory of 262½ kilometres, in 11 communes. The trade of the town, which is considerable, consists in cattle and corn; 21 miles N.N.E. of Niort. N. lat. 46° 38'. W. long. 0° 10'.

PARTHENIA, is the title of a thin folio book of lessons for the Virginal, that was engraved on copper, and published in the reign of king James I. under the following title: "Parthenia, or the Maidenhead of the first Musicke that ever was printed for the Virginals. Composed by three famous masters: William Byrd, Dr. John Bull, and Orlando Gibbons, Gentlemen of his Majesties most illustrious Chappel." Bird being here called "Gentilman of his Majesties chappel," seems to imply, that he was still living when it was published. King James died in 1525, and Bird in 1523. The three first movements in this collection, consisting of a *Preludium*; *Pavana*; fir William Peder; and a *Galiardo*; are in G minor, and may be called a *Suite* of lessons. The fourth and fifth movements, *Preludium*; and *Galiardo*, Mrs. Marye Brownlo, in C; and the sixth, seventh, and eighth, *Pavana*, the earle of Salisbury; *Galiardo primo*; and *Galiardo secundo*, Mrs. Marye Brownlo, in A minor; constitute what may likewise be regarded as two other *Suites de Pieces*, or sets of lessons.

PARTHENIA, or *Parthenos*, in *Mythology*, an epithet given to Minerva, because she is said to have preserved her virginity. When the Rhodians neglected the worship of that goddess, and their care in improving the fine arts, the Athenians began to distinguish themselves in this respect, and took her for their patroness. Accordingly they dedicated to her a magnificent temple under the name of Parthenos, the virgin. Phidias adorned it with a statue of gold and ivory, which was a master-piece; and the Athenians also celebrated to her honour a festival, which was afterward called "Panathenaia." *Parthenos* was also a name given to Juno, from a notion that this goddess, by bathing herself every year in the fountain called Canathos, which was at Nauplia, recovered her virginity; a fable, founded, according to Pausanias, upon

the secret mysteries that were celebrated in honour of this goddess.

PARTHENIA, in *Ancient Geography*, a town of Illyria, according to Polybius; called by Julius Cæsar "Oppidum Parthinorum."

PARTHENIAS, a river of Triphylia, which ran from N. to S. and discharged itself into the river Alpharus, near Olympia.

PARTHENIASTRUM, in *Botany*. See PARTHENIUM.

PARTHENICUM, in *Ancient Geography*, a town of Sicily, upon the route from Lilybæum to Tyndaride, between Segestena and Hyccara, according to the Itin. of Antonine.

PARTHENIUM, KARANDIP, a village of the Tauric Chersonesus, in the narrowest part of the strait called Cimmerian Bosphorus, 60 stadia above Panticapæum, and over against Achillæum. Strabo.—Also, a promontory of the Tauric Chersonesus, nearly S. of Chersonesus. Near this promontory was a temple and a statue of the goddess of the country.—Also, a town of the Peloponnesus, in Arcadia. Pliny.—Also, a town of Asia, in Mysia, in the vicinity of the Troade. Pliny.—Also, a town of Greece, in the island of Eubœa.

PARTHENIUM *Mare*, the name of a part of the Mediterranean sea, which bathed Asia and Africa, in the place where these two regions of the globe joined each other. Macrobius.—Also, a promontory in the vicinity of the town of Heraclea.

PARTHENIUM, in *Botany*, a name adopted from Dioscorides, whose *παρθενιον* however is sufficiently well described, particularly in the comparison of its leaves to those of Coriander, for us to perceive that his plant is the Feverfew, *Matricaria Parthenium* of Linnæus, *Pyrethrum Parthenium*, Sm. Fl. Brit. 900, as all commentators have been agreed. The name, from *παρθενος*, a virgin, alludes to its reputed efficacy in some female complaints; see MATRICARIA and PYRETHRUM. The above name being therefore unemployed as a generic one, Linnæus applied it to a new genus, much resembling the ancient herb in aspect, and perhaps in sensible qualities, which Nissol and Dillenius, on account of such resemblance, had called *Partheniastrum*. Linn. Gen. 489. Schreb. 636. Willd. Sp. Pl. v. 3. 2385. Mart. Mill. Dict. v. 3. Juss. 191. Lamarek Illustr. t. 766. Gærtn. t. 168. (Argyrochæta; Cav. Ic. v. 4. 54)—Class and order, *Monoecia Pentandria*, Linn. rather *Syngenesia Polygamia-necessaria*, as Willdenow, and even Linnæus in his earlier publications, have it. Nat. Ord. *Compositæ nucamentacea*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Cal.* Common Perianth perfectly simple, of five spreading, roundish, flat, equal leaves. *Cor.* compound, convex: perfect florets several, in the disk, each of one petal, tubular, erect, as long as the calyx, with a five-cleft regular border; female florets five, in the radius, scarcely taller than the others, each of one petal, tubular, ligulate, oblique, obtuse, roundish, the length of the former. *Stam.* in the perfect florets, filaments five, capillary, the length of their corolla; anthers as many, thickish, scarcely cohering. *Pist.* in the perfect florets, germen inferior with respect to the proper receptacle of the floret, but scarcely discernible; style capillary, rather shorter than the stamens; stigma none: in the female florets, germen inferior, heart-shaped, rather turbinate, compressed, large; style thread-shaped, the length of the petal; stigmas two, thread-shaped, as long as the style, rather spreading. *Peric.* none, except the calyx, which remains unchanged. *Seeds* of the florets of the disk abortive; those of the female flowers of the radius turbinate-

hear.-

heart-shaped, compressed, naked. *Recept.* very small, convex. There are scales separating the florets, in such a manner that each female has two perfect ones at its back.

Ess. Ch. Receptacle chaffy, small. Seeds obovate. Down none. Calyx of five leaves. Florets of the radius five; of the disk numerous.

1. *P. Hysserophorus*. Cut-leaved Bastard Feverfew. Linn. Sp. Pl. 1402. Ait. Hort. Kew. ed. 1. v. 3. 345. (*Argyrochæta bipinnatifida*; Cavan. Ic. v. 4. 54. t. 378. *Matricariæ Achaovan distæ similis*, &c.; Pluk. Phyt. t. 45. f. 3.)—Leaves pinnatifid, many-cleft.—Native of Jamaica, and other parts of the West Indies, as well as of Mexico. The root is annual. Stem much branched, two feet high. Leaves alternate, doubly pinnatifid, with rounded sinuses, nearly smooth. Panicles terminal, compound, spreading, of numerous small white flowers, which have little beauty to recommend them, so that although the plant is raised every now and then in gardens, from foreign seed, it is seldom preserved. Cavanilles was not aware of its being already described, when he saw it flowering at Madrid in July 1797, and therefore considered it as a new genus. He describes the *stamens* as four only, the *anthers* forming a tube. The Linnæan specific name alludes to the generic appellation given by Vaillant, founded on an obscure anatomical comparison.

2. *P. integrifolium*. Entire-leaved Bastard Feverfew. Linn. Sp. Pl. 1402. Mill. Illustr. t. 80. Willd. Hort. Berol. 4. t. 4. (*Parthenium helenii folio*; Dill. Elth. 302. t. 225.)—Leaves undivided, oblong, toothed.—Native of North America; Michaux says Virginia and the hilly parts of Carolina. It has been 150 years, or more, in our gardens, flowering from June to the end of autumn. Root perennial. Herb much stouter and taller than the former, rough and harsh. Leaves ovate-oblong, acute, rigid, rough, coarsely crenate or toothed, with one rib and many transverse veins; the upper ones clasping the stem; the lower larger, and somewhat stalked. Flowers in dense, terminal, corymbose panicles, white, said to droop on the approach of night, which we have had no opportunity of observing.

PARTHENIUM, in *Gardening*, contains plants of the annual and perennial kinds, of which the species are the cut-leaved parthenium, or bastard feverfew (*P. hysserophorus*); and the entire-leaved parthenium (*P. integrifolium*).

Method of Culture.—The first sort may be increased by sowing the seeds on a hot-bed early in the spring; and when the plants come up, transplanting them upon another hot-bed, about five or six inches distant, giving them water and shade until they have taken new root; after which, they must have a pretty large share of fresh air in warm weather, by raising the glasses of the hot-bed every day, and be duly watered every other day at least. When the plants have grown so as to meet each other, they should be carefully taken up, preserving a ball of earth to their roots, and each planted into a separate pot filled with light rich earth; and be plunged into a moderate hot-bed till fresh-rooted; after which they may be exposed, with other hardy annual plants, in a warm situation, where they will flower in July; but if the season should prove cold and wet, it will be proper to have a plant or two in shelter, either in the stove, or under tall frames, in order to have good seeds, if those plants which are exposed should fail.

The second sort may be increased by parting the roots in autumn, and be planted in the full ground, where it will abide the cold of our ordinary winters.

They afford ornament in the borders, and among potted plants.

PARTHENIUS, in *Ancient Geography*, a river of the isle of Samos.—Also, a river of Asia Minor, which ran into the

Euxine sea, and separated the territories belonging to the towns of Amathris and Teium. Strabo. This geographer represents it as a beautiful river which pursued its course among meadows, and it had the name of the "Virgin," on account of the worship paid to Diana on its banks.—Also, a river of Asia, in Cilicia, near the town of Anchiala. Suidas.—Also, a mountain of the Argolide, which extended from W. to E., from the Argolic gulf to the frontiers of Arcadia. The poet Callimachus describes this mountain by the expression, "The sacred mountain of Augé:" denoting, as it is supposed, that on this mountain passed the amours of Hercules and Augæa, of which Telephus was the fruit.

PARTHENOPE, an island of the Tyrrhenian sea. Ptolemy.

PARTHENOPOLIS, a town of Macedonia. Steph. Byz.—Also, a town of Asia, in Bithynia, which did not subsist in the time of Pliny.—Also, a town of Upper Mæsia, subjugated by Lucullus.

PARTHIA, called by the Greeks *Parthya* and *Parthyene*, a province of the Persian empire, bounded on the W. by Media, on the N. by Hyrcania, on the E. by Asia, on the S. by Carmania the Desert; surrounded with mountains, which served for boundaries on all sides. In this restricted sense, Parthia must not be confounded with what the ancients called the Parthian empire, which was of vast extent; being bounded on the E. by the Indus, on the W. by the Tigris, on the S. by the Red sea, and on the N. by mount Caucasus, so that it comprehended Arachosia, Parthia Proper, Assyria, Persis, and Media. The ancient geographers enumerate a great many cities in Parthia; the most noted of which were Calliope, Ispatis, Europum or Arface, Apamea, Heraclea, Crenonia, Charax, Artacana, Aspa, Marriche, Rhagæa, and Hecatompylos. The latter was the metropolis of Parthia, or the place where the first kings of that country resided; for after they had made themselves masters of Assyria, they abandoned Hecatompylos, passing the winter at Ctesiphon, and the summer at Ecbatan, or in Hyrcania. (See CTESIPHON.) Hecatompylos was only the metropolis of Parthia properly so called; nevertheless, it was a place of great note, and about nine miles in compass. It had a hundred gates, whence it borrowed its name. Most modern travellers are of opinion, that it stood on the spot where the present city of Ispahan stands. Parthia is at present known by the name of Erach or Irac, and may be called the royal province of Persia, since the king always resides in it; and, by way of distinction from Chaldæa, which is likewise called Erach or Irac, this is denominated *Irac-Agemi*, which see. The chief cities it contains at present, are, Casbin or Caswin, built on the ruins of the ancient Arface, Sawa or Sava, Kom, Hamadan, Kashan, and Ispahan. Ptolemy reckons twenty-five large cities within the province of Parthia; and it must certainly have been very populous, since many cities and about 2000 villages are reckoned to have been destroyed by earthquakes.

The air of Parthia was anciently, and is still, very clear and healthy; but the soil barren, and not affording provisions sufficient to maintain the inhabitants, who were once very numerous, and therefore obliged to transplant themselves into other countries. Upon the death of Alexander the Great, it was almost entirely neglected, and left as an appendage to Media, that prince's commanders declining the government of so poor and barren a province. In fabulous history the Parthians, who have been reckoned so famous, have been traced to Pathrusim, the son of Mizraim. However this be, they were, without doubt, originally Scythians, driven out of their own country, and obliged

PARTHIA.

to settle in this barren and inhospitable region. They called themselves, on their first settling here, Parthians; that is, in the old Scythian language, *exiles*; and hence, it is said, originated the name of Parthia.

The Parthians were a courageous and warlike people, not undeservedly esteemed the best horsemen and archers in the world. They were accustomed, from their infancy, says Dionysius (in Poem de situ Orb.), to the warlike and manly exercises of managing a horse and handling a bow; and in both excelled all other nations. They had the art, peculiar to themselves, of discharging their arrows with incredible dexterity, whilst they were retiring at full speed, so that their retreat was more formidable than their attack. To these exercises of horsemanship and archery, the air and country very much contributed; for the dry air, as Dio observes, seasoned their bows, and their extensive plains afforded them room for training their horses. From the age of 20 to 50, they were all, without exception, obliged to serve in war, to attend the musters, learn the military exercises, and be ready, at a very short warning, to take the field. Persons of any rank or distinction among them never appeared in public on foot, but always on horseback, armed with scimitars. In war they did not use trumpets like other nations, but large hollow vessels of brass, covered with skins, such as our kettie-drums, which, being beat with hammers, yielded a very warlike sound. The Roman poets often refer to the military character and evolutions of the Parthians. Thus Virgil says in his "Georgics," l. iii.

" Fidentemque fuga Parthum versifque Sagittis."

Horace, "lib. i. Carm. Od. 19." says:

" Et versis animosum equis
Parthum dicere."

And Ovid, "lib. iii. de Art. Am." observes,

" Ut celer aversis utere Parthus equis."

In his "Fasti, lib. v." we have the following couplet:

" Quid tibi nunc mitti solitæ post terga sagittæ?
Quid loca, quid rapidi præfugit usus equi."

Seneca, the tragedian, in his "Thyeste," says,

" Nil opus est equis
Nil armis et inertibus
Telis, quæ procul ingerit
Parthus, cum simulat fugas."

Some have said that they had recourse to the aid of lions in their combats, and that at the commencement of a battle, they let them loose against the enemy: to this purpose Lucretius (l. v.) says

" Et validos Parthi præ se misere leones
Cum ductoribus armatis, sævisque magistris."

Their religion was much the same with that of the Persians, and they worshipped the sun under the name of "Mithras." They believed that those who fell in battle enjoyed perpetual happiness; a doctrine suited to the genius of a warlike nation. They were religious observers of their promises, thinking it highly dishonourable not to perform their engagements, or to deceive those who reposed their confidence in them.

As to their government, it was monarchical, and in the highest degree absolute. The kings treated their subjects as the meanest of slaves, and scarcely as men, whilst they put themselves on a level with the immortal gods. Their usual titles were "the king of kings, the great monarch,

the brother of the sun and moon." These haughty titles they not only assumed in all the laws and edicts they enacted, but in their letters to other princes. Their conduct corresponded to the lofty titles which they assumed; for they obliged all whom they vouchsafed to see, to kiss the threshold on their first entrance into the royal palace; to prostrate themselves before them on the ground, and to acknowledge their majesty with some offering.

The history of the Parthians is involved in great obscurity before the time of Arsaces I. They were first subject to the Medes, afterwards to the Persians, and lastly to Alexander the Great, upon whose death Parthia fell to the share of Seleucus Nicator, whose successor held it till the reign of Antiochus Theus, when Arsaces, shaking off the Macedonian yoke, founded a new kingdom, which became much the most powerful in the East. Arsaces I. was properly the founder of the Parthian monarchy. Having induced the Parthians to revolt from Antiochus Theus, and having defeated and taken prisoner his son and successor, Seleucus Callinicus, he assumed the title of king, and established an empire in the East, which counterbalanced the overgrown power of the Romans in the west. He reduced Hyrcania, and some other neighbouring provinces; and was at last killed in a battle against Ariathes IV. king of Cappadocia. From him all his successors of the same race took the name of Arsaces; so that the empire of the Parthians was sometimes denominated the empire of the Arsacides. Arsaces II. succeeded his father, and made himself master of Media, whence he was driven by Antiochus the Great. Retiring into Hyrcania, he assembled a formidable army, and compelled the king of Syria to make a disadvantageous peace; for he abandoned Parthia and Hyrcania to Arsaces. After two reigns, the Parthians became very powerful under Mithridates I. The reign of this prince is regarded by authors as the epoch of the Parthian grandeur; for, under him, that empire was by far the most extensive, as well as powerful, in the East: all the countries that lie between the Euphrates and mount Caucasus receiving law from him, and most of the princes of Asia being either subdued, or obliged to enter into an alliance with him, upon his own terms. Phraates II, who succeeded him, was overcome in three successive battles by Antiochus Sidetes, king of Syria; and having been deprived of Mesopotamia, Babylonia, and the other countries which his father had reduced, was confined within the narrow limits of the first Parthian kingdom. However, the Scythians, and Greek mercenaries, came to the assistance of Antiochus, and falling upon the Parthians, cut their army to pieces, killed their king, and laid waste his dominions. On the departure of the Greeks and Scythians to their own countries, Artabanus I. took possession of the crown, and after a short reign, he was succeeded by his son Pacorus I., who, hearing of the great exploits of the Romans, sent ambassadors to Sylla, who was then in Cappadocia, soliciting the friendship and alliance of so powerful a people. In consequence of this alliance, peace was maintained for some time within the two empires, till at length M. Licinius Crassus, having been created consul at Rome with Pompey, and having, by the Trebonian law, obtained the dominion of Syria, and the neighbouring provinces, was prompted by his insatiable avarice to make war with the Parthians, whose army was entrusted to the command of Surenas. The presumption and ardour of the son of Crassus brought on a battle between the two armies, the event of which proved fatal, not only to the father and son, but to a great number of the Romans. Although the victory was chiefly owing to the skill and valour of Surenas, Orodes, the Parthian monarch,

PARTHIA.

jealous of his fame, perfidiously ordered him to be put to death. After this contest, the Romans and Parthians continued for some time in a state of mutual hostility; the latter having often the advantage, and pursuing their conquests in Syria, Phœnicia, and Asia Minor, &c. At length Ventidius re-established the honour of the Roman arms; and having surprised the Parthians, attacked them at an unfavourable moment, and defeated them; Pacorus, the son of the Parthian king, being killed, whilst he was fighting with incredible bravery at the head of the Parthian horse. Some time after, the Parthians took ample revenge; and Statianus, the lieutenant of Sylla, was cut off with 10,000 Romans. Orodes was assassinated by his son Phraates, who exercised the same cruelty over the nobility, and all the rest of the royal family, not sparing his eldest son, left the discontented Parthians should place him on the throne. This monster prolonged his reign under the character of a warlike prince, and prosecuted a prosperous war against Antony. In process of time he made peace with Augustus, and restored all the captives and ensigns which the Parthians had taken in their wars with Crassus and Antony. He also sent four of his sons, with their wives and children, as hostages to Rome. His son Phraatrus remained with him; and it is said that he was poisoned by his wife Thermosa, in order to place the son upon the throne. The Parthians, however, disdaining to be governed by so wicked a parricide, rose up in arms, and drove him into banishment, where he perished some years after. The succeeding reigns were of short duration; and Artabanus, one of the race of the Arsacides, who reigned in Media, was called to the Parthian throne. His cruelty rendered him detestable, and afforded to Tiberius an opportunity of placing on the throne Tiridates, who was likely to be more devoted to the will of the Roman emperor. Artabanus was ultimately restored to the kingdom by the influence of Izates, king of the Adiabeniens; and from this time he governed the kingdom with great equity and moderation; so that, after a reign of 30 years, he died, greatly lamented by all his subjects, leaving behind him seven sons, one of whom succeeded him. Under the reign of Nero, Vologeses, the Parthian king, sent ambassadors to the emperor, soliciting the kingdom of Armenia, and offering to renew the alliance made by his ancestors with the Roman people. Nero refused to renounce all pretensions to the crown of Armenia. Vologeses was incensed, but dreading the consequence of a war with the Romans, he at last consented that his brother Tiridates should go in person to Rome, and there receive the crown of Armenia, as a gift from Nero, who accordingly bestowed it upon him. Thus the ancient alliance between the two empires was renewed, and the affairs of the East were settled in peace. However, under the reign of Trajan, Armenia became a subject of difference between the two empires. Cosroes, for some reason that is not known, invaded Armenia, and expelled Exadorus, who had been appointed king of that country by the emperor Trajan, and placed his eldest son upon the throne. But Trajan, thus incensed, determined to humble the Parthians, and for this purpose hastened into the East. His journey was so sudden and unexpected, that he reduced the whole country without opposition, and took the Armenian king prisoner. He then entered Mesopotamia, and made himself master of that opulent kingdom, never before subject to Rome, and reduced it to a Roman province. After several contests of various issue, Cosroes was defeated by Lucius, a commander detached for this service by Trajan. The emperor having gained possession of all the best and most fruitful provinces of the Parthian empire, and perceiving that he could not maintain his con-

quests, without great expence and hazard, at such a distance from Italy, he appointed one of the royal family, named Parthaspates, king of Parthia. Thus the Parthians were at last subdued, and their kingdom made tributary to Rome. But, after Trajan's death, they revolted, drove the king whom he had appointed from the throne, and recalled Cosroes, who had retired into the country of the Hyrcanians. Adrian, who was then in the East, thought it imprudent to engage in a new war with the Parthians, but contented himself with making the Euphrates the boundary of the Roman empire. Cosroes died after a long reign, and was succeeded by his son Vologeses II., who invaded Armenia and Syria. Upon this, the emperor Verus, by the advice of his colleague Antoninus, surnamed the philosopher, hastened into Syria; and having forced the Parthians from that province, ordered Statius Priscus to invade Armenia, and Cassius, with Martius Verus, to enter the Parthian territories, and carry the war into the enemy's country. Priscus drove the Parthians, though not without great loss, out of Armenia; and Cassius, having repeatedly defeated Vologeses, though he had an army of 400,000 men under his command, reduced in four years all those provinces which had formerly submitted to Trajan, and gained other considerable advantages. After the revolt and death of Cassius, Antoninus the philosopher repaired into Syria, and having been met by ambassadors from Vologeses, who, being unwilling to part with those provinces that had been subdued by Cassius, but which he had recovered, solicited the emperor to confirm him in the possession of them, promising to acknowledge the sovereignty of Rome. Antoninus readily acceded to these terms, and a peace was concluded between the two empires. Upon the death of Vologeses, another prince of the same name succeeded him; but taking part with Niger, against the emperor Severus, the emperor laid siege to Ctesiphon, his metropolis, and took it. Vologeses, who had made a gallant defence, had the good fortune to escape. As soon as Severus had crossed the Euphrates, Vologeses recovered all the provinces, except Mesopotamia, which he had reduced. The Parthians were molested with intestine disturbances, but Vologeses died before he could restore the empire to its former tranquillity. Before Artabanus IV., the successor of Vologeses, had well settled the affairs of his kingdom, the emperor Caracalla, desirous of signalizing himself by some memorable exploit against the Parthians, sent a solemn embassy to him, desiring his daughter in marriage. Artabanus, rejoicing in the proposal, because he thought the connection would be attended with a lasting peace between the two empires, received the ambassadors with all possible marks of honour, and readily complied with their request. Caracalla, by a second embassy, informed Artabanus, that he was hastening to solemnize the nuptials; upon which the Parthian king, with the chief of the nobility, and his best troops all unarmed, went out to meet him; but the soldiers of the treacherous emperor, on a signal given, fell upon the king's retinue, and made a dreadful slaughter of the unarmed multitude. Artabanus himself escaped with great difficulty. However, he determined to revenge himself on the Romans, for their inhuman and barbarous treachery; and therefore he entered into Syria with a very numerous army, and put all to the sword. This was followed with an obstinate engagement between the Parthian and Roman armies, in which 40,000 on both sides were killed. When Artabanus heard that his great enemy, Caracalla, was dead, he embraced with eagerness the proposals of peace and amity made to him by the new emperor, Meccrenus; and then the one returned to Parthia, and the other to Antioch. Artabanus, being enfeebled by his com-

bat with the Romans, was alarmed by a revolt of the Persians; and prepared, by the whole strength of his kingdom, to suppress it. A bloody battle ensued, and the Parthians, after the most valiant exertions, were forced to yield to the Persians, who were commanded by Artaxerxes, who, though of mean descent, possessed great military experience. The Parthian king was taken prisoner, and soon after put to death by the order of Artaxerxes. The Parthians, having lost their king and their army, were forced to submit to the conqueror, and became vassals to a nation which had been subject to them for the space of 475 years. Thus was this gallant and warlike nation subdued at last, and the empire once more transferred to the Persians. However, the royal family of Arsaces did not end in Artabanus, but continued to reign in Armenia, till the time of the emperor Justinian, holding that kingdom of the Persian monarchs, to whom the Arsacidæ of Armenia were tributaries. See ARSACIDÆ. Anc. Un. Hist. vol. ix.

To this historical account of the Parthians we shall subjoin a concise statement of the geography of their country, more especially as very erroneous ideas concerning the local situation of this country have generally prevailed. Those, whose knowledge of it has been chiefly derived from its wars with the Romans, have conceived Parthia to be only the country bordering on the Euphrates and Tigris; whereas Parthia proper was a small province very near to the S.E. extreme of the Caspian sea, which territory, as we have already historically detailed, after the division of Alexander's empire, fell to the choice of the Seleucidæ, kings of Syria, and of the east, about 300 years before our era. About 50 years after, Parthia rebelled; and together with Hyrcania, and other adjoining provinces, became an independent state under Arsaces. As the empire of the Seleucidæ grew weaker, the Parthians extended their country westward; and the fine province of Media fell to them; and within a century after the foundation of their state, it had swallowed up all the countries from the Indus to the Euphrates, Bactria included: and this province had thrown off the yoke of the Seleucidæ, long before Parthia. The Parthian conquests in Armenia, about 70 years B. C., brought them acquainted with the Romans; whose conquests met theirs both in that country and in Syria. The Parthians, together with their conquests, had advanced their capital westwards, and had established it on the Tigris at Seleucia, or rather Ctesiphon (near the present Bagdad) before their wars with the Romans commenced. The expeditions of Pompey and Antony, and the defeat of Crassus, need not be again recited. On occasion of the last event, the Parthians extended their conquests farther westward, but afterwards were compelled to retire; and they generally lost ground in Armenia and Mesopotamia, during the time of the Roman emperors. Trajan penetrated to their capital; and satisfied his curiosity by embarking on the Indian sea. The moderation of Adrian restored the ancient boundary of the Euphrates. In A.D. 245, Persis, or Persia proper, which had for some ages ranked as a province of Parthia, gained the ascendancy; and, under Artaxerxes, put an end to the dynasty of the Arsacidæ, and restored the ancient name of Persia to the empire, after that of Parthia had existed about 480 years: so that, in fact, the Parthian empire, considered generally, was the Persian, under another name. Rennell's Memoir.

PARTHIA, a town of Asia Minor, in Caria.

PARTI, PARTY, or *Parted*, in *Heraldry*, is applied to a shield or escutcheon, denoting it divided, or marked out into partitions.

The French heralds, from whom we borrow the word,

have but one kind of *parti*, the same with our *parti per pale* which they simply call *parti*: but with us the word is applied to all sorts of partitioning: and is never used without some addition to specify the particular kind intended.

Thus we have *parti*, or *parted per cross*, *per chief*, *per pale*, *per fess*, *per bend dexter*, *per bend sinister*, *per chevron*, &c. See QUARTERING.

The humour of our ancestors, Colmbiere observes, turning much upon exploits of arms and chivalry, they used to preserve their battered and hacked armour as honourable symbols of their hardy deeds; and those who had been in the hottest service were distinguished by the most cuts and bruises that appeared on their shields. To perpetuate the memory hereof, says the same author, they caused them to be painted on their shields, and thus handed down to posterity. And when heraldry grew into an art, and officers were appointed to direct the manner of bearing, and blazoning; they gave names to those cuts, answerable to the nature thereof; appointing four, from which all the others proceed; these are *parti* (called by our heralds, *parti per pale*), *coupe* (*parti per fess*), *tranche* (*parti per bend dexter*), and *taille* (*parti per bend sinister*.) See COUPED, TRANCHE, &c.

PARTI *per pale*. See PALE.

PARTI *per fesse*. See FESSE.

PARTI *per bend dexter*, is when the cut comes from the upper corner of the shield on the right hand, and descends athwart to the opposite lower corner.

PARTI *per bend sinister*, is when the cut coming from the upper left corner, descends across to the opposite lower one.

From these four partitions have proceeded an infinite number of others of various and extravagant forms.

Spelman, in his *Aspilogia*, observes, that the present divisions of escutcheons were unknown in the reign of the emperor Theodosius; and were brought up in the time of Charlemagne, or later; they were little used among the English in the days of king Henry II. but more frequently under Edward III.

The erect or upright section, he observes, is called in Latin *palaris*, from its resemblance to a *palus*, or *stake*; and two coats are often entire on the sides, the husband's on the right, and the wife's on the left. The direct section across, being in the place of a belt, is called *baltica*, &c.

When the shield is *parti*, and *coupée*, it is said to be *ecartelé*.

It is said to be *parti one from the other*, when the whole shield is charged with some honourable bearing divided by the same line that parts the shield. Here it is a rule, that one side be of metal, and the other of colour. Thus he bears sable, parti d'argent, a spread eagle parti from one to the other.

PARTIAL CAUSE. See CAUSE.

PARTIAL Differences, *Theory of*, is one of the higher branches of the modern analysis, for the development of which we are principally indebted to d'Alembert, though the subject had been previously considered, in *abstractio*, by a few other mathematicians, but it does not appear that any of them had any explicit idea of its application.

Fontaine seems to have been the first who prepared and adopted the notation for expressing the partial differences of any variable function; but it is in a memoir of N. Bernoulli, on Trajectories, that we first find an attempt to ascertain the relation that has place between the partial differences of a function of two variable quantities. See Act. Eruditorum, ann 1720, or the works of John Bernoulli, tom. ii.

p. 443.

PARTIAL DIFFERENCE.

Clairaut also discovered the same theorem, of which he availed himself, in two memoirs on the Integral Calculus, printed amongst those of the Academy of Sciences, for the years 1739 and 1740. These memoirs are far more elegant and perspicuous than those of Fontaine, in which this notation is first adopted, and the latter in particular is very interesting: here we find the equation $\frac{dA}{dy} = \frac{dB}{dx}$ drawn from

the consideration of curve surfaces, and some remarks in this paper, first suggested by Fontaine, Lagrange employed as the base of his elegant theory of Particular Integrals, published by him in the Memoirs of Berlin for 1774, and afterwards in his *Leçons des Fonctions*. But of all those who preceded d'Alembert in the theory of partial differences, Euler has perhaps the greatest claim to priority of invention, having completely integrated an equation of this description in 1734, in vol. vii. of the *Acta Petrop.*, but afterwards forgot or neglected his new calculus, not being aware probably of its extensive application to physical problems. This application we owe entirely to d'Alembert, and the great ingenuity and taste displayed in the integration of his equations, cannot fail of placing him amongst the first of modern mathematicians. D'Alembert was first led to this integration on attempting the solution of certain problems relating to the vibration of musical chords, and afterwards employed it with great success in his theory of the winds, the resistance of fluids, and other very difficult and delicate investigations.

Theory of Partial Differences.—Having given a slight sketch of the progress of this interesting branch of analysis, let us now endeavour to explain more particularly the nature of the calculus, and its application in one or two particular cases.

When we have any function z of two variables x and y , or of a greater number, we know that in differencing at first with x as variable and y as constant, and again with y as variable and x as constant, we obtain $dz = p dx + q dy$, p and q being the co-efficients that affect dx and dy respectively. Hence the complete differential of z is $p dx + q dy$; and $p dx$ and $q dy$ the partial differences. This definition is sufficient for our present purpose, which will be farther illustrated in the sequel.

These co-efficients above denoted by p and q , are more commonly denoted by $\frac{dz}{dx}$, $\frac{dz}{dy}$, which are in fact the same; for, if we difference first with x variable and y constant, and divide by dx , we have $\frac{dz}{dx}$, which represents what the function becomes on this supposition, and in the same way $\frac{dz}{dy}$ will represent its value, supposing y variable and x constant; so that the complete value of dz is expressed by $dz = \frac{dz}{dx} dx + \frac{dz}{dy} dy$, and it is commonly under this form that equations of partial differences arise.

Hence every equation between the quantities

$$z, x, y, \frac{dz}{dy}, \frac{dz}{dx}, \text{ \&c.}$$

is called an equation of partial differences, and which may be compounded or not with known quantities: thus, $a \frac{dz}{dx} + b \frac{dz}{dy} - xy = 0$, is an equation of this kind, the

solution and integration of which requires, that we should find such a function of x and y , that the co-efficient of the differential dx plus the co-efficient of the differential dy ; the first multiplied by a and the second by b , may produce xy ; and the method of performing this is what is called the *integral calculus of partial differences*.

$$\text{Again,} \quad \frac{dz}{dx} + \frac{dz}{dy} - x^2 - 4xy - y^2 = 0,$$

is also an equation of partial differences, the integral of which is $z = x^2 y + y^2 x$.

For differencing this first with x variable and y constant, we have $\frac{dz}{dx} = 2xy + y^2$; and again, with y variable and x constant, $\frac{dz}{dy} = x^2 + 2xy$;

$$\text{whence} \quad \frac{dz}{dx} + \frac{dz}{dy} = x^2 + 4xy + y^2$$

$$\text{or} \quad \frac{dz}{dx} + \frac{dz}{dy} - x^2 - 4xy - y^2 = 0,$$

These equations, in which only the first differentials of the variables enter, are the most simple, and are called partial differential equations of the first degree. If the second differentials enter, the equation is said to be of the second degree; if the third enter, of the third degree; and so on of others:

$$\text{thus,} \quad \frac{d^2 z}{dx^2} + \frac{d^2 z}{dx dy} + P = 0,$$

is an equation of the second degree; and

$$\frac{d^3 z}{dx^3} + \frac{d^3 z}{dy^3} + P = 0,$$

is an equation of the third degree, and so on of superior orders; but the first and second are those only that can be employed to any advantage, the integration of the higher orders being too complex to admit of a solution except in a few partial cases: indeed, the complete integrations of equations of the first and second degree, is at present a desideratum of modern analysts.

In the preceding part of this article, we have only mentioned functions of two variables, but it is needless to apprise the reader that the same may have place in those of three or more variable quantities; we have merely limited our observation to those of two, for the sake of greater simplicity.

In the limits to which we are under necessity of confining this article, we cannot enter at any great length upon the method of integrating equations of this kind; but in order to give some idea of it, let us take one of the most simple

cases; viz. $\frac{dz}{dx} = P$, P being any function of x and y , with or without constant or known quantities.

Here, then, our object is to find a function z , of x and y , which being differenced with y as variable, and divided by dy , shall be equal to the given function P . In order to this, let us multiply the whole by dy , and we shall have $\frac{dz}{dy} dy = P dy$, from which it follows that $P dy$ is only a part of the differential of z , viz. that part which arises by considering y as variable; so that the integral of $\frac{dz}{dy} dy$, which is z , (since the expression above results from its differentiation)

PARTIAL DIFFERENCE.

rentiation) in making only y variable, will be equal to $\int P dy$ plus a function which contains only x , and which may be found after the same manner as the correction of any other integral to render it complete from the conditions of the problem.

Let us represent this function of x by $F(x)$, and we shall have $z = \int P dy + F(x)$; and in the same manner, if we had $\frac{dz}{dx} = P$, we should have for a solution $\int P dx + F(y)$.

Suppose, for example, the integration of the equation

$$\frac{dz}{dy} = axy + y^3$$

were required. Here we should have

$$\frac{dz}{dy} dy = axy dy + y^3 dy = P dy,$$

and
$$\int P dy = \frac{axy^2}{2} + \frac{y^4}{4};$$

and as in this expression of P , we have only y variable, we have, as above,

$$z = \frac{axy^2}{2} + \frac{y^4}{4} + F(x).$$

For differencing this with y variable, we obtain again

$$\frac{dz}{dy} = (axy + y^3) dy = P dy$$

$F(x)$ having no differential, from the nature of the equation being considered as constant with regard to y , and as to the particular value of $F(x)$, this must be determined from the nature of the problem from which the equation has been obtained, in the same manner as is found the correction of an integral or fluent.

The next equation to the preceding in the order of difficulty is,

$$\frac{M dz}{dy} + \frac{N dz}{dx} = 0.$$

then again

$$\frac{M dz}{dy} + \frac{N dz}{dx} + Pz = 0;$$

and, finally, the most general of all,

$$\frac{M dz}{dy} + \frac{N dz}{dx} + Pz + Q = 0;$$

in which M, N, P , are any functions of x, y , and constant quantities, and consequently these will be more or less complex, according to the degree of composition of M , &c. But the limits of this article will not allow of our entering more at length upon the integrations of equations of the first order; we can, therefore, only refer the reader for farther information to the "Traité du Calcul Integral" of Cousin and Boffut, and to the "Traité du Calcul Différentiel et du Calcul Integral" by La Croix, and the other works above referred to.

It will be proper, however, before we dismiss this article, to say a few words with regard to partial differential equations of the second degree; all that has been said above being with reference to the first degree only.

We have before observed, that every equation between a function z , of two variables x and y , and its partial differences

$$\frac{dz}{dx}, \frac{dz}{dy}, \frac{d^2z}{dx^2}, \frac{d^2z}{dy^2}, \frac{d^2z}{dx dy},$$

is an equation of partial differences of the second order, and from which an idea may be formed of those of a higher degree, as the third, fourth, or even of the indefinite order n ; as also of those comprehending a greater number of variables, as $x, y, u; x, y, u, t$, &c. We shall here, however, as in the preceding case, limit our remarks to those only of two variables, and of these we shall propose, first, the equation $xy - \frac{dz}{dx} = 0$, this being the simplest partial differential equation of the second degree.

Let it be then proposed to integrate the equation

$$xy - \frac{dz}{dx} = 0.$$

In order to this, make $\frac{dz}{dx} = u$, and we shall thus have

$$\frac{du}{dx} = \frac{dz}{dx^2},$$

considering dx as constant, and thus the proposed equation becomes $xy = \frac{du}{dx}$, or $yx dx = du$.

Integrating now only with regard to x , we shall have $u = \frac{x^2 y}{2} + F(y)$.

But now instead of u put its value $\frac{dz}{dx}$, and we obtain $\frac{dz}{dx} =$

$$\frac{x^2 y}{2} + F(y),$$

which, multiplying by dx , becomes $d^2z = \frac{yx^2 dx}{2} + dx F(y)$, and finally integrating with regard to x only, we have

$$z = \frac{yx^3}{6} + x F(y) + f(y);$$

and that this is the integral sought will appear by differencing again this expression, observing that $y, F(y)$, and $f(y)$, being each considered constant with regard to x , will have no difference; thus

$$dz = \frac{yx^2 dx}{2} + dx F(y),$$

$$\frac{dz}{dx} = \frac{yx^2}{2} + F(y)$$

And differencing again, and making dx constant, we have

$$\frac{d^2z}{dx^2} = \frac{2yx dx}{2} \text{ or } \frac{d^2z}{dx^2} = xy,$$

as first proposed.

Whence it appears, that in equations of the second degree, in order to render the integral complete, we must connect with it two different arbitrary functions of the variable, of which the differential enters not into the given equation, and the particular form of which must be found from the nature of the problem whence the equation is deduced.

If the equation were of the third order, as $xy = \frac{d^2z}{dx^2}$, the

steps of the operation would be nearly the same. Thus in

supposing at first $\frac{d^2z}{dx^2} = u$, we deduce $\frac{d^3z}{dx^3} = \frac{du}{dx}$; and sub-

stituting $\frac{du}{dx}$ in the place of $\frac{d^3z}{dx^3}$, we shall have $xy = \frac{du}{dx}$,

or

or $du = yx dx$; integrating again; $u = \frac{y x^2}{2} + F(y)$; that is $\frac{dz}{dx} = \frac{y x^2}{2} + F(y)$, by which the equation is reduced to the second degree; and in like manner it may now be transformed into one of the first, as

$$\frac{dz}{dx} = \frac{y x^3}{6} + x F(y) + f(y),$$

from which the final integral is obtained as above, *viz.*

$$z = \frac{y x^4}{24} + x^2 F(y) + x f(y) + \phi(y),$$

which may be verified the same as before by taking the successive differences.

If the proposed equation of the second order were

$$\frac{d^2 z}{dx dy} = xy; \text{ we must suppose } \frac{dz}{dy} = u, \text{ and then proceeding as above, we shall find } u \text{ or } \frac{dz}{dy} = \frac{y x^2}{2} + F(y), \text{ and consequently } dz = \frac{x^2 y dy}{2} + dy F(y), \text{ and integrating this again,}$$

$$z = \frac{y^2 x^2}{4} + \int dy F(y) + f(x);$$

or (because $\int dy F(y)$ is itself a function of y)

$$z = \frac{y^2 x^2}{4} + F'(y) + f(x).$$

Lastly, if z was a function, these variables x, y , and u , and the proposed equation for integration, was

$$z y u = \frac{dx dz}{dx dy du} = c,$$

we should find by similar substitutions,

$$z = \frac{x^3 y^2 u^2}{6} + F(y, u) + f(x, y) + \phi(x, u)$$

where the three arbitrary functions, necessary for completing the integral, are those formed from the different combinations of the three variables x, y , and u , taken two and two at a time.

And in a similar manner, the integral of a function consisting of any greater number of variables may be obtained, the number of arbitrary functions being equal to the exponent of the order of the equation.

The integral calculus of partial difference is sometimes considered under a different point of view, which is by finding a function of many variables, when we know the relation of the differential co-efficients of the total differential. The notation employed is also given by some authors, rather different from that given above, but our limits will not admit of entering, in this place, into any farther explanation; we shall, therefore, conclude this article with an enumeration of the principal memoirs and works on this interesting subject, not mentioned in the preceding part of this article, and to which the reader is referred for more complete information; *viz.* Lagrange Memoirs of Berlin, 1774, 1775; Leçons sur le Calcul des Fonctions by the same author; Legendre Memoirs de l'Académie de Paris 1787; La Place Memoirs de l'Académie 1773; and in various parts of his Méchanique Céleste. Condorcet Memoirs de l'Académie des Sciences for the years 1770, 1771, and 1772; Monge Memoirs presented to the Academy of Sciences, vols. vii. and ix. and in vol. iv. of the Memoirs of the Academy of Turin; Bossut,

Traité du Calcul Integral; Coufin, Traité Calcul Integral; La Croix Traité du Calcul Differentiel, et du Calcul Integral; Paoli Elementi d'Algebra, and the article *Integral Calcul des Differentiel Partielles*, Encyclopédie Methodique. We cannot but regret, that in this enumeration, we are under the necessity of confining our references to foreign works only; no English author, to the best of our knowledge, having any where attempted an investigation or illustration of this difficult branch of analysis.

PARTIAL Eclipse. See ECLIPSE.

PARTICIPATION, PARTICIPATIO, that which gives us a part or share in any thing, either by right or grace.

In Italy, they distinguish *participating* officers, as prothonotaries, &c. which have a real function; from *honorary* ones, which have only a title, without any duty or employ.

PARTICIPATION, in *Musick*, in the tuning of keyed instruments, implies equal harmony; that is, dividing the imperfections of the scale equally among all the sounds of the system. By this means the 5ths are better, and the sharp 3ds worse, than in common tuning, when there is a *wolf*. (See WOLF.) This manner of tuning seems necessary now, and to be generally received; as modulation is so licentious, that in a long movement it is impossible, by relative sounds, for the performer to guess where he shall be carried, as every key, and every chord on the instrument, are sure to be called into use before the final close in the original key. In making all the 5ths perfect, there is a redundancy of a half tone. Now, if that is divided into twelve parts among all the semitones, it should seem as if no one key would suffer much; yet an ear not accustomed to such harsh major 3ds, is at first much offended.

PARTICIPATIONIS MEDIUM. See MEDIUM.

PARTIPATO, Ital. see TEMPERAMENT. Participation is likewise a mixture of the diatonic and chromatic genera in the music of the ancients, according to Padre Martini. We may, indeed, say that all modulation in modern music is brought about by the mixture or participation of the diatonic and chromatic genera. The rising or falling by minor semitones is chromatic. So that in the key of C natural, an F which modulates into G is chromatic.

PARTICIPLE, PARTICIPIUM, in *Grammar*, an adjective formed of a verb; so called because it still participates of some of the properties of the verb; retaining the regimen and signification of it: whence most authors confound it with the verb.

Mr. Harris observes, that, as a complete verb is expressive of an attribute, of time, and of an assertion, if we take away the assertion, there will remain the attribute and the time, which make the essence of a participle. There are two kinds of participles, the one called *active*, because expressing the subject which makes the action of the verb; as *legens, audiens, reading, bearing*. The other called *passive*, because expressing the subject that receives the action of the verb; as *lectum, auditum, read, heard*.

As our adjectives are not declined, the participles, being real adjectives, are also not declined: in the Latin, &c. where the adjectives are declined, the participles active are declined likewise. Thus they say *audiens, audientis, audienti*, &c. and in the French the participles passive are declinable like their adjectives, as *j'ay lu, elle a lue, nous avons lus*, &c.

In our language, the participles and gerunds are not at all distinguishable.

The English grammar lays down a good rule with respect to its participle of the past, that they all terminate in *d, t, or n*; which analogy is liable to as few exceptions as any.

PARTICLE, PARTICULA, in *Physics*, the minute part of

of a body, or an assemblage or coalition of several of the atoms of which natural bodies are composed.

PARTICLE, in *Physics* and *Chemistry*. Those minute parts of matter, by which bodies are constituted, are called atoms or particles of simple bodies. The particles of simple bodies are unchangeable under all circumstances, so far as regards their weight and figure. The changes which bodies undergo by heat and chemical attraction, are to be ascribed only to a change of distance and arrangement of their unalterable atoms. Mathematicians may prove the infinite divisibility of matter, but nature has evidently given limits to this division. Without such limitation there would be no definite point for the commencement of compoundability, and the number and variety of compounds would be infinite. Nothing, however, is more clearly proved, than that the number and proportions of compounds are limited. This alone is sufficient to establish the following facts, that simple bodies are constituted by strictly similar atoms, which are unalterable in figure, size, and weight: that compound bodies are constituted by compound particles, which are equally unchangeable by heat or mechanical action, so long as they remain combined: and that their decomposition consists in the operation of their simple atoms. When chemists have ascertained the relative weights of the simple atoms, which is no difficult task, the proportions of all compounds will be known without the aid of experiment, and chemistry will stand on as firm a basis as mechanical science. Although we are indebted to Dalton for this beautiful system of chemical philosophy, the principles on which it is founded did not escape the penetrating eye of Newton. We find the following observations at the latter end of his 31st query.

“All these things being considered, it seems probable to me, that God in the beginning formed matter in solid, massy, hard, impenetrable, moveable particles, of such sizes and figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and these primitive particles being solids, are incomparably harder than any porous bodies compounded of them, even so very hard as never to wear or break in pieces: no ordinary power being able to divide what God himself made one in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break to pieces, the nature of things depending upon them would be changed. Water and earth, composed of old worn particles, and fragments of particles, would not be of the same nature and texture now with water and earth composed of entire particles in the beginning: and, therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations, and motions of these permanent particles, compound bodies being apt to break, not in the midst of solid particles, but where those particles are laid together, and only touch in a few points.” He farther supposes that these primitive particles may act upon each other by laws similar to gravity, which determines the motions of masses of matter. We may, perhaps, at some period find, that chemical affinity, or that power by which the particles of simple matter act upon each other, may be no more than the force of gravity, acting upon each other at such small distances, as to make their attractions equal to greater masses at greater distances. The primitive particles, even when their weights are the same, may attract other matter with very different forces, by being of different degrees of density. The attraction of one particle for another would be as their weights, and as the squares of their diameters inversely. For instance, the atom of copper appears to be nearly of the same weight with an atom of zinc,

but their attraction for oxygen are very different. If, then, chemical affinity be of the same force with gravity, we must suppose the atom of zinc to be denser than the atom of copper in the ratio of their affinity for oxygen. If the relative affinities of bodies can be known, and can be proved of the same force with gravity; the relative density, as well as the relative weight of the atoms of bodies, may be known. A view of the Daltonian theory, with more particulars on this interesting subject, will be given under the article **PROPORTIONS definite of chemical compounds**.

The cohesion of the particles of matter, the Epicureans imagined, was effected by means of hooked atoms; the Aristotelians by rest, that is, by nothing at all. But sir Isaac Newton shews it is done by means of a certain power by which the particles mutually attract, or tend towards each other.

By this attraction of the particles he shews that most of the phenomena of the lesser bodies are effected; as those of the heavenly bodies are by the attraction of gravity.

PARTICLES, for the laws of this attraction of the. See **ATTRACTION** and **COHESION**.

All bodies, the same great author shews, consist of the same solid, perfectly hard particles or corpuscles.

PARTICLE, in *Grammar*, denotes a little indeclinable word, consisting of one or two syllables at the most.

Those are properly particles which are neither declined nor conjugated.

Brightland calls particles, *manners of words*, because they rather serve to express the circumstances and manners of other ideas and objects of the mind, than to represent any distinct objects of their own.

Particles may be reduced under three heads: the first shew the manners or qualities of words, by being added to them; called *adverbs*.

The second denote some circumstances of actions, and join words to words, sentence to sentence, &c. See **CONJUNCTION**.

The third express the emotions of the soul. See **INTERJECTION**.

It is in the right use of particles, Mr. Locke observes, that more particularly consist the clearness and beauty of a good style. To express the dependence of his thoughts and reasonings one upon another, a man must have words to shew what connection, restriction, distinction, opposition, emphasis, &c. he gives to each respective part of his discourse. This cannot be rightly understood without a clear view of the postures, stands, turns, limitations, exceptions, and several other thoughts of the mind. Of these there is a great variety, much exceeding the number of particles that most languages have to express them by; for which reason it happens that most of these particles have divers, and sometimes almost opposite significations. Thus the particle *but*, in English, has several very different significations: as in, *but* to say no more, where it intimates a stop of mind in the course it was going, before it came to the end of it. I saw *but* two planets; here it shews, that the mind limits the sense to what is expressed with a negation of all other. You pray, *but* it is not that God would bring you to the true religion, *but* that he would confirm you in your own: the former of these intimates a supposition in the mind, of something otherwise than it should; the latter shews, that the mind makes a direct opposition between that and what goes before. All animals have sense, *but* a dog is an animal: here it signifies the connection of the latter proposition with the former.

PARTICLES is also a term in *Theology*, used in the Latin church for the crumbs or little pieces of consecrated bread, called *μικροδες* in the Greek church.

In the Greek church they have a particular ceremony, called *των μεριδων*, of the particles, wherein certain crumbs of bread, not consecrated, are offered up in honour of the Virgin, St. John Baptist, and several other saints. They also give the name *προσφορα*, oblation, to these particles.

Gabriel, archbishop of Philadelphia, has a little treatise express, *περι των μεριδων*, wherein he endeavours to shew the antiquity of this ceremony, in that it is mentioned in the liturgies of St. Chrysostom and Basil.

There has been a considerable dispute on this head, between the Reformed and the Catholic divines. Aubertin and Blondel explain a passage in the theory of Germanus, patriarch of Constantinople, where he mentions the ceremony of the particles as in use in his time; in favour of the former: Messieurs de Port Royal contest the explanation: but M. Simon, in his notes on Gabriel of Philadelphia, endeavours to shew, that the passage itself is an interpolation; not being found in the ancient copies of Germanus: and consequently that the dispute is very ill grounded.

PARTICLE out of Share, in *Astronomy*. See PARTICULA *Exfors*.

PARTICOTTY, in *Geography*, a town of Hindoostan, in the Carnatic; 7 miles N.E. of Tinevelly.

PARTICULA EXFORS, in *Astronomy*, the difference between the equatorial triangle L A C (*Plate XVIII. Astron. fig. 16.*) and its fellow B L Z.

To find the particula exfors, the mensural eccentricity A C, and the annual argument of the longitude H A D, being given; from the data in the triangle B C A, find the hypothenuse A B to the angle C, and to the angle C A B, find the subtense C B. Multiply C B into half the mensural eccentricity A C; the product is the area of the triangle A C B. Find likewise the area of a circle described by the radius of the eccentric B L. Then as the area of the circle is to 360° or 129600"; so is the area of the triangle A C B to its value in those seconds: which value is the particula exfors.

PARTICULAR, PARTICULARIS, a relative term referring to species, or individual; and opposed to general, or universal. See GENERAL, &c.

In the schools, particular is defined to be something included under an universal; as man under animal.

Though sometimes it is also taken for an individual, as Peter.

There is a difference between particular and singular, that particular denotes a thing taken as a part; as Peter in respect of mankind: whereas singular denotes the part taken after the manner of a whole; as Peter considered in himself.

PARTICULAR averment, character, geography, gravity, maps, nature, proposition, quality, rheumatism, tenant, theorem, and winds. See the several substantives.

PARTICULAR Estate, in *Law*. See REMAINDER.

PARTICULAR Integral, in the *Integral Calculus*, is that which arises in the integration of a given differential equation, by giving a particular value to the arbitrary quantity or quantities that enter into the general integral.

Thus, for example, in the equation

$$y = \frac{2x dy}{dx} - \frac{y dy^2}{dx^2},$$

the general integral is

$$y = 4m(x - m);$$

and by taking $m = 1$, we have

$$y = 4(x - 1),$$

which is a *particular integral*.

We call also a particular integral, that which is obtained by means of an equation of inferior dimensions; thus in the above, if we make $x = y$, we shall have

$$y = \frac{2y dy}{dy} - \frac{y dy^2}{dy^2} = 2y - y,$$

which obviously answers the conditions of the equation.

So likewise in the equation

$$x dx + y dy = dy \sqrt{x^2 + y^2 - a^2}$$

we see immediately, that $x^2 + y^2 = a^2$, will answer the conditions, and is therefore called by some authors a particular integral.

But neither this equation $x^2 + y^2 = a^2$, nor that obtained above, *viz.* $x = y$, is deducible from the general integration of their respective equations, and they therefore thus far differ from those integrals defined above, which arise out of the general integration, by giving to the arbitrary quantity some particular and definite value.

The term particular integral, then, though sufficiently expressive for either of these cases, ought not to be employed for both, and accordingly some authors distinguish the two cases as follows; they call a *complete integral* that which is drawn from the general integration; an *incomplete integral*, that which is found, as in the latter of the above equations, by means of an equation of inferior dimensions; and lastly, a *particular integral*, that which arises by giving to the indeterminate quantity in the general integral some particular determinate value. But Lagrange, in his *Leçons*, as also in his *Theorie des Fonctions Analytiques*, instead of incomplete integrals, used the term *valeurs singuliere*.

One of the most remarkable cases of these incomplete integrals was first noticed by Clairaut. He observed there are some differential equations of the first degree, of which the integration is attended with considerable difficulty by proceeding in the usual manner, which may sometimes be found by a second differentiation, instead of leading us farther from it, as in the usual cases. Such is the differential equation

$$y dx - x dy = a \sqrt{dx^2 + dy^2}$$

to which we are led in the solution of the following geometrical problem. A point being given to find a curve line such, that drawing to this line a tangent, and from the given point on the tangent a normal, it shall be always of the same length. We may arrive at the solution of this problem, by supposing $y = u \sqrt{a^2 - x^2}$, and separating the variables u and x , which ultimately produces the equation

$$\frac{du}{\sqrt{u^2 - 1}} = \frac{dx}{\sqrt{a^2 - x^2}}$$

But by differencing we are led to the solution in a much more simple manner; for if, in order to simplify the differentiation, we make $dx = p dy$, the above equation,

$$y dx - x dy = a \sqrt{dx^2 + dy^2},$$

$$y = px + a \sqrt{1 + p^2};$$

which, although in appearance an equation in finite terms, is

still a differential equation, because $p = \frac{dx}{dy}$. If now we

difference this equation again, we shall have

$$dy = p dx + x dp + \frac{ap dp}{\sqrt{1 + p^2}},$$

which, because $dy = p dx$, gives

$$0 = x dp + \frac{ap dp}{\sqrt{1 + p^2}}$$

and dividing by $d p$, we have

$$0 = x + \frac{a p}{\sqrt{(1+p^2)}}, \text{ or } x = -\frac{a p}{\sqrt{(1+p^2)}};$$

and, lastly, if in the above equation

$$y = p x + a \sqrt{(1+p^2)}$$

we put instead of $p x$ its proper value, as before determined,

$$\text{we find } y = \frac{a}{\sqrt{(1+p^2)}}.$$

Now, if by means of these two values of x and y , we eliminate p , we shall find ultimately

$$x^2 + y^2 = a^2,$$

which is the equation to the circle the curve required, as is obvious, on the slightest consideration of the nature of the problem. It is to be observed, however, that this question admits of another solution, which arises also out of the equa-

tion $x d p + \frac{a p d p}{\sqrt{(1+p^2)}} = 0$, by making $d p = 0$, whence

it follows that p is any constant quantity $= n$, that is $\frac{d x}{d y}$

a constant quantity, which shews it to be a right line; and because of the indeterminate n , an infinite number of right lines will equally answer the conditions of the equation; and this last is one of those cases of particular integrals, as above defined.

Euler has proposed many equations of this kind, which he was led to in the solution of certain geometrical problems, which he had proposed to himself; as also many others, which belong more directly to the cases of incomplete integrals, or singular values mentioned in the second case above; such are

$$x d x + y d y = a \sqrt{(x^2 + y^2 - a^2)},$$

in which the singular value is $x^2 + y^2 = a^2$, an equation to the circle: but in the complete integral, viz. $y + c = \sqrt{(x^2 + y^2 - a^2)}$, we can by no means arrive at the first equation.

This and some other cases mentioned by Euler were considered by that celebrated analyst as insolvable paradoxes; but Lagrange, in the Memoirs of Berlin for 1774, has explained this apparent anomaly nearly as follows.

The integral of a differential equation between two variables, contains one constant arbitrary quantity. If we regard these variables as the rectangular co-ordinates of a curve line, referred to some determined axis, it is obvious that we may imagine as many different curves to be described, all particular integrals of the proposed equation, as we can give different values to the constant arbitrary quantity, that is, we may have an infinite number. How if it happens that these curves have one constant quantity common to them all, the equation of this common tangent ought to satisfy the differential equation proposed; because some one element of this tangent is confounded with some of the elements of the curves: fill this tangent forms no part of the curves, and therefore ought not to be contained in the complete integral, but in an incomplete integral, as above defined; See Memoirs of Berlin for 1774; the Theorie des Fonctions Analytiques, and the Leçons des Fonctions, by Lagrange; the article *Integrals Particulieres*, Encyclopédie Methodique, and *Monucla Histoire des Mathematique*, tome iii. p.180.

PARTICULARIST, among *Polemical Divines*, a person who maintains particular grace, i. e. who teaches or be-

lieves, that Christ died for the elect only; and not for mankind in general. See GRACE.

PARTIDO, in *Geography*, a small island, under the hill of St. Martin, in the S.W. part of Campeachy gulf.—Also, a river of Mexico, which runs into the Pacific ocean, S. lat. 11° 20'.

PARTIE, Fr. *Part*, in English implies the melody or notes allotted to a single voice, or instrument, many of which parts constitute a chorus, symphony, or concerto. Three sounds, at least, are necessary to form a chord; but a complete chord built on the generator or fundamental base with its 3d, 5th, and 8th; and each of these sounds distributed into different parts, would furnish a first treble, second treble, tenor, and base. The high notes in most instruments played with a bow have no bounds, as the perfected audience can tell; but below there is a *ne plus ultra*. Violins can go no lower than G on the fourth space in the base, the tenor to C, unison with the second space in the base, and the violoncello to double C.

PARTIES, in *Law*, are those who are named in a deed, or fine, as parties to it; e. gr. those who levy the fine, and to whom the fine is levied.

So they who make any deed, and they to whom it is made, are both called parties to the deed.

PARTILE ASPECT, in *Astrology*. See ASPECT.

PARTING, in the art of refining metals, is a process by which gold is separated from silver. When those metals which are oxydable in the cupel have been separated from gold, the silver not undergoing that change remains alloyed with it. This is always the case in refining jewellers' gold. In order to separate the silver, the alloy is first rolled into very thin plates, the thinner the better; these plates are to be boiled with pure nitric acid. By this means, the silver is dissolved by the nitric acid, giving to the plates a corroded appearance, as if perforated with a small instrument. When the silver ceases to be dissolved, the plates are to be melted. If the gold is required of greater purity, it may be rolled in plates, and exposed to the acid a second time. If the nitric acid contains any muriatic acid, which is generally the case with the acid of commerce, some of the gold will always be dissolved. Should this be the case, the silver should first be precipitated in the form of muriat, with common salt, and the gold afterwards thrown down with green sulphat of iron.

The most effectual method of separating gold from silver is to dissolve the whole of the thin plates in nitro-muriatic acid. The silver will be found at the bottom of the vessel in the form of muriat, while the gold remains in solution, and may be precipitated with sulphat of iron. The silver may be obtained by heating the muriat with soda in a crucible. The muriat of soda sublimes, while the silver is left pure. See ASSAYING.

PARTING, *Dry*, or parting by fusion, is performed by sulphur, which has the property of uniting easily with silver, while it does not attack gold. The most advantageous method, says Dr. Lewis, of separating a small portion of gold from a large one of silver, appears to be by means of sulphur, which unites with and scorifies the silver without affecting the gold: but as sulphurated silver does not flow thin enough to suffer the small particles of gold diffused through it to re-unite and settle at the bottom, some addition is necessary for collecting and carrying them down.

In order to the commixture with the sulphur, fifty or sixty pounds of the mixed metal, or as much as a large crucible will receive, are melted at once, and reduced into grains by lading out the fluid matter, with a small crucible made red-hot, and pouring it into cold water stirred

with a rapid circular motion. From an eighth to a fifth of the granulated metal, according as it is richer or poorer in gold, is reserved; and the rest well mingled with an eighth of powdered sulphur. The grains enveloped with the sulphur are again put into the crucible, and the fire kept gentle for some time, that the silver, before it melts, may be thoroughly penetrated by the sulphur; if the fire was hastily urged, great part of the sulphur would be dissipated without acting upon the metal.

If to fulphurated silver in fusion pure silver be added, the latter falls to the bottom, and forms there a distinct fluid, not miscible with the other. The particles of gold, having no affinity with the sulphurated silver, join themselves to the pure silver, wherever they come in contact with it, and are thus transferred from the former into the latter, more or less perfectly according as the pure silver was more or less thoroughly diffused through the mixed. It is for this use that a part of the granulated metal was reserved. The sulphurated mass being brought into perfect fusion, and kept melted for near an hour in a close covered crucible, one-third of the reserved grains is thrown in; and as soon as this is melted, the whole is well stirred, that the fresh silver may be distributed through the mixed, to collect the gold from it. The stirring is performed with a wooden rod; an iron one would be corroded by the sulphur, so as to deprive the mixed of its due quantity of sulphur, and likewise render the subsequent purification of the silver more troublesome. The fusion being continued an hour longer, another third of the unfulphurated grains is added, and an hour after this the remainder; after which the fusion is farther continued for some time, the matter being stirred at least every half hour from the beginning to the end, and the crucible kept closely covered in the intervals.

The sulphurated silver appears in fusion of a dark brown colour: after it has been kept melted for a certain time, a part of the sulphur having escaped from the top, the surface becomes white, and some bright drops of silver, about the size of peas, are perceived on it. When this happens, which is commonly in about three hours after the last addition of the reserved grains, sooner or later, according as the crucible has been more or less closely covered, and the matter more or less stirred, the fire must be immediately discontinued; for otherwise more and more of the silver, thus losing its sulphur, would subside and mingle with the part at the bottom in which the gold is collected. The whole is poured out into an iron mortar greased and duly heated; or if the quantity is too large to be safely lifted at once, a part is first laded out from the top with a small crucible, and the rest poured into the mortar. The gold, diffused at first through the whole mass, is now found collected into a part of it at the bottom, amounting only to about as much as was reserved unfulphurated. This part may be separated from the sulphurated silver above it by a chisel and hammer; or more perfectly, the surface of the lower mass being generally rugged and unequal, by placing the whole mass with its bottom upwards in a crucible: the sulphurated part quickly melts, leaving unmelted that which contains the gold, which may thus be completely separated from the other. The sulphurated silver is assayed, by keeping a portion of it in fusion in an open crucible, till the sulphur is dissipated; and then dissolving it in aqua fortis. If it should still be found to contain any gold, it is to be melted again; as much more unfulphurated silver is to be added as was employed in each of the former injections, and the fusion continued about an hour and a half.

The gold thus collected into a part of the silver may be

farther concentrated into a smaller part, by granulating the mass and separating the whole process. The operation may be again and again repeated, till so much of the silver is separated, that the remainder may be parted by aqua fortis without too much expence.

The foregoing process, according to Mr. Schlutter, is practised at Rammelsberg, in the Lower Hartz. The prevailing metal in the ore of Rammelsberg is lead: the quantity of lead is at most forty pounds in a quintal or hundred pounds of the ore. The lead worked off on a test or concave hearth yields about a hundred and ten grains of silver, and the silver contains only a three hundred and eighty-fourth part of gold; yet this little quantity of gold, amounting scarcely to a third of a grain in a hundred weight of the ore, is thus collected with profit. The author above mentioned confines this method of separation to such silver as is poor in gold, and reckons parting with aqua fortis more advantageous where the gold amounts to above a sixty-fourth of the silver: he advises also not to attempt concentrating the gold too far, as a portion of it will always be taken up again by the silver. Mr. Scheffer, however, relates (in the Swedish Memoirs for the year 1752), that he has by this method brought the gold to perfect fineness; and that he has likewise collected all the gold which the silver contained; the silver of the last operations, which had taken up a portion of the gold, being reserved to be worked over again with a fresh quantity of gold-holding silver. The sulphurated silver is purified by continuing it in fusion for some time with a large surface exposed to the air; the sulphur gradually exhales, and leaves the silver entire. Lewis's Comp. Phil. Techn. p. 161, &c. See GOLD and REFINING.

PARTING-Glasses are used in the operation of parting: they have the form of truncated cones, the bottom being commonly about seven inches wide, the aperture about one or two inches wide, and the height about twelve inches. These glass vessels ought to have been well annealed, and chosen free from flaws; as one of the chief inconveniences attending the operation is, that the glasses are apt to crack by exposure to cold, and even when touched by the hand. Some operators secure their glasses by a coating. For this purpose they spread a mixture of quick lime slaked with beer and whites of eggs upon linen cloth, which they wrap round the lower part of the vessel, leaving the upper part uncovered, that they may see the progress of the operation; and over this cloth they apply a composition of clay and hair. Schlutter advises to put the parting-glasses in copper vessels containing some water, and supported by trevets, with fire under them. When the heat communicated by the water is too great, it may be diminished by adding cold water, which must be done very carefully by pouring against the sides of the pan, to prevent too sudden an application of cold to the parting-glass. The intention of this contrivance is, that the contents of the glasses, if these should break, may be received by the copper vessel. Into a glass fifteen inches high, and ten or twelve inches wide at bottom, placed in a copper pan twelve inches wide at bottom, fifteen inches wide at top, and ten inches high, he usually put about eighty ounces of metal, with twice as much aqua fortis.

PARTING Roots, in Gardening, the practice of dividing the roots of some sorts of plants in order to their being set out; which is an expeditious mode of increasing a great number of fibrous-rooted perennial plants. A great number of herbaceous, fibrous, and tuberous-rooted perennial plants often increase by the root into large clusters or bunches, composed of numerous small slips or offsets, particularly

ticularly many of the flowery tribe, such as the campanula, perennial sun-flower, golden-rod, perennial aster, polyanthus, and daisy, balm, mint, burnet, cives, and pennyroyal, with innumerable other sorts; which from one small slip or offset of the root, often in a season or two multiply into a large cluster of such offsets; and these clusters of roots being parted into several separate slips, with root-fibres at their bottom, and one or more buds at top, each commences a distinct plant; so that, by parting the roots in this way, one plant may instantly be multiplied into many, each of which becomes alike in growth and general habit to the original, and all flower in the ensuing season in their due course; and in their turns detach from their sides all around, a due supply of offsets for further propagation.

Commonly the best general season for parting roots is in the latter end of summer or autumn, after they have done flowering, and the stalks are decayed; which is in August, and the two following months; in which, when the detached offsets are planted directly, they will take good root before winter. But in many hardy sorts it may be performed almost any time, in open weather, from September till March; and some of the tender kinds succeed best in spring. In these cases it should, however, be done before they begin to shoot forth their stalks or advance considerably in their spring shoots.

In performing the business, when any plant designed to be increased has multiplied by its roots into a cluster of offsets, the whole may be either taken up entirely, and the root parted into as many slips as are furnished with fibres, &c., or a quantity of slips may be detached from the sides all around as the parent plant stands in the ground: in either method, the work may in many sorts be effected easily with the hand; and in others by the assistance of a knife, &c. And when it is wanted to make as great an increase as possible, the root may be parted into as many slips as may be convenient, provided each is furnished with some fibre or root-part, and crowned with one or more buds or eyes for forming shoots at top. But in the flowery tribe, when the detached offsets are wanted for flowering as strong as possible the ensuing season, they should not be parted too small, but into middling-sized slips, where practicable; which being planted in the proper places will flower in tolerable perfection in the following season. The slips should generally be planted directly by dibble; the very small ones in nursery-beds to stand till next autumn, to acquire strength: then transplanted with balls into the places where they are to remain; but the larger ones at once where they are to grow.

This method may be practised in many sorts annually, as numbers of the herbaceous perennials multiply in one season into large bunches.

PARTING, in *Sea Language*, denotes the state of being driven from the anchors, when the ship has broke her cable by the violence of the wind, waves, or current, or all of them together.

PARTISAN, in the *Military Art*, the commander of a partisan-party.

PARTISAN-Party, a small body of infantry, light horse, and hussars, given to a partisan, to make an incursion upon the enemy, to lurk about their camp, to disturb their foragers, to interrupt their convoys, and to procure intelligence.

PARTISAN has been also applied to a halberd or pike, and to a marshal's staff.

PARTITI, Ital. in *Music*, the score of a composition separated or drawn out in single parts.

PARTITION, the act of parting, dividing, or distributing, a thing.

The denomination *partitiones oratorie* is also given to a dialogue of Cicero's, between him and his son; in regard the discourse is, as it were, parted or divided between them.

PARTITION, in *Architecture*, that which divides or separates one room or apartment from another.

PARTITION, in *Heraldry*. See **QUARTERING**.

PARTITION, in *Husbandry*. The partitions in land sown with wheat by the drill, for the horse-hoeing husbandry, are different according as the wheat is sown, in double, treble, or quadruple rows. The double row has but one partition, and this is best to be used in cases where the land is suspected to be full of the seed of weeds, which must be taken out with the hand-hoe. This partition should be twelve or fourteen inches wide. Whole fields drilled in these rows might formerly have been hand-hoed at the expence of four shillings an acre; and when there is but one foot in six, the price of that work ought to be proportionable.

The common width of the two partitions, when the wheat is sown in treble rows, is six or eight inches. Care is to be taken in this particular; for if they are planted closer, they will starve one another before the intervals are hoed to give them a fresh supply of nourishment; and, if they are planted too far asunder, the two outer rows will thrive well, but the middle row will be starved, and look worse and weaker, because of its being at so great a distance from the hoed intervals.

In quadruple rows, the partitions are best to be seven inches wide each: at this distance the plants will thrive sufficiently, and if they are set nearer, the whole will be worse; and, if farther off the two outer rows will thrive, but the two inner ones will be starved, by reason of their distance from the ploughed intervals. See **ALLEY**, and **HUSBANDRY**.

PARTITION, in *Law*, a dividing of lands descended by common law, or custom, among coheirs, where there are two at least.

The partition is made several ways; whereof four are by agreement, and one by compulsion.

The first partition by agreement is, when the parceners divide the land equally themselves into so many parts as there are coheirs: and each has a determinate part.

The second is, when they agree to choose some of their friends to make the division for them: and each takes a part according to seniority of age, or otherwise, as shall be agreed. In this case seniority is personal; so that if the eldest sister be dead, the next sister, and not the issue of the first, chooses. However, with respect to an advowson it is otherwise: the eldest and her issue, and even her husband, or her assigns, shall present alone, before the younger.

The third method of partition is, when the eldest divides, but chooses last.

The fourth is by drawing lots, thus: having first divided the land into as many parts as there are persons, they write every part severally in a distinct scroll, and, wrapping it up, throw each into a hat, or such a thing; out of which each one draws according to superiority; and so the land is severally allotted.

The other partition, which is by compulsion, is, when one or more of the heirs, by reason of the refusal of some other, sues out a writ of *partitione facienda*, upon which the sheriff shall go to the lands, and make partition thereof by a verdict of the jury there impanelled; and assign to each of the parceners her part in severalty. In Kent, where land is of gavel-kind nature, they call their partition, shifting.

Partition

Partition also may be made by joint-tenants, and tenants in common, by assent, by deed, or by writ. By the 8 & 9 W. c. 31. it is enacted, that if the high sheriff cannot conveniently be present at the execution of any judgment in partition, in such case the under sheriff, in presence of two justices, may proceed to execution of the writ of partition.

PARTITION, in *Music*, is the disposition of the several parts of a song, set on the same leaf; so as upon the uppermost ranges of lines are found the treble; in another the bass; in another the tenor, &c. that they may be all sung or played either jointly or separately.

PARTITION, *Partitio*, in *Rhetoric*, otherwise called enumeration, is that part in which the orator acquaints his hearers with the several parts of his discourse upon which he designs to treat. Some also comprehend under this head separation, in which the orator shews in what he agrees with his adversary, and wherein he differs from him. The requisites of a good partition are the following: it must be short, so that each proposition contains in it nothing more than what is necessary; it ought to be complete, no necessary part being omitted in the enumeration; and it should consist of as few members as is consistent with the nature of the subject. The ancient rhetoricians prescribe three or four at the most; and Cicero never exceeds that number. It may be afterwards convenient to divide these general heads of a discourse, or at least some of them, into several parts or members: and this is best done as the speaker comes to each of them, in the order at first laid down. Instances of this kind occur in Cicero's oration for the Manilian law.

A good partition is attended with considerable advantages; it gives light and ornament to a discourse, and affords great relief and assistance to the hearers. However, some orations, particularly of the demonstrative kind, do not require any particular proposition, being little more than a continued narrative or illustration of the subject. Ward's Orat. vol. i. p. 210, &c.

PARTITIONE FACIENDA, in *Law*, a writ which lies for those who hold lands or tenements *pro indiviso*, and would sever to every one his part, against them that refuse to join in partition, as copartners, &c. F. N. B. 61. 31 H. VIII. cap. 1. Cowel.

PARTITURA, Ital., *Partition*, Fr., in *Music*, implies a *score*, or the several parts of a composition arranged over each other, and separated into equal portions of time by *bars*, or perpendicular lines drawn through all the parts; whence the word *score*.

PARTIUM PRECE. See PRECE.

PARTNER, and PARTNERSHIP. See COMPANY, CO-PARCENER, and FELLOWSHIP.

PARTNERS, in a *Ship*, are strong pieces of timber nailed round the several scuttles, or holes, in a ship's deck, wherein are contained the masts and capsterns. They are used to strengthen the deck, where it is weakened by such breaches, but particularly to support it when the mast leans against it, as impressed by a weight of sail, or when the capstern bears forcibly upon it, whilst charged with a great effort.

Some ships do not sail well unless their masts are loose, and have leave to play in the partners; but in a storm, this is dangerous, lest the partners should be wronged (as they say), *i. e.* forced out of their places; for then there is no help but to cut the mast by the board.

PARTNERS is also a name given occasionally to the scuttles themselves, wherein the masts and capsterns are fixed.

PAR-TOUT. See PASS-PAR-TOUT.

PARTRIDGE, *PERDIX*, the tetrao perdix of Linnæus,

in *Ornithology*, a bird well known and esteemed at table. See TETRAO *Perdix*.

The partridge is a timorous and simple bird, and yet so valuable at the table, that there are a great many ways of taking it invented by sportsmen, all of which succeed from the folly and fear of the animal.

The places which partridges most delight in are corn-fields, especially while the corn grows; for that is a safe retreat, where they remain undisturbed, and under which they usually breed. They frequent the same fields after the corn is cut down, and that with another intent; for they then feed on the corn that has fallen from the ears, and find a sufficient shelter for them under cover of the stalks, especially those of wheat stubble. When the wheat stubble is much trodden by men or beasts, they retire to the barley stubble, and will there hide themselves in coverts of twenty or thirty. When the winter comes on, and the stubble fields are trodden down or ploughed up, they can retire to the upland meadows, where they lodge in the high grass, and among the rushes; sometimes they resort to the low coppice woods, especially if there be corn lands near them.

In the harvest-time, when the corn-fields are full of men, they are found in the fallow fields next to the corn-fields, where they lie lurking among the woods till evening, and then they get over into the corn, and feed late and early on the corn in the sheaves. When the proper haunts are known, the next thing is to find the birds in them: this is done variously; some will do it by the eye only; and this art can never be taught, but can be had only from long observation: the colour of the birds being so like that of the earth at a distance, that no eye but a very conversant one could distinguish them. When they are once seen, the business is to keep an eye upon them, and then to keep in continual motion. They are a very lazy bird, and by this means will let a person almost tread upon them; though, if the person stands still to eye them, they will rise immediately, though they are at a considerable distance.

Another method of observing them is by going to their haunts very early in the morning, or at the close of the evening, which is called jucking-time. The noise of the cock partridge is to be attended to at this time, and is very loud and earnest. The hen will soon come up to the cock after her making the noise, which she does by way of answer; and when they are got together, their chattering will discover them. Thus they may always be found at these times: but there is a yet better method of finding this bird, which is by the call. The business, in order to have success in this way, is carefully to learn the notes of the partridge, and be able to imitate all the several sounds. When perfect in this, the person is to go to the haunts morning and evening, and, placing himself in some situation where he can see the birds without being seen by them, he is to listen to their calling; and, when they are heard, he is to answer in the same notes, doubling again as they do: by continuing this, they may be brought so near, that the person, lying down on his back, may count their whole number. Having in this manner found where the birds are, the next care is to catch them.

They are so foolish, that it is extremely easy to take them in nets. In order to this, there needs no more than the going out, provided with two or three nets, with meshes somewhat smaller than those of the pheasant nets, and walking round about the covey, a net is to be fixed so as to draw over them, on pulling a line at a distance. All this may be easily done; for so long as the sportsman continues moving about, and does not fix his eyes too intently upon them, they will let him come near enough to fix the nets, without moving.

moving. If they lie so straggling, that one net will not cover them, then two or three must be fixed in the same manner. The sportsman may then draw the nets over them; and they will often lie still with the nets upon them till he comes up to fright them, then they will rise, and be entangled in the net.

A second method of taking them is with bird-line: this is done by means of wheat-straws. These must be large, and cut off between knot and knot; they must be well limed with the best and strongest bird-lime, and the sportsman must carry a great number of them out with him. Having found a field where there are partridges, he is to call; and, if they answer, he is then to tick up the limed straws in rows across two or three lands, and, going backward, call again to them, leading them on in the road where the straws are: they will follow one another like a flock of chickens, and come out to the call; and will in their way run upon the straws, and liming themselves, they will daub one another by crowding together, so that very few of them will be able to escape.

But there is yet a pleasanter way of taking them than this, that is, by driving of them: in order to this, an engine is to be made of canvas stuffed with straw, to represent a horse: this horse and nets are to be taken to the haunts of the partridges, and the nets being placed slanting or slope-wise in the lower part of the field, the sportsman is to take the wind in his back, and get above them, driving them downwards; his face is to be covered with something green or blue; and, placing the horse before him, he is to go towards them slowly and gently; and by this means they will be raised on their legs, but not on their wings, and will run before the horse into the nets. If in the way they go into a wrong path, the horse is to be moved to face them; and they will be thus turned back again, and driven every way the sportsman pleases. See GAME.

Partridges are often found very troublesome and destructive to the grain produce of the farmer. These sorts of birds principally delight to lie and bask in the corn-fields, especially while the grain is upon the land in its growing state, as it then affords them a safe and pleasant retreat, where they can remain without being in any way disturbed, and in which they can the most conveniently breed and rear their young. In this way they, however, frequently commit much injury upon the different crops, by feeding and trampling upon them, and therefore require to be destroyed. When the corn is cut, they also frequently continue in the stubble of the same fields, feeding upon the grain which has fallen out of the ears, and find in these a sufficient cover for concealing them, especially in those of the wheat kind. Afterwards, when these become thin, and much trodden down, they betake themselves to the barley and oat stubbles, or the clovers, where they collect together in large coveys, and conceal themselves. In the winter part of the year they are not so often met with in these places, but retire to the low woods and uplands, or pastures, where they lie in the bushes, and among the high coarse plants. The low copices very frequently supply a covering for them at this season, particularly where there are corn lands at no great distance, where they can get food that is suitable for them. They likewise consume the grain at the time of putting it into the earth, in which way they are also mischievous to the farmer.

PARTRIDGE, *Indian*, *Coturnix Indica*, the name given by the Spaniards to a bird of the West Indies, of which there are three or four species; all of which Nieeremberg says, are properly of the partridge kind. See TETRAO (*Coturnices*). See also COLIN, and QUAHITZONECOLIN.

PARTRIDGE, *Red-legged*, a very delicate and valuable bird, called *coturno* by the Italians.

It is distinguished from the common partridge by the redness of its beak and legs; it is of a greyish-ash colour on the back; its throat is white near the head, but has a small black spot on each side at the angle of the bill, and this white space is surrounded by a black line; its breast is of a yellowish-brown, and its wings are variegated with black, yellowish, and white. It is not found in England, but is sometimes shot in the islands of Guernsey and Jersey. See TETRAO *Rufus*.

PARTRIDGE, *White*, *Perdix Alba*, a name given by many to the lagopus, a rough-footed bird of the gallinaceous kind, common on the snowy mountains, and by some called the *rabolane*. See PTARMIGAN. See also TETRAO *Lagopus* and *Albus*.

PARTRIDGE, *Sea*, *Perdix Marina*, in *Ichthyology*, a name given by some authors to the foal-fish, from the firmness and delicacy of its flesh.

PARTRIDGE *Bay*, in *Geography*, a bay on the south coast of Labrador. N. lat. 50° 16'. W. long. 63° 20'.

PARTRIDGE *Island*, an island of the South Pacific ocean, in the vicinity of Van Diemen's land, and discovered in the voyage for search of La Perouse, May 1792, and so called by some of the crew who first observed it, from an apprehension that it abounded with partridges, which were probably mistaken for quails. This small island is upwards of 100 toises in length, and situated in S. lat. 43° 23' 30". On the shore was found the low species of parsley, called "apium prostratum," in great abundance. Many species of the "cauarina" grow here, and, among the plants, seen for the first time, was a remarkable species of the "limodorum." Numerous kinds of ferns were also collected, and a beautiful species of the "glycine," remarkable for its scarlet flower. No fresh water was found upon this island; though several forsaken huts shewed that it had been frequented by the savages. Labillardiere's Voyage in Search of La Perouse, vol. 1.

PARTRIDFIELD, a township of America, in Berkshire county, Massachusetts; 26 miles W.N.W. of Northampton; containing 1361 inhabitants.

PARTUNDA, in *Mythology*, a goddess among the Romans, who presided over women at their delivery.

PARTURITION, in *Midwifery*, the act of bringing a child into the world, from *parturio*, to be in labour. See LABOUR.

PARTUS, LABOUR, the birth of a child, from *pario*, to bring forth. It is also used to denote the fruit, or thing produced. "Feræ diligunt partus suos." Cicero. Beasts love their offspring. See LABOUR.

PARTUS *Cæsareus*, the delivery of a child through an opening made through the integuments of the abdomen, and into the uterus. See CÆSAREAN *Section*.

PARTY or PARTIE, a faction, interest, or power, considered as opposite to another.

England was, for upwards of a century, divided into two parties. See WHIG and TORY.

PARTY, in *Law*. See PARTIES and CHARTER-PARTY.

PARTY, in the *Military Sense*, is used for a small body of men, whether cavalry, infantry, or both, commanded on any expedition, such as pillaging the country of an enemy, taking prisoners, and obliging the country to make contribution.

Parties are also sent out to view the roads and ways, get intelligence, seek forage, reconnoitre, or amuse the enemy upon a march; they are also frequently sent upon the flanks of an army, or regiment, to discover the enemy, it

near,

near, and prevent surprize or ambushade. The following allowances are granted to parties escorting deserters, in consideration of the unavoidable extraordinary wear of their clothing and necessaries on that duty; *viz.*

Distances from Quarters.		For each Man.			
Between	and	miles	£.	s.	d.
8	20	—	0	1	0
20	50	—	0	2	0
50	100	—	0	4	0
100	150	—	0	5	0
150	200	—	0	6	0
above	200	—	0	7	6

In the like proportion allowances are to be made for parties of four, five, and six men, but no higher. This, however, is to be understood as a regulation of allowance merely; it not being the intention of government thereby to restrain any commanding officer from employing larger parties on the escort duty, if he should think proper, but that whatever may be the actual number of the parties, the allowances are to be in the proportion of

Three men for an escort of	from	5 to 8 deserters.
Four	—	9 — 12
Five	—	13 — 16
Six	—	17 — 20

Exact returns of the said duty, as performed by each corps, are to be made up, according to a prescribed form, as soon as possible after every 24th of June and 24th of December, for the half years immediately preceding, and are to be transmitted to the office of the secretary at war, in order that the allowance may be settled. James Mil. Dict.

PARTY, Firing, denotes those who are selected to fire over the grave of any one interred with military honours, if below the rank of brigadier-general. The specific number of which the party is to consist, depends upon the rank of the officer interred.

PARTIES, Working, consist of small detachments of men under the immediate command and superintendance of officers who are employed on fatigues, which are not purely of a military nature. They are generally called fatigue duties, being different from those of parade, or of exercise in the field. They principally consist in digging canals, repairing roads, working on fortifications, except such as may be constructed in one field, or upon actual service. An addition is made to their pay, as a reward for their labour, and a compensation for their extraordinary wear of necessaries; half of which should always be paid into the hands of the captains and commanding officers of companies, for this latter purpose. James.

PARTY Arches, in *Building*, are arches built between separate tenures, where the property is intermixed, and apartments over each other do not belong to the same estate.

PARTY Bleu, in the *Military Art*, a name formerly given to a party of robbers, who infested the roads in the Netherlands. They belonged to neither army, but robbed both sides, without any regard to parties. Hence the term has been more generally applied to a band of military robbers.

PARTY China, a name given by the English merchants, and others, to a sort of porcelain or china-ware, which is elegantly painted on the outside with some bright colour, and blotted or variegated with round or square spots of a different tinge. The manner in which the Chinese do this is a very simple and easy one, and may be imitated in our potteries with great ease.

They prepare as many pieces of paper as they intend to have spots on the vessel, and cut them exactly into the shape of those spots: they wet these, and then spread them

smoothly on the places where the spots are to be. When this is done, they cover the vessel with the brown and gold, or any other varnish, and then take off the papers; in the places which they covered no varnish has come; so that they are so many regular white spaces. These they cover with some other colour, laying it on carefully with a pencil: when this is done, they varnish over the whole vessel with the common varnish, and bake it. In some vessels they lay on only plain blue, or plain black, in the spaces destined for spots; and after the first baking, they cover these with gold, and make them so many figures of squares, triangles, or globes, pure gold.

PARTY Walls, in *Building*, are partitions of brick made between buildings in separate occupations, for preventing the spread of fire. For the regulations prescribed by an act of 14 Geo. III. see **BUILDING**, substituting for 42d 14th.

PARTY Jury, in *Law*. See **MEDIETAS Lingua**, and **JURY**.

PARTY, in *Heraldry*. See **PARTI**, **PALE**, and **FESSE**.

PARU, in *Geography*, a fort of Brasil, in the jurisdiction of Paru, on the N. side of the river Amazon. N. lat. 1° 50'. W. long. 54° 10'.

PARU, or *Ginipape*, a river of Brasil, which runs into the Amazon, near Paru.

PARU, in *Ichthyology*, the name of a very singular American fish. See **STROMATEUS Paru**, and **CHÆTODON Paru**.

PARUA, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 13° 20'.

PARVATI, in *Mythology*, is the consort of the Hindoo deity Siva, the personification of the destructive, or rather renovating or changing power in their triad. (See **SIVA**.) The consorts of the Hindoo male divinities are termed their Sakti, which means their energy, or active power. (See **SAKTI**.) The females are thus coequal to their spouses, and are endowed with the same attributes, and differ, in sex excepted, very little from them. (See **MATRI**.) A history of the goddesses Parvati, under her various forms and names, might be extended to volumes, and many volumes, we may say scores of volumes, have, in fact, been written thereon. The sacred romances called Puranas, abound in legends relating to the origin and proceedings, the amours, quarrels, incarnations, battles, &c. adventures of this all-producing, all-pervading personification of nature. She is said, like her lord, to have a thousand names; they are strung metrically together, and are recited by her votaries in their propitiatory adorations. Parvati means *mountain-born*, she having, in one of her many terrestrial descents, sprung from such a parentage, as is noticed under the article **MERA**. In her name and character of Parvati, many magnificent temples are erected to her honour in different parts of India, especially on mountains and elevated situations. All mountains, as bearing a conical form, a form naturally assumed by fire, are typical of this goddess or her lord; he being a personification of that *destructive*, and in its form of heat, *renovating*, element. Throughout India, from Nepal to Ceylon, and from Siam to Surat, temples are raised to this extensively worshipped couple, and their sectaries, under various names, still offer adoration in them. At Poona the principal temple is on a high hill called Parvati, or Parbutty, which gives a name to the quarter of the city in its neighbourhood. Durga is another of her names, and this name, meaning *difficult of access*, is appropriately given to hill forts, provincially corrupted into **Droog** or **Durgam**. Chitteldroog, for instance, is corrupted from Sita, and Durga, names of this goddess, which, in composition, and with a grammatical copulative, mean the hill, or inaccessible place of Sita. See **CHITTEL-DROOG**;

PARVATI.

DROOG; and, in the same page of this work, CHITTAGONG, which latter is altered from Sita-gao, or gom, the town of Sita. Much of the geographical nomenclature of India is thus derivable from its mythological personages. Another instance of the extensive scope of Hindoo mythology will be found under the article LANKA, where a splendid temple is noticed as dedicated to this goddess in her character of Kaumari or the Virgin; corresponding, in this instance, as she does likewise in many others, with the Tauric Diana. She may be identified similarly with most of the female deities of Greece and Rome, not in name merely, but in attributes and character. Most of those female deities are found, on minute inspection, to melt into one, as do those of India into Parvati; who is a personification of the moon, as her consort Siva is of the sun; coequal emblems merely of "that infinitely greater light, whence all proceeded, whither all must return, and which alone can illumine our intellects." This is the substance of the most sacred text of the Hindoo scripture. (See O'M.) Under her names of *Idita* and *Ilita* in this work, she appears in the character of *Lucina*, one of whose names was *Ilythya*. See those articles.

The attributes of Durga are conspicuous in the festival called by her name Durgotsava; and, in this character, we are told by sir W. Jones the resemblances Minerva—"not the peaceful inventress of the useful and fine arts, but Pallas, armed with a helmet and spear; both represent heroic virtue, or valour united with wisdom. Both slew demons and giants with their own hands; and both protected the wife and virtuous, who paid them due adoration." Af. Ref. vol. i.

As the mountain-born goddess, or Parvati, she has many properties of the Olympian Juno; her majestic deportment; high spirit, and general attributes are the same; and we find her on mount Kailasa. (See KAILASA.) And at the banquets of the deities uniformly the companion of her husband." Ib. In her character of Bhavani, sir W. Jones supposes the wife of Mahadeva, or Siva, to be as well the Juno Cinxia, or Lucina of the Romans (called also by them Diana Solvizona, and by the Greeks Ilythya) as Venus herself; not the Italian queen of laughter and jollity, who, with her nymphs and graces, was the beautiful child of poetical imagination, and answers to the Indian Rhemba (see RHEMBA), with her train of Apsaras, or damsels of Paradise; but Venus Urania, so luxuriantly painted by Lucretius, and so properly invoked by him at the opening of a poem on nature. "Venus presiding over generation, and on that account exhibited sometimes of both sexes, (an union very common in the Indian sculptures,) as in her bearded statue at Rome; and perhaps, in the images called Herma-thena, and in those figures of her which had a conical form; for the reason of which we are left (says Tacitus) in the dark. The reason," continues our author, "appears too clearly in the temples and paintings of Hindoostan, where it never seems to have entered the heads of the legislators or people, that any thing natural could be offensively obscene; a singularity which pervades all their writings and conversation, but is no proof of depravity in their morals." Ib.

This highly gifted author, in his dissertation on the Gods of Greece, Italy, and India, identifies the Stygian, or the Tauric Diana, otherwise named Hecate, and often confounded with Proserpine, with Kali, a name and form of Parvati, in her character of wife of Kal, who corresponds with the Stygian Jove. Human victims, as well as the sacrifice of horses and bulls, enjoined by the Veda, being in the present age absolutely prohibited, kids are now offered to Kali, or the black goddess; and to palliate the cruelty

of the slaughter, which gave great offence to the Hindoo followers of milder tenets and practice, the Brahmans inculcate a belief, that the poor victims rise in the heaven of Indra (see INDRA), and become the musicians of his band. Under the article KALI of this work, a minute description is given of Hindoo images of this black goddess. A cap, called by both Romans and Hindoos *patera* (see PATRA), a whip, or cord (see PASH), a sceptre, a child, a car drawn by peacocks, and by lions, a turreted crown, a drum (called *dyndima* both in Greek and Sanscrit), a sphere, a torch, a lily or lotos, a serpent, a spear, a bow, with other common attributes, might be noticed as identifying the multiform, myrionimous goddesses in question. A consideration of what is given in this work under the articles ASTARTE, CYBELE, DIANA, JUNO, PROSERPINE, VENUS, and other names of the same goddess, compared with that under this, and the various articles hence referred to, is more than sufficient to convince us of their identity.

That the names just noted, as well as Urania, Isis, and many others, are in fact of the same goddess Nature, under different forms, there can be no doubt. The Pantamorphia Mater; Dea Jana, or Diva Jana, was easily made by the Romans into Diana. Devi-jenni, the teeming goddess; Vifwa-jenni, the all-producing, are Sanscrit terms, applicable to Parvati in her character of Prakriti or Nature. Juno may be derived from Yoni; Ceres from Sri, or in one case Sris; Anna Perenna, from Ana-purna, a name of Parvati, meaning, in Sanscrit, abundance of food, or one who fills with food. In this character she holds a ladle. Astarte, as well as Esther, Astartoth, and the Persian Sitara, meaning a star, or something sidereal, may be traced to Astarta, another name of the Hindoo goddess, derived from a legend in which she was seated among eight points, and hence applied to the radii of a star. The learned antiquary Spon (Misc. Erud. Ant.) gives a print of a monument where Diana is called Clatra; her attributes are those of Parvati, one of whose names is Kalratri, the goddess of darkness, the origin possibly of its unmeaning synonyme. Under the articles LINGA and SIVA, is shewn that the first in the shape of a cone, mostly a black conical stone, is the phallic emblem of the latter, and of course of his consort Parvati. Western mythologists tell us of a black conical stone that fell from heaven; it was placed in a temple of Astarte, or the moon, and itself adored as a type of the sun. See ASTARTE.

The Paphian goddess was also anciently symbolized by a cone. When Dr. Clarke, in his recently published "Travels," describes some antiquities of the holy land, we might almost imagine that he was in the country of the Hindoos. He describes "a subterraneous conical temple, having no resemblance to any Christian temple, its situation under the pinnacle of a mountain, one probably of the three points of the Mount of Olives, (see MERU,) the highest of which was set apart for the worship of Astartoth," &c. (vol. ii. p. 578.) denoting strongly the Hindoo superstition having been anciently prevalent there. The pyramids of Egypt, Stonehenge in England, and many other antiquities now remote from its scenes, are referred, and with plausible arguments, to the same polytheistic source.

It is curious to see in Dr. Clarke's plate delineating "the sacred pictures in use among the Calmuck tribes," exact representations of Hindoo deities. In the figure that he properly styles "Diva Triformis, Luna, Diana, and Hecate," we recognize, unequivocally, the Hindoo Parvati, in one of those many forms in which she is generally termed Devi, or the goddess. Devi Tri Sakti, or with three forms, or powers, is one of her names. In Dr. Clarke's plate, she has

PARVATI.

has her own mystical hieroglyphic, a type of the Yoni, on the forehead; collars, of skulls perhaps, round and pendent on her neck and belly; a glory, or nimbus round her head; six-handed, holding a bow and arrow, the trisula or trident of Siva (see TRISULA), a cone or linga, the chakra, or discus of Vishnu, his club, and lotos (see VISHNU), and the cord, or pasha of Devi, before referred to; and the Kalmuck divinity fits in one of Devi's commonest positions on a lotos throne. Such a subject we should have expected to find in the Hindoo Pantheon, rather than in Russian travels. A representation is likewise given of "Osiris or Bacchus of the Calmucks." This is also a Hindoo subject, but being only two-handed there is not much scope for attributes; it has the distinguishing forehead-mark, attitude, countenance, and character of the Hindoo school. The next, "Hyperion or Phœbus of the Calmucks," is a barbarous representation of Krithna, with the serpent Kaliya, and other Hindoo attributes. (See KALIYA.) The "Terpsichore of the Calmucks playing on the Balalaikas," is Sarafwati with her Vina. Dr. Clarke does not say where he obtained these subjects, nor in what degree they are honoured; but we see no reason to doubt their genuineness. They have found their way into Asiatic Tartary, through China probably; and would lead us to infer that the Kalmucks have, or have had, some Hindoo superstitions among them. Their name is easily traceable to the same source. Kal-mu-ki is pure Sanscrit, and means black-faced, or with the countenance of Kal; a name that is applicable to Parvati in some of her characters; although we do not recollect any specific authority for giving her that appellation.

But it would be tiresome and almost endless to follow this female Proteus through her varied changes, and the many legends detailing them in the Puranas. We will proceed to offer a list of some of her names; and for beauty's sake, such of them as have furnished articles for this work are put in capitals, to which articles the reader desirous of farther information is thus generally referred. Amba (see UMA). Annapurna. Annada. Anjanabha. Anumati. Antargati: under this name she is invoked as a martial goddess, for strength of heart and courage. Aparajita: this has been thought the same word as the Greek Aphrodite (see MATRI). Aranya-Devi, or the goddess of the forest. Ardha Nari, or half woman: in this character she is represented conjoined to her spouse; one side being Siva with his attributes, the other side her own. The celebrated one-breasted gigantic figure in the cavern temple at Elephanta, is of this subject. Ashtara. Asita. Asvini, meaning a mare; in this form the sun approached her as a horse, and on their nostrils touching she conceived twins, who are called Asvini-Kumari, represented like Castor and Pollux, and each has the character of Esculapius among the gods. It will be recollected, that he is fabled to have descended from a nymph, who in the form of a mare was impregnated with sun-beams. His name is traceable to the Sanscrit, in which language Asva-Kalupa means mare-descended. Bhadra. Kali (see KALI). Bhagi, as the consort of Bhaga, a name of Siva, and of the sun. Bhavani, as consort of Bhava, a name of Siva, the author of existence. Bhavani is the general power of fecundity. Venus generatrix. Bhudevi, goddess of the earth. (See PATALA-DEVI.) Kawfiki, or Kawfiki. Chamunda. Chandika: Charchika. Devi, the goddess, the queen, pre-eminently so called by her sectaries, and by others. This title is, however, sometimes given to other female divinities. Devi-jenni, the prolific goddess, or the mother of gods. Durga, or difficult of access, as noticed in an earlier part of this article. Feringahi. Ganga,

VOL. XXVI.

the river Ganges: in this character she sprung from the head of Siva, and bore a son to him, named *Kartikya*, which see, and MENA and MERA. Gauri, meaning fair or young. When seen together, in pictures or statues, or conjoined as noticed before of Ardha Nari, the goddess and her spouse are frequently called Har-gauri; Hara being a name of Siva, and Hari of his consort. IDITA. ILITA. ISI. ISANI. ISWARI (see ISWARA). IVA, or of one letter, derived from I, and pronounced as a disyllable exactly like Eve. Kalratri. Kirti. KAUMARI. KALI. KATTAYANI. Kawfiki. Lilefwari (see LILESWARA.) MA. MAHAKALI. MAHAMARI. Mahamayi. MAHESWARI. MAL-SARA. Manafa. MEKARA. NILA. PALLYANGHI. PARA. PARAMESWARI. PATALADEVI. PEDMADEVI. PIKESWARI. PRABHA. PRAKRITI. RAJARAJESWARI. RAMI. RAUDRI. RUDRI. RUDRANI. SAMI. SAMIDEVI. SAMIRAMI. SARASWATI. SARVAJAYA. SARVAMANGALA. SATORUPA. SATI. SATWI. SATWIKI. SHASHTI. SHYANULA. SRI. SUDURGA. SUKALI. SWARDEVI. SWETADEVI. SYAMA. TAMASI. TRIKALADEVI. TRISAKTIDEVI. TRIVIDHA. UMA. VAGESWARI. VAJRESWARI. VISWAJENNI. VYAGRAYAHI. YONI.

In her character of Parvati, she is usually seen in pictures in company with her spouse, and is represented as of perfect beauty, splendidly dressed and decorated; sometimes sitting on his knee, or on a carpet beside him, or on a tiger's or elephant's skin, presenting him amrita (ambrosia) in a golden goblet. Sometimes she is mounted with him on a white bull (see NANDI), with their reputed sons *Kartikya* and *Pollux*; see those articles.

Under her various forms and characters she is variously armed and arrayed; see, for instances, under KALI and MATRI. Sometimes she has four, eight, twelve, sixteen, and as far as thirty-two arms. In the plates of the Hindoo Pantheon, she is represented upwards of fourscore times, in varied form and character; and legends are said to be found in the theological and mythological writings of the Hindoos, detailing her origin and achievements in each. In some plates of the work just alluded to, she is represented, from original subjects, pre-eminently placed as the supreme object of adoration; the chief of the gods, even the three persons of the Hindoo triad, being among her votaries. See of the Hindoo triad, under TRIMURTI. Such pictures and sculptures may be ascribed to the sects who adore her exclusively as Nature. Such sects are called *Lingi-Lingaja*, and *Sakta*. See those articles, and LINGA.

Like their copies, the Jupiter and Juno of the Greeks, the Hindoo Mahadeva and Parvati, have, in the Puranic legends, many quarrels and reconciliations. These are, in fact, the phenomena of nature, hidden from the vulgar eye in a veil of allegory, and in such a veil sometimes, as not to be altogether decent to the taste of people less gross than the Greeks and Hindoos. The language of Parvati is occasionally as free as Juno's in the page of Homer. In illustration of this allegorical style, the following verse may be aptly introduced from sir W. Jones' spirited hymn to Ganga, a personification of the river Ganges. It exhibits the popular notion of a solar eclipse, for Siva's frontal or central is, like himself, the sun, obscured by the intervention of the hand of Parvati, or the moon. We see too, (for the ideas of the hymn accord strictly with the legends of Hindoostan,) the means confidently resorted to by a priest-ridden people for restoring the equilibrium of nature's elements; and that Ganga springs, like Pallas, from the forehead of the Indian Jove.

" Above the stretch of mortal ken,
On blest Kailasa's top, where every stem

Glow'd with a vegetable gem,
 Mahefa fate, the dread and joy of men ;
 While Parvati, to gain a boon,
 Fixed on his locks a beamy moon,
 And hid his frontal eye, in jocund play,
 With reluctant sweet delay.
 All nature straight was lock'd in dim eclipse,
 Till Brahmans pure, with hallowed lips
 And warbled prayers restored the day ;
 When Ganga from his brow, by heavenly fingers prest,
 Sprang radiant, and descending, graced the caverns of the
 [west.]

Parvati and Saraswati are sometimes seen to correspond in character. It may, perhaps, be thus accounted for ; Siva is the *changing*, or *renovating*, rather than the *destroying* power ; he re-produces : for destruction, say the philosophers, is but reproduction in another form. This is so similar to making or creating, the province of Brahma, that the terms and powers almost coalesce. Brahma, indeed, is merely a periodical reorganizer of chaotic matter. (See KALPA.) Parvati and Saraswati are the energies of the personification of those changing powers, and we may hence discern why their characters and attributes are sometimes made to accord. The consort of Brahma is occasionally, though but rarely called Prakriti, and the helpmate of Siva, Satarupa ; here changing names and characters, as it were. Bhavani is also occasionally invoked as the goddess of speech, or eloquence, a character more especially of *Saraswati*. (See that article.) In like manner this pantomorphic goddess is found now and then to correspond in name and attributes with Lakshmi. She is occasionally seen with the chank or shell of the latter power : and with the lotos, more especially her emblem, and hence Padma-devi is a name common to both, meaning the goddess of the lotos, that plant being the emblem of female beauty, and being aquatic, also of humidity ; and both these goddesses assume the character of the Venus of the Greeks. (See LAKSHMI and RHEMBA.) Sri, or the blessed or fortunate, is likewise a name given to them both.

The sectaries of this goddess, who under different names, and adoring her under different forms, are numerous, have various symbolical marks by which they are distinguished. Generally speaking, horizontal lines on the forehead distinguish the *Saivas* from the *Vaishnavas*, (see those articles,) the latter having them perpendicular. On the subject of such sectarial marks and distinctions, a plate exhibiting a great many, with copious remarks, is given in the Hindoo Pantheon, to which we refer those desirous of farther information hereon.

It has been noticed that to this goddess, in her character of Kali, it was that human victims were formerly offered. The rites and ceremonies to be observed on these horrid occasions, are minutely laid down in the Kalika Purana, extracts from which are given under the article NARAMEDAI of this work. See also KALI and PURANA.

PARVETI MOUNTAINS, in *Ancient Geography*, a chain of mountains described by Ptolemy, corresponding to the heights of Suhmandroog, lying S.E. of Candahar, and being the southern boundary of the province of Paro-pamisus.

PARVICH, in *Geography*, a small island in the Adriatic, near the coast of Dalmatia, fertile in grapes, olives, and mulberries.

PARVISE. See PERVERSE.

PARULIS, from *παρῦς*, and *σλοῖς*, the gums, in *Surgery*, an inflammation, or abscess of the gums ; a gumboil. See GUMS, *Diseases of*.

PARUR, in *Geography*, a town of Hindoostan, in Cochinchina ; 10 miles E.S.E. of Cranganore.

PARUS, the Titmouse, in *Ornithology*, a genus of birds of the order Passeres. The generic character is ; bill very entire, narrow, subcompressed, strong, hard, pointed and covered at the base with bristles ; the tongue is truncate, bristly at the end ; the toes are divided to the origin, the hind one large and strong. These birds are found in almost every part of the old continent, from the north of Europe to the south of India. They are highly prolific, laying eighteen or twenty eggs, which they hatch with unwearied patience. They build their nest with particular neatness and skill, and frequently on the extremity of some branch suspended over water, by which they secure it from the attack of various animals, to which it might otherwise fall a prey. They are wonderfully active and alert, rapid and assiduous in their search for insects, on which they principally subsist, under the bark, and in the crevices of trees, which they clear of the immense multitudes of caterpillars covering them in spring, and which would totally blast their vegetation. They are not migratory, though they occasionally change their residence for short distances. They are irritable and irascible to a great degree, and when angry, will display the ardent eye and ruffled plumage, which indicate the paroxysm of agitation. They possess a very extraordinary degree of courage, and will sometimes attack birds three times their size. The owl is not secure from their rage ; and whatever bird they pursue, their first attempts are levelled at the head, and particularly at the eyes and brains, the latter of which they devour with particular avidity and relish. According to Gmelin, there are thirty-one species, though Latham describes twenty-seven only.

BICOLOR ; Toupet Titmouse. Head crested, on the forehead black ; body emereous ; beneath whitish rufous. It inhabits the woods of North America, and is six inches long. The bill is black ; crest pointed, grey ; orbits pale rufous ; quill and tail-feathers edged with grey rufous ; the tail is slightly forked, the legs are of a lead colour. The female has a white belly.

CRISTATUS ; Crested Titmouse. Head is crested ; collar black ; belly white. Inhabits Europe, chiefly in fir-woods ; is five inches long, solitary, and not easily tamed.

* MAJOR ; Great Titmouse. Head black ; temples white, nape yellow. The bill, chin, and tail are black ; the back and wings are olive ; rump blue-grey ; belly greenish-yellow, divided in the middle by a band of black, extending to the vent ; the quill-feathers are of a dusky colour, edged partly with blue, and partly with white ; exterior sides of the outmost tail-feathers white, of the others blueish ; inner sides dusky, legs lead-coloured. This species weighs little more than an ounce, and is almost six inches in length. It is found in Europe, Asia, and Africa, and is very common in this country, frequenting gardens and orchards, where it does a deal of mischief, by picking off the tender buds of trees. The nest is made of moss, lined with hair, and placed in the hole of a wall, or of a tree. The female lays six or eight or ten eggs, which are white, spotted with a rusty kind of colour, and so exactly like those of a nut-hatch, as not to be distinguished from them. The common note of the great titmouse is a sort of chatter, but in the spring it assumes a greater variety, a shrill whistle, and a very singular noise, something like the whetting of a saw, but these cease with incubation. There is a variety of this species, called the cross-billed titmouse, which is olive-brown, beneath dirty-yellowish ; the head is black, the temples emereous ; the bill forked. This bird was killed once near Feversham in Kent ; it had its bill crossed, as in the *Loxia curvirostra*.

IGNOTUS ;

PARUS.

IGNOTUS; Stræmian Titmouse. Yellow-green; breast yellow, spotted with rufous; belly blue; vent yellowish. It inhabits Norway, and very much resembles the Major.

CYANUS; Azure Titmouse. Pale blue, beneath snowy; rump and crown whitish-hoary; neck above white, with a broad blue band; shoulders and tail-coverts blue. It is found in divers parts of Russia and Siberia, and is about five inches long.

AMERICANUS; Creeping Titmouse. Blueish; temples, breast, and back yellowish; flanks of a purple colour. It inhabits Carolina and Canada, is nearly five inches long; continually runs up and down trees in search after insects.

* **CHRULEUS**; Blue Titmouse. Quill-feathers blueish, the primaries white on the outer edge; front white; crown blue. The bill is blackish; line from the bill to the eyes, and one surrounding the temples, black; the back is of a yellowish-green; wing-coverts blue; quill-feathers black, with dusky edge; tail blue, the middle feathers longer, body whitish-yellow beneath; legs and claws black. It is about four inches and half long, and weighs less than half an ounce. This species would, probably, be much admired for its beauty, if it were less common. In winter it frequents houses, and will devour flesh very greedily. It is also a constant attendant where horse-flesh is kept for hounds, and in the farm-yard, being very fond of oats, which it plucks out, and retiring to a neighbouring bush, fixes the grain between its claws, and hammers it with the bill, to break the husk. In summer it feeds chiefly on insects, in search of which it plucks off a number of young buds from the trees. The nest is made very like that of the Major, and the female is so tenacious of her nest, that she will often suffer herself to be taken rather than quit it. She menaces every intruder in a singular manner, hissing like a snake, erecting all its feathers, and uttering a noise like the spitting of a cat, biting, at the same time, severely, if handled.

ATRICAPILLUS; Canada Titmouse. Cap and chin black; body cinereous, beneath it is white. It inhabits North America, is four inches and a half long; feeds on worms and insects, and is very patient of cold.

ATER; Colemouse. Head black, back cinereous; hind head and breast white; the bill and chin are black; a broad black stripe beneath the eyes, from the bill to the neck; belly and vent reddish-white; wing-coverts grey, tipped with white; quill and tail-feathers brownish ash, edged with grey; legs and claws lead-coloured. It does not weigh much more than a quarter of an ounce, and is four inches in length. It has frequently been confounded with the next, the *Palustris*, but is not so common; it keeps more to the woods, seems to live entirely on insects, and has also a different note.

* **PALUSTRIS**; Marsh Titmouse. Head black; back cinereous; temples white. There are three varieties. 1. Wings without the white bands. 2. Body beneath and band on the hind-head white. 3. Crown black; nape yellowish. This species inhabits different parts of Europe: it is fond of flesh and also of oats, like the blue titmouse. It is partial to low wet ground, in the holes of which it frequently nestles.

VIRGINIANUS; Virginian Titmouse. Rump yellow; body cinereous. It inhabits Virginia and Carolina, and is five inches long. The bill is blackish, body above olive brown, beneath grey; legs and claws brown.

PEREGRINUS; Crimfon-rumped Titmouse. Rump scarlet; body cinereous, beneath white. It is of the size of the *P. major*. The quill-feathers are brown; tail-feathers black, except the four middle ones, which are obliquely yellow on the hind part.

GRISEUS; Crimfon-crowned Titmouse. This is of a grey colour; the crown is red. It inhabits Greenland.

AFER; Black-breasted Titmouse. Blackish; cheeks, nape, and belly white; neck beneath, and breast black. It is found at the Cape of Good Hope, and is six inches long.

CAUDATUS; Long-tailed Titmouse. Crown white; tail longer than the body; it weighs about a quarter of an ounce, and measures five inches and a quarter in length. This is a very elegant and singular species, and is chiefly confined to the woods and thickets of Europe and Siberia, where it makes a curious oval nest of lichens, firmly woven together with wool, and having only a small hole on the side, placed in the fork of some bush, or branch of a tree. The female lays from nine to seventeen eggs, which are white, and sparingly marked with small rust-coloured spots towards the larger end.

CAPENSIS; Cape Titmouse. Grey-ash; quill-feathers black, edged with white; tail above black, beneath white. The bill and legs are black. It inhabits the Cape of Good Hope. It constructs a luxurious nest of the down of a species of *asclepias*; near the upper end projects a small tube, about an inch in length, with an orifice about three-fourths of an inch in diameter. Immediately under the tube is a small hole in the side, that has no communication with the interior of the nest. In this hole the male sits at night, and thus both male and female are screened from the weather.

BIARMICUS; Bearded Titmouse. Rufous; crown hoary; tail longer than the body; head bearded; vent black. It inhabits the marshy places in many parts of Europe, is about six inches long, suspends its nest between three reeds; the eggs are reddish-white, with small red spots.

SINENSIS; Chinese Titmouse. Rusty-brown; head and neck paler; quill-feathers and long tail brown, edged with black. It inhabits China; is not quite four inches long. The bill is black; the legs are red.

MALABARICUS; Malabar Titmouse. Grey; chin, wings, and middle tail-feathers black; body beneath, rump, spot on the wings, and base of the lateral tail-feathers, tawny. It inhabits Malabar, is nearly six inches long. The bill is black; the irids red. The under part of the female is rufous yellow.

ALPINUS; Alpine Titmouse. Black, beneath pale rufous, spotted with black; from the base of the bill to the neck there is a white line; hind-claw very long. It inhabits the alpine parts of Persia, and is about the size of the *P. caudatus*.

SIBIRICUS; Siberian Titmouse. Grey-brown, beneath whitish; belly rufous-grey; lower part of the neck black in the middle; sides pale rufous. A variety of this species has the belly and vent white. It is found in Siberia, and is about five inches long.

KNJASCIK. White; beneath, ocular line, and collar livid. It is found among the oak forests of Siberia.

HUDSONIUS; Hudson's Bay Titmouse. Reddish-brown; back cinereous; throat black; band under the eyes and breast white; the sides are rufous. It inhabits Hudson's Bay, and is about five inches and a half long.

MACROCEPHALUS; Great-headed Titmouse. Black; breast orange; belly yellowish; head tumid; spot on the front and wings, and two outmost tail-feathers, white. A variety of this species has the breast scarlet. It is found in New Zealand, and is about four inches and a half long.

NOVA ZEELANDIÆ; New Zealand Titmouse. Red-ash, beneath

beneath rufous-grey; eye-brows white; two middle tail-feathers black; the lateral ones in the middle with a square black spot. It inhabits New Zealand, and is five inches long. The bill is brown, tipped with black; legs dusky-black.

PENDULINUS; Penduline Titmouse. Head ferruginous; ocular band black; quill and tail-feathers brown, and edged on each side ferruginous. It is about four inches and a half long. It inhabits Europe and Siberia, frequenting watering-places for the sake of aquatic insects, on which it feeds. These birds display great art in the construction of their nests. They employ the light down found on the buds of the willows, the poplar, on thistles, and the dandelion. With their bill they entwine this filamentous substance, and form a thick close web, almost like cloth. This they fortify externally with fibres and small roots, which penetrate into the texture, and, in some measure, compose the basis of the nest. They line the inside with the same down, but not woven, that their young may lie soft; they shut it above to confine the warmth, and they suspend it with hemp, nettles, &c. from the cleft of a small pliant branch over some stream, that it may rock more gently, assisted by the spring of the branch. In this situation, the brood are well supplied with insects, which constitute their chief food, and, at the same time, they are protected from their enemies. The nest sometimes resembles a bag, and sometimes a short purse. The aperture is made in the side, and is almost always turned towards the water. It is nearly round, and only an inch and a half in diameter, and is frequently surrounded by a brim. These nests are found in the fens of Bologna, Tuscany, Lithuania, Poland, and Germany. The peasants regard them with superstitious veneration, one of them being usually suspended near the door of each cottage, as a charm against lightning.

NARBONENSIS; Languedoc Titmouse. Rufous-grey; crown hoary; wings and tail blackish, edged with rufous, primary quill-feathers edged with white; four inches long. It inhabits France, and builds a strong pendulous nest on the forked branch of a tree. The bill is black; the upper mandible edged with yellow-brown; the legs are of a lead colour.

CELA; Guiana Titmouse. Black; bill white; spot on the wings and base of the tail yellow. It inhabits Guiana.

AMATORIUS; Amorous Titmouse. Blackish-blue; longitudinal spot on the middle of the wings half yellow, and rufous; five inches and a half long. It inhabits Northern Asia, and is remarkable for the mutual affection of the two sexes. The bill is black at the base, and tipped with orange.

COCCINEUS; Scarlet Titmouse. Cinereous; breast, spot on the wings, rump, and lateral tail-feathers on the hind part, scarlet. The bill and legs black, the vent is yellowish.

INDICUS; Indian Titmouse. Above cinereous, beneath ferruginous; chin and throat of a dirty white; the limbs are a black-brown. It inhabits India.

PARUSHA, in *Mythology*, is a name applied by the Hindoos to several of their deities. The word seems to mean the primeval person or man; and in some fables it is related that he was produced by the Creator at the formation of the world, with Prakriti, a personification of Nature. (See **PRAKRITI**.) The allegorical union of these two powers, male and female, have furnished endless fancies for Hindoo metaphysicians, who, among such fancies, describe an allegorical immolation of this primeval being; sometimes making Parusha, or Purusha, the victim; sometimes

Brahma, or Narayana. In the Veda, called Yajur, or Yajush, the necessary ceremonies for the sacrifices called Aśwamedha and Purushamedha, are laid down; "but they are not," as the words imply, "really sacrifices of horses and men." In the first mentioned, six hundred and nine animals of various kinds, domestic and wild, including birds, fish, and reptiles, are made fast; the tame ones to twenty-one posts, and the wild ones in the intervals between them; and after certain prayers, the victims are let loose without injury. In the other a hundred and eighty-five men of various specified tribes, characters, and professions, are bound to eleven posts, and after a certain hymn concerning the allegorical immolation of Narayana has been recited, these human victims are liberated unhurt; and oblations of butter are made on the sacrificial fire. This mode of performing the Aśwamedha and Purushamedha as emblematical ceremonies, not as real sacrifices, is taught in this Veda; and the interpretation is fully confirmed by several rituals, and by commentators; one of whom assigns as a reason, "because the flesh of victims, which have been actually sacrificed, must be eaten by the persons who offer the sacrifice: but a man cannot be allowed, much less required, to eat human flesh." This passage is cited by Mr. Colebrooke from memory: he adds, "It may be hence inferred, or conjectured at least, that human sacrifices were not authorized by the Veda itself; but were either then abrogated, and an emblematical ceremony substituted in its place, as they must have been introduced in later times on the authority of certain Puranas and Tantras, fabricated by persons, who in this, as in other matters, established many unjustifiable practices on the foundation of emblems and allegories which they misunderstood." (As. Ref. vol. viii.) A human sacrifice is called *Naramedha*, and, as described under that article, was formerly a usage among the Hindoos. For the signification of the words *Narayana*, *Purana*, *Tantra*, and *Veda*, that occur above, the inquirer is referred to those articles.

PARUSHA-Medha, among Hindoos, is an allegorical sacrifice of a man, as noticed under the preceding article.

PARUTA, **PAOLO**, in *Biography*, a noble Venetian, was born in 1540. He succeeded Contarini as historiographer of the republic in 1579, and afterwards filled various offices in the state. He was employed in several embassies, was made governor of Brescia, and finally was elected a procurator of St. Mark. With a high character for wisdom, integrity, and zeal for the public welfare, he died in 1598, at the age of 58. The following is an enumeration of his principal works, "A funeral Oration to the Praise of those who fell in the Battle of Curzolari in 1571;" "Della Perfezione della vita Politica;" "Discorsi Politici," published by his sons in 1599; "A History of Venice, from 1513 to 1551, with the Addition of an Account of the War of Cyprus;" this work is written in Italian, and is accounted one of the best works of that class in the language. He had begun to write it in Latin, in imitation of the style of Sallust, and had finished four books in that language. A new edition of this history was given by Apostolo Zeno in 1703.

PARUTA, **FILIPPO**, a learned antiquarian, was a noble of Palermo, and secretary to the senate of that city, where he died in 1629. He was author of several works, but is principally known by his "Sicilia descritta con Medaglie," published at Palermo in 1612. This work was afterwards enlarged by Leonardo Agostini, and printed at Rome in 1649, and at Lyons in 1697. Havercamp published a Latin edition of it in three volumes folio, 1723, which

which makes part of the Italian antiquities of Grævius and Burmann.

PARVUM CAPE. See CAPE.

PARWAN, in *Geography*, a town of Candahar; 60 miles N.W. of Cabul.

PARWIDA, a town of Sweden, in Tavastland; 45 miles N.N.E. of Jamsö.

PARWIS, a town of the Tyrol; 18 miles W.N.W. of Inspruck.

PAR-YARD, in *Agriculture*, a term provincially applied to the straw, or fold-yard.

PARYPATE, in the *Ancient Music*, was the name of that note or chord of a tetrachord which lay next to the hypate.

As the hypate was the *principalis*, the first, or principal found, according to Martianus Capello's translation; so the parypate was, according to him, the *sub-principalis*. See TETRACHORD.

The name parypate was given to this second note when a tetrachord was considered separately from others; but, when combined, this chord sometimes took the name *trite*. See DIAGRAM, and TRITE.

PARYPATE *Hypaton*, in the *Ancient Greek Scale of Music*, was the second note of the hypaton tetrachord, and answers to the *C-fa-ut* of Guido's scale. See DIAGRAM, and PARYPATE.

PARYPATE *Meson*, in the *Greek Music*, was the second note of the meson tetrachord, and answers to the *F-fa-ut* of the Guidonian scale. See DIAGRAM.

PARYS, in *Geography*, a mountain of North Wales, in the island of Anglesea, about nine miles in length, and half as much in breadth; apparently waste and barren in the extreme, but abounding in the richest mines of copper and lead ore, with a mixture of silver in the latter: the bed of copper ore is supposed to be the largest that is known on the globe; 2 miles S.E. of Amlwch.

PARZANEGA, a town of Italy, in the department of the Serio; 15 miles E.N.E. of Bergamo.

PAS, MANESSES DE, *Marquis de Feuquieres*, in *Biography*, was the posthumous son of Francis de Pas, who was slain at the battle of Ivry. He was born at Saumur in 1590, and distinguished himself as an able general and negotiator. At the siege of Rochelle he was taken prisoner, was continued in confinement nine months, and was ransomed in exchange for general Ekenfort, two colonels, and 18,000 crowns. The reduction of the city of Rochelle has been attributed chiefly to him. He was afterwards ambassador to the court of Sweden and Germany, where he displayed great talents. In 1635 he commanded the army in conjunction with the duke of Saxe-Weimar. He died in 1640. His negotiations in Germany were printed in 1753, in 3 vols. 12mo. Moreri.

PAS, ANTHONY DE, *Marquis de Feuquieres*, grandson of the above, was one of the greatest generals of his time. He signalized himself at the battle of Stafarde, at the taking of Suza, and other strong places in Italy, but he was so severe a disciplinarian, that it was a common saying, that De Pas must be the bravest man in the world, since he slept every night in the midst of a hundred thousand enemies. He was governor of Verdun, and in 1689 he was made, on account of his great talents, a field-marshal. He died in January 1711, aged 63. His memoirs were printed in 4 vols. 12mo. Moreri.

PAS, in *Geography*, a town of Prussia, in Bartenland; 10 miles N.E. of Raftenburg.

PAS, a town of France, in the department of the Straits of Calais; 13 miles S.W. of Arras.

PAS de Calais. See STRAITS of Calais.

PAS de Souris, in the *Military Art*, the same with *liziere*.

PASA, or FESA, in *Geography*, a town of Persia, in the province of Farfistan; 68 miles S.E. of Schiras. N. lat. 29° 10'. E. long. 53° 40'.

PASAGINIANS, or CIRCUMCISED, in *Ecclesiastical History*, a singular sect, which sprung up in Lombardy towards the close of the 12th century. Like several other sects that subsisted about the same time, this sect had the utmost aversion to the dominion and discipline of the church of Rome; but it was distinguished, at the same time, by two religious tenets that were peculiar to itself. The first was a notion, that the observance of the law of Moses, in every thing except the offering of sacrifices, was obligatory upon Christians; in consequence of which, its followers were circumcised, abstained from those meats, the use of which was prohibited under the Mosaic economy, and celebrated the Jewish Sabbath. The second point that distinguished this sect was advanced in opposition to the doctrine of three persons in the divine nature; for the Pasaginians maintained that Christ was no more than the "first and purest creature of God." Nor will their adoption of this opinion seem very surprising, if we consider the prodigious number of Arians that were scattered throughout Italy long before that period. Mosheim.

PASAKA, or BUXADEWAR, in *Geography*, a town of Bootan; 60 miles S.S.E. of Tassafudon. N. lat. 26° 48'. E. long. 89° 30'.

PASAKAMENITZ, a town of Bohemia, in the circle of Chrudim; 8 miles W.N.W. of Politzka.

PASAL, a town of Africa, in the kingdom of Fonia. N. lat. 12° 40'. W. long. 15° 36'.

PASAN, *Antelope Oryx*, in *Zoology*, a species of antelope, with straight, slender, distinctly annulated horns, which taper to a point; the body and sides are of a reddish ash colour, having a raised dusky line along the back, the hairs of which at the posterior end are reversed. This is the *Gazella Indica*, or Indian antelope of Ray; the *capra gazella*, or goat antelope of Syst. Nat. ed. 12.; the *oryx* of Pliny, and other ancient writers; the Egyptian antelope of Pennant; and the *pasan* of Buffon. It inhabits Syria, Arabia, Persia, India, Egypt, Ethiopia, and near the Cape of Good Hope. It is about the size of a fallow deer; the horns are near three feet long, the points sharp, and about 14 inches asunder; the face is white, with a black spot at the base of the horns, another on the middle of the face, and one on each side reaching from the eye to the throat, joining that on the face by a transverse band of the same colour; the belly, rump, and legs are white; the white colour of the belly is divided, on the sides, from the reddish ash-coloured upper parts, by a broad longitudinal dusky band, which reaches to the breast; each leg is marked with a dusky spot below the knee; the tail is near two feet and a half long, and is covered with longish black hairs. This species is named *gems bock*, or *chamois*, at the Cape, and is supposed by Gmelin to be the *zibi* of the sacred writers.

PASANGA, in *Geography*, a small island in the East Indian sea, near the coast of Sumatra. S. lat. 5° 10'.

PASAR, a town of Hindoostan, in the Carnatic; 21 miles W. of Tiagar.

PASARGADA, or PASARGADÆ, in *Ancient Geography*, a town of Asia, in the Perside. The name signifies the camp of the Persians, and the town had been founded in the place where Cyrus had vanquished Astyages or Cyaxares in a pitched battle. According to Plutarch, there was in

this

this town a temple of the goddess of war, who was supposed to have been Pallas.

PASARNA, a town of Asia, in Lesser Armenia, at some distance from the Euphrates, in the Lavinian prefecture. Ptolemy.

PASCAGOULA, in *Geography*, a river of America, in the Mississippi territory, which, after pursuing a S. by E. course through West Florida, and part of Louisiana, discharges itself into the gulf of Mexico by several mouths, occupying a space of three or four miles, which is a continued bed of oyster-shells, with very shoal water. This river is said to be navigable more than 150 miles. The adjacent soil improves as you advance towards its source. The bay formed by it lies in N. lat. $30^{\circ} 23'$. W. long. $88^{\circ} 30'$.

PASCAL, BLAISE, in *Biography*, a celebrated mathematician and philosopher of the 17th century, was born at Clermont, in Auvergne, in the year 1623. His father was a man of great consideration in his province, was president of the court of aids, and was illustrious as a general scholar, as well as an able mathematician. To promote the studies of his only son Blaise, he relinquished his official situation, settled at Paris, and undertook the employment of being his tutor. The pupil was, from a very early period, remarkably inquisitive, and desirous of knowing the principles of things; and when good reasons were not given to him, he would search for better, nor would he rest contented with any that did not appear to his mind well founded. His father soon discovered that the bent of his genius was decidedly to mathematics, from which he was determined, if possible, to keep him, lest he should, by this pursuit, be prevented from learning the languages. He accordingly locked up all the books that treated of geometry, and the sciences properly called, and refrained even from speaking of them in his presence. On one occasion, however, the youth asked, with an importunity not to be put off, what was geometry? to which the father replied, "geometry is a science which teaches the way of making exact figures, and of finding out the proportions between them;" but at the same time, he forbade him to speak or think of the subject any more, which was perhaps the very readiest way to excite in him an earnest desire to become acquainted with it. Accordingly the science soon occupied all his thoughts; and though but twelve years of age, he was found, in the hours of recreation, making figures on the chamber-floor with charcoal, the proportions of which he sought out by means of a regular, though perhaps uncouth, series of definitions, axioms, and demonstrations. It is said, apparently upon unquestionable authority, that he had proceeded with his inquiries so far as to have come to what was just the same with the thirty-second proposition of the first book of Euclid, and that without any assistance either from living instructors, or the works of the illustrious dead. From this time, young Pascal had full liberty to indulge his genius in mathematical pursuits, and was furnished by his father with Euclid's Elements, of which he made himself master in a very short time. So great was his proficiency in the sciences, that, at the age of sixteen, he wrote a "Treatise on Conic Sections," which, in the judgment of the most learned men of the time, was considered as a great effort of genius. At the age of nineteen he contrived his admirable arithmetical machine, furnishing an easy and expeditious method of making arithmetical calculations, in the fundamental rules, without any other aid than that of the eye and the hand. About this time, owing to ill health, he was obliged to suspend his studies, which he was unable to renew for four years; when having been witness to the famous

Torricellian experiment respecting the weight of air, he instantly directed his attention to discoveries in the science of pneumatics. He made a vast number of experiments, of which he circulated a printed account through the whole of Europe. He soon ascertained the fact of the general pressure of the atmosphere, and composed a large treatise, in which he fully explained the subject, and answered the objections which were advanced against his theory: afterwards, thinking it too prolix, he divided it into two small treatises, one of which he entitled "A Dissertation on the Equilibrium of Fluids;" and the other, "An Essay on the Weight of the Atmosphere." These treatises were not published till after the author's death.

The high reputation which M. Pascal had acquired, caused him to be looked up to by the most considerable mathematicians and philosophers of the age, who applied for his assistance in the resolution of various difficult questions and problems. Among other subjects on which his ingenuity was employed, was the solution of a problem suggested by Mersenne, which had baffled the penetration of all who had attempted it: this was to determine the curve described in the air by the nail of a coach-wheel, while the machine is in motion; which curve was at that time known by the name of the *roulette*, but is now designated the CYCLOID; to which article we refer our readers for a farther account of the matter.

Before this time he had drawn up a table of numbers, which, from the form in which the figures were disposed, he called his "Arithmetical Triangle." He might perhaps have been an inventor of it, but it is certain that it had been treated of, a century before Pascal's time, by Cardan, and other arithmetical writers. See TRIANGLE.

When M. Pascal was in the 24th year of his age, and the highest expectations were formed of the advantages to be attained in science from his labours, he on a sudden renounced the study of mathematics, and all human learning; devoted himself wholly to a life of mortification and prayer; and he now became as great a devotee as almost any age has produced. From this period he renounced all kinds of pleasure, and not only denied himself the most common gratifications, but was in the habit of daily entrenching some part of his dress, food, &c. which he did not consider as necessary. He carried the matter much farther, and endeavoured to diminish his attachment to his dearest friends, because ardent affection was due to God alone. He occasionally wore an iron girdle, full of blunted points, to increase his mortification and pain, and to remind him of his duty to God. During the latter years of his life, his principal relaxation from the rigorous system which he prescribed to himself, consisted in visits which he paid to churches, where some relics were exposed, or some solemnity observed; and for that purpose he had a spiritual almanack, or ephemeris, which informed him of the places where particular services were performed. He was not, however, so completely abstracted from the world, as to be wholly indifferent to what was passing in it; and in the disputes between the Jesuits and Janfenits, he became a partisan of the latter, and wrote his celebrated "Provincial Letters," published in 1656, under the name of Lewis de Montalte, in which he only employed his talents of wit and humour in ridiculing the former. These letters have been translated into almost all the European languages, and probably nothing did more injury to the cause of the Jesuits. They attempted various answers, but with little effect: they then obtained a decree of condemnation against them, but they still maintained their ground, interesting the more serious readers by their solidity, and those of a lighter turn of mind by their wit. After the publication

publication of the "Provincial Letters," he became entirely a recluse, spending his whole time in meditation and prayer. He made his own bed, and performed almost all other menial offices; employing a servant only to dress his food, and to go on unavoidable errands. He allowed himself nothing in his apartment but a table, a bed, and two or three chairs. This course of life proved unfavourable to his health of body and mind. His reason became in some measure affected, and, in these circumstances, an accident produced on his mind an impression which could not be effaced. In 1654, while he was crossing the Seine in a coach and four, the two leading horses became unmanageable at a part of the bridge where the parapet was partly down, and plunged over the side into the river. Their weight fortunately broke the traces, by which means the other horses and the carriage were extricated on the brink of the precipice. From this fright it was difficult to excite the feeble Pascal, and he never afterwards had the possession of his mental faculties. He always imagined that he was on the edge of a vast abyss on the left side of him, and he would at no time sit down till a chair was placed there, to assure him there was no real danger. After languishing some years in this miserable state, he died at Paris in 1662, at the age of 39. He intended to have written a work against atheists and unbelievers in Christianity, and had collected a mass of materials for that purpose, which he did not live long enough to digest. These consisted of reflections upon devout, moral, and other subjects connected with the evidences of the Christian religion, which were written down by him at different times, on the first piece of paper which he could find. After his decease, these pieces of paper were found filed, but without any order or connection; and being exactly copied, were arranged and published in 32 chapters, under the title of "Pensées de M. Pascal sur la Religion et sur quelques autres Sujets." They have been translated in our own and other languages, and have been greatly admired as the precious remains of a great and a good, though certainly a misguided, man. They exhibit, in the original language, striking traits of his sublimity of genius, beautiful turn of sentiment, as well as force and true elegance of expression. Many of the ideas do not reflect honour on the wisdom and benevolence of the deity; and on some of them Voltaire has written able animadversions, in his "Lettres Philosophiques."

The works of M. Pascal were collected and published in five volumes, octavo, in 1779, at the Hague, and also at Paris. This collection, which consisted in part of posthumous pieces, was given to the public by the abbé Bossu, who thus describes the author: "This extraordinary man inherited from nature all the powers of genius. He was a geometrician of the first rank, a profound reasoner, and a sublime and elegant writer. If we reflect that, in a very short life, oppressed with continual infirmities, he invented a curious arithmetical machine, the elements of the doctrine of chances, and the method of resolving various problems respecting the cycloid; that he fixed, in an irrevocable manner, the wavering opinions of the learned concerning the weight of the air; that he wrote one of the most perfect works existing in the French language; and that in his own "Pensées," there are passages, the depth and beauty of which are incomparable; we can hardly believe that a greater genius ever existed in any age or nation." Bayle pronounces M. Pascal to have been one of the sublimest geniuses whom the world ever produced; and says, if he might make use of the expression, he would call him "a paradoxical individual of the human species." Voltaire, also, who did not spare the posthumous works of Pascal, says, in his

"Siècle de Louis XIV.," that the "Lettres Provinciales may be considered as a model of eloquence and humour. The best comedies of Moliere have not more wit than the first part of them; and the sublimity of the latter part is equal to any thing in Bossuet." In another place, speaking of this same work, he says, "that examples of all the various kinds of eloquence are to be found in it. Though it has been written almost an hundred years, yet not a single word occurs in it favouring of that vicissitude to which living languages are so subject. Here then we are to fix the epoch, when our language may be said to have assumed a settled form." In a moral point of view, as well as an adept in science and literature, Pascal has been most highly applauded. "His heart," says his biographer, "was the seat of the purest benevolence; and his exertions in alleviating the miseries, and contributing to the happiness of the unfortunate and indigent, were limited only by the extent of his means. Though his abilities entitled him to assume an air of superiority, he never displayed that haughty and imperious tone which is commonly observable in men of shining talents, but was distinguished by uncommon modesty and humility." Moreri. Bayle.

PASCALANK, in *Geography*, a river of North Carolina, which runs into Albemarle sound, N. lat. 36° 6'. W. long. 76° 32'.

PASCALIA, in *Botany*, so named by Professor Ortega, whose work we have not at present an opportunity of consulting, but we presume the genus is designed to commemorate some botanist. Ort. Dec. 4. 39. Willd. Sp. Pl. v. 3. 2228. — Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifoliæ*, Linn. *Corymbifera*, Juss.

Gen. Ch.

Ess. Ch. Receptacle chaffy. Seeds pulpy. Down a toothed border. Calyx imbricated.

1. *P. glauca*. Ort. Dec. 4. 39. t. 4.—Native of Chili. Root perennial. Stem erect, eighteen inches high, slightly branched in the upper part only. Leaves opposite, sessile, smooth, glaucous; the lower ones ovate, with angle-like teeth, three-ribbed, veiny; the upper ones lanceolate, narrow, three-ribbed, obscurely toothed towards the base. Flowers yellow, solitary at the summits of the stem and branches. The pulpy or drupaceous seeds appear to render this genus, as Willdenow observes, very distinct.

PASCATAQUA, in *Geography*. See PISCATAQUA.

PASCHAL I. pope, in *Biography*, a Roman by birth, who flourished in the ninth century, became a presbyter of the church, and abbot of the monastery of St. Stephen. In the year 817, upon the death of pope Stephen V., he was elected his successor, by the unanimous suffrages of the senate, the clergy, and people. Immediately after his elevation to the pontifical throne, he sent his nomenclator Theodore into France, to carry the tidings of his elevation to the emperor Lewis, who sent him assurances of his protection, and conferred the grants which had been made by his father and grand-father to the holy see. No sooner was his election known in the East, than letters were sent to him from the monk Theodore Studita, and the other defenders of image worship, containing grievous but very exaggerated complaints of the persecution which they suffered from the ICONOCLASTS (see the article); and exhorting him to assemble a council for the purpose of anathematizing those heretics. This measure he refused to adopt, but sent letters to the complainants, confirming them in their adherence to their usual practice; and to comfort them under their sufferings, he assured them that to be martyrs on account of Images, was in fact to be martyrs on account of Christ; and that the same reward was reserved in heaven for those who suffered under the Image-breaking

breaking emperors, which was conferred on those who suffered under the Pagan emperors for the sake of Christ. In the year 818, Paschal built a monastery at Rome for the Greek monks who had fled from Constantinople, and the other cities of the East, rather than renounce the worship of images. In the year 823, Lotharius, the eldest son of the emperor Lewis, who had taken him for his partner in the empire, came to Rome, where he was received with every possible mark of respect and distinction, and crowned by him emperor and king of Italy. Scarcely had the monarch returned to France, when two of his adherents were cruelly murdered at Rome. Lewis instantly sent commissioners to examine if the pope were at all implicated in the transaction, but after the strictest enquiry no certain information could be obtained as to the guilt or innocence of Paschal. They, therefore, acquiesced in an offer which the pope made of declaring his innocence upon oath. He could not be persuaded to deliver the assassins, alleging that they were his servants, and, in fact, guilty of no crime, since the persons who had been put to death had long and richly deserved that punishment by their treasonable practices. The pope died in February 824, and so firmly was it believed that he was privy to the assassination which his servants had perpetrated, that the people would not allow him to be interred with his predecessors in the Vatican, and he remained unburied till his successor caused his remains to be deposited in one of the churches that he had rebuilt. Three letters that have been attributed to him are inserted in the seventh volume of the "Collectio Conciliorum;" but very considerable doubts are entertained of their genuineness. Moreri. Bower.

PASCHAL II. pope, originally called Rainerius, or Ragnerus, was a Tuscan by nation, and was educated in the monastery of Cluny, where he embraced the monastic life while he was very young. At the age of 20, he was sent by his abbot to Rome on business relating to the monastery, when Gregory VII., who was then on the pontifical throne, struck with his talents and behaviour, retained him at his court, and, in a short time, he was ordained priest, and soon after was promoted to the dignity of cardinal, with the title of St. Clement. In 1099, upon the death of pope Urban II., the cardinals, bishops, and clergy of Rome, having assembled in the church of St. Clement, determined to elect cardinal Rainerius; he wished to escape, and withdrew himself, but being discovered, he was brought back, and unanimously placed on the pontifical throne. On the following day his consecration took place, when he assumed the name of Paschal II. His first object was effectually to crush his rival Guibert, who had maintained the name of pope for nearly 20 years, and had given considerable trouble to three of his predecessors. In this the new pope soon succeeded; attempts were made to introduce other rivals, but the interest of Paschal completely prevailed, and having secure possession of the apostolical chair, he began the exercise of his pontifical office by sending legates to France to remonstrate with king Philip on account of his living in open adultery with Bertrada, the countess of Anjou, and to cut him off from the body of the church, should not admonition bring him to a sense of his duty. The legates were unable to convince the adulterers of the errors of their conduct, and accordingly excommunicated them. In the year 1101 the pope, through the interest of Anselm, archbishop of Canterbury, attempted to introduce his own unlimited power into England, and sent over Guido, archbishop of Vienne, with the character of his *legate a latere*; but when king Henry and the nation understood that he was commissioned to exercise in this kingdom the same uncontrolled power over all persons which had been displayed in other countries, they would not acknow-

ledge him, nor was he allowed to exercise any function of his office. (See ANSELM and HENRY I.) In the following year Paschal assembled a council at Rome, in which the decrees of his predecessors against investitures were confirmed, and the pope himself, with great solemnity, and in the presence of an immense multitude, pronounced the sentence of excommunication against the emperor Henry IV. This prince was afterwards glad to abdicate his throne in favour of his son Henry V. Upon the death of the former the pope held a council, in which decrees were passed which re-united the whole of Lombardy to the apostolical see, from which all that country, excepting the places held by the countess Matilda, had been separated ever since the year 1080, when it declared in favour of the antipope Guibert. By this time the pope had the mortification to find, that the new emperor was determined, equally with his predecessors, to maintain his right to investitures; the pope, therefore, to strengthen his own hands, sought an alliance with Philip of France, whom he had, some time previously to this, absolved from the sentence of excommunication. An attempt was made by Henry to terminate all differences with Paschal, but as he would not recede in the least from his claims, the object was not accomplished. In 1107 the pope presided in a council at Troyes, consisting of the bishops from many places, who proved themselves to be wholly subservient to the ambition of the court of Rome, by confirming all the decrees relating to the pretended papal right to investitures. In 1110 a compromise took place, and in the following year Henry set out for Rome, at the head of a numerous army, to be crowned. He was received with every mark of respect, but when the conditions of the treaty were to be mutually fulfilled, the German and Italian bishops present protested unanimously against parting with their estates, which they said the pope had no right to dispose of. This produced a warm altercation between the king and the pope, Paschal declaring that he would not proceed with the coronation unless the monarch immediately ratified his part of the treaty. Henry, in reply, ordered his guards to arrest the pope and all his cardinals, thinking that, by this measure, he should compel Paschal to crown him. Two of the cardinals contrived to escape in disguise, and they animated the citizens of Rome to fly to arms, to rescue their pontiff. A civil contention took place, in which the friends of the pope were repulsed with great slaughter. After Paschal had been prisoner about two months, the monarch swore, in the presence of his army, that if he did not fulfil the articles of agreement, he would put him, and all his adherents, to death. The pope was still unmoved, till the cardinals, and other prisoners, begged him to yield for their sakes, and to prevent the calamities which must otherwise fall upon the church. The articles of agreement were accordingly signed, and the monarch received a papal bull, confirming to him the right of investiture. Things being thus settled, the pope and Henry proceeded to the church of St. Peter, where the king was crowned emperor of the Romans by the pope, with the usual solemnity; soon after which that prince took his leave of his holiness and returned to Germany. Paschal's reception at Rome was highly mortifying, he was accused of having sacrificed the rights of the church, and the dignity of his station, to his own safety. He affected great contrition, and sanctioned the excommunication of the emperor. Hostilities were carried on by both parties till 1117, when Henry resolved to bring matters to a crisis, and set out a second time for Italy, at the head of a numerous army. The contests now were carried on with great violence, till the beginning of the following year, when the pope died, after a reign of about eighteen years and a half, which he

spent in incessant efforts for extending the power, and promoting the aggrandisement of the papal see. More than 100 of his letters, and some fragments of his decrees, are inserted in the 10th vol. of the Collect. Concil. Moreri. Bower.

PASCHAL III. pope, or antipope, originally known by the name of Guy de Crema, was probably a native of the city whence he derived his surname. He was promoted to the sacred college by pope Adrian IV. who sent him into Germany as legate to appease the resentment of the emperor Frederic Barbarosa, which he had provoked by his exorbitant and arrogant claims to the temporal power and authority. He was not successful in the object of his mission; on the death of Adrian, in 1159, the cardinals were divided into two parties, the greater number of whom declared the election to have fallen upon Alexander III., while the minority, in which Guy was one, gave votes for cardinal Octavian, who had long aspired to the pontificate, and was even prepared to support his pretensions by an armed force. A double election took place, and the two rivals were consecrated by their respective partizans, on which occasion Octavian assumed the name of Victor. Supported by the emperor, he retained the pontifical dignity till his death in 1164, when cardinal Guy was chosen his successor, and took the name of Paschal III. This election was confirmed by the emperor, and in 1166, Paschal was acknowledged in the character of sovereign pontiff by the bishops and princes of the empire at the diet of Wurtzburg. The Romans, however, declared for Alexander, and received him with the same honours which had been paid to his predecessors. A furious contest was excited, but at length the greater part of the Romans submitted, and acknowledged Paschal as lawful pope. He died in 1168, after he had held the title about four years. One of the chief acts which he performed in this character was the canonization of Charlemagne in the year 1165, but as the Roman church classes Paschal among the antipopes, it does not agree to the honours of sainthood which are paid to that prince.

There was another antipope of the name of Paschal, who created a schism in the Roman church in the seventh century. He held the office of archdeacon, and upon the death of Conon, in 687, aimed at the papacy, and was elected by his friends to the high dignity, but in the end he was deposed even from the more humble office of archdeacon, and shut up in a monastery, where he died in about five years.

PASCHAL, *Paschalis*, something belonging to the Jewish passover, or to the Christian Easter.

The paschal lamb was a lamb which the Jews eat with great ceremony, in memory of their having been brought out of slavery in Egypt. It should be eaten standing, their loins girt, the staff in hand.

PASCHAL Canon. See CANON.

PASCHAL Taper. See TAPER.

PASCHAL Rents, are rents or annual duties paid by the inferior clergy to the bishop, or archdeacon, at their Easter visitations.

They are also called *synodals*.

PASCHAL Letter, in *Church History*, a circular letter, which the patriarch of Alexandria first, and afterwards the pope, anciently wrote to all the metropolitans; to inform them of the day whereon the feast of Easter was to be celebrated.

PASCHASIUS-RADBERT, in *Biography*, a celebrated French monk, who flourished in the ninth century, to whose writings Protestant controversialists trace the origin of the doctrine of transubstantiation, was a native of Soissons, and being deserted in his infancy by his relations, he was brought

up by the charity of the nuns in an out-house dependent on their convent. When he had attained to manhood, he embraced the monastic life among the Benedictines of the abbey of Corbie, where he applied, with great diligence, to his studies; became distinguished in polemic conferences, and wrote several books. In 844, when he was only in deacon's orders, he was, on account of his high reputation, elected abbot, which he soon after resigned, and returned to the simple condition of monk, spending the remainder of his life in the exercises of the cloister, close study, and the composition of various books. The first work which he gave to the public was a treatise "Concerning the Sacrament of the Body and Blood of Christ," composed by him in the year 831. In this he pretended to explain the doctrine of the church on this head, maintaining that after the consecration of the bread and wine in the Lord's supper, nothing remained of these symbols, but the outward figure, under which the body and blood of Christ were really and locally present, and that the body of Christ thus present in the eucharist, was the same body that was born of the virgin, that suffered on the cross, and was raised from the dead. That this doctrine was then new, may be concluded from the great astonishment which it excited, and the general opposition which it met with from the learned men of the age. Mosheim has given an abstract of the controversy to which this publication gave rise. In the year 846, Paschasius published a treatise entitled "De Partu Virginis," intended to support an opinion propagated at that time by certain German doctors, that Jesus was born in a manner entirely different from those general laws of nature that regulate the birth of the human species. He was author of many other pieces, all which were collected and published by father Sirmond in 1618, in one volume folio. They are also to be found in the fourteenth vol. of the Bibl. Patr. Moreri. Priestley, Hist. of the Christian Church. Mosheim.

PASCHIUS, GEORGE, a learned German Lutheran divine, was the son of a tradesman at Dantzic, where he was born in the year 1661. When he had completed his studies, he travelled for further improvement in Germany, France, and England. In 1701 he obtained the appointment of professor of moral philosophy at Kiel in Holstein, and in 1706 he was nominated professor extraordinary of divinity in the same university. He died in the following year at the age of forty-six. He was author of various publications, abounding in curious and highly useful learning. His first and principal work was published in 1695, entitled "Tractatus de novis inventis, quorum accuratori Cultui Facem prætulit Antiquitas," which afterwards appeared in a new and enlarged form in 1700, under the title of "Inventorum novantiquorum." It is a work replete with profound enquiries, and calculated to exalt former times at the expense of the present. The author attempts to prove, that the knowledge of the moderns has been imperceptibly borrowed from the rich stores of ancient wisdom, and that our boasted inventions are only improvements on the discoveries of the ancients. In endeavouring to establish his point, he brought forward a number of interesting facts relating to the history and progress of the arts and sciences. One of the other works of this author was entitled "De fictis Rebus publicis," being a treatise on the imaginary republics of Plato, sir Thomas More, and Campanella. The titles of his other pieces may be found in the General Biography, to which we refer the readers.

PASCOMAYO, in *Geography*, a sea-port of Peru, in the bishopric of Truxillo, and jurisdiction of Lana, at the mouth of a river of the same name.

PASEWALK, a town of Anterior Pomerania, situated

on the Ucker, by means of which the inhabitants transport their goods to the great Haff. In its vicinity are some iron works; 21 miles W. of Old Stettin. N. lat. 53° 30'. E. long. 13° 57'.

PASH, or PASHA, in *Mythology*, is an attribute or implement of several of the deities of the Hindoos. It seems to be an implement of punishment, a whip or lash to chastize, or cord to strangle, sinners. A doubled cord is often seen in the hand of Parvati, in any of her terrific or avenging characters, and it is to such characters that the pasha is chiefly confined. (See KALI.) In Hindoo books the pasha is frequently mentioned, and it is generally distinguished by the name of the deity to whom it is attributed. Thus the Varuna-pasha is the cord of Varuna, the Hindoo Neptune. "Varuna," says Menu, "most assuredly binds the guilty in fatal cords," ch. xi. v. 308. "The Dherma-pasha, the dreadful Kalapasha, and the highly valued Varuna-pasha," are mentioned in the Ramayana, as part of the "weapons, missile and manual," with which the gods armed Rama for the war of Lanka. They severally mean the cords of Justice, of Death, and of Varuna.

PASHA. See BASHAW.

PASHAUNA BEADY, in *Natural History*, a name given by the people of the East Indies to a kind of fibrous talc, found in the sides of the mountains, and used in medicine with them. They calcine it, and then powder and boil it in milk, and give half a dram for a dose mixed in milk, for the gravel and stone.

PASI, ANTONIO, of Bologna, in *Biography*, a disciple of Pistocche, highly extolled by the greatest masters of his time. Mancini, in his "Treatise on Singing," says that he was gifted with a taste and intelligence in the art of singing which were wonderful. To a very simple method, and a clear and dignified *portamento*, or carriage of his voice, he was the first who united those little licences which produce the greatest effects. By this art his style became extremely singular and piquant. But he had then and since many bad imitators, who abused the art of which he was the original, and by a redundancy of ornaments so disguised and disfigured the melody, that it became wholly unintelligible. Yet, from the ambition of shining by variations and heterogeneous ornaments, they lost the true expression of that melody which was thought so essential to music, which was the boast of the end of the 17th century, and the beginning of the next; but it is to be feared that it has not since been found.

PASICANA, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

PASIDIUM, a town of Asia, in Syria, situated on the sea-coast, W. of mount Casius.

PASIGA, in *Geography*, a river which rises in the province of Darien, and runs into the bay of Panama.

PASIGRAPHY, in *Literary History*, the art of universal writing. This art was suggested by lord Bacon in his "Instrument of Discourse;" where he says, "it is possible to invent such signs for the communication of our thoughts, that people of different languages may, by this means, understand each other; and that each may read immediately, in his own language, a book which shall be written in another." Lord Bacon did not think, however, of confining this, as citizen Memieux has lately proposed to do, to 12 characters, which may be learned in 12 hours; on the contrary, he requires a great number, at least as many as the number of radical words; on which head he quotes the example of the Chinese; "and although," he adds, "our alphabet may appear more commodious than this method of writing, the thing itself is nevertheless well deserving of attention. The problem relates to the signs by which thoughts may be rendered

current; and as money may be struck of other materials as well as of gold and silver, it is possible likewise to discover other signs of things as well as letters and words." Des Cartes, in his third letter to father Merfennus, discusses the invention of a Frenchman, whom he does not name, but who, by means of a certain language and an artificial writing, pretended to understand all the different idioms. He remarks on this subject, that it would be very possible to compose a short and convenient grammar, with general signs, which should render all foreign languages intelligible. In the year 1661, John Joachim Becher published a Latin folio, entitled "Characters for the Universal Knowledge of Languages; a Steganographic Invention hitherto unheard of." This was in effect paligraphy; or a method of making one's self understood by all foreigners by writing in one's own language, and also of comprehending what they write in theirs. Becher, being the first who gave a complete treatise on this art, may be considered as the inventor. He begins his work by a set of very delicate and highly interesting observations upon general grammar, and the fundamental relations of all languages with regard to each other. He gives a learned comparative table of the relations and harmony of the Latin, the Greek, the Hebrew, the Arabian, the Slavonian, the French, and the German. This work cannot be too highly esteemed, and assuredly was not unknown to the author of the work "Du Monde Primitif." A Latin dictionary then follows, in which every word corresponds with one or more Arabic numeral figures arbitrarily taken. Every number is assumed as distinctive, or denoting the same word in all languages; and consequently nothing more is required than to compose a dictionary for each, similar to that which he has given for the Latin. There is likewise a table of declensions and conjugations, which presents certain determinate numbers for all the cases, moods, tenses, or persons. By means of this general disposition, when a Frenchman is desirous of writing to a German the following phrase, *La guerre est un grand mal* (war is a great evil), he seeks in his index, *guerre, être, grand, mal*; and he writes the correspondent numbers,

13, 33, 67, 68.

The sentence might be understood by these four characteristic numbers; but to leave no room for ambiguity, he says, *Guerre* is the nominative case, and finds, as the characteristic of the nominative, the Arabic figure 1. *Est* is the third person singular of the indicative mode, present tense, of which the characteristic is 15. To *grand*, and to *mal*, belong likewise the figure 1, for the nominative case; he will therefore write

13.1 | 33.15 | 67.1 | 68.1

where the numbers are separated by small vertical bars to prevent confusion. It may easily be conceived how, by the inverse method, the German will find in his tables the words denoted by the cyphers, which will form *Der krieg ist ein grosses uebel*.

This invention of Becher, which is the same thing nearly with regard to language, as algebra is to arithmetic, could not have cost him any great effort of the imagination; and it evidently reduces itself, as is the case with regard to all paligraphy, to the learning a new language, or having a dictionary at hand for use. It is besides possessed of considerable simplicity, and even a few hours practice will render it easy. If any reader should be curious to see more applications of this kind, he may have recourse to the Latin work of Sturmius, "Essais d'Expériences curieuses," probably the "Collegium experimentale, five curiosum, &c. Joannis Christophori Sturmii," 4to. Norimberg, 1701.

In the same year George Dalgarme, an Englishman, published at London, a work of which the prolix title is sufficient to shew its object. It is "The Art of Signs, or an Universal Character and Philosophical Language, by means of which, Men of the most different Idioms may, in the Space of two Weeks, learn to communicate, whether by Word of Mouth or by Writing, all their Thoughts, as clearly as in their Mother Tongue. Besides which, young Persons may therein learn the Principles of Philosophy, and the Practice of true Logic, more speedily and more readily than in the ordinary philosophic Writings." The book of Dalgarme is written in Latin. Beckmann accuses him of extreme pedantry. His characters likewise were cyphers.

Joachim Frisichius, professor at the Gymnasium at Riga, was employed on a similar attempt, namely, to introduce a natural, rational, and universal language, of which some sheets printed at Thorn in 1681 may give an idea. The death of the author interrupted his labours. He purposed to call his new language Ludovicean, in honour of Louis XIV. under whose patronage he pursued his labours; a prince who extended his generosity to the learned of all countries.

The curious in researches of this nature may also find a project of this kind in a folio volume published at Rome in 1665, by the celebrated mathematician Athanasius Kircher, the title of which is, "A New and Universal Polygraphia, deduced from the Art of Combination;" and by means of which, says Morhoff (*Polyhistor*. l. ii. c. 5.), he who understands one single language only may correspond in writing with all the nations of the earth.

It would be perhaps unjust to pass in silence the little-known work of father Besnier, Jesuit, who, in a book entitled "La Réunion des Langues, ou l'Art de les apprendre toutes par une seule," that is, The Union of Languages, or Art of learning all Languages by one alone, printed at Paris in 1674, has given several intimations which lead directly to pagigraphy.

The most remarkable work of all which has been written on this subject is, perhaps, that for which we are indebted to bishop Wilkins, the brother-in-law of Cromwell. It is entitled "An Essay towards a Real Character and a Philosophical Language," London 1668. It is divided into four parts. I. Considerations on the various languages, their defects and imperfections, from which a philosophical language ought to be exempt. II. Philosophical enquiries respecting all the things and notions to which proper names ought to be assigned. III. The organic science of native grammar considered as the necessary means of representing simple ideas in discourse. IV. The application of the general rules to every character and language. Examples, &c. This concise outline sufficiently shews the importance of the work.

In his appendix, the author explains the utility of a method of writing without alphabetic characters, by means of signs, which are to be used to denote all the principal ideas, the relative attributes being designated by small strokes added at right, acute, or obtuse angles, to the right or left, &c. Of principal or chief ideas he admits but forty, under which he ranges all the others, by that means forming a kind of categories. His new language is calculated to afford great facility of comprehension, and new openings to the reasoning processes of science. A learner might make more progress in it in a month, than in the Latin in several years. The Chinese writing, which is a very complicated pagigraphy, has given two learned men the idea of forming one upon a more simple plan. The first is Caramuel, in his "Apparat Philosophique," p. 128; and the other Andrew Muller Grieffenbag, in his "Clé Chinoise." The latter promised to teach

to women and children, in the course of a few days, a kind of writing by which all the several languages should be rendered intelligible to them.

After so many attempts more or less philosophical, and of different degrees of perfection, with others probably of which we know nothing, we must not overlook the efforts of the celebrated Leibnitz for the introduction of a pagigraphy. His history and development of a characteristic universal language is in every library. Leibnitz exhibited, and with reason, his universal characteristic as the art of inventing and judging. He was convinced that an alphabet might be formed, and of this alphabet such words as would afford a language capable of giving mathematical precision to all the sciences. "Men may thus acquire," says he, "as it were a new organ, which would add energy to their moral faculties, as the microscopic lens increases the power of the eye. The compass is not more highly valuable to the navigator, than this philosophical language would be to him who embarks on the sea of reason and experiment, which is now so full of danger."

We must not forget the ingenious method of the abbé de l'Épée, who, by means of the same identical gestures, dictated to his deaf and dumb pupils certain discourses, which they wrote with equal readiness in four languages. Nothing can more assuredly resemble a true pagigraphy than these gestures.

The abbé de Condillac, a subtle metaphysician, particularly with regard to human language, has not neglected signs and characters. In his "Art of Thinking" (*Art de Penser*), in his "Art of Writing" (*Art d'Ecrire*), and more particularly in his "Logic," he has shewn the advantages of a philosophical language, which should proceed perfectly in the order of the ideas, and of which the signs should be the most simple and analytical. He expressly reduces the study of all the sciences to that of a well constructed language, and quotes, as an example, algebra in the mathematical sciences. Nicholson's *Journal*, vol. ii. or Anderson, on an Universal Character. Dr. Brown's Hints on the Establishment of an universal written character. See CHARACTERS, LANGUAGE, and WRITING.

PASIN, in *Geography*. See BADKIS.

PASIPEDA, in *Ancient Geography*, a town of India, on the bank of the Ganges, and on this side of it, between Pisca and Suficana. Ptolemy.

PASIRIS, a town of European Sarmatia, on the bank of the river Carcinite, between Torocca and Hercabum. Ptolemy.

PASITIGRIS, a name given to the junction of the Euphrates and Tigris, at the mouth of the Persian gulf.

PASKA, in *Geography*, a town of Africa, in the kingdom of Fonia, in which the king keeps a garrison of 100 men. The town is surrounded with palisades, and contains about 100 inhabitants.

PASKARETI, a town of Mingrelia; 20 miles N.N.E. of Anarghia.

PASKATAQUES, a large branch of Penobscot river, on its W. side, which waters more than 50 miles, and receives 10 tributary streams.

PASKAU, a town of Moravia, in the circle of Prerau; eight miles E. of New Titschein.

PASLAKEN, a town of Prussia, in Bartenland; 10 miles S.E. of Bartenlein.

PASMAN, an island of the Adriatic, near the coast of Dalmatia, 15 miles long, and two broad, which contains seven villages, and produces wine and oil in abundance. N. lat. 44° 8'. E. long. 15° 56'.

PASO FERREIRA, a town of South America, in the government of Buenos Ayres; 340 miles N.N.W. of Buenos Ayres.

PASO de Pefcado, a town of South America, in the province of Tucuman; 50 miles N. of St. Miguel de Tucuman.

PASOLATO, a river of Sicily, which runs into the sea, on the south coast, N. lat. 36° 49'. E. long. 13° 32'.

PASOMDSO, a lake of Thibet, about 50 miles in circumference. N. lat. 29° 42'. E. long. 94° 24'.

PASPALUM, in *Botany*, apparently so called from *πασπαλη*, an ancient name for Millet, which kind of grain this grass resembles in the appearance of its small round seeds; see *Panicum italicum*. *Πασπαλη*, or *πικιπαλη*, is also a name for any fine meal or flour, as Professor Martyn remarks. Linn. Gen. 32. Schreb. 46. Willd. Sp. Pl. v. 1. 330. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 138. Brown Prodr. Nov. Holl. v. 1. 188. Juss. 29. Lamarek Illustr. t. 43. Gærtn. t. 80. Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. Cal. Glume of two membranous, equal, almost orbicular, slightly concave valves, containing one floret; the inner one flattest, turned from the dilated unilateral receptacle. Cor. of two roundish, cartilaginous valves, the size of the calyx, externally convex, inflexed at the base. Nectary of two membranous scales at the base of the germen. Stam. Filaments three, capillary, the length of the calyx; anthers ovate. Pist. Germen superior, roundish; styles two, capillary, the length of the corolla; stigmas pencil-shaped, hairy, coloured. Peric. none, except the permanent closed glumes. Seed solitary, roundish, compressed, convex at one side, coated by the permanent cartilaginous corolla.

Eff. Ch. Calyx of two valves, nearly orbicular, single-flowered. Corolla of the same size and shape, compressed. Stigmas pencil-shaped. Seed coated with the hardened corolla. Common receptacle unilateral.

Obs. Mr. Brown remarks, that this genus is very closely related to *Panicum*, inasmuch that if, in those species of the latter which have an unilateral spike, the outer valve of the calyx be suppressed, it makes a real *Paspalum*. Such a defect does, according to this botanist, actually take place in some few, in which, however, either the nectariferous scales, as Linnæus thought them, or a very minute valve within the inner valve of the calyx, do indeed sometimes occur; but so likewise is a small valve, on the outside of the least convex valve of the corolla, sometimes observable, says Mr. Brown, in *Paspalum orbiculare*. There is a peculiar aspect of neatness, arising from the more or less perfectly orbicular form, and regular arrangement, of the flowers, which characterises the genus before us.

Linnæus at first referred such of its species as he knew, to *Panicum*, but in Syft. Nat. ed. 10. v. 2. 1359, he gives the generic character of *Paspalum* at length, for the first time, enumerating four species in p. 855 of the same volume, which were all he then knew. He subsequently, as we shall find, confused the history of the first of them, *dimidiatum*, in such a manner, that it could not be developed, but by investigation of his specimens and manuscripts. He erred at first in considering the genus as *dianthous*, but this is corrected in his *Species Plantarum*. The history of the species has hitherto been so imperfectly detailed, that we shall attempt a more ample, if not a complete one.

1. *P. dissectum*. Linn. Sp. Pl. ed. 2. 81. (*P. dimidiatum*; Syft. Nat. ed. 10. v. 2. 855. *Panicum dissectum*; Sp. Pl. ed. 1. 57. *Gramen panicum, spicâ simplicî, ad caulem intervallatâ, binis granorum ordinibus uno versu*

constante; Pluk. Mant. 9. Phyt. t. 350. f. 2.)—Spikes alternate, sessile, with a leafy, broad, rough-edged receptacle. Flowers smooth, slightly elliptical, three-ribbed. Leaves smooth. Stipula membranous, beardless.—Native of North America; sent to Linnæus by Kalm. Stem leafy, bent at the joints. Leaves linear-lanceolate, smooth, striated, a little rough at the edges, with long, rather tumid, smooth sheaths. Stipula membranous, jagged, unaccompanied by any hairs or bristles. Spikes three or four on the upper part of the stem, which scarcely rises above the leaves, each rather more than an inch long. Common stalk, or receptacle, of each spike much dilated, linear, exactly even, leafy, striated, rough-edged, one-eighth of an inch, or more, in breadth, having at its inner side a strong, angular, longitudinal rib, bearing numerous, alternate flowers, in two rows, on short stalks. The calyx-glumes are exactly but broadly elliptical, rather tumid, pale, with three fine green ribs, perfectly smooth and naked. Perhaps this may be *P. membranaceum* of Walter, Fl. Carolin. 75.

2. *P. setaceum*. Michaux Boreal-Amer. v. 1. 43.—Spikes one or two, on long straight stalks, with a narrow wavy receptacle. Flowers mostly in pairs, on short, winged, divided partial stalks, slightly obovate, smooth, scarcely ribbed. Leaves downy above. Stipula hairy. Sent from Lancaster, Pennsylvania, by the Rev. Dr. Muhlenberg. We at first confounded it with the former, but on examination it proves abundantly distinct, and answers well to the character in Michaux. The stem is erect, slender and smooth, terminated by one spike, two inches long, on a slender, stiff, naked stalk, many inches in length, whose base is folded by the very long sheath of the upper leaf, from which often proceeds another similar, but shorter-stalked, spike. The upper leaf, at least, is much shorter than its sheath, lanceolate, clothed above with soft hairs. Michaux says his plant grows in dry situations in South Carolina.

3. *P. debile*. Michaux *ibid.* 44.—“Stem weak, brittle-like at the top. Leaves hairy. Spike mostly solitary, slender. Flowers solitary, alternate, slightly downy, slightly obovate.”—Native of maritime situations, in Carolina and Georgia. This seems by Michaux’s character, which is all we know of it, to be akin to the last.

4. *P. conjugatum*. Bergius in Act. Helvet. v. 7. 120. t. 8. Willd. n. 12. Swartz Ind. Occ. v. 1. 133. (*P. dissectum*; Linn. Syft. Nat. ed. 12. v. 2. 86.)—Spikes two, terminal, equal, nearly sessile. Receptacle narrow, even, with a wavy rib. Flowers solitary, very numerous, alternate, imbricated, ovate, acute, ribless, fringed with long soft hairs. Common in the West Indies, in moist pastures. Linnæus obtained a specimen from Browne’s herbarium, which he confounded with the first species, though nothing can be more distinct. Hence the specific character of *P. dissectum* became corrupted in his Syft. Veg. which Willdenow has copied. The description however in the last-named author, copied from Sp. Pl. ed. 2, is right, except the downiness of the leaves. *P. conjugatum* is a larger species than any of the foregoing, with broad, taper-pointed, often downy leaves. Stipula hairy. Spikes two, on a level at the top of the stem, nearly sessile, slender, a little divaricated, each nearly four inches long, of innumerable, crowded, alternate, small, yellowish, ovate, acute flowers, each on a short stalk; their calyx ribless, remarkably fringed with long, lax, white hairs. One of our specimens bears a third spike, an inch below the others. Swartz says this is called, in the West Indies, Sour grass, and is not eaten by cattle.

5. *P. ciliatifolium*. Mich. Boreal-Amer. v. 1. 44.—“Leaves dilated, downy, finely serrated, fringed. Spikes one or two, terminal, elongated. Flowers in pairs, somewhat obovate,

PASPALUM.

vate, very obtuse, smooth, forming three rows.—Native of Carolina. *Michaux.* This seems akin to the last.

6. *P. praecox.* Walt. Carolin. 75. Mich. *ibid.* 44.—“Erect, smooth. Leaves linear, elongated. Spikes alternate, remote. Flowers short, obovate, even and smooth.”—Native of North America, from Carolina to Florida. *Michaux.*

7. *P. leve.* Mich. *ibid.* 44.—“Erect, very smooth. Leaves shortish; with compressed sheaths. Spikes several, alternate. Flowers in two ranks, ovate, somewhat orbicular, even and smooth.”—Native of Georgia. *Michaux.* We have adopted these three species from *Michaux*, that they might be recorded in a general view of the genus, though we are unacquainted with them. It seems the North American *Paspala* are but incompletely known; nor can we, by the above short, and far from scientific definitions, refer these to any in *Linnæus* or *Willdenow*. Two others, in the same predicament, will be noticed hereafter, among the species to which they may be presumed most nearly to belong.

8. *P. serobiculatum.* Linn. Mant. 29. Willd. n. 2. Ait. n. 1. Houtt. Nat. Hist. v. 13. 165. t. 89. f. 3. *Dryandr.*—Spikes alternate, with a leafy, broad, rough-edged receptacle. Flowers alternate, orbicular, on simple dilated stalks, many-ribbed, dimpled at the base externally.—Native of the East Indies, in watery places. Root perennial, of many long, blackish, branched fibres. Stem one or near two feet high, clothed with ribbed, smooth leaves; having long purplish sheaths, hairy at the bottom. Spikes few and distant; their receptacle flat, near a quarter of an inch wide, minutely fringed. Flowers not unlike hemp seed in size and aspect, very numerous, alternate, imbricated in two rows, each on a short, dilated, close-pressed partial stalk, and very nearly orbicular, tumid, smooth and naked, with numerous ribs near the margin, remote from the central one, the flatter valve of the calyx marked with a pair of depressions at the base.

9. *P. polyflachyum.* Brown n. 1.—“Spikes numerous, crowded. Flowers smooth, orbicular. Outer valve of the calyx five-ribbed. Leaves flat, smooth, with a thin finely-toothed margin.”—Gathered by Mr. Brown, in the tropical part of New Holland. This species is described by him as too nearly related to the last, except that the dimples in the base of the calyx are wanting. We have perceived that character to be doubtful or variable in various specimens of *P. serobiculatum*.

10. *P. villosum.* Thunb. Jap. 45. t. 8. Willd. n. 3.—Spikes alternate, with a hairy receptacle. Flowers alternate, elliptical, three-ribbed, villous.—Found by Thunberg, near Nagasaki in Japan, flowering in July. Stem three feet high, smooth. Leaves roughish to the touch, striated, naked. Spikes about three or four, inclining all one way. Flowers crowded, in two rows only, about the size of *P. serobiculatum*, but more oblong, and hairy. The receptacle is narrow, very hairy like the top of the stem. We have seen no specimen.

11. *P. virgatum.* Linn. Sp. Pl. 81. Willd. n. 4. (*Gramen dactylon majus, paniculâ longâ, spicis plurimis nudis crassis*; Sloane Jam. v. 1. 112. t. 69. f. 1.)—Spikes rather numerous, alternate, hairy at the base. Flowers in pairs, somewhat obovate. The tumid valve of the calyx fringed. Native of meadows in Jamaica. Perennial. About the size of *P. serobiculatum*, but differing in having smaller, obovate, fringed flowers, which being disposed in pairs along the narrow wavy receptacle, make four rows instead of two; each glume has a central rib, with a marginal one at each side, and the concave one is finely fringed in the upper part.

12. *P. floridanum.* Mich. Boreal-Amer. v. 1. 44.—“Erect. Lower leaves hairy; upper ones smooth, with long sheaths, upright. Spikes few, erect. Flowers in two rows, nearly orbicular, smooth, naked.”—Native of Florida and Georgia. This, says *Michaux*, is akin to *P. virgatum* of *Linnæus*. We know nothing of it but from the above character, which is essentially different in almost every point from the *virgatum*. *Michaux* adds that the flowers are rather large. We subjoin the only remaining species of that author, not knowing where else to place it.

13. *P. plicatum.* Mich. *ibid.* 44.—“Erect, very smooth and naked. Leaves elongated. Spikes numerous, alternate, upright. Flowers in three rows, short, ovate, naked. The flatter valve of the calyx transversely corrugated at the margin.”—Native of Georgia and Florida. The leaves are narrow. Flowers somewhat reddish.

14. *P. panicum.*—Spikes very numerous, crowded, hairy at the base. Flowers in four rows, orbicular, even and naked.—Gathered in Jamaica by W. Wright, M.D.—A very fine and handsome species, whose dense and very numerous spikes, crowded together into one common spike, a foot long, give, with their copious little round flowers and seeds, some idea of *Panicum italicum*, except that the whole is erect and unilateral. The leaves are long, near two inches broad in some parts, tapering to a rough-edged point, but otherwise very smooth to the touch, and finely ribbed. Each partial spike is two inches, or more, in length, with a flat rather narrow receptacle, bearing a few scattered hairs throughout, and very hairy at its base. Flowers disposed in four rows, on shortish capillary stalks, about the size of *Panicum italicum*, almost perfectly orbicular, of a light tawny hue, the calyx-valves even and smooth, each with a central rib, but no others, except at the very edge. This grass was formerly known in the Banksian herbarium, by the expressive name of *Paspalum polyflachyum*; now appropriated by Mr. Brown to our 9th species, which, from his description, must be very unlike the present.

15. *P. paniculatum.* Linn. Sp. Pl. 81. Willd. n. 5. Ait. n. 2. (*Gramen miliaceum, paniculâ viridi vel purpureâ*; Sloane Jam. v. 1. 115. t. 72. f. 2.)—Spikes numerous, crowded, somewhat whorled, spreading every way, hairy at the base. Flowers in alternate pairs, orbicular, even, slightly hairy.—Receptacle very narrow.—Sloane says this grows in several plantations in Jamaica, on a moist clay soil. The leaves are an inch wide, hairy on their upper side, as well as about the stipula on both sides; their sheaths long, smooth, ribbed. Common spike a span long, composed of numerous narrow spikes, two inches or more in length, partly scattered, partly whorled, spreading every way, each with an extremely narrow, though slightly winged, receptacle. Flowers numerous, small, rather loosely disposed in alternate pairs, on twin or combined stalks; their glumes very nearly orbicular, obtuse, somewhat hairy, single-ribbed.—Such is the genuine plant of Sloane and *Linnæus*; though the latter had in his herbarium another specimen, from which the particular description in *Sp. Pl.* was taken, but which is a very distinct species; see the following.

16. *P. repens.* Bergius in Act. Helvet. v. 7. 129. t. 7. Willd. n. 7. (*P. paniculatum*; Linn. Sp. Pl. 81, as to the description only.)—Spikes numerous, crowded, somewhat whorled, spreading every way, naked at the base. Flowers alternate, elliptical, acute. Leaves and receptacle rough.—Native of Surinam, according to Bergius, who describes the stem a foot or more in length, striated, smooth, jointed, leafy, creeping by means of fibrous roots thrown out at the joints. Leaves linear-lanceolate, acute, scarcely a finger's length, striated, downy, dark green, with a sheathing base, which

PASPALUM.

which in his figure and description is represented as flying off from the stem, probably in consequence of drying or pressure; the upper sheaths are smooth, the lower roughish, with minute points. *Stipula* oblong, membranous, lacerated, abrupt. *Spikes* numerous, slender, drooping, an inch or two long, the upper ones whorled, the lower opposite. *Receptacle* linear, broad, taper-pointed, leafy, roughish, dark green. *Flowers* ranged alternately, but solitarily and not in pairs, each on a short stalk. Their form is ovate, or rather elliptical, pointed, by no means orbicular; the larger valve convex, and in our specimen downy; the smaller concave and smooth, with a pair of minute, parallel, close-pressed, reddish, lanceolate scales at its base, which perhaps invalidate the generic character, even more than the shape of the glumes. (See PANICUM.) Whether they are the rudiments of abortive florets we presume not to determine. Our specimen, to which no place of growth is attached, is much more luxuriant than what Bergius has drawn, but has only an upper leaf. The *spikes* are for the most part above two inches long, half-whorled, spreading in every direction. There are none of the bristly hairs about the *stipula*, seen in *P. paniculatum*, nor are there any such hairs below the *spikes*, except a very few minute ones to the lowermost of all. The *stipula* is externally downy.

17. *P. stoloniferum*. Bosc. Tr. of Linn. Soc. v. 2. 83. t. 16. Willd. n. 6. Ait. n. 3. (*P. racemosum*; Jacq. Ic. Rar. t. 302.)—*Spikes* very numerous, crowded, racemose. *Flowers* alternate, elliptical, pointed, transversely corrugated, overtopping the lanceolate pointless receptacle.—Native of Peru, where it is commonly known by the name of *Alzaillo*. We received seeds from Mr. Bosc in 1791, from which plants were raised by Mr. Hoy, in Sion gardens. Sir Joseph Banks sent this species to Kew in 1794, where it is kept in the stove, flowering in July and August. This is a very handsome perennial grass, whose stem is branched, two feet high, leafy, smooth, procumbent at the base, and throwing out roots from the joints. *Leaves* broad, almost ovate at the base, from four to six inches long, acute, smooth, many-ribbed, rough-edged; their *sheaths* close, long, and smooth. *Stipula* short, membranous, without hairs. *Common spike* near a span long, elegantly variegated with purple, green and white; *partial* ones numerous, crowded, scattered or partly whorled, each scarcely an inch long, supported by a short downy stalk. *Receptacle* lanceolate, broad, wavy, rough-edged, green and leafy, without any taper point. *Flowers* from eight or ten to twenty in each spike, alternate, imbricated in two rows, elliptical with a small point; the margins, of the flatter calyx-valve more especially, strongly corrugated and crenate.

18. *P. corymbosum*.—*Spikes* several, alternate, corymbose; the lower ones longest. *Flowers* alternate, nearly orbicular, smooth, almost sessile. *Receptacle* wavy. *Leaves* and *sheaths* hairy.—Gathered by Dr. Afzelius at Sierra Leone. The lower part of the stem is decumbent, and bent at the joints; the rest erect, leafy, about 18 inches high. *Leaves* rather narrow, sharp-pointed, clothed on both sides with soft hairs. The *sheaths* are hairy likewise, especially at the upper part. *Stipula* chiefly composed of long hairs. *Spikes* about five, crowded near together at the top of the stem, alternate, spreading every way; the lowest two inches and a half long, the rest gradually shorter, so that all are about level at the summit. *Receptacle* linear, but rather narrow, wavy, smooth, except at the edge. *Flowers* very numerous, imbricated in two rows, nearly orbicular, smooth, single-ribbed, so gibbous as to be almost hemispherical, on short smooth stalks.

19. *P. orbiculare*. Forst. Prodr. 7. Brown n. 2.—*Spikes* alternate, distinct, bristly at the base. *Flowers* alternate, nearly orbicular, smooth; their outer glume three-

ribbed. *Leaves* flat; thickened and toothed at the margin.—Gathered by Forster in the Society islands; by Mr. Brown in the tropical part of New Holland, as well as near Port Jackson. We have seen no specimen of this or the next.

20. *P. pubescens*. Brown n. 3.—“*Spikes* alternate, distinct, sessile. *Flowers* ovate, downy; their outer glume three-ribbed. *Leaves* flat, hairy, and rough above, thickened and toothed at their margin.”—Gathered by Mr. Brown, in the tropical part of New Holland.

21. *P. littorale*. Brown n. 4.—*Spikes* two or three, alternate, downy at the base. *Flowers* ovate, acute, smooth. *Leaves* involute, naked. *Stem* compressed.—Found by Mr. Brown in the tropical regions of New Holland, as well as near Port Jackson. We have specimens, gathered by Dr. White at the last-mentioned place, which answer to Mr. Brown's definition, except that though in some of them the *spikes* are only two, one elevated above the other, in others they are three, ranged alternately along the angular top of the stem. Each stands on a very short downy stalk. The *receptacle* is leafy, wavy, rather narrow, one inch and a half or two inches long, smooth, except the edges. *Flowers* large, imbricated in two rows, projecting much beyond the receptacle, on short, smooth, compressed stalks.

22. *P. hirsutum*. Retz. Obf. fasc. 2. 7. Willd. n. 8.—*Spikes* about two, alternate. *Flowers* many-nerved, smooth. *Leaves*, *sheaths*, *stem*, and partial flower-stalks hairy.—Sent from China by Bladh. The stems are erect, leafy, hairy in their upper part. *Leaves* flat, ribbed, hairy all over, as well as their *sheaths*, which are bearded at the top. *Spikes* nearly erect, alternate, two only in Retz's specimen, their *receptacles* leafy, narrower than in *P. serobiculatum*. *Flowers* in two rows, alternate, smooth, with three or five ribs, on hairy stalks. Retz.

Willdenow by mistake copies from Retz's *spicis subbinatis*, (placed in pairs) for *subbinis*; an important difference.

23. *P. Kora*. Willd. n. 9, excluding Forster's Syn.—*Spikes* two or three, alternate, hairy at the base. *Flowers* orbicular, smooth, five-ribbed. *Stem* and *leaves* smooth. *Stipula* hairy.—Native of the East Indies. Sent from Tranquebar, by the Rev. Dr. Rottler. The stem is branched, decumbent in the lower part, smooth, as are the leaves and their *sheaths*. *Stipula* membranous, short, accompanied by a few long hairs. *Spikes* two or three, alternate, one and a half or two inches long, of numerous, alternate, crowded, nearly orbicular flowers, half as large as *P. serobiculatum*, on very short partial stalks. *Receptacle* leafy, narrow, straight and even, scarcely zigzag, except its midrib.

24. *P. distichum*. Linn. Sp. Pl. 82. Willd. n. 11. Ait. n. 4. Swartz. Obf. 35. t. 2. f. 1. (Gramen dactylon bicorne repens, foliis latis brevibus; Sloane Jam. v. 1. 112.)—*Spikes* two or three, alternate. *Flowers* ovate, acute, smooth, three-ribbed. *Receptacle* straight. *Leaves* smooth, as well as the stem. *Stipula* hairy.—Native of rather moist grassy pastures in the West Indies. The stem is simple, near two feet high, decumbent at the base, very smooth. *Leaves* flat, according to Swartz; involute when dry, taper-pointed, smooth; with long smooth *sheaths*, crowned with a hairy *stipula*, and not (as Swartz says) hairy at the base. *Spikes* usually two, one above the other, sometimes three, approximated, but really alternate, one inch and a half long, with a linear, even, straight, flat, smooth, rather glaucous *receptacle*. *Flowers* twenty or thirty, alternate, crowded, nearly sessile, ovate, acute, pale, concave on the outside, with three ribs. *Anthers* dark purple. *Stigmas* blue.

25. *P. longiflorum*. Retz. Obf. Fasc. 4. 15. Willd. n. 10.—*Spikes* two, terminal, equal, on short stalks.

Flowers

Flowers ovate, pointed, smooth, three-ribbed. Receptacle zigzag. Root creeping. Stems erect. Leaves smooth. *Stipula* hairy.—Native of the East Indies. Sent from Tranquebar, by the Rev. Dr. Rottler. This has a long creeping root, like *Carex arenaria*, throwing up, like that, many stems, hardly a span high, slender, smooth, leafy, rarely branched. Leaves smooth, narrow, acute, spreading, with long smooth sheaths, crowned with a short *stipula* beset with brittle hairs. Spikes two, an inch long, on a level at the top of the stem, first erect, then divaricated, each on a smooth, short, tapering stalk. Receptacle zigzag, smooth, with a zigzag furrow. Flowers ten or twenty, situated and shaped nearly as in the last, but rather more elongated and more pointed, slightly convex rather than concave at the back. Willdenow says it has sometimes three spikes, but he neglects to inform us how they are, in that case, situated. We have never seen more than two, always on stalks of equal length, springing from one point, which is not the case with the *distichum*.—The habit and aspect of this grass resemble *Panicum Daëylon*; and it appears destined, like that, to grow in loose blowing sand, which the many-branched fibres of its roots are calculated to bind together and to fix, thus performing a very important service in the economy of nature.

26. *P. vaginatum*. Swartz Ind. Occ. v. 1. 135. Willd. n. 13.—Spikes two, terminal, equal, on short stalks. Flowers ovate, pointed, smooth. Receptacle somewhat zigzag. Stem creeping, bent at the joints, branched. *Stipula* hairy.—Native of pastures, on a clay soil, in Jamaica. Swartz. By his description, which is our only source of information concerning this species, it comes very near the last in technical characters, except that it does not seem to have the same long creeping roots, and numerous, mostly simple, stems. He describes the roots as numerous and thread-shaped. Stem a foot high, creeping, bent at the joints, and subdivided. Leaves nearly linear, acute, spreading, with broad, compressed, two-ranked, striated, smooth sheaths, crowned with hairs. Spikes an inch long, spreading. The rest of his description we have compared with the last, in order to compile a specific character. Had we specimens of both, more differences might appear.

27. *P. filiforme*. Swartz. *ibid.* 136. Willd. n. 14.—Spike mostly solitary, linear, very slender. Flowers very numerous, on short stalks, elliptical, three-ribbed. Leaves brittle-shaped, channelled. Common in dry open fields in the West Indies. Communicated by Dr. Swartz. This species is known from all the rest by its extremely slender habit. It is two feet high, and grows in tufts. The stem is quite smooth, almost capillary, but rigid and erect. Leaves long, straight, almost equally slender; convex and smooth beneath; channelled above; with long close sheaths, hairy at the top. Spike two or three inches long, with a very narrow, slightly zigzag receptacle, covered on one side with a double row of closely imbricated, small, smooth, elliptical flowers. Anthers yellow. Stigmas bluish.

28. *P. decumbens*. Swartz. *ibid.* 138. Willd. n. 13.—Spikes solitary, on long, capillary, solitary or aggregate stalks. Flowers nearly orbicular, pointed. Leaves ovato-lanceolate, hairy.—Gathered in dry sandy mountainous situations, on the west side of Jamaica, by Dr. Swartz, to whom we are obliged for specimens. The stems are procumbent, about a foot long, branched, leafy, slender, smooth, bent at the joints, apparently compressed, though described as cylindrical. Leaves rather broad, lanceolate, acute, ovate at the base, clothed, more or less, on both sides, with soft scattered hairs; with slightly tumid sheaths, about their own length, whose edges are thickly

fringed. *Stipula* short, membranous, jagged, hairy. Flower-stalks from one to five, from the sheaths of some of the upper leaves, rather shorter than the leaf, capillary, loosely spreading, simple, angular, downy. Spikes solitary, hardly an inch long, drooping. Flowers from sixteen to twenty, loosely imbricated, in two rows, on short stalks, slightly obovate, or very nearly orbicular, quite smooth; convex and almost hemispherical, with slight furrows, on one side; quite flat, even, and ribless on the other. This flat side is accompanied at the base with a small abrupt scale, or imperfect glume, like what Mr. Brown mentions in *P. orbiculare*; see observations after the generic character; which appears to us to bring the present species very near indeed to *Panicum*. The receptacle is narrow and convex, smooth, except at the base, by no means of the leafy dilated form usual in *Paspalum*.

We have thus added thirteen species to the fifteen in Willdenow, nor are we without suspicion of some more, which we have not sufficient materials to determine. There can be no doubt, that the greater part of the described species constitute a natural genus, which ought to be kept distinct from *Panicum*, whatever may become of some ambiguous ones; especially as *Panicum* itself is so overloaded with species already, and so difficult, in many cases, to define.

It is remarkable that no *Paspalum* has been found in Europe, though the species of *Panicum* are scattered all over the world. S.

PASPARDO, in *Geography*, a town of Italy, in the department of the Adda and Oglio; 4 miles N. of Breno.

PASPAYA, a town of South America, in the viceroyalty of Buenos Ayres; 60 miles S. of La Plata.

PASQUA, a town of Mexico, in the province of Xalisco, situated at the mouth of a river, which runs into the Pacific ocean; 45 miles W.N.W. of La Purification. N. lat. 20° 5'.

PASQUALI, SIGNOR, in *Biography*, an excellent performer on the violin, and a good musician, who came to England about the year 1743, went to Edinburgh in 1752, where he had an establishment, and lived much respected as a professor, and beloved as a man by all who knew him, till the time of his death in 1757. The following is extracted from the Edinburgh Caledonian Mercury of Saturday, Oct. 15th, 1757.

“Thursday, October 13th, 1757. Died at Edinburgh signior Pasquali, master of music in this city, a person eminent in his profession as a composer, performer, and teacher. He joined to a singular probity of manners, good sense, and knowledge of mankind, free from the smallest tincture of caprice. One qualification most remarkable in him was, that although he did the greatest justice as a teacher, yet he acted in his profession more from a real *delight in music*, and regard to fame, than profit or gain. Under his conduct, the spirit of this branch of the fine arts has diffused itself through all ranks, and is now carried to a degree never before known in this kingdom. Signior Pasquali's death is a public loss to this city, that will not soon be supplied.”

PASQUILINI, SIGNOR, an Italian performer on the violoncello, who arrived in England about the year 1747, and remained here till the time of his death, about 1756. He had great knowledge of the finger-board, and his execution was very neat; but his tone was thin, crude, and uninteresting. After the death of Caposale, he was the principal performer on the violoncello at the opera, at Ranelagh, and at all the great concerts. He was a good musician, and performed correctly the part assigned him; but without effect. In Dublin, when he had played half his solo, the

steward

steward of the concert for the night, not knowing that his tone was always the same, or perhaps not knowing one tone from another, went up to him, crying out with some degree of impatience, "Come, come, Pasquali, don't be flourishing all night, but begin your solo!"

PASQUARO, or UTZILA PASQUARO, in *Geography*, a town of Mexico, and present capital of Mechoacan, on the S. side of a large lake abounding in fish. The population consists of 500 families of Spaniards and Mulattoes, and 2000 families of Indians, chiefly employed in sugar-mills, and neighbouring copper-mines; 120 miles W. of Mexico. N. lat. 19° 50'.

PASQUE-FLOWER, in *Gardening*, the common name of a well-known flower. See ANEMONE.

PASQUETANK, in *Geography*, a county of North Carolina, in the district of Edenton, N. of Albemarle sound, containing 5037 inhabitants, including 1593 slaves.—Also, a small river of North Carolina, which rises in the Great Dismal Swamp, and, passing by Hertford, falls into Albemarle sound.

PASQUIER, STEPHEN, in *Biography*, a celebrated lawyer and man of letters, was born at Paris in 1528. Having been educated for the bar, he was, at a proper time, admitted an advocate in the parliament of Paris, and became distinguished as one of the most eloquent pleaders of his time, as he really was one of the most learned men of the age. He shone particularly in the causes which he pleaded against the Jesuits, who, he contended, ought not only to be excluded from the university, but banished wholly from the kingdom. He was at all times a zealous friend to the royal authority, and was rewarded by Henry III. with the post of advocate-general of the chamber of accounts, which he exercised with great credit, and transmitted to his eldest son. He died in 1615, at the great age of 87. He had been thrice married, the first time, as he says, in a Latin epigram, for enjoyment, the second for the sake of money, and the third for help. He was a considerable writer in verse and prose. His poems are in Latin and French; the former are reckoned by much the best. The most important of Pasquier's works is entitled "Recherches sur la France," of which he published seven books, and three more were given from his papers after his decease. The best edition of it is that of 1665. His letters, in five volumes, are full of curious anecdotes and remarks. His "Catechisme des Jesuites" is a very severe attack upon the founders and principles of that order. His second son Nicholas, a matter of requests, left a volume of letters abounding with historical anecdotes. Moreri.

PASQUIN, a mutilated statue, seen at Rome, in a corner of the palace of the Ursini. It takes its name from a cobbler of that city, called Pasquin, famous for his sneers and gibes; and whose shop was the resort of a number of idle people, who diverted themselves with bantering folks as they passed by.

After Pasquin's death, as they were digging up the pavement before his shop, they found a statue of an ancient gladiator, well cut, but maimed, and half spoiled. This they set up, in the place where it was found, at the corner of the deceased Pasquin's shop; and, by common consent, called it by the name of the defunct.

From that time all satires and lampoons are ascribed to this figure, and are put in its mouth, or pasted against it; as if they came from *Pasquin redivivus*. Pasquin usually addresses himself to Marforio, another statue in Rome; or Marforio to Pasquin, whom they then make reply.

The answers are usually very short, poignant, and unlucky. When Marforio is attacked, Pasquin comes to his

assistance; and Pasquin is assisted by Marforio in his turn; *i. e.* the people make the statues speak just what they please.

PASQUINADE, or PASQUIL, is properly a satirical libel, fastened to the statue of Pasquin.

Hence, by extension, the term becomes used for any satire, lampoon, or sneer upon the public, or upon the ruling powers.

There is this difference between a *pasquinade* and a *satire*; that the end of the latter is to correct and reform; whereas that of the former is only to scoff and expose.

The Italians have published several books which they call *Pasquino in estasi*, *Pasquin in an ecstasy*.

PASQUINO, ERCOLE, in *Biography*, a great organ-player at Rome, began to flourish about the year 1620, and his son, Bernardo Pasquino, the master of Gasparini, about 1672. This last was contemporary with Corelli, and frequently played in the same orchestra with him at the opera in Rome. See Paral. des Fran. et des Ital.

PASS, in *Military Language*, a straight, narrow and difficult passage, which shuts up the entrance into a country.—Also, a voucher for the absence of a non-commissioned officer or soldier.

PASS, *To*, is to march by open order of columns, for the purpose of saluting a reviewing general. Each division or company, on its march, will open its ranks at the distance of 50 paces from the general, and again close them, after it has passed thirty paces. The whole march in ordinary time, till the leading division arrives at the spot where the left of the battalion originally stood. The commanding officer then halts the regiment, the music ceases to play, and the different divisions which supported arms march in quick time until they have completed the third wheel from the ground of original formation, when arms are ordered to be carried, the music plays, and as each division completes the third wheel, the officers shift to the right, and the whole pass the general.

PASS, *All's well*, a term used by a British sentry, after he has challenged a person that comes near his post, and has given him the proper parole, watchword, or countersign.

PASS-Parole, a command or word, which is given out at the head of an army, and from thence passed from mouth to mouth, till it reach the rear.

PASS. See PASSPORT.

PASS, *Passade*, in *Fencing*, a leap, or advance upon the enemy.

Of these are several kinds; as *voluntary passes*, commencing from the left foot out of measure of the firm foot; as when the enemy is not expected.

Others, *necessary*, made after a push from the right foot; where, being to pressed by the enemy as not to have time to retire, you endeavour to seize the guard of his sword.

The measure of the pass is, when the two smalls of the swords are so near, that they may touch one another.

There are passes within, above, beneath, to the right, the left; and passes under the sword, over the line, &c.

PASS, among *Miners*, a frame of boards consisting of two or three bottom boards, and two side ones, set slopewise; through which the ore slides down into the coffer of the stamping-mill.

PASS of *Arms*, in *Chivalry*, a place which the ancient knights undertook to defend, *e. gr.* a bridge, road, &c. which was not to be passed without fighting the person who kept it.

The knights who held the pass, hung up their arms on trees, pales, columns, &c. erected for the purpose; and such as were disposed to dispute the pass, touched one of these

these armories with his sword, which was a challenge the other was obliged to accept. The vanquished gave the victor such prize as was before agreed on.

PASS-Guards, in *Ancient Tilting Armour*, were plates fixed on each shoulder, declining from the face like wings, which were intended to protect the eyes from the point of the lance: the left side of the face, the left shoulder and breast were covered by a plate called *grand-guard*.

PASSA, Uva Passu, in *Pharmacy*, a term applied to those dried grapes, which we call raisins.

Uve PASSÆ is sometimes also used, with less propriety, for figs.

PASSACAGLIO, a slow dance, resembling the chaconne; the only difference is, that it is generally somewhat slower, and more pathetic: on this account, the *passacaglii* are almost always composed in the minor keys. Brossard.

PASSACAILLE, Fr. Rousseau gives nearly the same definition; adding, that the *passacaille* of "Armida" and "d'Ifé" are famous in the operas of Lulli and Mondonville.

PASSADE, or *PASSADO*, in *Fencing*, a thrust or pass.

PASSADE is also a benevolence or alms given to poor passengers.

PASSADE, in the *Manege*, signifies a turn or course of a horse backwards or forwards on the same plot of ground, passing or repassing from one end to the other.

This cannot be performed without changing the hand, or turning and making a demi-tour at each of the extremities of the ground. Hence it is, that there are several sorts of *passades*, according to the different ways of turning, in order to part or put again, and return upon the same piste, or tread; which we call closing the *passade*.

The *passades* are the truest proofs a horse can give of his goodness. By his going off, you judge of his swiftness; by his stops, you discover the goodness or imperfection of his mouth; and by the readiness with which he turns, you are enabled to decide upon his address or grace.

A *passade of five times*, or a demivolt of five times, is a demitour made at the end of the straight line, one hip in, in five times of a gallop upon the haunches; and, at the fifth time, he ought to have closed the demivolt, and to present upon the *passade* line straight and ready to return. The demivolts of five times or periods are the most common airs of changing the hand, or turning, that are now practised.

A *perfect passade* is made in this manner: your horse standing straight and true upon all his feet, you go off with him at once, you stop him upon his haunches, and in the same time or cadence in which he made his stop, being exactly obedient to the hand and heels, he ought to make the demivolt, balancing himself upon his haunches, and so waiting, till you give him the aid to set off again. In this case it is necessary, that the least motion or hint of the rider should be an absolute command to the horse. If you would have him go off at full speed, yield your hand, and close the calves of your legs upon him: if he does not answer to this aid, give him the spurs, in such a manner as not to remove them from the place where they were, and without opening or advancing your legs before you strike.

Raised, or high passades, are those which a horse makes, when, being at the end of his line, he makes his demivolt in any air he has been taught, either in the mezoir, or in curvets. In high *passades*, let your horse go off at full speed; let your stop be followed by three curvets; let the demivolt consist of the same number, and demand of him three more before he sets off again. It is usual to make nine curvets, when you work a horse alone.

VOL. XXVI.

Furious, or violent passades, are when a horse gallops at his utmost speed straight forward, and makes his half stop, bending, and playing his haunches two or three times before he begins his demivolt, which is made upon one line in three times; for at the third time he should finish the demivolt, and be straight upon the line of the *passade*, in order to go off again and continue it. This kind of *passade* was formerly used in private combats.

Passade of one time, is a demivolt or turn, made by the horse, in one time, of his shoulders and haunches.

In all *passades* the horse should, in making the demivolt, gather and bring in his body, making his haunches accompany his shoulders, without falling back, or not going forward enough each time; and he should go in a straight line, without traversing or turning his croupe out of the line. Berenger's Horsemanship, vol. ii. chap. 15.

PASSADUNKEAG, in *Geography*, a considerable branch of Penobscot river, meandering through four townships, and affording a route by which the Indians have an inland communication with the Schooduck lakes, and other waters which flow into Passamaquoddy bay by a short portage.

PASSAGE, in *Sea Language*, denotes a voyage from one place to another by sea; an outward or homeward bound voyage.

PASSAGE Boat, a boat to carry passengers and luggage from one place to another by water.

PASSAGE, in *Commerce*, or *Right of Passage*, is an imposition, which some princes exact by their officers or farmers, in certain narrow close places of their territories, either by land or sea, on all vessels, vehicles, and carriages of all kinds; and even sometimes on persons as passengers coming in or going out of ports, &c.

The passage of the Sound (that famous streight, which carries us out of the German into the Baltic sea,) is the most celebrated passage in Europe. The dues thereof belong to the king of Denmark, and are paid at Elsinore or Cronenburg.

PASSAGE, in the *Manege*, an action, in which the horse raises two legs together, a hind and a fore-leg, in form of St. Andrew's cross; when setting those two on the ground again, he raises the other two; and thus alternately, never gaining above a foot of ground at a time.

The beauty of the passage consists in keeping the legs a good while in the air: setting that aside, the motion of the legs in the passage is the same as in pacing and trotting.

As the passage is the key which opens to us all the justness of the art of riding, and is the only means of adjusting and regulating horses in all sorts of airs, it is necessary to observe, that there are many kinds of it. In that which is derived from the trot, the action of the horse's legs is the same as in the trot; and this passage is distinguished from the trot, merely by the extreme union of the horse, and by his keeping his legs longer in the air, and lifting them both equally high, and being neither so quick nor violent as in the action of the trot. In the passage which is founded on the walk, the action of the horse is the same as in the trot, with this difference, that he lifts his fore-feet a good deal higher than his hinder; that he makes a certain time or interval sufficiently long between the motion of each leg; his action being much more together and shortened, more distinct and slow than the ordinary walk, and not so extended as in the trot, so that he is, as it were, kept together and supported upon himself. There is another sort of passage, to which the trot likewise gives birth, and in which the action is so quick, so diligent, and so supported, that the horse seems

not to advance, but to work upon the same spot of ground. No horse should be put to passage till he has been well trotted out, is supple, and has acquired some knowledge of the *union*, which see. Berenger's Horsemanship, vol. ii. chap. 10.

To passage a horse upon his own length, see LENGTH.

PASSAGE, *Passo*, Ital. in *Music*, as in literature, is a single period, or sentence, selected for praise, censure, or illustration. But in France, according to Rousseau, it is a flourish, or division in gracing a particular bar, or trait of melody. But in Italy, fingers are obliged to know how to invent passages extemporaneously upon any given notes; whereas in France, and, we fear, in England, young fingers dare not hazard a single passage that has not previously been written down and practised.

PASSAGE, *Birds of*, in *Ornithology*, are such as only come to us at certain seasons, and then disappear again; being supposed to pass the sea to some other climate.

Among the birds of passage are the stork, swallow, nightingale, martin, woodcock, quail, hooded crow, cuckoo, wry-neck, several species of the pigeon and thrush, snipe, curlew, several species of sand-piper, long-legged plover, land-rail, several species of grebe, divers, terns, mergansers, many species of ducks, &c.

Mr. Pennant remarks, that every species of the genera of curlews, woodcocks, sand-pipers, and plovers, that forsake us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed; and as soon as the young can fly, they return to us again; because the frosts which set in early in those countries, deprive them of the means of subsistence; and the dryness and hardness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills in search of worms, which are the natural food of these birds. Of the numerous species of migrating fowl, there are scarcely any that may not be traced to Lapland, a country of lakes, rivers, swamps, and alps, covered with thick and gloomy forests, that afford shelter during summer to these fowls, which in winter disperse over the greatest part of Europe. In those northern regions, by reason of the thickness of the woods, the ground remains moist and penetrable by the woodcocks, and other slender-billed fowl; and for the web-footed birds, the waters afford larvæ with numbers of the gnat. The days are long, and the light nights are favourable to their collecting this food; to which we may add, that mankind are very sparingly scattered over that vast northern waste. *British Zoology*, vol. ii. Appendix. See MIGRATION.

Beside the migratory birds, which live in different countries a whole winter, or a whole summer, there are some others which annually appear in particular places, at the time of the ripening of particular kinds of grain which their own country is destitute of; and these depart after a short stay, and are no more seen till that time the following year. Of this kind are the rice-bird, and blue-wing of Carolina. Birds, like men, pursue their searches after food, or whatever else is necessary and agreeable, through distant climes; and, when they discover some new grain, or pleasing food, they return and acquaint their community of the good fortune; and then, joining in numerous flights, make annual excursions to solace themselves on this exotic food.

Since the discovery of America, there have been introduced from Europe several sorts of grain which were before unknown there, and which, not before some length of time, were found out, and covered by birds of this migratory kind. Of this sort there is a very beautiful species, which has very lately made its first appearance in Virginia; these arrive annually at the time that the wheat is ripe, or nearly

so; and constantly, since they found it out, have appeared in great droves every year, at the season of its ripening; the inhabitants call them, for this reason, *wheat-birds*. Phil. Trans. N^o 483.

There are also fishes of passage, as herrings, mackerel, &c. See FISHERY.

PASSAGE, in *Geography*, a town of South America, in the government of Tucuman, on a river of the same name; 116 miles N. of St. Miguel de Tucuman.

PASSAGE Canal, an inlet in Prince William's sound. N. lat. 60° 48'. E. long. 212° 15'.

PASSAGE Fort, a small town of Jamaica, in the road between Port Royal and Spanish Town; 7 miles S.E. of the latter, and at the mouth of the river Cobre, where it has a fort, with ten or twelve guns. Its trade is brisk, and it contains about 400 houses, most of them being houses of entertainment.

PASSAGE Island, a small island at the entrance of a channel from the North Pacific ocean, among the Philippine islands, about 20 miles E. from the island of Leyta. N. lat. 10° 44'. E. long. 125° 27'.—Also, a small low island in the gulf of Georgia, at the entrance into Howe's sound. N. lat. 49° 21'. E. long. 237° 3'.

PASSAGE Islands, two small islands among the Virgin islands in the West Indies, near the coast of Porto Rico.

PASSAGE, Great, one of the Virgin islands in the West Indies, about seven miles long and two wide; 12 miles E. of Porto Rico.

PASSAGE, Little, one of the Virgin islands, near the former.

PASSAGES, Los, a sea-port town of Spain, in Guipuscoa, with a good harbour, sheltered by mountains, with depth of water sufficient for a 50-gun ship. This is one of the largest and safest harbours in Europe; 3 miles E. of St. Sebastian. N. lat. 43° 10'. W. long. 2°.

PASSAGE Point, a cape on the coast of Patagonia, in the straits of Magellan. S. lat. 53° 15'. W. long. 73° 40'.

PASSAGE Rocks, two rocks in Prince William's sound, one north, about 2½ miles N.N.W. from the north point of the entrance into port Chalmers, Montague's island, and the other south, half a mile W. from the same point.

PASSAGERS. See ALBIGENSES.

PASSAGIO, in the *Italian Music*. See PASSAGE.

PASSAGO, in the *Glass Trade*, the instrument with which the workman makes the bowl of the drinking-glasses, or other the like vessels.

PASSAIC, in *Geography*, a river of America, which rises in a large swamp, in Morris county, New Jersey, and pursues its course from W.N.W. to E.S.E. until it unites with the Hackinoc at the head of Newark bay, N. lat. 40° 43'. W. long. 74° 8'. The cataract, or Great Falls, in this river, is one of the principal natural curiosities in the state. The river is about 40 yards wide, and moves with a gentle current till it approaches a deep cleft in a rock which crosses the channel, and then falls above 70 feet perpendicularly, presenting a most beautiful, though tremendous, scene. The new manufacturing town of Patterson is erected on the Great Falls of this river, and its banks are adorned with many elegant country seats. It abounds with various kinds of fish. A bridge, 500 feet in length, crosses this river on the post-road from Philadelphia to New York.

PASSAIS, a town of France, in the department of the Orne, and chief place of a canton, in the district of Domfront; 6 miles S.W. from Domfront. The place contains 2224, and the canton 14,556 inhabitants, on a territory of 170 kilometres, in 9 communes.

PASSA-

PASSALORHYNCHITES, *PASSALORHYNCHITÆ*, in *Eccl:astical History*, a sect of Montanists in the second century, who made profession of perpetual silence, and, the better to maintain it, kept the thumb continually upon the lips; founding their practice on that of the Psalmist, *Set a guard, O Lord, on my mouth*.

St. Jerom mentions his having met with some of them in his time.

PASSAMAN, in *Geography*, a town on the W. coast of the island of Sumatra, near the equator.

PASSAMAQUODDIES, a tribe of Indians, who inhabited the vicinity of Passamaquoddy bay.

PASSAMAQUODDY, a town and river of America, near which is the division line between the British province of New Brunswick and the United States. The island of Camoo Bello in the North Atlantic ocean, is at the middle or W. passage of the bay, in N. lat. $44^{\circ} 50'$, and W. long. $66^{\circ} 46'$. The distance from Crofs isle, Machias, to W. Passamaquoddy head, is nine leagues N.E. by E.; and from the head over the bar to Allen's isle N.N.W. two leagues. Three rivers fall into the bay; the largest of which is called by the Indians the Scoodich, but by De Moins and Champlaine, Etchemina. Its main source is near Penobscot river, and the carrying place between the two rivers is only three miles.

PASSAMEZZO, from *passer*, to walk, and *mezzo*, the middle, in *Musie*, is a slow dance, differing little from the action of walking. As a galliard consists of five paces, or bars, in the first strain, and is, therefore, called a cinque pace, the passamezzo, which is a diminutive of the galliard, has just half that number, and from that peculiarity takes its name.

PASSANGAN, in *Geography*, a town on the N. coast of the island of Sumatra. N. lat. $4^{\circ} 45'$. E. long. $97^{\circ} 2'$.

PASSANT, in *Heraldry*, a term applied to an animal in a shield, appearing to walk leisurely; or, to the ordinary posture of terrestrial animals.

Thus we say, he bears gules two lions *passant*, in pale. For most beasts, except lions, they frequently use the word *tripping* instead of *passant*.

PASSARA, in *Geography*, a town on the W. coast of the island of Borneo; 80 miles S.W. of Borneo.

PASSARADO, or PASSAREE, in a *Ship*, is a rope whereby all the sheet-blocks of the main and fore-sails are hauled down; the clew of the main-sail to the cubbridge-head of the main-mast, and the clew of the fore-sail to the cat-head. This is to be done when the ship goes large; and they are also kept firm down, and hindered from flying up, by this passarado rope.

PASSARGA, in *Geography*, a river of Prussia, which runs into the Frisch Haff, N. lat. $54^{\circ} 23'$. E. long. $19^{\circ} 42'$.

PASSARGOS, Los, a small island in the Grecian Archipelago, between the coast of Natolia and the island of Scio. N. lat. $38^{\circ} 17'$. E. long. $26^{\circ} 14'$.

PASSARO, a town of Sicily, in the valley of Noto; 30 miles S. of Syracuse.

PASSARON, a town of the Morea; 18 miles S. of Argos.

PASSAROWITZ, a town of European Turkey, in Servia, near the river Morava; 33 miles E.S.E. of Belgrade.

PASSARUAN, PASSAROWAN, *Passorouang*, or *Pasfourwang*, a town of the island of Java, and capital of a kingdom, situated on the N. coast; the chief trade of which consists in cotton. The houses are neatly built, and the country appears to be well cultivated. The pro-

duce of this settlement is rice, of which they export large quantities. The Dutch here are few; the Javanese are numerous, and their chief lives with considerable splendour. They have good roads, and posts are established along the coast; and it appears to be a busy and well-regulated settlement. S. lat. $7^{\circ} 36'$. Stavorinus's *Voyage*, vol. ii.

PASSAU, a city of Germany, in the circle of Bavaria, and capital of a bishopric and principality of the same name, situated on the Danube, where it receives the Inn and the Ilz. It consists of three towns, viz. Passau properly so called, betwixt the Danube and the Inn, Innstadt, and Ilzstadt. The city, where it is surrounded by water, is without the walls, but towards the land side of Bavaria is fortified with ramparts and ditches. Passau is well situated for trade. It remained under the power of the Romans till it was taken by the Alemanni in the year 475. After its fall under the dominion of the Franks, it continued subject to the dukes of Bavaria. In 999, it was made subject to the bishop by the emperor Otho III. In 1552, the religious peace, usually denominated "The treaty of Passau," was concluded here. In 1802, part of the bishopric beyond Iltz and the Inn, towards Austria, was given to the grand duke of Tuscany; 82 miles E.N.E. of Munich. N. lat. $48^{\circ} 34'$. E. long. 13° .

The famous treaty of "pacification" with the Protestants was concluded at Passau, soon after the advantage gained by Maurice of Saxony against the emperor Charles in the year 1552: the emperor also promising to assemble, within six months, a diet, in which all the tumults and dissensions that had been occasioned by a diversity of sentiments in religious matters should be removed. (See AUGSBURG.) As this treaty is considered by the German Protestants as the basis of their liberty, it may not be improper to insert here some of its principal articles.

By the three first articles it was stipulated that Maurice and the confederates should lay down their arms, and should lend their troops to Ferdinand to defend Germany against the Turks, and that the landgrave of Hesse should be set at liberty. By the fourth, it was agreed that the rule of faith, called "Interim," should be considered as null and void; that the contending parties should enjoy the free and undisturbed exercise of their religion, and a diet should be assembled to determine amicably the present disputes: and that this religious liberty should continue always, if it should be found impossible to come to an uniformity in doctrine and worship. It was also resolved, that all those who had suffered banishment, or any other calamity, on account of their having been concerned in the league or war of Smalcalde, should be re-instated in their privileges, possessions, and employments; that the imperial chamber of Spire shall be open to the Protestants as well as to the Catholics; and that there should be always a certain number of the Lutheran persuasion in that high court.

PASSAWAY, a town of Hindoostan, in the circar of Jyenagur; 30 miles E. of Parasaoli.

PASSE-BLEU, in *Ornithology*. See TANAGRA *Cerulea*.

PASSE-HENDAELE, in *Geography*, a town of France, in the department of the Lys, and chief place of a canton, in the district of Ypres. The place contains 2664, and the canton 14,117 inhabitants, on a territory of 110 kilometres, in 5 communes.

PASSEMANT, CLAUDE SIMEON, in *Biography*, an able French optician and mathematical instrument-maker, was born at Paris in the year 1702. He had little more than his industry to depend on, and for some time he wrote in an attorney's office: after this he entered himself as a

clerk or shopman to a woollen-draper, and then carried on the business of a haberdasher on his own account. Being married, he committed the care of his shop to his wife, and directed his own attention to the study of natural philosophy, optics, and astronomy, which he had cultivated from his youth at leisure hours. He devoted likewise much of his time to the construction and improvement of mathematical instruments, for which he seems to have had a decided mechanical turn. In 1738, he published "A Treatise on the Construction of Reflecting Telescopes." Some time after this, he published "The Description and Use of Telescopes, Microscopes, &c." of his own invention. He constructed an astronomical pendulum, crowned with a moving sphere, which was made to represent the revolutions of the planets, in a manner that exactly corresponded with the astronomical tables. He presented this machine to Lewis XV. and it was formerly to be seen in the royal apartments at Versailles. He made a similar instrument for the Turkish emperor, which shewed the rising and setting of the sun and moon. He furnished the king and other great men in France with sets of instruments for making experiments in optics, and other branches of science. He died suddenly in 1769, respected as well for his integrity and amiable character, as for his talents and acquirements.

PASSENHEIM, in *Geography*, a town of Prussia, in the province of Oberland; 70 miles S. of Königsberg.

PASSE-PIED, a dance, though of the same measure as the minuet, except that it admits of no binding-notes, and begins with an odd quaver. Indeed it more resembles the courant than the minuet.

PASSER, in *Geography*, a river of the Tyrol, which runs into the Adige, near Meran.

PASSER, in *Ichthyology*. See PLEURONECTES.

PASSER *Aquaticus*, in *Ornithology*. See *Water Sparrow*.

PASSER *Arundinaceus*, & *arundinaceus torquatus*, the reed sparrow. See *EMBERIZA Schoeniclus*.

PASSER *Asper*, in *Ichthyology*. See *DAB*.

PASSER *Britannicus*, a name given by Charleton to the foal-fish, and by some others to the turbot. See PLEURONECTES.

PASSER *Canadensis*, or *Canarius*, in *Ornithology*. See *CANARY-BIRD*.

PASSER *Domeslicus*. See *FRINGILLA Domeslica*.

PASSER *Faber*, a name given by Nieremberg to a bird, the genus of which is not certainly known; it being also called *turdus chiappæ*. It is remarkable for perforating the bark of the pines, and lodging its acorns there, which it afterwards occasionally eats.

PASSER *Fluviatilis*, in *Ichthyology*. See *FLOUNDER*.

PASSER *Indicus*, *macrourus alius* of Aldrovand, or the other long-tailed Indian sparrow, in *Ornithology*, is a very beautiful bird, with a blue beak, and a black head; the body being mostly of a fine scarlet. See *EMBERIZA Paradisea*. See also *TANAGRA Brasilia*.

PASSER *Muscatus*, a name by which some have called the *juviumbi*, or humming-bird. See *TROCHILUS Colubris*.

PASSER *Niger*. See *FRINGILLA Nottis*.

PASSER *Rubi*. See *MOTACILLA Modularis*.

PASSER *Solitarius*, the solitary sparrow. See *TURDUS Solitarius*.

PASSER *Stultus*, a name given by Nieremberg to the noddy, a species of the *Sterna*, so tame and foolish, that it will stand still for any one to lay his hand upon it. See *STERNA Stolidus*.

PASSER *Troglodytes*, the name by which authors call the wren. See *MOTACILLA Troglodytes*.

PASSERAT, JOHN, in *Biography*, an ancient French

poet and man of letters, was born, in 1534, at Troyes, in Champagne. After studying law at Bourges under the celebrated Cujas, he went to Paris, and taught the belles lettres in the colleges of the university. In 1572 he succeeded Peter Ramus as professor-royal of eloquence. His lectures were extremely well attended by persons of rank and consideration, and he was warmly patronized by Charles IX. and Henry III. The disorders and contests occasioned by the League obliged him to shut up his school, till the entry of Henry IV. into Paris in 1594. Being at Epernay when that place was besieged by the prince of Condé, who threatened to put the inhabitants to the sword, he was deputed by them to intercede with the prince in their behalf, who pardoned them at his request. He had the misfortune to lose an eye by the stroke of a tennis-ball, and this accident aggravated the naturally severe and gloomy expression of his countenance, but he was perfectly amiable in his temper, and free in his conversation. He was too much attached to his studies, and often passed days together without a regular meal. Excess of application was thought to have excited paralytic affections, which put an end to his life in 1602, at the age of sixty-eight. He is principally known by his Latin and French verses. The Latin are chiefly distinguished by their purity and facility, and by the elegant turn which he gives to common thoughts. As a French poet his metamorphosis of a man into a bird is particularly admired, and served, it is said, as a model to La Fontaine in his tales. Passerat is still regarded by some critics as one of the most agreeable of the French poets. He was author of many pieces, of which may be mentioned "Commentaries on Catullus, Tibullus, and Propertius," and a "Translation of the Bibliotheca of Apollodorus." Moreri.

PASSERES, in *Ornithology*, the sixth order of birds according to the Linnæan system, are distinguished by a conical and pointed bill; the nostrils are oval, pervious, and naked; the legs are formed for hopping; the toes are slender, and divided; the bodies of those that feed on grain are pure, but of those that feed on insects impure; the nest is formed with much art. They live chiefly in trees and hedges, are monogamous, and feed the young by thrusting the food down their throats. This order includes all the singing birds; the males are the songsters. They are divided into four sections, as follow:

The genera in section A have thick bills, and are

Colius,	Loxia,
Emberiza,	Phytotoma.
Fringilla,	

The genera in section B have the upper mandible somewhat hooked at the point; these are

Caprimulgus,	Hirundo.
Pipra,	

The genera in C have the upper mandible notched near the end, as in the

Ampelis,	Tanagra,
Muscicapa,	Turdus.

The genera in D have the bill straight, simple, and tapering, as in the

Alauda,	Parus,
Columba,	Sturnus.
Motacilla,	

PASSERG, in *Geography*, a town of Prussia, in the province of Natangen, in the Frisch Haff; 22 miles S.W. of Brandenburg.

PASSERI, GIAMBATISTA, in *Biography*, a celebrated antiquarian, was born at Farnese in 1694. He was destined to the profession of the law, but his inclination led him to

the study of antiquities, which he pursued with assiduity during a four years' residence at Rome. Returning thence to Todi, he collected the monuments of antiquity in that place and its vicinity. In 1726, he turned his attention to Etruscan antiquities, and collected a great number of lamps, and other things, which he arranged in classes. In 1738, having lost his wife, he entered into the ecclesiastical order, and obtained the office of vicar-general of Pefaro. This he exercised many years with zeal and fidelity. He was killed by a fall from his carriage in the year 1780, as he was returning from his country house. He was author of a great number of works, among which are the following: "Lucernæ fistiles Mussæi Passerii," three volumes, being a description of the earthen lamps in his collection; "Picturæ Etruscorum in Vasculis, in unum collectæ, Dissertationibus illustratæ," in three volumes: "Dissertationes on the ancient Monuments in the Musæum Clementinum." When he died, the first volume of an extensive work of his was printing at Rome, entitled, "Thesaurus Gemmarum Selectissimarum."

PASSERINA, in *Botany*, from *passer*, a sparrow, a name which has been applied to some plants, on account of the resemblance of their leaves to the tongue of a small bird. Such at least is its application with respect to *Lysimachia Linum-stellatum*, *Linum striatum*, and *Stellera Passerina*. But Linnæus, who has chosen this appellation for the genus that now bears it, cites Pukenet for saying it is so called because the fruit represents the head of a little bird with its beak; see Linn. Hort. Cliff. 146. The resemblance is not very striking, but the name is preferable to that given by Clusius to the same genus, *Sanamunda*, supposed to be derived from *fano*, to heal, and *munda*, clean; though he adopted it from the Moors of Granada, who were accustomed to use some of this tribe as a purge. Linn. Gen. 193. Schreb. 261. Willd. Sp. Pl. v. 2. 429. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 414. Juss. 77. Lamarck Illustr. t. 291. Class and order, *Oëandria Monogynia*. Nat. Ord. *Veprucule*, Linn. *Thymelææ* Juss.

Gen. Ch. Cal. Perianth of one leaf withering, externally rude, internally coloured; tube cylindrical, slender, tumid below the middle; limb spreading, in four deep, concave, ovate, obtuse segments. Cor. none. Stam. Filaments eight, bristle-shaped, the length of the limb, inserted into the top of the tube; anthers nearly ovate, erect. Pist. Germen ovate, within the tube of the calyx; style thread-shaped, springing from the side of the summit of the germen, as long as the tube; stigma capitate, rough all over with bristly hairs. Peric. leathery, ovate, of one cell. Seed solitary, ovate, obliquely pointed at each end.

Eff. Ch. Calyx coloured, four-cleft, withering. Corolla none. Stamens prominent. Style lateral. Seed solitary, coated.

Obs. The analogy of *Daphne* renders it indispensable to consider this flower likewise as having a coloured calyx, not a corolla, especially as others of the same natural order have *petals*, or *nectaries*, besides; see COROLLA and DAPHNE. Linnæus has observed that, in *P. capitata*, there are eight interior abortive stamens; and in *uniflora*, the rudiments of eight supernumerary anthers, in the bottom of the flower. These instances lessen the value of the reputed petals, nectaries, or glands, which distinguish other genera from this and *Daphne*. Accordingly, of the eight *Passerina* in Linn. Sp. Pl. ed. 2, *sericea*, *dodecandra* and *levigata* are now removed from hence; though recent discoveries have, on the other hand, enlarged the genus to sixteen species. How far any of the new ones may be liable to exception in the generic character, we have no infallible means of deter-

mining, but we shall briefly enumerate the whole. All, except *hirsuta*, *orientalis*, and *canescens*, are natives of the Cape of Good Hope; five are cultivated in Britain.

1. *P. filiformis*. Filiform Sparrow-wort. Linn. Sp. Pl. 513. Ait. Hort. Kew. v. 1. (*P. foliis linearibus*; Linn. Hort. Cliff. 246. t. 11.)—Leaves linear, convex, imbricated in four rows. Branches downy.—This is often seen in green-houses, flowering in summer. The stem is shrubby, repeatedly branched; the younger branches downy, covered with innumerable smooth narrow leaves, about half an inch long. Flowers solitary, small, yellowish, from the bosoms of many leaves together towards the tops of the branches, such leaves having at their base, on each side, a broad, membranous, stilled, furrowed dilatation.—The synonym of Breynius, still retained by Willdenow, belongs to *Gnidia simplex*, under which he repeats it. Linnæus in Hort. Cliff. has several faulty synonyms besides, as he there confounds not only various African, but even European, plants.

2. *P. hirsuta*. Shaggy Sparrow-wort. Linn. Sp. Pl. 513. Ait. n. 2. Sm. Tour. ed. 2. v. 2. 105. Prodr. Fl. Græc. Sibth. v. 1. 262. Fl. Græc. t. 360, unpublished. (Sanamundatertia; Claf. Hist. v. 1. 89. Ger. em. 1506. Breyn. Cent. 1. t. 19. Sefamoides minus; Dalech. Hist. 1670.)—Leaves ovate, fleshy; convex and smooth externally; concave and woolly on the upper side. Stem and flowers woolly.—Native of heathy places, especially near the sea, in the south of France, Spain, Italy, Greece, and the Levant, flowering from November to March.—More bushy and spreading than the former, with totally different leaves. Flowers in little tufts at the ends of short lateral shoots; white and woolly externally; lemon-coloured within, powerfully and delightfully fragrant. Nothing can be more elegant or desirable than this shrub in its wild state; in green-houses it generally makes a poor figure.

3. *P. ericoides*. Heath-like Sparrow-wort. Linn. Mant. 236.—Leaves oblong, obtuse, polished, bluntly keeled; with a woolly furrow above. Tube of the calyx globose and hairy; limb smooth. From the Cape.—This has much the aspect of an *Erica*, and yet is closely allied to both the foregoing, as if intermediate between them, yet perfectly distinct. The branches are downy or woolly when young. Leaves not a quarter of an inch long, of a short, oblong, prismatic shape; green and polished, except a narrow hairy furrow along their upper or inner surface. Flowers axillary, sessile, the accompanying leaves being dilated and ovate. The globose hairy tube of the flower is filled by the germen, and finally forced off by the ripe fruit, which appears to be pulpy, and if so, the plant becomes perhaps more properly a *Daphne*. The seed is black and shining.

4. *P. nervosa*. Ribbed Sparrow-wort. Thunb. Prodr. 75. Willd. n. 4.—"Leaves lanceolate, three-ribbed, smooth. Flowers capitate."—Of this and the following we have seen no specimen.

5. *P. cephalophora*. Great-headed Sparrow-wort. Thunb. ibid. Willd. n. 5.—"Leaves prismatic, in four rows. Heads of flowers woolly." Thunb.

6. *P. capitata*. Smaller-headed Sparrow-wort. Linn. Sp. Pl. 513. Ait. n. 3. (*Thymelæa foliis linearibus alternis, floribus ex uno petiolo copiosis*; Burm. Afric. 133. t. 48 f. 3.)—Leaves linear-awlshaped, smooth on both sides. Heads of flowers downy, or downy, club-shaped, terminal stalks.—Sent from the Cape in 1789, by Mr. F. Masson. It flowers at Kew from June to September, being kept, like all the rest, in the green-house. Burmann describes this as of very lofty growth, with red or purplish branches two feet long, which are repeatedly subdivided; the younger shoots

PASSERINA.

shoots only slightly hairy. *Leaves* scattered, linear, acute, keeled, smooth, convex above; rather more than half an inch long. *Flowers* white, about ten or more in each dense, hairy terminal tuft, whose stalk is thickened upwards, downy, crowned with a hairy ring or border beneath the flowers. Burmann by mistake uses the word *petiolo* for *pedunculo* in his definition above.

7. *P. orientalis*. Oriental Sparrow-wort. Willd. n. 7. (*P. folius lanceolatis*; Gronov. Orient. 48. Sanamunda prima; Clus. Hist. v. 1. 88. Rauwolf. Raif. 281.)—*Leaves* lanceolate, somewhat fleshy, blunt, slightly hairy. *Flowers* axillary. Native of Spain and the Levant, in open sunny spots, flowering in March and April. A bushy *shrub*, about two feet high, with a dark-coloured bark. *Leaves* compared by Clusius to those of *Cneorum tricoccum*, but smaller, shorter, and fleshy, somewhat hairy, ranged in a regular manner along the branches. *Flowers* among the leaves, oblong, resembling those of the Olive, but yellow. *Fruit* like that of *Thymelæa* (*Daphne Gnidium*), but blackish. This is all we can gather from Clusius, whose synonym was originally cited by Linnæus under *Passerina ciliata*, but afterwards struck out, in his own copy of Sp. Pl. Willdenow has established the present species, on the authority of the authors quoted; but if Clusius be right, the *fruit* should make it a *Daphne*. We have a specimen gathered by the Abbè Durand in Barbary, which answers well to the description and figure of Clusius except that the *flowers* are terminal, in little heads on the short lateral branches, and by no means as he represents them.

8. *P. ciliata*. Fringed Sparrow-wort. Linn. Sp. Pl. 514. Willd. n. 8. Thunb. Prodr. 75. (*Thymelæa foliis oblongo-acutis, ad oras fimbriatis, floribus ex foliorum alis spicatis*; Burm. Afric. 129. t. 47. f. 2.)—*Leaves* opposite, lanceolate, acute, many-ribbed, fringed. *Flowers* axillary; their tube capillary, twice as long as the leaves.—Native of the Cape of Good Hope, not of Europe. The history of this species is extremely confused, as the late Mr. Dryander has shewn, in Tr. of Linn. Soc. v. 2. 234, that excellent botanist and critic having been able to prove rather what it was not, than what it was. The plant described in *Hort. Cliff.* is merely *Struthiola virgata*, with which it seems three others are confounded in the Cliffortian collection. The Herbarium of Linnæus has no specimen. We can, therefore, only depend on Burmann's synonym, which Linnæus uniformly cited, and which he has marked in his copy of Burmann's book. Of this the young *branches* are square and purplish. We cannot learn why Willdenow defines the *stem* as villous. The *leaves* are sessile, opposite, crossing each other in pairs, ovato-lanceolate, acute, entire, many-ribbed, half an inch, or more, in length, smooth, except a dense silky marginal fringe. *Flowers* solitary, with a slender tube, about twice the length of the leaf. Burmann's figure has all the appearance of a *Gnidium*. We know nothing of the colour of the *flowers*, for what Willdenow has on that subject is taken from Bergius, whose *P. ciliata* is evidently a different thing. What the Spanish botanists send under this name is either *P. orientalis*, or *Daphne villosa*. Thus we must still leave the matter in uncertainty, till the genus of Burmann's plant be ascertained.

9. *P. uniflora*. One-flowered Sparrow-wort. Linn. Sp. Pl. 514. Ait. n. 4. (*Thymelæa ramosa, linearibus foliis angustis, flore solitario*; Burm. Afric. 131. t. 48. f. 1.)—*Leaves* opposite, triangular-awl-shaped, smooth and even. *Flowers* terminal, solitary; their segments acute.—From the Cape. Miller cultivated it in 1759. This is a humble, bushy, smooth *shrub*, whose slender *branches* are clothed with opposite awl-shaped *leaves*, crossing each other in pairs, and

keeled at the back. *Flowers* solitary at the top of each branch, erect, pale purple; their *tube* hairy, as long as the leaves; limb of the same length, in four ovate, acute, spreading segments, hairy at the back. Burmann's fig. 2. is a doubtful variety. See the next species.

10. *P. grandiflora*. Great-flowered Sparrow-wort. Linn. Suppl. 226. Ait. n. 5? Curt. Mag. t. 292? (*P. lineoides*; Thunb. Prodr. 75? *Thymelæa foliis imbricatis oblongis, floribus fericeis, ramosa*; Brum. Afric. 123. t. 46. f. 1.)—*Leaves* opposite, elliptical, smooth; concave above; convex and somewhat ribbed beneath. *Flowers* terminal, solitary; their segments obtuse.—Such are the characters of the original specimen of this plant, gathered at the Cape by Sparrmann. It seems to be of much loftier growth than the last, with thicker *branches*, downy when young. *Leaves* short and elliptical; very concave above; and no less convex at the under side, which presents itself to the spectator, and which is smooth and shining, furnished with an obscure midrib, but by no means keeled: in a dry state there is some appearance of lateral ribs at the base, and many corrugations all over the surface, but these latter seem the effect of drying. *Flowers* terminal, solitary, twice the size of the last, apparently pale red, very silky externally, and downy within; their segments broadly elliptical and obtuse. *Stamens* and *style* rising above the tube, but shorter than the limb. By this description it will appear that the plant of the Botanical Magazine answers but imperfectly to ours. Its *leaves* are much narrower and longer, *flowers* white, smaller, with acute segments. We are rather inclined to think this latter may be what is represented in Burmann's t. 48. f. 2, which Linnæus, and the editors of Hort. Kew. have cited as *P. uniflora*; and possibly both may be the real *lineoides* of Thunberg; but this we have no materials to determine. This author has nothing under the name of *grandiflora* in his Prodomus, nor any single-flowered species, except *uniflora* and *lineoides*. Burmann's t. 46. f. 1. is evidently our *grandiflora*; his f. 2. may be that of the Bot. Mag. See sp. 17, at the end of the genus.

11. *P. canescens*. Hoary Sparrow-wort. "Schousboe in Act. Hafn." Willd. n. 11.—"Leaves oblong, imbricated in four rows, clothed with soft wool. *Flowers* terminal, woolly."—Native of Morocco. A *shrub* with numerous short *branches*, small, imbricated, very woolly *leaves*, and cylindrical *flowers*. Willd.

12. *P. spicata*. Spiked Sparrow-wort. Linn. Suppl. 226. Willd. n. 12. Thunb. Prodr. 75. Wendl. Obf. (in Roem. Archiv. v. 1?) 19. t. 2. f. 19. Willd.—"Leaves ovate, villous. *Flowers* lateral, solitary."—Gathered by Thunberg, at the Cape. The flowering *branches* are said by Linnæus to resemble a leafy spike. We have no specimen.

13. *P. laxa*. Slender-branched Sparrow-wort. Linn. Suppl. 226. Willd. n. 13. Thunb. Prodr. 75? Wendl. Obf. 20. t. 2. f. 20. Willd.—"Leaves scattered, lanceolate, keeled, smooth. *Branches* hairy, divaricated. *Flowers* capitate, terminal, bristly."—Gathered by Sparrmann at the Cape. If the younger Linnæus has not described from the collection of Thunberg, whom he quotes, a different plant from the marked specimen in his herbarium, given to his father by Sparrmann, nothing can be worse than his description. The *branches* indeed are slender, and loosely spreading, clothed when young with upright hairs. But the *leaves* are of a narrow elliptic-lanceolate form, not ovate, nor are they hairy, as Thunberg describes them, except when young. Nevertheless, the allusion in the Suppl. to *P. ericoides*, convinces us that the specimen in the herbarium is correct. The *flowers* grow several together, in terminal leafy heads, and are slender, clothed

clothed externally with long, erect, filky hairs, the segments of the limb scarcely half the length of the tube.

14. *P. striata*. Rigid Sparrow-wort. Thunb. Prodr. 75. Willd. n. 14. —“Leaves ovate, hairy. Flowers capitate. Branches rigid.” Thunb.—Totally unknown to us.

15. *P. anthylloides*. Hairy-headed Sparrow-wort. Linn. Suppl. 225. Thunb. Prodr. 76. Willd. n. 15. (*Thymelæa foliis imbricatis latioribus subrotundis, ac subtus incanis; Burm. Afric. 126. t. 46. f. 3.*)—Leaves scattered, ovate, hairy. Flowers capitate, terminal, externally bristly.—Gathered by Thunberg, at the Cape. A very handsome species, well described, though not very well figured, by Burmann, whose synonym is unnoticed by Linnæus and his followers. The branches are stout, erect, repeatedly subdivided in a fasciculate or determinate manner, hairy and most leafy while young. Leaves scattered, imbricated, about three-fourths of an inch long, elliptic-ovate, nearly flat, ribbed, hairy beneath, especially when young. Flowers in large terminal heads, encompassed with numerous large hairy leaves; their outside covered with long, dense, erect, white, silvery hairs; the inside smooth, yellow when fresh, black when dry. Burmann, who saw them in the latter state only, supposed them to be purple. Fruit ovate, of a shining brown, clothed with upright bristles. Seed minutely dotted.

16. *P. pentandra*. Pentandrous Sparrow-wort. Thunb. Prodr. 76. Willd. n. 16.—“Leaves ovate, hairy. Spikes ovate, terminal.” Thunb.—Known only by this definition of Thunberg. If the flowers have precisely five stamens, it cannot but excite some doubts as to the genus.

Linnæus admitted into *Passerina*, in the Supplementum, three diandrous species, which formed the genus *Banksia* of Forster. These are now, with many others, established as a separate genus, by the name of *Pimelæa*; see that article. Meanwhile the name of *Banksia* has been applied to a fine genus of the *Proteaceous* order, with which it remains.

Having under *P. grandiflora*, sp. 10, suggested some doubts respecting the *linoides* of Thunberg, we shall here venture to propose that, with what appear to be its synonyms, as a supplementary species, for future consideration.

17. *P. linoides*. Flax-like Sparrow-wort. Thunb. Prodr. 75. (*P. grandiflora*; Curt. Mag. t. 292. Ait. n. 5. *Thymelæa foliis imbricatis angustioribus, floribus sericeis, spicata; Burm. Afric. 125. t. 46. f. 2. T. scaphoides, monomotapensis, five foliolis glabris triquetris cavis cymbæformibus, floribus solitariis amplis summo caule villosis; Pluk. Mant. 180. t. 445. f. 8.*)—Leaves opposite, elliptic-lanceolate, smooth, concave above; convex, even and three-ribbed beneath. Flowers terminal, solitary; their segments acute.—Native of the Cape, from whence it was sent by Mr. Masson in 1789. If we are right in this species, it differs from *P. uniflora* in being a much taller shrub, with elliptical (though narrow) concave leaves, not awl-shaped keeled ones, and the flowers are white, not purplish or blue. From *grandiflora*, to which it is most allied, it differs in having much narrower leaves, even, not rugose, at the back, and flowers but half as large, whose segments are ovate and acute, not obtuse. Plukenet is inaccurately quoted by Burmann, which the confused plan of his work renders it difficult to avoid.

This species is said by Mr. Curtis to be a hardy greenhouse plant, flowering in May and June, and increased without difficulty by cuttings. It is still, if we mistake not, cultivated by Messrs. Lee and Kennedy, at Hammer-smith. S.

PASSERINA, in *Gardening*, contains plants of the shrubby, exotic, evergreen kind, of which the species cultivated are, the filiform sparrow-wort (*P. filiformis*); the shaggy spar-

row-wort (*P. hirsuta*); the headed sparrow-wort (*P. capitata*); the ciliated sparrow-wort (*P. ciliata*); and the one-flowered sparrow-wort (*P. uniflora*).

Method of Culture.—All the sorts may be increased by cuttings planted in a bed of loamy earth, during the summer months, and closely covered with a bell or hand-glass to exclude the air, shading them from the sun, and refreshing them now and then with water. When well rooted they may be planted out, each into a small pot filled with loamy earth; placing them in the shade till they have taken new root; then be removed into a sheltered situation, to remain till the beginning of autumn, when they must be placed in the green-house, and treated as the myrtles. They may likewise be increased by layers.

The second sort may also be raised by sowing the seeds in autumn, soon after they are ripe, in small pots filled with light earth, plunging them into an old bark-bed under a common frame in winter: the plants rise in the spring, and must be treated like the cuttings. The seedling plants grow the most erect, and make the handsomest appearance.

This sort is capable of living abroad in common winters, in a dry soil and warm situation; but in hard frosts the plants are frequently destroyed: one or two should therefore be kept in pots, and sheltered during that season.

They afford variety among other potted green-house plants.

PASSERON ISLANDS, in *Geography*, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. 11° 10'.

PASSEROTTI, BARTOLOMEO, of Bologna, in *Biography*, was a pupil of Zuccari, and a very ingenious painter, one of whose works, (a picture of Tityus,) was mistaken by the connoisseurs of Bologna for the painting of Michael Angelo, and whose portraits were thought by Guido to have nearly approached those of Titian. He was a skilful draftsman, and aided in forming the Carracci, particularly Agostino; who made his lines in his penned drawings the guide of his graver. He composed a book on anatomy and symmetry: but was not always guided by his own directions. The debauchery of true taste, begun by the freedom of his master, he aided in its progress; and allowed his better talents to bend to facility of execution, and looseness of manner.

PASSE-VERT, in *Ornithology*. See TANAGRA *Cayana*.

PASSIDAGPOUR, in *Geography*, a town of Hindoostan, in Oude; 24 miles N. of Manickpour.

PASSIFLORA, in *Botany*, a name altered by Linnæus, from the *Flos Passionis* of preceding authors. This was applied to the beautiful genus in question, known universally at present by the appellation of Passion Flowers, because the instruments of Christ's passion were thought to be represented in the parts of fructification. The five stamens were compared to his five wounds; the three styles, more aptly, to the nails by which he was fixed to the cross; the column, which elevates the germen, to the cross itself, or to the pillar to which he was bound; and the rays of the nectary to his crown of thorns. There are cuts to be found in some old books, apparently drawn from description, like the hog in armour upon our signs to represent the rhinoceros, in which the flower is made up of the very things themselves. Linn. Gen. 466. Amoen. Acad. v. 1. 211. Schreb. 199. Willd. Sp. Pl. v. 3. 606. Ait. Hort. Kew. ed. 1. v. 3. 306. Mart. Mill. Dict. v. 3. Cavan. Diff. 442. Swartz. Ind. Occ. v. 2. 1133. Juss. 397. Lamarck Dict. v. 3. 32. Illustr. t. 732. (*Granadilla*; Tourn. t. 123, 124. Gærtn. t. 60. Murucua; Tourn. t. 125. Juss. 398. Tacsonia; Juss. 393.)—Class and order, *Gynandria Pentandria*. Linn. *Monadelphia Pentandria*, Cavan. Willd. *Pentandria Trigynia*, Schreb.

PASSIFLORA.

Schreb. which last we prefer. Nat. Ord. *Cucurbitaceæ*, Linn. Juff.

Gen. Ch. *Cal.* Perianth of one leaf, in five deep, oblong, equal segments, much resembling the petals, but pointed below the top; its base concave or tubular. *Cor.* Petals five, oblong, flat, obtuse, usually the size and shape of the calyx, and alternate with its segments; sometimes wanting. Nectary a manifold radiating crown, rarely simple, within the base of the petals; the outer rows longest; the inner of more or less complex, separate or combined, rays or membranes. *Stam.* Filaments five, awl-shaped, spreading, inserted at the base of the germen, upon the column which elevates it; anthers incumbent, pendulous, versatile, oblong, depressed, obtuse. *Pist.* Germen roundish, elevated upon the top of a straight cylindrical column, generally shorter than the petals; styles three, spreading, swelling upwards; stigmas capitate, broad. *Peric.* Berry fleshy, nearly ovate, stalked, of one cell. *Seeds* numerous, ovate, with a pulpy tunic. *Receptacles* of the seeds three, attached lengthwise to the inside of the pericarp.

Ess. Ch. Calyx in five deep coloured segments. Petals five, inserted into the calyx. Nectary a complex radiating crown. Berry stalked. Seeds with a pulpy tunic.

Obs. In the *Murucua* of Tournefort, of which two or three species are now known, the nectary is a conical abrupt membrane, not split into rays. *P. suberosa*, *minima*, and some allied to them, have no petals. We gladly, at the suggestion of Willdenow, resume the Linnæan ideas of the calyx and corolla of this genus, which some new-discovered species, the base of whose calyx is elongated into a cylindrical tube, had formerly induced us, like Cavanilles, to give up. These make the genus *Tacsonia* of Jussieu, *Tacso* of the Peruvians; a name no less exceptionable than the genus. Willdenow errs nevertheless greatly, in still terming the bractæas an involucre.

This is one of the most natural genera that can possibly be. Its root is perennial. Stem climbing to a great extent, branched; more or less shrubby below. Leaves alternate, either undivided or lobed, scarcely ever compound, stalked, with glands, for the most part, upon their stalks, and accompanied by a pair of stipulas, as well as by solitary, simple, spiral tendrils. Flowers on axillary undivided stalks, solitary or in pairs. Bractæas very various in form, usually three, a little remote from the flower, and deciduous; in the long-tubed species often combined into a three-cleft tube, and permanent. Hence when the petals and calyx, both together, came to be considered as a monopetalous corolla, in ten segments, the bractæas were taken for a calyx. See Plant. Ic. ex Herb. Linn. fasc. 1. t. 24, 25.

The species of this genus are numerous. Linnæus in his dissertation, *de Passiflorâ*, published in 1745, and reprinted in the first vol. of his *Amœnitates*, describes 22, with imperfect indications of 18 more. The leaves of those 22, on which the specific differences chiefly depend, are there very neatly engraved. Twenty-six species are given in Sp. Pl. ed. 2, and 28 only in the 14th edition of Syst. Veg. Lamarck in his Dictionary, v. 3, (*Grenadille*), has 35. Cavanilles in his tenth dissertation describes 44, of which 31 are there figured. Willdenow in his Sp. Pl. has 46. We add five to the list, from the fifth volume of Cavanilles' Icones, and four new ones.

The two last-mentioned authors refer the genus to *Monadelphica*, and even Schreber has added a note, in his second vol. 826, that the filaments are combined at their base. This union appears to us so slight, and indeed so often wanting, that we much prefer continuing *Passiflora* in *Pentandria*, where Schreber first placed it. The Linnæan idea, of its

being gynandrous, is totally exploded; for there is no insertion of the filaments upon, or above, the germen; the organs of fructification are merely elevated, all together, on a columnar receptacle.

It is remarkable that every described species is exclusively of South American or West Indian origin, except two found in Virginia and Florida, one in the remote counties of New Caledonia and Norfolk island, and one in Cochinchina; see n. 2.

The whole are disposed in four artificial sections, by the forms of their leaves. Being such general favourites, we must briefly notice every species, especially as Willdenow is, in some points, very imperfect. Since we follow his arrangement, it is needless to cite him throughout, and we shall confine ourselves in the synonyms to what is absolutely essential, or to what he has omitted.

Section 1. *Leaves undivided.* Thirteen species.

1. *P. ferratifolia*. Notch-leaved Passion-flower. Linn. Sp. Pl. 1355. Jacq. Hort. Vind. v. 1. t. 10. Curt. Mag. t. 651.—Leaves ovate, finely serrated, downy beneath.—Native of Surinam. A stove plant in England, flowering copiously all summer long. Houston introduced it to Chelsea garden in 1731. The branches are very long and slender. Leaves green on both sides, smooth above, very soft beneath. Flowers peculiarly delicate, distinguished by the very long capillary curling rays of their nectary, which are purple at the base, pale blue upwards. The scent of the flower is aromatic, but to us unpleasant, partaking of rubarb-root. Curtis commends it.

2. *P. pallida*. Pale Passion-flower. Linn. Sp. Pl. 1355. (*Clematis indica alia*, flore minore pallido; Plum. Amer. t. 89.)—Leaves ovate, entire. Footstalks with two glands. Petals none. Fruit elliptical. Gathered in Hispaniola by Plumier, by whose figure and short description only have we any knowledge of this species. He represents the flowers as scarcely above an inch broad, and destitute of petals, so that it cannot be, as he thinks, the *Murucua-miri* of Piso 248, which is described with very evident red ones. In other respects the figures are not dissimilar. Plumier's has no bractæas, which may be an accidental omission. The fruit is the size and shape of an olive. Piso's cut expresses nothing as to the bractæas or fruit, but he says the latter is pear-shaped. His plant is greatly commended as a deobstruent, even superior in virtues to Saraparilla. Loureiro gives *P. pallida* as a native of Cochinchina; how correctly we know not.

3. *P. adulterina*. Oval-leaved Tubular Passion-flower. Linn. Suppl. 408. Sm. Plant. Ic. t. 24.—Leaves elliptical, revolute, somewhat toothed; woolly at the back. Tube of the calyx thrice as long as the limb. Bractæas distinct. Sent by Mutis to Linnæus from New Granada. A very curious species, the tube of whose calyx is three inches long and exactly cylindrical. Petals purple. Nectary of very short rays. Bractæas three, distinct, ovate-oblong, close to the flower. Young branches woolly, as well as the footstalks, and backs of the leaves. Stipulas serrated. Flowers pendulous. Fruit ovate, spotted.

4. *P. cuprea*. Copper-coloured Passion-flower. Linn. Sp. Pl. 1355. Jacq. Ic. Rar. t. 606.—Leaves ovate, entire, three-ribbed, obtuse. Footstalks without glands. Bractæas minute, deciduous. Fruit elliptical.—Native of the Bahama islands, from whence the seeds were brought by Cateby to England, in 1724. It is a tender stove plant, scarcely, if at all, to be seen here at present. The three-ribbed ovate leaves, glaucous at the back, with several dots between the ribs, and the almost linear petals, and segments of the calyx, both

PASSIFLORA.

both of a dull red on the upper side, mark the species. The glands of the *footstalks* are perhaps entirely wanting, but not the *bractæas*, though the latter are minute, and fall off early, as Jacquin's plate, and even that of Dillenius, expresses.

5. *P. tiliaefolia*. Linden-leaved Passion-flower. Linn. Sp. Pl. 1355. Cavan. Diff. t. 285.—Leaves heart-shaped, entire. Footstalks without glands. Bractæas ovate, shorter than the calyx. Native of the neighbourhood of Lima, where it is cultivated in gardens, but seems never to have been brought to Europe. Cavanilles's plate seems to be fabricated from Feuillée's, at least it does not appear that the former had seen a specimen, any more than Linnæus. The broad heart-shaped *leaves*, reticulated with copious veins at the back, distinguish this from all the foregoing. For the want of glands on their stalks we must rely on Feuillée's figure. The *rays* are crimson, divided by a white line. *Fruit* globular, two inches and a half in diameter, variegated with crimson and yellow, full of sweet watery pulp.

6. *P. maliformis*. Apple-fruited Passion-flower. Linn. Sp. Pl. 1355. Jacq. Hort. Schoenbr. t. 180. Andr. Repof. t. 207.—Leaves ovate, pointed, entire. Footstalks with two glands. Bractæas ovate, downy, longer than the calyx. Native of the West Indies, and known in Jamaica by the name of Sweet Calabash. Our specimens in flower came from the Hon. Mrs. Barrington's stove at Mongewell, in 1795, where the fruit was also ripened, which seems to be much like the last. The *leaves* however are narrower, ovate, very slightly cordate, four inches long. Bractæas large, pale, soft and downy, extending beyond the flower. *Petals* lanceolate, much narrower than the segments of the *calyx*, pale flesh-coloured. *Rays* variegated with red and white in their lower part, with purple and white towards the ends.

7. *P. quadrangularis*. Square-stalked Passion-flower. Linn. Sp. Pl. 1356. Jacq. Amer. t. 143. Sowerby, a single plate.—Leaves ovate, with numerous transverse nerves, entire. Flower-stalk triangular. Stipulas ovate. Stem with four membranous angles.—Native of the West Indies. It has long been in our gardens, but to flower and fruit in perfection, requires a whole spacious stove to itself, along whose horizontal windows it must be trained, being cut down every year to the main trunk, which soon acquires the size of a small cherry-tree. Thus we have seen it at lord Harewood's in Yorkshire, laden with huge *flowers*, magnificently variegated with violet-purple and crimson, and with abundance of green oval *fruit*, the size of a large melon. The cavity however is very small in proportion, filled with sweet pulp, most esteemed perhaps for its rarity. The *stem* has four very sharp, thin, prominent angles, or wings. *Leaves* near a foot long, broad-ovate, entire, smooth, with four or six cup-like glands, full of honey, on their footstalks; ten or twelve transverse ribs spring from the main one at each side. The *stipulas* are ovate, broad, and entire. The triangular *flower-stalk* is well indicated by Mr. Sowerby, in Tr. of Linn. Soc. v. 2. t. 3, as the most certain distinction of this from the next.

8. *P. alata*. Wing-stalked Passion-flower. Ait. Hort. Kew. ed. 1. v. 3. 306. Curt. Mag. t. 66.—Leaves ovate, with few transverse nerves, entire. Flower-stalk cylindrical. Stipulas lanceolate. Stem with four membranous angles.—Native of the West Indies, from whence it is said to have been introduced at Kew in 1772. This is smaller in every part than the last, generally with four, glands only on the *footstalks*; not more than five or six curved transverse ribs, on each side of the principal one; lanceolate *stipulas*, which

are now and then slightly serrated; and much smaller *bractæas*. The *flowers* are very agreeably and powerfully fragrant; the upper sides of the *petals* and *calyx* of a peculiar deep scarlet red, the *rays* erect, as long as the *petals*, variegated with purple, white and crimson, incurved at the points. No *fruit* has ever been produced in England. The plant is propagated by cuttings, and is a great ornament to a stove. We have a specimen gathered by Commerfon in the isle of Bourbon, to which country this species was probably brought originally from the West Indies. We must observe that the *flower-stalks*, cylindrical when fresh, become triangular in drying.

9. *P. laurifolia*. Laurel-leaved Passion-flower. Linn. Sp. Pl. 1356. Jacq. Hort. Vind. v. 2. 76. t. 162.—Leaves elliptical, with a small point, entire, veiny, smooth. Footstalks with two glands at their summit. Bractæas elliptical, concave, toothed, as long as the calyx.—Native of Surinam and Martinico. Known in the West Indies by the name of Water Lemon, its yellow oval fruit being extremely grateful for its sweetness and fragrance. The *leaves* are oval, coriaceous, smooth and shining, reticulated with small veins. *Stipulas* linear-lanceolate, toothed. *Flowers* remarkably handsome, though less vivid in colour than the last; their *petals* and *calyx* reflexed, pale, dotted with red; their *rays* erect, thick, richly speckled with blue and white. This is easily cultivated in a stove, and has been known in England ever since 1690, when the first earl of Portland introduced it. The two doubtful *Passifloræ*, Pl. Surinam. n. 152 and 74, Linn. Am. Acad. v. 8. 262, appear to belong to this.

10. *P. coccinea*. Scarlet Passion-flower. Aubl. Guian. 828. t. 324.—Leaves ovate, somewhat heart-shaped, sharply serrated, nearly smooth. Footstalks with four or six glands. Bractæas elliptical, concave, obtuse, as long as the calyx. Observed by Aublet in Guiana, flowering in August, when also he gathered the *fruit*, which he describes as divided into three cells, full of a pleasant eatable pulp. The strong sharp serratures of the *leaves* distinguish this from all the rest of the present section. Cavanilles, who saw specimens in Jussieu's collection, says they are downy beneath when young; and he also represents the large inflated *bractæas* as serrated throughout; Aublet figures them entire. The *flowers* are of a brilliant red, with orange rays.

11. *P. mucronata*. Pointed Passion-flower. Lamarck Dict. v. 3. 33. Cavan. Diff. t. 282.—Leaves heart-shaped, obtuse, reticulated, smooth, entire. Footstalks with two glands. Stipulas and bractæas broad-ovate, pointed, entire, flat. Stem cylindrical. Gathered by Commerfon at Rio Janeiro. The texture of the *leaves* is like *laurifolia*, but their form is ovate, heart-shaped at the base. *Stipulas* and *bractæas* remarkably pointed; the latter are flat, and hardly above half the length of the *calyx*. The *petals* are narrow, and, as far as we can judge by the dried flower, pale. The young *leaves* seem elegantly speckled.

12. *P. glandulosa*. Glandular Passion-flower. Cavan. Diff. 453. t. 281.—Leaves ovate, acute, reticulated, smooth, entire, footstalks with two glands. Bractæas much shorter than the tube of the calyx, with two glands at their base. Nectary extremely short.—Gathered by Mr. Stoupy in Cayenne. Cavanilles. This appears to be one of the *Tacsonie* of Jussieu, having a tubular *calyx*, though not of any great length; and a very short fringe to the *nectary*, as in our third species. The *leaves* however are smooth, of the nature of *P. laurifolia* and *mucronata*. Bractæas very small; usually awl-shaped; sometimes oblong; always furnished with a pair of glands at their base. *Fruit* the size and shape of a hen's egg.

13. *P. multiflora*. Many-flowered Small Passion-flower.

PASSIFLORA.

Linn. Sp. Pl. 1356. Cavan. Diff. t. 272.—Leaves ovate-oblong, entire, downy on both sides. Flower-stalks aggregate, hairy. Petals none.—Native of the West Indies. Our specimen is from Santa Cruz. This is much smaller, in all its parts, than any of the foregoing, and clothed all over, even the outside of the *calyx*, with soft pubescence. Several small greenish flowers, without petals, grow together from the bosoms of the leaves. Plumier says they are very fragrant.

See n. 29. *P. angustifolia*, as apparently belonging to this section.

Section 2. *Leaves two-lobed.* Ten species.

14. *P. perfoliata*. Stem-clasping Passion-flower.—Linn. Sp. Pl. 1356. Jacq. Hort. Schoenbr. t. 182. Andr. Repof. t. 547.—Leaves smooth, with two oblong, obtuse, spreading lobes, dotted beneath; their base heart-shaped, clasping the stem. Calyx bell-shaped; its segments awl-shaped, much narrower than the petals.—Native of dry bushy places, near the sea, in the south part of Jamaica. It flowered at Messrs. Lee and Kennedy's in 1796, and since in the Comtesse de Vandes' fine collection. The leaves consist of two oblong, almost linear, obtuse, divaricated, entire lobes, connected with a heart-shaped base, with some traces of an intermediate lobe; altogether varying greatly in breadth, and, though supported by short footstalks, often clasping the stem; they are smooth on both sides, reticulated with veins; glaucous, and furnished with a variable row of glandular dots, beneath. *Stipulas* small, awl-shaped. *Flowers* on long stalks, with minute, capillary, remote, deciduous bractees. *Calyx* with a bell-shaped tube, closed by the plaited nectary, and with awl-shaped crimson segments. *Petals* of the same colour, elliptical, an inch long, rather exceeding the calyx. Willdenow well remarks that the flowers are open from their very first budding.

P. normalis is surely but a narrow-leaved variety of this; see n. 16.

15. *P. rubra*. Red-fruited Passion-flower. Linn. Sp. Pl. 1356. Jacq. Ic. Rar. t. 186.—Leaves downy, heart-shaped, with two acute spreading lobes. Flower-stalks hairy, without bractees. Stem round.—Native of the West Indies and of Mexico; not uncommon in our stoves, where it flowers in the spring, and sometimes ripens its small, reddish, ovate fruit. The whole plant is more or less clothed with soft pubescence. *Leaves* rather deeply lobed, entire. *Stipulas* linear. *Flowers* pale flesh-coloured, horizontal. *Germs* bristly. *Fruit* oval, red, with six angles.

16. *P. normalis*. Compass-leaved Passion-flower. Linn. Sp. Pl. 1357.—Leaves smooth, with two linear, obtuse, rectangular lobes, and a small pointed intermediate one; their base emarginate.—Native of Jamaica. Linnæus had it from Browne. This seems to us merely a variety of *perfoliata*, with narrow linear leaves. The synonym of Hernandez does not belong to it, though a part of his figure, with the longest leaf, is like our plant. See *P. Contrayerva*, n. 23.

17. *P. lunata*. Crescent-leaved Passion-flower. Sm. Ic. Pic. t. 1. (*P. biflora*; Cavan. Diff. t. 288.)—Leaves smooth, heart-shaped, with two obtuse spreading lobes, dotted beneath. *Flowers* in pairs. Rays club-shaped, compressed, obtuse.—Native of the West Indies. Long known in our gardens, but mistaken for the *punctata*, which even Linnæus confounded with it in his *Mant.* 492, and *Syst. Veg.*—The lobes are so shallow, broad and spreading, that the whole leaf nearly forms a crescent. *Flowers* in pairs, drooping, about the size of a half crown, smelling like honey. *Petals* white. Rays of the nectary yellow, re-

markably quadrangular. *Bractees* distant, scattered and scateous.

18. *P. Murucuja*. Tubular-crowned Passion-flower. Linn. Sp. Pl. 1357. Cavan. Diff. t. 287.—Leaves smooth, somewhat wedge-shaped, with two obtuse spreading lobes, dotted beneath. Nectary tubular, abrupt, undivided.—Native of the West Indies. We have never seen it alive. The leaves are shorter than in the last, and not heart-shaped at the base. *Flowers* deep red, distinguished by the undivided crown of their nectary. *Bractees* like the last. The column of the *germen* is remarkably long, and the aspect of the whole flower is much like that of *perfoliata*, whose nectary indeed appears likewise tubular, the rays being all brought together round the column, but they are not combined.

19. *P. Vespertilio*. Bat-winged Passion-flower. Linn. Sp. Pl. 1357. *Granadilla bicornis*, &c.; Dill. Elth. t. 137.—Leaves wedge-shaped, smooth, with two, rather pointed, spreading lobes, and two glands at the base. Rays capillary, twisted, longer than the petals.—Native of Surinam and the West Indies. Sherard cultivated it at Eltham in 1732, having received it from Amsterdam. The leaves appear to vary much in shape, and in the dots more or less scattered over their under surface; indeed we are inclined to doubt whether some Surinam specimens, in the Linnæan herbarium, may not be more than a variety. Yet their flower agrees with the true *P. Vespertilio*, whose rays are remarkably long and slender, variously bent and twisted. The calyx is horizontal and shallow, totally unlike that of *perfoliata* and *Murucuja*, and most agreeing with *rubra* and *lunata*, the whole flower being about the size and shape of *rubra*. The berry on one of the Surinam specimens, N^o 76. of the Pl. Surinamenses, Linn. Am. Acad. v. 8. 262, is globular, the size of a large gooseberry; its seeds transversely furrowed.

20. *P. clypeata*. Peltate Bat Passion-flower.—Leaves smooth, peltate, five-ribbed, with two rounded, pointed, widely-spreading lobes.—Of this we have an incomplete specimen in the herbarium of the younger Linnæus, marked as from the West Indies, and a single leaf, sent by Mutis from New Granada, and called in his letter "*Passiflora folium magnum*." This last expands six inches; the former are smaller and younger. The stem is slender, angular. Footstalks an inch or more in length, with two cup-like glands near the base, and in one instance two at the top. Leaves truly peltate, the stalk being inserted above a quarter of an inch from the base. Five strong radiating ribs spring from its insertion; with two much smaller, directed towards the base. Both sides are smooth, reticulated with innumerable veins; lobes very broad, rounded, with short points; in the leaf from Mutis only there is a shallow, minutely pointed, intermediate lobe; but that character is sometimes found to be variable in this tribe. A few large glandular dots are scattered towards the margins of the lobes. The stipulas are minute and awl-shaped. No traces of flowers are to be seen. This seems a most distinct species, though mentioned hitherto by no author that we have met with. Its habit comes very near *hederacea* of Cavanilles, see n. 33, but if there be any reliance on the outline of the leaves, they must be different.

21. *P. oblongata*. Oblong-leaved Passion-flower. Willd. n. 20. Swartz. Ind. Occ. v. 2. 1135.—"Leaves oblong; dotted beneath; rounded at the base; with two erect, lunate, very short terminal lobes, and a minute intermediate bristle."—Gathered by Swartz, on shrubby hills in Jamaica. The stem is rough and rigid, climbing by its tendrils to a great height. Leaves stalked, two or three inches long, entire, three-ribbed, veiny, thin, smooth; paler beneath, with a double row of remote dots. Footstalks without glands. Stipulas linear-awl-shaped, rigid. Flowers solitary, rather large;

PASSIFLORA.

large; of their structure nothing is mentioned. Our knowledge of this species is derived entirely from Swartz's work.

22. *P. capsularis*. Capsular Passion-flower. Linn. Sp. Pl. 1357. (*Granadilla fructu rubente, folio bicorni*; Plum. Ic. 129. t. 138. *Clematis indica, flore clavato, &c.*; Plum. Amer. 68, the first species, with a triangular stem.)—Leaves smooth, somewhat heart-shaped, with two acute slightly spreading lobes. Flower-stalks without bractæas. Stem triangular.—Found by Plumier in Hispaniola only. The late Hon. Mrs. Barrington received a plant from Jamaica, which flowered in Oct. 1793, at Messrs. Lee and Kennedy's, and answers well to this species, which Linnæus never saw, nor has any succeeding author been able to verify. It is in many points allied to *P. rubra*, n. 15, along with which Plumier describes it; but is distinguished by the triangular branches; the smoothness of the leaves, which in our specimen are scarcely cordate at the base. This last character, and the flowers being in pairs, not solitary, are the only circumstances in which our Jamaica plant does not correctly agree with Plumier's figure and description. The fruit is said to be longer, and more pointed, than that of *rubra*, apparently with less pulp. The rays are shorter than the petals, somewhat club-shaped. Calyx shallow and broad. Germen smooth. There are two glands at the base of the leaf, at least in our specimen.—In the herbarium of the younger Linnæus are specimens, without flowers, gathered by Smeathman in the West Indies, which agree very nearly with what we have just described, except that the leaves have much narrower, more deeply separated, lobes, elegantly variegated, with a white central stripe on the upper side. We procured a similar leaf in 1791, from the stove of Mrs. Barrington, who had the plant from Jamaica. This may be a distinct and very curious species, which the flowers, when known, may serve to distinguish hereafter.

23. *P. Contrayerva*. Horse-shoe Passion-flower. (*Coanepilli seu Contrayerva*; Hernand. Mex. 301.)—Leaves smooth, without glands, somewhat heart-shaped, with two obtuse, oblong, pointless, slightly spreading lobes. Foot-stalks without glands or stipulas. Stem angular. Calyx spreading.—This appears to us a very interesting species, hitherto totally misunderstood. We have unmarked specimens in the two Linnæan herbariums, answering precisely to the figure and description of Hernandez, whose synonym was certainly very ill applied by Linnæus to *normalis*; see n. 16. Hernandez says his plant is found in various parts of the country of Mexico, and the root is famous for its medicinal virtues, being sweetish, with some pungency and fragrance, and considered as a powerful counter-poison, deobstruent, cordial, &c.; three ounces of the bruised root being a dose. Hence the appellation of *Contrayerva*, which it possesses in common with *Dorstenia*, and some other reputed counter-poisons. Hernandez well describes the leaves as shaped like a crescent, or a horse-shoe. They are about an inch long, his figure being scarcely half the natural size. He represents three dots, like nails, on their disk, which he says are yellow, but which our specimens do not shew. The stems are slender, angular, twining, and climbing by tendrils. We have no flowers. He describes them as shaped like a carnation, but much smaller, and of many colours; the berries globular, dark chestnut-coloured. His figure well expresses one of the flattish, spreading, or shallow-flowered kinds, with thick horizontal rays, and a moderately elevated column. Root as thick as the little finger, long and twisted.

Section 3. *Leaves three-lobed*. Twenty-seven species.

24. *P. rotundifolia*. Round-leaved Passion-flower. Linn.

Sp. Pl. 1357. Cavan. Diff. t. 290. Willd. n. 22.—Leaves roundish, with three very shallow equal lobes; dotted beneath and at the base. Footstalks without glands. Calyx flat. Nectary with spreading rays.—Native of South America and the West Indies; sent to Kew in 1786, by Baron Hake, but we have never heard of its flowering in any garden. The leaves are about two inches in length and breadth, quite smooth on both sides in our specimen, as is also the ripe fruit, though authors attribute some downiness to both. The flowers we have not seen. Cavanilles and Plumier represent them of the size and general form of *rubra* and *capsularis*, with thickish rays.

25. *P. orbiculata*. Orbicular Tubular-crowned Passion-flower. Cavan. Diff. 456. t. 286. Willd. n. 23.—Leaves roundish, with three very shallow obtuse lobes; dotted beneath, but not at the base. Footstalks without glands. Petals none. Nectary tubular, abrupt, undivided.—Native of Hispaniola. Given by Thouin to the younger Linnæus. The leaves of this rare species much resemble the last, but the lobes are very obtuse, the middle one broadest; in a young state the under side is downy, and always very much reticulated with prominent veins. Stipulas and bractæas awl-shaped. Tendrils short. Flowers in pairs, crimson, the size of *Murucuja*, n. 18, and with the same undivided nectary, but no petals. The base of the calyx is globose; when young downy, like the flower-stalks. Column very long and slender, extending far beyond the calyx.

26. *P. punctata*. Dotted Passion-flower. Linn. Sp. Pl. 1358. Cavan. Diff. t. 269. (*Granadilla folio tricuspido, obtuso et oculato*; Feuill. Peruv. 718. t. 11.)—Leaves roundish, slightly heart-shaped, with three shallow obtuse lobes, and many rows of dots at the back, but not at the base. Footstalks without glands. Calyx flat. Rays spreading half the length of the petals.—Gathered by Feuillée in a garden at Malambo, a suburb on the north of Lima. He never met with this plant elsewhere. Cavanilles saw it in flower at Paris. We have never seen a specimen, nor did Linnæus; his description in the *Mant.* and *Syst. Veg.* copied by Willdenow, being taken from our *lunata*, which is the *punctata* of Ait. Hort. Kew. ed. 1. (See *Sm. Ic. Pic. t. 1.*) The leaves are broader and shorter than in the two last described, and more copiously dotted at the back. Flowers solitary, with a flattish expanded calyx, whitish ovate petals, and violet rays, tipped with bright yellow, which are much shorter than the petals, and somewhat club-shaped. Fruit rather oval, with a sweet pulp.

27. *P. lutea*. Small Yellow Passion-flower. Linn. Sp. Pl. 1358. Jacq. Ic. Rar. t. 607. Michaux Boreal-Amer. v. 2. 37.—Leaves heart-shaped, three-lobed, obtuse, smooth. Footstalks downy, without glands. Flowers in pairs. Petals half the breadth of the calyx.—Native of North America, from Virginia to Florida, as well as of Jamaica. It has long been in our gardens, but is little valued, the flowers being small and pale. The leaves somewhat resemble, in shape and size, those of *Anemone Hepatica*. They are smooth, glaucous beneath, without dots or glands. Footstalks and flower-stalks hairy, without glands, or bractæas. Flowers horizontal, flattish, with narrow pale-yellow petals, and spreading rays of the same length and colour.

28. *P. pannonia*. Cloth-leaved Passion-flower.—Leaves heart-shaped, unequally three-lobed, bluntish, downy on both sides, as well as the stalks, tendrils, and branches. Petals none. Germen bristly.—Native of the West Indies. We obtained a specimen from Kew garden, in November, 1791, but have never elsewhere seen or heard of this species, which from its sordid habit, and minute, greenish, inconspicuous flowers, is likely to have generally escaped notice.

PASSIFLORA.

The form and size of the *leaves* are like *rubra*, n. 15, and some of them have actually but two lobes, as in that; but most have a broad central lobe, as long as the others. Every part is pubescent like *rubra*, and the *germen* bristly, but the *flowers* are otherwise totally unlike that species, scarcely a quarter so large, destitute of *petals*, and with a very small *nectary*; though their stalks bear conspicuous finely three-cleft *bractæas*, which *rubra* wants. However deficient in splendour, this plant is worthy the attention of a curious botanist, on account of its various resemblances and affinities. See *fatida* and *holosericea* hereafter.

29. *P. angustifolia*. Narrow-leaved Passion-flower. Willd. n. 26. Swartz Ind. Occ. v. 2. 1133. (*P. heterophylla*; Ait. n. 13. Jacq. Hort. Schoenbr. v. 2. 28. t. 181. *P. longifolia*; Cavan. Diff. t. 270.)—Leaves smooth; the lower ones three-lobed; the rest undivided, lanceolate, elongated, pointed. Footstalks with two glands. Petals none.—Native of thickets in Jamaica; said to have been brought to England about the year 1773. It flowers in the stove most part of the summer. Those who should observe the upper *leaves* only, which are quite undivided, long, ovato-lanceolate, and taper-pointed, would refer this species to the first section; but as more or less of the lower *leaves* are furnished with one or two lateral lobes, it obtains a place here, among species to which it is most naturally allied. Some indeed have thought it is a variety of the next. The *footstalks* bear a pair of minute, globular, stalked glands, near the leaf. *Stipulas* bristle-shaped. *Flowers* in pairs, small, about half an inch wide, yellowish, on slender stalks without *bractæas*. *Calyx* spreading or recurved, slightly concave at the base. *Petals* none. *Rays* erect, recurved, yellow, rather shorter than the *calyx*, purple at the base. *Berry* roundish, deep violet, sweet, the size of a black currant.

30. *P. minima*. Dwarf Passion-flower. Linn. Sp. Pl. 1359. Jacq. Hort. Vind. v. 1. t. 20. Cavan. Diff. t. 266.—Leaves deeply three-lobed, entire, rather downy; the middle lobe longest. Footstalks with two glands. Petals none.—Native of Curassao; not uncommon in stoves, flowering in July. Every part of the herbage, in all our specimens, is finely downy, but not at all hoary. *Leaves* rather paler at the back, but not glaucous; the side lobes are the shortest; all of an ovate, or rounded shape, sometimes more oblong, and in that case more deeply separated. The *glands*, as well as the *flowers*, nearly accord with the last. The *calyx* however is downy at the back, and the *stipulas* are downy, and rather broader. *P. hirsuta*, n. 38, seems to be a hairy variety of this.

31. *P. suberosa*. Cork-barked Passion-flower. Linn. Sp. Pl. 1358. Jacq. Hort. Vind. v. 2. 77. t. 163. Sm. Exot. Bot. t. 28.—Leaves three-lobed, entire, smooth; the lateral lobes very short. Footstalks with two glands. Petals none. Fruit ovate. Stem with corky angles.—Native of the West Indies; easily cultivated in a stove, where it bears greenish *flowers*, and ovate black *fruit*, both twice the size of the two last species, throughout the summer and autumn. The *leaves* are of a dark shining green above, paler beneath, of a broad ovate figure, with two small, acute, lateral lobes. *Rays* of a much shorter proportion than the last, recurved at the points. *Germen* speckled with white. The bark of the old *stems* is white, and very corky; something of which indeed is observable in *angustifolia* and *minima*.

32. *P. peltata*. Peltate Spreading-lobed Passion-flower. Cavan. Diff. 447. t. 274. Willd. n. 29. (*Clematis indica*, folio angusto trifido, fructu oliviformi; Plum. Amer. 70. t. 85.—Leaves peltate, smooth, three-ribbed, with three

deep, equal, oblong, spreading lobes. Footstalks with two glands. Flowers solitary, without petals.—Found in hedges in the Antilles, according to Plumier; few other botanists have seen it. The peltate insertion of the *footstalks*, and the large, deeply three-lobed *leaves*, mark this species. Its *flowers* are twice the size of *P. suberosa*, with longer and straighter rays. *Fruit* much the same.

33. *P. hederacea*. Peltate Ivy Passion-flower. Cavan. Diff. 448. Willd. n. 30. (*Clematis indica*, folio hederaceo, major, fructu oliviformi; Plum. Amer. 70. t. 84.)—Leaves peltate, ovate, smooth, five-ribbed, three-lobed. Footstalks with two glands. Flowers solitary, without petals.—From the same country as the last, where Plumier only appears to have seen it. The *leaves* are peltate and five-ribbed exactly as in our *clypeata*, n. 20, but of a very different outline, rounded at the base, and terminating in three rather spreading but not deep lobes. Their size and appearance, except having but three lobes, is like our broadest variety of *Hedera helix*, called Irish Ivy. *Flowers* like the last.

34. *P. viridiflora*. Tubular Green Passion-flower. Cavan. Ic. v. 5. 15. t. 424.—Leaves peltate, smooth, with three deep obovate lobes. Tube of the calyx as long as its segments. Petals and bractæas wanting.—Gathered by Louis Née, near Acapulco, flowering in February. The *leaves* have seven radiating ribs, and three deep lobes, of which the middle one especially is greatly contracted at the base; each two or three inches long. The *footstalks* have two sessile glands towards their origin. *Stipulas* lanceolate. *Bractæas* and *petals* wanting. *Calyx* green; its tube an inch long; segments spreading, linear-oblong, of about the same length. *Rays* short, combined by an entire base. *Column* very slender. A curious species, known only from the work of Cavanilles. We have however a West Indian specimen from the late Mr. Smeathman, which answers to it nearly in every respect, except being hairy all over.

35. *P. reflexa*. Reflexed Passion-flower. (*P. reflexiflora*; Cavan. Ic. v. 5. 15. t. 425.)—Leaves peltate, smooth, with three deep, spreading, obtuse lobes; their sinuses and stalks glandular. Tube of the calyx as long as its segments. Bractæas ovate, veiny.—Gathered by Louis Née near Panama. About the size of the last. The *leaves* are somewhat hastate, entire, five-ribbed, with six stalked glands on their *footstalks*, and as many sessile ones in each sinus, between the lobes. *Stipulas* large, half-ovate, wavy. *Bractæas* large, veiny. Tube of the *calyx* an inch long, the thickness of a goose-quill, its segments, as well as the *petals*, oblong, of the same length, reflexed, scarlet. *Nectary* a double fringe, of minute upright rays. *Column* very slender.

36. *P. glauca*. Glaucescent-leaved Passion-flower. Ait. n. 11. Willd. n. 31. (*P. stipulata*; Aubl. Guian. t. 325. *Balsamina altera*, indica, &c.; Ambros. Phyt. 99.)—Leaves slightly peltate, heart-shaped, smooth, with three broad, spreading lobes; glaucous beneath. Footstalks glandular. Base of the calyx hemispherical. Bractæas minute.—Native of Cayenne, introduced by Messrs. Lee and Kennedy in 1779. It flowers in the stove in August and September, and is very ornamental as well as fragrant. The *flowers* somewhat resemble those of *P. serratifolia*, and are remarkable for the innumerable dense tufted filaments of their *nectary*, the outermost nearly equal to the *petals*, the rest gradually shorter and more erect. Every part of the plant is somewhat glaucous, and very smooth. *Leaves* divided about half way down. *Stipulas* large, half heart-shaped. *Bractæas* a quarter of an inch long, at some distance from the convex glaucous base of the calyx. Nobody before us has noticed the old figure of Ambrosinus, though

PASSIFLORA.

though it cannot be mistaken, and is the only one with flowers.

37. *P. holosericea*. Velvet-leaved Passion-flower. Linn. Sp. Pl. 1359. Cavan. Diff. t. 291. (*Granadilla folio hastato holosericeo*, &c.; Mart. Decad. t. 51.)—Leaves ovate, three-lobed, downy on both surfaces, with a recurved tooth on each side at the base.—Native of Vera Cruz, from whence it was originally sent by Houttoun. The leaves are remarkable for their exquisite velvet-like softness, and for the two recurved teeth at their base; their side-lobes are small. Flowers flat, one inch and a half broad. Petals white, often minutely dotted with red, as well as the segments of the calyx, which they resemble in size and shape. Rays spreading, straight, parti-coloured with red and yellow.

38. *P. hirsuta*. Hairy Passion-flower. Linn. Sp. Pl. 1359. Ait. n. 16. Cavan. Diff. 443. (*Clematis indica, flore minimo pallido, foliis hirsutis*; Plum. Amer. 74. t. 88. f. A.)—Leaves hairy, with three oblong entire lobes, the middlemost longest; the lower leaves smooth on the upper side. Footstalks with two glands. *Solander in Ait. Hort. Kew.*—Native of the West Indies. Sent to Kew in 1778, where it is said to flower in the stove in September. This is a doubtful species. What the younger Linnæus collected for it in England, if we mistake not, is certainly only a hairy specimen of *minima*, n. 30, and has no petals. Plukenet's t. 212. f. 1. and the figure in Hermann's Paradisus, p. 176, appear to belong to some species unknown to us, with jagged leaves, and flowers with petals. Linnæus, having no specimen, evidently adopted the species from Plumier, whose plant we believe to be no other than *minima*, and whose solitary leaf is copied in Am. Acad. f. 16.

39. *P. fetida*. Stinking Passion-flower. Linn. Sp. Pl. 1359. "Giseke Ic. t. 20." Willd. n. 34. Cavan. Diff. t. 289.—Leaves hairy, heart-shaped, somewhat three-lobed. Bractæas repeatedly pinnatifid, in capillary glandular segments, like the stipulas.—Native of the West Indies; not rare in our stoves, where it blossoms in summer, and ripens fruit, which resembles a gooseberry in size, and somewhat in flavour. The whole plant is hairy, viscid, and fetid, of a pale green. Flowers whitish, distinguished from all the foregoing, by large finely divided bractæas, encompassing them in the bud, as well as the fruit, like the involucre of *Nigella damascena*. The root is said to be annual or biennial, but we doubt whether it be so in a state of nature.

40. *P. ciliata*. Fringe-leaved Passion-flower. Ait. n. 18. Willd. n. 35. Curt. Mag. t. 288.—Leaves smooth, with three wavy, somewhat ferrated, fringed lobes; the middlemost longest. Bractæas repeatedly pinnatifid, in capillary segments, like the stipulas.—Mrs. Norman, a lady long celebrated for the cultivation of botanical rarities, received this plant from Jamaica in 1783, or earlier. Linnæus knew it not. The bractæas resemble the last, but are not so much divided. Petals and calyx pink. Rays spreading, variegated with purple and white. The leaves are coriaceous, veiny, quite smooth except their margin. It is not impossible that Hermann's t. 176 may be a diminished and very imperfect representation of this; see n. 38.

41. *P. ferrulata*. Finely-ferrated Passion-flower. Jacq. Obs. fasc. 2. 26. t. 46. f. 2. Willd. n. 36.—Leaves three-lobed, very minutely ferrated; the middle lobe longest. Footstalks with two glands. Bractæas distinct, entire.—Gathered by Jacquin at Carthage. He compares it with *incarnata*, n. 44, from which he says it is very certainly distinguished by the leaves not being cut away close to the side ribs at the base, and by the minuteness of their

ferratures. The flowers are variegated with purple and white, delightfully fragrant, two inches and a half wide.

42. *P. aurantia*. Norfolk-island Passion-flower. Forst. Prodr. 62. Willd. n. 37. Andr. Repof. t. 295.—Leaves smooth, dotted beneath, with three spreading bluntish lobes; rounded at the base. Calyx somewhat tubular, longer than the petals. Nectary tubular, abrupt, lobed, surrounded with upright rays.—Native of New Caledonia and of Norfolk Island. It flowers copiously in a stove in summer, requiring a light dry soil. The leaves are sometimes slightly five-lobed. Flowers orange, the tube of their nectary green, longer than the purple upright rays which surround it. This is akin to n. 24 and 25 of our list, near which Willdenow ought to have placed it. The nectary is very peculiar, being, like the whole flower, shaped much as in *P. Mucuruja*, n. 18, but nevertheless accompanied with rays; its orifice moreover is lobed or jagged.

43. *P. cuneifolia*. Wedge-leaved Passion-flower. Cavan. Diff. 460. t. 292. Willd. n. 38.—Leaves deeply three-lobed, ferrated, acute; three-ribbed, with two glands, at the base. Bractæas distinct, elliptical, entire. Calyx flat. Rays not half so long as the petals.—Native of America. Seen by Cavanilles in Thouin's herbarium. We have it not. The specific characters distinguish it from the next, which it greatly resembles.

44. *P. incarnata*. Flesh-coloured Passion-flower, Maracoc, or May-cock. Linn. Sp. Pl. 1360. Sm. Insects of Georgia, t. 12. Jacq. Ic. Rar. t. 187. (*Clematis trifolia, five flos passionis*; Ger. em. 1592.)—Leaves deeply three-lobed, ferrated, acute; three-ribbed, with two glands, at the base. Bractæas distinct, lanceolate, with glandular teeth. Calyx flat. Rays as long as the petals.—Native of North America. One of the first species introduced to the knowledge of European botanists, and cultivated here in the days of Gerard and Parkinson, though now seldom met with, as it will scarcely ever survive the English winter, or rather spring. It however merits a place in the conservatory. The leaves are very deeply three-lobed, three-ribbed, ferrated, finely downy on both sides; paler beneath. Flowers rather large, flesh-coloured or pale purple, the long slender spreading rays elegantly speckled with crimson and white. Jacquin's figure is too blue.

45. *P. sanguinea*. Blood-coloured Passion-flower.—Leaves deeply three-lobed, ferrated, acute, without glands. Bractæas distinct, lanceolate, with glandular teeth. Calyx downy, its tube half as long as the segments. Rays half the length of the petals. Stamens linear, flat.—Gathered by Smeathman in the West Indies. A very fine species, of which we can find no description nor figure. The branches, and all the stalks, are downy; tendrils smooth. Footstalks, and base of the leaves, destitute of glands; ferratures rather coarse; upper surface smooth; lower downy, with prominent ribs and veins. The stipulas seem fallen. Flowers near three inches broad; as far as can be judged from the dried specimen, they appear of a rich deep red. Tube of the calyx above half an inch, or twice its diameter, in length, clothed with fine rusty down; limb horizontal, its segments linear-lanceolate, with the awl-shaped tips longer than usual; petals rather smaller than the calyx, but of the same shape and colour. Rays reddish, slender, much curled in a dry state, but apparently half the length of the petals, the inner row erect about the column, which is tall and slender. Filaments remarkably broad and flat, somewhat combined at the base, with large anthers. Germen finely downy.

46. *P. peduncularis*. Long-stalked Passion-flower. Cavan. Ic. v. 5. t. 426.—Leaves with three rounded ferrated lobes. Bractæas combined, tubular, downy. Calyx downy, its

PASSIFLORA.

its tube nearly equal to the segments. Rays very minute. Stem square.—Gathered by Louis Née, in several places in Peru, flowering in March. The square stem, which is slightly downy, and the bractæ united into an ovate, obtuse, slightly notched, and three-cleft tube, full half as long as the tube of the calyx, are characteristic of this species, which is one of Jussieu's genus *Tafsonia*, like the four following. The leaves of this are rather broader than long, their lobes broad and rounded, equally ferrated; glaucous, and in some degree downy, at the back. Footstalks with four sessile glands. Stipulas squarish, toothed. Flower-stalks near four inches long, being twice the length of the leaves. Flowers rose-coloured, large and handsome, externally downy; their petals elliptical, an inch long, a little shorter than the calyx. Nectary crowned with minute teeth rather than rays, as in *adulterina*, n. 3. Filaments flattened. Fruit globose, rather downy, one inch and a half in diameter.

47. *P. trifoliata*. Three-leaved Passion-flower. Cavan. Ic. v. 5. 16. t. 427.—Leaves ternate, elliptical, downy, entire. Bractæas distinct, toothed. Tube of the calyx as long as the segments, tumid at the base. Rays very minute.—Native of Peru and Chili, where it was found by Louis Née, flowering in March and April.—Remarkable for its truly ternate leaves. The stipulas are half heart-shaped, with bristly ferratures. Footstalks downy, without glands. Bractæas large, ovate, downy, with broad, blunt, tooth-like ferratures, half an inch below the calyx. Flowers rose-coloured, large and handsome, like the last, but with a longer calyx-tube, whose base is inflated and umbilicated.

48. *P. pennipes*. Wing-footed Passion-flower. (*P. pinnatipula*; Cavan. Ic. v. 5. 16. t. 428.)—Leaves three-lobed, ferrated, acute; woolly beneath. Bractæas distinct, ferrated. Tube of the calyx as long as the segments. Rays half as long as the petals. Stipulas deeply pinnatifid.—Found by Louis Née in various parts of Chili, from whence also we have a specimen, gathered by Mr. Menzies. The leaves are three-cleft more than half way, reticulated, ferrated, two or three inches long; very smooth, and bright green, above; their backs, like the branches and stalks, clothed with dense, white, woolly pubescence. Stipulas finely and deeply pinnatifid, smooth. Bractæas ovate, sharply ferrated, deciduous, rather downy externally only. Flowers much larger than in the last, of a pale rose-colour, very finely downy externally, as is also the germen. Rays capillary, spreading on the petals, and full half as long. Column remarkably angular, smooth. With great reluctance we have been obliged to alter the uncouth name given by our lamented correspondent Cavanilles, but have retained his idea. The singularly divided stipulas are like a pair of wings to the footstalk.

49. *P. tomentosa*. Downy Long-tubed Passion-flower. Cavan. Diff. 450. t. 275, 276. Willd. n. 40.—Leaves three-lobed, ferrated; downy on both sides. Bractæas combined, tubular. Tube of the calyx thrice as long as the segments.—Gathered long ago, by Joseph de Jussieu, in Peru. His specimens were seen in his celebrated nephew's herbarium at Paris, by Lamarck and Cavanilles, from whose publications only our knowledge concerning this magnificent plant is derived. The respective proportions of the flower, and its minute rays, agree with our third species; but the whole flower appears to be larger, and the bractæas are combined into a sharply three-cleft downy tube. The leaves have three broad, moderately deep, lobes, and, like the rest of the plant, are clothed with fine short down. The footstalks bear numerous stalked glands. The stipulas are half-ovate, pointed, and downy. The flower expands

three inches, and is said to be rose-coloured; its tube is five inches long, whether smooth, or downy as in the next, is not mentioned; nectary a row of very small, roundish, slightly stalked glands, or obtuse rays, crowning the tube. Fruit ovate-oblong, soft, full of yellow eatable pulp. The Peruvians know this plant by the name of *Tacfo*.

50. *P. mixta*. Smooth-leaved Long-tubed Passion-flower. Linn. Suppl. 408. Sm. Plant. Ic. t. 25. Willd. n. 41. (*P. longiflora*; Lamarck, n. 28. *P. Tacfo*; Cavan. Diff. 451. t. 277.)—Leaves with three or five lobes, ferrated, acute; smooth on both sides. Bractæas combined, tubular. Tube of the calyx thrice as long as the segments.—Sent by Mutis from New Granada to Linnæus, along with drawings, in Indian ink, of this and our third species. The present differs from the last in having smooth, more deeply lobed leaves, whose side-lobes are occasionally slightly divided; but that such a circumstance is accidental, may be presumed, not only from the coincidence of every other part, but because there are always five ribs, more or less apparent; see the plates quoted. The footstalks bear about six glands, and are rather downy; the flower-stalks, tubular bractæas, and especially the outside of the calyx, are finely and densely pubescent. Flowers: rose-coloured or purplish, a little smaller than those of *P. tomentosa*, with much the same sort of nectary. Fruit obovate, with a slight longitudinal furrow.—Linnæus roundly asserts that this species is produced between *incarnata* and *adulterina*, for which there is no authority, except the affinity of its fructification to the latter, and some resemblance in the shape of its leaves to the former. Nothing could be greater acquisitions to our conservatories than these tubular Passion-flowers, whose seeds the Spaniards surely might obtain with great ease, and which would probably prove almost hardy in our climate, like the elegant *Fuchsia*, *Cobæa*, and other late discoveries, from the same country.

Section 4.—Leaves with many segments. Five species.

51. *P. carulea*. Common Blue Passion-flower. Linn. Sp. Pl. 1360. Willd. n. 42. Cavan. Diff. 461. t. 295. Mill. Illustr. t. 74. Curt. Mag. t. 28.—Leaves deeply palmate, in five entire smooth segments.—Native of Brasil. This species, though not brought to Europe till long after the *incarnata*, has now, from its much greater hardness, and facility of culture, taken place of that, and is generally dispersed throughout the more temperate parts of Europe. In Italy, Spain, Portugal, and the Levant, it combines with the Jasmine, more especially, to form luxuriant bowers; and in those countries bears abundance of orange-coloured fruit, as well as fragrant and beautiful flowers. With us it only blossoms in the open air; requiring protection for its roots and stems against hard frosts. Loureiro speaks of *P. carulea* as wild about Canton in China, and there is a narrow-leaved rather tender variety, known in our stoves, reported to have come from that country, or the East Indies. But we are inclined to suspect both may originally have gone thither from Europe or the Brasils.—The whole plant is smooth, of a rather glaucous hue, and the entire edges of the leaves distinguish it from all the rest of this section. Stipulas half-heart-shaped, wavy. Bractæas ovate, concave, entire, scarcely half so long as the full-grown bud. Calyx spreading and nearly flat, its segments elliptic-oblong, like the petals, and of the same white, or pale greenish, hue. Rays spreading widely, shorter than the petals, purple at the base, white in the middle, blue at the end. Each flower lasts only one day, but there is a copious succession.

52. *P. filamentosa*. Long-rayed Blue Passion-flower. Cavan. Diff. 461. t. 294. Willd. n. 43.—Leaves palmate,

in five acute serrated segments. Footstalks with two sessile glands. Bractæas distinct, serrated. Rays longer than the corolla.—Native of America. Cavanilles described it from the garden of the late Duke del Infantado, to whose family he was preceptor. We had, at the first view of his figure, for we have seen no specimen, a suspicion that this might be a variety of some three-lobed species. The glands of the footstalks agree with those of *ferrulata*, n. 41, but the shape of the leaves, and their coarser serratures, as well as the serrated bractæas, materially differ. From *incarnata*, n. 44, and *cuneifolia*, n. 43, the only species besides with which it can be compared, it is distinguished by the leaves not being cut away close to the ribs at the base, as well as by the situation of the glands on their stalks, and the presence of other glands in the sinuses. The stipulas moreover are half-pinnatifid, not awl-shaped and entire; and the bractæas differ in size from *incarnata*, and in their serratures from *cuneifolia*. The leaves we understand to be smooth; their side-lobes much smaller than the others. Flower coloured somewhat like the *cerulea*; furnished with five rows of rays, of which the outermost extend beyond the calyx and petals. Fruit globose, with white viscid pulp.

53. *P. ferrata*. Many-lobed Serrated Passion-flower. Linn. Syst. ed. 10. v. 2. 1248. Syst. Veg. ed. 14. 823. Willd. n. 44. Cavan. Diff. 449. t. 296. (*P. ferratodigitata*; Linn. Sp. Pl. ed. 1. 960. *P. digitata*; ed. 2. 1360. *Clematis indica polyphylla major*, flore clavato, fructu colocythidis; Plum. Amer. 62. t. 79.)—Leaves palmate, in five or seven very deep serrated segments. Footstalks with several glands. Bractæas combined, entire.—Gathered by Plumier in Martinico, in one place only, near St. Mary's river. Cavanilles saw a specimen in Jussieu's collection, and there is one without flowers, in that of the younger Linnæus; but this very magnificent species is unknown in our gardens. The flowers equal even those of *quadrangularis*, n. 7, in magnitude and splendour, and the broad many-lobed leaves, whose under side is somewhat downy, are much more handsome. Plumier says the shoots are as large, hard, and knotty as those of a vine, spreading widely over the trees and bushes, which they decorate with verdant foliage. The flower-bud, invested with its large, ovate, pale, purple-veined bractæas, combined at their base, and entire at their margin, is as big as a hen's egg. The calyx has a broad funnel-shaped base; its segments are of a violet colour, like the petals, but much broader, each about one inch and a half long. Rays about the same length, very numerous, thick, and somewhat angular, in a double row, the outermost shortest, each ray whitish at the point, violet in the middle, paler from thence to the base, with five violet bands. The tube of the calyx is internally lined with short, red-headed, glandular rays. Fruit as big as an orange, with a thick coat. Plumier did not meet with it ripe, but it seems much like that of the *quadrangularis* in colour and structure. The flowers are fragrant.—The synonyms display remarkable changes in the specific name, made by Linnæus himself. We should have preferred *digitata*, not only as given in his most classical work, but as the most expressive, had it been strictly correct; the leaves however are not truly digitate, but merely divided in a fingered manner, and not more so than in *cerulea*, n. 51. The young ones have sometimes but three lobes, though five or seven ribs. The stipulas are small, half-pinnatifid, as in *filamentosa*, n. 52.

54. *P. pedata*. Curled Passion-flower. Linn. Sp. Pl. 1360. Ait. n. 21. Cavan. Diff. 462. (*Clematis indica alia polyphylla*, flore crispato; Plum. Amer. 66. t. 81.)—Leaves pedate, of seven serrated acute leaflets. Bractæas

distinct, serrated. Rays twisted.—Found by Plumier, by the road side near Miragoan in Hispaniola, and no where else. The shoots are somewhat angular. Leaves remarkable for being pedate, as in *Helieborus niger*, consisting of seven, almost entirely distinct, elliptic-lanceolate, acute, single-ribbed, sharply serrated leaflets, of a fine shining-green, the central one three or four inches long. Footstalks rather long, with a pair of glands in the middle. Stipulas not represented. Flowers surpassing all the rest, according to Plumier, in size, fragrance, and brilliancy of colours. Bractæas large, ovate, acute, concave, very sharply jagged and serrated at the edge. Calyx pale green, dotted on the inside with red. Petals blue. Rays in one principal row, spreading, longer than the petals, deep red, with two or three white bands, their extremities of a fine violet, tapering, zigzag, and twisted. Column, stamens and styles white, speckled with red. Stigmas divided. Fruit globose, like a small gourd, the size of a moderate apple, speckled with shades of green.—Mr. Masson is recorded as having sent this noble plant to Kew in 1781, from the West Indies, but there is no account of its flowering, and we fear it is now lost.

55. *P. heterophylla*. Various-leaved Passion-flower. Lamarck, n. 32. Willd. n. 46. Cavan. Diff. 462. (*Granadilla heterophylla*, flore albo; Plum. Ic. 129. t. 139. f. 1.)—Leaves pedate, of five, nearly entire, abrupt leaflets; the lower ones linear, ternate or simple. Rays straight.—Gathered by Plumier, near a rivulet in the fourth part of Hispaniola, flowering and fruiting in September. Lamarck. This is the most remarkable of all, for the difference between the lower leaves, which are long, very narrow, undivided, and entire, either simple or ternate, and the upper ones, which are pedate, of five broad, short, abrupt, entire, sometimes slightly lobed leaflets, an inch or two long. Flowers yellowish-white, scarcely above an inch wide, their calyx horizontal and flat, twice as long as the rays, the petals being of an intermediate length between both. Fruit oval, rather bigger than an olive, deep violet, full of violet juice. Nothing is known of the bractæas.—This singular species approaches in foliage to the last, in flower to *lunata*, n. 17, and in fruit to *suberosa* and its allies. No other botanist than Plumier seems to have met with it, nor is it known in the European collections.

The scientific botanist who contemplates the above view of this interesting genus, will perceive that it has many claims to be considered as a natural order, requiring subdivision into several genera. This task will at first appear easy, as nothing can be more striking than the difference of structure in the *nectaries* of several species, nor are the tubular calyces of others less remarkable. On a further inspection, however, more and more difficulties will arise. The calyx is tubular in various species, otherwise very unlike, and flat in others, no less dissimilar among themselves. The minuteness of the rays in some of the *Tacsonia* of Jussieu, loses its importance when we consider the several new species in the fifth volume of Cavanilles' Icones. The bractæas, which Cavanilles reckons a calyx, and on the absence or presence of which, as well as their union or separation, he forms his subdivisions of the genus, are of all things most improper, even for that purpose, and lead to a less natural arrangement than the leaves themselves, which last we have followed, from necessity rather than choice, after the example of Linnæus, Lamarck, and Willdenow. The want of petals collects several species into a most natural assemblage, but others, as *orbiculata* and *peltata*, for instance, totally overlook the authority of that character. A minute and regular investigation of all their *nectaries*,

such as Mr. Sowerby has bestowed upon six species, in the second volume of the Transactions of the Linnæan Society, might throw considerable light upon the subject, but is not to be undertaken without a great variety of specimens, either fresh, or preserved in spirits. It is much to be regretted that these fine plants have received so little attention from our periodical authors, to whose pages many of them, easily to be procured, would prove a great accession. S.

PASSIFLORA, in *Gardening*, contains plants of the herbaceous and shrubby flowering kinds, of which the species cultivated are: the common or blue passion-flower (*P. cærulea*); the rose-coloured passion-flower (*P. incarnata*); the yellow passion-flower (*P. lutea*); the notch-leaved passion-flower (*P. ferratifolia*); the apple-fruited passion-flower (*P. maliformis*); the square-stalked passion-flower (*P. quadrangularis*); the wing-stalked passion-flower (*P. alata*); the laurel-leaved passion-flower, or water lemon (*P. laurifolia*); the many-flowered passion-flower (*P. multiflora*); the red-fruited passion-flower (*P. rubra*); the moon-shaped-leaved passion-flower (*P. murucuja*); the bat-winged passion-flower (*P. vespertilio*); the round-leaved passion-flower (*P. rotundifolia*); the ciliated passion-flower (*P. ciliata*); the cork-barked passion-flower (*P. fuberosa*); the silky-leaved passion-flower (*P. holosericea*); the glaucous-leaved passion-flower (*P. glauca*); and the dwarf-leaved passion-flower (*P. minima*).

Of the first sort there is a variety with much narrower lobes, divided almost to the bottom; the flowers come later in the summer; the petals are narrower, and of a purer white colour.

It is observed, that if the seventh sort does not equal the first in elegance, it exceeds it in magnificence, in brilliancy of colour, and in fragrance, the flowers being highly odoriferous.

Method of Culture.—In all the sorts it is either by seeds, layers, or cuttings, according to the kinds.

The first or hardy sort is capable of being raised either by seeds, layers, or cuttings; the seed should be sown in the early spring, as March, in large pots, half an inch deep, either plunging them in a warm border, and as the weather becomes warm moving them to the shade; or in a hot-bed, which will forward the germination of the seed more fully, and the plants will rise sooner; which should afterwards be hardened gradually to the open air till the autumn, and then placed under a garden frame for the winter, to have shelter from frosts, and in the spring planted out in pots, or some in the nursery; and in a year or two they may be transplanted where they are to remain, against some warm south wall.

The layers should be laid down from some of the branches in the common way in the spring, when they will readily emit roots, and make proper plants by autumn; when, or rather in the spring following, they should be taken off and transplanted either into pots in nursery rows, or where they are to remain.

The cuttings should be made in February or March, from the strong young shoots, in length from about eight to ten or twelve inches, planting them in any bed or border of common earth, giving frequent watering in dry weather, and when sunny and hot, if in a situation exposed to them, a moderate shade of mats will be of much advantage. They will emit roots at bottom, and shoots at top, and become good plants by autumn, allowing them the occasional shelter of mats, &c. during the winter's frost; and in the spring let them be planted out. If a quantity of these cuttings be planted close, and covered down with hand-glasses, it will forward their rooting; observing, however, when they

begin to shoot at top, to remove the glasses, in order to admit fresh air.

The second and third, or green-house kinds, may be increased by seed, layers, and parting the roots; the seed, obtained from America, should be sown in pots in March or April, plunging them in a hot-bed to raise the plants, which afterwards inure to the open air in summer, giving them the shelter of a green-house or frame in winter; and in the spring following plant some out in pots, placing them among the green-house plants; and others may be planted in the full ground, under a warm fence, to take their chance.

The layers should be made in the summer from young shoots, which will readily grow, and become good plants for potting off in autumn. The parting the roots should be done in spring, before they begin to shoot. The second sort multiplies exceedingly by its creeping roots; which should be divided into slips, and planted in a bed of rich earth till autumn, when some should be transplanted into pots for occasional shelter in winter.

All the more tender stove kinds are capable of being increased by seeds, layers, and cuttings; the seeds are procured chiefly from abroad; and should be sown in spring in pots, plunging them in a hot-bed, or in a stove bark-bed; the plants soon appear, which, when three inches high, should be pricked out in separate small pots, giving water, and re-plunging them in the hot-bed, occasionally shading them till rooted; as they advance in growth, they should be shifted into larger pots, and be retained constantly in the stove.

The layers should be made from the young branches in the spring or beginning of summer, which will readily grow, and be fit to pot off separately in autumn.

The cuttings should be made in the spring or summer, from the young shoots, planting them in pots, plunging them in the bark-bed, and giving water frequently; when most of them will take root, and be fit to pot off singly in autumn.

In respect to their general culture; as in severe winters, in the first sort, the branches, if not duly protected, are sometimes killed, it is advisable at such times, whilst the plants are young in particular, to give them the shelter of mats during the inclement season, and protect their roots with dry litter laid over the ground; carefully uncovering their branches as soon as the frost breaks; this covering, however, is only necessary in very severe frosts.

The green-house sorts should generally be potted, to move to shelter in winter, either in a green-house, or deep garden-frame; some plants of each sort may also be planted in the full ground, in a warm border, to take their chance; covering the ground over their roots in severe weather; and in the different orders of planting, placing stakes for the support of their climbing growth in the summer. And all the stove kinds must constantly be kept in pots, placed in the stove, and for the most part plunged in the bark-bed; placing strong stakes for the purpose of training the branches to, and managing them as other stove plants of a similar growth. See *STOVE-Plants*.

The first sort is highly ornamental in the open ground, when trained against southern walls, &c.; and those of the green-house, and stove kinds, among other plants in these collections.

PASSIGNANO, in *Geography*, a town of Italy, in the Perugian, on the N. side of the lake; 22 miles N.W. of Perugia.

PASSING-NOTES, in *Music*. This is a subject so well treated by Dr. Pepusch, in his Treatise on Harmony, that we shall do little more than transcribe his rules.

After giving instructions for preparing and relieving regular discords, he says, we will now shew how discords may be used without being prepared, particularly by suppositions; but then they are no longer to be called discords, but *passing* or *transient notes*.

In diminutions or divisions, all the notes that are not to be found in the chord upon which the passage is built, are called *passing notes*. Passing notes must be used in a regular ascent or descent, not by leaps, or wide intervals. See in *Music Plates* examples of passing notes selected from Pepusch.

PASSING-Places, are wider places than the ordinary breadth of some canals, for boats to lie in, while others pass, and to turn in, &c.

PASSING-Tickets, or *Permits*, are notes or checks which the toll-clerks on some canals give to the boatmen, specifying the lading which they are found to have on board.

PASSION, *PASSIO*, *παθος*, or *παθημα*, is applied to the different motions and agitations of the soul, according to the different objects that present themselves to the senses. In propriety, all those motions, whereby the soul is carried towards any thing; as love, ambition, revenge, &c. are rather actions than passions.

Those motions, by which the soul finds itself interrupted in its actions, as grief, &c. are the only real passions.

We find various modifications and impressions of pleasure and pain inseparably annexed by an established law of nature, to the several judgments we form concerning good and evil: these judgments, with their respective modifications of pleasure or pain annexed, according to the various appearances and relations of the object considered, either as good or evil, present or absent, certain or uncertain, probable or improbable, possible or impossible, and affecting the machine in a certain manner peculiar to such modifications, make what we call the passions.

How, or by what means, this mutual action and communication between soul and body are effected, we are, in a great measure, ignorant: we have but very obscure and faint notions of any thing prior, or more simple, to resolve it into, except the immediate will and agency of the first cause itself.

Malebranche defines the passions to be all those emotions naturally arising in the soul, on occasion of extraordinary motions of the animal spirits, and the blood: in opposition to those motions of the soul, which are common to us with pure intelligences, and which he calls *natural inclinations*.

Though the passions be inseparable from inclinations; and though a man be only capable of sensible love or hatred, because he is capable of spiritual ones; yet does it appear just in that author to distinguish between them? Passions are much stronger and warmer than inclinations; their objects also are different, and so are their causes: in truth, passions and inclinations differ just as much as sense and imagination.

In effect, the passions of the soul are the impressions of the author of nature, which incline us to our bodies, and all things that may be of use to their preservation: natural inclinations are the impressions of the Author of nature, which determine us primarily to love him, as our supreme good.

An ingenious writer has accurately distinguished between our affections and our passions: the former, which we apply indiscriminately to all reasonable beings, may most properly signify the desires and inclinations, founded in the reasonable nature itself and essential to it; such as self-love, benevolence, and the love of truth. These, when aided and strengthened by additional, instinctive determinations, are, properly,

passions. Those tendencies within us, that are merely arbitrary and instinctive, such as hunger and thirst, and the desires between the sexes, we commonly call appetites or passions, indifferently, but seldom or never affections. Price's *Rev. of Morals*, p. 125, &c. For the difference between appetites and passions, see *APPETITE*.

Passion, says another excellent writer, is a kind of medium between a simple affection of the mind, and the appetites and sensations of the body. Passion is an affection of the mind, which distinguishes it from the appetites of the body, hunger and thirst, and from bodily sensations; and it is attended with a peculiar and extraordinary emotion of the animal spirits, by which it is distinguished from pure affection, and from the several sensations; in all which, though there be some motion of the blood and spirits, yet that motion is natural and regular; whereas in the agitation, occasioned by the passions, the spirits are moved after a more vehement and tumultuous manner. Grove's *System of Moral Philosophy*, vol. i. chap. 7.

Dr. Cogan, who merits a place among other approved authors on this subject, observes, in his "Philosophical Treatise of the Passions," that one or other of the three terms, passion, emotion, affection, is always employed to express the sensible effects which objects, or ideas concerning them, have upon the mind; but these terms are so frequently employed in a vague and indeterminate manner, that some difficulty attends the attempt to restore them to their precise and discriminating signification. Accordingly the word *passion* is rendered subject to several peculiarities in the application of it. Sometimes it is used, in a generic sense, as expressive of every impression made upon the mind, whether they be weaker or stronger. In one instance the word is emphatically employed to express "suffering," as "our Saviour's passion;" in another it indicates "anger" exclusively. Sometimes the term "passion," and also its adverb "passionately," express a very strong predilection for any pursuit, or object of taste; a kind of enthusiastic fondness for any thing. In a sense similar to this the word is also applied to every propensity, which operates strongly and permanently upon the mind; as the *selfish* passions, the *generous* passions. Yet when we mean to particularize any of these, a different phraseology is used. The word "passion" is appropriated to the *evil* propensities which are uniformly operative. Thus, we do not say the "affection" of pride, or of avarice, but the "passion." The term "affection," on the other hand, is appropriated to the *virtuous* propensities; as the *social*, *friendly*, *parental*, *filial* affections, &c.; though, philosophically considered, the relation they bear to the state and workings of the mind is perfectly analogous. This latitude of expression is not confined to the language of the vulgar, but it is obvious even among philosophers, who are not agreed in their ideas of the terms they employ. The controversy between the ancient Peripatetics and the Stoics, with regard to the passions, was probably owing to their affixing different meanings to the word. The one sect maintained, that the passions are good, and useful parts of the constitution, while they are held under the government of reason. The other sect, conceiving that nothing is to be called passion, which does not, in some degree, becloud and darken the understanding, considered all passion as hostile to reason, and therefore maintained, that, in the wise man, passion should have no existence, but be utterly exterminated. One sect considered passion only as the cause of those bad effects which it often produces. And the other considered it as fitted by nature to produce good effects, while it is under subjection to reason; but both allowed, that no dictate

of passion ought to be followed in opposition to reason. Their difference therefore was verbal more than real, and was owing to their giving different meanings to the same word. The precise meaning of this word seems not to be more clearly ascertained among modern philosophers. Mr. Hume gives the name of "passion" to every principle of action in the human mind; and consequently maintains, that every man is and ought to be led by his passions, and that the use of reason ought to be subservient to the passions.

Dr. Hutcheson, considering all the principles of action as so many determinations or motions of the will, divides them into the calm and the turbulent. The turbulent, he says, are our appetites and our passions. Of the passions, as well as of the calm determinations, he says, that some are benevolent, others are selfish; that anger, envy, indignation, and some others, may be either selfish or benevolent, according as they arise from some opposition to our own interests, or to those of our friends, or persons beloved or esteemed. It appears, therefore, that this excellent author gives the name of passions, not to every principle of action, but to some; and to those only when they are turbulent and vehement, not when they are calm and deliberate. This view of the subject coincides with Cicero's translation of the Greek word *παθος*, which he renders by *perturbatio*. It is evident, says Dr. Reid, that this meaning of the word "passion" accords much better with its common use in language, than that which Mr. Hume gives it.

When he says, that men ought to be governed by their passions only, and that the use of reason is to be subservient to the passions, this, at first hearing, appears a shocking paradox, repugnant to good morals and to common sense; but, like most other paradoxes, when explained according to his meaning, it is nothing but an abuse of words. For if we give the name of "passion" to every principle of action, in every degree, and give the name of "reason" only to the power of discovering the fitness of means to ends, it will be true, that the use of reason is to be subservient to the passions.

Dr. Reid, adverting to the use of words in common language, means by the word "passion," not every principle of action distinct from those desires and affections which he had previously explained (see the terms DESIRE and AFFECTION), but such a degree of vehemence in them, or in any of them, as is apt to produce those effects upon the body or upon the mind of which we have already taken some notice, and which will be further considered in the sequel of this article.

According to the statement of Dr. Cogan, the primary idea annexed to the word "passion" is that of *passiveness*, or being impulsively acted upon. In this sense the term properly signifies the sensible effect, the feeling to which the mind is become subjected, when an object of importance suddenly and imperiously demands its attention; and as several of our passions are of a disagreeable and powerful nature, and as this passive or helpless state is so frequently connected with *suffering*, the transition from one signification to the other is not only natural but unavoidable; and a passion will often be considered as synonymous with suffering. Upon the whole, the mind is equally passive in every effect suddenly and unexpectedly produced upon it, whether its influence be of a pleasant, or unpleasant nature. Accordingly this writer observes, that the term "passion" may, with strict propriety, be used, and used exclusively, to represent the *first feeling*, the *percussion* as it were, of which the mind is conscious from some impulsive cause, by which it is wholly acted upon without any efforts of its own, either to solicit or escape the impression. For the difference be-

tween passion and emotion, see EMOTION; and between passion, emotion, and affection, see AFFECTION.

Writers on this subject have differed very much in their arrangement or classification of the passions. The ordinary distribution is into passions of the *concupiscible appetite*, which are pleasure and pain, desire and aversion, love and hatred; and those of the *irascible appetite*, which are anger, courage, fear, hope, and despair. See the authors on the subject of the passions; Des Cartes, who considers them physically; Coeffeteau, who gives us the tableau, or picture of the passions; La Chambre, the characters of the passions; Senault, the uses of the passions; and Hutcheson, Watts, and others, who consider them in a moral and religious view.

Some authors have placed the passions in contrast to each other, as hope and fear, joy and sorrow: some have considered them, as they are personal, relative, social: some, according to their influence at different periods of life: others, according as they relate to past, present, or future time; as sorrow refers principally to things past, joy and anger to present occurrences, hope and fear to future events. The academicians advanced that the principal passions were fear, hope, joy, and grief. Thus Virgil:

"Hinc metuunt, cupiunt, gaudentque, dolentque."

They included aversion and despair under the fourth; and hope, fortitude, and anger, under desire. But this arrangement is in some respects too general, and in others defective.

Dr. Hartley has arranged the passions under five grateful and five ungrateful ones. The former are love, desire, hope, joy, and pleasing recollection: the latter are hatred, aversion, fear, grief, displeasing recollection. To this classification it has been objected, that all these cannot be considered as cardinal passions; nor do the distinctions themselves appear sufficiently accurate; hope is certainly a species of desire; pleasing recollection is a modification of love; aversion is only a particular manner of testifying hatred; and displeasing recollections are sometimes the renewal of grief, sometimes of anger.

Dr. Watts has distinguished the passions into two classes, *viz. primitive and derivative*. The primitive passions he subdivides into two ranks: 1. Admiration, love, and hatred. 2. The diverse kinds of love and hatred, as esteem, contempt, benevolence, malevolence, complacency, displacency. The derivative passions are desire, aversion, hope, fear, gratitude, anger, &c. Thus, if an object be rare or uncommon, either in its kind or qualities, it excites our admiration or wonder: if such an object is presented to us in a sudden and unexpected manner, the passion is called surprise; and when our wonder rises to a high degree, it is called astonishment. Moreover, admiration, according to the different character of its object, is denominated esteem or contempt; though some writers make esteem and contempt to be particular species of love and hatred. Esteem is the admiration of an object, on account of its excellence, contempt, for its insignificance or worthlessness; whence proceed veneration, and slight or scorn.

If we look on any object as good, or in any respect agreeable to us, it may engage our love; but if it be evil or disagreeable, it excites our hatred, or an endeavour of the soul to disunite itself from the apprehended evil. When the evil is present, it produces grief, and a desire of its removal; this desire of escaping an evil may be considered as solitary, without desiring it may befall another person, in which case it is called aversion; but when accompanied with such a desire, it is denominated malevolence. The ancient

philosophers meant much the same by their *ἐπιθυμία καὶ βόμω*, the concupiscent and the irascible part.

To this arrangement, it has been objected, that admiration has not an equal title to be considered as a primitive passion with love and hatred. Besides, a subdivision of the primitive into two ranks creates a suspicion, if it do not fully indicate, that they cannot all be equally primitive; and the instances given under the second rank may justly be considered as different modifications of the two grand principles, and not as primitives of a distinct character. Moreover, this plan makes no distinction between the passions and affections, which the nature of the subject not only admits, but requires.

Mr. Grove, adopting in part the arrangement of Dr. Watts, reduces all the passions to the three heads of admiration, love, and hatred, which he styles accordingly the primitive passions: the others he denominates mixed passions, of which some have admiration blended with them, and others are compounded only of the passions which fall under love and hatred. Those passions, in which admiration is a principal ingredient, are ambition, glory (made up of joy, self-love, and esteem), shame (compounded of sorrow, self-love, and contempt), emulation, horror, and consternation. The other passions, compounded of love and hatred, may be distributed into such as more immediately regard ourselves, and such as have others for their objects: of those which concern ourselves, the principal are the following, *viz.* fluctuation, consisting of desire and grief; resolution, hope, fear; security, which is hope advanced beyond the fear of a disappointment; despair, which is fear without any mixture of hope; jealousy, and disgust. Of those which express our dispositions towards others, the chief are the following, *viz.* irritation, or that mirth which is excited in us by the sight of another's absurdities or misfortunes; commiseration, which is a compound of love and sorrow; congratulation, or that joy which our love to another makes us receive from the gifts of nature or Providence bestowed upon him; envy, anger, gratitude, and that which the Latins call *desiderium*, or fondness for the memory of persons and things that have been greatly beloved by us, springing from the reflection on a past good, which we despair of enjoying again.

Dr. Cheyne considers the passions as either spiritual or animal. *Spiritual* passions he defines to be those sentiments produced in the soul by external objects, either spiritual ones, immediately; or material ones, by the mediation of the organs of the body.

Animal passions he defines to be those effects produced by spirits, or bodies, immediately on the body.

Hence, as outward objects may be considered either as goods or evils, the most natural division of the passions, whether spiritual or natural, as they regard those objects, is into *pleasurable* and *painful*.

And, in this sense, all passions may be reduced to love and hatred; of which joy and sorrow, hope and fear, are only so many modifications or complexions, according to the various appearances, positions, &c. of the object.

In effect, all the passions may not only be reduced to two, *viz.* love and hatred, but, perhaps, to one, love; and even that may be all resolved into self-love; and this into a principle of self-preservation, or necessary invincible desire of pleasure and happiness. The rest are only rivulets from this source, or special applications of this principle to particular occasions.

Thus, the desire of any thing, under the appearance of its goodness, suitableness, or necessity to our happiness,

constitutes the passion of love; the desire of eschewing or avoiding any thing apprehended to be mischievous, hurtful, or destructive, constitutes hatred or aversion; the desire of a good, which appears at the same time probable, and in our power, constitutes hope; but, if the good appear improbable, difficult, or impossible, it constitutes fear or despair; the unexpected gratification of desire is joy; the desire of happiness to another under pain, or suffering, is compassion; and the desire of another's punishment, is revenge or malice, &c.

The single desire of happiness, then, is the spring or motive of all our passions, as those are of all our actions. Some wise and reasonable motive, or end of action, says Dr. Morgan, is certainly necessary to all wise and reasonable action: to act without a motive, would be the same thing as not to act at all, that is, such an action could answer no farther or better end than not acting; and consequently the action, as well as the agent, would be so far insignificant and useless. He, who should have no object at all of his love or aversion, hope or fear, joy or grief, must be simply and purely indifferent to all action; and, consequently, he must either be in a state of perfect rest and inaction, or in a state equivalent thereto; wherein the action of such a being could be of no more signifiçancy than the uncertain fluctuation of an atom, or the quivering of a feather in the air.

But we can by no means approve the opinion of those, who will allow no ultimate object of desire, or motive to action, besides private good. It is justly observed by a writer already cited, that this opinion sprung from not carefully distinguishing between desire, and the pleasure implied in the gratification of it. The latter is subsequent to the former, and founded in it; that is, an object such as fame, knowledge, or the welfare of a friend, is desired, not because we foresee, that, when obtained, it will give us pleasure, but *vice versa*; the obtaining it gives us pleasure, because we previously desired it, or had an affection carrying us immediately to it, and resting in it. And if there were no such affections, the foundations of private enjoyments and happiness would be destroyed. Of our several passions and appetites, some are subordinate to self-love, and given with a view to the preservation and welfare of individuals; others are subordinate to benevolence, and given in order to secure and promote the happiness of the species; and both the one and the other are essentially distinct parts of our intelligent frame. Price's Rev. p. 127, &c.

Dr. Cogan, in the Treatise already cited, having expressed his dissatisfaction with any of the arrangements of the passions which he has had occasion to consider, proposes another classification, which he conceives to be less liable to objections. Of this he has given an ample detail, in which our limits will not allow us to follow him. We shall, however, give as concise, and at the same time as satisfactory, an account of it as possible. He begins with stating, that it is essential to the nature of every sensitive and intelligent being to be gratified with, or delight in, "well-being." This well-being is an essential good, and its opposite an essential evil. Whatever is productive of this desirable state, we esteem as *good*; and we characterise as *evil*, whatever is inimical to it. Under the impression of this sentiment, we indulge a *predilection* for the one, and feel an *abhorrence* of the other. Upon that which we deem to be a good, or conducive to happiness, we look with a *pleasant* sensation: we deem it desirable, and it inspires the affection of "love." Whatever occasions or threatens a privation of happiness, or inflicts positive misery, we view with displeasure, and regard as injurious, or as an absolute evil; and it inspires the affec-

PASSION.

tion of "hatred." "Love" and "hatred" are entitled to the denomination of *primary* or *cardinal* affections.

"Love" may be considered either as a principle or as an affection. As a principle, it may be defined "an invariable preference of good; an universal and permanent attachment to well-being or happiness." When this principle is directed to any particular good, it becomes an *affection*; and whenever this love is more violent in its effects upon the system, it is even deemed a *passion*. When the affection of love immediately relates to *ourselves* personally, it is called "self-love." When our love or desire of good goes forth to others, it is termed "good-will," or "benevolence." When love extends to the whole human race, it is termed "philanthropy." And when the love of benevolence embraces all beings capable of enjoying any portion of good, it becomes *universal* benevolence. When the dispositions springing from this source are acting principally towards every thing capable of enjoyment, they are called the *benevolent affections*: and as these become, in those who indulge them, operative rules of conduct, or principles of action, we speak of the *benevolent principle*.

"Hatred" expresses the disposition we entertain concerning, or the manner in which we are affected by, the contemplation of whatever we suppose to be *evil*. Hatred of misery, and its causes, is a natural and necessary consequence of our solicitude to possess good. Personal hatred, or malevolence towards an individual, commences with some circumstance, quality, or disposition, which is displeasing to us, or with some species of injury committed or intended. These are its professed objects. But notwithstanding the excesses and exaggerations of hatred and malevolence, yet they cannot possibly be so extensive in their operations as the principle of love; because the affection of hatred has for its objects only particular and partial evils, while the principle of love may embrace the universe.

With the affections of love and hatred are intimately connected those of desire and aversion. As love and hatred may be resolved into that one principle, "the love of well-being;" the affections of desire and aversion may be resolved into "desire." After these preliminary remarks, and others on those introductory emotions which produce *surprise*, *wonder*, and *astonishment*, the author proceeds to develop his plan of the arrangement of the passions.

CLASS I. comprehends the passions and affections which owe their origin to the principle of "self-love."

This class includes two distinct orders, *viz.* that in which "love," and the "idea of good," that is, something either beneficial or pleasant, are more immediately present to the will; and that in which "hatred," and the "idea of evil," are most impressive. The *first order* comprises two kinds; the one relating to good in *possession* the other to that in *expectation*. The first kind inspires *joy*, *gladness*, which is an inferior degree of joy, *cheerfulness*, or an emotion of still gentler influence, *nirrh*, or a higher degree of cheerfulness, *contentment*, *satisfaction*, and *complacency*. The latter affection of complacency has its counterfeit; and false conceptions of our own talents, a requirements, and conduct, may inspire *pride*, *vanity*, *haughtiness*, and *arrogance*. The second division under this order comprehends *desire* and *hope*. A *wish* is an inactive desire. As the above passions and affections are inspired by the contemplation of good, they are most of them of a *pleasant* nature.

The *second order* comprehends those passions and affections operating upon the principle of "self-love," in which the idea of *evil* is present to the mind. Of these there are three kinds, the *first* relates to actual losses and disappointments:

the *second* to evils of which we are apprehensive: and the *third*, to the conduct which seems to deserve reprehension. These inspire the passions of *sorrow*, *fear*, and *anger*, with their different modifications and combinations. *Sorrow* sometimes assumes the appearance of *discontent* and *dissatisfaction*. *Impatience* is a mixture of sorrow and anger: *repining* is sorrow united with a degree of resentment against some superior agent, where the mind cannot burst forth into strong expressions of anger; and *sympathetic sorrow* is that which we participate with others, in consequence of our social connections, or the general benevolence of our nature. (See SYMPATHY.) Of the virtuous affections inspired by sorrow, which are personal, the most conspicuous are *patience*, *resignation*, and *humility*. *Fear* is a painful sensation produced by the immediate *apprehension* of some impending evil. The modifications of this passion are *consternation*, *albeit* fear, and *terror*. The affections, that is, the more permanent impressions of fear, unaccompanied with external signs: characteristic emotions, are *dread*, *despair*, *remorse*, *cowardice*, *pusillanimity*, *timidity*, *doubt*, *irresolution*, *shame*, *modesty*. The affections and dispositions opposed to fear, are *fortitude*, which expresses that firmness of mind that resists dangers and sufferings; *courage*, which is active fortitude; and *intrepidity*, expressing a courage perfectly undaunted, or a superiority to the very sensation of fear. The third strong effect produced by the immediate perception of evil, is *anger*. Anger, in the excess of its violence, is termed *rage*; *wrath* is violent and permanent anger, and as such it may be denominated an affection: *resentment* is a lesser degree of wrath; *indignation* is resentment against a conduct that appears peculiarly unworthy. Although anger, and its principal ramifications, are generally directed against the conduct of others, they are sometimes directed against ourselves, when our conduct has been either negligent or criminal. In *repentance*, *contrition*, and *remorse*, self-reproach, and even *indignation*, are largely intermixed with the affection of sorrow. *Vexation*, *chagrin*, and *impatience*, do not relate to persons so much as to particular circumstances of a teasing nature. *Peevishness* may be considered as a lighter degree of anger perpetually recurring to irritable persons from trifling causes. Fortitude, courage, and intrepidity, which have been referred to *fear*, might, without impropriety, have been placed under the passion of *anger*.

CLASS II. comprehends the passions and affections derived from the "social principle." The social principle extends its regards to the state, the conduct, and the character of others. No one general term is adapted to all those passions and affections which belong to this principle. Dr. Hartley, however, has comprehended them all under the name and character of "sympathy;" which he divides into four classes; rejoicing at another's happiness; grieving at his misery; grieving at his happiness; and rejoicing at his misery. But the word sympathy, whether we advert to its genuine import or common usage, is ill adapted to the two last divisions. The usual idea of sympathy is that of suffering with another, which is the most opposite possible to grieving at his happiness, or rejoicing at his misery. These two opposite dispositions are usually expressed by the opposite terms *benevolence* and *malevolence*. The first referring to kindly dispositions towards its objects, and the other to the reverse: yet these terms are not wholly unexceptionable, as they do not always convey ideas perfectly correspondent with the various differences comprised under these general heads. Instead of malevolence, Dr. Cogan substitutes *displacement* as a generic term.

The second class is divided into two orders. The *first order* includes passions and affections excited by benevolence, in

in which *good* is the predominant idea. Of these there are the following kinds. 1. Those which respect benevolent *desires* and *dispositions*. Of those which respect *distresses*, the principal are *compassion, mercy*, which is the most exalted branch of compassion, *commiseration, condolence, pity, generosity, liberality, charity*, and *condescension*. Another important branch of benevolence consists in partaking of the good fortune of others; in the participation of their joy, upon the accession of good or liberation from evil. The immediate expressions of our joy are denominated "congratulations." 2. The affections derived from *good opinion*. Of these the most conspicuous are *gratitude, admiration, esteem, respect, veneration, awe, and reverence*. As self-complacency has its counterfeits in pride and vanity, the complacential affections are liable to abuse, and give rise to the following imperfections, *viz fondness and partiality*.

The *second order* comprises passions and affections excited by *displacency*, in which *evil* is the predominant idea. Of this order there are two kinds. 1. The displacency which is indicated by *malevolent desires and dispositions*. The first species of malevolence is a branch of the general principle of hatred. To this kind belong *malignancy or malignity, malice, envy, rancour, cruelty, censoriousness, prejudice, ingratitude, and apathy*. The second species of malevolence relates to those occasional and more transient fits of ill-will, which are excited by particular provocations, and which are not totally repugnant to the benevolent affections. These are indicated by anger, and its various modifications. Such are *rage, revenge, wrath, resentment, suspicion, and jealousy*. 2. The displacency, which is indicated by *unfavourable opinions* of conduct and disposition; and this gives rise to the following emotions and affections, *viz. horror, indignation, contempt, disdain, and irrision*.

The natural or occasional cause of all the passions, Malebranche makes to be the motion of the animal spirits, which are diffused through the body, to produce and preserve a disposition therein suitable to the object perceived; to the end that the body and mind may mutually assist each other on this occasion, it being the order of the Creator, that our wills be followed by motions of the body proper to execute them; and that the motions of the body, mechanically excited in us by the view of external objects, be accompanied with a passion of the soul, which inclines to will or nill what appears serviceable or noxious to the body.

It is a continual impression of the will of the Creator, that unites us thus intimately to a piece of matter, and occasions this reciprocation of motions and sensations; were this impression of the Creator's will suspended a moment, we should be delivered from all dependence, all passions, &c. For what people usually imagine of a necessary connection between the motions of the spirits and blood, and the emotions of the soul, is wholly inconceivable.

Certain little parts of the bile, say they, move with some violence among the fibres of the brain; therefore, the soul must necessarily be agitated by some passion, and this passion must be anger rather than love. What relation can we conceive between the faults of an enemy, a passion of contempt or hatred, and a bodily motion of the parts of the blood striking against certain parts of the brain? How can the union or alliance of two things so different as spirit or matter be effected, but solely by the omnipotent will of the Author of nature?

Dr. Cogan observes, that the essential and characteristic difference between a passion and an affection depends upon the super-addition of surprise to the natural effect produced by the real or supposed quality of an object, and that this emotion,

conjoined with the specific nature of its *exciting cause*, is virtually the *efficient cause* of a passion; the percussive rendering the affection visible by characteristic signs, correspondent with its specific nature. This observation is exemplified in the passions of joy and anger.

There has been much controversy about the seat of the passions; whether it be in the spiritual, or in the animated material part of man. Some philosophers place the passions solely in the corporeal system; among these was the celebrated Descartes: but when we consider, says Mr. Grove, that passion signifies a sensation of the soul, it must be lodged there, and not in any part of the body. As this sensation is joined with a tumult or agitation of the spirits, the passion must go along with the spirits moved. Those in admiration, which seems to be a more speculative passion, on being employed chiefly about the novelty or grandeur of objects, are in the brain, the great instrument or condition rather of thought and contemplation. In other passions, which, respecting the good or evil of objects, proceed from a principle of self-preservation, the spirits agitated are in the heart, the fountain of life, and sitest residence of those motions of the animal spirits, which are intended for the benefit and preservation of life.

Others again ascribe some of the affections to the animal principle, and some to the rational. Dr. Reid doubts whether the principle of esteem, as well as that of gratitude, ought to be reckoned in the order of animal principles, or if they ought not rather to be placed in a higher order. He has, however, finally placed the esteem of the wise and good in the order of animal principles, though the same affection is sometimes placed by this philosopher under the animal, and sometimes under the rational principle. Speaking of resentment he observes, that sudden or instinctive resentment is an animal principle, common to us with brute animals; but that resentment, which some authors call deliberate, must fall under the class of rational principles. He also excludes parental affections from the rational principle, because it is not grounded on an opinion of merit in the object. (See his *Essays on the Active Powers of Man*, *ess. iii. chap. 4.*) This embarrassment of Dr. Reid seems to arise from the expectation that the rational principle must always act rationally; which leads him to infer that whenever the passions and affections do not receive the sanction of reason, they are to be assigned over to the animal principle. But this hypothesis would tempt us to doubt of the very existence of the rational principle, in numbers of our species; it leads us to conclude that the two natures, deemed so diametrically opposite to each other, possess powers so perfectly similar, that it is difficult for the keenest discernment to distinguish between their operations; and it compels us to infer, that whenever some of our affections become conformable to reason, they have changed their seat from the animal to the rational principle.

Philosophers and divines, who distinguish man into the three constituent parts of body, soul, and spirit, which, notwithstanding the intimacy of their union, they suppose to be different in their natures, ascribe the appetites to the body, the passions and affections to the soul, and to the spirit those intellectual powers which seem remote from passions or emotions of any kind. But if the affections pertain to the soul exclusively, that alone is capable of *enjoying*: the spirit is deprived of every motive for speculation; and since it sometimes happens that speculations of the most abstruse kind excite pleasing sensations, the spirit must certainly *perceive*, though it has no faculties to *lament* its hard lot, as often as it is conscious, that these delightful sensations, which are its own work, are transferred to the soul. After all,
it

PASSION.

it must be admitted, that every passion, emotion, and affection, proceeds from certain impressions or ideas excited concerning the nature, or state, or quality, or agency of the exciting cause. These ideas have undoubtedly their seat in that part of man which we distinguish by the appellation of *mind*. The exciting cause, therefore, changes the state of the mind respecting the particular object. From total indifference it becomes some way or other *interested*. This impression, if it be possessed of a certain degree of strength, produces a correspondent change upon the body. Universal observation, and universal phraseology, which is doubtless founded upon this observation, unite to evince that a very perceptible influence of every strong emotion is directed towards the *heart*. The heart experiences various kinds of sensation, pleasant or unpleasant, over which it has no controul; and from thence the influence of agitated spirits seems to be diffused over the body. This state of mind is styled an *affection*, and it appears to be totally mental; but stronger influences produce such changes, that the inward disposition becomes obvious to the spectator, through the medium of the corporeal frame. It is now called an *emotion*, and this may increase in strength, until the whole system becomes agitated and convulsed. From this statement it appears incontestible, that the affections and passions have their origin in the mind, while emotions are corporeal indications of what passes within, according to the conjecture of Mr. Grove above mentioned.

It is a point, about which the divines and philosophers can never agree, whether this relation and connection of thoughts of the mind, and motions of the body, be the gift of nature, or the punishment of the first sin; and whether the passions be the institution of nature, or its corruption. Indeed, considering the good and wise purposes the passions serve, with regard to knowledge, virtue, and happiness, and their absolute necessity, it is surprising it should ever be doubted that they are essential to human nature.

This union or relation is found in all men, but in different degrees, and of different extent, according to the different temperaments, conditions, ages, sexes, occasions, objects, &c.

In every passion there may seven things be distinguished: the first, the judgment the mind makes of an object, or the view of the relation which the object bears to us. The second, a new determination of the will towards that object, supposing it to appear as good or evil. The third, the peculiar sensation of modification, which accompanies them; as the sensation of love, hatred, desire, or joy, which sensations are always different in the different passions, and are, at it were, the characteristics of them. The fourth, a new determination of the course of the blood and spirits towards the several parts of the body: before the sight of the object of the passion, the animal spirits were pretty equally diffused throughout the body; but the presence of the new object disturbs the whole economy; and the greatest part of the spirits is sent into the muscles of the arms, legs, face, &c. The fifth is, the sensible emotion of the soul, which finds itself shaken by this sudden overflowing of spirits. The sixth is, the different sensations of love, hatred, &c. caused, not by the intellectual view of good or evil, but by the different shakes or movements the animal spirits occasion in the brain. The last is, a certain sensation of joy, or an inward satisfaction, which detains the soul in its passions, and attends its being in the state it ought to be in with regard to that object.

The influence of the affections and passions has been the subject of copious discussion; and it may be considered in three different points of view: as, to the *physical*, or medical

influence of the passions, (for which see the next article,) their *metaphysical*, or influence upon the train of our ideas, correspondent language, &c. and their *moral*, or influence upon character and happiness.

The influence of the passions on thoughts and language is a matter of universal experience and observation. When any subject presents itself to the mind, with sufficient force to excite a passion, or very strong affections, all the powers of the imagination become immediately active, the whole soul is engaged upon its object, and the whole train of ideas is turned into a channel correspondent with the view we entertain of them. This state of mind not only manifests itself by gestures, looks, and tones correspondent with the nature of the passion, but it has a characteristic influence upon the language and expressions employed to give vent to the passion, as it is emphatically termed. Upon the first impulse, the thoughts are tumultuous and confused; but as the *passion* approaches somewhat nearer to an *affection*, the mind recovers in some degree its power over itself; though still, as it continues to feel strongly, it is eager to do justice to its feelings, by the strength, pertinency, and impetuosity of its language. Impetuosity equally despises precision or detail. It eagerly seizes upon tropes and figures the most concise, and the most suited to its new conceptions. When passions and emotions give place to more permanent affections, language becomes less vehement and more diffuse. Nature has accommodated the mode of utterance to the character of the passion; thus it has rendered joy loud and vociferous, producing strong exclamations mixed with triumphant laughter. Sorrow communicates a plain-tiveness to the voice, best adapted to wailings and lamentations. Anger is loud and turbulent; the voice rises with the passion in order to strike terror and silence opposition. Fear is oppressed and breathless, or screams aloud for help. Love is soft, soothing, insinuating, and gentle; sometimes assuming the plaintiveness of sorrow, sometimes the vivacity of hope, and the transports of joy.

The nature of the passions and affections indulged, and of the objects by which they are excited, and the degree of influence and permanency which they are allowed to exert upon us, constitute the moral characters of men; pointing out their innocence, their excellencies, or their defects. By character is generally understood the kind of reputation acquired by the prevalent disposition or temper, which suggests almost every motive, and takes the lead in almost every action; and *moral* character refers to that prevalent temper which relates to moral obligation, respecting either ourselves or others. The cardinal affections of love and hatred, in themselves, possess neither merit nor demerit. It is neither a duty, nor a possibility to divest ourselves of them. The passions, emotions, and affections which are immediately consequent upon these, or may be deemed simple modifications of them, are also inseparable from our nature, and are both unavoidable and innocent: such as joy, satisfaction, contentment, hope, desire, fear, sorrow, anger, resentment, &c. Virtue, however, directs, restrains, and controuls their influence.

There is another distinction of the passions and affections, as they relate to the moral character, indicating a scale of comparative merit and demerit. Some are innocent simply, as hope, joy, moderate grief. Some are laudable, as contentment, satisfaction, complacency. Others are deemed peculiarly noble: thus the virtue of benevolence is much more dignified than any of the affections that originate and terminate in *self*. And in the different branches of this virtue there are also degrees of excellence. But sentiments

of this kind are familiar and obvious to the reader, and it is needless to enlarge. Upon the whole it appears, that character depends upon the prevalent use or abuse of certain propensities or affections of our natures. Those who select and cultivate the most beneficial, are the *best* of characters; those who are habituated to the most injurious, are the *worst*.

With regard to the influence of the passions and affections on happiness, we may observe, that although the desire of good is in reality the cause of every passion, emotion, and affection, yet the immediate effects of each on our sensations are correspondent to its own specific nature. The influence of some is productive of temporary well-being; while others are comfortless, irksome, or productive of a great degree of wretchedness. Love, placed upon a deserving object, and recompensed with a reciprocal affection, joy, ecstacy, complacency, satisfaction, contentment, lively hope, are decidedly sources of personal enjoyment. The social affections of benevolence, sympathy, compassion, and mercy, are also other ingredients of happiness, from a less selfish and more refined source than the preceding. Every species of benevolence possesses the quality our great dramatic poet has ascribed to a merciful disposition.

“ The quality of mercy’s not restrain’d :
It droppeth as the gentle rain from heaven
Upon the land beneath. It is twice blessed ;
It blesses him that *gives*, and him that *takes*.”

Emotions and affections of another class are of the unquiet and irritating class: as the whole family of anger. The emotions and affections of fear, dread, horror, despair, are of the most horrid and tremendous class. Excessive jealousy, envy, remorse, despair, shame, arising from the detection of guilt, are misery unmix'd. Surprise, wonder, astonishment, principally receive their complexion from the subjects that inspire them: and they are introductory to happiness or misery according to the nature of the cause that excites them. For a farther detail, see Cogan’s Treatise already cited.

PASSIONS, in a *Medical View*, constitute one of the six *non-naturals*, as they have been called, and are of great importance, whether considered as a cause of disease, or as exerting a remedial influence when certain diseases exist.

The theoretical discussions of the metaphysicians about the essential distinctions of the mind and the body, have confus’d, rather than elucidated, the subject, and have led to erroneous views of the operations of the animal economy. All that we can know upon the subject, from experience, is, that the living body presents two series of phenomena, one of which comprehends the functions of thought, sensation, volition, and various emotions, which we refer to the mind, and call *mental power*, and the other includes the more mechanical or chemical functions, which resemble the operations produced by inorganized machines, such as digestion, respiration, the circulation of the blood, and the secretions from it, which we deem more strictly *corporeal* functions. Nevertheless we have no actual knowledge of these functions, of either class, except in conjunction, and in that organized form, which constitutes the living body. If the subject be viewed in this light, independently of speculative opinions, it is at once obvious, that these two classes of functions constitute but one whole, and that they are, as far as the physician is concerned, inseparably connected, and mutually dependent upon each other. How extensive this reciprocal influence is, and how powerfully the corporeal functions are modified by those which are called mental, we have taken pains to demonstrate, at great length, in a preceding article. (See IMAGINATION,

Influence of, on the Corporeal Frame.) In common language, we are apt to separate the intellectual faculties from the passions and emotions, and, in compliance with that custom, we ascribed to the imagination simply, the numerous phenomena detailed in the article referred to. But, in truth, the passions were more or less concerned in the production of these phenomena; since the imaginary powers of the agents (as in the case of animal magnetism, &c.) necessarily excited the hopes and fears and anxieties of the persons on whom they operated. Having detailed many proofs, in the article just referred to, of the effects of these emotions, when excited by imaginary agents, upon the corporeal frame; we have now to point out the influence of these emotions, when excited by real and common causes.

The passions have been commonly considered by physicians as of two kinds, in respect to their influence on the state of the body, namely, as *exciting* and *depressing* its vital powers, and consequently as producing analogous effects on the functions. To those which arise from the operation of *stimulant* and *sedative* agents of a material nature. Among the *exciting* passions, are anger, terror, joy, cheerfulness, hope, desire, love, admiration, and the emotions of taste; the *depressing* passions are grief, fear, shame, and anxiety.

It is matter of observation, that the agency of these exciting and depressing emotions in the animal economy, follows the same laws, as that of the material stimulants and sedatives just alluded to. The moderate excitement of the former contributes to the free and perfect performance of all the functions, and therefore to the support of the general health; and debility equally ensues from the immoderate influence of the exciting, and from the direct operation of the depressing causes, which uniformity of effect affords an additional proof of the identity of the living system. The operation of the passions and emotions, both as a cause of health and disease, and also as a remedy in many morbid conditions, is illustrated by the observations of many physiologists and pathologists, and by numerous cases, which have been recorded, as may be seen by consulting the comprehensive and indefatigable Haller. *Elementa Physiologiæ*, tom. v. lib. xvii. p. 580 et seq.

The *exciting passions* have been observed to produce the following effects in the corporeal frame. *Cheerfulness* and moderate *joy* are found to give vigour to the circulation, and to increase the action of the heart and arteries, and consequently to support the vital functions connected with it; they render the respiration easy and free, increase the heat and perspiration, and assist the operations of digestion and of secretion in the various organs of the body; whence the healthy condition of the system is universally promoted. Nevertheless, when the excitement of joy has been excessive and sudden, it has sometimes brought on an acute fever, not unfrequently it has occasioned syncope or fainting, and in a few instances even sudden death. Examples of death thus produced, from an unexpected restoration from imprisonment, from the return of a beloved son, who was supposed to have been dead, or from extraordinary and unlooked for accession of wealth, have been recorded. (See Thoresby, *Nat. Hist. of Leeds*, p. 625. Robinson on the Spleen, p. 91. Nichols, *de Anim. Med.* p. 16.) It were superfluous to repeat the various hypotheses, which different writers have framed to account for these phenomena; as they are altogether gratuitous, or merely statements of the fact, with a change of words. Haller considered the affection as a kind of apoplexy, occasioned by the increased action of the vessels of the brain; but Dr. Cullen appears to have been nearer to the truth, in deeming it the mere result of over-excitement of the nervous system; which is generalizing it to that

that universal law of the animal economy, by which extreme exhaustion invariably follows excessive stimulation. See EXCITABILITY.

The passion of *love*, being a pleasurable emotion, produces effects similar to those of joy. It excites the powers of the mind, as well as those of the body, causes a glow of heat, and an acceleration of the pulse; and, when it is vehement, it excites palpitation of the heart, and a sense of burning heat, through the circulation. The acceleration of the pulse, however, is mostly accompanied with some irregularity, occasioned perhaps by fear and apprehension of the want of success. The love of Antiochus for his step-mother Stratonica, is recorded to have been discovered from the pulse.

The *ardent desire* accompanying *ambition*, or other strong passions, especially if attended with a prospect of success, produces nearly similar effects. So powerful its excitement has been, in some instances, as to have even cured paralytic affections, and roused the body to exertions, far above those to which the strength seemed adequate, and has even protracted death. Muley Moluc, emperor of Morocco, who was wearing away under an incurable disease, when the Portuguese invaded his territories, did not expect to live out the day when his last decisive battle took place. Before the battle begun, he was carried along the ranks in an open litter, to encourage his troops; but finding afterwards the battle to go against him, though very near his last agonies, he threw himself out of his litter, rallied his army, and led them on to the charge, which ended in a complete victory to his party. He had no sooner brought his men to the engagement, than finding himself utterly spent, he was again replaced in his litter, where, laying his finger on his mouth, to enjoin secrecy to his officers, who stood around him, he died a few moments after in that posture. See Spectator, No. 349.

Anger is another actively stimulant passion. It rouses the powers of the body and mind, and impels them into action, accelerates the pulse, and produces redness and heat of the skin. These exertions are often so violent as to exhaust the vigour of the nervous system, as appears from the tremor of the limbs, and the faltering voice with which they are accompanied. When this passion has been still more vehement, various diseases have sometimes been the result, such as echymoses, hemorrhages, apoplexies, great distention of the heart, ruptured cicatrices of wounds, local inflammations, profuse perspiration, vomiting, and diarrhoea. Indeed the increase of the biliary secretion by this passion is very remarkable, and has been well attested both by ancient and modern observation; inasmuch that *bile* and *cholera* are deemed synonymous with *anger*. On the other hand, these stimulant effects have, under certain circumstances, proved remedial. Thus gout, palsy, dumbness, have all been removed by paroxysms of rage, and life itself evidently prolonged for several days. See Haller, loc. cit. and Falconer's Diff. on the Influence of the Passions on the Disorders of the Body, p. 13.

The genial and salutary influence of *hope*, in supporting the health against the impending evils of disease, by maintaining a steady excitement both of body and mind, has been strikingly illustrated on various occasions; and in no instance more remarkably, than in that of the siege of Breda, as described by Vander Mye, which we have detailed under the article IMAGINATION, before referred to. The distributions of an insignificant medicine among the garrison, said to be sent from their prince, and to possess infallible powers of curing the scurvy, effectually prevented the progress of that fatal malady. After mentioning this fact, the celebrated Dr. Lind, (in his Treatise on Scurvy,) observes, "an

important lesson is hence to be learned, the wonderful and powerful influence of the passions of the mind on the states and disorders of the body. This is too often overlooked in the cure of disorders, many of which are sometimes attempted to be cured by the sole mechanical operation of drugs, without calling in to our assistance the strong powers of the imagination, or the concurring influences of the soul. Hence it is, that the same remedy will not always produce the same effect, even in the same person, and that common remedies often prove wonderfully successful in the hands of bold quacks, but do not answer the purpose in a timorous and distrustful patient."

The *depressing* or debilitating passions produce an opposite effect; they rob the body of its vigour, diminish and interrupt the secretions, weaken the digestive powers, and, if continued, wear out the energies of life; while some of them, like a sudden and violent narcotic poison, instantaneously deprive the brain and nervous system of its powers, and occasion immediate death. *Fear* and *grief* are the most injurious, perhaps, of the depressing passions. Under the influence of *fear*, the force of the heart is diminished, and the pulse is rendered weak, variable, and intermittent; whence paleness, shivering, tremor, faintness, and even actual syncope, are attendant symptoms on the operation of this passion; whence also hæmorrhages of every kind have ceased under its influence, the natural secretions, as of the milk and perspiration, have been suppressed, and discharges from sores have stopped, and even the blood has not flowed from an opened vein. Or, on the other hand, from the general relaxation of the vessels, a cold and clammy sweat has been poured out by the exhalants, like that which attends syncope and great weakness; or a colliquative diarrhoea has occurred from the relaxed exhalants of the intestines. The effects of fear, very much resemble those of fatigue, watching, and other sources of debility, in rendering persons much more liable to receive the infection of pestilential diseases; whence the panic, which often accompanies an epidemic, tends greatly to increase the number of its victims. (See many references upon this point in Haller, loc. cit. p. 584.) It greatly debilitates the organs of digestion; whence flatulence, eructations, acidity, cramp at the stomach, and various other symptoms of want of power in the stomach and bowels are produced by it. When its impressions have been more violent, many severe examples of its directly sedative and paralyzing effects on the nervous system have occurred. Some persons have instantaneously lost the power of muscular exertion, remaining equally unable to fly or to defend themselves from the universal tremor which seized them. Van Swieten has recorded an instance, in which the tremor, so produced, continued during the remainder of life, namely, for twenty years. In other cases, palsy, amaurosis, loss of voice, mental imbecility, permanent melancholy, epilepsy, and even sudden death, have resulted from the violent impressions of fear.

Yet it is justly remarked by Haller, that *terror* and *alarm* have often a stimulant effect, like that of *anger*, and have produced violent exertions both of mental and corporeal power, and strong muscular action, even in the heart. Whence those who had lost the use of speech, have recovered it suddenly, and paralytic limbs have been roused to action, by a sudden alarm. Van Swieten relates from Hildanus, that a man, disguised to represent a ghost or spectre, took another, labouring under a paroxysm of gout, out of his bed, and carried him upon his back down the stairs, dragging his feet and legs, which were the seat of his pain, down the steps, and placed him at last on the ground. The man thus treated immediately recovered the use of his limbs, and ran

up the stairs again with great swiftness, and under the strongest impressions of terror. After this incident, he lived many years free from any symptoms of the gout. In a similar way, the gout has been suddenly cured by a fit of anger.

A sudden impression of *fear*, when accompanied by *despair* and *distress*, has sometimes occasioned a singular disorder of the cutaneous exhalants; we once witnessed an universal anasarca, or superficial dropsy, which was produced in the course of one night, in a poor woman, who had lost her pocket, containing a few pounds, which were her all, and the savings of many years. And *fear* combined with *anxiety* have, in many cases, which have fallen under our observation, produced extensive diseases of the skin, of an inflammatory and scaly nature. See Bateman's Pract. Synops. of Cutan. Dis. p. 149, note. Also Edin. Med. and Surg. Journ. vol. v. p. 127.

Grief is another depressing passion, the effects of which resemble in several respects those of fear, but differ in consequence of the longer duration of this passion. Grief diminishes the bodily strength in general, and particularly the force of the heart and circulation, as is obvious from the frequent sighs and deep respirations which attend it, and which seem to be necessary exertions, in order to promote the passage of the blood through the lungs. It diminishes perspiration, obstructs the menstrual discharge, produces paleness of the skin, and anasarca, and scirrhus obstructions in the glandular parts. It aggravates the scurvy, and the malignity of febrile and contagious distempers, and also renders people more apt to receive the infection of them. When it comes on suddenly and in a great degree, it excites palpitation of the heart, and renders the pulse irregular, and unequal in the two arms. Blindness, gangrene, and sudden death, have followed excessive grief; and its effects in changing the colour of the hair are well known.

One of the most remarkable effects of the passions on the body is exemplified in the *nostalgia*, or that vehement desire of re-visiting one's native country, which occurs in persons abroad. This is much allied to *grief*, and *hope* is its cure; for the moment that assurance of the opportunity of returning is given, the disease, which would otherwise terminate in atrophy and death, begins to disappear. See NOSTALGIA.

From this sketch of the effects of the passions on the operations of the animal economy, it must be obvious that they are important agents in the modifications of health, and the regulation of them becomes a matter of interesting inquiry to the physician, and affords him a source of considerable influence over the corporeal functions. Many difficulties, however, must occur in the management of these nice and precarious instruments, and the direction of them will be most successfully undertaken by those who possess the greatest discernment in estimating individual character and constitution, and who are possessed of what is called a knowledge of mankind and the world. A considerable influence towards the cure and alleviation of diseases, may, however, be easily exerted by the inspiration of hope and confidence, and by dispelling groundless fears and apprehensions: and even fictitious means, or such as a great philosopher might despise, are not to be neglected, where a depressing passion is thwarting the operation of medicine, and the natural efforts of the constitution. The powers of the traectors, and of animal magnetism, although purely imaginary, were nevertheless capable of producing substantial effects; and where the efficacy of our instruments can be thus augmented, by employing such mental aid, it is neither unphilosophical nor useless to resort to it. See IMAGINATION, *Influence of*.

We shall here subjoin some of those instances to which we

VOL. XXVI.

have referred in the preceding article, and with which ancient history presents us, of fatal effects from the excess of joy; but it plainly appears from their narration, that the subjects were, at the instant preceding, under the pressure of extreme anguish of mind. Pliny informs us (lib. vii. § 7.) that Chilo, the Lacedæmonian, died upon hearing that his son had gained a prize in the Olympic games. Valerius Maximus tells us (lib. ix. cap. 12.) that Sophocles, the tragic writer, in a contest of honour, died in consequence of a decision being pronounced in his favour. - Aulus Gellius (Noet. Attic. lib. iii. cap. 15.) mentions a remarkable instance of the effects of what may be termed accumulated joy, in Diagoras, who expired at the instant, when his three sons were crowned in the same day as victors; the one as a pugilist, the other as a wrestler, and the third in both capacities. Livy also (lib. xxii. cap. 7.) mentions the instance of an aged matron, who, while she was in the depth of distress, from the tidings of her son's having been slain in battle, died in his arms from the excess of joy upon his safe return. We are also told by the Italian historian Guicciardini, that Leo X. died of a fever, occasioned by the agitation of his spirits, on his receiving the joyful news of the capture of Milan, concerning which he had entertained much anxiety. In all these instances the previous state of mind, with its pathological effects upon the body, made the impulse of joy the stronger, and contributed to render it fatal.

PASSION, *Cæliac*. See CÆLIACA.

PASSION, *Hypochondriac*. See HYPOCHONDRIASIS.

PASSION, *Hysteriæ*. See HYSTERIA.

PASSION, *Iliac*. See ENTERITIS.

PASSIONS, in *Poetry*, denote the passionate sentiments, gestures, actions, &c. which the poet gives his persons.

The passions are, as it were, the life and spirit of the longer poems. Their necessity in tragedy and comedy is obvious; nor can the epopœia subsist without them.

It is not enough that the epic narration be surprising; it must likewise be moving and passionate, hurrying away the reader's mind, and filling it with anxiety, joy, terror, or some other violent passion, and this for subjects which it knows are feigned. Though passions be always necessary, yet all are not equally necessary, or suitable to all. Comedy has joy, and agreeable surprises, for its part; tragedy, on the contrary, has terror and compassion. The proper passion of the epopœia is admiration; though the epopœia, as a medium between the two others, takes in both their kinds of passions; as we see in the griefs of the fourth book of the *Æneid*, and the games and diversions of the fifth. Admiration, in effect, is consistent with each; we admire with joy the things that surprise us agreeably, and with terror and grief those that amaze and afflict us.

Besides the general passion, which distinguishes the epic from dramatic poems, each epopœia has its peculiar passion, which distinguishes it from other epic poems. This peculiar passion still follows the character of the hero. Thus wrath and terror reign in the *Iliad*, because Achilles is watchful, and *πανταρ εκ πανηλοτατ ανδρα*, the most terrible of men. And, on the contrary, the *Æneid* is all in the tender, softer passions; such being the character of *Æneas*. The prudence of Ulysses not allowing these excesses, we find none of them in the *Odyssey*.

As to the conducting of the passions, to make them have their effect, there are two things required; viz. that the audience be prepared or disposed to receive them; and that several incompatible passions be not mixed together.

The necessity of disposing the audience is founded on the natural necessity of taking up things where they are, in order to remove them elsewhere. The application of this maxim

is easy; a man is calm and at ease, and you would put him in a passion by a discourse made on purpose. You must begin, then, in a calm manner; by this means you join yourself to him; and afterwards, walking together, he will not fail to follow you in all the passions, to which you lead him insensibly.

If you shew your anger at first, you will be as ridiculous, and will have as little effect, as Ajax in the *Metamorphoses*; in whom the ingenious Ovid gives a fine example of this failing. He begins his harangue in the height of passion, and with the most violent figures, before his judges, who are in the deepest tranquillity.

“ ————— Sigeia torvo,
Litora prospexit, classemque in litore, vultu;
Protendensque manus, Agimus, pro Jupiter! inquit,
Ante rates causam, & mecum confertur Ulysses.”

The necessary dispositions arise from some preceding discourse, or, at least, from some action, which has already begun to raise the passions before they are mentioned. The orators themselves sometimes use this last means; for though ordinarily they do not raise the passions till the end of their discourse, yet when they find their audience already moved, it would be ridiculous in them, by an unseasonable tranquillity, to lay them again.

Thus, the last time Catiline came to the senate, the fathers were so shocked at his presence, that those near the place where he sat down, rose up, retired, and left him alone. On this occasion, Cicero had too much sense to begin his oration with the usual tranquillity and coolness of exordiums: by this means, he would have palled and abated the indignation of the senators against Catiline, which it was his business to spirit up and inflame; and he would have eased the parricide of that consternation the behaviour of the senators had given him, and which it was Cicero's business and design to aggravate. Omitting, therefore, the first part of this oration, he takes his auditors in the condition he finds them, continues and augments their passions: “*Quousque tandem abutere, Catilina, patientia nostra? Quamdiu nos etiam furor iste tuus eludet? Quem ad finem sese effrenata jactabit audacia? Nihilne te nocturnum praesidium palatii, nihil urbis vigiliae, nihil timor populi, nihil, &c.*”

The poets are full of instances of this kind, where the passion is prepared or kept up by actions. Dido, in Virgil, begins a discourse like Ajax: *Proh Jupiter, ibi hic, ait, &c.* But then the motions are here well disposed; Dido is before represented under terrible apprehensions of Æneas's quitting her, &c.

Seneca's conduct, indeed, is quite opposite to this rule. If he has a passion to raise, he is sure first to take from his audience any disposition they might have to be affected. If they be in grief, fear, or the expectation of something horrible, &c. he will begin with some fine description of the place, &c. In the *Troades*, Hecuba and Andromache being prepared to hear the violent and barbarous death of their son Astyanax, whom the Greeks precipitated from the top of a tower; of what avail was it to tell them, that, of the spectators that crowded from all quarters to see the execution, some placed themselves on stones, which the ruins of the walls made to project; that others shook their legs, as being placed too high, &c.

“*Alta rupes, cujus e cacumine
Erecta lummos turba libravit pedes.*”

The second thing required in the management of the passions is, that they be found pure, and disengaged from any thing that might prevent their effect.

Polymythy, therefore, *i. e.* a multiplicity of fables, actions, or histories, must be avoided; all adventures much broken, and hard to be retained, and all intrigues intricate, and difficult to conceive, are at once to be excluded. These embarrass the mind, and require so much attention, that there is none to spare for the passions. The soul must be free and disengaged to feel; on the contrary, we divert ourselves even from our real sorrows, by an application to other things.

But, of all others, the greatest enemies to the passions are the passions themselves: they oppose and destroy each other; and if two opposite ones, *e. gr.* joy and sorrow, meet in the same object, they will neither of them stand it. It is the nature of these habits that imposes this law: the blood and spirits cannot move gently and equally, as in a state of tranquillity, and, at the same time, be stopped and suspended with a violence occasioned by admiration. Nor can they be in either of those situations, while fear calls them from the outer parts of the body, to assemble them about the heart, or rage sends them into the muscles, and makes them act there with violences very opposite to the operations of fear.

The causes and effects, therefore, of the passions in the soul are to be studied, in order to be able to manage them with all their force. Virgil furnishes two examples of what we have said about the simplicity and engagement of each passion, in the deaths of Camilla and Pallas. See the *Æneid*.

PASSIONS, in *Rhetoric*, are objects that demand particular attention, both in the composition and delivery of public discourses. Accordingly one branch of rhetorical invention relates to the passions, and a suitable address to them forms a distinguishing part of the conclusion, or *peroration*, which see. As the passions are moving springs of action in the human frame, the orator who disregards them is not likely to accomplish the end at which he aims. As it is often highly necessary, it will likewise require his greatest skill, to engage them in his interest. Accordingly Quintilian calls this “the soul and spirit of his art,” and without doubt, nothing more discovers its empire over the minds of men, than this power which it possesses of exciting, appeasing, and swaying their passions, agreeably to the design of the speaker. The orator who engages the passions of his hearers will be thus aided on many occasions in convincing their judgment, and more especially in persuading them to pursue the course of conduct which he recommends. The passions are constituent parts of our frame as well as the understanding; and unless they are called forth into exercise, and when roused, properly directed and governed, we shall need some of the most powerful incentives to our inquiry after truth and to the regulation of our conduct agreeably to the conviction of our minds. Although the passions are liable to be perverted and abused, this is no reason why they should not be employed to important and useful purposes; more especially as this is the most likely method of guarding against the danger and injury, to which the want of due direction and controul would expose us. Quintilian makes it a necessary qualification of an orator, that he should be an honest man, and one who will not abuse his art. He will therefore engage the passions in the interest of truth and virtue; and he will thus render them instrumental in promoting the most useful purposes. The Stoics, who pretended to eradicate the passions, attempted what was in itself impossible, and in its consequences prejudicial to mankind. For while they appeared zealous assertors of the government of reason, they scarcely left it any thing to govern: for the authority of reason is principally exercised in ruling and moderating

derating the passions, which, when duly regulated, are the springs and motives to virtue. The passions, therefore, are not to be extirpated, as the Stoics asserted, but put under the direction and conduct of reason. The charge that has been brought against the art of oratory, for giving rules to influence the passions, is groundless and unjust; since the proper use of the passions is not to hinder the exercise of reason, but to engage men to act agreeably to reason. And if an ill use be sometimes made of this, it is the fault not of the art, but of the artist. But that an orator may be enabled to manage this part of his province to the best advantage, it is necessary that he should, in some measure, be acquainted with the nature, causes and objects of the passions. The passions to which the orator more particularly addresses himself differ according to the nature of the discourse. In demonstrative orations, when laudatory, love, admiration, and emulation are usually excited; but in invectives, hatred, envy, and contempt. In deliberative subjects, either the hope of gratifying some desire is set in view; or the fear of some impending evil. And in judicial discourses, almost all the passions have place, but more especially resentment and pity; insomuch that most of the ancient rhetoricians mention only these two. The objects of the passions are either *things* or *persons*, and orators make use of both for putting in motion these springs of the human mind. With regard to *things*, the nature and circumstances of them are to be considered; and different passions applied to, in order to induce people either to pursue or avoid them. *Persons* may be considered either as agents or patients. In the former sense, different regards are due to them, according to the different qualities with which they are possessed, and a suitable course of actions. So because virtue excites esteem, and vice hatred; answerable regards are paid to virtuous, or vicious men. But in considering them as patients, whatever befalls them according to their demerits, be the thing good or ill, others are generally pleased; and if the contrary happens, it gives them an uneasiness. So that if some good thing accrues to one, who does not deserve it, it causes indignation; and where a misfortune happens to a good man, it occasions pity. And thus persons are apt to be affected with respect to the circumstances of others. But every one is naturally inclined to think well of himself, that every prosperous occurrence is but answerable to his merit, and that every misfortune comes undeservedly. And sometimes there is joined with the occurrence the consideration of the agent, or person, who occasioned it; and the design in doing it is often more regarded, than the thing itself. The orator therefore will observe what circumstances either of things, or persons, or both, will furnish him with motives, proper to apply to those passions he desires to excite in the minds of his hearers. Thus Cicero, in his *orations for Plancus and Sylla*, moves his hearers from the circumstances of the men; but in his *accusation of Verres*, very frequently from the barbarity and horrid nature of his crime; and from both in his *defence of Quintus*.

But the same passion may be excited by very different methods. This is plain from the writings of those Roman satirists, which are yet extant; for they have all the same design, and that is to engage men to a love of virtue, and hatred of vice; but their manner is very different, suited to the genius of each writer. Horace endeavours to recommend virtue, by laughing vice out of countenance. Persius moves us to an abhorrence and detestation of vice, with the gravity and severity of a philosopher. And Juvenal by open and vehement invectives. So orators make use of all these methods in exciting the passions, as may be seen by their discourses, and particularly those of Cicero. But it

is not convenient to dwell long upon the same passion. For the image thus wrought up in the minds of the hearers, does not last a great while, but they soon return to reflection. When the emotion therefore is once carried as high as it well can be, they should be left under its influence, and the speaker proceed to some new matter, before it declines again. Moreover, orators sometimes endeavour to raise contrary passions to each other, as they are concerned for opposite parties. So the accuser excites anger and resentment, but the defendant pity and compassion. At other times, one thinks it sufficient to allay and take off that passion which the other has raised, and bring the hearers to a calm and sedate consideration of the matter before them.

But this especially is to be regarded, that the orator expresses the same passion himself, with which he endeavours to affect others, and that not only in his action, and voice, but likewise in his language; and therefore his words, and manner of expression, should be suited to that perturbation and disorder of mind, which he designs to represent. However, a decency and propriety of character are always carefully to be observed. For as Cicero very well remarks: "A neglect of this is not only very culpable in life, but likewise in discourse. Nor do the same things equally become every speaker, or every audience; nor every time, and every place." And therefore he greatly commends that painter, who designing to represent in a picture the sacrifice of Iphigenia, Agamemnon's daughter, drew Calchas the priest with a sad countenance; Ulysses, her father's great friend, more dejected; and her uncle Menelaus, most disconsolate; but threw a veil over the face of Agamemnon himself, as being unable to express that excess of sorrow, which he thought was proper to appear in his countenance. And this justness of character is admirably well observed by Cicero himself, in his *defence of Milo*. For as Milo was always known to be a man of the greatest resolution, and most undaunted courage, it was very improper to introduce him, as the usual method then was in capital cases, moving pity, and begging for mercy. Cicero therefore takes this part upon himself, and what he could not do with any propriety in the person of Milo, he performs in his own address to the judges. Cicero Orat. cap. 21, 22. 34. Ward's Orat. vol. i.

It is observed by Dr. Blair, that the higher eloquence (see ELOQUENCE) is the offspring of passion; or of that state of mind in which it is agitated and fired, by some object it has in view. A man may convince, and even persuade others to act, by mere reason and argument. But that degree of eloquence which gains the admiration of mankind, and properly denominates one an orator, is never found without warmth or passion. Passion, under due restraint, exalts all the human powers; it renders the mind infinitely more enlightened, more penetrating, more vigorous and masterly, than it is in its calm moments. A man, actuated by a strong passion, becomes much greater than he is at other times: he is conscious of more strength and force; he utters greater sentiments, conceives higher designs, and executes them with a boldness and a facility, of which, on other occasions, he could not think himself capable. But the power of passion is particularly felt with respect to persuasion. Almost every man, in passion, is eloquent. Then, he is at no loss for words and arguments. He transmits to others, by a sort of contagious sympathy, the warm sentiments which he feels: his looks and gestures are all persuasive; and Nature here shows herself infinitely more powerful than art. This is the foundation of that just and noted rule; "Si vis me flere, dolendum est primum ipsi tibi." Admitting this principle, that all high eloquence

flows from passion, we are able to account for the univerfally acknowledged effect of enthufiafm, or warmth of any kind, in public fpeakers, in affecting their audience. Hence alfo we perceive why laboured declamation, and affected ornaments of ftyle, which fhew the mind to be cool and unmoved, are fo inconfiftent with perfuafive eloquence; and alfo why all ftudied prettineffes, in gefture or pronounciation, detract fo much from the weight of a fpeaker. Hence alfo a difcourfe that is read, moves us lefs than one that is fpoken, as having lefs the appearance of coming warm from the heart. Hence it is, that to call a man cold is the fame thing as to fay, that he is not eloquent. Hence a fceptical man, who is always in fufpence and feels nothing ftroingly, and a cunning mercenary man, who is fufpected rather to affume the appearance of paffion than to feel it, have fo little power over men in public fpeaking. Hence, in fine, the neceffity of being, and being believed to be, difinterefted, and in earneft, in order to perfuade.

In reference to the queftion, whether it be confiftent with firmnefs and candour in a public fpeaker to address the paffions of his audience, Dr. Blair obferves, that this is a queftion about words alone, and which common fenfe eafily determines. In enquiries after truth, in matters of fimple information and inftruction, the paffions have no concern, and all attempts to move them are abfurd. Whereas, conviction is the object we are to apply only to the underftanding. It is by argument and reafoning that one man attempts to fatisfy another of what is true, or right, or juft; but if perfuafion be the object, the cafe is changed. In all that relates to praftice, there is no man who ferioufly means to perfuade another but addresses himfelf more or lefs to his paffions; for this plain reafon, that paffions are the giant fprings of human action. The moft virtuous man, in treating of the moft virtuous fubject, feeks to touch the heart of him to whom he fpeaks; and makes no fcruple to raife his indignation at injuftice, or his pity to the diftreffed, though pity and indignation be paffions. Blair's Lectures, vol. ii. See PATHETIC.

PASSION, in *Heraldry*. *Crofs of Passion* is a crofs thus called, becaufe in ftape of that on which our Saviour fuffered; *i. e.* not croffed in the middle, but nearer the top; with arms fhort, in proportion to the length of the ftap.

PASSION of our Lord *Jesus Chrift*, *Order of*, an order of knighthood faid to have been instituted on the conclufion of the peace between Richard II. king of England, and the French king Charles VI., with a view of protefting and affifting fuch Chriftians as were oppreffed in the Holy Land. The badge of the order was "a red crofs four fingers' broad, edged with gold, and charged on the centre with a cartouche, or octagon fhield, thereon a holy lamb," which crofs was worn by the knights, fewed on their habit, which was white.

PASSION, *Noble, Order of the*, was instituted in the year 1704, by John George, duke of Saxony Weifenfels, with a view to infpire the nobility of his dominions with great and elevated fentiments. The enftgn of the order is "a broad white ribband edged with gold," worn fcarfwife from right to left; pendent to which is a medal of gold; and on it "a ftar of eight points, charged with a crofs gules, furred with an oval blue, thereon the letters J. G. in a cypher in gold;" the ground of the medal without the ftar enamelled white, with thefe words "J'AIME L'HONNEUR QUE VIENET PAR LA VERTU:" on the reverfe are the arms of the principality of Querfurt, with this infcription, "SOCIÉTÉ DE LA NOBLE PASSION, INSTITUÉE PAR J. G. D. D. S. Q. 1704."

PASSION-Flower, in *Botany*. See PASSIFLORA.

PASSION *Week*, the week next preceding Eafter.

It is thus called from our Saviour's paffion, *i. e.* his crucifixion, &c. which happened on the Friday of this week, now called *Good Friday*.

PASSIONATO, in the *Italian Mufic*, intimates that the part to which it is annexed ought to be played paffionately, or in a moving and affecting manner.

PASSIONEI, DOMINICO, cardinal, in *Biography*, was born of a noble family, at Foffombrone, in the duchy of Urbino, in the year 1682. He was educated at the Clementine college in Rome, and at this early period of life he began to collect the copious library which he afterwards rendered fo ufeul to men of learning. In 1706 he vifited Paris, and contracted an acquaintance with Mabillon and Montfaucon, and other eminent fcholars of this metropolis. In 1708 he went to Holland, in the character of a negotiator. The belligerent powers in the Spanifh fucceffion-war, had fent deputies thither to treat for peace; and pope Clement XI., who could not have a nuncio in that country, fecretly commiffioned Paffionei to take care of the interefts of the Holy See. His efforts were fucceffful in procuring the evacuation of the papal territories by the German troops. In the year 1713, he was amply recompenf for his labours, by the pofts of privy chamberlain, and domeftic prelate to that pope, and afterwards by other high official fituations. He was employed in legations as well by Clement XI. as by his fucceffors. Benedict XIV. entrusted him with the moft important affairs, and in 1755 nominated him to the office of librarian of the Vatican. He exerted himfelf in augmenting the riches of this celebrated collection, and extended its ufeulnefs to literature by his correffpondences. The Academy of Infcriptions and Belles Lettres chofe him the fame year one of the foreign affiliates. He died of an apoplexy in 1761. He was juftly regarded as a great benefactor to learning, by the generous affiftance that he afforded to its votaries, and the liberal communication of his literary treafures. As an author, he joined Fontanini in a revision of the "Liber diurnus Romanorum Pontificum," and he wrote fome fcriptural paraphrafes, commentaries, and tranflations, and a funeral oration on prince Eugene. He alfo compiled the "Acta Legationis Helvetice," which has been found a ufeul guide to fucceeding nuncios. He had a nephew Benedict Paffionei, who published at Lucca, in 1765, a volume containing all the Latin and Greek infcriptions collected by this cardinal.

PASSIR, in *Geography*, a fea-port town, on the E. coaft of the ifland of Borneo, on a river which runs into the ftraits of Macaffar, about 45 miles from its mouth, with two fathoms water. The town contains about 300 wooden houfes, on the N. fide of the river, moft of them inhabited by Bugguets merchants, who carry on a confiderable trade in opium, Hindooftan piece-goods, fpices, gold, wax, &c. The houfe or wooden fort of the fultan, a Malay prince, is fituated on the S. fide, a very little way from the river. S. lat. 1° 57'. E. long. 116 10'.

PASSIVE, a term of relation, implying a thing to fuffer, or undergo the action of fome other; which, in refpect hereof, is denominatd *active*.

In all generations, philofophers conceive an active power, and a paffive.

In civil life, we fay, fuch a perfon, in fuch an election, has both an active voice, and a paffive, *i. e.* he is both capable of electing, and of being elected.

Some alfo ufe the term *paſſive debt*, for a debt which we owe another, in contradiftinction to an active debt, which is owing to us.

The ancient chemifts divide their principles, or elements, into

into active and passive. Passive are such as have no active force inherent in themselves, and which only act by being joined with some of the others.

PASSIVE Obedience, a doctrine held by the nonjurors, or high-churchmen, who maintained, that it was never lawful for the people, under any provocation or pretext whatever, to resist their sovereign. This doctrine has been warmly opposed by many, who think it both lawful and necessary, in certain circumstances, and in cases of an urgent and momentous nature, to resist the prince for the happiness of the people. In the present advanced state of civil and religious liberty, this doctrine is now almost exploded in our country.

PASSIVE Qualities. See **QUALITY**.

PASSIVE Understanding. See **UNDERSTANDING**.

PASSIVE Prayer, in the *Language of Mystic Divines*, is a total suspension or ligature of the intellectual faculties, in virtue whereof, the soul remains, of itself, and as to its own power, impotent with regard to the producing of any effects. See **PRAYER**.

The passive state, says Fenelon, is only passive in the same sense as contemplation is so, *i. e.* it does not exclude peaceable, disinterested acts, but only unquiet ones, or such as tend to our own interest.

In the passive state, the soul has not properly any activity, any sensation of its own: it is a mere infinite flexibility of the soul, to which the feeblest impulse of grace gives motion.

PASSIVE, in *Grammar*, denotes a second voice or inflexion of verbs, which, of active, become passive, by assuming, in the modern languages, new auxiliary verbs; and, in the ancient, by new terminations. See **VERB**, **VOICE**. &c.

The English verbs become passive, by taking the auxiliary verb *I am*, in lieu of *I have*, with which the active are conjugated; the French, by *Je suis*, in lieu of *J'ay*; the Italian, by *Io so*, for *Io ho*, &c.

Latin verbs become passive, by changing their terminations; as *amor*, for *amo*, &c. *amari*, for *amare*, &c.

English verbs passive are nothing else, in effect, but the verb *I am* in all its inflexions, joined to the particle passive; as *I am praised*, in Latin, *laudor*; in French, *Je suis loué*; *I have been praised*, *J'ay été loué*, *laudatus sum*, &c.

Mr. Harris, who considers all verbs, that are strictly so called, as energies, distinguishes active and passive verbs in the following manner. Every energy, he says, is naturally situate between two substantives, an energizer, which is active, and a subject, which is passive. Hence then, if the energizer lead the sentence, the energy follows its character, and becomes what we call a verb active. (See **ACTIVE**.) Thus we say, *Brutus amat*, *Brutus loves*. On the contrary, if the passive subject be principal, it follows the character of this too; and becomes what we call a verb passive. Thus we say, *Portia amatur*, *Portia is loved*.

PASSIVE, Neuter, is a verb that has a passive conjugation, but a neuter signification.

Of these there are a very small number in Latin, more in French, and fewer in English; as, *I am entered*, *ingressus sum*, *Je suis entré*, &c.

Grammarians are frequently mistaken here, taking verbs for neuters passives, which, in effect, are actives, and only differ in that they act on themselves, by adding the pronoun personal; and which, on that footing, should rather be neuters active than neuters passive.

Some admit of no genuine passive verbs in the modern tongues; such we mean as answer to the notion of passives in the ancient, where all is done by different terminations.

On which footing, there should be none but actives passive, and neuters passive.

PASSIVE Vassalage. See **VASSALAGE**.

PASSO, in *Music*. See **PASSAGE**.

PASSO, in *Geography*, a town of Portugal, in the province of Beira; seven miles E.S.E. of Lamego.

PASSODE' MOIA, a town of Naples, in Capitanata; 17 miles W.S.W. of Viclla.

PASSOVER, פסחא, a solemn feast, celebrated among the Jews, on the fourteenth day of the moon next after the vernal equinox, or the 14th day of the first month, that is, of the ecclesiastical year, which commenced with the flight of the Israelites out of Egypt; and which had the two names of Abib and Nisan. On the 14th day at even, the paschal lamb was to be killed and eaten, and from thence the feast was to be kept seven days, till the 21st. Exod. xii. 6. 8. 15. Lev. xxiii. 5, 6.

This feast was called, by the ancient Latins and Greeks, pascha, not from πασχα, *I suffer*, as Chrysostom, Irenæus, and Tertullian, weakly imagine, but from the Hebrew פסח, *pesach*, *passage*, *leap*; the design of the feast being to commemorate the destroying angel's *passing over* the houses of the Israelites, when he entered in, and destroyed the first-born in those of the Egyptians. Exod. xii. 27.

Many erroneously imagine, that it was in memory of their passing the Red sea that the passover was instituted; though it is certain the feast was held, and had its name, before the Israelites took a step of their way out of Egypt, and consequently several days before their passing the Red sea.

Besides the passover celebrated on the fourteenth of the first month, there was a second passover held on the fourteenth of the second month after the equinox, instituted by God in favour of travellers, and sick persons, who could not attend at the first, nor be at Jerusalem on the day.

The Greeks, and even some of the Catholic doctors, and several considerable critics, from the thirteenth, eighteenth, and nineteenth chapters of St. John, take occasion to conclude, that Jesus anticipated the day marked for the passover in the law; but the authority of three evangelists seems to evince the contrary. See Whitby's Dissertation on this subject, in an appendix to the fourteenth chapter of St. Mark.

F. Lamy is of opinion, that he did not attend at the passover the last year of his life; which sentiment has drawn upon him abundance of opposers.

F. Hardouin maintains, that the Galileans celebrated the passover on one day, and the Jews on another.

Some divines have maintained, and not without a considerable degree of probability, that the passover had a typical reference to Christ. Accordingly the apostle (1 Cor. v. 7.) calls him "our passover." Godwin and Witfius have stated a variety of particulars, in which this type resembles its anti-type; but in accommodating allusions of this kind, the imagination is too apt to mislead the judgment.

PASSOURA, in *Botany*, a genus of Aublet's, of which the flower is totally unknown. He describes the fruit as follows. "*Peric.* Capsule oblong, triangular, of one cell, and three valves. *Seeds* orbicular, three affixed to a longitudinal partition in the middle of each valve." No account is given of the origin of the name. The tree, which is a native of the Timoutou woods in Guiana and bore fruit in May, is described by Aublet as having a trunk sixteen or eighteen feet high, branched to the summit. *Leaves* opposite, stalked, ovate, acute, smooth, entire. *Fruit* forming a terminal spike, yellowish. *Seeds* spherical, green.

Jussieu has suggested, that it is very closely allied to

Riana,

Riana, Aubl. Guian. t. 94, in which case it must be classed in *Pentandria Monogynia*.

PASS-PAROLE. See *PASS-Parole*.

PASS-PAR-TOUT, a master-key; or key that opens indifferently several locks belonging to the same lodge or apartment.

PASSPORT, a licence or letter from a prince or governor, granting liberty and safe-conduct to travel, enter, and go out of his territories, freely, and without molestation.

The passport is properly given to friends, and the safe-conduct to enemies.

For the provision by Magna Charta, in favour of merchandize, see *MERCHANT*.

The violation of safe-conducts, or passports, expressly granted by the king or his ambassadors to the subjects of a foreign power in time of mutual war, or committing acts of hostility against such as are in amity, league, or truce with us, who are here under a general implied safe-conduct, are breaches of the public faith, without which there can be no intercourse or commerce between one nation and another; and such offences may, according to the writers upon the law of nations, be a just ground of a national war. And it is enacted by the statute 31 Hen. VI. cap. 4. now in force, that if any of the king's subjects attempt, or offend, upon the sea, or in any port within the king's obedience, or against any stranger in amity, league, or truce, or under safe-conduct, and especially by attacking his person, or spoiling him, or robbing him of his goods; the lord chancellor, with any of the justices of either of the king's bench or common pleas, may cause full restitution and amends to be made to the party injured.

Pasquier takes passport to have been introduced for *pass-par-tout*. Balzac mentions a very honourable passport given by an emperor to a philosopher in these terms: "If there be any one on land, or sea, hardy enough to molest Poramon, let him consider whether he be strong enough to wage war with Cæsar."

PASSPORT is also used for a licence, granted by a prince, for the importing or exporting merchandizes, moveables, &c. without paying the duties.

Merchants sometimes procure such passports for certain kinds of commodities; and they are always given to ambassadors and ministers, for their baggage, equipage, &c.

PASSPORT is also a licence obtained for the importing or exporting of merchandizes deemed contraband, and declared such by tariffs, &c., as gold, silver, precious stones, ammunition of war, horses, corn, wool, &c. upon paying duties.

PASSPORT, or *Pafs*, in *Sea Language*, denotes a permission granted by any state to navigate in some particular sea, without hindrance or molestation from it. It contains the name of the vessel, and that of the master, together with her tonnage, and the number of her crew, certifying that she belongs to the subjects of a particular state, and requiring all persons at peace with that state to suffer her to proceed on her voyage without interruption.

PASSULATUM, a name given by the ancients to a medicine composed of the pulp of raisins passed through a sieve, sometimes alone, sometimes with other ingredients.

PASSUM, a name given by the ancients to a kind of wine made of grapes, which had been suffered to remain on the vines till much withered and dried up: it is hence used also by some of the moderns to express raisin wine.

PASSUMACAN BAY, in *Geography*, a bay on the

east coast of the island of Luçon; 15 miles S. of cape Engano.

PASSUMPSICK, a small river of America, in Vermont, which, pursuing a southern course, discharges itself into Connecticut river, below the Fifteen Mile Falls, in the town of Barnet.

PASS-VOLANT, or PASSE-VOLANT. See *FAGGOT*. - In France, the *passé-volants* are condemned to be marked on the cheek with a fleur-de-lis.

PASSYUNK, in *Geography*, a town of America, in Philadelphia county, Pennsylvania, containing 884 inhabitants.

PASTACA, a river of Quito, which rises near Riobamba, and runs into the Maragnon, 50 miles W. of St. Joachim de Omaguas.

PASTE, in *Cookery*, a soft composition of flour, wrought up with proper fluid, as water, milk, or the like, to serve for cakes or coffins, therein to bake meats, fruits, &c.

Paste is the basis or foundation of pies, tarts, patties, pasties, and other works of pastry.

PASTE is also used in *Confectionary*, &c. for a preparation of some fruit, made by beating the pulp thereof with some fluid, or other admixture, into a soft pappy consistence, spreading it into a dish, and drying it with sugar, till it becomes as pliable as an ordinary paste. See *CONFECTS*.

It is used occasionally for making the crusts and bottoms of pyes, &c.

Thus, with proper admixtures, they make almond pastes, apple pastes, apricot pastes, cherry, currant, lemon, plum, peach, and pear pastes.

PASTE is also used for a preparation of wheaten flour, boiled up, and incorporated with water; used by various artificers, as upholsterers, saddlers, bookbinders, &c. instead of glue or size, to fasten or cement their cloths, leathers, papers, &c.

When paste is used by bookbinders, or for paper-hangings to rooms, it is usual to mix a fourth, fifth, or sixth, of the weight of the flour of powdered resin; and where it is wanted still more tenacious, gum arabic, or any kind of size, may be added. Paste may be preserved, by dissolving a little sublimate, in the proportion of a dram to a quart, in the water employed for making it, which will prevent not only rats and mice, but any other kinds of vermin and insects, from preying upon it.

PASTES, in the *Glass Trade*, a sort of composition of the glass kind, made from calcined crystal, lead, and metallic preparations, to imitate the several natural gems. These are no way inferior to the native stones, when carefully made and well polished, in brightness and transparency, but want their hardness.

The general rules to be observed in making them are these: 1. That all the vessels in which they are made are firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels are chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone, not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantities of the several ingredients be nicely observed. 5. That the materials be all well mixed; and if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot; for, if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make a paste of extreme hardness, and capable of all the

the colours of the gems, with great lustre and beauty, take of prepared crystal ten pounds; salt of pulverine, six pounds; sulphur of lead, two pounds: mix all these well together, into a fine powder; make the whole, with common water, into a hard paste; and make of this paste small cakes, of about three ounces weight each, with a hole in them, made in their middle: dry these in the sun, and afterwards calcine them in the straightest part of a potter's furnace; after this powder them, and levigate them into a perfect fineness on a porphyry, and set this powder in pots in a glass furnace to purify for three days; then cast the whole into water, and afterwards return it into the furnace, where let it stand fifteen days; in which time all foulness and blisters will disappear, and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a sea-green, brass simply calcined to redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in paste, by the same way of working as the making of the coloured glasses; and this is so hard, that they very much approach to the natural gems.

The colours in all the counterfeit gems, made of the several pastes, may be made deeper or lighter, according to the works for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones a paler. Besides the colours made from manganese, verdigris, and zaffer, which are the ingredients commonly used, there are other very fine ones, which care and skill may prepare: very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brass or copper, and a sky-colour from silver; and a much finer one from the common small garnets of Bohemia, which are of little value. The gems also afford glorious colours like their own.

The fine blue from silver is, probably, only from the small quantity of copper used in the alloy.

A very singular and excellent way of making the paste to imitate the coloured gems is this: take a quantity of saccharum saturni, or sugar of lead, made with vinegar in the common way; set it in sand, in a glass body well luted from the neck downwards; leave the mouth of the glass open, and continue the fire twenty-four hours; then take out the salt, and if it be not red, but yellowish, powder it fine, and return it into the vessel, and keep it in the sand-heat twenty-four hours more, till it becomes as red as cinnabar. The fire must not be made so strong as to melt it, for then all the process is spoiled. Pour distilled vinegar on this calcined salt, and separate the solution from the dregs: let the decanted liquor stand six days in an earthen vessel, to give time for the finer sediment to subside: filter this liquor, and evaporate it in a glass body, and there will remain a most pure salt of lead; dry this well, then dissolve it in fair water; let the solution stand six days in a glazed pan; let it subside, then filter the clear solution, and evaporate it to a yet more pure white and sweet salt; repeat this operation three times; put the now perfectly pure salt into a glass vessel, set it in a sand-heat for several days, and it will be calcined to a fine impalpable powder, of a lively red. This is called the sulphur of lead. Neri's Art of Glass.

Take all the ingredients as in the common composition of the pastes of the several colours, only instead of red lead, use this powder, and the produce will well reward the trouble of the operation, as experience has often proved.

A paste proper for receiving colours may be readily made by well pounding and mixing six pounds of white sand, cleaned, three pounds of red lead, two pounds of purified pearl-ashes, and one pound of nitre. A softer paste may be

made, in the same manner, of six pounds of white sand cleaned; red lead, and purified pearl-ashes, of each three pounds; one pound of nitre, half a pound of borax, and three ounces of arsenic. For common use, a pound of common salt may be substituted for the borax. This glass will be very soft, and will not bear much wear, if employed for rings, buckles, or such imitations of stones, as are exposed to much rubbing; but for ear-rings, ornaments worn on the breast, and those little used, it may last a considerable time.

In order to give paste different colours, the process is as follows.

PASTE resembling amethyst.—Take ten pounds of either of the compositions described under *Colouring of GLASS*; one ounce and a half of manganese, and one dram of zaffer; powder and fuse them together. See *AMETHYST*.

PASTE perfectly black.—Take ten pounds of either of the compositions just referred to, one ounce of zaffer, six drams of manganese, and five drams of iron, highly calcined; and proceed as before.

PASTE, Blue.—Take of the same composition ten pounds; of zaffer, six drams; and of manganese, two drams; and proceed as with the foregoing.

PASTE resembling the chrysolite.—Take of either of the compositions for paste above described, prepared without salt-petre, ten pounds, and of calcined iron five drams; and pursue the same process as with the rest. See *CHRYSOLITE*.

PASTE resembling the red cornelian.—Take of the compositions mentioned under *Colouring of GLASS*, two pounds; of glass of antimony, one pound; of the calcined vitriol, called scarlet ochre, two ounces; and of manganese, one dram. Fuse the glass of antimony and manganese with the composition; then powder them, and mix them with the other, by grinding them together, and fuse them with a gentle heat.

PASTE resembling white cornelian.—Take of the composition just referred to, two pounds; and of yellow ochre, well washed, two drams; and of calcined bones, one ounce. Mix them and fuse them with a gentle heat.

PASTE resembling the diamond.—Take of the white sand, six pounds; of red lead, four pounds; of pearl-ashes, purified, three pounds; of nitre, two pounds; of arsenic, five ounces; and of manganese one scruple. Powder and fuse them.

PASTE resembling the eagle-marine.—Take ten pounds of the composition under *GLASS*; three ounces of copper, highly calcined with sulphur; and one scruple of zaffer. Proceed as before.

PASTE like emerald.—Take of the same composition with the last, nine pounds; three ounces of copper, precipitated from aquafortis, and two drams of precipitated iron. See *EMERALD*.

PASTE like garnet.—Take two pounds of the composition under *GLASS*; two pounds of the glass of antimony; and two drams of manganese. For vinegar garnet, take of the composition for paste, described in this article, two pounds; one pound of glass of antimony, and half an ounce of iron, highly calcined; mix the iron with the uncoloured paste, and fuse them; then add the glass of antimony, powdered, and continue them in the heat till the whole is incorporated. See *GRANITE*.

PASTE, gold, or full yellow colour.—Take of the composition for paste ten pounds, and one ounce and a half of iron strongly calcined; proceeding as with the others.

PASTE, deep purple.—Take of either of the compositions for paste ten pounds; of manganese, one ounce; and of zaffer, half an ounce.

PASTE, resembling ruby.—Take one pound of either of the compositions for *paste*, and two drams of *calx cassii*, or precipitation of gold by tin; powder the *paste*, and grind the *calx* of gold with it in a glass, flint, or agate mortar, and then fuse them together. A cheaper ruby *paste* may be made with half a pound of either of the above compositions, half a pound of glass of antimony, and one dram and a half of the *calx* of gold; proceeding as before.

PASTE resembling sapphire.—Take of the composition for *paste*, ten pounds; of *zaffer*, three drams and one scruple; and of the *calx cassii* one dram. Powder and fuse them. Or the same may be done, by mixing with the *paste* one-eighth of its weight of *smalt*. See **SAPPHIRE**.

PASTE like topaz.—Take of the composition under **GLASS** ten pounds, omitting the *sal-petre*; and an equal quantity of the gold-coloured hard glass. Powder and fuse them. See **TOPAZ**.

PASTE like turquoise.—Take of the composition for *blue paste*, already described, ten pounds; of calcined bone, horn, or ivory, half a pound. Powder and fuse them.

PASTE, opaque white.—Take of the composition for *paste*, ten pounds; and one pound of calcined horn, ivory, or bone; and proceed as before.

PASTE, semi-transparent white, like opal. See **OPAL**.

PASTE for angling.—There are many receipts which particular people are fond of; but the following composition seems one of the best: take equal quantities of fresh butter and sheep's suet, about half as much of good old cheese, and the crum of an old stale white loaf, as much as will, when they are all beaten in a mortar, make the whole into a *paste*; add a little wool or tow, that it may keep the better on the hook. The place should be baited with blood and grains over night, and in the morning this *paste* will be found an excellent bait. See **FISHING**.

PASTES for birds, a general sort of food made by the people who breed up birds from the nest, and suiting almost all kinds.

It is made in the following manner: grind half a peck of large beans, well dried, to a very fine meal; take of this meal two pounds; of the best sweet almonds blanched, one pound; these must be well beat together in a mortar, till perfectly mixed; then to a quarter of a pound of fresh butter, in a sauce-pan well tinned, add the *paste*, and mix all well together over a charcoal fire, stirring it as it boils with a wooden spoon; then add the yolks of four eggs, and a little saffron, and finally a small quantity of the finest virgin honey. When these are well incorporated, and are tolerably thin and without lumps, the whole is to be poured into a colander, made with such holes as will let the composition pass through: if any of it is so stiff that it will not go through, it must be beat again in a mortar, and by that means made fit to pass the holes, and mix with the rest. When the whole is done, it is to be put into a pot, and a little clarified honey being melted and poured on it, it will keep very well for six months or longer.

PASTEBOARD, a kind of thick paper, formed of several sheets pasted together.

There is also a coarse kind of *pasteboard*, made of old paper, and old *pasteboard*, beaten in a mortar with water, and reduced into a kind of pulp; to which is added a little *paste*, to give the mass a consistence, after which it is formed into a mould, and, to finish it, laid in a press, to squeeze out all the water, and reduce it to its proper thickness.

Each kind is distinguished by numeroes, which express the fineness and value: the finest is covered on both sides

with a very white smooth paper; others only on one side; and others on both sides with common paper.

The chief use of *pasteboard* is in the binding of books, and the making of letter-cases, hat-cases, gloves, &c. See **BOOK-BINDING**.

For the duty on *pasteboard*, see **PAPER**.

PASTEHI, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 56 miles W.N.W. of Diarbekir.

PASTEL. See **PASTIL**.

PASTERN of a horse, the distance between the fetlock or joint next the foot and the coronet of the hoof.

This part should be short, especially in the middle-sized horses; because long pasterns are weak, and cannot so well endure travel.

PASTERN Joint, is the joint above the pastern.

The pastern joint, after travelling, is very apt to be crowned, *i. e.* to have a swelling round it, beneath the skin, in form of a circle, a third of an inch broad.

PASTICCIO, literally means, in Italian, a pie or pastry; but in music implies an opera composed of detached airs by different composers, frequently introduced without any connection with the drama, character, or situation of the singer.

PASTIL, or **PASTEL**, among *Painters*, &c. a sort of *paste*, made of several colours, ground up with gum-water, either together or separately, in order to make crayons to paint with on paper or parchment. See **CRAYON**.

PASTIL, *Pastillus*, is also used for a dry composition, yielding a fragrant smell when burnt in a perfuming pan, to clear and scent the air of a chamber.

It is composed of odorous resins, mixed with aromatic woods or drugs pulverised, and incorporated with mucilages of gum tragacanth. Some call these compositions *offelets* of Cyprus.

There are also *pastils* for the mouth, chewed to procure a sweet breath. These have several names, and consist of several preparations, as muscadines, conserves, &c.

PASTIL, or *Pastil*, is sometimes used for the plant otherwise called *wood*.

PASTIL, in *Confectionary*, is a preparation of sugar with lemon-water, &c. boiled up with gum-water, strained, beat up, and, by the addition of more dry sugar, worked into a pliable *paste*, and thus formed into round or oblong figures, and dried in a stove. See **LOZENGE**.

PASTINACA, in *Botany*, said, by some authors, to be derived from *pasco*, to feed, or from *pastus*, a pasture, on account of the nourishing qualities of its roots which are eaten by the poor. Linnæus rather considered the name as derived from *pastinum*, a forked tool, used in digging or planting vineyards, which the root of *Pastinaca* resembles. Linn. Gen. 144. Schreb. 194. Willd. Sp. Pl. v. 1. 1465. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 328. Prodr. Fl. Græc. v. 1. 202. Ait. Hort. Kew. ed. 2. v. 2. 157. Tournef. t. 170. Juss. 219. Lamarck Illustr. t. 206. Gærtner. t. 21.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellata*, Linn. *Umbellifera*, Juss.

Gen. Ch. *General umbel* of many rays, flat; *partial* of many rays. *General involucre* none; *partial* none. *Petianth* obsolete. *Cor.* *Universal*, uniform; flowers all fertile; *partial* of five, lanceolate, involute, undivided petals. *Stam.* Filaments five, capillary; anthers roundish. *Pist.* Germen inferior; styles two, reflexed; stigmas obtuse. *Peric.* Fruit much compressed, elliptical, divisible into two parts. *Seeds* two, elliptical, girt round the margin, nearly flat on both sides.

PASTINACA.

Ess. Ch. Fruit elliptical, compressed almost flat. Petals involute, entire. Involucrum neither general nor partial.

1. *P. lucida*. Shining-leaved Parsnep. Linn. Mant. 58. Jacq. Hort. Vind. v. 2. p. 94. t. 199. Gouan. Illustr. 19. t. 11. and 12. —Leaves simple, heart-shaped, lobed, thinning, acutely notched.—Native of the south of Europe, especially in the Balearic islands. It flowers in June and July.—*Root* biennial, thick, milky. *Stem* upright, rugged, grooved and angular, branched from the bottom, and, according to Gouan, five or six feet in height, yielding, when cut, a foetid, tenacious gum, smelling like rue. *Leaves* alternate, on stalks, large and handsome; dark green on the upper side; much paler, and veiny beneath. In luxuriant specimens they are sometimes ternate, or even quinate. *Flowers* yellow.—This elegant umbelliferous plant is smooth all over, having a strong, unpleasent taste and smell, which remains unimpaired even after the plant has been dried many years.

2. *P. fativa*. White Parsnep. Linn. Sp. Pl. 376. Engl. Bot. t. 556. Mart. Rust. t. 83.—Leaves simply pinnate, downy beneath.—Native of Great Britain, and of the south of Europe, on hills, and in the borders of fields, on a calcareous soil.—It flowers in July.—*Root* biennial, spindle-shaped, aromatic, sweet, but acrid. *Stem* three feet high, erect, branched, angulated, furrowed, roughish. *Leaves* pinnate; leaflets from five to nine, cut or serrated, the terminal one three-lobed. *Flowers* small, yellow, in terminal, solitary, erect, roughish umbels of many rays. *Fruit* large, elliptical, flat, ribbed, smooth, light brown when ripe.

The common garden parsnep is a cultivated variety of this species, with larger, smoother leaves, and a mild eatable root.—The highly saccharine juice of this plant is found to render it exceedingly nutritious food for various kinds of animals. The roots are sweeter than carrots, and Gerarde says, that “a good and pleasant food or bread may be made of them.” Nevertheless, they disagree with some stomachs.

3. *P. Opopanax*. Rough Parsnep. Linn. Sp. Pl. 376. Gouan. Illustr. 19. t. 13, 14. Woody. Med. Bot. v. 2. 309. t. 113.—Leaves pinnate; leaflets gashed at the base in front.—Native of the east of the south of Europe, flowering in June and July.—*Root* perennial, thick, fleshy, tapering. *Stalk* seven or eight feet high, strong, branched, rough towards the bottom. *Leaves* pinnate, composed of many pairs of oblong, serrated veined leaflets. *Flowers* small, yellow, in terminal, flat umbels.

This species has long held a distinguished place in the *Materia Medica*, as affording the gum-resin called *Opopanax*.

Woodville says the plant bears the cold of our climate very well, but it is only in the warm regions of the East, that the juice concretes into the appearance under which we have it, imported from Turkey and the East Indies, viz. “in little round drops or tears, more commonly in irregular lumps, of a reddish-yellow colour, on the outside with specks of white, internally of a paler colour, and frequently variegated with large white pieces.”

We have already mentioned that *Laserpitium Chironium* of Linnæus is probably the same plant with this. See *LASERPITIUM*.

PASTINACA, in *Gardening*, contains plants of the herbaceous eulent kind, of which the species cultivated are, the common parsnep (*P. fativa*); and the rough parsnep (*P. opopanax*).

The garden or cultivated variety of this species has smooth leaves, of a light or yellowish-green colour, in which it differs from the wild plant: the stalks also rise higher, and are deeper channelled: the peduncles are much longer, and the flowers of a deeper yellow colour: the roots are sweeter than those of the carrots, and are much eaten by those who

abstain from animal food in Lent, or eat salt-fish; and are highly nutritious. Hogs are fond of these roots, and cattle will eat them with avidity.

Method of Culture.—This in the first sort is easily effected by sowing fresh seed in the latter end of February, or beginning of the following month, upon a bed prepared in a spot of the best light, rich, deep soil, in one of the most open airy quarters of the garden, by being trenched one full spade deep at least, or if two the better, provided the depth of good staple admit, that the roots have a due depth of loose soil to run down straight to their full length. And if the ground be previously trenched up in rough ridges in winter, especially where stiff or wet, and lie exposed some time to the sun and air, it will be much improved for this purpose. At the time of sowing, the ground should be made level and even on the surface, but not raked till after the seed is sown, which should be performed while the ground is fresh stirred, or before the surface becomes too dry, so as, in raking, the clods will readily fall under the rake to bury the seed regularly.

And the seed should be sown broad-cast thinly, either all over the surface, or the ground may be divided into four-foot-wide beds, as most convenient, but for large quantities the former is the most eligible practice. As soon as the sowing is done, if light ground, it is the practice with some to tread down the seeds evenly, and finish with an even good raking, to cover them equally, smoothing the surface. In about three weeks the seeds begin to germinate, and the plants soon appear above ground. When they are two or three inches high, they should be thinned to regular distances, and cleaned from weeds; which may be done either by hand or small hoeing; but the latter is preferable for the benefit of the crop, and considerably the most expeditious: it should generally be performed by a three or four-inch hoe. Dry weather should be chosen for the purpose, and the plants cut out to about ten or twelve inches distance, as they should have large room, cutting up all weeds as the work proceeds. After this, no more culture is required till the future progress of the weeds renders another hoeing necessary; and probably another repetition may also be required, till the plants are in full leaf, when they cover the ground, and bid defiance to any further interruption from weeds.

In the autumn, about October, the roots will be arrived nearly at their full growth; when the leaves begin to turn yellow and decay, which is a certain sign of their maturity, they may then be dug up for use, as they are wanted.

They may also either remain in the ground all winter, and be taken up as wanted, or a quantity may be dug up in autumn, and their tops pared off close, and then buried all winter in sand, in a shed or other dry place, to be ready at all times for use: some should also be left in the ground for spring service, as January or the beginning of February, digging them up just before they begin to shoot, and laying them in the sand; as by taking them up at this time, it retards their effect for shooting, so as that they continue in tolerable perfection until the latter end of April or longer.

But in order to have parsneps in due perfection, great care is necessary to save seed only from some of the finest rooted plants; for which purpose, a quantity of the large, long, straight roots should be selected, trimming off their leaves, and planting them in rows three feet asunder, and two distant in the lines, about an inch deep over their top; in which method they will shoot up strong in spring for flowering, and ripen seed in the latter end of August, or early in September; when in a dry day, the umbels of seed should be cut off and spread upon mats to dry and harden,

afterwards thrashing out the seeds, and putting them up in bags for use.

And the second sort may be raised, by sowing the seed in the places where the plants are to remain, at the same season as the above; keeping the plants afterwards properly thinned and clear from weeds.

The first is an useful esculent root, that contains a large proportion of nutritious matter; but the latter is chiefly cultivated for affording variety in the borders or other parts of pleasure-grounds.

PASTINACA Marina, in *Ichthyology*, the name of a fish, called in English the *poison-fish*, *fire-flaire*, or *sting-ray*. It is one of the flat cartilaginous fishes, and something like the common skate. It is a species of the raia, or ray-fish, and distinguished by Artedi from the other species, by the name of the smooth-bodied ray, with no fins to the tail, but with a long, bony, serrated spine in it. See *RAJA Pastinaca*.

This fish is the *τρογύνη* of Aristotle and Oppian, and is called by the modern Italians, *banco*.

Its tail, in which all its poison is said to be lodged, is long, smooth, and round, with a thorn, or dart, of a finger's length, toothed on each side like a saw, with the teeth standing upwards, or toward the head. This is placed at the distance of about one-third of the length of the tail; and that from this place grows very slender, and ends in a very slender point. It grows, sometimes, to ten pounds weight; and when the tail is cut off, is commonly sold in the markets of Italy, and elsewhere.

Authors give us many remarkable accounts of the poison of this fish, which it communicates to animals by the stroke of its tail. They mention also two kinds of it; that is, beside the ordinary species, which is smooth, another called the *pastinaca marina aspera*, which is rough and prickly.

Mr. Pennant observes, that there is no credit due to the generally received opinion of its venomous qualities, though even Linnæus has adopted it. The spine is the weapon of offence belonging to the fish, which is capable of giving a very bad wound, attended with dangerous symptoms, when it happens on a tendinous part, or to a person with a bad habit of body. Pennant's *British Zool.* vol. iii. p. 95.

PASTINATION, a term sometimes used in *Agriculture*, for the act of opening, loosening, and preparing the earth for planting.

PASTO, in *Geography*, a town of Peru; 80 miles N. N. E. of Lima.

PASTO, *St Juan de*, a town of South America, in the province of Popayan, capital of a district, in the viceroyalty of New Granada, containing above 7000 inhabitants; 80 miles S. S. W. of Popayan. N. lat. 1° 15'. W. long. 76° 46'.

PASTOPHORI, *παστοφοροι*, among the ancients, priests whose business it was, at solemn festivals, to carry the shrine of the deity, when they were to pray to him for rain, fair weather, or the like.

PASTOPHORIA, in *Antiquity*, the apartments, near the temples, where the *pastophori* were lodged.

Clemens Alexandrinus, describing the temples of the Egyptians, says, that, after having passed through magnificent courts, you are conducted to a temple, which is at the farther end of these courts, and then a *pastophorus* gravely lifts up the veil, which is the door, to shew you the deity within; which is nothing but a dog or a cat, or some other animal. These *pastophori* also supported the shrine, or niche of these ridiculous divinities, when they were carried in procession. Apuleius speaks of the *pastophori* that carried the Syrian goddesses.

In the temple of Jerusalem there were two courts sur-

rounded with galleries, and all round about were several lodging rooms for the priests, to lay up wood, wine, oil, salt, meal, spices, incense, vestments, valuable vessels, and provisions necessary for the sacrifices and lamps, as also for the support and maintenance of the priests. See 1 Chron. ix. 26, 33. Ezek. xl. 17, 18. 1 Chron. xxvi. 16.

PASTOR, originally signifies one that (*pasceit*) feeds. Hence it was anciently used for a *shepherd*, or *advocate*; and is now appropriated to a *minister*, or one that has the cure of souls.

PASTOR Piscis, in *Ichthyology*, the name of a fish of the mullet kind, caught in the American seas and rivers, and esteemed a very well-tasted one.

It is the usual size of our river trout, and not unlike that fish in shape; its scales are large, and of a silvery white, and are ranged in the same order with those of the perch, with greyish lines between the several arrangements; it has seven fins, all very large, especially that on the back, and its tail is remarkably forked; all the fins are white, and the covering of the gills are scaly; not bony, as in most other fishes; whence it has been supposed to have no gills.

PASTORAL, something that relates to shepherds, *pastores*. The poets represent the innocence of a pastoral life, and pastoral manners, in the most agreeable light. We must not imagine them so beautiful in nature as in their descriptions.

PASTORAL, in *Poetry*, denotes a composition, the subject of which is something in the pastoral, or at least in rural life, and the persons shepherds, or at least rustics.

Most authors, says Dr. Blair, have indulged the fancy, that because the life which mankind led at first was rural, their first poetry was therefore pastoral, or employed in the celebration of rural scenes and objects; but he is of opinion that, though it would borrow many of its images and allusions from those natural objects, with which men were best acquainted, the calm and tranquil scenes of rural felicity were not the first objects which inspired that strain of composition, which we now call poetry. The first themes were furnished to the bards of every country by objects and events that roused men's passions; such as the actions of their gods and heroes, their own exploits in war, and the successes or misfortunes of their countrymen and friends. What was of a pastoral kind in their compositions was merely incidental. It was not till men had begun to be assembled in great cities, after the distinctions of rank and station were formed, and the bustle of courts and large societies was known, that pastoral poetry assumed its present form. It was in the court of king Ptolemy, that Theocritus wrote the first pastorals with which we are acquainted, and in the court of Augustus, he was imitated by Virgil. Pastoral poetry, whatever was its origin, is undoubtedly a natural and very agreeable form of composition. It recalls to our imagination those gay scenes, and pleasing views of nature, which are commonly the delight of our childhood and youth; and to which, in more advanced life, most men recur with pleasure. It exhibits to us a life, with which we are accustomed to associate the ideas of peace, of leisure, or of innocence; and therefore we readily set open our hearts to such representations as promise to banish from our thoughts the cares of the world, and to transport us into calm Elysian regions. No subject, at the same time, seems to be more favourable to poetry. Amidst rural objects, nature presents, on all hands, the finest field for description; and nothing appears to flow more, of its own accord, into poetical numbers, than rivers and mountains, meadows and hills, flocks and trees, and shepherds void of care. Hence

PASTORAL.

it is, that this species of poetry has, at all times, allured many readers and excited many writers. Nevertheless, there is hardly any species of poetry more difficult to be carried to perfection, or in which fewer writers have excelled. Pastoral life is described by the author now cited in three different states of it; either as it now is, when shepherds are reduced to a mean, servile, and laborious condition; or such as it may be supposed to have been, in the more early and simple ages, when flocks and herds were numerous, and shepherds, though unrefined in their manners, were respectable in their situation; or such as it never was, nor can be, when to the ease, innocence, and simplicity of the early ages, we attempt to add the polished taste and cultivated manners, of modern times. The first of these states is too gross and mean, and the last too refined and unnatural, to become the ground-work of pastoral poetry. Theocritus is censured for having deviated too much to the first extreme: and some of the French and Italian writers of pastorals have erred in making their shepherds discourse like courtiers and scholars: and in either way a person may retain the name, whilst he wants the spirit of pastoral poetry. He that would succeed in this species of composition must keep in the middle station between these two extremes. The great charm of pastoral poetry arises from the view which it exhibits of the tranquillity and happiness of a rural life. This pleasing illusion the poet must be careful to maintain. The true spirit of a pastoral poet is conspicuously displayed by Virgil in the following beautiful lines of the first eclogue, in which he has brought together as agreeable an assemblage of images of rural pleasure as can any where be found.

“Fortunate Senex! hic inter flumina nota, &c.”

“Happy old man! here mid th’ accustom’d streams
And sacred springs, you’ll shun the scorching beams;
While from yon willow fence, the pasture’s bound,
The bees that suck their flowery stores around,
Shall sweetly mingle, with the whispering boughs,
Their lulling murmurs, and invite repose.
While from steep rocks the pruner’s song is heard;
Nor the soft cooing dove, thy fav’rite bird,
Meanwhile shall cease to breath her melting strain,
Nor turtles from th’ ærial elms to plain.” Wharton.

Pastoral poetry offers to our consideration its scenery, its characters, and the subjects and actions which it should exhibit. As to the *scene*, it must be laid in the country, and the poet’s merit much depends on describing it beautifully. Virgil is, in this respect, deemed to have been excelled by Theocritus, whose descriptions of natural beauties are richer and more picturesque than those of the other. The following description exhibits rural scenery painted in very lively colours.

“——— ἐν τῷ Βαβυλίῳ, &c.” Idyll. vii. 132.

“——— on soft beds recline
Of lentisk, and young branches of the vine;
Poplars and elms above, their foliage spread,
Lent a cool shade, and wav’d the breezy head;
Below, a stream, from the nymph’s sacred cave,
In free meanders led its murmur’ing wave;
In the warm sun-beams, verdant shades among,
Shrill grasshoppers renew’d their plaintive song:
At distance far, conceal’d in shades, alone,
Sweet Philomela pour’d her tuneful moan:

The lark, the goldfinch, warbled lays of love,
And sweetly pensive, coo’d the turtle dove:
While honey bees, for ever on the wing,
Hum’d round the flowers, or sipt the silver spring.
The rich, ripe season gratified the sense
With summer’s sweets, and autumn’s redolence.
Apples and pears lay strew’d in heaps around,
And the plum’s loaded branches kiss’d the ground.”

Fawkes.

As to the *characters*, or persons, that are proper to be introduced into pastoral poetry, they must be shepherds, or persons wholly engaged in rural occupations; whose innocence and freedom from the cares of the world may, in our imagination, form an agreeable contrast with the manners and characters of those who are engaged in the bustle of life.

In the choice of the *subjects* of pastoral poetry, the principal difficulty of this kind of writing occurs. The active scenes of country life will be thought by many, and perhaps not without reason, too barren of incidents. The tenor of the shepherd’s life is uniform, and does not admit of that variety which renders poetry interesting. Hence it is that, of all poems, the most meagre commonly in the subject, and the least diversified in the strain, is the pastoral. Common-place topics have been thrummed over by all eclogue writers, since the days of Theocritus and Virgil; and to this circumstance is owing much of that insipidity which prevails in pastoral composition. But why, says Dr. Blair, may not pastoral poetry take a wider range? Human nature, and human passions, are much the same in every rank of life; and whenever these passions operate on objects that are within the rural sphere, there may be a proper subject for pastoral.

The two great fathers of pastoral poetry are Theocritus and Virgil. In those Idylls of the former, which are properly pastorals, there are many great beauties. He is distinguished for the simplicity of his sentiments; for the great sweetness and harmony of his numbers; and for the richness of his scenery and description. He is the original after which Virgil has copied; but he has followed him with judgment, and in some respects improved upon him. Moschus and Bion, two other Greek poets, have also considerable merit in the pastoral style; and if they want the simplicity of Theocritus, they excell him in tenderness and delicacy.

The modern writers of pastorals have generally contented themselves with imitating the ancient poets. Sannazarus, indeed, a famous Latin poet in the age of Leo X., attempted a bold innovation, by composing Piscatory eclogues; changing the scene from woods to the sea, and from the life of shepherds to that of fishermen. But he has gained no followers among all the moderns. M. Gesner, a poet of Switzerland, has been, in the judgment of Dr. Blair, the most successful in his pastoral compositions. He has introduced into his Idylls many new ideas. His rural scenery is striking, and his descriptions are lively. He presents pastoral life to us, with all the embellishments of which it is susceptible, but without any excess of refinement. The chief merit of this poet consists in his writing to the heart; and he has enriched the subjects of his Idylls with incidents, which give rise to much tender sentiment. Scenes of domestic felicity are beautifully painted. The mutual affection of husbands and wives, of parents and children, of brothers and sisters, as well as of lovers, are displayed in a pleasing and touching manner.

Neither Mr. Pope’s, nor Mr. Philips’s pastorals, do any great honour, in our author’s opinion, to the English poetry. Mr. Gay published his *Shepherd’s Week*, in six pastorals, with a design of ridiculing that sort of simplicity which

Philips and his partizans extolled, and they are an ingenious burlesque of pastoral writing, when it rises no higher than the manners of modern clowns and rustics. Mr. Shenstone's pastoral ballad, in four parts, may justly be reckoned, says Dr. B., one of the most elegant poems of this kind in the English language.

Pastoral writing has appeared in later ages under the form of a regular drama, blending plot, characters, and passions, with the simplicity and innocence of rural manners. Accordingly pastoral has been defined a dramatic piece, in which the persons are clad like nymphs and shepherds, and act their own amours. The scene is always in the fields or woods; whence Tasso calls pastoral "favole boscareccia." Such are the Pastor Fido, of Guarini; the Aminta, of Tasso; the Sylvia, of Mairet, the French poet; and the Comus of Milton, &c. Tasso assumes to himself the honour of having invented pastoral; but the first idea of this kind of drama seems to be Beccari's, who made the first attempt of this kind in 1552. But Tasso's Aminta, which did not appear till the year 1573, effacing what had been done by Beccari, the first author was forgot, and Tasso left as the inventor.

It is certain this kind of pastoral fable, composed according to the rules of the stage, was unknown among the ancients. The Greeks and Latins have indeed introduced shepherds in their eclogues; but these eclogues had nothing theatrical in them: nor were the shepherds ever brought upon the stage.

Tasso's Aminta claims the preference, as it is less intricate in the plot and conduct, and less strained and affected in the sentiments than the Pastor Fido of Guarini. Both possess great beauties, and are entitled to the reputation they have gained. Dr. Blair mentions another pastoral drama, which will bear being brought into comparison with any composition of this kind, in any language; that is, Allan Ramfay's Gentle Shepherd. The characters are well drawn, and the incidents affecting; the scenery and manners lively and just. It affords a strong proof, both of the power which nature and simplicity possess, to reach the heart, in every sort of writing; and of the variety of pleasing characters and subjects, with which pastoral poetry, when properly managed, is capable of being enlivened. Blair's Lectures, vol. iii.

PASTORAL Staff. See CROSIER.

PASTORALE, Ital. and Fr, in Music, an air of the pastoral kind, is generally in Siciliana time. "French airs called pastorals (according to Rousseau) are generally in $\frac{6}{8}$ measure, or two triplets in a bar, and in the character of the musette. Italian pastorals have more accent, more grace, as much sweetness, and are less insipid; their measure is always $\frac{6}{8}$." A mistake; the celebrated pastoral at the end of Corelli's eighth concerto, is in $\frac{3}{4}$.

Among French pastorals, they have whole dramas, called *opera champêtres*, the personages of which are shepherds, and the music ought to be suitable to their state, simple and rustic, such as we suppose their manners to be.

A pastoral is also a piece of music, set to words relative to pastoral life, or a melody which imitates the songs of the shepherds, which is equally sweet, tender, and natural. The air of a dance composed in the same character, is also called a pastoral.

PASTORIUS, JOACHIM, in Biography, a writer of history, was born in the year 1610, in Great Glogau, in Silesia. He was brought up to the medical profession, and received the title of honorary professor at Elbing and Dantzic, but the avowal of Socinian principles subjected him to va-

rious ill offices. At length his constancy gave way, and he conformed to the Roman Catholic religion; he was almost immediately ennobled, created apostolic protonotary, advanced to other high offices, and finally made historiographer, secretary, and commissary of the kingdom of Poland. He died at Frauenberg, in Prussia, in 1681. He was author of a number of historical pieces, written in the Latin language, and he published the Aristotelian Ethics of Crellius, with a life of the author, and some orations and poems. Moreri.

PASTRY, that branch of cookery which teaches the preparation of paste, with several savory ingredients of flesh, fruits, spices, sugar, butter, &c.

Pastry is chiefly conversant in the making of pies, pasties, patties, cakes, biscuits, &c.

PASTURE, PASTURA, in our law-books, is any place where cattle are occasionally fed. By which it differs from *pasua*, which is a place set wholly apart for feeding, and never ploughed.

"Pastura omne genus pascendi significat, sive in pratis, sive in stipula, sive in agris, sive in campis: fed pasua est locus principaliter deputatus pecoribus pascendis, ut puta in montibus, moris, mariscis, et planis non cultis nec aratis." Linwood.

PASTURE, Common of. See COMMON of Pasture.

PASTURE, Admeasurement of. See ADMEASUREMENT.

PASTURE, in Agriculture, a field kept fed down by cattle, sheep, or other animals. These differ considerably according to the modes in which they are managed, some being almost wholly appropriated to the fattening of animals, under which system they are termed grazing, or fattening pastures; while those which are almost solely applied to the support of such animals as afford useful products, such as cheese or butter, are denominated dairy pastures. The situations and inclosure of pastures have also some effect on the manner of employing them, the lower and more inclosed kinds being in general more adapted to the fattening system, while the higher are more suited to sheep-pastures. The state of the sward may likewise have some influence in the same way, as the new lays are said to be more proper for the store flock, while the old grafs lands are better for feeding. See the following article.

PASTURE Land, a general name for all sorts of land reserved for the purposes of pasturing and feeding cattle upon. Pasture ground is of two sorts: the one is low meadow land, which is often overflowed; and the other is upland, which lies high and dry. The first of these will produce a much greater quantity of hay than the latter, and will not require manuring or dressing so often: but the hay produced on the upland is much preferable to the other; as is also the meat which is fed in the upland, more valued than that which is fed in rich meadows: though the latter will make the fatter and larger cattle, as is seen by those which are brought from the low rich lands in Lincolnshire. But where the people are nice in their butcher's-meat, they often give a much larger price for such as has been fed on the downs, or in short, upland pastures, than for the other, which is much larger. Besides this, dry pastures have an advantage over the meadows, that they may be fed all the winter, and are not so subject to poach in wet weather; nor will there be so many bad weeds produced; which are great advantages, and which, in a great measure, recompense for the smaller produce of grafs.

The author of a late practical work has stated, that the grounds that are the most perfectly adapted to this use, are all those which have a considerable depth of good mould, and, at the same time that they afford a good herbage, are so dry in their nature, as to admit animals to feed upon them at almost

all

PASTURE-LAND.

all seasons, without injury by poaching. Coarse rusby lands may, however, in many cases, be converted into good pastures, by proper attention in draining, and cutting over the rushes in the early part of the spring, as by this means the water enters their stems, and the plants decay, the young shoots being afterwards eaten by young stock, and the good grass plants allowed to flourish. He likewise adds, that there is also another sort of land that may be employed in this way, which is that of the moory kind, consisting of much imperfectly reduced vegetable matter, proceeding from the leaves and roots of various decayed vegetable productions, that require to be brought into a suitable condition for the support of grass plants by proper drainage, and the application of substances of the fossil kind. And he observes, that pasture lands should likewise, as much as possible, possess properties in the nature of their grasses that are the most advantageous for the particular method of management under which they are to be conducted. In this view, some may be more adapted to the producing of milk and butter, others of cheese, and others again of feeding or fattening animals. It is in some measure on this account, as well as that of local convenience, that different modes of management are employed on grass lands.

And it is suggested, that the difference of situation in pasture lands has likewise much influence in directing the uses to which they may be applied with the greatest benefit. The higher and more elevated grounds being, in general, more proper for sheep, while those of the lower and more inclosed kinds are mostly better suited for the purpose of neat cattle, or other animals under the fattening system. And besides, the age of the lay makes a difference in some cases; new laid-down pasture lands being commonly found more proper for the support of young store animals, while those that have been long in the state of sward, are in general better adapted to the feeding or fattening stock. It is also obvious, that the mode of inclosing has some effect in the same way; as when the inclosures are of a moderate size, they are found more suitable for the purposes of feeding, than where the contrary is the case.

It may be observed, that this sort of grass land, as well as that of the hay kind, is subject to be overrun and much injured in its produce, both by moss, coarse plants, and ant as well as mole-hills. These should therefore be constantly removed, or spread about as soon as possible, and prevented from obstructing the complete pasturage of the lands, in the manner that is recommended under these different heads.

It is suggested, that on the marsh grazing lands in Kent, where ant-hills frequently occur, they have a mode of extirpating them in an easy and expeditious way, and of bringing the surface level at the same time, which is by the use of an implement, eight or nine feet in breadth, which is armed with a sort of strong cutting blade. When in use it is drawn by a horse directed by a boy, and guided behind by a man, and is capable of often cutting off several of the hills at one stroke, and of course of clearing a number of acres in a very short space of time. There are various other implements in use for this sort of work, in different parts of the island, which answer the intention in a very perfect manner.

There can be no doubt that pastures, when not well attended to, must frequently be prevented from being properly fed by various kinds of shrubby plants, such as those of the alder, brier, broom, surze, and other sorts that spring or shoot out upon the surface, and which should always be extirpated as soon as possible, as by remaining upon and shading the ground, they render the herbage sour, coarse, and improper for the food of cattle. This sort of work may be performed by cutting them closely down, as

they rise in the early spring months, by a strong scythe; but a better practice is to dig them or plough them completely out, where it can be done, which should be the case while it is under the state of tillage, in order to its being laid down to the condition of sward.

And the shrubby, black, and other thorns and briars, that spring up from suckers on the sides of the hedge-rows of pasture grounds, should likewise be exterminated, especially where sheep are pastured, as they do great mischief by pulling and entangling their coats. Besides, much ground is often lost in this way, and the appearance of the hedges is disgusting. In many cases, after the plants are stocked up, the earth about them might be thrown into a compost with a small proportion of well-rotted dung, and spread upon the land with much benefit; and at the same time the land thus cleared be brought into a proper condition for being sown down with grass seeds.

Besides, where pasture lands are productive in grasses of the more sharp coarse-bladed kinds, which rise in tufts or tussocks, and such as are known to agricultors under the titles of pink or carnation grasses, and there are other sorts of aquatic plants presenting themselves, it is a certain indication that the soil is too retentive of moisture, and not only stands in need of draining, but also of being kept in a close state of feeding by different sorts of stock, so that every part of them may be kept quite pared down by the animals.

It has been well suggested, that the manuring of pasture lands is a business much less in practice than ought perhaps to be the case; as where the soil is not good, and they are kept in a constant state of feeding or pasturage, it would seem probable that their fertility must in some measure decline, if proper means be not taken to preserve and keep it up, even though they should be fed down with sheep, which is unquestionably, in this view, the most favourable sort of stock. It is indeed hardly to be supposed, that the small proportion of excrementitious matter that is dropped at random during the feeding of animals, especially the larger kinds, under an exposure to the dissipating and washing effects of the atmosphere, at different seasons, where no other sorts of food than that of the natural grasses of the pastures is consumed, can in such sorts of land be adequate to the restoration of the great degree of fertility that is constantly conveyed away in the time of pasturing. In the better kinds of pasture lands, where the produce of grass is considerable, improvement may, and undoubtedly does take place by feeding them, especially by sheep, as the discharges of the animals are not only more abundant, but a proportion of old grass is left to decay during the winter season, and in that way make an annual addition to their fertility. It appears probable to this writer, however it may differ from opinions that have been held on this subject by some cultivators, from much close attention to the management of grass lands of the less rich kinds in the state of pasture; that, in such cases, unless attention be paid to improve their condition by some other means than merely that of the manure dispersed over the land by the animals in simply consuming the herbage, they must in time become gradually deteriorated, and the quantity of pasturage be lessened so as to support smaller proportions of stock than was formerly the case. This supposition seems indeed, in some degree, supported by the condition of downs, and other uninclosed lands, that have been in a state of pasturage for a great length of time; as in these cases, if feeding had rendered them more fertile, they must long since have been enabled to carry a vastly increased proportion of stock; which is certainly not the case, as has been strongly re-

PASTURE-LAND.

marked long ago, by Dr. Anderfon in his useful *Essays on Rural Affairs*.

But that feeding down pasture lands, of these as well as other kinds, in a judicious manner, has the effect of rendering the herbage more fine, and better for the support of stock in general, there cannot be the smallest doubt; though it does not certainly follow that the fertility of the land, in such cases as have been just mentioned, is thereby really improved, as has been supposed by some employed in the business of grazing in particular situations and circumstances. Where the pastures, as has been just observed, are in such heart as to afford a large quantity of herbage for being converted into manure, and sufficient to permit a portion annually to revert to the state of vegetable mould by its undergoing the process of putrefaction, a considerable progressive improvement must, without doubt, be the case under the pasturing system, especially where sheep constitute the principal stock. And in most cases, the fining of the herbage by this practice must be advantageous. It seems, therefore, not improbable, but that the bettering of the condition of the herbage, by feeding the lands with sheep, may have occasionally led to the supposition, that the fertility of the grounds was thereby, in all cases, really improved. That an increase of fertility is produced, in most instances, by the pasturing of lands with sheep, is not disputed; it is only in particular circumstances that the contrary is contended to take place. And in all cases the injury that may be sustained in this way, must evidently be very small, when compared with that which takes place from repeated mowing without the application of suitable dressings to the lands.

The improvement of the fertility of pasture grounds may be effected in different ways, as either by the direct application of manure in its natural state, such as that of rotten dung, lime, marle, or in that of earthy compost, occasionally spread over their surfaces in a thin even manner; or indirectly by the folding or confining of sheep upon the land during the time they consume other sorts of green food, such as turnips, &c. The latter mode is unquestionably the most advantageous and convenient, as it is in but very few situations that the former can be practised without injury to the arable or hay lands. By proper attention in this way the more poor pasture grounds might soon, and at little expence, be brought into a good state of pasturage; which could seldom or ever be the case without some such means of increasing their productiveness.

The writer of the Report of Salop states, that upon upland meadows, the manure from the chaff at the barn-doors mixed with soil, ashes, and shovellings, is very properly applied. But that the farmer's pastures are more neglected than any other part of his land, as very little manure is ever put upon them; they consider it as more wanted elsewhere. All grass lands at a distance from towns are, in general, too much neglected. The barn-door muck and ashes, mixed with the shovellings of roads and cleanings of ditches and ponds, should be more frequently applied to such as cannot be watered. Ponds may be frequently made on the sides of roads and water-courses, to catch the fine soils that are washed down by the rains in winter: this should form part of a compost. It is added that, for the hay fields, which are shut up for a crop at Candlemas, or before; the best time of manuring them is immediately after the hay harvest. Some farmers do this work in winter, when the ground is sufficiently hardened by the severity of continued frost. For the purpose of manuring, the diligent husbandman provides a large compost mixen. With this view he cleanses his ponds, he scours his ditches, he shovels

his fold, he collects his ashes, he sends to the lime-kiln, he provides fern, weeds, stubble, &c.; in a word, he amasses all materials that will increase the bulk, and promote the fermentation, of a general dunghill. Melioration of soil is best obtained by an unremitted attention to this business of manuring. Hereby the quantity of grass is greatly increased, and the quality of it much improved. Two tons of hay *per acre* is produced instead of one, and trefoil and white clover flourish and abound instead of moss and rushes. And for the improvement of pasture as well as meadow-lands, it is advised to suffer no weeds to seed, nor mole or ant-hills to continue; the land to be either mowed or grazed bare once in every year. Such as is mowed should be manured in the autumn of every second year with dung or compost, consisting of dung and earth or mud, at the rate of about ten cubic yards to the acre. Close attention should be paid to examining the streams of water, by the assistance of the spirit level, for generally the water from the summits will be found to cover much more land than is expected; and where it takes its course through several properties, it may be agreed to be used to the mutual benefit of the owners, by stipulating the times for each to use it, in due proportion to the quantity they respectively have suitable to that purpose. He knows of no improvement upon grass land (after being drained when necessary) greater than this, though but little attended to in comparison of the large tracts that may be improved. See *AFTER-GRASS* and *MEADOW*.

PASTURE Lands, Stocking of, the art of eating them down with the greatest economy and advantage by one or more sorts of live stock. This is a point of management in grass husbandry that has hitherto been but little attended to by farmers in general. It is obvious, however, that a great deal must depend upon its being judiciously performed, both in respect to the improvement of the stock, and the lasting of the grass, as, under some circumstances, much more waste will be incurred than under others. A practical writer has observed, that the most proper period for turning the stock into the pastures in the spring season has been a matter of dispute among those employed in the management of grass lands; some contending, that it should be done early, before the natural grass has risen to too great a bite, while others maintain the contrary opinion. And that there are probably inconveniences attending each of these extremes, as in the first the stock, especially when of the fattening kind, may sustain injury from the want of a sufficient bite to permit the animals to fill themselves in an expeditious manner; and in the latter, there may not only be much waste by the stock not being capable of keeping it under, but great loss and inconvenience from its running up in tufts to feed, and by that means rendering the pasture patchy and unevenly fed down, by which the extent of real pasturage is lessened. That it has been also observed by Mr. Marshall, in his *Rural Economy of Yorkshire*, that by turning the stock upon the pastures when there is a full bite, the better sorts of grasses are only consumed, the more coarse herbage being rejected and let run to seed, by which the lands are greatly injured at the time as well as in future; while, on the contrary, if the stock be allowed to enter during the time such coarse plants are in their more tender early growth, and before the pasture is covered with better herbage, the whole of the other plants will be fed down in a regular manner with the grass. And that the want of a full bite on the first turning out of the store stock is of advantage to the animals, as they become more gradually accustomed to the change from dry food to succulent herbage. And it is supposed that fattening stock only

PASTURE-LAND.

only require a full bite on being at first put upon the pasture. The first of these writers further states, that in answer to the objection that has been made, that early turning upon pastures exposes them more to the effects of drought in the spring months, it is said, that it is in a great measure ill founded, since cattle milk and thrive well in such cases. It is not, Mr. Marshall remarks, the length of grass, but the quantity of nourishment which it contains, that makes cattle pay for their pasturage. And it is not supposed improbable, but that the richness of the herbage may in some degree depend on the sun or heat of the season. Facts and observations are however here much wanted, as little, till within these few years, has been attempted in respect to the most advantageous system of feeding down pastures. The former of the writers, whom we have just mentioned, has observed, that as the state of the grass, which is the most favourable to the feeding of the stock, and their expeditious filling themselves and taking their rest, as well as that of their wanting the least possible proportion of the food, would seem to be that of a middle degree of growth; it is not improbable, but that that may be the most proper and advantageous period for breaking the pastures; the exact time of which must obviously be regulated by the nature of the soil, the situation of the land, and the state of the season, as well as the circumstances of the farmer; but that from the end of March to the latter end of April, or beginning of the following month, according to the forwardness of the season, may be the most advantageous in the southern districts, while in those of the north it may be deferred a week longer or more with propriety and advantage in many cases.

In regard to the general eating down of pasture lands, there is much difference of opinion, some advising that it should be done in as close a manner as possible, others, that this should never be the case. It would seem, however, that the closeness or degree of feeding that is the most proper should be directed by the nature of the grass and the time at which it is performed, as where the herbage is of the coarser kind and consumed in the autumnal season, it may be done much more closely than in the contrary circumstances, as such sorts of grass must always be improved by such close feeding, and no injury can be sustained at such seasons from the roots of the grasses being left so much exposed, which would be the case in the latter spring or early summer months, from the constantly increasing heat at such periods. The advice, that has been given by an intelligent observer on this subject, may in general be adopted with propriety, which is, to be cautious not to overstock, as by that means great loss may be sustained, as land when fed too bare is apt to burn in the summer and to be chilled in the winter. Besides, the necks of the roots are so injured by very close biting, that they do not afford so quick or free a spring or growth to the succession of blade as there would otherwise be. But, on the other hand, it is not recommended to leave a long bite of grass on the land: a middle degree will suit all lands the best, and afford the most benefit to the persons who occupy them. This advice of Mr. Kent's deserves to be well attended to, as being founded in real practice.

It has been further stated, that by the too thin stocking of pastures, though loss may be sustained in their not supporting the proper number of animals, as well as from the injury which is done by the grass plants running so much up to stems, the broken grass, in such cases, can be mown when in sufficient proportion for hay; but the disadvantages of over-stocking are scarcely capable of being repaired, according to Mr. Marshall, as besides the lands being often ex-

posed to much injury by the crowns of the plants being so closely pared down, especially in the finer kinds of grass, the cattle, from suffering a check in their feeding, are long in regaining their former thriving disposition; that, of course, almost the whole of the produce of pasture lands may, in this way, be often thrown away, and that it is an error that young farmers are extremely liable to fall into. It is therefore obvious that the medium degree of stocking, which has been advised above, is, in general, to be carefully adopted from the experience obtained upon the land; in the procuring of which it is best to begin by an under proportion of stock, that the effect may be the better perceived.

Among graziers there has been a considerable difference of opinion in respect to the manner of stocking, or feeding down such lands; some contending that it should be done with only one sort of stock, while others suppose that they should be mixed, in order to produce the best effects both on the lands and stock; Mr. Kent has supposed that the more various the kinds of cattle are that are fed upon the pastures at different times, the better. But it has not been shewn, the author of *Practical Agriculture* says, on what principle this advantage depends. If the different modes of feeding in the different animals be attended to, and minutely examined, it will be found that though some sorts may consume grass when in a more luxuriant state of growth than others, they are all fondest of pasturing on that which is the most sweet and tender. This is rendered extremely obvious by the observations of an attentive inquirer, who has found, that although horses appear partial to particular patches of sward, he has never been able to discover any peculiarity in the soil or the herbage of such barely eaten spots. It has been supposed that they have been fed down by such animals at first in so close a manner merely by accident, but that afterwards they are kept in such a close state of feeding from their peculiar sweetness depending on the peculiar shortness of the herbage. It would, however, seem more probable, from the circumstance of the animals being almost wholly directed by the taste in the choice of their food, that the sweet or tender nature of the herbage in these parts first induces them to feed upon and consume them in so close a manner, as well as the continuing the close eating them down afterwards. The same thing is observed to happen in the vicinity of preserved covers, with hares and rabbits, from their keeping spots of barley or other grain crops closely fed down. And sheep are well known to ramble over the whole of the pastures in order to nibble and pick out the most sweet and delicate morsels. The feeding of neat cattle is, perhaps, less particular and delicate in this respect; but where not forced by hunger they mostly appear to fix upon such parts of the land as possess the most sweet and palatable herbage, rejecting the coarser spots where it is less tender and agreeable. It is contended that, if the conclusion be therefore well founded, that stock of all sorts prefer the best, sweetest, and most tender herbage, it is evident that no mixture of animals can insure the even and regular feeding down of pastures, as they will, in some degree, be all attracted by the sweetest and most tender parts, and those of the more coarse four kinds be in consequence almost wholly rejected. An agricultor of great experience and nice observation, the Rev. Mr. Clove, has remarked, that in pastures, stock naturally pick the most palatable grasses first, leaving the others to run up to bents; and though it is admitted that one sort may have a preference for one species of grass, and another for another, there is no mixing the animals in such a manner as to prevent this circumstance from taking place. It is wholly impracticable to proportion each kind of stock in such a way to the species of grass that may be most agree-

able

PASTURE-LAND.

able to it, as to prevent the scarcity of one sort and the abundance of the other. It is of course obvious, that there are therefore not only difficulties in the regular feeding down of pastures, from the cattle being more fond of some sorts of herbage than others, but also from the inability of the grazier to proportion them in a way that may fully answer the purpose which he has in view. These observations, at the same time that they shew the difficulty of the business, convince us of the advantage and importance of keeping pasture lands regularly and evenly fed down, which is perhaps only to be fully effected by one sort of flock properly succeeding another, till the want of the finer sorts of herbage obliges them to feed upon those that are of a more coarse nature. In this, as well as other views, the fattening flock should be first turned into the lands, and kept upon them so long as they continue to improve in a proper manner; they may then be succeeded by the older sorts of cattle that require to be brought into condition, and the more young store flock may consume the remainder of the grass, according to the intentions of the farmer. That great utility and advantage may be derived from often shifting the cattle, by having recourse to a *head* flock and proper *followers*, there can be little doubt. The few writers that have touched upon the subject of grass husbandry, have, in general, indeed, recommended the practice as highly beneficial both in respect to the pasture and the flock. And Mr. Marshall, in his *Rural Economy of Yorkshire*, speaks of this being a defect in the grass land management of that district. The correct grass farmer should, therefore, be more attentive to this part of his management than is commonly the case, taking care that the changes of his stock are made in a seasonable and judicious manner, and without either the stock or the land suffering any injury from it.

It is suggested that this is probably a practice from which greater utility may be derived than that of permitting many different sorts of stock upon the ground at the same time, as, besides their not answering the intention of feeding the pastures down with more regularity and evenness, they are inconvenient and disadvantageous in other respects. For when the pastures are fed down with a mixed stock, the animal's seldom thrive or fatten so well as where the contrary is the case. They are too much driven about and disturbed by the different kinds teasing each other, especially where horses and neat cattle are put together. A mixed flock is also improper in another point of view; many sorts of animals feed closer and more expeditiously than others; of course, when there happens to be any scarcity of feed, some of the kinds may be greatly injured from the want of proper support. The horse, like the sheep, feeds close and quick, while the contrary is the case with the cow; it would of course seem improper to mix horses with neat cattle in the pasturing of grass lands, though the practice has been prevalent in many places. It has indeed been observed, that sheep and horses may feed and thrive best together, both from the similarity of their manner of eating and that of the former consuming the rich luxuriant herbage which springs in consequence of the manure dropped in the season, while the latter prefer the less vigorous, but the more clean grass. It is a practice, however, that has sometimes been found useful to mix sheep with neat cattle. The notion of deriving advantages from the mixing of stock, from the circumstances of some sorts having a greater dislike to feed near their own dung, and less towards that of others, is probably not founded on just observation, as animals have a fixed aversion to both their own and that of other animals, and none of them will feed near either till compelled by the scarcity of food. This aversion does not perhaps depend wholly on

the dung, but it is in some measure avoided in consequence of the grass becoming rank and coarse about such places, and of course more sour and unpalatable to the animals.

But very little attention has, till lately, been bestowed upon the manner or state of feeding down grass lands, the business being mostly left to chance, accident, or the caprice of the farmer. It is, however, obviously a matter of vast importance, not only in so far as it respects the economy of the pastures, but the success and proper progress of the flock that consume it; as by improper management that proportion may be wastefully eaten down in a short space of time without the stock being brought more forward, that under a better system would last out a longer time with a greater increase or progress in the animals that feed upon it. And that, as it is a matter of consequence to keep pastures and grazing-grounds as even as possible, a proportion of stock fitted to produce this purpose should always be put upon the lands. On the rich and more fertile kinds where the grass springs quick and in great abundance, more stock will be necessary to effect this purpose than where the contrary is the case. It has been found, on the marsh lands in Lincolnshire, that where the most grass is left in the autumn the herbage is the coarsest and the worst in the succeeding year. In the extensive feeding tract of Romney Marsh, the close feeding system is also found to answer in the most perfect manner. These facts shew the necessity of hard stocking on the richer descriptions of land. In other parts of the first of the above districts, on turning upon a full bite in the spring, they flock in such a manner as to prevent the grass from becoming coarse by running up to stem. The necessity of sweeping over the rough tufty parts by the scythe is thus avoided, except in very wet seasons. And it is a practical remark of a cautious observer, on describing a field not sufficiently stocked, that on the marsh just mentioned, the grazing farmers would be ruined if they suffered so much grass on their lands. It seems to be a bad practice to allow the grass in pastures to advance to such a state as to require to be swept over by the scythe, though it may be right to do it under such circumstances, in order to prevent the greater injury that might otherwise be produced. It appears extremely probable, indeed, that by permitting the grass plants to run up to seed-stems, the pastures may sustain vast injury, not only by the exhaustion of the soil that takes place during the efforts of the plants to form and fill the seeds, but in consequence of their whole vegetative powers being directed to that purpose, from their sending forth few or no leaves. This is extremely evident in all the coarser sorts of grass plants, and fully explains the utility of keeping them closely fed down, as by such means a more abundant grassy herbage is provided for the support of stock. There are various observations that seem to support this opinion. Thus it has been recommended to stock pasture lands in such a manner as will keep the grass in a young succulent state; as in this way there is a benefit, by the whole of the produce being consumed, and at the same time the stems of the grass plants are prevented from seeding, which exhausts the roots and the lands; the soil is of course preserved in a better state of fertility, more shoots are thrown out, the sward is rendered more close, and a more constant verdure kept up.

Therefore the true principle of grazing, in the opinion of this writer, is to eat *all*, and particularly at those seasons when vegetation is rapid, that it may not weaken the turf and soil, but by keeping the grass in a young state, have the shoots more vigorous.

And it is practically remarked, that, as for the purpose of feeding the larger sorts of neat cattle, it is necessary for the

PASTURE-LAND.

the grafs to have grown to a pretty full bite before they are turned in, and of courfe numerous feed-ftems to be formed; it feems not improbable, but that the fuperior benefit of feeding with fheep may depend upon the circumftance of their eating more clofely, and thereby preventing fuch effects from taking place. That of courfe, in the ftocking of paf-ture grounds, the growth of the grafs fould be particularly attended to, and the proportion of flock adapted to it; care being always taken to have a full proportion during the fummer months, from May to Auguft; a proper referve being then made for the winter feafon; as Mr. Price has well fuggel- led, in this bufinefs, that the farmer fould be as careful as poffible to neither over or under-ftock, as by either means he muft fuftain lofs and inconvenience, in the different refpects that have been already noticed.

But on this interefting point of management there is another matter, upon which farmers have differed very con- fiderably in their opinions; each contending, as in many other cafes, for the propriety of their praftice, on the ground of experience. It is that of giving the flock, of whatever fort it may be, the whole range of the lands, how- ever extenfive, at once; or having them divided, fo as to let it have the grafs at different times, in a frefh, unbroken, and untrampled ftate. This is a queftion, which, from its involved nature, and from few experiments having been made directly in refpect to it, that is not readily decided; yet much in the economy of feeding down grafs land depends upon it. The obfervations of Mr. Young may perhaps throw fome light upon it. When cattle, whether cows, fattening beafts, or young flock, are turned out to grafs, it is requifite to confider the beft method of feeding. There are two opinions on this point directly contrary to each other. Firft, it is affirmed by one fet of graziers, that, let the grafs to be fed confift of ever fo many acres, the cattle fould have it all at once: if it is divided into eight or ten fields, the gates of all to be fet open, for the flock to feed where they like. Secondly, thofe of the other fet advance, that large fields of fifty, eighty, or an hundred acres, fould be divided, that the farmer may change his flock from one to the other, and give the grafs frefh and frefh. And each of thefe parties affert, that they know themfelves to be right from experience. But that is impoffible: one muft undoubtedly be wrong. Let us confider the point from reafon: it is one that will never be decided fairly from experiment; for two pieces of grafs, each of eighty or an hundred acres, contiguous and perfectly alike, are not to be met with in the king's do- minions; and, if they were, two fets of flock, exactly fimilar, would not be found. The divifions into fields by hedges and ditches, for the purpofes of draining and fhelter, is not the inquiry, the comparifon not being fair; as fuch divifions may be fed at once, by fetting all the gates open, as well as one field. The inquiry is, whether the cattle will fpoil the grafs more in one way than in the other? and whether the grafs will go as far in one as in the other, by fattening and feeding the beafts as well? The argument of giving the grafs frefh and frefh appears to be rather vague; for it fup- pofes that the cattle will not eat it frefh, if they have the whole range at once, which may be a miftake: they will not be feen in the evening where they were feeding in the morning, but vary their food in the manner moft agreeable to themfelves; and we may in general obferve, that the fa- gacious animals, when left to their own conduct, manage fuch points better than we can for them. As to the tread- ing and fpoilage, it is an equal objection to both methods; the legs of the beafts are not tied in fmall clofes, any more than in large ones. In cafe all the fmall pieces have not

water, the objections to feeding them feparate are much greater.

On the other hand, it muft be admitted that there are dif- advantages attending this way of pafuring: for a time the trampling may be greater, as cattle are difpofed to beat a fort of march around the fields, on firft turning in, and alfo on fome kinds of difturbance. But the greater evil is that of difturbance a large herd, inftead of a fmall one: this a dog may effect in one inclofure, unfeen from others, and con- fequently the flock in them left without interruption; and, perhaps, a motive greater than this is, its having been ob- ferved that cattle, and fheep alfo, do better when well pro- portioned to their pafure, when divided into fmall lots rather than large ones.

Mr. Young here leaves the matter without any decifion. There are, however, a variety of circumftances that would feem to fhew the mode of feeding in divifions to have the fuperiority over that of turning upon the whole at a time. There can be no doubt but that much greater wafte of grafs is made in turning upon the whole at once, efpecially if the full proportion of animals for the land be put in; as it muft be well known to the praftical farmer, that when grafs has been once trampled upon, flock of all forts reject or eat it with great reluctance. And in cow farming, where vaft numbers are often turned upon the land at one time, in order to procure the greateft poffible abundance of milk for a fhort period, as is frequently the cafe near London, and other large towns, no one can have avoided obferving the uncom- mon lofs and deftruction of food that is the confequence. The writer has attended to many circumftances of this na- ture, in which he is convinced that the fame proportion of flock might have been equally well kept for one-fourth of the time longer, by having the grafs confumed by the fame flock in fuitable divifions.

It is ftated by a writer in the third volume of the Farmer's Magazine, that in the management of pafurage, he would carry on a fucceffive flock, and a feries of pafure fields, fo as to give three fifts. Thus, the fattening flock is to get the top of the pafure firft broken upon. Before the pafure is eaten too bare, this flock is to be removed into a fecond field of frefh grafs, and is to be followed on the firft field by the keeping flock. Before the fecond field is too bare, the fatteners are to be removed into the third, and the keepers into the fecond. While thefe two flocks are employed in this fift, in eating the fecond and third fields, the firft field has time to get again into full herbage. It is certainly, he thinks, needlefs to enlarge on this courfe, as the principles and praftice are both fufficiently obvious.

And in a late praftical work it is noticed, that the ex- perience of a writer, who has examined grafs hufbandry with much minutenefs and attention in different diftricts, would feem alfo, in fome meafure, to favour the fame conclufion, while it fhews the benefit of one fort of flock following another; as he advifes that, in all cafes where fattening cattle or dairy cows conftitute a part of the flock, and where foil, fituation, and water will admit, every range of grazing lands fould have three divifions; one for the head flock, as the cows and fattening animals; another for followers, fuch as the rearing or other lean flock; and a third for being preferved in order to frefhen, for the reception of the prin- cipal flock. Befides, he is decidedly of opinion, that whether the ground may confift of one, two, or a greater number of divifions, not a weed fould be fuffered to feed, or a tuft of ftale grafs to ftand on it; but once, at leaft, in the fummer feafon, be levelled down by the fcythe; as, by fuch means, weeds may be converted into nourifhment, and

PASTURE-LAND.

waste into after-grafs. But it has been seen above, that by proper stocking, there need not be any necessity for the operation of the scythe; as the practice of close feeding renders it unnecessary, and at the same time affords a superior advantage to the grazier.

The proportions of stock of different sorts, that can be properly supported on any given space of pasture ground, must vary considerably, according to the natural goodness of the soil, the properties of the grafs, and the differences in the sizes of the animals. And there is likewise another circumstance which should be attended to, which is the length of time the land has been in the state of sward; as new lays are seldom capable of carrying so much stock on the acre as those of the older kinds. But it is also a point that ought to be attended to, that those lays should be stocked as much as possible with sheep.

Mr. Young advises, that, in the stocking of grafs lands, the farmer should attend well to the proportion between his stock and the quantity of his feed. Let him remember, when he stocks his grounds, that he should be pretty nice in this proportion: for if he overstocks, his loss will be certain and great; and if he does not throw in as many cattle as he ought, then he will suffer in his profit.

The exact number of animals, whether of the cattle or other kinds, that may be grazed on the acre, is not easily ascertained, so as to avoid leading the farmer into error, as it will differ so greatly in different situations and circumstances. Besides, it is unnecessary, as the proportion of different sorts of stock that may be admitted upon grazing lands, in different districts, has been shewn, in speaking of the manner of feeding or fattening animals at grafs, in considering the practice of grazing. See *GRAZING*.

Lands employed for the purpose of pasture are frequently occupied by stock during the autumn and winter, as well as the spring and summer months: it is, however, only those of the very dry kinds that can be turned upon in the winter season, especially by heavy cattle; and it is probably, in all cases, a much better practice to confine that sort of stock wholly to the fold-yards at such seasons, as by suffering them to be turned upon the pastures, there must be a great loss in the waste of manure. And it has been found an advantageous practice by some, to shut up their pastures late in the autumn, according to the state of the grafs, and other circumstances; eating them down as close and evenly as possible, previous to the stock being removed; and keeping them perfectly free, till they are wanted for ewes and lambs in the early part of the year, or for cattle at a later period, as when the first shoots appear in the spring, which, from being intermixed with those of the autumn, are supposed to afford more nourishment for the support of the stock, than when either of them are eaten separately.

In the Agricultural Report of Perthshire, it is advised that, in fields that are pastured by cattle, care should be taken that all such plants as are hurtful to stock be completely eradicated from them; as much injury is often done by them to the cattle, as well as the products which they afford. The plants most prejudicial in this way are those of the hemlock, henbane, nightshade, and yew kinds. It has been suggested, that while the grafs is plentiful, there is not much danger of their feeding upon such plants; but when it becomes scarce, and they are confined, it is likely to take place, especially in the spring season, when they are fond of devouring young shoots of almost any kind. And a writer in the Farmer's Magazine strongly advises the following practice, which he has uniformly followed himself, and is thoroughly sensible of its beneficial effects: it is re-

gularly to cut down all weeds, that spring up in the fields, in spite of the stock, before they get into seed. This is by no means expensive, as two or three children are sufficient to keep down the weeds of a large pasture farm. And it is an old and true proverb in husbandry, that "once feeding causes seven years' weeding."

It is indispensably necessary to attend to the circumstance of pastures being well supplied with water, as, without having this in some degree at command, it is impossible that the stock can thrive well, or answer in the most perfect manner in other views. Where they are not, therefore, supplied by brooks or streams running through them, it will be necessary to have recourse to the forming of ponds or pools for the purpose in the fields. And in situations where the natural stratum of the clay is of considerable thickness, there is little difficulty in the constructing of such watering ponds, so as to be perfectly retentive or water-tight; but in loose porous soils, the business is not executed without considerable care and attention, as well as much art. See *WATERING Ponds*.

It is advised, in the Treatise on Landed Property, that in laying out perennial pasture lands, as those of grazing and cow grounds, attention should be particularly paid to the circumstance of water; and that wherever good water is naturally found, or can be brought conveniently by art, to that point the pasture grounds ought to tend, in order that they may have a due supply of so necessary an article to the pasturing of them with cattle.

The first improvement of upland pasture, before eating it down with stock, when not inclosed, is by fencing it in, and dividing it into small fields of four, five, six, eight, or ten acres each; planting timber trees in the hedge-rows, which will screen the grafs from the dry pinching winds in March, which prevent it from growing in large, open, exposed lands; so that, if April proves a dry month, the land produces very little grafs: whereas, in the sheltered fields, the grafs begins to grow early in March, covers the ground, and prevents the sun from parching the roots, whereby it keeps growing, so as to afford a tolerable bite, if the spring should prove dry. But, in fencing in the land, it must be observed not to make the inclosures too small, especially where the hedge-rows are planted with trees; because, when the trees are advanced to a considerable height, they spread over the land, and, where they are close, render the grafs sour, and in that way, instead of being of advantage, greatly injure the pasture. A second improvement of upland pasture is that of making the turf or sward good, where, either from the badness of the soil, or for want of proper care, the grafs has been destroyed by rushes, bushes, or mole-hills. Where the surface of the land is rough, clayey, and cold, it may be best improved by paring it off, and burning it in the manner directed under that head, breaking it up, and then laying it down again to sward; but if it is hot sandy land, then chalk, lime, marl, or clay, are very proper manures to apply upon it: but this should be laid in pretty good quantities, otherwise it will be of little service to the land. Where the ground is over-run with coarse plants, as rushes, &c. it will be a great advantage to it, to cut or grub them up towards the latter part of summer; and, after they are dried, to burn them, and spread the ashes over the ground just before the autumnal rains; at which time the surface of the land should be levelled, and sown with grafs-seeds, which will come up in a short time, and make good grafs the following spring. So also, when the land is full of ant-hills, these should be pared off as above, and either burnt for the ashes, or spread immediately on the ground, when

when they are pared off, observing to sow the bare patches with grafs-seeds in the autumn. See *ANT-Hill*.

And where the land has been thus managed, it will be of great service to roll the turf, in the months of February and March, with an heavy wooden roller, in moist weather, that the roll may make an impression; this will render the surface level, and cause the turf to thicken, so as to have what the people usually term a good bottom. The grafs will likewise be sweeter, and bad weeds be destroyed.

Another improvement of these pastures is, by judicious feeding as above. Where this is not practised, the land must be manured at least every third year: but where a farmer has much arable land in his possession, he will not care to part with his manure to the pasture. Therefore every farmer should endeavour to proportion his pasture to his arable land, especially where manure is scarce, otherwise he will soon find his error; as the pasture is the foundation of all the profit which may arise from the arable land.

But whenever such upland pastures are to be mended by manure, there should be a regard had to the nature of the soil, and a proper sort of manure applied; as for instance, all hot sandy lands should have a cold manure; neat's dung, swine's dung, and earthy composts are very proper for such lands; but for cold lands, horse-dung, ashes, and other warm manures are more proper. And when these are applied, it should be done in autumn, before the rains have soaked the ground, and rendered it too soft to cart on; and it should be carefully spread, breaking all the clods as small as possible, and then harrowed with bushes, to let it down to the roots of the grafs. When the manure is laid on at this season, the rains in winter will wash down the valuable parts, so that the following spring the grafs will receive the advantage of it. And there should also be great care had to the destroying of weeds and coarse plants in pastures every spring and autumn as above; for where this is not practised, they ripen their seeds, which spread over the ground, and fill it so as soon to overpower the grafs, and destroy it. Besides, it is very difficult to root them out, after they have gotten such possession. But in these pastures, the grafs seldom degenerates if the land is tolerably good; whereas in the low pastures, which are overflowed in winter, in a few years it often turns to a harsh rushy nature.

Perhaps there is no part of husbandry, which, till of late, farmers were, in general, more ignorant of, than that of the management of pastures; most of them supposed, that when old pastures were ploughed up, they could never be brought to have a good sward again; of course their common method of managing their land, after ploughing, was to sow, with their crops of barley, some grafs-seeds, as they call them; that is, either red clover, which they intended to stand two years after the corn was taken off the ground, or rye-grafs mixed with trefoil; but as most of these are but biennial plants, whose roots decay soon after their seeds are perfected; so the ground, having no crop upon it, was again ploughed for corn; and this was the constant round which the lands were employed in by most farmers: they had not any notion of laying down their lands to grafs for any longer continuance. Modern husbandry has, however, shewn that it is possible to lay down land, which has been in tillage, with grafs, in such a manner, as that the sward shall be as good, if not better than any natural grafs, and of as long duration. See *LAYING down to Grafs*.

In the improvement of wet pastures, it has been suggested that, the first thing to be done is, to make large deep ditches round every field, and if the fields are large, to divide them into smaller, of five, six, or seven acres each, by new ditches; nothing is attended with a more sudden improve-

ment of all the ground near the borders of the fields than good ditches. They are generally made six feet deep perpendicularly, seven wide at top, and three at bottom. They should be made in such a manner that no water can remain in them, but have a descent from one to another to carry it quickly off. As soon as the ditching is done, the next work is to land-drain the whole fields in such a manner that every part of them may be laid dry. If there is the least fall in any part, or any place more wet than another, the drains should be cut through them. If the surface be exactly level, the depth of the drains should vary, so that the water may every where have a descent. These drains are made, in general, thirty-two inches deep, twenty inches wide at the top, and four wide at the bottom. They are filled eight inches deep with either stones or wood; but the former are the most effectual and lasting to those who are not desirous of saving the difference of expence. However, wood answers extremely well in many cases. See *DRAINING of Land*, and *WATER, Removing of, from Land*.

The prodigious advantage of these drains appears the very first year, especially if the season proves wet; the grafs being fresh, vigorous, and sweet. And the materials taken out of the ditches should, after being well mixed with dung, or some other manure, be spread evenly over the surface of the ground. The expence of this sort of improvement will vary greatly according to the nature of the land, the situation, and other circumstances.

PASTUS, the procuration of provision, which the king's or lord's tenants are bound to make for them at certain days or seasons, or as often as they make a progress to their lands.

This, in many places, has been converted into a pecuniary fee; as in the procurations of the clergy.

PASTY, in *Cookery*, a work of pastry; being a preparation of some proper meat, as beef, venison, lamb, or the like, well boned, beaten up to a pulp, and highly seasoned; put up in a paste, and then baked in an oven. They also make veal patties, umbel patties, kidney patties, marrow patties, &c.

PASZBERG, or PAS, in *Geography*, a town of Istria; 25 miles S.S.E. of Trieste.

PATA, a town on the N. coast of the island of Luçon. N. lat. $18^{\circ} 15'$. E. long. $121^{\circ} 20'$.—Also, a small island in the Sooloo Archipelago. N. lat. $5^{\circ} 45'$. E. long. $121^{\circ} 10'$.

PATA, in *Ornithology*, the name by which the Portuguese in Brasil call a large and very beautiful American duck, known among others by its Brasilian name, *ipccatiapoa*.

PATABEA, in *Botany*, a plant described and figured by Aublet, the derivation of whose name we are unable to trace. Jussieu considers the genus as allied to *Lonicera bubalina* of Linnæus. Aubl. Guian. v. 1. 110. t. 43. Juss. 208. Lamarck Dict. v. 5. 52. Illustr. t. 65.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, with four, acute, little teeth. Cor. of one petal; tube oblong, inserted into the disk above the germen; limb cloven into four, oblong, acute lobes. Stam. Filaments four, short, inserted into the tube at its throat; anthers oblong, two-celled. Pist. Germen inferior, firmly united to the bottom of the calyx, crowned by the disk; style oblong, cloven; stigmas two, obtuse. Peric. and seeds unknown.

Ess. Ch. Calyx four-toothed. Flowers in little heads, which are scaly on the outside. Corolla tubular, four-cleft. Anthers nearly sessile.

1. *P. coccinea*. Aubl. Guian. t. 43.—Native of woods and forests in Guiana, particularly at Orapu, where it flowers

in the month of June. The *stem* of this shrub is four or five feet in height, furnished with numerous *branches* even to its summit, scattered in all directions; the smaller ones knobbed and opposite. *Leaves* opposite, stalked, oval, smooth, pointed, paler beneath. *Stipules* two, oblong, acute, at the base of each footstalk. *Flowers* red, in a terminal head, separated from each other by little scales.

PATACA, in *Commerce*, coins of Brasil, of 600 and 640 rees' value, which are current only in that country, and whose intrinsic value is 10 *per cent.* less than that of the Portuguese coins. The Spanish patacas, or dollars, are reckoned in Lisbon at 830 rees, more or less. The assay of the old pataca of Brasil, of 640 rees, is worse than the English standard, being 2 dwt.; its weight is 12 dwt. $4\frac{3}{4}$ gr.; its content in pure silver grains is 268.3; and its sterling value 3*s.* 1 $\frac{1}{2}$ *d.* The pataca of 600 rees (1755) is 4 dwt. worse than the English standard; its weight 11 dwt. $7\frac{1}{2}$ gr.; its content in pure silver grains 246.4; and its sterling value 2*s.* 10 $\frac{1}{2}$ *d.* The assay of the pataca of 640 rees (1768) is $4\frac{1}{2}$ dwt. worse than the English standard; its weight 11 dwt. $9\frac{3}{4}$ gr.; its contents in pure silver grains 247.8; and its sterling value 2*s.* 10 $\frac{3}{4}$ *d.* The assay of the pataca of 640 rees (1801) is 7 dwt. worse than the English standard; its weight 12 dwt. $4\frac{3}{4}$ gr.; its content 262.2; and its sterling value 3*s.* 0 $\frac{1}{2}$ *d.* the half, quarter, &c. pieces are in proportion. The impression on the pataca is the arms of Portugal, with 640 on the side, and the date near the top; legend, the name and title of the reigning sovereign, with the addition of BRAS D. *Brasilie dominus* or *domine*, lord or lady of Brasil; reverse, an armillary sphere, placed on a cross; legend, SUBQ. SIGN. NATA STAB.; *i. e.* SUBQUE SIGNO NATA STABIL; born under a steady sign. There is a pataca of 600 rees bearing the letter J, with a crown over it, 600 on the side, and the date at the bottom; reverse, an armillary sphere, with an R in the centre.

PATACA is also the name given to the German dollars in Egypt; which formerly passed for 85 medini, but have been raised to 90 medini. In making bargains, however, where patacas are to be received in payment, it is necessary previously to settle the value of the coin.

Contracts also at Grand Cairo are made in funducli and Mahhub sequins. The funducli are reckoned at 146 medini; and three Mahbubs are equal to four patacas, so that the Mahhub is worth 120 medini.

PATACA Chica and **PATACA Gourda**, two monies of account at Algiers, the former being eight temins or 232 aspers. The pataca chica is worth 11 $\frac{1}{2}$ *d.* sterling: the pataca gourda, or piaſtre, contains three patacas chicas, a Sultanin passes for 8 $\frac{1}{2}$ patacas chicas, more or less, a sequin for 10, and a Portuguese dobraon, or Joaneſe, of 6400 rees, for 36. A Spanish dollar is worth from 4 $\frac{3}{4}$ to 4 $\frac{7}{8}$ patacas chicas.

PATAK, in *Geography*, a town of Hindooſtan, in Palnaud; 20 miles W. of Timerycotta.

PATACON, or **PATAGON**, in *Commerce*, a silver coin in Switzerland, and also at Liege in Germany. The patacon of Bern consists of 3 livres 6 sous, or 33 batzes; the livre, according to the Tariff of 1755, being equal to 1*s.* 2 $\frac{1}{2}$ *d.* sterling.

The patagon, or ecu, of Geneva, which is sometimes used in accounts, is a real coin, worth 3 livres, or 10 $\frac{1}{2}$ florins.

The patagon, or crown of Bern (and the half in proportion) appears by the assay to be 7 dwt. worse than the English standard; 18 dwt. 22 gr. in weight; its content in pure silver 411.5; and in value 4*s.* 9 $\frac{1}{2}$ *d.* sterling. The old patagon, or ecu, of Brasil, is 14 dwt. worse than the English standard; 18 dwt. 4 gr. in weight; in content of pure silver 377.9;

and in value 4*s.* 4 $\frac{1}{2}$ *d.* sterling. The patagon, or ecu, of 1795 (the double and half patagons, and six-dollars in proportion) is 1 oz. 0 $\frac{1}{2}$ dwt. worse than the English standard; in weight 16 dwt. 14 gr.; in content of pure silver 329.3; and in value 3*s.* 10*d.* sterling. The patagon of Geneva is 1 oz. worse than the English standard; in weight 17 dwt. 9 gr.; in content of pure silver 351; and in value 4*s.* 1*d.* sterling.

The patacon of account at Liege is 4 florins, 8 escalins or schillings, or 80 stivers. The patacon is also a silver coin of 4 $\frac{1}{2}$ current florins, or 8 $\frac{1}{2}$ escalins. The patacon weighs 429 $\frac{1}{2}$ English grains, and is 20 oz. 8 $\frac{1}{2}$ dwt. fine; it is therefore worth 4*s.* 4*d.* sterling; but the patacon of account is worth only 4*s.* 2 $\frac{1}{2}$ *d.*; the escalin weighs 75 $\frac{1}{2}$ English grains, and is 7 oz. 5 dwt. fine. A deterioration of the coins took place about the year 1792, as the patacon then coined is found to weigh only 423 grains, and to be 10 oz. 5 dwt. fine, which reduces its value to 4*s.* 3*d.*: since that period there has been no coinage at Liege, the city and its territory having been shortly after united to France, and the new French monies and coins introduced there.

The old patagon of Liege is 14 dwt.; worse than English standard; in weight 17 dwt. 20 $\frac{3}{4}$ gr.; and in value 4*s.* 4*d.* sterling. The patagon of 1792 is 17 dwt.; worse than the English standard; in weight 17 dwt. 15 gr.; in content of pure silver 362.3; and in value 4*s.* 2 $\frac{1}{2}$ *d.* sterling.

The impression on the patagon of Basil is a view of the city, over which is the name BASILEA; reverse, a griffin supporting the arms of the city; legend, DOMINE CONSERVA NOS IN PACE. But the new ecus of 1795, &c. bear the arms of the city, with a hat and feathers, and the legend, RESPUBLICA BASILEENSIS; and on the reverse, a wreath of oak, inclosing the legend as on the ducat. The impression on the patagon of Bern is a man resting on his sword, legend, DEUS PROVIDEBIT; reverse, arms of the city; legend, RESPUBLICA BERNENSIS. The old patagon or ecu of Geneva, has upon it a two-headed eagle crowned; legend, POST TENEBRAS LUX; reverse, arms of Geneva, and over them a sun, with the letters I. H. S. in the centre; legend, RESPUBLICA GENEVENSIS. The ecu of 1794 bears the head of a woman with a mural crown, legend, REPUBLIQUE GENEVOISE, and under it EGALITÉ, LIBERTÉ, INDEPENDENCE; reverse, two ears of corn, and between them the words PRIX DU TRAVAIL, L'AN III. DE L'EGALITÉ; legend, APRES LES TENEBRES LA LUMIERE. But the ecus coined since that period have a sun with the letters I. H. S. in the centre; the legend, POST TENEBRAS LUX, with XII FLORINS, IX SOLS; reverse, the arms of Geneva encircled by a wreath of oak; legend, GENEVE REPUBLIQUE, L'AN V. DE L'EGALITÉ. The half ecu bears the same impressions, except that it is marked within the sun VI FLORIN, IV S. VI D.

PATADA, in *Geography*, a town of Hindooſtan, in the circar of Aurungabad; 30 miles N. of Darore.

PATÆCI, or **PATAICI**, in *Mythology*, images of certain gods carried by the Phœnicians on the prows, or, as others say, on the stems, of their gallees.

Herodotus, lib. iv. calls them παταίκιοι. The word is Phœnician, and derived from *patibica*, *i. e.* *titulus*. (See Bochart's Chanaan, lib. ii. cap. 3.) But Scaliger does not agree. He derives the name from the Hebrew word *patach*, inſculpere, to engrave; and Bochart from *batach*, confidere, to trust in; neither of which etymologies agrees to the use which the Phœnicians, and after them the Greeks, made of the gods pataici. Morin derives it from πατακός, *monkey*, this animal having been an object of worship among the Egyptians, and hence might have been honoured by their neighbours.

Mr. Elfner has observed, that Herodotus does not call the *pataci* gods; but that they obtained this dignity from the liberality of Hesychius and Suidas, and other ancient lexicographers, who placed them at the sterns of ships, whereas Herodotus placed them at the prow. This ancient historian intimates that they resembled little pigmies, and that they were so ugly that they provoked the scorn of Cambyses, when he entered into the temple of Vulcan in Egypt.

Seager, Bochart, and Selden, have taken some pains about this subject.

Mr. Morin has also given us a learned dissertation on this head, in the *Memoires de l'Acad. des Inscrip. & Belles Lettres*, tom. i. but Mr. Elfner thinks it defective in point of evidence.

PATAGOA, in *Geography*, a river of Brasil, which runs into the sea near Rio Janeiro.

PATAGONIA, or as it is called by some geographers, "The Magellanic Lands," and by others "Tehuelia," a country of South America, bounded on the N. by the viceroyalty of La Plata or Buenos Ayres, on the E. by the Atlantic ocean, on the S. by the straits of Magellan or Magellaens, and on the W. by the South Pacific ocean; extending from about $64^{\circ} 30'$ to $74^{\circ} 30'$ W. long., and from about 38° to 54° S. lat. The boundaries of this country, however, are not accurately ascertained, and its figure is very irregular. This country was first discovered by Magellan in the year 1519 (see *Straits of MAGELLAN*); but his account of it is defective and erroneous. The inhabitants have been represented by Dr. Robertson, as occupying that vast, but least known, region of America, which extends from the river De la Plata to the straits of Magellan. Their proper station, however, is in that part of the interior country which lies on the banks of the river Negro; but in the hunting season, they often rove as far as the straits already mentioned, which separate Terra del Fuego from the main land. The first accounts of this people were brought to Europe by the companions of Magellan, who described them as a gigantic race, above eight feet high, and strong in proportion to their enormous size. Several navigators have, in the course of the last century, visited the country of the Patagonians; but, like their predecessors, they differ in their account of its inhabitants. Commodore Byron and his men, who entered the straits in 1764, represent them to be of a gigantic stature, and to realize the tales of monsters in a human shape. One of them, who appeared to be a chief, had the skin of some wild beast thrown over his shoulders, and was painted so as to exhibit a hideous appearance: round one eye was a large circle of white, a circle of black surrounded the other, and the rest of his face was streaked with paint of different colours. Captain Byron did not measure him; but judging of his stature by its proportion to his own, he concluded it could not be much less than seven feet. This was the general size of the men, and the women were proportionably large. They were all painted and clothed nearly in the same manner: their teeth were as white as ivory, remarkably even and well set; but, except the skins, which they wore with the hair inwards, most of them were naked, some few only having upon their legs a kind of boot, with a short pointed stick fastened to each heel, which served as a spur. When they were prevailed upon to sit down, they accepted a quantity of yellow and white beads, which were distributed among them, with pleasure. They did not appear to be wholly strangers to European ornaments; for one woman among them, of an enormous size, and having her face frightfully painted, had bracelets, either of brass, or very pale gold, upon her arms, and some beads

of blue glass strung upon two plaits of her hair. These apparent giants had with them a great number of dogs, with which, it was supposed, they chased the wild animals which served them for food. Their horses, though not large, nor in good condition, seemed to be nimble, and well broken. Their bridle was a leathern thong, with a bit of a small piece of wood, and their saddles resembled the pads used among the country people in England. The women rode astride, and both men and women without stirrups; and yet they galloped without fear over the spit on the shore, the stones of which were large, loose, and slippery. Such is the account given by Byron, in *Hawkeforth's Voyages*, vol. i. Mr. C. Clarke, an officer of Byron's ship, in a letter published in the *Philosophical Transactions*, vol. lvii. describes the Patagonians as of a copper colour, with long black hair, and says, that some of them were certainly nine feet, if they did not exceed this stature. They are stout and well made: the women, he says, were from seven and a half to eight feet, though there was hardly a man less than eight feet. It does not appear, however, that these people were actually measured. The country is represented as somewhat hilly: the soil, in that part which lies off Port Desire, is sandy, producing nothing but a coarse harsh grass. Captain Wallis, who visited this coast in 1766, measured those that appeared to be the tallest among them. One of these was six feet seven inches high, several more were six feet five inches, and six feet six inches; but the stature of most was from five feet ten inches to six feet. Captain Carteret's account agrees with that of captain Wallis. (See *Philosophical Transactions*, vol. lx.) These seem to have been the same people, whose size had been so much over-rated in the year 1764; for several of them had beads, and red baize, such as that which had been put on board captain Wallis's ship, and which he naturally concluded they had got from captain Byron. In 1767 they were again measured by M. Bougainville, whose account agrees nearly with that of captain Wallis. To these testimonies we may here add another of great weight. In the year 1762, Don Bernardo Ibagnez de Echavari accompanied the Marquis de Valdelirios to Buenos Ayres, and resided there several years. He observes, that the southern extremity of America is inhabited, not by the fabulous Patagonians, who have been supposed to occupy this district, but by Indians of the same stature with Spaniards, among whom no one was seen that exceeded in height two varas and two or three inches, *i. e.* about 80 or 81.332 English inches, if Echavari makes his computation according to the vara of Madrid. This agrees nearly with the measurement of captain Wallis. Mr. Falkner, who resided as a missionary forty-eight years in the southern parts of America, says, that "the Patagonians, or Puelches, are a large bodied people; but I never heard of that gigantic race which others have mentioned, though I have seen persons of all the different tribes of Southern Indians." Captain Wallis describes them as being of a deep copper colour, like that of the Indians in North America, with straight hair as harsh as hog's bristles, which was tied back with a cotton string: they are well made, robust, and bony, but their hands and feet are remarkably small. They were clothed with the skins of the guanico, an animal resembling a deer, without horns, and having a hump on its back: these skins were sewed together in pieces about six feet long and five feet wide, wrapped round the body, and fastened with a girdle, with the hairy side inwards: some of them had a square piece of cloth made of the downy hair of the same animal, through which a hole being cut for the head, the rest hung round them about as

low as the knee. They also wore a kind of drawers, and buskins, reaching from the mid-leg to the instep before, and behind brought under the heel: the rest of the foot was without any covering: round their eyes were the circles already mentioned, and they were painted on their arms, and on other parts of the face. The eye-lids of all the young women were painted black. They talked much, but their language, a single word or two excepted, was unintelligible. Every one had a missile weapon, tucked into the girdle. This weapon consisted of two round stones, covered with leather, and weighing about a pound, which were fastened to the ends of a string about eight feet long. This they used as a sling, keeping one end in the hand, and whirling the other round the head, till with the force it had acquired, they discharged it upon the object. In the management of this double-headed shot they are so expert, as to be able to hit a mark not larger than a shilling, with both the stones, at the distance of fifteen yards: it is not, however, their custom to strike either the guanico or ostrich with them, in the chase, but they discharge them so that the cord comes against the legs of the ostrich, or two of the legs of the guanico, and so twisted round them by the force and swing of the balls, that the animal, being unable to run, became an easy prey to the hunter. They eat their flesh raw, and the paunch of the ostrich without any preparation besides turning it inside out and shaking it. Each of these people, both men and women, says captain Wallis, had a horse with a decent saddle, stirrup, and bridle. The men had wooden spurs, except one who had a large pair of such as are worn in Spain, brass stirrups, and a Spanish scymitar, without a scabbard: but notwithstanding these distinctions, he did not appear to have any authority over the rest: the women had no spurs. Their horses, about fourteen hands high, appeared to be of a Spanish breed. Although they had no objection to familiar intercourse, manifested no intention of mischief, and jumped into the English boats with alacrity and joy, and when in them sung several of their country songs; when on board they expressed no curiosity or wonder which the multiplicity of objects around them had a tendency to excite: they partook of the ship's provisions without hesitation or scruple, but they would drink nothing besides water. The animals on board, particularly the hogs and sheep, and the Guinea hens and turkeys, engaged their attention, but they seemed not to desire any thing which they saw except the apparel; and only one of them, who was an old man, asked for that. When the first volley was fired by the marines in their exercise, they were struck with astonishment and terror; the old man, in particular, threw himself down upon the deck, pointed to the muskets, and then striking his breast with his hand, lay some time motionless, with his eyes shut; thus, as it was supposed, intending to shew that he was not unacquainted with fire-arms, and their fatal effect. The rest seeing the people on board merry, and finding themselves unhurt, soon resumed their cheerfulness and good humour, and heard a second and a third volley fired without much emotion: but the old man continued prostrate upon the deck for some time, and never recovered his spirits till the fire was over. Although they were pleased with the beads and other trinkets which were distributed among them, and seemed very desirous of hatchets and bill-hooks, they did not give the least intimation that they would part with any provisions; therefore no traffic was carried on between them and the English navigators.

This country consists, for the greatest part of it, of open deserts and savannas, with a few willow trees on the rivers; and seems to enjoy a temperate but rather cool climate.

But separated in the middle by the vast mountains of the Andes, one part of it, and also its inhabitants, differ widely from the other. To the northward of La Plata this part of South America is covered with wood and stored with an inexhaustible fund of large timber: but to the southward of that river the eye can scarcely discover a single tree or shrub fit for any mechanical purpose; but even this seemingly barren country has some good pastures, and numerous droves of wild horned cattle, and every district abounds with horses, which are supposed to have been brought hither by the Spaniards.

It has been suggested, that the Patagonians, called also Tehuels, are descendants of the natives of the Canaries, who were a tall people; and it is said that they bury their dead on the eastern shores, as looking towards the country of their ancestors. Bougainville suggests, that they lead the life of Tartars. They are said to ramble through the immense plains of South America, being constantly on horseback, pursuing the game or wild beasts with which these plains abound, and dressing or covering themselves with skins. They also resemble the Tartars in another respect, by pillaging the caravans and travellers.

In a country which lies E. of Bootan, it is said there are men of gigantic stature, being not less than eight feet high. See Turner's Tibet, p. 156.

PATAGONULA, in *Botany*, altered by Linnæus from the original name **PATAGONICA**, bestowed on it by Dillenius, in his *Hortus Elthamensis*, v. 2. 304. t. 226. f. 293. —It was so called from being a native of Patagonia. Such generic names however as are taken from countries being very unexceptionable, it is fortunate that the present one has been abolished, the plant belonging to another genus. See **CORDIA**.

PATAIA, or **PATHAY**, in *Geography*, a town of Hungary; 7 miles N. of Colocza.

PATAK, a town of Hungary, on the Latorcza, in which the Protestants have a college; 25 miles S.S.E. of Caschan.

PATALA, a town of Sweden, in Tavastland; 45 miles N.N.E. of Jamso.

PATALA, one of the receptacles for sinners, or hells of the Hindoos; for a list of which, see **NARAKA**. The name *patala* does not, however, occur there. It means rather the lower regions, a sort of purgatory perhaps, over which Yama presides, who is, however, usually styled king of hell. (See **YAMA**.) It is this word, probably, that some European writers have altered to *Padalon*. As consort to Yama, who is a form of Siva, Parvati assumes the name of *Patala-devi*; which see.

PATALA-DEVI, in *Mythology*, a name of the Hindoo goddess Parvati, in her character of consort of Yama, regent of the lower, or infernal regions. In this character she corresponds with Proserpine, or Hecate, and, like the Grecian goddess, has a triple character; and is sometimes called *Tri-fakti-devi*, and *Tri-fakti-devi-kumari*, meaning the goddess with three powers, and the thrice-potent-virgin-goddess. Thus the triple-virgin-goddess Diana is so named as a terrestrial deity, and Parvati is similarly named *Bhu-devi*, goddess of the earth. Luna and *Svardevi* are severally the celestial goddesses, and *Patala-devi* corresponds with Proserpine, in their subterranean, or infernal designations. See farther hereon under the articles **PARVATI** and **YAMA**.

PATANAM, in *Geography*, a town of Hindoostan, in Marawar; 40 miles N.W. of Ramanadporum.

PATANI, the capital of a kingdom of the same name, in the peninsula of Malacca; 250 miles N. of Malacca. N. lat. 6° 58'. E. long. 103° 40'. See **MALACCA**.

PATAN-

PATANJALI, in *Philosophy*, one of the systems or schools among the Hindoos. It corresponds, in many points, with that of the stoics, and its promulgator Patanjala, with Zeno; but the commentators on the Hindoo systems have buried the succinct works of the founders in such a mass of illustration, as they term it, that their precise differences are not easily determinable. The system called Sankya is two-fold; one division was promulgated by Kapila, of which some notice is taken under that article, and the other by Patanjala. See *PHILOSOPHY of the Hindoos*, and SANKYA.

PATAPA, in *Geography*, a town on the N. coast of the island of Samar. N. lat. $12^{\circ} 40'$. E. long. $125^{\circ} 14'$.

PATAPSCO, a river of America, in Maryland, which rises in York county, Pennsylvania, and pursuing a S. and S.E. course till it reaches Elkridge Landing, about eight miles S.W. of Baltimore, turns eastwardly over falls, and widens into a broad bay-like stream to its mouth, formed in Chesapeake bay by N. point, and Bodkin point on the S., the last being in N. lat. $39^{\circ} 8' 30''$. It is about 30 or 40 yards wide just before it communicates with the basin, on which stands the large commercial town of Baltimore. By its first discoverer it was called Bolus river, from the red earth found near it, resembling bole armeniac. It is navigable for vessels drawing 18 feet water to Fell's point at Baltimore; but its navigation further is prevented by the falls a little above Elkridge Landing.

PATARD, or PATAC, in *Commerce*, a copper coin in Flanders. Patacs are florins or gilders of 20 stuyvers or stivers, each of which was formerly subdivided into 16 pennings, but for a long time they have been divided into 12 parts or deniers. Accounts were formerly kept at Dunkirk, as at Antwerp, in florins, patards, and pennings. The following proportions subsisted among the old monies of Dunkirk; 17. Flemish = 6 florins = $7\frac{1}{2}$ livres Tournois = 20 shillings = 120 patards = 150 sous = 240 pence or gros = 1800 deniers = 1920 pennings. But of late years the new French system of francs and centimes has been adopted, and the new coins of France are also used at Dunkirk. At Lisle, a patard, or stiver, is reckoned at $1\frac{1}{4}$ sou, or 15 deniers; however, the present current coins are chiefly those of France.

PATARINS. See ALBIGENSES and PAULICIANS.

PATARNE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Mamers. The place contains 717, and the canton 9941 inhabitants, on a territory of 175 kilometres, in 17 communes.

PATASPOUR, a town of Bengal; 28 miles S.S.E. of Midnapour. N. lat. $22^{\circ} 3'$. E. long. $87^{\circ} 37'$.

PATATE, a town or village of South America, in the audience of Quito, and jurisdiction of the assiento of Hambergs, situated between Riobamba and Latacunga. Patate is famous for its plenty of sugar-canes, and the fineness of its sugar.

PATAVINITY, PATAVINITAS, among *Critics*, a fault objected to Titus Livy, which he derived from his country Padua, by the ancients called Patavium.

Afinius Pollio, as we are informed by Quintilian, taxed Livy with Patavinity. But what this Patavinity consisted in, the critics have been much puzzled to find out.

Morhof believes it to be a certain turn of expression, and some phrases peculiar to the Paduese. All we know for certain is, that it was a fault in the language of Livy, not in the sentiments or manners. In all probability it is one of those delicacies that are lost in a dead language.

Dan. Georg. Morhof has an express treatise, "De Pata-

vinitate Liviana," printed at Kiel in 1685, where he explains, very learnedly, the urbanity and peregrinity of the Latin tongue.

PATAVIRCA, in *Geography*, a town of Peru, in the jurisdiction of Santa, or Guarmey, consisting of about 60 houses; and lying upon the road from Paita to Lima, 67 miles N. of that city. In its vicinity, at the distance of about three quarters of a league, and near the sea-coast, are the ruins of a palace of the Indian princes. S. lat. $10^{\circ} 25'$.

PATAVIUM, in *Ancient Geography*, a town of Italy, in Venetia. The honour of its foundation is ascribed to Antenor. It was situated in a country so fertile, that Constantine Palæologus is said to have declared, that throughout the East, he did not know a place so proper for the seat of the terrestrial paradise. Its citizens were distinguished at Rome more than those of other towns, as they had a right of suffrage in common with the Roman citizens themselves. It was taken and destroyed by Attila, about the year 450 or 452, and soon after re-established by Narsetz. It was taken by the Lombards in 601, and reduced to ashes; but Charlemagne restored its former lustre. See PADUA.

We learn from Tacitus (*Annal.* l. xvi. c. 21.) that this city was accustomed to celebrate the antiquity of its origin, and the name of its founder, in annual games, said to have been instituted by that hero. Livy informs us (l. x. c. 2.) that a Naumachia, exhibited annually on one of the rivers that water the town, perpetuated the memory of a signal victory obtained by the Paduans, long before their union with Rome, over a Lacedæmonian fleet, commanded by Cleonymas. They are also said to have not infrequently assisted the Romans, and contributed in no small degree to their victories, particularly over the Gauls, the common enemy of both states, while an immense population furnished them with the means of giving effect to their measures, by sending powerful armies into the field. Padua afterwards submitted to the genius of Rome, but submitted with dignity, and was accordingly treated not as a conquered, but an allied republic. She was admitted to a participation not only of the franchise, but even of the riches of Rome, as she could count at one period 500 Roman knights among her citizens, and drew by her manufactures, from the emporium of the world, no small share of the tribute of the provinces. After having shared the glory of Rome, Padua partook of her disasters; like her she was plundered by Alaric and Attila; and, like her, half depopulated by the flight of her dismayed inhabitants, and obliged to bend under the yoke of a succession of barbarian invaders. Padua was, after the expulsion of the Goths, subjected to the Lombards, the Franks, and the Germans. At length it shook off the yoke, and with its sister states, Verona, Vicenza, Ferrara, and Mantua, experienced the advantages and disadvantages of republicanism, occasionally blessed with the enjoyment of freedom, and occasionally, with all its forms, smarting under the rod of a powerful usurper. At length, in the 15th century, Padua united itself to the Venetian territory, and under the influence of its laws acknowledged the supreme authority of that republic. At a late period it suffered much by fire and sword, as well as by earthquakes and pestilence. Nevertheless, it is still a great, and in many respects a beautiful city, as its circumference is near seven miles, its population about 40,000 persons, and notwithstanding the general narrowness of its streets, many of its buildings, public and private, are truly magnificent. The abbey of St. Giustina deserves particular attention; it was planned by Palladio, and built by Andrea Riccio in the highest style of architecture. The piazza before it, called Prato della Valle, is perhaps one of the largest and noblest in Europe. The cathedral deserves

deserves to be ranked in the class of eminent buildings; and the church, called "Il Santo," from St. Antony of Padua, is of Gothic architecture, and was enriched, before the late French invasion, with a valuable treasury; the tomb of the saint, however, still remains, adorned with fine marble, and most exquisite sculpture. The town-hall, "Il Salone," is remarkable for its magnitude, being 312 feet long, 108 broad, and 108 high, and contains a monument in honour of Livy, with an ancient bust. In ancient times, Padua was famous for its woollen manufactures, celebrated in prose by Strabo, and in verse by Martial; it still retains much of its reputation in this respect, its wool, and woollen articles, being considered as the best in Italy. But the principal glory of Padua arises from its literary pursuits, and an ancient, and well directed propensity to literary science. The university was founded about the 11th century, and its foundation was to Padua the commencement of an era of glory and prosperity. Students, amounting in number to 18,000, are said to have crowded its schools during ages. Of 18,000 students, 600 only remain; though the lecturers are men of zeal and abilities, the plan of studies, the result of long and successful experience, and its libraries, collections and cabinets of every kind numerous and magnificent. Its decline is owing to the establishment of similar institutions in other countries, and to the general diffusion of the means of knowledge. Besides the university, in which is an agricultural lecture, encouraged by the allotment of 15 acres of land for experiments, Padua has several academies, which have been established at different times, and are supported with spirit. Eustace's Classical Tour through Italy, vol. i.

PATAY, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Orleans; 12 miles N.N.W. of Orleans. The town contains 930, and the canton 6198 inhabitants, on a territory of 227½ kilometres, in 15 communes. This place is famous for the defeat of the English by the French, under the conduct of the celebrated Maid of Orleans, in the year 1429.

PATAZ. See CAXAMARQUILLA.

PATCHEPALIAM, a town of Hindoostan, in Coimbatore; 13 miles N.N.E. of Coimbatore.

PATCHIEU, a river of Bootan, called by the Bootans Jumba Chieu, or the junction of three rivers, viz. the Hatchieu, the Tchintchieu, and the Patchieu.

PATCHWARY, a town of Bengal; 32 miles S. of Rajamal.

PATCOOM, a town of Bengal; 50 miles S.W. of Rongonapour. N. lat. 23° 3'. E. long. 87 2'.

PATE, in *Fortification*, a kind of platform, like what they call a horse-shoe; not always regular, but generally oval, encompassed only with a parapet, and having nothing to flank it. It is usually erected in marshy grounds, to cover a gate of a town, or the like.

PATE, in *Geography*, a small island of France, in the river Gironde, near Baye.

PATEABARRY, a town of Bengal; 20 miles S. of Moorshedabad.

PATEAGUR, a town of Hindoostan, in the circar of Sollepour; 35 miles N.W. of Sollepour.

PATEE, or PATTEE, a term, in *Heraldry*, for a cross, small in the centre, and widening towards the extremes. The field, sable, a cross patee, argent; by the name of Cross.

This form of a cross is also called *formé*.

It is also a term used by some to express a sort of irregular line, differing from the indented, ingrailed, and all the other regular and common lines, and called by some the dove-tail line.

It is somewhat like the joint called by our joiners by this last name, but it is not in general use, and is by some reckoned among what the French call the *clatte*.

PATEEBA, in *Geography*, a town of Hindoostan, in Benares; eight miles S. of Chunar.

PATEES, PATTY. See PETTY.

PATEGOW, in *Geography*, a town of Hindoostan, in the circar of Hindia; eight miles S. of Hurdah.

PATEL, in *Biography*, a French landscape painter much esteemed. The place of his birth, and the date of it, are equally unknown. The execution of his pictures is of an easy, light, and agreeable character; and his general taste of a pleasing nature; but he does not rank above the class of artists merely agreeable.

PATELI, or PUTALA, in *Geography*, a town of Thibet, in the district of Lassa, where is situated, upon a mountain, the temple or palace of the grand Lama; five miles E. of Lassa.

PATELLA, in *Anatomy*, the knee-pan, a small bone situated in the tendon of the extensor muscles of the knee, and occupying the front of the joint. See EXTREMITIES.

PATELLA, *Fractures of*. See FRACTURE.

PATELLA, *Dislocations of*. See LUXATION.

PATELLA, the *Limpet*, in *Natural History*, a genus of worms of the class and order Vermes Testacea, of which there are about 250 species described. The animal is a limax: the shell is univalve, subconic, shaped like a basin, and without a spire. In all cases the shells of this species are attached to some hard body. Their summit is sometimes acute, sometimes obtuse, flattened, turned back or perforated. The rock, or other hard body to which they are always found adhering, serves as a kind of second or under shell to preserve them from injury; hence they have by some naturalists, though erroneously, been classed among the bivalves. The shells have been analysed, and they are found to consist chiefly of carbonate of lime. When exposed to a red heat, they emit a smell like horn; and when dissolved in acids, a semi-liquid gelatinous matter was left behind. The various species, which are so numerous, are distinguished by the peculiarities in their shells. The species are separated into five sections.

Species.

Section A. *Furnished with an internal lip; shell entire.*

EQUESTRIIS. Shell orbicular, perfoliate outwardly; lip vaulted perpendicular. This species, of which there is a variety, inhabits the Indian and American seas. It is an inch wide.

NERITOIDEA. Shell ovate, with a subspiral tip; lip lateral. The native place of this species is not known. It is generally found adhering to other testaceous substances. The shell is the size of a cherry, and the inhabitant is red.

SINENSIS. Shell subconic, smooth; lip somewhat lateral. It inhabits the Mediterranean, Atlantic, and Indian seas. The shell is very thin and pellucid, sometimes it is of a chestnut colour speckled with minute grey dots, but generally it is white, with brown spots and rays.

PORCELLANA. Shell oval, with a recurved tip; lip placed behind, and flat. It inhabits India and Goree. The shell is convex, within white, the outside red, with white scaly spots, and transverse undulate blue lines.

FORNICATA. Shell oval, obliquely recurved behind; lip placed behind, and concave. This is found in the Mediterranean and near the island of Barbadoes,

ACULEATA. Shell oval, brown, with prickly striz; the

the crown is recurved. This is found in the American islands.

TROCHIFORMIS. Shell conic, longitudinally plaited; internal lip lateral. It inhabits Tranquebar and the Falkland islands.

AURICULA. Shell roundish, with radiate grooves and striate; crown recurved; internal cavity ear-shaped. It inhabits Borneo, Santa Cruz, and St. Thomas's islands.

RUGOSA. Shell ovate, thin, hyaline, obsolete wrinkled transversely; margin unequal; lip unequally repand, hyaline. It inhabits China, and is generally found in the *Buccinum spiratum*.

GORENSIS. Shell oval, flat, thin, white, glossy, lamellate on the outside. This is found adhering to rocks at Goree, and is about half an inch in diameter.

CONTORTA. Shell granulate with white, with very fine perpendicular oblique ribs; the lip is very thin, oblique and covering half the cavity. This is a very small shell.

EXPLANATA. Shell white, very finely striate; crown inclining downwards, and dilated, behind which the shell is depressed.

PLICATA. Shell conic ochraceous, with ferruginous rays within, with longitudinal transversely striate plaits.

STRIATA. Shell conic, white and striate, with undulate grooves; the crown is a little lateral.

SOLEA. The shell of this is a little twisted, pellucid, with ferruginous spots, thinly plaited, and transversely grooved above; lip undulately repand.

ECHINATA. Shell conic, prickly, glabrous within. It is found fossil near Crignon. The shell is calcareous and whitish, covered on the outside with prickles.

Section B. *With the margin angular or irregularly toothed.*

CREPIDULA. Shell oval, flattish, smooth, the lip flat behind. It is found in the Mediterranean, especially about the coasts of Barbary.

LACINIOSA. Shell with elevated unequal rays, thicker and obtuse on the outside. This is an inhabitant of India.

SACCHARINA. The shell of this species is angular, with seven carinate obtuse ribs. It is found at Java and Barbadoes.

BARBARA. Shell toothed, with nineteen elevated vaulted muricate rays. It is found near the Falkland islands.

GRANULARIS. Shell toothed, with elevated angular imbricate striæ. Inhabits Southern Europe, and the Cape of Good Hope.

GRANATINA. Shell angular, with numerous muricate striæ. It inhabits Jamaica and Southern Europe, is from one to three inches long.

* **VULGATA.** Shell with about fourteen obsolete angles, and dilated acute crenate margin; crown central. This is described and figured in Donovan's Shells: it inhabits the marine rocks of Europe and India. It is about two inches high, and from three to four wide: in the older shells the margin is nearly even, and the number of ribs irregular.

* **DEPRESSA.** Shell with fourteen angles, oblong; crown lateral. This is described and figured in Pennant's British Zoology. It inhabits the rocks of Europe.

CERULEA. Shell crenate, subangular, with numerous unequal striæ; beneath it is blue. This is an inhabitant of the Mediterranean.

TUBERCULATA. The shell of this species is slightly toothed, conic, tuberculate, retuse behind. The shell is yellowish, with white tubercles disposed in rows.

LEPAS. Shell roundish, pectinate, with imbricate tuberculate transversely striate rays; crown incurved. There are two varieties, the one found in Cluli, the other in the

Falkland islands. The second is usually named the Bronze limpet.

TRICOSTATA. Shell oval, three-ribbed, white, striate at the sides; internal margin flattish and a little jagged. It is found in the Indian ocean.

MYTILINA. Shell carinate, rounded on the fore-part, with undulate striæ, brown, perlaceous within, the hinder margin crenate. Found in different parts of South America, and is an inch and a quarter long.

OVATA. Shell toothed, oval, rather conical, ribbed, white, brown between the ribs, within brown with white grooves.

STELLATA. Shell angular, ovate, depressed, with ten elevated rays, and shorter intermediate ribs.

ISLANDICA. Shell solid, ovate, gibbous, unequally ribbed, within glabrous, with alternate cinereous and horny rays; margin crenate. It inhabits, as its specific name denotes, the shores of Iceland, and is about an inch and a half long.

CYPRIA. Shell oval, subpellucid, ribbed, the ribs are occasionally tuberculate, and foliaceous on the outside. It inhabits the shores of Cyprus.

COSTATA. Shell ovate, a little gibbous, white, with crowded unequal tuberculate rugged ribs.

LEUCOPLEURA. Shell ovate, dusky, with crowded white smooth unequal ribs.

STRIATULA. The shell of this species is a little rugged, white, with brown flexuous striæ branching outwards, with two brown spots in the bottom of the hollow.

OCTORADIATA. Shell convex, with eight larger tuberculate ribs besides lesser ones. It inhabits the American islands.

RUBRA. Shell toothed, red under the brown skin, with elevated rounded striæ, and lesser imbricate ones, within white.

HEPATICÆ. Shell ovate, gibbous, thin, toothed, and of a liver colour, with elevated carinate, obtusely spined striæ.

BADIA. Shell subconvex, brown, within bay, with twelve larger rays each surrounded by a rib, and as many lesser ones.

FUSCESCENS. Shell flattish and brown, with ten elevated striæ; crown of a different colour; bottom with a pale liver coloured spot, edged with glaucous and gold; the inner margin in brown. The shell is from two to four inches long; more or less convex.

MACULOSA. Shell flattened, the fore part narrow and rounded; yellowish, spotted with brown, with a white crown; with flat rounded equal rays.

ROTUNDATA. Shell suboval, flattened, varied with brown, with rounded flat ribs and a differently coloured crown and bottom.

PECTEN. Shell ovate, obscurely edged with white, radiate, with distant striæ pectinate outwardly; crown grey; bottom with a spot surrounded with a white belt. It is found in North America.

CORRUGATA. Shell ovate, wrinkled, chestnut; crown with a white circle; within cinereous, radiate with white; bottom pale edged brown edged with white.

ALBORADIATA. Shell ovate, each side brown, radiate with white, with elevated pectinate striæ; the crown is white and the bottom yellowish. It is about half an inch long.

OLIVACEA. Shell ovate and olive colour; within brown, varied with white, with elevated unequal striæ; the margin with two rows of unequal spines; crown pale yellow; bottom silvery, with a brown centre. The shell is half an

PATELLA.

inch long, and the bottom is surrounded with a white belt.

CEREA. Shell ovate, both sides waxen colour, perpendicularly striate, with thirteen flattened ribs and white bottom.

IMPRESSA. Shell ovate, with elevated, transversely striate, brownish striæ, spotted with white, and reaching half way down; crown with a white impressed circumference.

AURANTIA. Shell ovate, solid; citron undulate with brown, with elevated crowded wrinkled striæ and white bottom.

CINGULUM. Shell ovate, denticulate, cinereous, with three black belts, within milk-white, with elevated unequal striæ, nodulous on the outside, and spinous at the margin.

OCULATA. Shell ovate, white, with flattened ribs of unequal length, brownish between them; crown with a brown belt.

MAGELLANICA. Shell thin, ovate, white, with a nodulous margin, within perlaceous, with elevated striæ; crown pointed, brown; bottom brown. It inhabits the straits of Magellan.

OCHROLEUCA. Shell ochraceous, with three yellow bands, and elevated, acute, unequal striæ; crown white; bottom silvery.

DENTATA. Shell white, denticulate, with elevated, acute, unequal striæ; crown surrounded with a double row of cinereous dots, and a dusky-grey band.

NODOSA. Shell yellow, radiate with brown, with elevated, nodulous, unequal striæ; crown and bottom white.

CINEREA. Shell toothed, cinereous, with unequal elevated striæ, between which it is brown and rugged; crown pointed, milk-white.

EXALBIDA. Shell whitish, with brown rays, and elevated, rounded, unequal striæ, between which it is rugged; crown obtuse, white, with a broad interrupted brown band, and another marginal one.

CANCELLATA. Shell cinereous and brown, with decussate striæ and two rows of tubercles; the crown is yellowish, and the bottom has a white spot. There is a variety that is grey, with dusky rays, and a few yellow striæ; within dirty yellow with a white bottom. It is found in Jamaica, and is about one inch and a half long.

LÆVIS. Shell rounded, smooth, yellowish, with a broad citron marginal band spotted with brown, and another narrow one; margin dilated, acute, and a little rugged.

ARGENTEA. Shell smooth, thick, a little silvery; with eleven brown rays; margin silvery; crown pale yellow; bottom ivory, with a double white ring. This is about two inches long, but is very rare.

CUPREA. Shell white, with strong, rounded, brown ribs, within perlaceous; crown and bottom coppery.

RUBIDA. Shell pale, liver-coloured both sides, with alternate larger and lesser carinate ribs; it has a flat and white crown.

GLABRA. Shell brown, glabrous above, with elevated crowded white striæ beneath; crown obtuse, white, with a fulvous border; bottom fulvous.

FLAVEOLA. Shell yellowish, varied with brown; with flattened unequal ribs; crown obtuse; bottom varied reddish and white.

INFUNDIBULUM. Shell denticulate, compressed on each side, rounded, yellow, with perpendicular striæ and carinate ribs; bottom varied with white and cinereous.

CYATHUS. Shell rounded, glabrous, white.

SINICA. Shell ovate, entirely yellow, with undulate grooves, within striate perpendicularly; margin scalloped.

It is found in China, and is about three inches and a half long.

PUNCTATA. Shell roundish, white, with many-coloured dots, radiate at the base, and surrounded with two brown rings; margin a little flexuous.

LUGUBRIS. Shell ovate, with annular striæ, black, with elevated unequal striæ; margin crenate; crown and bottom white.

ULYSSIPONENSIS. Shell ovate, toothed, yellowish, with elevated flattened striæ; crown pointed, and of an orange colour.

UMBELLA. Shell oblong, red, with elevated, unequal, white striæ; the margin is crenate. It inhabits Africa, in numerous varieties. The shell is rarely of a straw-colour; it is sometimes spotted or clouded.

CRENATA. Shell thin, pellucid, striate, blackish, with olive rays, within glaucous or cinereous; crown pointed; margin crenate; bottom milk-white. It is found on the shores of Africa, Malaga, and Lisbon.

FERRUGINEA. Shell ferruginous, with angular or undulate ruffet lines, and cinereous belts, within milk-white, with elevated knotty striæ; the margin is plaited.

MELANOGRAMMA. Shell oval, ochraceous, with elevated black striæ, within silvery, spotted; crown pointed, white; bottom with a straw-colour spot.

REPANDA. Shell ovate, thin, within silvery, with brownish rays, and thin undulate striæ, with bay-coloured granulations. The margin is flexuous. It inhabits the seas of Magellan.

ANGULOSA. Shell oval, white, with very thin striæ, and varied with red spots and dots; margin eight-angled.

TIGRINA. Shell oval, smooth, polished; pellucid, striate with seven yellowish ribs; the colour is blueish-olive, dotted with brown; the margin is seven-angled.

MONOPIS. Shell oblong, flattish, bay striate with white, within milk-white, with eleven elevated unequal striæ; crown rounded, white. It inhabits the American islands.

CHLOROLICTA. Shell ovate, toothed, brown, dotted with green, with eleven elevated, hollow, broader striæ, and as many narrower ones; the crown is white.

MARGARITACEA. Shell thin, unequally striate, white, within perlaceous; crown with an orange mark, surrounded with a yellowish ring; the margin crenate. This is an Iceland shell.

TENUSSIMA. Shell oval, thin, ochraceous, with angular chestnut lines, and elevated, obtuse, hollow, unequal striæ.

MITRULA. Shell solid, sub-conic, transversely plaited, with a flexuous margin. It inhabits Barbadoes.

PLICARIA. Shell ovate, toothed, with thirty elevated, obtuse, undulate, and transversely wrinkled striæ. Found in the straits of Magellan.

PENTAGONA. Shell whitish, obtusely pentangular, with a dilated crenate margin; crown obtuse; bottom reddish.

ÆNEA. Shell ovate, tender, pellucid, with elevated striæ, covered with a whitish cuticle, under which it is silvery, with ruffet rays; crown and bottom coppery. It inhabits the straits of Magellan.

CONCHACEA. Shell thin, oblong-ovate, with very fine undulate striæ, yellowish, with elevated darker rays; crown recurved. It inhabits South America, and resembles the common muscle, except in the hinge.

STANNEA. Shell ovate, silvery, with elevated flattened striæ; crown obtuse, coppery; bottom with an oval bay mark; the margin is flexuous.

CANDIDISSIMA. Shell orbicular, striate, white, with a brownish band, dotted with brown, within grey, with unequal striæ; margin transversely wrinkled.

PATELLA.

Section C. *With a pointed recurved tip or crown.*

* **HUNGARICA.** Shell entire, conic, striate, with a hooked revolute crown. This is described and figured in Donovan's British Shells; and likewise in Pennant's British Zoology, vol. iv. It inhabits the American, Mediterranean, and Asiatic seas.

IMBRICATA. Shell entire, oblong, imbricate, the crown placed behind.

* **MAMMILLARIS.** Shell entire, conic, striate, sub-dia-phanous, with a reflected smooth crown. This is described and figured by Pennant, and it inhabits the shores of the Mediterranean and Africa.

TRICARINATA. Shell substriate, with three ribs on the fore-part.

PECTINATA. Shell entire, ovate, with wrinkled slightly branched striæ; crown nearly central, reflected, and pointed. It is found on the shores of the Mediterranean, and is about two inches long.

LUTEA. Shell entire, oval, convex, striate, with a sub-marginal, reflected, mucronate crown. It inhabits divers parts of India, and is about the size of a melon seed.

CRISTATA. Crown revolute; back crested, carinate.

* **LACUSTRIS.** Shell very entire, oval, membranous, with a nearly central, mucronate, reflected shell. It inhabits the fresh waters of Europe.

* **FLUVIATILIS.** Shell very entire, oval, a little horny, with a marginal mucronate crown; aperture oval. This is very like the last, and inhabits, like it, the fresh waters of Europe.

CÆCA. Shell entire, with elevated dots, and striate; crown acute, straight. Found in the bays of Norway, on stones. The shell is white, with from sixty to eighty striæ; the inhabitant is white, ovate, without the least appearance of eyes.

VIRGINEA. Shell very entire, white, with red bands. This is found on the fuci, in the bays of Norway.

TESSLATA. Shell, very entire, of a whitish colour, tessellate with red. Found on the rocks and fuci about Norway.

FULVA. Shell very entire, orange, with a mucronate and nearly vertical crown. It inhabits Norway, on fuci and testaceous substances.

SUBSPIRALIS. Shell ovate, with an obtuse sub-spiral tip. Found in Norway.

AMBIGUA. Shell ovate, with a slightly toothed margin, and a rather acute and reflected point. Inhabits Norway.

RUBICUNDA. Shell very entire, rather conical, smooth, and reddish. It inhabits the deeps of Greenland.

BORNIANA. Shell ovate, very entire, with very fine longitudinal striæ, white, with red veins.

CALYPTRA. Shell entire, with imbricate ribs; the crown is hooked; the margin sinuate. Inhabits North America.

MELANOLEUCA. Shell striate, very entire, alternately black and white.

PECTUNCULUS. Shell oblong, convex, with elevated nodulous striæ, slightly toothed, within polished; crown curved forwards.

FASCIATA. Shell ovate, white, with a brown band, and elevated acute striæ; the margin is dilated, crenate, and cinereous within.

ELEGANS. The shell of this species has decussate striæ that are white, radiate with red, denticulate; the crown is grey.

SQUAMOSA. Shell with elevated striæ, transversely undulate on the outside, brown, silvery towards the margin, crown bronzed, hooked.

SQUALIDA. Shell entire, brown, within whitish with a blueish bottom; the margin blueish, radiate with brown, with elevated obsolete striæ; crown knotty.

CROCEA. Shell smooth, sub-angular, yellow, radiate with brown; crown obtuse, white; bottom with a whitish spot.

CANDIDA. Shell ovate, smooth, on both sides white, with a rosy belt on the outside.

TRIGONA. Shell compressed, convex in the middle, cancellate, white, with a brownish band on the outside, and margin within; crown marginal, obtuse.

MINIMA. Shell rounded, convex, thin, smooth, whitish with reddish spots; crown very obtuse, and white. It inhabits Ferroe island.

TRANQUEBARICA. Shell ovate, thin, pellucid, with very fine crowded striæ, chestnut with white scales, within milk-white, with a brown spot at the bottom; the crown is marked with an azure spot. It inhabits Tranquebar, as its name imports.

PERVERSA. Shell oblong, horny, very thin, pellucid, glabrous, with a ferruginous base. It is found in Africa. The point of the crown is bent back towards the hind parts of the snail.

CERNUA. Shell with decussate grooves, thin, pale flesh-colour, with an oblong aperture.

INCURVA. Shell entirely white, flat; point of the crown twisted.

INTERRUPTA. Shell oval, depressed, glabrous, brownish, with green dots disposed in oblique interrupted rays; crown with an obtuse hook.

Section D. *Very entire, and not pointed at the tip or crown.*

AFRA. Shell conic, striate, greenish or pale brown, within white; crown glabrous, white, obtuse, central; margin glabrous. It inhabits the island Gorée.

LUSITANICA. Shell conic, white, with brown rays marked with striæ, granulate with black; crown acute, not radiate, and surrounded with a chestnut ring. It inhabits Portugal, on the sea rock, and is very small.

RADIATA. Shell rounded, convex, grey, with decussate striæ; crown pointed, central, and marked with twelve orange radiate lines; the bottom is horny. It inhabits Jamaica.

ARÉOLATA. Shell pyramidal, reddish-grey, with very thin circular striæ, crossed by longitudinal ones; crowned violet. It resembles the *P. magellanica* of a former section, but is more depressed, and broader at the base.

FLAMMEA. Shell ovate, with very fine annulate striæ, reddish-grey, with undulate brown rays; the crown is acute, central, white in the middle.

INDICA. Shell reddish-grey, with radiate striæ, glabrous, narrower on one side; crown acute, smooth, surrounded with a reddish ring. It inhabits India, is nearly four inches long, and resembles the *P. rustica*, to be described hereafter.

SURINAMENSIS. Shell thick, subovate, yellowish, with black rays, and longitudinal unequal striæ, and surrounded with knotty belts; crown obtuse, smooth and white. It inhabits Surinam.

VITELLINA. Shell ovate, yellow, with an unequally striate base, and obtuse whitish crown.

SANGUIOLENTA. Shell ovate, convex, white, solid, with intermixed, capillary, and flexuous elevated longitudinal striæ; the crown is surrounded with a broad ring, dotted with red. It is found in Africa.

LÆVIGATA. Shell ovate, yellow, within blueish-white, with oblique striæ, the crown is white, smooth, and polished.

PATELLA.

PUNCTULATA. Shell rounded, white, with many-coloured dots, radiate towards the base, and surrounded with two brown rings.

* **PELLUCIDA.** Shell very entire, ovate, gibbous, pellucid, with four blue rays. This is described and figured by Donovan, Pennant, Lister, and others. It is about the size of a walnut, and is found in the European and Northern seas.

TESTUDINARIA. Shell very entire, acute, smooth, glabrous. It inhabits the Indian and Northern seas in numerous varieties.

TESTUDINALIS. Shell very entire, ovate, and striate; a variety has its crown obtuse, and nearly central. It inhabits the seas about Greenland, among fuci.

COMPRESSA. Shell very entire, oval, oblong, striate, smooth, compressed on the back. It inhabits India, and is about four inches long.

RUSTICA. Shell very entire, conic, with fifty obtuse striæ.

FESCA. Shell very entire, ovate, obtuse, with elevated striæ.

NOTATA. Shell entire, striate, with a sub-mucronate erect crown, within white, with a black heart-shaped spot white in the middle. It inhabits the Mediterranean.

CRUCIATA. Shell very entire, oval, sub-convex, brown, with a white cross.

RADIANS. Shell entire, oval, pellucid, depressed, striate, horny, radiate, with black spots. It inhabits New Zealand.

ROTA. Shell roundish, the inside somewhat silvery, the outside with reddish streaks and a yellowish border. It inhabits the Indian and American seas.

UMBELLATA. Shell entire, roundish, diaphanous, depressed, with yellowish rays within; crown pale yellow, margin very acute. It is about four inches and a half long, and is found in the Indian ocean.

PASTULATA. Shell thin, oval, depressed, radiate, white, dotted with red, within smooth.

SYMMETRICA. Shell ovate, conical, solid, brown, divided into partitions by perpendicular white lines, within smooth, white; margin cut archwise.

CITRINA. Shell ovate, convex, with very fine decussate striæ, white, with two broad yellow bands, within whitish, with a milk-white bottom; crown brownish.

CAPENSIS. Shell oval, with decussate striæ, the longitudinal ones alternately brown and white, within somewhat perlaceous, with a white bottom. It inhabits the Cape of Good Hope.

ANOMALA. Shell coarse, brown, orbicular, with a sub-marginal crown. It inhabits the deeps of the Norway seas, on rocks and dead testaceous substances. The shell of this species is very minute, rough, with very fine raised dots, sometimes cinereous, beneath blue; the inhabitant consists of two reddish tough twisted masses, fringed down the whole length; the fringes composed of crowded yellow rigid crisp hairs united to the rest of the body by a blue tendon; ovaries branched, orange; eggs globular.

GUTTATA. Shell finely striate, and varied with dots of different colours; the bottom is dusky. It is about an inch and a half long, and resembles the compressa.

MYTILIFORMIS. Shell glabrous, lead colour, with a white horse-shoe shaped band within. It inhabits the Ferroc island, adhering to zoophytes.

SCUTIFORMIS. Shell oval, thin, black, with white perpendicular flattened striæ.

COCHLEAR. Shell white, flattish, one part narrow, caniculate within, with a blueish callus shaped like a horse-shoe, the other part rounded.

CRATICULATA. Shell oval, thin, depressed, cancellate, radiate.

CRUENTATA. Shell oval, a little convex, varied with red, and slightly toothed, with elevated unequal rough striæ.

PAPYRACEA. Shell depressed, thin, hyaline, dotted with red, with chestnut rays outwardly, and crowded thinner, and granulate thicker striæ.

CYLINDRICA. Shell oval, flat, with crowded longitudinal striæ of unequal thickness, and all granulate.

DECUSSATA. Shell somewhat convex, white, with crowded red dots, within radiate with red and white, with decussate glabrous striæ, and a few longitudinal thicker white ones.

HÆMATOSTRICTA. Shell thin, depressed, white, dotted with red, within brownish, spotted, striate; crown varied with cinereous and brownish.

ASTEROIDES. Shell flattish, cancellate, cinereous, with a chestnut star and rays towards the margin; crown smooth, grey, surrounded with brown dots.

OVALIS. Shell oval, somewhat convex, thin, with crowded striæ, grey, with blackish rays and spots.

RUBELLA. Shell a little convex, striate, reddish; crown whitish, spotted with red; the bottom part is whitish.

SPECTABILIS. Shell flattish, a little wrinkled, striate, reddish-white, with a chestnut band towards the crown, and another bay one at the margin.

CONSPURCATA. Shell solid, flattish, striate, black, with striate dots, within blueish, crown dirty-yellow.

MELANOSTICTA. Shell solid, flattish, striate, whitish, with cinereous rays and black dots, within blueish; crown a little pointed and whitish.

ATRA. Shell black, striate, with a paler crown; bottom with a brownish mark surrounded with a white horse-shoe shaped band.

SPECULARIS. Shell oval, convex, solid, glabrous, liver-colour, within and the crown brownish, the latter surrounded with a white border, and interrupted brownish band.

CANESCENS. Shell oval, black, within blueish, striate, the larger striæ flattened and grey; crown obtuse, brownish, with a whitish area.

VIRESCENS. Shell oblong, flattish, dilated on each side and striate, olivaceous, radiate, and spotted with white, within blue.

PULLA. Shell rounded, convex, longitudinally striate, and transversely wrinkled, brownish, within russet-brown, with whitish and brownish rays, and two milk-white bands above.

REVOLUTA. Shell sub-oval, crenate, striate, ochraceous, with red spots and rays, broader on one side; margin revolute.

SQUAMATA. Shell ovate, convex, striate, the striæ scaly, varied with white and black; crown nearly central, grey.

TESTACEA. Shell ovate, very finely striate, testaceous, with three transverse brownish rings, within pale yellow, with a whitish bottom.

CAPILLARIS. Shell ovate, thin, brown, with darker bands, and paler striæ, within brownish; crown and bottom white.

GLAUCA. Shell ovate, narrower on one side, very finely striate, blueish, with a white band towards the margin, and another blueish one; crown and margin white.

OBSCURA. Shell ovate, flattish, striate, varied with yellowish and brown, dotted with green, within brown, crown bay.

PATELLA.

EXOLETA. Shell oval, sub-convex, unequally striate, whitish, with a few black lines reaching half way; bottom with an ochraceous spot.

AFFINIS. Shell oval, flattish, solid, with a few black rays reaching half way; the bottom is marked with a white spot.

* **ROTALIS.** Shell white, opaque, flat, round, with a regular toothed margin. It is found occasionally at Sandwich; is very minute and rare.

FUSCATA. Shell ovate, convex, very finely striate, and varied with brown.

MELLIA. Shell rounded, solid, glabrous, honey-colour, within white; crown brownish; margin spotted with brown, and silvery within; bottom with a liver-colour spot.

ANCEPS. Shell solid, glabrous, a little pointed, pale chestnut, within pale flesh-colour.

GUINEENSIS. Shell ovate, convex, very smooth, one side broader and chestnut-coloured, the other with the crown pale yellow; margin flesh-coloured on each side.

COMPLANATA. Shell depressed-hemispherical, obsoletely cancellate, varied with white and brownish.

VIRGATA. Shell ovate, longitudinal striate, whitish with brown rays and crown, within perlaceous.

NIVEA. Shell subconic, solid, glabrous, snowy, with transverse concentric rings. Inhabits Africa.

GRISEA. Shell oval, with crowded radiate grooves, within polished; crown nearly central. It inhabits Africa.

NAVICULA. Shell narrow, with decussate striæ, rosy with a whitish callous belt on one side in the middle, and whitish bottom, the margin is revolute on each side.

CINGULATA. Shell suboval, obsoletely striate, ferruginous, with two elevated obscurely barred belts; crown nearly central.

SCARPA. Shell clear white, with undulate striæ, narrow, the broader side with an acute callus, the narrower side repand.

* **PARVA.** Shell small, entire, without gloss, whitish, faintly radiate with red. This is described and figured by Donovan. It is found on the Devonshire coasts, but is very rare.

Section E. *With the crown or tip perforated.*

* **FISSURA.** Shell oval, conic, with reticulate striæ cleft on the fore-part; crown recurved. It is found on divers parts of the coasts of Europe and Barbary, and in this country. It has been described by Donovan, Pennant, and others.

FISSURELLA. Shell grooved and perforated on the fore-part; crown recurved. It is found adhering to stones in the Iceland seas.

PUSTULA. Shell oval, gibbous, convex, with reticulate striæ, and crenate margin. It inhabits the Mediterranean, Atlantic, and Indian seas.

* **GRÆCA.** Shell ovate, convex, reticulate; the margin crenulate inwardly. Described and figured by Donovan, Pennant, Lister, and other naturalists.

NIMBOSA. Shell ovate, striate, rugged, brown, with an oblong perforation. It inhabits the Mediterranean and Atlantic.

NUBECULA. Shell subovate, rugged, white, radiate with red, with an ovate perforation. It inhabits the Mediterranean, and resembles the last species.

PICTA. Shell ovate, solid, clouded, white and green, with oblique, undulate, alternate violet and white rays. It inhabits the straits of Magellan.

BARBADENSIS. Shell oblong, unequally striate, within

smooth, milk-white, with greenish bands; margin crenulate. It inhabits Barbadoes.

JAMAICENSIS. Shell whitish, transversely annulate, with longitudinal striæ covered with foliaceous tubercles, which are larger outwardly. This is found on the coasts of Jamaica and Barbadoes.

CAFFRA. Shell ovate, compressed, striate, very finely annulate, and radiate with black; bottom milk-white; perforation nearly central. It inhabits the Cape of Good Hope.

PERFORATA. Shell a little convex, transversely wrinkled, brownish with straw-coloured rays and spots, with longitudinal striæ alternately larger and fealy.

PORPHYROZONIAS. Shell oblong, compressed, unequally striate, white with five purple interrupted belts, within greenish-white. It inhabits North America. The perforation is very minute, orbicular, and surrounded on the inside with a red circle.

ROSEA. Shell very thinly striate, with alternate rosy and white rays; the perforation is oval.

SCUTELLUM. Shell each side repand, compressed; perforation radiate with grooves.

AVELLANA. Shell thin, white, with very fine striæ; perforation oblong, and divided by a ligament. There is a variety of which the margin is a little revolute on each side.

SPINOSA. Shell ovate, convex, white, with elevated striæ, growing thicker towards the margin, and marked with four rows of tubercles, the exterior tubercles are spinous.

DENTICULATA. Shell ovate, gibbous, whitish radiate with brown, within green, with elevated striæ; margin denticulate, crenate within.

NODULOSA. Shell ovate, convex, with elevated nodulous striæ, crossing thinner transverse ones, within white; crown black.

ANGUSTA. Shell depressed, white, with elevated striæ, every fourth of which is larger; perforation very narrow, and surrounded with a chestnut band on the outside, and a green one within.

INÆQUALIS. Shell ovate, convex, with decussate striæ, white, something triangular on the broader side; perforation surrounded with an elevated ring, round which is a red line.

MINUTA. Shell oval, pyramidal, reddish, with twelve elevated white striæ; bottom white; perforation oval, and nearly central; margin denticulate.

CONSPERSA. Shell ovate, convex, striate, yellowish, with red dots, and three oblique rays; within smooth, white.

RUBESCENS. Shell oval, striate reddish, with a white band in the middle; within it is white; margin entire; perforation linear.

SANGUINEA. Shell oval, thin, red, within greenish-white, with longitudinal striæ crossing finer transverse ones, which are rugged outwardly.

VENTRICOSA. Shell oval, ventricose, with decussate red striæ, within white; crown depressed, with an orbicular perforation; margin entire.

TRIRADIATA. Shell oval, flattish, striate, white with three brown rays, within whitish, perforation linear; margin entire.

TENUIS. Shell oval, a little convex, pellucid, longitudinally striate, white, with five half-brown rays; within yellowish.

MELANXONIAS. Shell convex, rosy, with an interrupted black

black band, and elevated unequal white striæ; within smooth, white; margin denticulate.

EFFUSA. Shell convex, rosy, with elevated nodulous white, alternately larger striæ; perforation round and large.

PUNICEA. Shell convex, chefnut, with unequal, crowded decussate striæ, within smooth, with alternate green and white bands; the perforation is round.

RUFESCENS. Shell convex, white shaded with red, and here and there striate with red, with granulate striæ; within it is smooth and white.

DIMIDIATA. Shell convex, above clear white, cancellate, longitudinally striate towards the margin, with a rosy band.

LACTEA. Shell convex, white, with unequal acute glabrous striæ; within smooth; the crown is rosy; the perforation large and orbicular.

PYRAMIDALIS. Shell convex, rosy, striate, with twelve smooth ribs; within smooth and greenish-white.

BICOLOR. Shell narrow, alternately radiate with chefnut and white, with unequal, thick, lamellate striæ; within smooth, white, margin crenulate.

ERYTHROCEPHALA. Shell convex, white, with red lines outwardly, and elevated rugged contrary striæ, ten of them larger; the margin repand and inflected.

VERRUCOSA. Shell above brown, striate, terminated by a knotty belt, beneath radiate with red, with acute nodulous ribs; margin denticulate, repand.

CONTAMINATA. Shell convex, with nodulous unequal ribs, the larger ones yellowish-brown, and marked with black dots disposed in interrupted circles, within greenish-white; the crown is cinereous.

ATRATA. Shell a little convex, narrow, white with red lines, outwardly spotted with black, with elevated, convex, unequal striæ; the perforation is oblong, with a chefnut margin.

CANDICANS. Shell white, chefnut-coloured towards the margin, with twenty alternately larger ribs; the crown is reddish, with an oblong perforation.

SUCCINCTA. Shell ovate, pointed, white, above smooth, with an elevated belt in the middle, dotted with ferruginous towards the margin, with elevated unequal smooth striæ; margin denticulate.

PUSILLA. Shell flattish, white, sub-orbicular, with twenty alternately less and shorter elevated striæ; the perforation is round, and surrounded on each side with a reddish circle.

FLAVESCENS. The shell of this species is very thin, pointed, finely striate, yellowish, with six brown rays; margin denticulate; crown cinereous, with an oblong perforation.

ANTIQUATA. Shell a little convex, obsoletely striate; white with red striate rays on the outside. The perforation is oblong and unequal.

GALEATA. Shell solid, ovate, compressed, within white; crown a little recurved, obtuse, with a linear perforation; margin crenate.

PERSONATA. Shell convex, with decussate lines and black rays. It inhabits the Falkland islands.

PATELLA, in the *History of Insects*, a name given by Lister, and some others, to a certain little husk or shell, found on the bark of the cherry, plum, and rose trees, and some others, containing an animal within, and useful in colouring. These patellæ are of a globular form, except when they adhere to the tree, and are of a shining chefnut colour in most kinds. The husk itself strikes a very fine crimson colour on paper, and within it is found a white maggot of no value: this, in time, hatches into a very small but beautiful bee.

The whole size of this bee is not more than that of half the body of an ant. They have the sting of bees, and the three spots placed in a triangle on the forehead, which are supposed to be eyes. They are black, and have a large round whitish or pale yellow spot upon the back. The upper pair of wings are shaded and spotted, but the other pair are clear.

The shells or husks deserve a trial, to find whether the colour they yield might not be brought to use; it is to be observed, that the deepest coloured husks afford the finest and deepest purple: they must be also used while the creature contained in them is in the maggot form; for when it is changed into the bee state, the shell is dry and colourless. Dr. Lister, who had observed these patellæ, went so far, on comparing them with the common kermes, as to declare that they were of the same nature with that production: but this history of their being the workmanship of a bee, to preserve her young maggot in, is not agreeable to the true history of the kermes; for that is an insect of a very peculiar kind. This author has been too justly censured for his precipitancy of judging of things, and perhaps has fallen into an error by means of it here.

It is very possible that this patella may be the same sort of animals with the kermes, but then it produces its young within this shell or husk, which is no other than the skin of the body of the mother animal; but as there are many flies, whose worms or maggots are lodged in the bodies of other animals, it may be, that this little bee here described, may love to lay its egg in the body of the proper insect now mentioned, and the maggot hatched from that egg may eat up the proper progeny, and, undergoing its own natural changes there, issue out at length in form of the bee. This may have been the case in some few which Dr. Lister examined, and he may have been misled by this to suppose it the natural change of the insect. Phil. Trans. N^o 72.

PATELLA *Fera*, the *wild limpet*, a name very improperly given by Rondeletius and Aldrovand, to the *auris marina*, or *concha Veneris*. This is by no means of the patella kind. See *EAR-shell*.

PATELLARIA, in *Botany*, from *patella*, a dish with a broad brim, a name first adopted by Ehrhart, in his *Phytopyllacium*, for some of the *Lichen* tribe; and retained by Hoffmann, *Pl. Lichenosa*, v. 1. 54, for what Linnæus termed *leprosi scutellati*. Acharius, in his *Prodrromus* 36, receives it on a larger scale, so as to admit the *leprosi tuberculati*, at least in part; such as afterwards, in his *Methodus*, constituted the genus of *Lecidea*. *Patellaria* is, in that work, sunk in his multifarious genus *Parmelia*; and though its idea is restored, in his more recent *Lichenographia*, the name has given place, apparently without necessity, to *Lecanora*. See *LICHENES* and *PARMELIA*.

PATELLARII, in *Mythology*, among the Romans, placed by Plautus in the lowest clats, and called by Horace also the little gods.

PATENA, in the *Romish Church*, the cover or lid of the chalice, made of the same metal with it, serving to hold the particles of the host, and give the people to kiss, when they make an offering.

It has its name *patena*, a *patendo*; and this is a general name, in Columella, for any broad flat vessel.

PATENODE, in *Geography*, a town of the island of Ceylon, near the E. coast; 78 miles E. of Candy. N. lat. 7°. E. long. 82°.

PATENTS, or *Letters PATENT*, in *Law*, the king's letters, sealed with the great seal, serving to convey the title

title or property of some grant, favour, privilege of a new establishment, or the like. See *LETTERS Patent*.

They have their name from their being delivered open, *et pateant omnibus*; by way of contradistinction from *letters de cachet*, or *literæ clause*, or *close rolls*, which are sealed.

Grants or letters patent must first pass by bill; which is prepared by the attorney or solicitor-general, in consequence of a warrant from the crown; and is then signed, that is, superferibed at the top, with the king's own sign manual, and sealed with his privy signet, which is always in the custody of the principal secretary of state; and then sometimes it immediately passes under the great seal, in which case the patent is subscribed in these words, "per ipsum regem; by the king himself." Otherwise the course is to carry an extract of the bill to the keeper of the privy seal, who makes out a writ or warrant thereupon to the chancery; so that the sign manual is the warrant to the privy seal, and the privy seal is the warrant to the great seal: and in this last case the patent is subscribed, "per breve de privato sigillo, by writ of privy seal."

It is to be noted, that patents differ from writs: a coroner is made by *writ*, not by patent.

To this office, enacted 18 Jac. I. belongs a clerk, &c.

PATENT, Letters, under the royal authority, confer on a person the exclusive privilege of making and selling any thing, so that no person be restrained in what he had before, or in using his lawful trade. The latter part of the definition of letters patent, or of a monopoly conferred by letters patent, will apply only to such as have been granted since the statute of the 21st of James, c. 2, commonly called the statute of Monopolies; prior to that period, letters patent conferred such a monopoly as interfered with the rights of other people, and restricted the freedom of trade.

Monopoly, in the latter acceptation of the word, has already been considered under its proper head: it existed in this kingdom unrestrained till the time of king John, who first granted municipal franchises. In the 25th year of the reign of Edward III. a statute was passed, which granted a free trade equally to foreigners and natives; this statute, however, was afterwards repealed; and monopolies that not only excluded foreigners from the advantages of English trade, but also injured the English nation at large, in order that the favourites of monarchs might be rewarded, or that the crown might be enriched, were established. During the reign of queen Elizabeth, they had spread so widely over the commercial transactions of the country, as to threaten the utter ruin of trade; when a list of only part of the commodities, which had been appropriated to monopolists, was read in the house of commons, a member cried, "Is not bread in the number?" "Bread," said every one with astonishment; "yes, I assure you," replied he, "if affairs go on at this rate, we shall have bread reduced to a monopoly before next parliament." At this period, most extraordinary powers were granted to the patentees; especially to those who held the exclusive privilege of selling saltpetre; they had the power of entering every house, and of committing what havoc they pleased in stables, cellars, and wherever they suspected saltpetre might be gathered. Hume.

It might have been supposed, that such a sagacious princess as Elizabeth would have perceived the evil consequences of granting monopolies; but either the reduced state of the royal funds, or her fondness for favourites, blinded her to the true interests of her people. Towards the end of her reign, however, the clamour of the country was so loud and general, that she sent a message to parliament, that she would immediately cancel the most oppressive of the exclusive privileges she had granted.

Before proceeding to the consideration of the statute of James I. already alluded to, it may be proper very briefly to take a view of the statute law, as it respects patents prior to that period. Monopolies are expressly contrary to Magna Charta, (29, 30.) The statute of Edward III. declared all grants by monopolies void; and when Philip and Mary granted by letters patent, to the mayor, bailiffs, and burghesses of Southampton, the exclusive privilege of importing Malmsey wine at that place, the judges were unanimous in their opinion, that the statute was void, as being against the freedom of trade. The principal statutes relating to patents in the 16th, and in the beginning of the 17th century, were in the 6th of Henry VIII., the 4th of Edward VI., and the 13th and 43d of Elizabeth.

The 21st of James I. ch. 3, is regarded as the declaration statute, by which the law on this subject is determined, and the 6th section of this statute particularly relates to patents for new inventions: this section contains the exception to the general law of the statute; the general law is, that all monopolies, and all commissions, grants, licences, letters patent, &c. for the sole buying, selling, making, using, &c. of any thing, shall be void; the excepting clause declares, that the law of the statute shall not extend to any letters patent, for the term of 14 years or under, granted to the true and first inventor, or inventors of manufactures, &c. which others, at the time of making such letters patent, shall not use. Sir Edward Coke, in his explication of this statute, gives it as his opinion, that the new manufacture, to which letters patent may be granted, must not be generally inconvenient; and this construction seems to have been adopted in his time, as he says, that a patent for a fulling-mill to thicken bonnets and caps, was set aside, on the ground, that it was holden inconvenient to turn labouring men to idleness. But this construction does not prevail now, and, indeed, if it did, it would effectually defeat the object of the sixth section of the statute of monopolies.

In the letters patent which are granted for new inventions, the improvements or inventions are first stated; the prayer of the petitioner to have the exclusive benefit for himself, or his assigns, for fourteen years, is next given; and this prayer is declared to be complied with, according to the statute. After commanding all subjects not to interfere with the patent right, and issuing a mandate to all officers not to molest the patentee in the exercise of it, the letters patent declare the patent void, if it appear that the grant is contrary to law, or prejudicial to the subject; or if the thing invented have been in use before the date of the grant; or if the patentee be not the inventor; or if it interfere with prior letters patent; or if the patent be transferred to more than five persons, or to any who act as a corporate body; or finally, if the nature of the invention be not described, or the description be not enrolled within one calendar month after the date of the letters patent. The letters patent conclude with a declaration, that they shall be construed in the most beneficial sense for the patentee.

A writ of *scire facias*, to repeal letters patent, lies in three cases; 1st, when the king grants the same thing to two or more persons; 2dly, when the king is deceived in his grant; and 3dly, when the grant is against law. The following rules are laid down by chief justice Lee, respecting the cases in which mistakes do not vitiate the grant: 1. If the king's intention is manifest, a false recital in a thing not material, will not vitiate the grant. 2. It is not vitiated in cases where the king is deceived, not by the false suggestion of the party, but by his own mistake, upon the surmise and information of the party. And 3. Although the king is mistaken in point of law, or matter of fact, if that is not part

part of the consideration of the grant, it will not vitiate it.

Patents for new inventions are granted for a term of fourteen years; and any royal grant for such purpose beyond that term is void. The fourteen years are accounted to commence from the date of the first letters patent. The patent right, however, may be extended by act of parliament.

A patent may be granted for an improvement on an old manufacture; but the improvement must be material and useful; and the patent extends to the improvement only. The statute considers a manufacture brought from abroad into the kingdom (provided it has not been practised before) as a new manufacture, and entitled to letters patent. No old manufacture in use before, can be prohibited by the grant of the sole use of a new invention; nor can a patent be granted for a method, or principle; its object must be some substantial thing produced.

The following rules are laid down by judge Butler, respecting the description required in the specification, which by the patent grant, the patentee is to cause to be enrolled in the high court of chancery. The invention or improvement must be disclosed, and described in such a manner, that others of the same trade may be taught to do the same thing for which the patent is granted: 2. He must describe it in such a manner, that the public, after the expiration of the term, may have the use of the invention in as cheap and beneficial way as the patentee himself; and therefore, if the specification describes many parts of a machine, &c., and the patentee uses only a few of them, or does not state how they are to be put together, the patent is void. 3. If the specification be in any part materially false or defective, the patent is against law, and cannot be supported.

The enrolment of the specification in the high court of chancery, where it is open to the inspection of every one, enables those who are inclined to purchase the machine, invention, &c., to become acquainted with its nature and merits; and, at the same time, prevents such as are employing their skill, time, and money on improvements, or inventions of a similar nature, from merely doing what has been done before.

With respect to the form of the specification, it must be under the hand and seal of the inventor; the enrolment must take place within one calendar month after the date of the letters patent; if the patentee passes over this time, it cannot be enlarged without an act of parliament for that express purpose.

When a patentee brings an action against any person for infringing his patent, it is incumbent on him to shew, that the invention was new, and that the specification is full and complete.

It is frequently for the convenience or interest of a person, who has invented or improved a machine, &c. to delay taking out a patent for it; in this case, he may enter a *caveat*. A *caveat* will protect his invention or improvement for the space of one year, after which, if he have not brought his contrivance to maturity, he may renew it again for an equal period, and so on for any successive number of years. The caveat must be delivered at the chambers of the attorney and solicitor-general; and if an application be made for a patent for an invention of the same nature, notice is given to the person who has entered the caveat: if he requires it, the attorney-general gives a separate audience to each of the rival inventors, and makes his report to the king, according to his opinion respecting the priority of invention. A petition to the king, stating the nature of the invention, and praying letters patent, accompanied by an oath taken before

a master in chancery, that the invention is new, are the steps preparatory to taking out a patent. Separate patents must be taken out for England, Scotland, and Ireland; but in a patent for England, the patentee may, on the payment of a small additional sum, have the colonies and plantations abroad included. The petition and oath are referred by the secretary of state for the home department to the attorney-general, and on his report, recommending letters patent, his majesty issues his warrant, in consequence of which the bill is made out, which is the grant of his majesty, and of this the patent is the transcript; the nature of the specification, and the enrolment of it, have been already noticed.

Having thus considered letters patent in a legal light, we shall conclude with a few remarks on them, as a subject of political economy. It is plain from what we have stated, that they are the remains of that system of monopoly, which formerly prevailed in this and all the other countries of Europe; and so far, at first sight, they may appear objectionable. But when we consider the object for which they are granted, we shall probably be of opinion, that it takes them completely out of the force of those objections, which are so justly brought against all monopolies.

It is evident, that no man will bestow his time, ingenuity, and money, in endeavouring to invent or improve any thing, unless, when he has succeeded, he is secure in being rewarded. This reward can be secured to him, only by granting him, for a certain number of years, the exclusive privilege of his invention or improvement; or by government purchasing it from him. In the former case, while his patent right lasts, he has a monopoly; he may put what prices on his invention he pleases; or he may execute it in a careless or improper manner; but, on the other hand, the public will in a great measure be protected from too high a price, by the alternative they have, of following the old methods; and if they gain by purchasing the new invention, the price put upon it by the inventor can hardly be said to be exorbitant. With respect to his doing his work in a careless manner, the public are equally guarded against this; for by such conduct, he would act against his own interest, and the sale of his invention.

If, indeed, we could suppose that government would examine, in all cases, thoroughly, impartially, and scientifically, into the merits of every invention, it might be better for them to throw it open to the public, by rewarding the inventor, though in this case, the nation at large would pay for what directly and materially benefited only certain classes, whereas, by letters patent, those reward the inventor, whose interest it is to reward him. On the whole, therefore, the present mode is the best, with perhaps this alteration, that the letters patent should vary in their duration, according to the importance of the invention, and the money and time expended by the inventor.

PATENT of *Peerage*. See PEER.

PATENT of *Precedence*. See PRECEDENCE.

PATENT *Rolls*. See ROLLS.

PATENT *Writs*. See WRITS.

PATENT *Leaf*, in *Botany*. See LEAF.

PATENTEE, is he to whom the king grants letters patent.

PATEQUEMADE, in *Geography*, a town of the island of Cuba; 20 miles E. of Vella del Principa.

PATER, or PADER, a river of Germany, which rises near Paderborn, and runs into the Lippe, about one mile E. of Neuhans.

PATER *Patrus*, among the Romans, the first and principal person of the college of heralds, which formed a kind of board or council, to examine the differences that arose between

tween neighbouring states, and endeavour amicably to accommodate the same.

PATERA, among *Antiquaries*, a goblet, or vessel, used by the Romans in their sacrifices, in which they received the blood of their victims, offered their consecrated meats to the gods, and with which they made libations.

The word is formed from *pateo*, *I am open, quod pateat*, because it had a great aperture; in contradistinction to bottles, &c.

On medals, the patera is seen in the hands of several deities; and frequently in the hands of princes, to mark the sacerdotal authority joined with the imperial, &c.

Hence F. Joubert observes, that besides the patera, there is frequently an altar, upon which the patera seems to be pouring its contents.

The patera was of gold, silver, marble, brass, glass, or earth; and they used to enclose it in urns with the ashes of the deceased, after it had served for the libations of wine and liquors at the funeral. See *PATRA*.

The patera is an ornament in architecture, frequently introduced in friezes, fascias, and impostes, over which are hung festoons of husks or flowers; and they are sometimes used by themselves, to ornament a space; and in this case it is common to hang a string of husks or drapery over them: sometimes they are much enriched with foliage, and have a mask or a head in the centre.

PATERA, in *Geography*, a town of Asiatic Turkey, in Natolia. This town, originally called "Patara," was a city of Lycia, and famous for a temple of Apollo, said to have been equal to that of Delphos, for its oracle, magnificence, and riches, and this god is said to have divided his person between them, being six summer months at Delphos, and the six winter months at Patara. Ptolemy Philadelphus ordered it to be called "Arfinoe," but it recovered its former name, and is celebrated as the place of the martyrdom of St. Leo and St. Gregory. It was once the see of a bishop, but is now a mean place; 8 miles E. of Ekenide.

PATERCULUS, VELLEIUS, in *Biography*, a Roman historian, was descended from an ancient family in Campania, which had borne various important offices in the state. He was himself a military tribune; and served under Tiberius in Germany as commander of the cavalry, and accompanied him in all his expeditions during nine years. After having been quaestor he was nominated praetor. These are all the facts relating to the personal history of Paterculus that have come down to us. As he was the friend to Sejanus, it has been conjectured that he was involved in the ruin of that minister. Paterculus is known principally by his abridgment of the Roman History, addressed to the consul M. Vinicius, but of this work the greater part has perished, and what remains is extremely deficient, only one MS. having been discovered. The style of this author is pure and elegant. In chronology he is more exact than was customary with most ancient writers, and he has introduced many brief but curious notices of the foundation of cities and states. Few writers excel him in drawing characters, sketching, with few strokes, a striking and masterly likeness. He was the friend and adulator of Tiberius and Sejanus, and his attachment to monarchical power has biased him in his representation of the actions and characters of the republican party. The best editions of his history are those of Burmann 1719, 1744, and of Ruhmann in 1779.

PATERO. See *PADRERO*.

PATERNA, in *Geography*, a town of Spain, in New Castile; three miles E. of Alcaraz.

PATERNITY, the quality of a father.

Vol. XXVI.

PATERNO, in *Geography*, a town of Sicily, in the valley of Demona, built on the ruins of Ilybla, so celebrated for its honey. Hybla was ruined by the Saracens, who built a castle there, upon an ancient crater. The Normans erected a new building on the foundation of this ruined castle, which serves as a prison. The ruins of many baths erected here are still visible. The waters of different qualities which supplied these baths are now lost and so intermingled, as to cause the pestilential air of Paterno, which, nevertheless, contains a population of from 10 to 12,000 persons; 15 miles W. of Catania.—Also, a town of Naples, in Principato Ultra, three miles N. of Monte Marano.

PATER-NOSTER, the Lord's prayer, a form so called from the two initial words thereof in Latin.

PATER-NOSTER is also used for a chaplet or string of beads; because serving to number the rehearsals of that prayer.

PATER-NOSTERS, in *Architecture*, a sort of ornaments cut in form of beads, either round, or oval; used on baguettes, astragals, &c.

PATER-NOSTERS, in *Geography*, rocks in the Atlantic, on the S. side of the entrance into the bay of St. Helena. S. lat. 32° 20'.—Also, rocks near the N. coast of the island of Jersey.

PATER-NOSTERS, *Little*, a cluster of thirteen rocks in the East Indian sea, between the islands of Borneo and Celebes, called by the Malays, "Pulo Balabataken." They are covered with trees, and have navigable channels between them.

PATER-NOSTERS, *Great*, a cluster of shoals and islets in the East Indian sea, about 120 miles long from N.E. to S.W. and 30 broad. S. lat. 6° 30' to 7° 42'. E. long. 117° 10' to 119° 10'.

PATER-NOSTRE', in *Heraldry*. A cross pater-nostre is a cross made of beads. This cross is to be so shadowed in drawing, as that the sphericity of the beads may appear, to distinguish them from besants.

PATERSONIA, in *Botany*, very deservedly named by Mr. R. Brown in honour of his friend colonel William Paterson, a gentleman to whose researches at the Cape of Good Hope many years ago, and more recently in Norfolk Island, as well as New South Wales, of which last settlement he has long been lieutenant-governor, botany is much indebted. Brown Prodr. Nov. Holl. v. 1. 303. Ker in Curt. Mag. v. 26. 1041. Ait. Hort. Kew. ed. 2. v. 4. (Genofiris; Labill. Nov. Holl. v. 1. 9?)—Class and order, *Monadelphia Triandria*. Nat. Ord. *Ensatæ*, Linn. *Irides*, Juss.

Gen. Ch. *Cal.* Sheath many-flowered, of two compressed, keeled, rigid leaves, embracing each other, with numerous inner membranous scales, separating the flowers. *Cor.* of one petal, salver-shaped, regular; tube very slender, about as long as the sheath; limb in six deep segments, three of them very large, ovate, horizontal, the three alternate ones very small, erect. *Stam.* Filaments three, united into a tube nearly all the way up, longer than the shorter segments of the corolla; anthers erect, oblong. *Pist.* Germen within the sheath, below the corolla, angular; style capillary, about as long as the stamens, generally swelling towards the top, contracted at the apex; stigmas three, dilated, somewhat hooded, undivided. *Peric.* Capsule membranous, prismatic, with three blunt angles, three cells and three valves. *Seeds* numerous, roundish.

Eff. Ch. Sheath of two leaves. Three inner segments of the corolla equal, minute, erect. Filaments distinct at the top. Stigmas dilated, undivided.

Obf. There can fcarcely be a doubt that this is the fame genus which Labillardiere calls *Genofiris*, however incorreétly he may have defcribed it; happily however his name for it is exceptionable, being compounded of an eftablifhed one, *Iris*.

The fpecies known are feven, all perennial herbaceous fibrous-rooted plants, with either none, or a fhort, moftly fimple, *ftem*. *Leaves* fword-shaped, narrow and compact. *Flower-ftalk* either radical, or terminal, fimple, naked. *Flowers* coming out in fucceffion, handfome, but very fhort-lived, blue, without fpoats. *Anthers* and *ftigmas* yellow. *Capsules* nearly feffile, invefted with the theaths. *Seeds* ufually infered into the inner angle of the cell; fometimes into a central column.—The fpecies, as far as known, are all natives of New Holland, moftly without the tropic, growing in open, barren, ftony or fandy places, near the fhore; rarely in moift meadows.

1. *P. fericea*. Silky Paterfonia. Curt. Mag. t. 1041. —Stigmas deflexed. Sheath, and upper part of the ftalk, filky. Leaves ftraight, finely fringed, doubly ftriated, woolly at the bafe of their keel.—Native of the country about Port Jackfon, as well as of the tropical part of New Holland. It was one of the firft plants of which fpecimens were fent to England by the fettlers. Mefirs. Lee and Kennedy raifed it from feed, and it flowered with them in 1807, being kept in the greenhoufe. The *leaves* are feveral, erect, narrow, rigid, and elastic, about a foot high, in two ranks. *Flowers* violet, not unlike *Tradefcantia virginica* at the firft glance, but rather larger, without fcent.

2. *P. lanata*. Woolly Paterfonia.—Stalk round, ftriated, longitudinally woolly, as well as the fheath. Leaves flightly convex, fimplly ftriated; woolly at the bafe.—Obferved by Mr. Brown, in the fourth part of New Holland. The *ftigmas* were not remarked.

3. *P. longifolia*. Long-leaved Paterfonia.—Stigmas deflexed. Sheath and ftalk filky. Leaves linear, narrow, many times longer than the ftalk; fringed below the middle with fpreading or inflexed hairs.—From Port Jackfon.

4. *P. media*. Intermediate Paterfonia.—Stigmas deflexed. Inner fegments of the corolla but one-fourth as long as the tube of the ftamens. Sheath filky. Flower-ftalk fmooth, longer than the ftem. Keel of the leaves woolly at the bafe.—From Port Jackfon.

5. *P. glabrata*. Smooth Paterfonia.—Stigmas deflexed. Inner fegments of the corolla half as long as the tube of the ftamens. Flower-ftalk longer than the ftem, very fmooth and fhining, like the fheath. Keel of the leaves woolly at the bafe.—From the fame country.

6. *P. glauca*. Glaucous Paterfonia. (*Genofiris fragilis*; Labill. Nov. Holl. v. 1. 13. t. 9.)—Stigma erect. Style flightly thickened at the top. Sheath about three-flowered, ftriated, fmooth. Leaves linear, rather convex, naked at the edges and bafe, twice as long as the fender, thread-shaped, fmooth ftalk.—Gathered by Labillardiere, in Van Diemen's land; by Mr. Brown near Port Jackfon. The *leaves* are enveloped at the bafe by numerous fhorter leaf-like feales. *Corolla* blue, rather fmall than in *P. fericea*.

7. *P. occidentalis*. Weft-coaft Paterfonia.—Stigma erect. Style of equal thicknefs throughout. Sheath about five-flowered, even. Stalk very fmooth, as long as the fword-shaped leaves, which are naked at the edges and bafe.—Native of the fouth-weft coaft of New Holland, where it was gathered by Mr. Brown, to whole work we are indebted for the fpecific diftinétions of all the fpecies.

PATETHISÆ UVÆ, a name given by the ancients to grapes which were fuffered to remain on the vine till they

were greatly dried and withered. They were alfo called *patete uvæ*, and were fuffered to hang thus to make a peculiar wine called *passum*.

PATGONG, in *Geography*, a town of Hindooftan, in Bengal; 120 miles W. of Beyhar.

PATH, in *Rural Economy*, a track or road acrofs a field: a path acrofs arable land is as great a lofs as a crooked hedge, and fhould always be avoided as much as poffible, both in arable and pature grounds, in the laying them out at firft, where they are directed, on the inclofing of wafte or other lands.

PATH of the *Vertex*, a term frequently ufed by Mr. Flamfteed, in his doctrine of the fphere, fignifying a circle, defcribed by any point of the earth's furface, as the earth turns round its axis.

This point is confidered as vertical to the earth's centre; and is the fame with what is called the vertex or zenith in the Ptolemaic projeétion.

The femi-diameter of this path of the vertex is always equal to the complement of the latitude of the point or place that defcribes it; that is, to the place's diftance from the pole of the world.

PATH fly, the name given by us to the fly called in Latin *humifuga*; it is found in foot-paths, and fuppofed to live by fucking the ground; it is of a grey colour, ftreaked with duiky white.

PATHETIC, παθητικός, from παθος, *paſſion*, *emotion*, fomething that relates to the paſſions; and particularly that is proper to awake or excite them.

In *oratory*, pathetic is applied to that part of a difcourfe, or to that mode of expreffion, that is immediately addreffed to the *Paſſions* (which fee), and which feems to render it interefting and impreffive. In this part of a difcourfe, if any where, eloquence reigns, and exerts its power. On the head of the pathetic, Dr. Blair has laid down the following ufeul direétions. It fhould *firft* be confidered whether the fubjeét admit of the pathetic, and render it proper; and if this be the cafe, in what part of the difcourfe it fhould be attempted. An attempt to excite the paſſions in a wrong place, may expoſe an orator to ridicule. He fhould be careful, in the firft place, to bring over to his fide the underftanding and judgment; otherwife he is not likely to produce any beneficial or permanent effect. That the emotion may not only remain, when he ceafes to ſpeak, moft writers aſſign the pathetic to the peroration or conclufion, as its natural place; and when all other things are equal, this is the impreffion that one would chooſe to make laſt, leaving the minds of the hearers warmed with the fubjeét, after argument and reaſoning had produced their full effect. But wherever the pathetic is introduced, it is recommended, *ſecondly*, never to fet apart a head of a difcourfe, in form, for raifing any paſſion; never to give warning that you are about to be pathetic, nor to call upon your hearers to follow you in the attempt. This almoſt never fails to prove a refrigerant to paſſion. The indireét method of making an impreffion is likely to be more fucceſsful. This may often be done more happily, in a few inſtances inſpired by natural warmth, than in a long and ſtudied addreſs. *Thirdly*, it fhould be confidered, that there is a great difference between ſhewing the hearers that they ought to be moved, and aétually moving them. To every emotion or paſſion Nature has adapted a fet of correſponding objects; and without ſetting theſe before the mind, it is not in the power of any orator to raife that emotion. The foundation of all fucceſsful execution in the way of pathetic oratory, is to paint the object of that paſſion which we wiſh to raife, in the moſt natural and ſtriking manner; to deſcribe it with ſuch circumſtances

circumstances as are likely to awaken it in the minds of others. Every passion is most strongly excited by sensation; next to the influence of sense is that of memory; and next to memory is the influence of the imagination. Of this power, therefore, the orator must avail himself, so as to strike the imagination of the hearers with circumstances, which, in lustre and pleasingness, resemble those of sensation and remembrance. For this purpose, *fourthly*, the only effectual method is to be moved yourselves. The inward emotion of the speaker adds a pathos to his words, his looks, his gestures, and his whole manner, which exerts a power almost irresistible over those who hear him. *Fifthly*, it is necessary to attend to the proper language of the passions. We should observe in what manner any one expresses himself who is under the power of a real and strong passion; and we shall always find his language unaffected and simple. It may be animated, indeed, with bold and strong figures, but it will have no ornament or finery. He is not at leisure to follow out the play of the imagination. A person who takes time to polish and adorn his style, will infallibly cool his own ardour; and then he will touch the heart no more; his composition will become frigid; and it will be the language of one who describes but who does not feel. Although he may amuse the fancy, he will not reach the heart. In the former case, labour may appear; but the latter must be the work of nature only. *Sixthly*, nothing of a foreign nature should be interwoven with the pathetic part of a discourse. All digressions must be avoided; beauties must be sacrificed; comparisons are always dangerous, and generally quite improper, in the midst of passion. Reasoning is unseasonable, especially if it be pursued in a long and subtle train, when the principal aim is to excite warm emotions. Lastly, the pathetic should not be prolonged too much. Warm emotions are too violent to be lasting. Study the proper time and mode of making a transition from the passionate to the calm, recollecting a maxim, which, though trite, is just, that nothing dries up sooner than a tear. Beware, therefore, of straining passion too far, and of raising it to unnatural heights, as well as of prolonging its duration. Dr. Blair, to whose "Lectures" (vol. ii.) we refer for the illustration and application of these rules, closes with setting before his readers the example of Cicero in his last oration against Verres, wherein he describes the cruelty exercised by Verres, when governor of Sicily, against one Gavius, a Roman citizen. But our limits forbid our enlarging. See PERORATION and STYLE.

PATHEIC, in *Music*. The general import of this word, which is purely English, is so well known, as seemingly to need no explanation; yet, to render music pathetic, so many circumstances must concur, that it has been thought necessary by Rousseau to point them out. The poetry, the musical composition, the figure, countenance, tone of voice, expression, and situation of the character represented, must all combine to produce the full effect of a pathetic air. All are requisite in dramatic and theatrical music, which tend to move and paint the great passions, particularly those of grief and sorrow.

All the expression which the French can give to pathetic airs, is to drag, reinforce the notes, and howl; and in so slow a movement, that all sentiment of measure is effaced. Hence the French think, that whatever is slow is pathetic, and all that is pathetic ought to be slow.

They have airs which become gay and playful, or tender and pathetic, as they happen to be sung quick or slow. Such is the advantage of French melody; it serves for whatever they please: *fiet avis, et, cum volet, arbor*.

But Italian music has not the same advantages. Each song,

each melody, has its distinct character so strongly impressed on it, that it is impossible to destroy the pathos of its accent and melody, which is felt in all measures, even in those the most lively. French airs change their character, as the time is accelerated or retarded. Each Italian air has its movement so determined, that it cannot be altered without annihilating the melody. An air thus disguised, does not change its character, it loses it; it is no longer melody, it is nothing.

If the pathetic character is not in the movement, we cannot say that it is in the genus, the melody, or the harmony: as there are pieces equally pathetic in the three genera, the three modes, and all the harmony imaginable. The true pathetic is in the accents of passion, which are not to be taught by rule; but let genius find, and the heart feel, without applying to art to give the law.

Nieuwentyt tells us of a musician at Venice, who excelled in the pathetic to that degree, that he was able to play any of his auditors into distraction; he adds, that the great means he made use of was the variety of motions, &c.

PATHEICUS, in *Anatomy*, a name given by some anatomists to the nerve of the fourth pair, or nervus trochlearis. See NERVE.

PATHEICHEAD, in *Geography*, a considerable manufacturing town in the parish of Dyfart, and county of Fife, Scotland, is situated on the acclivity of a hill, looking towards the Frith of Forth, at a short distance to the north-eastward of the ancient burgh of Kirkcaldy. It is divided into two parts, one called Dunnikier, and the other Sinclair-town, from the estates on which they happen to be respectively placed. Formerly Pathhead was noted for the number of its nail manufactories; but these have now considerably declined, and the inhabitants are chiefly engaged in different branches of weaving. There is no regular market held in this town; but it has the privilege of a large annual fair for woollen and linen cloths. According to the parliamentary returns of 1811, it contains 237 houses, and 1692 inhabitants.

On a free-stone rock, which projects into the Frith immediately below Pathhead, stand the venerable ruins of Riven's, or Raven's-Craig castle, which was granted, with the neighbouring lands, by James III. of Scotland, to William St. Clair, or Sinclair, earl of Orkney, on his resignation of that title. During the time of the commonwealth it was garrisoned by a party of Cromwell's troops, but is now uninhabitable. Beauties of Scotland, vol. iv. Sinclair's Statistical Account, vol. xviii.

PATHEICGNOMONIC, in *Medicine*, from *παθος*, a disease, and *γνωσκω*, I know, an epithet signifying that a symptom, or concurrence of symptoms, to which it is applied, is inseparable from, or exclusively characteristic of, a particular disease, and found in no other. There is, perhaps, no disease in which any single symptom can be strictly said to be pathognomonic; but the concise definitions of diseases given by the nosologists, should exhibit the congeries of symptoms which are pathognomonic. Thus the *four symptoms*, "fever, cough, dyspnoea, and pain in the chest," which constitute Dr. Cullen's definition of pneumonia, are the pathognomonic symptoms of inflammation of the lungs. See NOSOLOGY.

PATHEICLOGY, from *παθος*, a disease, and *λογος*, a discourse, signifies the science or doctrine of diseases.

As *Physiology* teaches the nature of the functions of the living body in a state of health; so *Pathology* relates to the various derangements of these functions, which constitute disease. Its objects, therefore, are to ascertain the various symptoms which characterise the different disorders of each

organ of the body, and especially the *diagnostic* and *pathognomonic* symptoms, which afford the means of discrimination between diseases that resemble each other; to determine the causes, both predisposing and exciting, by which diseases are induced; to point out the *prognosis*, or the tendency and probable event of each disease, from the changes and combination of the symptoms; and, lastly, to teach the *indications of cure*, and the nature and operation of the remedies adapted to the various circumstances and periods of diseases.

The general doctrines of pathology, however, we have already anticipated, under the head of DISEASE, an article of more popular reference. See also CAUSE, in *Medicine*; and NOSOLOGY, under which a classification of diseases will be found.

PATHOS, *πάθος*, *passion*, a term frequently used in speaking of the movements which the orator excites in his audience.

We sometimes also use the word for energy, or strength.

PATI, in *Geography*. See PATTÀ.

PATIA, a river of South America, which rises near Popayan, and runs into the Pacific ocean, N. lat. 2° 13'.

PATIALA, a town of Hindoostan, in the circar of Sirhind; 12 miles S.W. of Sirhind. N. lat. 30° 18'. E. long. 76° 5'.

PATIENCE, in *Botany*, the name by which some people call the monk's rhubarb; but the French, from whom we have borrowed the word, mean by it all the species of the *lapathum* or dock kind.

PATIENCE, in *Ethics*, is that virtue which preserves the mind firm and unbroken, under the evils of life; so that the spirits are kept from becoming tumultuous, and precipitating the sufferer into indecent or repining thoughts, words, or actions; and by which he is disposed to pay calm attention to the reasons of sacred philosophy, and to observe them.

PATIENCE, in *Geography*, a small island near the coast of America, in Naragansett bay, belonging to the state of Rhode island.

PATIENT, among *Physicians*, a person under the direction of a physician, or surgeon, to be cured of some disease.

Agent and PATIENT. See AGENT.

PATIENTIA, *Straits of*, in *Geography*, a channel of the East Indian sea, between the island of Bachian, and the S. coast of Gilolo.

PATIENTIÆ MUSCULUS, in *Anatomy*, the levator scapulae, so called, because it was supposed to be principally concerned in shrugging up the shoulders. See LEVATOR.

PATIMA, in *Botany*, a genus so named by Aublet from its Caribbean name, *Patima-rana*. Aubl. Guian. v. 1. 197. t. 77. Juss. 207. Lamarck Dict. v. 5. 70. Illustr. t. 159. —Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, the limb with about five incisions. *Cor.* and *Stam.* unknown. *Pist.* Germen inferior, firmly united to the bottom of the calyx; style and stigma wanting. *Peric.* Berry green, roundish, crowned with the margin of the calyx, of four, five, or six cells. *Seeds* numerous, very small, imbedded in soft pulp.

Obf. Jussieu and Lamarck observe, that, although Aublet was unacquainted with some parts of the flower of this plant, yet he has shewn enough to satisfy them that it must be monopetalous, and of the natural order of *Rubiaceae*.

Ess. Ch. Calyx superior, almost entire, of six obtuse angles. Berry crowned by the calyx, mostly five-celled, many-seeded.

1. *P. guianensis*. Aubl. Guian. t. 77.—Native of low

marshy places in Guiana, bearing fruit in May. — *Root* perennial. *Stems* numerous, shrubby, erect, three feet high, tubular, cylindrical. *Leaves* opposite, on long stalks, very large, ovate-oblong, acute, smooth, entire. *Stipulas* intra-foliaceous, in pairs, short, acute, permanent, at the base of the footstalk. *Fruit* axillary, consisting of green berries, on longish solitary stalks.

PATIN, GUY, in *Biography*, a physician distinguished for his wit and learning, was born at Hodenc, in Bray, near Beauvais, in August, 1601. His parents being in humble life, though respectable, his first views were not very elevated. He was employed for some time in a printing-office at Paris, as corrector of the press, where his abilities gained him the esteem and friendship of Riolan, a celebrated physician. In consequence of this connection, he was led to turn his attention to medicine, and took the degree of doctor in that faculty in 1627, and was admitted a member of the Parisian body. He continued to reside as a practitioner in that metropolis, where he was more esteemed, however, for his learning, and the satirical vivacity of his conversation, than for his medical skill. Indeed, he was too much attached to personal independence to push his way at court or among the great, yet he had many persons of distinction among his friends, particularly the president de Lamoignon, who enjoyed his society as the greatest relaxation from the labour of public business. Patin was, however, very zealous for the maintenance of the honours and privileges of his faculty, and was elected dean in the two successive years 1650 and 1651; and, soon afterwards, was appointed successor to Riolan the younger, in the chair of medicine at the College Royal. He expressed himself in Latin with so much fluency and elegance, that his theses became the centre of attraction to the fashionable idlers of Paris. He was a great opponent of all innovations in medicine, but more especially of the doctrines and drugs introduced by the chemical physicians; and he pursued a violent course in the dispute, which at that time agitated the physicians of Paris, respecting the virtues of antimony. He was even profuse in his personalities against all who defended that medicine, and drew up a long register of the unsuccessful cases in which it had been employed, which he called the *Antimonial Martyrology*. He derided, however, the complicated and costly compounds and specifics, which the generality of practitioners were in the habit of prescribing; and was of opinion, that by means of the lancet and purgatives, and a few simple expedients, every thing within the power of the healing art might be accomplished; a rational and just view of the subject, if it had not been perverted by other false theories, and by strong prejudices with respect to bloodletting, and some particular articles of medicine.

This learned physician died in 1672, in the seventy-first year of his age. He had read much, and had collected an extensive and valuable library, with the contents of which he was well acquainted: but he wrote few works in his own profession, and these of little importance. He had projected a history of celebrated physicians, but this he never accomplished. After his death a great number of his letters were published, which have been the chief means of preserving his memory. Of these there are two collections; one addressed to various friends, printed in 1685 and 1692, two volumes 12mo; the other all written to his friend Charles Spon, of Geneva, and published by that family in 1718, two volumes 12mo. Patin's letters are an amusing miscellany of political and literary intelligence, biographical anecdotes, free opinions, medical history and criticism, with a plentiful mixture of spleen and sarcasm. It is difficult to say whether he lashes most severely the court and ministry, the clergy, or the chemical

mical doctors; but the pictures which he gives of the manners and sentiments of the time are in most respects equally just and lively. Eloy Dict. Hist. Gen. Biog.

PATIN, CHARLES, a physician and distinguished antiquary, was the second son of the preceding, and was born at Paris, in February, 1633. His father educated him with great care, and he made a very extraordinary progress in learning, having, at the age of fourteen, sustained theses on philosophy in Greek and Latin, before a large and splendid audience, at which there were thirty-four bishops present, besides many other persons of distinction. He was intended to be brought up to the bar, and even became a licentiate in law at Poitiers, and afterwards an advocate in the parliament of Paris: but he afterwards abandoned the profession of the law, and chose that of physic, in which he took the degree of doctor in 1656. He had not only begun to practise with reputation and success, but had also taught in the schools of the faculty of Paris, when he was obliged to quit France, from the fear of imprisonment. The cause of this disgrace is somewhat doubtful. By some it has been said, that, having been sent into Holland by a great prince, in order to buy up all the copies of a work of court scandal, and burn them on the spot, he saved a number of them, and dispersed them among his friends. His father, however, in one of his letters, lamenting his son's misfortune, gives no hint of such a fact, but mentions the discovery of some obnoxious books in his library. After spending a few years in travelling through Holland, England, Germany, and Switzerland, to Italy, he at length settled with his family at Padua, where he soon acquired the public esteem. In 1676, he was appointed to an extraordinary professorship of medicine in that university; and in 1681, he was transferred to the first chair of surgery; and ultimately, in 1683, to that of medicine. He fulfilled the duties of these stations with so much distinction, that the republic of Venice conferred on him the dignity of a knighthood of St. Mark. He was also elected a member of the *Academia Naturæ Curiosorum*, and he was for a long time chief and director of the Academy of the *Ricovrati*. He died at Padua, on the second of October, 1693. He left a considerable number of learned works, amounting to nearly 40, in the Latin, French, and Italian languages. Few of these relate to medicine, and those only in the form of detached orations; such as "Oratio Inauguralis de optima Medicorum Sectâ," "Oratio de Febribus,"—"De Avicenna,"—"De Scorbuto," &c. The works by which he is best known, relate to the numismatic, or medallic science, in which he was a great proficient. The following are upon that subject. "Familia Romanæ ex antiquis numismatibus ab urbe condita ad tempora D. Augusti," 1663, folio. This is chiefly founded on the work of Fulvius Ursinus. "Introduction à l'Histoire par la Connoissance des Medailles," 1665, 12mo. "Imperatorum Romanorum Numismata," 1671, folio. "Thesaurus Numismatum," 1672, 4to. "Practica delle Medaglie," 1673, 12mo. "Suetonius ex Numismatibus illustratus," 1675, 4to.; and some other pieces. In the way of medical biography, he published the lives of the professors of Padua, with the title of "Lycæum Patavinum, sive Icones et Vitæ Professorum Patavi, anno 1682, docentium." Pat. 1682, 4to.

The wife and two daughters of Charles Patin were learned women, and all members of the Academy of *Ricovrati*, at Padua, in which they distinguished themselves. Charlotte-Catherine, the eldest daughter, pronounced a Latin oration on the raising of the siege of Vienna, and published "Tabellæ selectæ," which contained an explanation of forty-one engravings from the most celebrated painters. Gabrielle-Charlotte, the youngest daughter, published a panegyrical

oration on Louis XIV., and a Latin dissertation on the phoenix on a medal of Caracalla, Venice, 1683. His wife was author of a collection of moral and Christian reflections. Eloy Dict. Hist. de la Med. Gen. Biog.

PATIN-Shoe, in the *Manege*. See **PATTEN-Shoe**.

PATINA, a name given to the rust of medals. See *Conservation of MEDALS*.

This rust, which, when genuine, gives value to medals, is sometimes counterfeited, and a false patina is substituted for that which is true. The false varnish is black, greasy, and shining, besides being very tender when touched with a needle or burin; while the ancient has none of these qualities, and is as hard as the coin itself. Sometimes, says Mr. Pinkerton, a light-green coat-like varnish is given, spotted with a kind of iron marks. It is made of sulphur, verdigris, and vinegar; and is often distinguished, among other marks, by hair-strokes of the brist with which it was laid on. Vico, cited by Pinkerton, gives the following hints concerning false patina. He says it is green, black, russet or brown, grey, and iron-colour. The green is made with verdigris; the black is smoke of sulphur; the grey is formed of chalk steeped in urine, in which the coin is left for some days. The russet is next to the natural, because it is a kind of froth which the fire forms from ancient coins; but when false it is too shining. To make it, they often take the large brass coins of the Ptolemies, because they are frequently corroded, and making them red-hot in the fire, put the coins upon them; and there adheres a fine patina. The process of iron colour Vico does not explain. Sometimes, he adds, they take an old defaced coin, covered with real ancient patina, and stamp it anew; but the patina is then too bright in the cavities, and too dull in the protuberances. It may further be observed, that the trial of brass coins with the tongue is not to be despised; for, if modern, the patina tastes bitter, or pungent; while, if ancient, it is quite tasteless.

PATINO, in *Geography*, an island in the Grecian Archipelago, which was the ancient Patmos. See **PATMOS**.

PATINOON, a town of Hindoostan, in Marawar; 72 miles N.W. of Ramanadporum.

PATIOQUA, a town of Mexico, in the province of Guaxaca; 63 miles S. of St. Yago de los Valles.

PATIS, in *Ornithology*, the name of a small sea-bird, described by Ovidius, and seeming to be the same with the storm-fink, described by Hoier, in his epistle to Clusius. It is a little larger than our sparrow, and skims the surface of the water very nimbly, and is supposed a forerunner of storms.

PATIXA, or *Grande River*, in *Geography*, a river of Brazil, which runs into the Atlantic, S. lat. 15° 50'.

PATKUL, JOHN REINHOLD, in *Biography*, was born of a noble family in Livonia, a northern province belonging to the crown of Sweden. The Livonians having been stripped of their privileges, and great part of their estates, by Charles XI., Patkul was deputed to make their complaint; which he did with such eloquence and courage, that the king, laying his hand upon his shoulder, said, "you have spoken in behalf of your country as a brave man, and I esteem you for it." Charles, however, who added the baseness of hypocrisy to the ferocity of a tyrant, was determined to punish the zeal and honesty which he had just before applauded, and in a very few days afterwards caused Patkul to be declared guilty of high treason, and condemned him to death. The hero, however, found means to escape into Poland, where he continued till Charles was dead. He now hoped that his sentence might have been reversed, but being disappointed in this expectation, he applied to Augustus, king of Poland, and solicited

cited him to attempt the conquest of Livonia from the Swedes; which he said might be easily effected, as the people were ready to shake off their yoke; and the king of Sweden, being a child, was incapable of compelling their subjection. Augustus took the hint, possessed himself of Livonia, and afterwards, when Charles XII. entered the province to recover it, Patkul commanded in the Saxon army against him. Charles was victorious, and Patkul entered into the service of the czar of Russia, with whom Augustus was in strict alliance. The czar sent Patkul, with the title of his ambassador, into Saxony, to prevail with Augustus to meet him at Grodno, that they might confer on the state of their affairs. This conference took place, and immediately afterwards the czar went from Grodno to quell a rebellion in Astracan. As soon as the czar was gone, Augustus, to the surprise of all Europe, ordered Patkul, who was then at Dresden, to be seized as a state criminal. The czar claimed him as his ambassador, and Charles demanded that he should be put into his hands. The latter obtained his wish, and cruelly put him to death, in the year 1707. Charles XII. has been generally censured for not extending to him his mercy, but it must not be forgotten that Patkul had incited foreign powers to attack his country when the king was a mere child, hoping that, under such circumstances, it would become an easy conquest. It has been said also in behalf of the king, that this is the only instance of his cruelty, and that in ordering the execution of Patkul he thought he was doing his duty. Nothing, however, can palliate the unfeeling barbarity of putting the veteran to the rack. The monarch was one of the credulous philosophers of the time, who believed in the possibility of discovering the methods of transmuting the baser metals into gold. Patkul, while under sentence of death, contrived so far to impose on the senate at Stockholm, as to persuade them that he had, in their presence, converted to gold a quantity of less precious metal. An account of the experiment was transmitted to the king, accompanied with a petition for the life of so valuable a subject; but Charles, blending magnanimity with severity, replied, that he would not do that for interest which he had refused at the call of humanity and the intreaties of friendship.

PATLADAH, in *Geography*, a circar of Bengal, bounded on the N.E. by Curriharry, on the S. and S.E. by Dacca, and on the W. by Goragot and Islamabad; about 30 miles long, and 16 broad. The chief towns are Chilmay and Dewangunge.

PATMOS, in *Ancient Geography*, an island in the Grecian archipelago, now denominated by navigators "St. Jean de Patino," celebrated in ecclesiastical history, on account of its being the place of St. John's exile, and still more from the revelations and visions which he received there, and which form the subjects of the Apocalypse, or Revelation, exhibits little more than arid rocks and numerous capes. Some Caloyers, or Greek monks, who inhabit a monastery built on an eminence, still shew the grotto where the sacred writer received his communications and wrote his book. But in this convent there is no library, and, indeed, it would be of little use, as among the 80 monks who reside there, three only were found who could read, and they made little use of their scanty knowledge. This island is little more than six leagues in circuit; considerably longer than broad, its direction being from N. to S., and its form very irregular. Its coasts are intersected by a variety of gulfs and coves, and are remarkable for the number of good harbours which they present to navigators, among which that of "Scala" is one of the finest in the Archipelago. But notwithstanding the advantages which these harbours might afford it as a place of trade, it presents to the view of the observer a very wretched

appearance. Vallies, which might insure abundance, are uncultivated, and from their state of abandonment and nakedness, offer, with the hills that surround them, only the same aspect of ruggedness and misfortune. Population, which follows in the train of agriculture and industry, is here singularly diminished, and while the monasteries swarm with sluggards, the fields become deserts. In the summer few men remain here; they all migrate to a distance to seek means of subsistence, or carry on with their caiques, a traffic which feeds, but does not enrich them. The women remain intrusted with domestic cares, and to make the most of a few pieces of land during the absence of their fathers or husbands; and that timid tribe hide or shut themselves up when they see strangers land in their island. Such is the account given of this desolate spot by Sonnini. Although it is destitute of wood and rivers, and almost without gardens, its spring-water is pure and its air healthy. The inhabitants are chiefly Greek Christians, sailors or ship-builders, who sail as far as Venice, whither they carry cotton and stockings of their own manufacture. The island abounds with rabbits, pigeons, partridges, and quails. The abbot of the convent already mentioned is prince of the island, and pays annually 1000 crowns to the grand seignor, besides presents to the captain pacha: 16 miles S.W. of Samos. N. lat. $37^{\circ} 24'$. E. long. $26^{\circ} 24'$.

PATMOUR, in *Geography*, a town of Hindoostan, in Golconda; 25 miles N.N.E. of Rachore.

PATNA, a very ancient city of Hindoostan, erected on or near the site of Pataliputra, or Patelpoo'ther, afterwards denominated Palibothra. This is the chief city of Bahar, and is very extensive and populous; built along the southern bank of the Ganges, about 400 miles from Calcutta, and 500 from the mouth of the river. As it is seated on an eminence, it is secure against the inundations, which, at particular seasons, are prejudicial and dangerous. Having been often the seat of war, it is fortified in the Indian manner with a wall and a small citadel. It is a place of very considerable trade. Most of the saltpetre imported by the East India company is manufactured within the province of Bahar. N. lat. $25^{\circ} 37'$. E. long. $85^{\circ} 21'$.

PATNA, a town of the province of Bukovina; 30 miles W. of Sucava.—Also, a river of Moldavia, which runs into the Milebow, at Foedna.

PATNOURA, a town of Hindoostan, in the circar of Kerieh; 55 miles N.W. of Maltoy.

PATOKA, a town of Hindoostan, in Dowlatabad; 30 miles N.W. of Darore.

PATOMA, a river of Russia, which runs into the Lena, N. lat. $59^{\circ} 53'$. E. long. $116^{\circ} 24'$.

PATOMACK. See **PATOWMACK**.

PATONCE, in *Heraldry*. A cross patonce is a cross flossy at the ends; from which it only differs in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the patee form. He bears gules; a cross patonce, argent; by the name of Latimer.

PATOOK, or **PURTOCK**, in *Geography*, a river of Honduras, which runs into the bay, N. lat. $15^{\circ} 55'$. W. long. $84^{\circ} 25'$.

PATOS, a river of Brasil, which runs into the Atlantic, S. lat. $28^{\circ} 28'$.—Also, a town of Mexico, in the province of Zacatecas; 80 miles N. of Zacatecas.

PATOU, a town of Hindoostan, in the circar of Aurungabad; 45 miles E. of Aurungabad.

PATOUAL, a town of Hindoostan, in Baglana; 18 miles S.E. of Bahbelgong.

PATOWMACK, a large river of America, which rises by two branches, the northern and southern, originating in and

and near the Alleghany mountains, and forms, through its whole course, part of the boundary between the states of Virginia and Maryland. It passes by many flourishing towns, the chief of which are Shepherdstown, Georgetown, Washington city, Alexandria, New Marlborough, and Charlestown, or Port Tobacco. It is seven miles and a half wide at its mouth, and its soundings are seven fathoms. The distance from the capes of Virginia to the termination of the tide-water in this river, is above 300 miles, and it is navigable for ships of the greatest burden through nearly that distance; and the inland navigation it affords is much extended by the numerous and long rivers that run into it.

PATQUASHAGAMA LAKE, a lake of Canada, 450 miles W. of Quebec. N. lat. 48° 20'. W. long. 82° 5'.

PATRA, a town of Hindoostan, in Guzerat; 18 miles N.N.E. of Amood.

PATRA, a vessel of capacity among the Hindoos, to which, under a mythological aspect, a great deal of mysticism is attached. It is seen in the hand of Parvati, and of some other deities of avenging character, in the shape of a small basin or cup, and is said to be for the purpose of receiving the blood of her victims, which she is poetically represented to quaff. The patra is, however, still more mystically contemplated in India, as an emblem or type of the world, and is then called Argha-patra. The argha means a cup or dish, in which fruits or flowers are offered to the deities, and ought to be shaped like a boat, as some are still seen, but more usually of a round form. A rim round the argha represents the mysterious Yoni, and a boss or convexity in the centre refers to the navel of Vishnu, whence, according to some popular fables, the creative Brahma sprang on a lotos to perform his great work. We shall here notice no farther on this point than the coincidence of wild umbilical mysteries common to the mythologists of India, Egypt, and Greece. Such mythological coincidences are striking and curious, and we shall proceed to notice some connected with the subject of this article. The name, form, and use of it as a drinking vessel, or for oblation, reminds us at once of the patera of the ancients. See PATERA.

Invol. xiv. of the *Archæologia*, a description and plate are given of a Roman patera and vase dug up when sinking a ditch in Essex in June 1800. They were found near an ancient Roman road between Camulodunum and Camboritum. "The metal vase and patera merit attention, as none similar to the first have been figured or described in the works of the society; nor do I know that any like either have been presented for their inspection. The vase is of that form which Montfaucon has figured in his 2d vol. pl. 19. fig. 10, and calls a præfericulum, used by the Romans at their sacrifices, for pouring wine into the patera. See p. 88, where he controverts Festus's opinion that the præfericula were without handles. Another more nearly resembling that here presented is given in his 3d vol. pl. 24. fig. 9, and called by Beger an epichysis, but not allowed to be such by Montfaucon. The metal patera which belongs to the above, differs from the earthen pateræ, in general, by being bossed in the centre, a circumstance not easily to be accounted for, unless it was for the firmer fixing the præfericulum upon, when placed with the body at the time of interment." With the above Roman antiquities were found several little cups of Samian ware. "The uses of these elegant little cups have not," the antiquary continues, "that I know of, been ascertained by any author. The real purposes to which they were applied must remain at present in obscurity."

The learned author of this communication, Thomas Walford, esq. F. A. S. earnestly invites an explanation of these

several Roman antiquities. It is, perhaps, no explanation to state that the Hindoos, in their sacrifices and ceremonies, have immemorially used, and still use, articles exactly similar to those exhibited, with the above communication, in vol. xiv. of the *Archæologia*, pl. 4. and 5. But it is curious to see how nearly they agree in form. A comparison of the article in the plates just adverted to, with those in plates 83, 86. and 105. of the *Hindoo Pantheon*, will strikingly evince this. The "sacrificial vase," in the latter plate, has the same form, though more elaborately ornamented, as the above described præfericulum; and the others exhibit metallic circular pateræ, and the central embossment, which, though "not easily accounted for," is found among Hindoo mystics to have very profound allusions. The Roman patera has also the mysterious rim or Yoni, respecting which the reader may consult the work last referred to. Dr. Clarke, in his recently published "Travels," notices that "the pateras used by priestesses in the rites of Ceres, had this pyramidal node or cone in the centre. A priestess is represented holding one of these, on a bas-relief, in the vestibule of Cambridge University Library." Vol. ii. p. 334. *Greek marbles*, No. xv. p. 37. Similar articles are still used in the rites of the Hindoo Ceres; as are also the "little cups" described and exhibited in the *Archæol.* as above referred to, and in many of the plates of the *Hindoo Pantheon*. In India they are used for holding clarified butter, a common ingredient in the frequent oblations to fire; and unguents, and holy water, in the Sradha or funeral obsequies, and in other rites and ceremonies.

Adverting for a moment to the place near which the Roman patera was found, we may remark, without laying any stress on it, that Camulodunum might, by a determined etymologist, be derived from the Sanscrit word Kamal, or goddesses KAMALA, see that article. And long after this remark was written, we find such a derivation adopted in the 11th vol. of the *Asiatic Researches*, art. ii. ch. 4.

It is shewn under the article SIVA of this work, that any objects conical or pyramidal are peculiarly typical of that deity. The mysticisms connected with that igneous form, he being a personification of fire with the Hindoos, are endless. Sufficient, probably, thereon will be found under the articles LINGA, MERU, YONI, and others thence referred to; if not, the reader may farther consult those articles in the *Hindoo Pantheon*.

PATRÆ, or PATRAS, in *Ancient Geography*, a town of Achaia, on a promontory, N. of mount Panachaichus. It was more anciently called "Aroé," derived, as it is said, from *αρου*, *I labour*, and applied to it, probably from its being the first place of Achaia in which the inhabitants occupied themselves in labour. Patraus, one of the chiefs of the Achæans who were driven from Lacedæmon on the arrival of the Heraclidæ, enlarged and fortified Aroé, and gave it his own name. Of all the Achæans the inhabitants of Patras were the only persons who defended the Ætolians, when they were attacked by the Gauls. This incursion was probably that of the year 278 B.C., and this followed the irruption of this people into Macedonia, in the preceding year, when they were defeated. Augustus, allured by the situation of Patras, collected the scattered inhabitants, and re-established them. He also united several towns under its dominion, and conferred on the inhabitants all the advantages enjoyed by Roman colonies. In the time of Pausanias this town was adorned with a statue of Diana Laphria, an odeum, which, next to that of Athens, was the most beautiful in Greece, and a fountain near the temple of Ceres, where oracles were issued for the relief of bodily maladies. Pausanias says, that Patras contained more women than men, and that they employed

ployed themselves in spinning the silk of the country, and in the manufacture of stuffs.

PATRAS, in *Geography*, a sea-port town of the Morea, situated on the S. coast of the entrance into the gulf of Lepanto. (See the preceding article.) This town is the see of a Greek archbishop, and contains about 80 Christian families, 250 of Turks, and 108 of Jews. Consuls from England, Holland, and Venice, have been accustomed to reside here. The principal articles of trade are coarse oil, silk, honey, wheat, manna, &c. In the year 1447 this place made a brave defence against sultan Murat, and held out till peace was concluded, when the Morea was surrendered to the Turks. The port is choked with mud, and the road for vessels is very indifferent; 28 miles N.E. of Chiarenza. N. lat. 38° 33'. E. long. 21° 43'.

PATREE, a town of Hindooſtan, in Guzerat; 70 miles W. of Amedabad.

PATRES CONSCRIPTI, in *Antiquity*, a denomination given to the senators of Rome.

The first hundred senators, appointed by Romulus, were called simply *patres, fathers*; another hundred being added by Romulus and Tatius, upon the union of the two people, these latter were called *patres minorum gentium*, and the former *majorum gentium*.

At length Tarquinius Priscus, making up the number three hundred, the two latter classes were called *patres conscripti*, because *adscripti*, or written down to the former.

Livy gives a different account of their origin. See **CONSCRIPTI**.

Those afterwards chosen from among the knights were called *patres adlecti*.

PATREZ, a name for a sort of vermicelli, a paste made of flour and water, and formed into beads. This and all other kinds of vermicelli are often stained with saffron.

PATRI, GLORIA. See **GLORIA**.

PATRIA, in *Geography*, a town of Naples, in Lavora, near a lake to which it gives name; 13 miles N.W. of Naples.

PATRIAM, TRIAL PER, in *Law*. See **JURY**.

PATRIARCH, PATRIARCHA, formed of *πατρις, family*, and *αρχων, chief*, one of those first fathers who lived towards the beginning of the world; and who became famous by a long line of descendants.

Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament. Seth, Enoch, &c. were antediluvian patriarchs.

Long life and a number of children were the blessings of the patriarchs.

The patriarchal government consisted in the fathers of families, and their first-born after them, exercising all kinds of ecclesiastical and civil authority in their respective households; and to this government, which continued till the time of the Israelites dwelling in Egypt, some have ascribed an absolute and despotic power, extending even to the punishment by death. In proof of this, they allege the curse pronounced by Noah upon Canaan, Gen. ix. 25; but it is replied that in this affair Noah seems to have acted rather as a prophet than a patriarch. Another instance of supposed despotic power is Abraham's turning Hagar and Ishmael out of his family, Gen. xxi. 9, &c.; but this furnishes no evidence of any singular authority vested in the patriarchs as such, and peculiar to those ages. The third instance alleged to the same purpose is that of Jacob's denouncing a curse upon Simeon and Levi, Gen. xlix. 7, which is maintained by others to be an instance of prophetic inspiration more than of patriarchal authority. The fourth instance is that of Judah with regard to Tamar, Gen. xxxviii. 24; concerning which

it is observed, that Jacob, the father of Judah, was still living, that Tamar was not one of his own family; and that she had been guilty of adultery, the punishment of which was death by burning, and that Judah on this occasion might speak only as a prosecutor. Jennings's *Jewish Antiq.* vol. i. p. 1, &c. Sydney's *Discourses concerning Government*, chap. i. sect. 7.

PATRIARCH is also used, in Christendom, for the bishops in possession of some of the grand sees, independent of the papal jurisdiction; or for the chief bishop over several countries or provinces, as an archbishop is of several dioceses; who hath several archbishops under him.

The patriarchate has been always esteemed the supreme dignity in the church: so that, to rise by degrees, the bishop had only under him the territory of the city of which he was bishop; the metropolitan commanded a province, and had for suffragans the bishops of his province; the primate was the chief of a diocese, and had several metropolitans under him; and the patriarch had under him several dioceses, and the primates themselves were under him. But this order was not always observed.

Usher, Pagi, De Marca, and Morinus, attribute the establishment of the grand patriarchates to the apostles. They suppose that the apostles, according to the description of the world then given by geographers, pitched on the three principal cities in the three parts of the known world; viz. Rome, in Europe; Antioch, in Asia; and Alexandria, in Africa: and thus formed a trinity of patriarchs.

Others, far from attributing this institution to the apostles, maintain that the name patriarch was unknown at the time of the council of Nice; and that, for a long time afterwards, patriarchs and primates were confounded together; as being all equally chiefs of dioceses, and equally superior to metropolitans, who were only chiefs of provinces. Hence it is that Socrates gives the title patriarch to all the chiefs of dioceses, and reckons ten of them. In effect, it does not appear, that the dignity of patriarch was appropriated to the five grand sees of Rome, Constantinople, Alexandria, Antioch, and Jerusalem, till after the council of Chalcedon, in 451. For when the council of Nice regulated the limits and prerogatives of the three patriarchs of Rome, Antioch, and Alexandria, it did not give them the title of patriarchs, though it allowed them the pre-eminence and privileges thereof. Thus, when the council of Constantinople adjudged the second place to the bishop of Constantinople, who, till then, was only a suffragan of Heraclea, it said nothing of the patriarchate.

Nor is the term patriarch found in the decree of the council of Chalcedon, whereby the fifth place is assigned to the bishop of Jerusalem; nor did these five patriarchs govern all the churches.

There were still many independent chiefs of dioceses, who, far from owning the jurisdiction of the grand patriarchs, called themselves patriarchs: such as that of Aquileia; nor was Carthage ever subject to the patriarch of Alexandria.

Mosheim supposes, that those prelates who enjoyed a certain degree of pre-eminence over the rest of the episcopal order, were distinguished by the Jewish title of patriarchs in the fourth century. *Ecccl. Hist.* vol. i.

The authority of the patriarchs grew by insensible degrees, till at length we find, that about the close of the fifth century, all affairs of moment, within the compass of their patriarchate, came before them; either at first hand, or by appeals from the metropolitans.

They consecrated bishops, assembled yearly in council the clergy of their respective districts; pronounced a decisive judgment in those cases where accusations were brought against

against bishops; and appointed vicars or deputies, clothed with their authority, for the preservation of order and tranquillity in the remoter provinces.

Nothing, in short, was done without consulting them; and their decrees were executed with the same regularity and respect as those of the princes.

It must, however, be observed, that the authority of the patriarchs was not acknowledged through all the provinces without exception. Several districts, both in the eastern and western empires, were exempted from their jurisdiction.

The Latin church was unacquainted with patriarchs till the sixth century; and the churches of Gaul, Britain, &c. were never subject to the authority of the patriarch of Rome, whose authority only extended to the suburbicary provinces. There was no primacy, no exarchate nor patriarchate, owned here; but the bishops, with the metropolitans, governed the church in common.

Indeed, after the name patriarch became frequent in the West, it was attributed to the bishops of Bourges and Lyons; but it was only in the first signification, *viz.* as heads of dioceses. Du-Cange adds, that there have been some abbots, who have borne the title of patriarchs.

PATRIARCH is also applied to the chief of several churches in the East, who live out of communion with the Roman church; such are the patriarch of the Armenians, residing in the monastery of St. Gregory; the patriarch of the Abyssinians, called *Abuna*; the patriarchs of the Cophti, the Jacobites, &c. See ARMENIANS, COPHTI, JACOBITES, &c. See also GREEK CHURCH.

PATRIARCHAL, in *Heraldry*. A patriarchal cross is that where the shaft is twice crossed; the lower arms or traverses being longer, and the upper shorter. Such a cross is said to belong to patriarchs, as the triple cross does to the pope.

PATRICA, in *Geography*, a town of Italy, in the Campagna di Roma; 13 miles S. of Rome.

PATRICIAN, PATRICIUS, in ancient Rome, a title given to the descendants of the hundred, or, according to others, of the two hundred first senators chosen by Romulus, and by him called *patres, fathers*.

Romulus established this order in imitation of the Athenians, who were divided into two classes, *viz.* the *επαλειδας, patricios*, and *δημοτικους, populares*.

Patricians, therefore, were originally the ancient nobility; in opposition to the plebeians.

They were the only persons whom Romulus allowed to aspire after the magistracy; and they exercised all the functions of the priesthood till the year of Rome 495.

But the cognizance and character of these ancient families being almost lost and extinguished, by a long course of years, and frequent changes in the empire; a new kind of patricians were at length set on foot, who had no pretensions from birth, but whose title depended wholly on the emperor's favour.

This new patriciate, Zofimus tells us, was erected by Constantine, who conferred the quality on his counsellors, calling them *patricii*, not because descended from the ancient fathers of the senate, but because they were the fathers of the republic, or of the empire.

This dignity, in time, became the highest of the empire. Justinian calls it *summam dignitatem*: in effect, the patricians seem to have had the precedence of the consules, and to have taken place before them in the senate; though F. Faber asserts the contrary. What embroils the question is, that the two dignities often met in the same person; because the

patriciate was only conferred on those who had gone through the first offices of the empire, or had been consuls.

Pope Adrian made Charlemagne take the title of patrician before he assumed the quality of emperor; and other popes have given the title to other kings and princes, by reason of its eminence.

PATRICIAN, *Patricius*, is also a title of honour frequently conferred on men of the first quality in the time of our Anglo-Saxon kings. See THANE.

PATRICIAN Deities, *Patricii Dei*, in *Mythology*, were Jaanus, Saturn, the Genius, Pluto, Bacchus, the Sun, the Moon, and the Earth.

PATRICIANS, in *Ecclesiastical Writers*, denote ancient sectaries who disturbed the church in the beginning of the third century; thus called from their founder Patricius, preceptor of a Marcionite called Symmachus.

His distinguishing tenet was, that the substance of the flesh is not the work of God, but that of the devil; on which account his adherents bore an implacable hatred to their own flesh; which sometimes carried them so far as to kill themselves.

They were also called Tatianites; and made a branch of the Eneratizæ.

PATRICIDE, PATRICIDIUM, the same with parricide.

PATRICK, SIMON, in *Biography*, a learned English prelate, was the son of a mercer at Gainsborough, in Lincolnshire, where he was born in the year 1626. Great care was taken of his education; and having been well grounded in classical learning, he was, in 1644, sent to Queen's college, Cambridge. He took his degree of B.A. in 1647, and in the following year was chosen fellow of his college. In 1651 he took his degree of M.A. and about the same time received holy orders from Dr. Joseph Hall, bishop of Norwich. He next became domestic chaplain to sir Walter St. John of Battersea, who presented him to that living towards the beginning of the year 1658. In 1661 Mr. Patrick was elected master of Queen's college by a majority of fellows, notwithstanding the king's recommendation of Mr. Anthony Sparrow; but the affair being brought before the king and council, judgment was speedily given against our author, and some, if not all, of the fellows who had voted for him were ejected. Upon the ejection of Dr. Manton from the rectory of St. Paul's, Covent-Garden, in 1662, Mr. Patrick was presented to that benefice by the earl of Bedford; and he won the affection of the parishioners, not only by his preaching and exemplary manners, but particularly by his constant residence among them, during the time of that awful calamity the plague. In the year 1666, being disgusted at some circumstances that happened at Cambridge, he entered himself of Christchurch college, Oxford, where he was at first incorporated bachelor, and soon afterwards was admitted doctor of divinity; and about the same time, he was appointed chaplain in ordinary to the king. In 1672 Dr. Patrick was made a prebendary of Westminster; and his next promotion was to the deanery of Peterborough, in 1679, where he completed and published, in the year 1686, "The History of the Church of Peterborough," from the manuscript of Simon Gunton, formerly a prebendary of that church. Dr. Patrick made very considerable additions to it, and added a supplement, containing a fuller account of the abbots and bishops of Peterborough than had been drawn up by Mr. Gunton. In 1680 Dr. Patrick had the offer of the valuable living of St. Martin's-in-the-Fields from the lord chancellor Finch; but he declined accepting it, on account of the regard which he felt for his parishioners of Covent-Garden; and on this occasion

he recommended Dr. Thomas Tennison, who was presented to that rectory. During the reign of James II., Dr. Patrick, in opposition to all his worldly interests, shewed his zealous attachment to the Protestant religion, by writing and preaching against the errors of the church of Rome. The sovereign condescended to reason with the doctor on the subject, but to no purpose: he told the king very plainly, "that he could not give up a religion that was so well proved as that of the Protestants." His zeal went much farther than this: he opposed, to the utmost of his power, the reading of the king's declaration for liberty of conscience, which was published in favour of the Papists; and he assisted Dr. Tennison in establishing a school at St. Martin's, to counteract the influence of the Popish one opened at the Savoy, for the purpose of making converts of the children of poor Protestants. At the revolution, he was called upon to preach before the prince and princesses of Orange, who paid him particular attention; and in 1689 he was nominated to fill the vacant see of Chichester. He was next employed, with others of the episcopal bench, in settling the affairs of the church of Ireland; with which view, they sent back all the clergy who fled into England for refuge from the tyranny and persecution of the late reign. In the year 1691 the bishop was translated to the see of Ely, of which he proved himself a liberal benefactor, by the improvements which he introduced into its temporalities. At the same time he consecrated his labours to the interests of piety and virtue, by many valuable writings. He died at Ely in 1707, in the 81st year of his age. His works were numerous, but the most important are his "Commentaries" upon the historical books of the Old Testament, and "Paraphrases" on the books of Job, Psalms, Proverbs, Ecclesiastes, and Solomon's Songs. These were collected into three volumes, folio, and, with Lowth's "Commentaries" upon the Prophets, Arnald's upon the Apocrypha, and Whitby on the New Testament, form a complete collection, in high estimation. Biog. Brit. Toulmin's Neal.

PATRICK, in *Geography*, a county of Virginia, in America, containing 6682 free, and 647 black people.

PATRICK'S, St., a small island in the Irish sea, near the east coast of Ireland. N. lat. 53° 36'. W. long. 6° 5'.

PATRICK'S, St., a small town, the chief of Camden county, Georgia, situated on Great Satilla river, about 32 miles from its mouth.

PATRICK'S, St., *Purgatory*. See *Lough DERG*.

PATRICK, Order of St., is an institution which took place in Ireland in the year 1783. It was on the 5th day of February in this year, that his majesty ordered letters-patent to be passed under the great seal of the kingdom of Ireland, for creating a society or brotherhood, to be called knights of the illustrious order of St. Patrick; of which his majesty, his heirs, and successors, shall perpetually be sovereigns; and his majesty's lieutenant-general, and general-governor of Ireland, &c. for the time being, shall officiate as grand-masters; and also for appointing prince Edward, and several of the prime nobility of Ireland, knights-companions of the said illustrious order.

The badge of this order is a saltire red on a field azure, surrounded with a shamrock, or trefoil vert, charged with three imperial crowns or, within a garter, on which is the motto, *QUIS SEPARABIT*, "who shall separate them," **MDCCLXXXIII**. The whole is surrounded by a star of silver, with eight points; all which is embroidered, and worn on the outer garment of the knights of the order. The collar is of fine gold, composed of four harps and five roses, alternately joined or linked together by ten knots enamelled

white: the rose gules, surrounded by a border or, and enamelled azure. In the centre before is an imperial crown, to which is pendant an harp, and thereto the jewel of the order, being a cross saltire enamelled red, charged with a sky-blue enamelled tressil, surmounted with three imperial crowns of gold; the whole surrounded with a bordure of gold, on which the motto is enamelled blue. This jewel, except on public days, is worn pendant to a sky-blue ribbon, and ornamented with jewellery, agreeably to the will of the possessor.

This order is to consist of the sovereign, a grand master, a prince of the blood royal, and thirteen knights, making in the whole sixteen; and eight officers, *viz.* the prelate of the order, the chancellor, registrar, secretary, genealogist, usher of the black rod, Ulster king of arms, attendant on the order, and A'lhore pursuivant at arms. The lord lieutenant for the time being is the grand master. *New Ann. Register*, 1783. Debreit's Peerage.

PATRII DIU. See **DIU**.

PATRIMONIA, in *Geography*, a town of the island of Corsica; 4 miles W of Bastia.

PATRIMONIO, or *Patrimony of St. Peter*, a province of Italy, so called, as it is said, because it was granted by the emperor Constantine to support a church, which he had built in honour of St. Peter, and for the use of the pope. This country is bounded on the north by the Orvietan and part of Umbria, on the east by the Sabina and Campagna di Roma, on the south-west by the Mediterranean, and on the north-west by the duchy of Castro; about 43 miles long, and 32 broad. It is fertile in corn and fruit, and yields a considerable quantity of alum. The principal places in it are Viterbo, Monte Fiascone, Bolsena, Civita Castellana, and Civita Vecchia.

PATRIMONY, **PATRIMONIUM**, a right or estate, which a person inherits from his ancestors.

The name patrimony was also anciently given to the effects or revenues, with which a church or religious house was endowed. In which sense authors still say the patrimony of the church of Rimini, of Milan, &c.

The church of Rome, at the time of the fall of the Roman empire, acquired considerable territories, partly by purchase, and partly by the generosity of princes, &c. not only in Italy, but also in Sicily, and other remoter parts of Europe. These were called the patrimony of St. Peter, which were afterwards augmented by the benefactions of Pepin, king of France, who added the exarchate of Ravenna; and by Charlemagne, who gave to the pope several towns and provinces, which belong at this time to the estate of the church, over which the pontiff exercises sovereign authority.

To make what belonged to the churches the more respected, they usually gave their patrimonies the names of the saints they held in the highest veneration.

Thus the church of Ravenna called its inheritance the patrimony of St. Apollinaris; that of Milan the patrimony of St. Ambrose, as is observed by Fra. Paolo.

PATRINGTON, in *Geography*, is a small market-town and parish, in the south division of the wapentake of Holderness, and east riding of Yorkshire, England. The town is situated 18 miles S.S.E. from Kingston-upon-Hull, and 193 miles N. by E. from London. It is of great antiquity, and, according to Camden, was the ancient Prætorium of Antoninus; and with his opinion the best informed antiquaries coincide, as its distance from the neighbouring station of Delgovitia agrees with that mentioned in the Itinerary, whether we place the latter at Loudesbrough, or at Market-Weighton. The buildings of this town are much dispersed.

The

The parish church is a large and spacious edifice; its tower is surmounted by a lofty spire. The market is held here on Saturday weekly, and is much frequented by corn dealers. Here are, besides, three fairs during the year, principally for drapery, millinery goods, shoes, and other articles of dress. Patrington stands within less than a mile of the estuary of the Humber, which forms here a small creek, capable of affording shelter and anchorage to vessels of small burden. According to the parliamentary returns of 1811, the town and parish contain 190 houses, and a population of 1016 inhabitants.

About a mile and a half to the north-west of Patrington is the pleasant village of Winestead, which is adorned with two elegant villas, the seats of sir Robert d'Arcy Hildyard, bart., and of Henry Masters, esq. The seat of the former is denominated Winestead-hall, and both being seated upon gently rising ground, command a beautiful prospect of the town of Patrington, the Humber, and Sunk island. This island has its name from the circumstance of its having been entirely under water till the reign of Charles I., when it began to appear by the receding of the ocean. At first, only a few acres were left dry at low water; but as it increased in extent every year, it was at length embanked, and laid down as pasture land. Other embankments, however, were made at subsequent periods, in proportion as the waters retired; so that the island is now of considerable extent, and only separated from the Holderness marshes by a ditch a few feet in breadth. The last embankment was effected in 1808, and inclosed an area of 4570 acres. Sunk island is divided into several farms, and a church has lately been built upon it, for the accommodation of the inhabitants. The soil is peculiarly fertile.

Spurn-head, or Spurn-point, situated about ten miles to the south-east of Patrington, constitutes the extremity of the noted "Ocellum Promontorium" of Ptolemy, which projects nearly half-way across the entrance into the Humber. Its present name of Spurn-head is of Saxon origin; the verb "spurien," in that language, signifying to explore or spy out. A light house is placed here, as a guide to vessels navigating the estuary. Somewhere in this vicinity was anciently the celebrated sea-port Ravenspur, or Ravenfer, remarkable in the annals of England as the landing-place of Henry IV., A.D. 1399, and of Edward IV., A.D. 1471, when these princes came to contend for the possession of the English sceptre. This town has long since been swallowed up, either by the ocean, or by the Humber; so that the spot on which it stood is uncertain. Several other towns and villages hereabouts have experienced a similar fate. Among them are mentioned Frismerk, Tharlethorpe, Redmayr, Pennysmerk, Upsal, and Pottenfleet; all of which Dr. Gibson supposes were overflowed in the 30th or 38th year of Edward III., when the tides are recorded to have risen to a most extraordinary height. The inundation of Ravenspur, however, must have taken place at a much later period.

Near the village of Halsham, about three miles and a half beyond that of Winestead, is a superb mausoleum, erected by the late William Constable, esq., as a burying-place for that family. The architecture of this building displays an union of elegance and simplicity, which at once captivates the eye, and is appropriate to the nature of the structure. The position of this mausoleum is lofty, and the surrounding grounds are covered with trees. Beauties of England and Wales, vol. xvi. by John Bigland.

PATRINI and MATRINI, among the Romans, children whose father and mother were both living.

It was by a certain number of these that hymns were sung to supplicate the gods.

PATRIOT is a denomination given to a person who, under a free government, loves his country, and exerts all his power for promoting its glory and welfare. Whence patriotism is used to denote the love of one's country. Rome, Athens, and Lacedæmon, owed their existence and glory to patriotism, founded on noble principles, and supported by distinguishing virtues. But the most perfect patriotism is that which comprehends the rights of mankind in general. The author of the Spirit of Laws seems to have been actuated by sentiments of universal patriotism.

PATRIPASSIANS, PATRIPASSIANI, a name given to the Sabellians, because they did not believe it was the Son, but the Father himself that suffered and was crucified.

The council of Antioch, held by the Eusebians in 345, says, that those whom the Romans call Patripassians, the eastern people called Sabellians: it adds the reason of the name Patripassians in their condemnation; viz. that by the incarnation of the Father, they rendered him comprehensible and passible.

The Patripassian heresy was first broached by Praxeas, who was seconded by Victorinus, at the beginning of the third century. They confessed Christ to be God, and that God suffered and died for us; but they confounded the divine persons, and denied in effect the Trinity; meaning by Father, Son, and Spirit, not three persons, but one person under three names. So that he who suffered for us, was according to them as much Father as Son. Tertullian wrote expressly against Praxeas.

Hermogenes espoused the error of the Patripassians, whence they came to be denominated also Hermogenians. Afterwards Noetius gave into it, which occasioned them the name of Noetians. His disciple Sabellius the Libyan followed, about the year 250, whence they are called Sabellians. Lastly, because Sabellius was of Pentapolis, and the heresy spread much there, it was called the Pentapoltan doctrine.

PATRIS, *Dower ex Assensu*, in Law. See DOWER.

PATRIS, in Geography, a town of Hindoostan, in the circar of Aurungabad; six miles S.E. of Aurungabad.

PATRIZI, FRANCESCO, in Biography, a philosopher and man of letters, was born, in 1529, in the island of Cherfo, on the coast of Dalmatia, but he derived his origin from the family of Patrizi, in Sienna. He was educated at Padua under the most eminent masters of the time. In 1553 he began to appear as an author by some miscellaneous Italian tracts. In 1557, with the view of obtaining the patronage of the duke of Ferrara, he published a panegyric poem on the house of Este, entitled "L'Eridano," in a novel kind of heroic verse of thirteen syllables. After this, for several years, he passed an unsettled kind of life, in which he twice visited the isle of Cyprus, where he took up his abode for seven years, and which he finally quitted on its reduction by the Turks in 1571. He also travelled into France and Spain, and spent three years in the latter country, collecting a treasure of ancient Greek MSS. which he lost on his return to Italy. In 1578 he was invited to Ferrara by duke Alphonso II. to teach philosophy in the university of that city. Afterwards, upon the accession of Clement VIII. to the popedom, he was appointed public professor of the Platonic philosophy at Rome, an office which he held with high reputation till his death, in 1597. He was chiefly distinguished by his attainments in ancient philosophy. His work entitled "Discussiones Peripateticæ,"

pateticæ," is characterised as a learned and elegant performance. After having been a defender of the Aristotelian philosophy and its author, he became a violent oppugner of it, and undertook entirely to subvert it, in a second work entitled "Nova de Univerſis Philoſophia." In this he propoſes a new ſyſtem founded on the Platonic philoſophy, with ſuch additions and alterations as ſeemed requiſite. He is highly deſerving of praiſe as having been one of the firſt of the moderns who attentively obſerved the phenomena of nature, and he made uſe of every opportunity, that his travels afforded him, for collecting remarks concerning various points of aſtronomy, meteorology, and natural hiſtory. In one of his "Dialogues on Rhetoric," he advanced, under the ſiſtion of an Ethiopic tradition, a theory of the earth perfectly ſimilar to that afterwards propoſed by Dr. Thomas Burnet. His other principal works were "Nova Geometria," 1587; "Paralleli Militari," 1594, both of which are full of whimſical theories. Patrizi appeared likewiſe as a learned editor of "Oracula Zoroaſtris, Hermetis Trimegiſti, et aliorum ex ſcriptis Platonicorum collecta, Græce et Latine, prefixa Diſſertatione Hiſtorica." 1591. Moreri.

PATRO, in *Geography*, a town of France, in the department of Gola (iſland of Corſica) and chief place of a canton, in the diſtrict of Calvi. The canton contains 1455 inhabitants.

PATROCLUS, in *Biography*, a Grecian chief, ſignaliſed in the Trojan war, was the ſon of Menoetius, by Sthenela, who is named by ſome authors Philomela, or Polymela. The murder of Clyſonymus, the ſon of Amphidamus, by accident, in the time of his youth, obliged him to fly from Opus, where his father reigned. He went to the court of Peleus, king of Pythia, was very cordially received, and contracted the moſt intimate friendſhip with Achilles, the king's ſon. When the Greeks went to the Trojan war, Patroclus went with them at the expreſs deſire of his father, who had viſited the court of Peleus, and he accordingly embarked with ten ſhips from Pythia. He was the conſtant companion of Achilles; lodged in the ſame tent; and when he reſuſed to appear in the field of battle, becauſe he had been offended by Agamemnon, Patroclus imitated his example, and by his abſence was the cauſe of much evil to the Greeks. At length, however, Neſtor prevailed upon him to return to the war, and Achilles permitted him to appear in his armour. The bravery of Patroclus, together with the terror which the ſight of the arms of Achilles inſpired, ſoon routed the victorious armies of the Trojans, and obliged them to fly to the city for ſafety. He would have broken down the walls, but Apollo, who intereſted himſelf for the Trojans, oppoſed him, and Hector, at the inſtigation of that god, diſmounted from the chariot to attack him as he attempted to ſtrip one of the Trojans whom he had ſlain. This engagement was obſtinate, but Patroclus was at length overpowered by the valour of Hector, and the interpoſition of Apollo. His arms became the property of the conqueror, and Hector would have beheaded him, had not Ajax and Menelaus prevented it. His body was at laſt recovered, and carried to the Grecian camp, where Achilles received it with the loudeſt lamentations. His funeral obſequies were obſerved with the greateſt ſolemnity. Achilles ſacrificed near the burning pile twelve young Trojans, four of his horſes, and two of his dogs; and the whole was concluded by the exhibition of funeral games, in which the conquerors were liberally rewarded by Achilles. The death of Patroclus gave riſe to new events. Achilles forgot his reſentment againſt Agamemnon, left the field to

avenge the fall of his friend; and his anger was affuaged only by the ſlaughter of Hector, who had more powerfully kindled his wrath by appearing at the head of the Trojan armies in the armour which had been taken from the body of Patroclus.

PATROL, or PATROUTLE, anciently *Patoul*, in *War*, a round, or march made by the guards, or watch in the night-time, from the beating of the tattoo till the reveille, to obſerve what paſſes in the ſtreets, and to ſecure the peace and tranquillity of a city or camp.

The patrol conſiſts generally of a body of ſix or twelve men, detached from a *corps de guard*, and commanded by a ſerjeant.

When the enemy is near at hand, patrols conſiſt of an officer and thirty or forty men, as well infantry as cavalry.

PATRON, PATRONUS, a term uſed in various acceptations, though all reducible to the relation of a protector, or guardian.

In the church of Rome, a ſaint, whoſe name a perſon bears, or under whoſe protection he is put, and whom he takes particular care to invoke; or a ſaint in whoſe name a church or order is founded; or a perſon who firſt eſta-bliſhed it, and who is choſen protector of it; are called the patrons thereof. Thus, St. Peter and St. Paul are the patrons of the church of St. Genevieve, St. Dionyſius the patron of the city of Paris, St. George of England, St. Benedict the patron of the Benedictines, St. Michael of the armourers, St. Ignatius of the Jeſuits, &c.

PATRON, *Patronus*, among the Romans, was an appellation given to a maſter who had freed his ſlave.

Hence, as the right and relation of maſter expired, that of patron commenced.

For the Romans, in giving their ſlaves their freedom, did not deſpoil themſelves of all rights and privileges in them; the law ſtill ſubjected the freed-men to conſiderable ſervices and devoirs toward their patrons, the neglect of which was always very ſeverely puniſhed.

The principal right, which patrons had, was that of being the legal heirs of their freedmen, if they died without lawful iſſue, born after their enfranchiſement, and in teſtate.

By the Papien law it was farther provided, that if the eſtate of the freed-man were one hundred thouſand ſeſterces, and he had three children, the patron ſhould have a child's portion.

PATRON was alſo a name, which the people of Rome gave to a perſon of power, under whoſe protection they put themſelves.

The common people uſually choſe ſome perſon of eminence and authority, to whom they paid all kind of honour and reſpect; denominating themſelves his clients: and the patron on his ſide granted them his credit and protection.

By this reciprocal relation was the patron bound to his client, and the client to his patron.

Hence the appellation of patroni was given to thoſe lawyers, who defended the cauſe of their clients in matters of law, in contradiſtinction to the *procuratores*: they were called *advocati*. See *ADVOCATE*.

PATRON, in the *Canon and Common Law*, denotes a perſon who founds or endows a church or benefice, and reſerves to himſelf the right of patronage.

The king is patron paramount of all eccleſiaſtical benefices in England.

PATRON, in *Navigation*, is a name given in the Mediterranean to a perſon who commands the veſſel, and ſeamen; ſometimes

sometimes the person who steers it; the former, in other places, being called *master*; the second, *pilot*.

PATRONA, or **PADRON**, in *Geography*, a town of Syria, near the sea-coast, said to have been founded by Iobalus, contemporary and ally of Ahab, king of Israel; its ancient name was "Botrys" or "Botryum." Mr. Maundrell found in this place the remains of an old church and monastery, which, as well as the town, were in a state of ruin; 20 miles S.W. of Tripoli. N. lat. $44^{\circ} 12'$. E. long. $35^{\circ} 35'$.

PATRONAGE, **PATRONATUS**, the right of giving or disposing of a church or benefice, properly belonging to the founder or endower thereof. See **ADVOWSON**.

The right of patronage was introduced among Christians towards the close of the fourth century, with no other view than to encourage the opulent to erect a great number of churches, by giving them the privilege of appointing the ministers that were to officiate in them.

Patronage consists in having the nomination, or presentation to the benefice by him founded or endowed; in having the honourable rights of the church; in being interred in the chancel, &c.

Of patronages, some are *lay*, others *ecclesiastical*.

PATRONAGE, *Lay*, is a right attached to a person, either as founder, or as heir of the founder; or as possessor of a fee to which the patronage is annexed.

PATRONAGE, *Ecclesiastical*, is that which a person is intitled to by virtue of some benefice which he holds.

If an ecclesiastic have a right of patronage on his own account, independent of his ecclesiastical capacity; this is still *lay* patronage. *Lay* patronage, again, is *real* or *personal*.

PATRONAGE, *Real*, is that attached to the glebe, or to certain lands and hereditaments.

PATRONAGE, *Personal*, is that belonging immediately to the founder of the church, and transmissible to his children and family; without being annexed to any fee.

Personal patronage cannot be alienated or sold; real may, together with the glebe to which it is annexed. There must ever be some body or matter to fix to it, in order to its being transferred to another.

The origin of the right of patronage, we find in the tenth canon of the council of Orange: where it is expressed, that a founder may present to the diocesan the clerks he thinks proper for his church. And by a law of Justinian it is ordained, that the founders of churches may not put clerks in them on their own authority, but only present them to the bishop.

Some canonists look on the right of patronage, as a kind of ecclesiastical servitude. The right of patronage sleeps, but is not lost, while a person is out of the communion of the church.

PATRONAGE, *Disturbance of*, is an hindrance or obstruction of a patron to present his clerk to a benefice. Disturbers of a right of advowson may be the pseudo-patron by presenting to a church to which he has no right, and thereby making it litigious or disputable; his clerk, by demanding or obtaining institution; and the ordinary, by refusing to admit the real patron's clerk, or admitting the clerk of the pretender. These disturbances are vexatious and injurious to him who hath the right; and, therefore, the law (besides the writ of the right of advowson, which is a final and conclusive remedy) hath given him two inferior possessory actions for his relief; an *assise of darrein presentment*, and a writ of *quare impedit*, in which the patron is always the plaintiff, and not the clerk.

PATRONAGE, *Arms of*, in *Heraldry*, are those, at the top

of which are some marks of subjection and dependence. Thus the city of Paris bears three fleurs-de-lis in chief, to shew her subjection to the king.

The cardinals on the top of their arms bear those of the pope, who gave them the hat, to shew that they are his creatures. See **ARMS**.

PATRONYMIC, Πατρωνυμια, formed from πατήρ, *father*, and ονομα, *name*, among *Grammarians*, is applied to those names which the Greeks gave to the race, or lineage; and which were taken from him who was the founder thereof.

Thus the descendants of Æacus were called Æacidae; and those of Hercules, Heraclidae.

These patronymic names the Romans called *gentilitia*, which amount to much the same with our *surnames*.

Thus, those of the late reigning family in France, we call the Bourbons; those of the late in England, the Stuarts, &c.

PATROON GALLEY. See **GALLEY**.

PATROUILLE. See **PATROL**.

PATROURA, in *Geography*, a town of Hindoostan, in Boggilund; 25 miles S.E. of Makoonda.

PATRU, **OLIVER**, in *Biography*, a distinguished French writer, was born at Paris in 1664. He was intended by his father for the bar, and he cultivated with great assiduity the talent of writing and speaking with purity. He visited Rome, and on his return his reputation procured him admission into the French academy in 1640. At his reception he delivered an oration of thanks, which pleased that body so well, that it became thenceforth the rule for every new member to pronounce a similar harangue. Patru was connected with most of the eminent literary characters in France of that period, and was consulted as an oracle upon every question relative to language. Boileau, Racine, and other wits, read their works to him, and profited by his remarks. Racine, it is said, frequently shrunk from the severity of his animadversions, but Boileau was fully sensible of their value. Patru fell into a state of indigence, and Boileau purchased his library, and generously permitted him to retain it during his life. "That a poet," says his biographer, "should be the pecuniary benefactor of a celebrated pleader, seems contrary to the usual order of things; but Patru was probably more intent in polishing his style, than in turning over law-books and hunting for clients. He was a man of a philosophical spirit, generous, compassionate, and not depressed by the frowns of fortune. His opinions were sceptical, on which account he was visited by Bossuet in his last illness, for the purpose of exhorting him to edify the public by some demonstrations of religious conviction. It will more become me, said Patru, to be silent, for men in their last moments talk only through weakness or vanity." On his death-bed he had a visit from the minister Colbert, who brought him a donation of 500 crowns. He died in January 1681, in his 77th year. Patru is chiefly known as an author by his "Plaidoyers;" but he likewise wrote harangues, letters, and the lives of some friends, which have in a good measure lost their reputation. The best edition of his works is that of 1732, in two vols. 4to. Moreri.

PATSA, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 25 miles N.E. of Surgooja.

PATSAAN, a small island on the E. side of the gulf of Bothnia. N. lat. $60^{\circ} 48'$. E. long. $20^{\circ} 58'$.

PATSCHKAU, a town of Silesia, in the principality of Neisse; 13 miles W. of Neisse. N. lat. $50^{\circ} 18'$. E. long. $16^{\circ} 50'$.

PATSHIKAMISTICK, a river of Canada, which runs into the Sable, N. lat. $49^{\circ} 45'$. W. long. $72^{\circ} 36'$.

PATTA,

PATTA, or **PATI**, an island in the Indian sea, near the coast of Africa, about 10 miles in circumference; chiefly inhabited by Arabians, with whom the English, Portuguese, and Indians trade for ivory and slaves; it is situated near the coast, at the mouth of a river of the same name. S. lat. $1^{\circ} 56'$. E. long. $43^{\circ} 20'$.

PATTALA, in *Ancient Geography*, a town of India, that has been commonly referred to the Delta of the Indus. Alexander arrived at this place about the middle of August. 326 years B.C., and having made proper arrangements for the safety and convenience of his fleet and army, and having viewed also the two principal mouths of the Indus, on which he experienced some degree of surprize, if not of terror, from the "bore," or sudden influx of the tide, he departed by land for Susa, leaving Nearchus with the fleet to follow as soon as the Etesian winds should cease. Nearchus failed in October with the N.E. monsoon, conducting, according to Dr. Gillies, in his elegant History of Greece, "the first European fleet which navigated the Indian seas." Pattala is supposed to have been the site of the modern city of *Tatta*, which see. According to a tradition among the people of Sindy, Pattala stood in the superior delta, whereas Patta is placed in the inferior delta. Renneil's Memoir.

PATTALIA, in *Natural History*, a word used by Aristotle and the rest of the old Greek writers, to express a stag or deer of two years old.

PATTALLY, in *Geography*, a town of Hindoostan, in Bahar; 33 miles E.N.E. of Hajypour.

PATTAN, **LELIT**, a city of Asia, in Nepal or Napaul, the capital of an independent kingdom, S.W. of Cat'h-manda or Cat'manda; containing near 24,000 houses: the southern boundary of this kingdom is at the distance of four days' journey, bordering on the kingdom of Macwanpur. N. lat. $28^{\circ} 5'$. E. long. $85^{\circ} 10'$.

PATTAN, a town of Hindoostan, in Mewat; 16 miles S.W. of Cotputly.—Also, a town of Hindoostan, in Vilia-pour; 20 miles N.W. of Sattarah.

PATTANCHERU, a town of Hindoostan, in Gbl-conda; 20 miles W.N.W. of Hydrabad.

PATTAPOOW-WINEPEE, a lake of North America. N. lat. $54^{\circ} 50'$. W. long. 96° .

PATTEERAH, a river of Thibet, which runs into the Ganges, on the borders of Hindoostan.

PATTELBACHEES, one of the smallest Molucca islands. N. lat. $0^{\circ} 3'$. E. long. $127^{\circ} 21'$.

PATTEN-SHOE, in the management of horses' feet, is a term applied to that sort of shoe which has a kind of half ball of iron welded to it underneath, which is hollow within. It is intended for the use of such horses as are lame in the hip, being put upon the sound foot, in order that the animal, by not being able to stand upon that foot without pain, may be under the necessity of supporting itself upon the lame foot, and in that way contract the disposition in the sinews to contract or draw up the haunch. It is the method of practice with some, where horses are newly lamed in the shoulders, either to peg the other foot, or set on a patten-shoe, in the view of bringing the lame shoulder upon the stretch; but with others it is the custom to immediately turn them out to graze; both of which some think very exceptionable modes of proceeding, and the most ready ways of rendering them incurably lame; the patten-shoe being simply necessary in long standing lamenesses, where the tendons of the muscles have been a long while contracted or drawn up.

PATTEN'S Creek, in *Geography*, a river of America, in Kentucky, which runs into the Ohio, N. lat. $38^{\circ} 22'$. W. long. $85^{\circ} 50'$.

PATTENSBURG, a small town of America, in

Botetourt county, Virginia, situated upon James' river; 26 miles from Lexington.

PATTENSEN, a town of Westphalia, in the principality of Calenberg, formerly encompassed with walls, moats, and ramparts; 6 miles S. of Hanover.

PATTERGAUT, a town of Hindoostan, in the Subah of Delhi; 20 miles W. of Coel.

PATTERGOTTA, a town of Hindoostan, in Bengal; 10 miles E. of Pucculoe.—Also, a town of Assam; 15 miles E. of Gentiah.—Also, a town of Bengal; 22 miles S.W. of Dinagepour.—Also, a town of Bengal; 18 miles E. of Boglipour.

PATTERGUR, a town of Hindoostan, in the circar of Sambal; 4 miles N.E. of Nidjibabad.

PATTERPURRA, a town of Bengal; 47 miles S.W. of Burdwan.

PATTERRA, a town of Bengal; 5 miles E. of Midnapour.

PATTERSON, a town of America, in Bergen county, New Jersey, established in consequence of an act of the legislature of New Jersey in 1791, incorporating a manufacturing company with peculiar privileges. Its situation on the Great Falls of Passaic river is healthy and agreeable. It contains about 50 dwelling houses, besides the buildings appropriate to the manufactures of all kinds, which it was proposed to carry on in this place, the most convenient for the purpose of any on the continent; but they did not succeed to the degree that was expected; 19 miles N.E. of Morristown. N. lat. $40^{\circ} 12'$. W. long. $74^{\circ} 57'$.

PATTERSOOT, a town of Prussia, in the circle of Natangen; 6 miles S.W. of Brandenburg.

PATTERWALDT, a town of Prussia, in the circle of Natangen; 24 miles E.S.E. of Königberg.

PATTES, in *Heraldry*, the paws of a beast. See **PAW**.

PATTI, **PATI**, or **Piatti**, in *Geography*, a sea-port town of Sicily, in the valley of Demona, situated on the N. coast, in a bay or gulf to which it gives name, built on the ruins of Tindaro, by count Roger, after he had vanquished the Saracens: the see of a bishop suffragan of Messina; 32 miles W. of Messina. N. lat. $38^{\circ} 10'$. E. long. $15^{\circ} 2'$.—Also, a river of Sicily, which runs into the sea, one mile E. of Patti.

PATTIAD, a town of Hindoostan, in Guzerat; 35 miles N.W. of Gogo.

PATTIARY, a town of Hindoostan, in Oude; 55 miles E.N.E. of Agra. N. lat. $27^{\circ} 35'$. E. long. $79^{\circ} 26'$.

PATTICAUT, a town of Hindoostan, in Cochin; 38 miles E.N.E. of Cranganore.

PATTIGAM, a town of Hindoostan, in Orissa; 30 miles N. of Orissa.

PATTMES, a town of Bavaria; 8 miles N. of Aicha.

PATTSCHOW, or **PATZOW**, a town of Bohemia, in the circle of Bechin; 38 miles S. of Prague. N. lat. $49^{\circ} 30'$. E. long. $14^{\circ} 50'$.

PATTUNGAM, a town of Hindoostan, in Orissa; 18 miles N. of Sonnepour.

PATTYAH, a town of Hindoostan, in Oude; 22 miles S.S.W. of Canoge.

PATTYPOUR, a town of Hindoostan, in Bahar; 52 miles S.S.W. of Patna.

PATUCKET, a small village of America, about four miles N.E. of Providence in Rhode island, a place of considerable trade and manufactures. Through this village runs Patucket or Pawtucket river, which empties into Seekhonk river at this place. The river Patucket, called in its more northerly course Blackstone's river, has a beautiful fall of water,

water, directly over which has been built a bridge on the line, which divides the commonwealth of Massachusetts from the state of Rhode island; distant about 40 miles S. by W. from Boston.

PATURAGES, a town of France, in the department of Jemmapes, and chief place of a canton, in the district of Mons. The place contains 3208, and the canton 14,126 inhabitants, on a territory of 117½ kilometres, in 17 communes.

PATUXENT, or **PATUXET**, a navigable river of America, in Maryland, which rises near the source of Patapsco river, and runs into the W. side of Chesapeake bay, between Drum and Hog island points; 15 or 20 miles N. of the mouth of the Patowmack. It admits vessels of 250 tons to Nottingham, nearly 46 miles from its mouth, and of boats to Queen Anne, 12 miles higher.

PATZLAWITZ, a town of Moravia, in the circle of Olmutz; 18 miles S. of Olmutz.

PAU, a town of France, and chief place of a district, in the department of the Lower Pyrenées; situated on a river called the "Gave of Pau." It is divided into the East and West parts: the former contains 5800, and its canton 9708 inhabitants, on a territory of 52½ kilometres, in 10 communes; and the latter 2785, and its canton 12,593 inhabitants, on a territory of 122½ kilometres, in 11 communes. It was, before the revolution, the capital of Bearn, and the seat of a parliament, a governor, a seneschal, &c. and contained an university, an academy of sciences, two hospitals, a college, and several convents. This place has manufactures, linen, &c. and its hams are highly esteemed. The environs are planted with vineyards. N. lat. 43° 17'. W. long. 0° 18'.

PAU, *St.* a town of Spain, in the province of Catalonia; 12 miles N.W. of Gerona.

PAVAGE, **PAVAGIUM**, in our old *Law Books*, money paid towards the paving of streets, or highways.

PAVAIS, **PAVACHE**, or *Tallevas*, in *Ancient Armour*, was a large shield, or rather a portable mantlet, capable of covering a man from head to foot, and probably of sufficient thickness to resist the missile weapons then in use. These were, in sieges, carried by servants whose business it was to cover their masters with them, whilst they with their bows and arrows shot at the enemy on the ramparts. In the list of the army that accompanied king Edward III. to Calais, we find many "Pavifors:" these were probably men trained to the use of the pavais, which must have required dexterity as well as courage. Pavaches were sometimes supported by props: they were also used at sea to defend the sides of the vessels, like the present netting of our ships of war: this defence was called a "pavifade," and may be seen in the representation of ancient ships. The pavais was rectangular at top, the sides being consequently parallel, but the angle is rounded off at the bottom. Under the protection of the pavaches, workmen also approached to the foot of the wall in order to sap it.

PAVAKA, in *Mythology*, is the Hindoo regent of fire, and is a deity frequently invoked in the variety of sacrificial ceremonies observed by that superstitious race. The element of fire being of such vital importance in all the operations of nature, and in its evident and hidden phenomena so striking and mysterious, it has, of course, excited the wonder and invited the research of the vulgar and the wise of all ages and nations. The sun, the supposed source of heat, is naturally joined with his offspring in the awe and adoration with which each is contemplated; and among the Hindoos, as with other polytheists, we find the attributes and characters of the regents of light and heat

often coalescing. The Hindoos have, however, depicted their fire-king in colours and forms not common to others. He is painted of a deep red; with two faces, three legs, and seven arms, riding on a ram, and bearing a flag with that animal on its field. Few, if any, of the numerous ceremonies of the Brahmans are complete without invocatory oblations to the all-pervading element of fire, or to its personification, under the name of Pavaka or Agni; the latter is indeed his most popular and common name. In sacrificial ceremonies, as ordained by Menu (see MENU), Agni is generally the deity primarily invoked. A Brahman is directed in his domestic fire for dressing the food that he daily offers to the gods, to make an oblation, "First, to Agni, god of fire, and to the lunar god, severally; then to both of them at once." (C. iii. v. 85.) Again, in offering to the *Dii Manes*: "The divine manes are always pleased with an oblation in empty glasses, naturally clean, on the banks of rivers, and in solitary spots. First, as it is ordained, having satisfied Agni, Soma, and Yama, with clarified butter, let him proceed to satisfy the manes of his progenitors." Ib. c. iii. v. 207. 211.

The Brahmans subdivide the igneous element, first, into two, the solar and terrestrial; or creative and destructive fire. Here Agni, as its general personification, coalesces with Brahma and Siva, and hence it has been furnished his two faces. Terrestrial fire is again subdivided into three, *viz.* the nuptial, the ceremonial or funeral, and the sacrificial. Agni's three feet may allude to these, or to the influence of fire over the three regions of the universe. The sun is preceded by a seven-headed horse, or by seven horses yoked to his car; allusive, it is supposed, to the prismatic variety of a ray of light; and fire, like the sun, is supposed by the Hindoo philosophers to emit seven rays. This number is mysteriously repeated in invocations to Agni and Surya, the latter their Phœbus or Apollo. (See SURYA.) Hence the number of arms bestowed on Agni.

The following verses from Menu are illustrative of the attributes of Agni connected with the sacred triad of fires.

Ch. xi. v. 229. "Due reverence to these three (the parents and preceptor) is considered as the highest devotion; and without their approbation, no man must perform any other duty.

230. "Since they alone are held equal to the three worlds; they alone, to the three principal orders; they alone, to the three vedas; they alone, to the three fires.

231. "The natural father is considered as the *garbapatra*, or nuptial fire; the mother, as the *dakṣiṇa*, or ceremonial; the spiritual guide, as the *ahavaniya*, or sacrificial: this triad of fires is most venerable.

232. "By honouring his mother, he gains this terrestrial world; by honouring his father, the intermediate, or ethereal; and by assiduous attention to his preceptor, even the celestial world of Brahma."

Like other Hindoo deities, Agni has a wife or *fakti*, of whom some mention is made under the article SWAHA, who appears to have been a form of *Lakṣmi*. (See that article.) In one of the tales of the Puranas, it is related how "Lakṣmi performed tapasya for 100,000 years, in the flower of the padma or lotos, standing on one foot, (see PADMA and TAPAS), in order to obtain Viṣṇu. She then saw Sri Krishna or Viṣṇu, who said, 'Thou shalt be my wife when I assume the shape of Varaha; but in the mean time be the *fakti* of Agni, which *fakti*, or energy, burns every thing: be also the wife of Siva. Vahni, Agni, or Fire, for an hundred years of the gods, will have no other wish but to please thee.' She conceived by him: the gestation lasted twelve years, and three beautiful sons were born unto

unto her ; Dakshinagni, Garhapatya, and Ahavanya, three sacred fires." (Af. Ref. vol. xi. art. 2.) In this manner the theogonical legends of the Puranas run into each other ; very confusedly as would seem on partial examination, but connectedly, as it is said, will appear whenever that mass of romantic fables shall have been competently inspected. See PURANA.

The number seven, we have seen, is that of the arms of Agni, and of many allusions to him in his form of fire. In the ceremony called *vishvadeva*, a comprehensive one to *all the gods*, which is the meaning of the word, including the essentials of the whole detail of daily sacrifice, and practised therefore chiefly by Brahmans not exclusively engaged in the priesthood, the mystical number frequently occurs in this invocation ; for instance, to Agni. " Fire ! seven are thy fuels ; seven thy tongues ; seven thy holy fages ; seven thy beloved abodes ; seven ways do seven sacrifices worship thee ; thy sources are seven ; may this oblation be efficacious." An explanation of this mysterious passage is given by Mr. Colebrooke, in his " Essay on the Religious Ceremonies of the Hindoos," in the seventh volume of the Af. Ref.

We have noticed three of the sons of Agni or Pavaka, in the three sacred fires, by Lakshmi, in her form of his fakti. He had three other sons, perhaps by a different wife, named Uttama, Tamasa, and Riavata, whose names occur in the list of seven Menus, or sages, under the article MENU. Their names have probably some allusions, direct or inverse, to fire, or heat, or light. By another wife he had nine sons. Another son is noticed in the form of an ape under the article NILA. He had also seven brothers, whose names are varied significations of *flame*.

The three sons of Agni above named, are on other occasions called sons of Brahma, as mentioned under the article MENU, above referred to. Between Agni or Brahma we see here some identity : both are also painted red. It is in reference to his creative heat that he is connected with Brahma. He is also called Vahni, a name likewise of Saraswati, the consort of Brahma. A passage above quoted has shewn that the spouse of Agni coalesces with those of the other two persons of the Hindoo head : as doth Agni : his igneous property concentrated, connects him with the destructive Siva, who is also fire ; and his light, so intimately related to fire, with Vishnu the conservator. This triple connection between the deity of heat and the three great powers, is similar to what is remarked of the sun under the article SURYA.

Sir W. Jones, in his " Dissertation on the Gods of Greece, Italy, and India," has the following passage, applicable to the subject of our present article.

" The worship of solar or vestal fire may be ascribed, like that of Osiris and Isis, to the second source of mythology, or an enthusiastic admiration of nature's wonderful powers ; and it seems, as far as I can yet understand the Vedas, to be the principal worship recommended in them. We have seen that Mahadeva himself is personified by fire ; but subordinate to him is the god Agni, often called Pavaka, or the Purifier, who answers to the Vulcan of Egypt, where he was a deity of high rank ; and Agni's wife, Swaha, resembles the younger Vesta, or Vesta, as the Æolians pronounced the Greek word for a *heart*. Bhavani, or Venus, is the consort of the supreme destructive and generative power ; but the Greeks and Romans, whose systems are less regular than that of the Indians, married her to their divine artill, whom they also named Hephaistos, or Vulcan, and who seems to be the Indian Vishwakarma, the forger of arms for the gods, and inventor of the

Agniaster, or fiery shaft, in the war between them and the Daityas, or Tritons." Vol. i. art. 9.

We thus find that the Indian Venus, like her of the Greeks and Romans, is the consort of the fiery god, both as Lakshmi and Bhavani, or Parvati : for in a former extract from a Purana it was shewn that Lakshmi was bestowed on Agni by Vishnu, and became his fakti, or energy, and mother of his fiery triple offspring, and also was bade to become the wife of Siva.

With the Hindoos, purification is resorted to in divers modes, according to the nature of the sin ; and fire is the most efficacious. Hence the name Pavaka means the Purifier. Under the article KARSUAGNI an instance is given of its efficacy in the case of great enormity, and under SATI something farther will be found on that point. Under KARTIKYA and KRITIKA some Puranic fables are noticed, in which Agni bore a part.

To this deity a portion of the Vedas is ascribed, as having been revealed or promulgated by him. (See VEDA.) Seven books of the Yajurveda he is the reputed author of : and one of the Puranas, which details his history, is called the Agni Purani. See an outline of its contents under PURANA. He is therein also named Agnidhra, Anala, and Jivani : to the latter appellation it is added, " he, who does good to all ; from whom sprung the Vedas." Under the article MARUT it is noticed, that the Hindoos have guardians over the cardinal and intermediate points of the heavens. Among these is Pavaka ; and he rules or governs the south-east. In the Gita, when Krishna describes his own pre-eminence among all things and creatures, he says to Arjun, " Among the Vasus, I am Pavaka." See KRISHNA and VASU.

Among the offspring of Agni may be noticed the commander of the celestial armies, named Kartikya, who is hence called Agniya, and Agnihuva ; but he is more commonly reputed the son of Siva ; the instrumentality of the god of fire having been apparently confined to warming or inflaming the frigidty of Siva to a due pitch ; the charms of his consort Parvati appearing, by the Puranic fables, to have been unequal to that effect ; and a warlike son, being at the then critical period, essential to the safety of the gods. This fiery parentage of *Kartikya* is noticed under that article, and under MUNI : in the latter, the following correction is necessary ; second column, third line from the bottom, instead of many-mothered for, read many-mothered son.

PAVAN, PAVANA, the air of an ancient stately dance, which has been long out of use. It had its name from the dancer's assuming the dignity of the peacock ; or, perhaps, from Pavana, an Indian author of a system of music that goes under his name. In all sets of lessons for the virginal, from the time of queen Elizabeth to the reign of Charles I., there was a Pavan, which served as an adagio, or slow movement to the galard, as the saraband did afterwards to the courant.

PAVANA, in *Mythology*, is the Hindoo regent of the winds, and of the north-west quarter of the heavens ; the Hindoos having, as noticed under the article MARUT, a separate ruler or guardian for each cardinal and intermediate point. The name of this deity is usually pronounced Pavan ; and we may herein recognize the Faun-us of ancient Italy ; a contraction of Favon-ius, the north-west wind of the Mediterranean mythology, derived probably from a faun or antelope, apt emblem of its celerity, and allotted, therefore, in India, as a vehicle for Pavana, who, in pictures, usually appears so mounted. The Puranas contain particular directions to artists in respect to their delineating the gods.

In the Matsya Purana, the following point out the attributes of the one in question. "Let Pavana be painted young, clothed in robes of many colours, mounted on a fleet antelope, and with a standard in his hand, which the wind waves behind him as he cleaves the air." A farther instance of analogy in the European and Indian mythological tales, and connected with this article, will be found under MARUTY, a name of Hanuman, a simian hero, reputed son of Pavana, one of whose names is *Marut*, which see; a word, like Pavan, meaning the wind. He is lord or chief of the maruts, or winds. Vayu is another of his names, and Anila and Yahi. This deity is honoured by frequent invocation and sacrifice in the Brahmanical ceremonies. An instance is given under NIRRIITI. One of the Puranas is named after this deity, and feigned to have been promulgated by him; but as the found of Pavana immediately preceding *purana*, would be harsh in the fastidious ear of the Brahmans, that poetical sect, to avoid this cacophony, always call it after another of the names of the windy regent Vayupurana. See PURANA.

PAVANA, in *Botany*, the name of the plant which produces the grana tiglia of the shops. It is a species of ricinus.

PAVANA-Wood, when fresh, operates very violently, both by vomit and stool: when dried, it is much more gentle, never vomiting at all; but at present it is scarcely heard of in the shops.

PAUCARA, in *Geography*, a town of Peru, in the diocese of Guimanga; 20 miles E. of Guanca Velica.

PAUCARCOTTA, a town of Peru, which gives name to a jurisdiction, in the diocese of La Paz; 32 miles N. of Puno, which is the capital of the jurisdiction. This jurisdiction borders S. on that of Chucuito, and has the same temperature; and is therefore obliged to recur to other provinces for the greatest part of its grain, and esculent vegetables; but abounds in all kinds of cattle, both of the European and American kinds. The Indians of the town weave bags with their wool, and sell them to great advantage. The mountains in this province contain several silver mines, and among the rest the famous Layacota, in which the metal was often cut out of the mine with a chissel; but its prodigious richness accelerated the death of its owner, Joseph Salcedo; soon after which the waters broke into it, nor have any labour and expence been sufficient for draining it, so that it has been abandoned. Few of the other mines are wrought.

PAUCARTAMBO, a jurisdiction of Peru, in the diocese of Cusco, which commences eight leagues E. of Cusco, and is of considerable extent. In the time of the Incas it produced the greatest quantity of cocoa, with which it carried on a very profitable commerce. But since this shrub has been planted in other provinces, it has greatly declined. The soil is equally fertile in other productions.—Also, a river, that rises about 50 miles S.W. of Cusco, and after a northerly course of about 200 miles, through the jurisdiction to which it gives name, joins the Maranon at 10° 45'; but in fact it is the river styled by La Cruz Ynambari.

PAUCTON, ALEXIS, in *Biography*, a mathematician, was born near Laffay, in Mayenne, in 1732. He received his education in the mathematical and naval academy at Nantes, after which he went to Paris, where his integrity and talents obtained for him a considerable share of patronage. He died in the year 1799. His works are; 1. "Theory of the Force of Archimedes." 2. "A Treatise on the Weights, Measures, and Monies of all Countries, ancient and modern." 3. "Theory of the Laws of Nature, with a Dissertation on the Pyramids of Egypt."

PAVEMENT, a layer or stratum of stone, or other matter, serving to cover and strengthen the ground of divers

places, for the more commodious walking on, or for the passage of carriages.

The word is formed from the Latin *pavimentum*, of *pavire*, to beat down the earth, in order to make it firm and strong.

In England, the pavements of the grand streets, &c. are usually of flint or rubble-stone; courts, stables, kitchens, halls, churches, &c. are paved with tiles, bricks, flags, or fire-stone; sometimes with a kind of free-stone, and rag-stone.

In some cities, *e. gr.* of Venice, the streets, &c. are paved with brick; churches sometimes are paved with marble, and sometimes with mosaic work, as the church of St. Mark, at Venice. In France, the public roads, streets, courts, &c. are paved with gres or grit, a kind of free-stone.

In Amsterdam, and the chief cities of Holland, they call their brick pavement the *burgher-master's* pavement, to distinguish it from the stone or flint pavement, which usually takes up the middle of the street, and which serves for carriages; the brick which borders it being destined for the passage of people on-foot.

Pavements of free-stone, flint, and flags, in streets, &c. are laid dry, *i. e.* in a bed of sand; those of courts, stables, ground-rooms, &c. are laid in a mortar of lime and sand; or in lime and cement, especially if there be vaults or cellars underneath. Some masons, after laying a floor dry, especially of brick, spread a thin mortar over it; sweeping it backwards and forwards to fill up the joints. The several kinds of pavement are as various as the materials of which they are composed, and whence they derive the name by which they are distinguished: as, 1. *Pebble-paving*, which is done with stones collected from the sea-beach, mostly brought from the islands of Guernsey and Jersey; they are very durable, indeed the most so of any stone used for this purpose. They are used of various sizes, but those which are from six to nine inches deep, are esteemed the most serviceable. When they are about three inches deep they are denominated bolders, or bowlers; these are used for paving court-yards, and other places not accustomed to receive carriages with heavy weights; when laid in geometrical figures they have a very pleasing appearance.

2. *Rag paving*, was formerly much used in London, but is very inferior to the pebbles; it is dug in the vicinity of Maidstone, in Kent, from whence it has the name of Kentish rag-stone; there are squared stones of this material for paving coach-tracks and footways.

3. *Purbeck pitchens*; squared stones used in footways; they are brought from the island of Purbeck, and also frequently used in court-yards; they are in general from six to ten inches square, and about five inches deep.

4. *Squared paving*, for distinction by some called *Scotch paving*, because the first of the kind paved in the manner that has been and continues to be paved, came from Scotland; the first was a clear close stone, called blue wynn, which is now disused, because it has been found inferior to others since introduced in the order they are hereafter placed.

5. *Granite*, a hard material, brought also from Scotland, of a reddish colour, very superior to the blue wynn quarry.

6. *Guernsey*, which is the best, and now almost the only stone in use; it is the same stone with the pebble before spoken of, but broken with iron hammers, and squared to any dimensions required of a prismoidal figure, set with its smallest base downwards. The whole of the foregoing paving should be bedded and paved in small gravel.

7. *Purbeck paving*, for footways, is in general got in large surfaces, about two inches and a half thick; the blue sort is the hardest and the best of this kind of paving.

8. *Yorkshire paving*, is an exceeding good material for the same purpose, and is got of almost any dimensions of the same thickness of the Purbeck; this stone will not admit the wet to pass through it, nor is it affected by the frost.

9. *Ryegate, or fire-stone paving*, is used for hearths, stoves, ovens, and such places as are liable to great heat, which does not affect this stone, if kept dry.

10. *Newcastle flags*, are stones about two feet square, and one and a half, or two inches thick; they answer very well for paving out-offices; they are somewhat like the Yorkshire.

11. *Portland paving*, with stone from the island of Portland; this is sometimes ornamented with black marble dots.

12. *Sweedland paving*, is a black slate dug in Leicestershire, and looks well for paving halls, or in parti-coloured paving.

13. *Marble paving*, is mostly variegated with different marbles, sometimes inlaid in mosaic.

14. *Flat brick paving*, done with brick laid in sand, mortar, or grout, as when liquid lime is poured into the joints.

15. *Brick on edge paving*, done with brick laid edgewise in the same manner.

16. Bricks are also laid flat or edgewise in herring-bone.

17. Bricks are also sometimes set endways in sand, mortar, or grout.

18. Paving is also performed with paving bricks.

19. With ten-inch tiles.

20. With foot-tiles.

21. With clinkers for stables and out-offices.

22. With the bones of animals, for gardens, &c. And

23. We have knob-paving, with large gravel-stones for porticoes, garden-seats, &c.

Pavers' work is done by the square yard: and the content is found by multiplying the length by the breadth.

Pavements of churches, &c. frequently consist of stones of several colours; chiefly black and white, and of several forms, but chiefly square, and lozenges, artfully disposed. Indeed, there needs no great variety of colours to make a surprising diversity of figures and arrangements. M. Truchet, in the Memoirs of the French Academy, has shewn by the rules of combination, that two square stones, divided diagonally into two colours, may be joined together chequerwise sixty-four different ways: which appears surprising enough; since two letters, or figures, can only be combined two ways.

The reason is, that letters only change their situation with regard to the first and second; the top and bottom remaining the same: but in the arrangement of these stones, each admits of four several situations, in each of which the other square may be changed sixteen times, which gives sixty-four combinations.

Indeed, from a farther examination of these sixty-four combinations, he found there were only thirty-two different figures; each figure being repeated twice in the same situation, though in a different combination; so that the two only differed from each other by the transposition of the dark and light parts.

The paving of streets is one of the most beneficial regulations of police that have been transmitted to us from our ancestors. Several cities had paved streets before the commencement of the Christian era; nevertheless those which are at present the ornament of Europe, Rome excepted, were def-

titute of this great advantage till almost the 12th or 13th century. It is probable that those people who first carried on the greatest trade, were the first who paid attention to have good streets and highways, in order to facilitate that intercourse which is so necessary to keep up the spirit of commerce. Accordingly we are told by Isidorus (Origin. l. xv. c. 16.) that the Carthaginians had the first paved streets, and that their example was soon copied by the Romans. Long before that period, however, Semiramis paved highways, as appears by the vain-glorious inscription which she herself caused to be put up. (Strabo, l. xvi. Diod. Sicul. l. ii. v. 13. Polyæni Stratagem. l. viii. c. 26.) The streets of Thebes, and probably those of Jerusalem, were paved. But neither the streets of Rome, nor the roads around it, were paved during the time of its kings. In the year 188, after the abolition of the monarchical form of government, Appius Claudius, being then censor, constructed the first real highway, called after him the Appian way, and on account of its excellence, the queen of roads. The time when the streets were first paved cannot be precisely ascertained; some have referred this improvement to the year 578, after the building of the city; others to 584; and others to 459; at which several periods some parts of the city and suburbs might have been paved. That streets paved with lava, having deep ruts made by the wheels of carriages, and raised banks on each side, for the accommodation of foot-passengers, were found both at Herculaneum and Pompeii, is well known.

Of modern cities, the oldest pavement is commonly ascribed to that of Paris; but it is certain that Cordova in Spain was paved so early as the middle of the 9th century, or about the year 850. The capital of France was not paved in the 12th century, but the orders for this purpose were issued by the government in the year 1184, on which occasion it is said that the name of Lutetia, deduced from its dirtiness, was changed into that of Paris. Nevertheless, in the year 1641, the streets in many quarters of Paris were not paved. That the streets of London were not paved at the end of the 11th century, is asserted by all historians. It does not appear when paving was first introduced; but it was gradually extended as trade and opulence increased. Several of the principal streets, such as Holborn, which are at present in the middle of the city, were paved for the first time by royal command in the year 1417; others were paved under Henry VIII., some in the suburbs in 1544, others in 1571 and 1605, and the great market of Smithfield, in 1614.

PAVEMENT of *Terrace*, is that which serves for covering in manner of a platform; whether it be over a vault or a wooden floor.

Those over vaults are usually stones squared, and bedded in lead. Those on wood, called by the Latins *pavimenta con-signata*, are either stones with beds for bridges, tiles for ceiling of rooms, or lays of mortar made of cement and lime, with slints or bricks laid flat: as is still practised by the eastern and southern people a-top of their houses.

All those pavements which lie open were called by the Latins *pavimenta subdialia*.

PAVEMENT, *Mosaic*. See MOSAIC WORK.

PAVEMENT, *Tessellated*. See TESSELLATED.

PAVENTIA, in *Mythology*, the tutelary goddess of children. Among the Romans this goddess was invoked to avert from them frightful objects.

PAVETTA, in *Botany*, the Malabar name, retained by Rheede and adopted by Linnæus and others, contrary to rule, except as far as it is well-sounding. Linn. Gen. 54. Schreb. 71. Willd. Sp. Pl. v. 1. 610. Mart. Mill. Dict.

v. 3. Ait. Hort. Kew. ed. 2. v. 1. 244. Juff. 203. Gærtn. t. 25. Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Stellate*, Linn. *Rubiaceae*, Juff.

Gen. Ch. *Cal.* Perianth fuperior, very fmall, bell-shaped, four-toothed, crowning the germen, permanent. *Cor.* of one petal, funnel shaped; tube ufually long, flender, cylindrical; limb in four deep, lanceolate, fpreading fegments. *Stam.* Filaments four, very fhort, above the mouth of the corolla; anthers awl-shaped, fpreading, the length of the limb. *Pijl.* Germen inferior, roundifh; fyle thread-shaped, twice as long as the corolla; ftigma oblong, club-shaped, oblique. *Peric.* Berry roundifh, of two cells, one of them often abortive. *Seeds* folitary, roundifh, cartilaginous, convex on one fide.

Eff. Ch. Calyx bell-shaped, four-toothed, fuperior. Corolla of one petal; tube cylindrical; limb four-cleft, fpreading. Stamens rifing above the mouth. Style longer than the flamens. Stigma club-shaped, curved. Berry of two cells. Seeds folitary, cartilaginous.

Obf. We have already hinted the difficulty of eftablifhing a certain diftinftive character between this genus and *IXORA*; fee that article. Whether the greater length of the fyle, more entire ftigma, and lefs deeply divided calyx of *Pavetta* be of any great weight, a comparifon of all the fpecies of both genera together can alone determine.

1. *P. indica*. Linn. Sp. Pl. 160. Suppl. 121? Willd. n. 1. Ait. n. 1. (*P. feu* Malleamoth; Rheede Hort. Mal. v. 5. 19. t. 10.)—Leaves elliptic-lanceolate, fmooth, as well as the flower-ftalks. Calyx very flightly toothed. Style twice the length of the corolla. Found in many parts of the Malabar coaft, from whence Dr. Roxburgh fent us fpecimens. A humble fpreading ever-green fhrub. *Leaves* oppofite, ftalked, thin, fmooth and fhining, with many ftraight tranfverfe ribs. *Stipulas* broad, triangular, firmly combined with the foot-ftalks, quite fmooth. *Flowers* very numerous, white, fragrant, in fmooth, flender, repeatedly forked, cymofe panicles. Burmann's Ind. t. 13. f. 3, accords in no refpect with our plant. The plant of Rumphius, v. 4. t. 47, cited by Willdenow, after Linn. Mant. 331, is furely our *Ixora flammea*, and has neither the form nor colour of *Pavetta*.

2. *P. tomentofa*. Roxb. MSS.—Leaves elliptical, downy, as well as the flower-ftalks. Calyx cloven half way down. Style twice as long as the corolla.—Sent from India by Dr. Roxburgh, along with the former, from which it feems to differ chiefly in its broader leaves, which, like the *flower-ftalks* and *calyx* are downy, efpecially when young. The teeth of the *calyx* are much more conspicuous than in *P. indica*, and this character appears of confequence, from the confideration of other fpecies.

3. *P. villofa*. "Vahl. Symb. v. 3. 12." Willd. n. 2.—"Branches and calyx villous and hoary. Leaves lanceolate-elliptical. Flowers in tufts."—Native of Arabia Felix. We know nothing of this but from Willdenow. The *inflorefcence* is probably like *P. indica*, as Vahl ufes the fame term for both.

4. *P. longiflora*. "Vahl Symb. v. 3. 12." Willd. n. 3.—"Branches fmooth. Leaves lanceolate-elliptical. Stipulas hairy on the infide. Calyx four-cleft. Flowers in tufts."—Native of Arabia Felix, where it was gathered by Forkfall, as well as the laft. The *calyx* appears to be more deeply divided than in the firft fpecies, or perhaps the laft.

5. *P. caffra*. Linn. Suppl. 121. Thunb. Prodr. 29. Willd. n. 4. (*Criniva capensis*; Houttuyn Linn. Pfl. Syfl. v. 5. 357. t. 40. f. 1. *Willd.*)—Leaves obovate, fmooth. Flowers in terminal heads. Teeth of the calyx awl-shaped, above half the length of the tube of the corolla.—Gathered

by Sparrmann and Thunberg at the Cape of Good Hope. The length of the *calyx* is very remarkable, as well as the long white denfe hairs, clothing the common *receptacle*, or inner fide of the *bractees*. The *fyle* is twice as long as the *corolla*.

6. *P. barbata*. Leaves lanceolate-oblong, pointed, fmooth. Panicles forked, divaricated, fmooth. Tube of the corolla but half the length of the five-cleft limb, briftly at the mouth.—Gathered by the late Mr. Christopher Smith, at Honimoo, or Honimao, April 2, 1797. He fufpected it to be a *Pavetta*, and we can only prefume it to be fo. The whole appearance agrees with the figure of the next, and the *flowers*, as in that, are five-cleft; but their fhort tube diftinguifhes them from every other fpecies. The *anthers* are very long, equal to the *corolla*; nor does the *ftigma*, which is cylindrical and acute, though curved, project beyond them. The *calyx* is a little hairy, flightly toothed, decidedly bell-shaped. The *leaves* are coriaceous, a foot long, two inches broad, with taper points. *Panicles* axillary, many-flowered.

7. *P. pentandra*. Swartz Ind. Occ. 233. Willd. n. 5. (*Jafminum arborefcens*, folani foliis, baccis nigro-violaceis; Plum. Ic. 149. t. 156. f. 1. *Cerafo affinis* arbor baccifera racemofa, fructu cæruleo, monopireno, tellicuato; Sloane Jam. v. 2. 95. t. 202. f. 2.)—Leaves elliptic-lanceolate, pointed, fmooth. Panicles forked, divaricated, fmooth. Tube of the corolla twice as long as the five-cleft limb, naked at the mouth.—Native of uncultivated hills in Jamaica, where it is called Wild Coffee. The *leaves* appear to be broader, and lefs coriaceous, than in the laft. The *ftem* is the height of a man, or much more. *Flowers* white, highly fragrant, produced in the vernal months.

Swartz confiders the *SIDERODENDRUM* of Schreber, fee that article, akin to this plant, which he fays is, in a manner, intermediate between the three very clofely allied genera of *Pfychothria*, *Coffea* and *Pavetta*. We cannot help adverting to Willdenow's continuing the erroneous reference to Sloane, from Swartz's Prodrum, though he quotes the page in that author's Flora Ind. Occ., where the miltake is exprefly pointed out and rectified.

PAUGANARY, in *Geography*, a town of Hindooftan, in Marawar; 10 miles S. of Tripatore.

PAVIA, in *Botany*, fo called by Boerhaave in honour of Peter Pavius, who was profefor of Phyfic at Leyden, and to whom the care of the Botanic Garden there was confided in May 1592. The botanical Profeforship being conferred upon Clufius two months afterwards, Bontius and Pavius were affociated with him in this charge for feveral years. In 1609 the whole devolved upon Pavius, and he continued to enrich and improve the garden till his death in 1617. He does not appear to have publifhed any thing, not even a catalogue of the garden. The prefent plant is now referred by botanifts to another genus, fee *ÆSCULUS*, in which it bears the fpecific name of *Pavia*, and is well known in our gardens as the Scarlet Horfe-chefnut.

PAVIA, in *Geography*, a city of Italy, and capital of the department of the Teino, fituated on a beautiful plain, on the river Tefino. It was once the capital of Lombardy, but few evidences remain of its having been once thus diftinguifhed. The fortifications of the citadel have been neglected; the ftreets are broad and ftraight, and have fome good buildings. Pavia is the fee of a bifhop, and beides the cathedral, contains 18 parifh churches, and 38 convents. The univerfity was founded by Charlemagne, and re-eflablifhed by Charles IV. It is ftill in good repute, its profefors having diftinguifhed themfelves in natural hiftory, and is regarded as the firft in Italy. This city was founded by the Gauls; but they were expelled by the Romans, and the

Romans by the Goths, about the middle of the fifth century. In 476 or 477, Odoacer granted the inhabitants an exemption from taxes for five years, in order to enable them to rebuild the town, which had been ruined, and which till that time had been denominated Tifinum; and when it was rebuilt, it was called Papia or Pavia. In 568 it was taken by the Lombards, and became their capital; but this distinction terminated with Didier, who was taken prisoner by Charlemagne in the year 774, afterwards it became the prey of several tyrants, till it fell under the dominion of the dukes of Milan. After several disasters, this town was taken in 1800 by the French, who found in it immense stores belonging to the Austrians; 17 miles S. of Milan. N. lat. 45° 10'. E. long. 9 9'.

PAVIA, *Duchy of*, or the *Pavesi*, is now part of the department of the Tesino, and is bounded on the N. by the Milanese, on the E. by the Lodofan and Placentia, on the S. by the territory of Genoa, and on the W. by the Lumellin and Tortonese.

PAVICULA, among the Romans, a rammer, or instrument for beating down and levelling a spot of ground.

It consisted of a block of wood one foot long and half a foot thick, with a long handle.

PAVIGNANO, in *Geography*, a town of Italy, in the department of the Mela; 10 miles E.N.E. of Brescia.

PAVILION, in *Architecture*, signifies a kind of turret, or building usually insulated, and contained under a single roof; sometimes square, and sometimes in form of a dome; thus called from the resemblance of its roof to a tent.

The word comes from the Italian *padiglione*, tent; and that from the Latin *papilio*.

Pavilions are sometimes also projecting pieces, in the front of a building, marking the middle of them. Sometimes the pavilion flanks a corner, in which case it is called an *angular pavilion*. The Louvre is flanked with four pavilions. The pavilions are usually higher than the rest of the building.

There are pavilions built in gardens, popularly called summer-houses, pleasure-houses, &c. Some castles or forts consist only of a single pavilion.

PAVILION, in *Heraldry*, denotes a covering in form of a tent, which invests, or wraps up, the armories of divers kings and sovereigns depending only on God, and their sword.

The French heralds hold, that none but sovereign monarchs may bear the pavilion entire, and in all its parts.

The pavilion consists of two parts: the top, which is the chapau, or coronet; and the curtain, which makes the mantle. Those who are elective, or have any dependence, say the heralds, must take off the head, and retain nothing but the curtains.

The use of pavilions and mantles in armories are derived from the ancient lambrequins, which are sometimes found stretched out in form of coverings; and tucked back on either side.

Others will have it derived from the ancient tournaments, wherein were exposed the arms of the knight, in rich tapestry-work, on tents and pavilions, with the chiefs of the quadrils planted to shelter themselves in, till the time of entering the lists.

PAVILION, in *War*, denotes a tent raised on poles to lodge under in the summer time. See *TEXT*.

PAVILION is also sometimes applied to flags, colours, ensigns, standards, banners, &c. all which authors usually confound with one another.

The custom of bearing pointed pavilions, as at present, first came from the Mahometan Arabs, at the time when they conquered Spain. Till then, all colours were stretched

on cross pieces like church-banners; whence they were called in Latin, *vesilla quasi velilla*, a diminutive of *vela*, sails.

The pirates all along the coasts of the Atlantic, and Barbary, bear hexagonal pavilions, gules, charged with a little Turk, dressed in his turban; though contrary to their law, which prohibits the making any image of a man; from an opinion that those who make the figure here will be obliged to furnish a soul for it at the day of judgment, or, in default thereof, be damned.

But this portrait, it seems, is that of Hali Sulficar, Mahomet's son-in-law, to whose party the Africans adhere: and who appointed his picture to be represented on their banners; imagining himself so terrible to the Christians, that the mere sight of his image would put them to flight; as we are told by Leunclavius.

PAVILIONS, among *Jewellers*, the under sides and corners of the brilliants, lying between the girdle and the collet.

PAULLAC, in *Geography*, a town of France, in the department of the Gironde; and chief place of a canton, in the district of Lesparre; 10 miles S.E. of Lesparre. The place contains 1443, and the canton 6941 inhabitants, on a territory of 165 kilometres, in six communes.

PAVILLON, STEPHEN, in *Biography*, a man of letters, was born at Paris in 1632. He was educated for the law, and obtained the post of advocate-general of Metz, but a delicate constitution, and a love of study and refinement, caused him to resign that office, and devote himself to literature. The mildness of his manners, and the charms of his conversation, procured him many distinguished friends, and during the fits of the gout, to which he was a martyr, his chair was surrounded by persons of rank and eminence. He refused the office of preceptor to a young prince, though it seemed to open the way to a good fortune. Lewis XIV. gave him a pension of 2000 livres. He died in 1705, at the age of 73. He was a member both of the French academy, and that of Inscriptions, without having solicited a seat in either. His literary reputation was chiefly founded on his poems, which were characterized by ease, gaiety, and great delicacy. The most complete edition of his works was printed at Paris in two vols. 12mo 1747. Moreri.

PAVILLY, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Rouen; nine miles N.W. of Rouen. The place contains 2245, and the canton 14,584 inhabitants, on a territory of 155 kilometres, in 25 communes.

PAVISADE, and PAVISORS. See PAVAIS.

PAUKATUCK, in *Geography*, a small river of America, which runs into Stonington harbour, and forms a part of the division line between Connecticut and Rhode island.

PAUL, ST., called also SAUL, in *Sacred Biography*, an eminent apostle of Jesus Christ, was a descendant of the patriarch Abraham, of the tribe of Benjamin, and a native of Tarsus, then the chief city of Cilicia. He was also by birth a citizen of Rome. (Acts, xvi. 37, 38. xxii. 25, 29, xxiii. 37.) This privilege he claimed by his birth, and not, as Dr. Lardner has shewn, by his nativity at Tarsus, which does not appear to have been a municipium, or town of Roman citizens. The excellent writer just named supposes, that some of St. Paul's ancestors had obtained the privilege of citizenship for services performed to the Roman commonwealth in the wars. (Vid. Grotius ad Act. xxii. 28.) His father was a Pharisee, and he himself was of the same sect. (Acts, xxiii. 6. xxvi. 5. Philip. iii. 5.) His sister's son, and some others of his relations, were Christians, and had been so before his conversion; and this circumstance is alleged as a proof of the virtue and piety of his family. That St. Paul was educated in Greek literature in his early life

life at Tarsus, may be inferred from the place of his nativity, which was celebrated for polite learning, and also from his quotations of several Greek poets. (Acts, xvii. 28. 1 Cor. xv. 33. Titus, i. 12.) It appears that he was likewise for some time under the instructions of Gamaliel, a celebrated Jewish rabbi, at Jerusalem, and that he had made great proficiency in the study of the law, and the traditions, much esteemed by that people. (Acts, xxii. 3. xxvi. 5. Gal. i. 14.) He seems to have been a person of great natural abilities, of quick apprehension, strong passions, and firm resolution, and thus qualified for signal service, as a teacher of such principles as he should embrace, whatever they were. He appears likewise to have been always unblameable in his life, and strictly faithful to the dictates of his conscience, according to the knowledge which he had. This appears from his appeals to the Jews, (Acts, xxiii. 1. xxvi. 4, 5.) and from the undissembled satisfaction which he expresses upon a serious recollection of his former and later conduct. (Philip. iii. 6. 1 Tim. i. 13. 2 Tim. i. 3.) For some time after the first appearance of Christianity in the world, he was a bitter enemy, and furious opposer of all who made profession of it. Nevertheless he did not long persist in that course; but was converted, in an extraordinary manner, to that faith himself; and ever after he was a steady friend, and zealous advocate for it, and very successful in defending and propagating it, diligently improving the gifts and qualifications extraordinarily vouchsafed for that purpose. These particulars are recorded in those writings which are in the highest esteem, and reckoned sacred among Christians, and indeed well known to all the world.

Dr. Lardner has taken great pains to settle the time of his conversion; and this has been thought the more necessary, as various opinions have been entertained among ancient writers, cited by Valesius in his Annotations upon Eusebius's Eccl. Hist. and also among the moderns. Some thought that Stephen was stoned and Paul converted in the year of our Lord's ascension, A. D. 33, or the beginning of the year following. Pearson supposes, that Stephen was stoned in 34, and Paul converted in 35, near the end of the year. Frederic Spanheim, after diligent inquiry, fixes the conversion of Paul in the year 40, the last of Caius Caligula; and inclines to defer it to the first of Claudius, or the year 41. Witius and J. A. Fabricius adopt the same opinion. Lenfant and Beaufobre place his conversion in the year 36, and his first coming to Jerusalem after it in 39; and this opinion is thought by Dr. Lardner to be nearer the truth than any of the foregoing. Upon the whole Lardner concludes that Paul was converted in 37, or possibly, before the end of the year 36; and Stephen was stoned in the beginning of the same year, or, at the soonest, near the end of the year 35. The first notice we have of Paul is in the account of St. Stephen's martyrdom; and it is probable, that he had not long before made his appearance in the world. If we advert to his situation and circumstances, we shall discern the proper vindication of his moral character. It is probable, that he had not seen Jesus during his abode on earth; and it is possible that he did not come from Tarsus to Judea, till after the close of our Lord's ministry; nor is it any unfair supposition, that he had not any acquaintance with any of Christ's apostles, and that he had not seen any miracles wrought by them, before he became a persecutor; and afterwards, he would not admit of instruction from the followers of Jesus. Whilst he was under the tuition of Gamaliel, we may reasonably imagine, that he knew little of the public affairs of Judea, though he was in that country; but when he came from the schools, animated with a high degree of zeal for the law of Moses, and for the traditions of its elders, and found a number of

men, called followers of Jesus, who spoke of him as the Messiah, and as raised from the dead, representing him as greater than Moses himself, he was filled with indignation, and thought that it was his duty to oppose them to the utmost, which he did till Jesus met him and reclaimed him. Although he speaks of himself as *injurious* (1 Tim. i. 13. Acts, xxvi. 10.), yet we may suppose that, even then, he would not have injured any man, in his person or property, from worldly considerations. The moving principle by which he was actuated was not envy, malice, covetousness, or any worldly view, but a false zeal for God and religion; and this induced him to be a persecutor, which is a character, in certain circumstances, not inconsistent with integrity. This might have been the case, with respect to Paul, who was a young man, little acquainted with the world, and just emerging from a Jewish school, where he had been engaged in the study of the law, and the Rabbinical interpretations of it. To this purpose Chrysostom distinguishes between Paul and the Jews; observing that he had a sincere zeal for religion, according to his knowledge at that time, and that they had no concern for Jerusalem, and aimed at nothing but their own honour. But although Paul was sincere, and did not act contrary to conviction, his conduct cannot be justified. He should have examined; he should have taken care to be well informed: if, upon his first coming out into the world, he had pursued this course, he might have received satisfaction, and consequently might have been prevented from acting that part against Jesus, and his disciples, which he afterwards bewailed. His prejudices, however, were strong; and they were not to be overcome in an ordinary way. But though he was prejudiced, he was not obstinate. Our blessed Lord knew him to be tractable, and open to conviction; and he knew, that the measures which he adopted for this purpose would change his heart, and melt him down to ready obedience. The event corresponded to expectation. Although he sat out for Damascus under the full influence of enmity against the disciples of Jesus, he was soon changed, as the history (Acts, ix. 3—6) relates. He trembles and acquiesces, all his rage was subdued, and he became a disciple of Jesus.

Satisfied in his own mind, he imagined that others would manifest a disposition similar to his own, and that an account of his conversion, with all the reasons and circumstances of it, which he was prepared to lay before his countrymen, the Jews, must persuade them. Jesus better knew the disposition and character of the people, whom he thought of convincing and reclaiming; and therefore, instead of permitting him to labour unprofitably among them, renewed his orders to Paul, to proceed, without delay, in the work of preaching to the Gentiles, on which he had already entered. The event proved that the over-ruling providence of God disposed of his person and concerns more wisely and more beneficially than he was capable of judging and acting for himself. It was a very happy and favourable circumstance, that he did not return to Judea immediately after his conversion; because the violent persecution, which commenced about the time of Stephen's death, had continued at least three years after Paul left Judea to go to Damascus.

Dr. Lardner has taken pains to settle Paul's age at the time of his conversion. Witius supposes that he was born near the end of Herod's reign, about the same time with our Saviour. In the epistle to Philemon, (v. 9.) written about the year of the vulgar era 62, he calls himself Paul the aged; and this must lead us to suppose, that he was then 60 years of age, or not much less. In the account of the martyrdom of Stephen, he is called a young man (Acts, vii. 58.); but among the ancients the term youth is used with latitude: and

ST. PAUL.

from some circumstances related of him at that time (Acts, xxvi. 10—12.) we have reason to conclude, that he was arrived to years of maturity, or discretion; and that at the time of his conversion he was of an age at which men are able to judge concerning the evidence of things, and so form a reasonable determination with regard to their future conduct.

It has been generally supposed, that Paul was called to the apostleship at the time of his conversion, or very soon after it. Spanheim, Witius, Cave, Pearson, Basnage, and Hallet are of this opinion. The requisite qualification of an apostle appears to have been, that he should see Christ in person, and that after his resurrection. (See Acts, i. 21, 22.) Accordingly Paul, when he claims the character of an apostle, speaks of his having seen Christ, as a fact well-known and uncontroverted. (1 Cor. ix. 1. 8. 9.) In his way to Damascus, Christ had personally appeared to him. (Acts, ix. 3—6.) The learned author, of whose research we are availing ourselves in the compilation of this article, thinks it highly probable, from all the accounts which we have of Paul's wonderful conversion, (Acts, ix. xxii. and xxvi.) that he received his apostolical commission from the mouth of Christ in person, when he called to him from heaven, and spoke to him in the way to Damascus. As he was, from the beginning, called, and appointed to be an apostle, he was by degrees qualified for it as his commission opened; and in time he was called out by divine providence to the full execution of it.

Paul, having been baptized by Ananias at Damascus, stayed for a short time with the disciples there, and then went into Arabia, where he probably might meet with some believers. (Acts, ii. 11. 41.) Whilst he remained in Arabia, he was fully instructed, as we may reasonably think, by special revelation, in the doctrines preached by Jesus Christ, when on earth, and all the things said and done by him, and his sufferings, crucifixion, resurrection, and ascension, the fulfilment of the ancient prophecies in Jesus, the Christ, the son of David, and the son of Abraham; and received also the holy ghost, in a measure equal to that of other apostles. He was thus qualified to preach the gospel, and to testify the resurrection of Jesus, and to prove him to be the Christ, without receiving either instruction or gifts from other apostles. Having been some time in Arabia, he returned to Damascus; but here a design being formed against his life, he removed to Jerusalem. (Acts, ix. 20. 25.) The period of three years, or three years and somewhat more, which elapsed from Paul's conversion to his coming to Jerusalem, reaches, according to Lardner's computation, from near the end of the year 36 to near the end of 39, or the beginning of the year 40, or from the beginning of the year 37 to the former part of the year 40. Paul travelled through the countries of Cilicia and Syria, during the remainder of the year 40, and the whole of 41, and 42, or the greatest part of the last-mentioned year, till about the beginning of the year 43, preaching, undoubtedly, in the name of Jesus, to native Jews, and to profelytes of the Jewish religion. Afterwards he went to Antioch, and began to preach to Gentiles. Here he probably had the rapture, mentioned by him (2 Cor. xii.) Having fulfilled the commission, mentioned Acts, xi. 27—30, by a journey to Jerusalem, where, in the year 44 he had the trance taken notice of in his speech to the Jewish people (Acts, xxii. 17—21), Paul, and also Barnabas, who had accompanied him, soon after this, left Antioch, and made a farther progress in preaching the gospel to Gentile people. For this journey Pearson allots three years, viz. 45, 46, 47, and somewhat more. Tillamont thinks, it might have been performed in two years, from 44 to 46; or from the beginning of the year

45 to the former part of the year 47, which is Lardner's opinion. Having made some stay at Antioch after their return, they attended a council at Jerusalem, held in the year of Christ 49, or in the beginning of the year 50, and afterwards returned to Antioch. In the beginning of the year 50, St. Paul and Barnabas set out from Antioch; and having gone through Syria and Cilicia, they came to Phrygia; and it is very probable, that Paul preached in the chief cities of that country, Hierapolis, Laodicea, and Colosse. St. Paul also went to Galatia, and there founded many churches; but they were forbidden to preach in Asia, properly so called. After passing through several countries and cities, mentioned in the book of Acts, ch. xvi. xvii. xviii. St. Paul went to Corinth, where he might have been before the end of the year 51. Here he tarried a year and six months, *i. e.* as Lardner supposes, the remainder of the year 51, the whole of 52, and part of 53. Having passed through Galatia and Phrygia, he came to Ephesus, before the end of the year 53, in October or November; and here he remained till the year 56, about pentecost. As the emperor Claudius died Oct. 13, in the year 54, the tidings of his death, and the accession of Nero, might not have reached Ephesus before the beginning of the year 55. Soon after St. Paul determined to visit Rome, proposing first to go to Macedonia, Greece, and Jerusalem. (Acts, xix, xx.) Some time before pentecost, or about that season, in the year 56, Paul left Ephesus to go into Macedonia. Here he staid about a year; at Corinth he staid three months; and there must have elapsed an interval of two years, or nearly as much, between Paul's leaving Ephesus and coming to Troas, in his way to Jerusalem. At this time Paul was in Illyrium and Crete. He arrived in Jerusalem at the pentecost in the year 58. From Jerusalem he was sent away to Rome near the end of the year 60. (See Acts, xxi. 17. ch. xxvi. 1—32.) In ch. xxvii and xxviii. 1—16. we have a very distinct relation of Paul's voyage to Rome; where he arrived in the spring of the year 61; and he was released from his confinement in the former part of the year 63. It has been a subject of debate, whither Paul went after he had obtained his liberty. Some think that he went from Rome to Spain; but Lardner is of opinion that he came from Rome to Jerusalem, as soon and as directly as he could. Here he made a short stay, and from Judea he went to Ephesus; from Ephesus he might go to Laodicea and Colosse; and, possibly, he returned to Rome by Troas, Philipp, and Corinth. It is the opinion of Pagi and Basnage, that Peter and Paul suffered martyrdom in the year of Christ 65. Orosius, they say, having given an account of Nero's persecution of the Christians, and of the death of the two apostles in it, adds, that it was followed by a pestilence in the city, and other disasters. Sulpicius Severus has given an account of the fire at Rome, and Nero's persecution of the Christians, and also of the martyrdom of Peter and Paul therein; adding, that while these things were doing at Rome, the Jews, being uneasy under the oppressions of their governor Gessius Florus, began to rebel; upon which passage Basnage observes, the Jewish war began in May 66; and therefore the martyrdoms of the apostles happened in the year before, that is, 65. Epiphanius places the death of Peter and Paul in the 12th year of Nero, part of which, as he says, fell in the year 65. Dr. Lardner does not presume to assign positively the year of the martyrdom of these two apostles; he is of opinion that they did not survive the year 65; but he cannot say whether their martyrdoms happened in the year 64 or 65. If Peter and Paul were come to Rome before the city was set on fire, and before the persecution of the Christians began, which is not improbable, they

they might be taken up and soon put to death before the end of the year 64. Lardner's Works, vol. vi.

For an account of the undesign'd and casual, but very remarkable, coincidence or correspondence, between the circumstances that are recorded in the history of St. Paul's preaching and travels, and others, similar to them, which are either explicitly stated, or obviously implied, in the epistles of the same apostle; and of the conclusion that results from this coincidence in favour of the truth of the history, and the genuineness of the epistles, we refer to archdeacon Paley's excellent work, entitled "Horæ Paulinæ." See ACTS of the Apostles, and PALEY.

Lord Lyttelton, in his "Letter to Gilbert West, esq.," has deduced from the conversion and apostleship of St. Paul, an argument, which, duly considered, amounts of itself to a demonstration sufficient to prove Christianity to be a divine revelation. Although within our limits we cannot do full justice to the admirable reasoning of this distinguished advocate for our holy religion, we shall endeavour to give such an abstract of it as may testify our own conviction of the truth of Christianity, and promote similar sentiments concerning it in the minds of our readers. Our noble author, having cited from the book of the Acts (ch. ix. 12. 18. xx. 6. 13. 14. xxii. 10—16. xxvii. 1, &c.) the account which St. Paul himself gives of his conversion and preaching, and which is recorded in his history by a contemporary author, and a companion of the apostle, compares these records with the manner in which St. Paul speaks of himself in the epistles written by him to the several churches which he planted, and the authenticity of which cannot be doubted without overturning all rules, by which the authority and genuineness of any writings can be proved or confirmed. (See Galat. i. 11—16. Philip. iii. 4—8. 1 Tim. i. 12, 13. 2 Cor. i. 1. Col. i. 1. 1 Tim. i. 1. Gal. i. 1. 1 Cor. xv. 2.) He then states, that the person who attests these things of himself, and of whom they are related in so authentic a manner, either was an impostor, who said what he knew to be false with an intent to deceive, or an enthusiast, who, by the force of an overheated imagination, imposed upon himself; or, he was deceived by the fraud of others, and all that he said must be imputed to the power of that deceit; or what he declared to have been the cause of his conversion, and to have happened in consequence of it, did all really happen; and therefore the Christian religion is a divine revelation.

That the apostle was not an impostor, who said what he knew to be false with an intent to deceive, our author undertakes to prove, by shewing that he could have no rational motives to engage in such an imposture, nor could have possibly carried it on with any success by the means which we know he employed. His inducement to such an imposture must have been one of these two, either the hope of advancing himself by it in his temporal interest, credit, or power, or the gratification of some of his passions under the authority of it, and by the means it afforded. From the circumstances in which St. Paul declared his conversion to the faith of Christ, and which our author has recited, it appears to every reasonable person's satisfaction, that he could have had no hope of increasing his *wealth*. The certain consequence of his taking the part he did, was not only the loss of all that he had, but of all hopes of acquiring more. Those whom he left were the disposers of wealth, of dignity, and of power, in Judea; those with whom he united were indigent men, oppressed, and deprived of all means of improving their fortunes. Those among them, who had more than the rest, shared what they had with their brethren; and even with this assistance, the whole community was hardly supplied with the necessaries of life, and even in churches

which he afterwards planted himself, which were much more wealthy than that of Jerusalem, St. Paul was so far from availing himself of their charity, in order to draw that wealth to himself, that he often refused to take any part of it for the necessaries of life. (See 1 Cor. xv. 8. 2 Cor. xii. 14. 1 Thess. ii. 4, 5, 6. 9. 2 Thess. iii. 8. Acts, xx. 33, 34.) As to credit or reputation, that also lay altogether on the side he forsook. The sect he embraced was under the greatest and most universal contempt of any then in the world; the chiefs and leaders of it were men of the lowest birth, education, and rank; they had not a single advantage of parts or learning, or other human endowments to recommend them; the doctrines they taught were contrary to those which they, who were accounted the wisest and the most knowing of their nation, professed; the wonderful works they did were imputed either to magic or to imposture; the very author and head of their faith had been condemned as a criminal, and died on the cross between two thieves. Could the disciple of Gamaliel think he should gain any credit or reputation by becoming a teacher in a college of *fishermen*? Could he flatter himself, that, either in or out of Judea, the doctrines he taught could do him any honour? He knew and professed the contrary. Experience soon convinced him that, in all parts of the world, contempt was the portion of any one who engaged in teaching a mystery so unpalatable to all mankind, to all their passions and prejudices, and so irreconcilable to the pride of human reason, as "Christ crucified," which was "a stumbling block to the Jews, and to the Greeks foolishness." "We are made (says he to the Corinthians) as the filth of the world, the off-scouring of all things unto this day." Yet he went on as zealously as he set out, and was "not ashamed of the gospel of Christ." The desire of glory, or the ambition of "making to himself a great name," was, therefore, not his motive to embrace Christianity. But was it the love of power? Power! over whom? over a flock of sheep driven to the slaughter, whose shepherd himself had been murdered a little before. All he could hope from that power, was to be marked out in a particular manner for the same knife, which he had seen so bloodily drawn against them. Could he expect more mercy from the chief priests and the rulers, than they had shewn to Jesus himself? Would not their anger be probably fiercer against the deserter and betrayer of their cause than against any other of the apostles? Was power over so mean and despised a class of men worth the attempting with so much danger? But let it be considered, what power St. Paul actually assumed and exercised over the Christians. Did he pretend to any superiority over the other apostles? So far from it, that he declared himself *the least of them* (Ephes. iii. 8.) and *less than the least of all saints*. (1 Cor. xv. 9.) In the churches which he himself planted, he never pretended to any primacy or power above the other apostles. (See 1 Cor. i. 12, 13. 1 Cor. iii. 5. 2 Cor. iv. 5.) The authority which St. Paul exercised over Christians was purely of a spiritual nature, tending to their instruction and edification, without any mixture of that civil dominion in which alone an impostor can find his account. In this respect his authority was very different from the dominion acquired and exercised under a pretence of divine inspiration, by many ancient legislators; by Minos, Rhadamanthus, Triptolemus, Lycurgus, Numa, Zaleucus, Zoroaster, Xamolxis: nay, even by Pythagoras, who joined legislation to his philosophy, and, like the others, pretended to miracles and revelations from God, to give a more venerable sanction to the laws which he prescribed. Such, in later times, was attained by Odin among the Goths, by Mahomet among the Arabians, by Mango Capac among the

the Peruvians, by the Sofi family among the Persians, and that of the Zeriffs among the Moors: and to such a dominion did many false Messiahs among the Jews aspire. In such and similar instances, a *spiritual* authority was only desired as a foundation for *temporal* power, or as a support of it. How different were the views and conduct of St. Paul! He made no innovation in government or civil affairs: he meddled not in legislation, he formed no commonwealths, he raised no seditions, he affected no temporal power. He both taught and practised obedience to civil rulers; nor did he practise any of those soothing arts by which ambitious and cunning men recommend themselves to the favour of those whom they endeavour to subject to their power. What was wrong in his disciples he reproved in a manner becoming a teacher from God; and as were his discourses when present with them, so were likewise his writings, when absent. (See Phil. iii. 15, 16, 17.) If it be said that he affected an *absolute* spiritual power over the churches which he formed, it may be replied, that *he preached CHRIST JESUS, and not himself*. He even renounced any advantage which a higher education, superior learning, and more use of the world might have afforded him for claiming to himself any superiority over the other apostles. (See 1 Cor. ii. 1, 2-5.) An impostor, on the contrary, would have availed himself of these advantages for securing pre-eminence and influence to himself.

As St. Paul had nothing to *gain* by his new profession, let us consider what he *gave* up, and what he had reason to *fear*. He gave up a *fortune* which he had a fair opportunity of advancing: he gave up that *reputation* which he had acquired by the labours and studies of his whole life, and by a behaviour, which had been *blameless, touching the righteousness which is in the law* (Phil. iii. 6.); he gave up his *friends, his relations, and family*, from whom he estranged himself for life; he gave up that *RELIGION, in which he had profited above many of his equals in his own nation, and those TRADITIONS of his fathers, which he had been more exceedingly zealous of*. (Gal. i. 14.) Such were the sacrifices which he made in becoming a Christian. The inconveniences he had to *fear* were, the implacable *vengeance* of those whom he deserted; that sort of *contempt*, which is hardest to bear, the contempt of those whose good opinion he had most eagerly sought: and those other complicated *evils*, which he describes in the 11th chapter of the second epistle to the Corinthians; evils, the *least* of which were sufficient to have frightened any impostor even from the most hopeful and profitable cheat.

The next object of enquiry is, whether the gratification of any other passion, besides the desire of wealth, fame, or power, under the authority of the religion to the profession and service of which he was devoted, or by the means which it afforded, could be his inducement to becoming a disciple and apostle of CHRIST. His writings and his conduct furnish the most satisfactory answer to this enquiry. The former breathe nothing but the strictest morality, obedience to the order and government of magistrates, with the utmost abhorrence of all licentiousness, idleness, or loose behaviour, under the cloak of religion (Rom. xi. xiii. Col. iii.): and the latter, both before and after his conversion to Christianity, does not bear any mark of a licentious disposition. See his appeal to the Thessalonians, (1 Thess. ii. 10. See also 2 Cor. i. 12. iv. 2. vii. 2.) If it should be again said, that although St. Paul could have no selfish or interested view in undertaking such an imposture, yet for the sake of its moral doctrines, he might be inclined to support the Christian faith, and make use of some pious frauds to advance a religion, which, though

erroneous and false in its theological tenets, and in the facts upon which it was founded, was in its precepts and influence beneficial to mankind. In discussing this subject, it should be recollected, that the circumstances of St. Paul were very different from those of some good men in the Heathen world, who pretended to divine revelation, and introduced or supported doctrines and forms of religion which they knew to be false, under a notion of public utility. They not only did it to serve good ends, but were secure of its doing no harm. Thus when Lycurgus persuaded the Spartans, or Numa the Romans, that the laws of the one were inspired by Apollo, and those of the other by Egeria; when they taught their people to put great faith in oracles, or in augury, no temporal mischief, either to them or to their people, could attend the reception of that belief. It drew on no persecutions no enmity with the world. But at the time when St. Paul undertook the preaching of the gospel, to persuade any man to be a Christian, was to persuade him to expose himself to all the calamities human nature could suffer. This St. Paul knew. (See Thess. iii. 4. 2 Cor. vi. 4, 5. Eph. vi. 10-16. Phil. i. 28-30. Col. i. 9-11. Rom. viii. 35, 36.) Could any man who had in his nature the least spark of humanity subject his fellow-creatures to so many miseries, as were justly to be expected, and even actually announced? or could one that had in his mind the least ray of reason, expose himself to share them with those he deceived, in order to advance a religion which he knew to be false, merely for the sake of its moral doctrines? Such an extravagance is too absurd to be even supposed. The case of St Paul was, in one respect, different from that of the other apostles. To them it may be objected, by those who are resolved not to credit their testimony, that having been deeply engaged with JESUS, during his life, they were obliged to continue the same professions after his death, for the support of their own credit, or from having gone too far to recede. This can by no means be said of St. Paul. If there can be any force in this reasoning, it tends to convince us, that St. Paul must actually have continued a Jew, and an enemy of CHRIST JESUS. If they were engaged on one side, he was as strongly engaged on the other. If shame withheld them from changing sides, much more ought it to have restrained him, who, being of a much higher education and rank in life than they, had more credit to lose, and must be supposed to have been much more sensible to that sort of shame. The only difference was, that they, by quitting their master after his death, might have preserved themselves; whereas he, by quitting the Jews and taking up the cross of CHRIST, certainly brought on his own destruction. Upon the whole we may very justly conclude, that when a man of St. Paul's understanding embraced the faith of CHRIST, he was in reality convinced of the truth of it, and that, consequently, he was not an impostor, who said what he knew to be false, with an intent to deceive.

If it be again said, that St. Paul might have been capricious, and might have acted without any rational motive; to this kind of argument it may be replied, that if he had been so unaccountably wild and absurd as to undertake an imposture so unprofitable and dangerous both to himself and to those who were deceived by it, he could not possibly have carried it on with any success by the means which he is known to have employed. His imposture was such, that it could not have been carried on by one man alone. He could not have acted as he did, but in confederacy at least with the apostles; but till he came to Damascus, he had no communication with the apostles; he acted in no concert with them, and learnt nothing from them.

them, except the doctrines which they had publicly taught to all the world. When he came there, he told the Jews, to whom he had brought letters from the high-priest and the synagogue against the disciples of CHRIST, of his having seen, in the way, a light from heaven, and heard CHRIST JESUS reproaching him with his persecution, and commanding him to go into the city, where it should be told him what he was to do. But to account for his choosing this method of declaring himself a convert to CHRIST, we must suppose that all who came with him, when he pretended he had his vision, were his accomplices: and yet, how can we suppose, that all these men should be willing to join in this imposture? They were either officers of justice, employed in executing the orders of the high-priest and the rulers against the Christians; or they were persons chosen for this expedition because they might be trusted for their zeal in promoting its object. The instructor at Damascus, to whom he was referred, must also have been his accomplice; and yet they appear to be absolute strangers to one another. But how could this man venture to act such a dangerous part, without the consent of the other disciples, especially of the apostles, or by what means could he obtain their consent? But would it not have been much more easy to have made Saul be present at some pretended miracle wrought by the disciples, or by Ananias himself, when none were able to discover the fraud, and have imputed his conversion to that, or to the arguments used by some of his prisoners whom he might have discoursed with, and questioned about their faith, and the grounds of it, in order to colour his intended conversion? This would have been the safest, and also the most natural method of bringing about such a change, instead of ascribing it to an event which lay so open to detection. If this story had been an imposture, and Ananias had joined with Paul in carrying it on, is it not strange, that, after their meeting at Damascus, we should never hear of their consorting together, or acting in concert? But dismissing this part of the business; how could Paul get himself owned and received as an apostle by the apostles? This was necessary to be done without delay, but instead of attending to this very important, and, indeed, essential object, St. Paul went into Arabia, and then returned again to Damascus; nor did he go to Jerusalem till after an interval of three years. (Gal. i. 17, 18.) He had also exposed himself to danger, when at Antioch he withstood Peter to the face, and reproved him before all the disciples, because he was to be blamed. (Gal. ii. 11—14.) Accomplices in a fraud are obliged to shew greater regards to each other; such freedom belongs only to truth. Moreover, in the enterprise he undertook of going to the Gentiles, making himself their apostle, and converting them to the religion of CHRIST, he had many difficulties to encounter among the Gentiles themselves. In this enterprise, he had to contend with the policy and power of the magistrates; with the interest, credit, and craft of the priests; with the prejudices and passions of the people; and with the wisdom and pride of the philosophers. His success against this combined opposition he ascribes to the efficacy of divine power. (1 Cor. ii. 4. 1 Thess. i. 5.) If that power attended him, it would enable him to overcome all those difficulties that obstructed his enterprise; but then he was not an impostor. Our enquiry, therefore, must be, whether (supposing him to have been an impostor) he could, by pretending to miracles, have overcome all those difficulties, and carried on his work with success? For this purpose, two circumstances were principally necessary: an apt disposition in those whom miracles are designed to impose upon, and a

powerful confederacy to carry on and assist the cheat. But what prepossessions could there have been in the minds of the Gentiles, either in favour of Paul or the doctrines he taught? or rather, what prepossessions could be stronger than those, which they undoubtedly had against both? Without the advantage of this predisposition, and the assistance it would have afforded, was there any confederacy strong enough to impose his false miracles upon the Gentiles, who were both unprepared and indisposed to receive them? The contrary is apparent from the nature of the case, and the history of the apostle.

Our illustrious author, having proved that St. Paul was not an impostor, proceeds to consider whether he was an enthusiast, who, by the force of an overheated imagination, imposed upon himself. The ingredients, he says, of which enthusiasm is generally composed, are, great heat of temper, melancholy, ignorance, credulity, and vanity or self-conceit. He then shews, that none of these qualities, which dispose the mind to enthusiasm, and which are characteristic of it, belonged to St. Paul. His zeal indeed was eager and warm, but tempered with prudence, and even with the civilities and decorums of life, as appears by his behaviour to Agrippa, Festus, and Felix: not the blind, inconsiderate, indigent zeal of an enthusiast. As to melancholy, it neither appears by his writings, nor by any thing told of him in the Acts of the Apostles, nor by any other evidence, that St. Paul was inclined to it more than other men. As to ignorance, St. Paul was so far from it, that he appears to have been master, not of the Jewish learning alone, but of the Greek. The history of his life likewise shews, that St. Paul could not be justly chargeable with credulity. On the contrary, he seems to have been slow and hard of belief in the most extreme degree, having paid no regard to all the miracles performed by our Saviour, to the fame of which he could not be a stranger, as he lived at Jerusalem; nor to that signal one wrought, after his resurrection, and in his name, by Peter and John, upon the lame man at the beautiful gate of the temple; nor to the evidence given in consequence of it by Peter, in presence of the high-priest, the rulers, elders, and scribes, that CHRIST was raised from the dead. Other circumstances are enumerated, which amply vindicate the apostle from this charge. From vanity or self-conceit St. Paul was as free as any man, as we may collect from all that we see in his writings, or know of his life. Throughout his epistles, there is not one word that favours of vanity, nor is any action recorded of him, in which the least mark of it appears. See Eph. iii. 8. 1 Cor. xv. 9. 1 Tim. i. 15, 16. 2 Cor. xii. 12. xi. 1. 16—19. 30. xii. 2. 6. 1 Cor. xv. 10. xiii. 2, 3, 4.

Allowing, for the sake of argument, that St. Paul was an enthusiast, our author shews that he could not have imposed on himself by any power of enthusiasm, either in regard to the miracle that caused his conversion, or to the consequential effects of it, or to some other circumstances to which he bears testimony in his epistles. Although the power of imagination in enthusiastical minds is very strong, yet it always acts in conformity to the opinions imprinted upon it at the time of its operation, and can no more act against them than a rapid river can carry a boat against the current of its own stream. The mind of St. Paul, in his way to Damascus, was strongly prepossessed with opinions against CHRIST and his followers. His passions concurred at that time in giving those opinions a more active force: and therefore whatever delusions his imagination might raise to impose on his reason, must at that time have been raised agreeably to the notions imprinted upon it, and by which it was heated to a degree of enthusiasm, not

in direct contradiction to all those notions, while they remained in their full force. With respect to the *vision* that is recorded in this part of his history, it is plain that it could not have been a phantom of his own creation, because he was not *alone* when he saw it: many others were in company, whose minds were no better disposed than his to the Christian faith, and it must be supposed, against all motive and all possibility, that the imaginations of *all* these persons were, at the *same* time, so strangely affected, as to make them believe that they saw and heard what in reality never occurred. But supposing, that, as Saul and his companions were journeying towards Damascus, an extraordinary meteor did actually appear, how shall we account for the *distinct words* heard by St. Paul, to which he made answer, and for what followed, agreeably to these words, on his arrival at Damascus? That St. Paul saw CHRIST, both *now* and *after* this time, appears not only by what he relates Acts, xxii. 17, 18; but by other passages in his epistles, 1 Cor. ix. 1. xvi. 8. Acts, ix. 17. From him, as he asserts in many places of his epistles, he learned the gospel by immediate revelation, and by him he was sent to the Gentiles: Acts, xii. 31. xxiii. 11. If St. Paul had been a mere *distempered enthusiast*, how can we account for the miracles he wrought, and for the progress he made in converting the Gentile world? If the difficulties that impeded his efforts for this purpose were such as the ablest impostor could not have overcome, how much more insurmountable were they to a madman? Of all the miracles recorded in scripture, none are more clear from any possible imputation of being the effect of an enthusiastic imagination than that of persons speaking languages which they had never learned: and it is a power which has never been pretended to by any enthusiast, ancient or modern.

Having shewn that St. Paul could not be an enthusiast, who, by the force of an over-heated imagination, imposed on himself, our noble author proceeds to enquire, whether he was *deceived* by the *fraud* of others, and whether all that he said of himself can be imputed to the power of that deceit? But this supposition is so palpably absurd, that we need not enlarge in the confutation of it.

If, then, the apostle was not deceived by the fraud of others, and what he said of himself cannot be imputed to the power of that deceit, no more than to wilful imposture or enthusiasm, it must follow, that what he related to have been the cause of his conversion, and to have happened in consequence of it, did assuredly happen, and therefore "the Christian religion is a divine revelation." See two excellent sermons on the subject of this article by Dr. Duchal, in his "Presumptive Arguments, &c." forming the fourth volume of his sermons, but published separately.

PAUL of Samosata, in *Biography*, so named from the place of his birth, was a celebrated prelate of the third century, after whom such Christians as entertained the same opinions were generally called Paulians, till the council of Nice. In the year 260 he was chosen bishop of Antioch, and by his talents and character recommended himself to the favour of Zenobia, the celebrated consort of Odenatus. He rendered himself obnoxious to the orthodox by denying the doctrine of the pre-existence of Christ, and maintaining that he was a mere man, on whom the wisdom of God descended from

heaven, and dwelt in him, enabling him to work miracles, and instruct nations. A council was assembled at Antioch in the year 264, before which Paul was accused of a dangerous heresy, and of a life and conversation unworthy of the episcopal character. The result of this accusation was, that Paul was admonished. For this mild sentence he was probably indebted to the prudence and moderation of Firmilian, bishop of Caesarea, who presided in the council, and prevented those who composed it, by his influence, from adopting harsher measures. In the year 269 or 270, a second council was assembled at Antioch, in order to take into consideration the principles and conduct of the bishop. Firmilian was summoned to this council, but died on his journey towards Antioch, and it was owing to this event that the enemies of Paul succeeded in their design, and procured a sentence which condemned him to be deposed from his episcopal dignity. Paul refused submission to the decree of the council, and retained possession of the house of the church, and was supported in this step both by the protection of Zenobia, and the good will of the people. When that princess was driven from Antioch, Paul's enemies petitioned the emperor Aurelian to expel him, with whose request he complied in the year 272 or 273. What became of Paul after this event is not known; it has been thought by some writers, that those who adhered to him were formed into a separate society by Lucian, who suffered martyrdom in the year 312. There is no doubt that Paul was author of some publications that have not come down to our times, because his adversaries say that there was scarcely a page in his works without citations out of the Old and New Testament. According to the judicious and candid Lardner, who formed his judgment after much consideration, Paul had a great mind, with a mixture of haughtiness, and too much affectation for human applause. He was generally well respected in his diocese, and by the neighbouring bishops, in esteem with the great, and beloved by the common people. He preached frequently, and was a good speaker. Lardner's *Credibility*. Mosheim's *Ecc. Hist.*

PAUL I. pope, was a native of Rome, and brother to his predecessor Stephen II. He became deacon of the Roman church, and in the year 752, Stephen sent him with rich presents to the king of the Lombards, in order to obtain confirmation of the treaty of peace in which that prince had entered with his predecessor pope Zachary. In this object he succeeded without much difficulty, and the king granted an extension of the term agreed on for forty years longer, that he might divert the pope from interfering with the design he had then formed, and soon after carried into execution, of subjugating the exarchate of Ravenna. Upon the death of Stephen in 757, the Roman people were divided about the choice of a successor, some declaring for the deacon Paul, and others for the archdeacon Theophylact. At length, after a vacancy of more than a month, the nobility, clergy, and magistrates, all zealously promoting the interests of Paul, the election was carried in his favour, and this is the only instance which occurs in the whole history of the popes, of two brothers being raised successively to the papal chair. No sooner had Paul secured his election, than he dispatched a messenger to Pepin, king of France, to acquaint him with his promotion, and to entreat his protection, and that of the French nation in general, for the temporal dominions of the church. He had the satisfaction of receiving from that prince, in answer to the letters by his messenger, the most friendly congratulations on his exaltation to the papacy, and the strongest assurances of his resolution to maintain St. Peter and his successors in the full possession and quiet enjoyment of what he had given them, and to employ

ploy for that purpose, if necessary, the whole force of the kingdom.

During the pontificate of Stephen II. Pepin had conquered from the Lombards some of their dominions, which he had bestowed on the Roman see by an instrument of donation, and compelled the king to confirm the grant. This donation raised the bishop of Rome to the rank of prince, and may be considered as the foundation of the temporal grandeur of the popes. As, however, the places which were to have been yielded up to the Roman see, had not been evacuated by the Lombards before the death of their king; Paul, as soon as he was ordained, made a demand of them from his successor Desiderius. This prince professed the utmost readiness to satisfy the pope; but alleging that the affairs of his kingdom engrossed all his attention, he requested that till these should be settled, his holiness would excuse him in not complying with his demand. Of this delay the pope complained in a letter to Pepin. Indeed, much of his time, during the whole of his pontificate, was occupied in writing to Pepin, or his two sons, letters of complaint against the emperor, and in endeavouring, by frequent legations, as well as by letters, to keep the French, the Greeks, and the Lombards, ever at variance. To counteract this policy, the emperor and the king of the Lombards made every effort to gain Pepin, and to persuade him to withdraw his protection from the pope, representing him to be a public incendiary, who, instead of striving to unite the Christian princes, made it his study to create divisions among them, with no other view than that he might aggrandize himself at their expence. Pepin, however, remained the steady friend of his holiness through life. Paul died in 767, after he had presided over the Roman church ten years and a month. He gave sufficient evidence of his piety, by founding or repairing numerous churches. Thirty-one of his Letters have come down to our times, of which twelve are inserted in the sixth volume of the Collect. Concil. and the whole are in the "Caroline Code," so called from Charlemagne, who himself formed the collection which was published by James Gretzer in the year 1613. Moreri. Bower.

PAUL II. pope, originally known by the name of Peter Barbo, was descended from an ancient family, and born at Venice in the year 1417. He was educated in the mercantile line, and was on the point of embarking with some property on board a ship, when he received intelligence that his maternal uncle had been promoted to the papacy under the name of Eugenius IV. He now thought there were good prospects opened to him in the church, immediately quitted his business for study, and though he made but little progress in literature and the sciences, he was, in the course of a very few years, preferred by his uncle to the archdeaconry of Bologna, the bishopric of Cervia in the Romagna, the office of apostolical protonotary, and in the year 1440 to the dignity of cardinal. By his address and obliging manners, he recommended himself to several succeeding popes, of whom Calixtus III. gave him the appointment of legate in Campania. While he continued a cardinal, men of all ranks and conditions had free access to him, and he made it his study to gratify, as far as lay in his power, all who applied to him. Upon the death of Pius II. in 1464, Barbo was chosen pope. As he was a handsome man, and extremely proud of his person, he intimated his intention of taking at his coronation the name of *Formosus*, but he was dissuaded from this design by the cardinals, and he chose the name of Paul II. One of the first public measures of Paul's government, was a declaration in favour of Ferdinand, king of Naples, against the family of Anjou; and as the

party of the latter had begun to revive in the kingdom, many of the barons being dissatisfied with the arbitrary government of Ferdinand, he sent a considerable body of troops to the assistance of that prince, who was thus enabled speedily to quell the insurgents, and to restore peace to the kingdom. At this period, when a sense of his obligations to Paul was yet fresh in the king's memory, the pope applied to him for the arrears of the tribute due from the kings of Naples to the papal see, which had never yet been paid either by himself or his father Alphonso. Ferdinand, however, refused, which had nearly caused a civil war, but the affair was accommodated, upon the king promising to pay what was in justice due to the apostolic chamber, whenever he conveniently could.

Among the departments of the Roman government one was filled by persons called abbreviators, whose business it was to abridge the bulls and letters of the pope. This employment Paul considered as useless, and discharged the persons who filled it, though most of them were men of great learning and abilities. In this number was the historian Platina, who represented to his holiness the injustice of dismissing them from offices which they had purchased, when not chargeable with any neglect of duty, without returning the money. This remonstrance offended the pope; but Platina went farther, and insinuated that he and his brethren would appeal to the kings and princes of Christendom, which so incensed the pope that he had him thrown into prison under charge of high treason. His sufferings were very great, and continued four months, before he could obtain his release; and even then Paul was not contented, and would not forgive the boldness with which the historian had dared to resist his injustice. In the year 1466, the pope had the mortification to hear of the ruin of one of his plans for maintaining the authority of the Roman see, by punishing offenders against its injunctions. In Bohemia the principles of John Huss had obtained a wide diffusion, and Podiebrad, the king of the country, had, from his accession to the crown, favoured those who espoused them, insisting that the sacrament should be administered to all communicants in both kinds. The pope, enraged at his conduct, not only excommunicated him, but caused a crusade to be preached all over Germany against this Christian prince, while the Turks were pursuing their conquests without opposition. The indulgences that were granted to those who took the cross, proved the means of speedily raising a numerous army, which, however, Podiebrad soon put to flight with great slaughter, and returned triumphant to Prague with a number of prisoners, exceeding that of his whole army. After the defeat, the pope contented himself with issuing his anathemas, declaring the king of Bohemia a rebel to the church, and incapable of holding any dignity whatever. During the following year Paul gave orders for arresting Platina, under the pretence of his being engaged in a conspiracy against his person and government; the historian nobly vindicated himself from the heavy charge, but the merciless tyrant, instead of releasing, ordered him to be put to the rack. He was accordingly tortured with the utmost cruelty, but it had no effect upon his mind. Many of his known friends, the most eminent characters of the time, were also arrested, and exposed to the same kind of treatment, to some of whom it proved fatal. Mr. Roscoe, in speaking upon this subject, says; "During the pontificate of Paul II., letters and science experienced at Rome a cruel and unrelenting persecution, and their professors exhibited in their sufferings a degree of constancy and resolution, which in another cause might have advanced them to the rank of martyrs. The imprisonment of Platina, who, on being arbitrarily deprived of a respectable office, to which

he was appointed by Pius II., had dared to thunder in the ears of the pope the dreaded name of a general council, might, perhaps, admit of some justification; but this was only a prelude to the devastation which Paul made among the men of learning, who, during his pontificate, had chosen the city of Rome as their residence. A number of these uniting together, had formed a society for the research of antiquities, chiefly with a view to elucidate the works of ancient authors, from medals, inscriptions, and other remains of art. As an incitement to, or as characteristic of, their studies, they had assumed classic names, and thereby gave the first instance of a practice, which has since become general among the academicians of Italy. While these men were employing themselves, in a manner that did honour to their age and country, Paul was indulging his folly and vanity in ridiculous and contemptible exhibitions; and happy had it been if he had confined his attention to these amusements; but on a pretext of a conspiracy against his person, he seized upon many members of the academy, which he was pleased to consider as a dangerous and seditious assembly, accusing them of having, by the adoption of heathen names, marked their aversion to the Christian religion." In the year 1467, the pope brought about a reconciliation between several states of Italy, which had taken up arms as auxiliaries to the opposite factions in Florence. Soon after this event the emperor Frederic arrived at Rome, in consequence of a vow, and was entertained with great magnificence by the pope; and they agreed, as a proper expedient to engage the Christian princes in a league against the Turks, that letters should be written, in their joint names, to princes and states of Christendom, inviting them to send their ambassadors to Rome, in order to treat about means for defending their faith. About the same time, Paul was instigated by his ambition to obtain possession of the city of Rimini, and he called in the Venetians to aid him in the project; but after an appeal to arms, the forces of the church and its allies were completely defeated, and Paul was at length compelled to accede to such terms as the conquerors thought proper to dictate. In 1471 the pope published a bull, by which he reduced the jubilee circle to twenty-five years, and thus accelerated the return of a most absurd and superstitious ceremony. To him, however, it was of little moment, as he died suddenly of an apoplexy, in July of the same year, after a pontificate of almost seven years. The historian Platina, who could scarcely be deemed an impartial judge, charges him with avarice and simony; with selling even bishoprics to the highest bidders. With respect to the former of these charges, that there was no solid foundation for it is quite clear from Platina's own account, who speaks of him as profuse in his expences in buildings; in entertaining distinguished personages; in relieving the poor and decayed nobility; in purchasing, at any price, jewels and precious stones to adorn the papal crown, and in exhibiting public shows for the entertainment of the Roman people. Mathieu, the historian of Lewis XI. says, that he was greedy of money, and little cared by what means he acquired it, but was too fond of pomp to hoard it up in his coffers. He created eleven cardinals during his pontificate, among whom were two of his own nephews, although he had, previously to his election, taken a solemn oath not to increase the number of cardinals, or introduce more than one promotion to that high dignity. Two of the letters of this pontiff are in the thirteenth volume of the Collect. Concil. and several others in the fourth volume of d'Archery's "Specilegium," and in Cherubini's "Bullarium Magnum." This pope met with a most zealous apologist in one of the ablest men of the last century, who published a work entitled "Paul II. Vita ex Codice Anglica Bibli-

otheca desumpta, præmissis ipsius Vindicis adversus Platina, aliosque Obtretractores," 1740. Moreri. Bower. Roscoe's Life of Lorenzo de Medici.

PAUL III. pope, originally called Alexander Farnese, was of Roman descent, from an ancient and noble family, and born about the year 1467, at Carino in Tuscany. He pursued his studies under the celebrated professors whom the Medici family had invited to Florence, where he was, at a very early age, distinguished by his application to, and proficiency in, the different branches of literature. By pope Innocent VIII. he was appointed apostolical protonotary, and by Alexander VI. he was advanced to the bishopric of Monte Fiascone, by whom he was, in 1493, raised to the dignity of cardinal, when he was but twenty-six years of age. He was warmly patronized likewise by Julius II., Leo X., and Clement VII. By the latter he was successively nominated to the bishoprics of Palestrina, Sabina, Porto, and Ostia. The same pope appointed him to the legation of Viterbo, and received important services from him during the time of his imprisonment. So highly did Clement estimate the character of Alexander, that when he was sensible that his end was approaching, he recommended him to the cardinals as the most worthy of the whole college to be his successor. The death of Clement happened on the 25th of September 1534, and on the 13th of October following, the thirty-four cardinals present in the conclave concurred unanimously in voting for the cardinal Farnese. To this unanimity two circumstances contributed: one was his having arrived to the advanced age of sixty-seven, and the other the general belief that his constitution was broken up.

At the coronation the new pope assumed the name of Paul III., and the first object to which he directed his attention was to crush the progress of the Reformation, which he foresaw was pregnant with ruin to the authority and interests of the papal see. He was, like his predecessor, enraged at the innovations in Germany, and equally averse from any scheme for reforming either the doctrines of the church, or the abuses of the court of Rome. (See LUTHER.) At the same time he concluded an alliance with the emperor Charles V. and the Venetians against the Turks, and is said to have entertained such confidence of ultimate success, that he even made a partition of the Turkish empire with his allies. This object, as well as the extirpation of heresy, he had much at heart, but he considered peace between the emperor, and the king of France, who were then at war, to be an essential preliminary to both. He accordingly proposed an interview between the two monarchs at Nice, and offered to repair thither in person, that he might act as mediator in composing all differences. After long negotiations, he prevailed upon them to sign a truce for ten years, and in the mean time to send ambassadors to Rome to discuss their pretensions at leisure. During the private conference of the pope with the emperor at their interview, a marriage treaty, which had been some time negotiating, was concluded between Octavio Farnese, the pope's grandson, and Margaret, the emperor's natural daughter, and the widow of Alexander de Medici, who had been lately murdered by one of his own family. Soon after Paul's return to Italy, he dispatched cardinal de Medici with a grand retinue to Florence, who conducted the princess to this city, where he was received by the pope, the cardinals, and the Roman nobility, and the nuptials were celebrated with extraordinary pomp and magnificence. In the year 1538 the pope thundered out his bull of excommunication against king Henry VIII. of England, by which the monarch was deprived of his kingdom, his subjects were absolved from their allegiance, and the whole island laid under an interdict. But Henry's power was not to be thus shaken,

shaken, and the insolence of the pope only stimulated the king to imitate his tyranny, by persecuting all, without distinction, who refused to renounce the papal supremacy, and acknowledge his own. The year 1540 was rendered memorable by the establishment of the order of the Jesuits, and about the same time different diets were held in Germany for the purpose of terminating the religious disputes, and the divisions arising from them among the members of the empire, the result of which was various concessions to the Protestants, which suspended all prosecutions carried on against them in the imperial chamber, and left them in the full possession of the privileges which they had ever enjoyed. These proceedings gave great offence to the pope, who complained of them. During an interview which he had with the emperor at Lucca in 1541, when he suggested various things relating to the proper method of putting an end to the disputes about religion, and to the extinguishing of those mutual animosities between that prince and the king of France, which threatened to break out again into open hostility. In the year 1542, Paul, finding it impossible to avoid any longer calling a general council, sent John Morone, bishop of Modena, to announce to the diet of the empire at Spire, his determination of assembling such a council without delay, and to propose that Trent should be the place of its meeting. This proposal met with the approbation of the Catholic princes of the diet, but the Protestants totally objected to it. Without taking any notice of their opposition, Paul immediately published a bull, nominated three cardinals to preside as his legates, and fixed the day for opening the council, which was on the first of the following November. His legates repaired to Trent at the time appointed, where they remained several months; but as no persons appeared there, except a few prelates from the ecclesiastical states, the pope recalled them and prorogued the council. Having learnt, about this time, that the principles of Luther met with a favourable reception in many parts of Italy, he appointed a congregation of six cardinals, with full power to act as inquisitors of the faith at Rome. He also instigated the emperor to attempt the introduction of that tribunal into the kingdom of Naples, but the design was frustrated by the spirited opposition of the Neapolitans, of all ranks and conditions, who flew to arms upon the first step that was taken towards carrying it into execution, and obliged the viceroy to drive out of Naples all who belonged to that bloody office. During the summer of this year, the pope, with a view to the aggrandizement of his family, knowing the emperor's great want of money to carry on his war against France, offered him 150,000 ducats, if he would bestow the duchy of Milan on his grandson, Octavio Farnese, which proposal the emperor rejected. Paul now returned home greatly mortified, and his ill humour was not a little increased by the information, that the emperor had courted the Protestants, and granted them extraordinary indulgences at the diet of Spire, in order to secure their concurrence with the other members of the diet, in declaring war against France in the name of the empire, and granting extraordinary aids in troops and money: he also learnt that Charles had contracted an alliance with the excommunicated heretic, Henry VIII. of England. In the year 1545 the pope summoned the council of Trent to assemble anew in the month of November, but before that meeting the emperor gave the Protestants reason to suspect his hostile intentions against them; and he and the pope being intent upon one common object, *viz.* the suppression of the reformers, they mutually sacrificed to it their emotions of jealousy or resentment, that they might the more effectually pursue what each deemed to be of

greater importance. Still, however, Charles contrived to amuse the Protestants with professions of his pacific and favourable intentions towards them, and employed every art to quiet their fears and jealousies, though events soon occurred which convinced them of his perfidy. On the 13th of December 1545, the general council was opened at Trent, though as yet only twenty-five bishops had arrived, and these were Italians or Spaniards. Such was the first appearance of an assembly of men, who assumed authority as representatives of the universal church, and proceeded to determine the most important points of doctrine in its name. (See TRENT.) The council shewed an eagerness in condemning the opinions of the Protestants, which was soon followed by a striking instance of the pope's resolution to punish those who embraced them. The appeal of the carons of Cologne against their archbishop having been carried to Rome, Paul eagerly seized that opportunity of displaying his zeal for the established church, and as no person appeared in behalf of the archbishop, he was held to be convicted of the crime of heresy, and a papal bull was issued, depriving him of his ecclesiastical dignity, inflicting on him the sentence of excommunication, and absolving his subjects from the oath of allegiance, which they had taken to him as their civil superior. Charles now saw, that he should be soon obliged to declare openly, what part he would take in the business. At the same time, he was strongly urged to commence operations against them by the pope. At length he agreed to the proposals of the pontiff, who proud of having been the author of such a formidable confederacy against the Lutheran heresy, and happy in thinking that the glory of extirpating it was reserved for his pontificate, published the articles of his league with the emperor, and published a bull containing the most liberal promises to all who should engage in this holy enterprise. This war of religion commenced in 1546, and the papal troops, amounting fully to the number which Paul had stipulated to furnish, commanded by Octavio Farnese, the pope's grandson, assisted by able officers, formed in the long wars between Charles and Francis, seasonably joined the imperial army. Immediately upon hearing of the rapid success of the emperor's troops, the pope saw the danger that would result to him and his cause, from an extension of the imperial authority, and ordered his grandson to return instantly to Italy with all the troops under his command, while he recalled, at the same time, the licence, which he had granted for the appropriation of church lands in Spain to the emperor's use. He also foresaw, that if Charles acquired absolute power in Germany, he would become master of the council, should it continue to meet at Trent; for this reason he translated the council to Bologna. These circumstances occasioned a breach between the emperor and the pope, which was rendered irreparable by the assassination of the pope's son, Peter Lewis Farnese, one of the most odious tyrants that ever disgraced the world, and the loss of the city of Placentia, which had declared for the emperor. The pope instantly demanded satisfaction of the emperor for both injuries, but Charles eluded all his demands, and resolved to keep possession of the city together with its dependent territories. Paul would willingly have attacked the emperor by force of arms, but having in vain solicited the assistance of France and the republic of Venice, he was obliged to endure the injuries which his own weakness would not allow him to revenge. Various other causes of dispute occurred, and at length, in 1548, Charles resolved to terminate all differences by his famous system of doctrine, known by the name of the INTERIM, which see. Paul condemned the Interim in the strongest terms, and in a short

time after he dissolved the council, the weakness of whose measures had become the object of contempt to all Christendom. As the pope advanced in years, he grew more strongly attached to his family, and more jealous of his authority, but in the midst of his schemes for the aggrandizement of the latter, his grandson Octavio threatened to join the emperor, which so much irritated his holiness, that he was resolved to proceed against his relation with the utmost severity, from which, however, he was prevented by his death, which occurred in 1549, when he was in the eighty-second year of his age, and had held the Roman see more than fifteen years. It is difficult to appreciate the character of this pope. Cardinal Quirini has displayed much talent in defending his probity and general measures, while others represent him as a perfidious politician, whose great qualities were dissimulation and fraud; who was wholly intent upon raising his family, and ever ready to sacrifice the good of the church or state to the grandeur and interests of his illegitimate offspring. Besides his natural son, Peter Lewis, he had a natural daughter, named Constantia, who was married into the *Sforza* family, and their children, Alexander Farnese, and Guido Ascanio Sforza, he created cardinals soon after his election, when they had scarcely arrived to the years of manhood. He is said to have been well versed in most branches of literature, and a generous encourager of learned men. He wrote a commentary upon Cicero's "Epistles to Atticus" before his promotion to the pontificate, and after that period some to his friend Sadolet and to Erasmus, which have been applauded for the purity of the Latin style. Moreri. Bower. Mod. Un. Hist.

PAUL IV., whose former name was John Peter Caraffa, was the son of count Montorio, a nobleman of an illustrious family in the kingdom of Naples, and born in the year 1476. Being destined for the church, he from his early years applied to study with the greatest assiduity, acquired a profound skill in scholastic theology, and a considerable knowledge of the learned languages and of polite literature, the study of which had lately been revived in Italy. His mind, naturally gloomy and severe, was more formed to imbibed the spirit of the former, than to receive any tincture of elegance or liberality of sentiment from the latter; so that he acquired rather the qualities and passions of a monk, than the talents requisite for the conduct of the affairs of the world. When he was only eighteen years of age, he was made chamberlain to pope Alexander VI., and in the year 1504, pope Julius II. created him an archbishop. After this he was sent by the same pontiff as nuncio to Ferdinand, king of Arragon, when that prince took possession of the kingdom of Naples. In 1513 pope Leo. X. sent him in the same character to Henry VIII., king of England, at whose court he staid three years. Upon his return, he was appointed to other missions, but becoming disgusted with public life, he languished to be in a situation more adapted to his taste and temper, and having relinquished the paths of ambition, refused a valuable archbishopric, which was offered him by Charles V., and even resigned all his ecclesiastical preferments in the year 1524. He then retired to mount Pincio, where he instituted a new order of regular priests, whom he denominated *THEATINES*, and conformed himself to the rules which he had laid down for others who entered that body, preferring the solitude of a monastic life, with the honour of being the founder of a new order, to the highest dignities and greatest grandeur which the court of Rome could offer. In this retreat he continued many years, till pope Paul III., induced by the fame of his sanctity, called him to Rome, in order to consult him concerning the most proper and effectual means for

suppressing heresy, and re-establishing the ancient authority of the church. In 1536, the pope persuaded him to accept a cardinal's hat. He now shewed himself, what he had ever been in his heart, a bitter enemy to all innovation, and a furious zealot against Lutheranism. Upon the death of pope Marcellus II. in 1555, the conclave united in the choice of cardinal Caraffa, who was then at the advanced age of seventy-nine. At his coronation, out of gratitude to Paul III., he took the name of Paul IV. The Roman courtiers, from the known austerity of his character, anticipated a severe and violent pontificate, and that monastic manners would be substituted in the room of the gaiety and magnificence to which they had been accustomed. Paul, however, began his government by ordering his coronation to be conducted with greater pomp and ceremony than usual, and when he was asked in what manner he chose to live, he haughtily replied, as becomes a great prince. He used great pomp in his first consistory, when he allowed audience to the ambassadors of Mary, queen of England, who came to tender her obedience to the papal see, on which occasion he gave the title of a kingdom to Ireland. Afterwards, he insisted that all ecclesiastical possessions, which had been seized by Henry VIII., should be restored to the church, and that Peterpence should be immediately collected for the use of the Roman see. Having now attained to the highest dignity to which he could aspire, his principal object appears to have been the aggrandizement of his nephews; on the eldest, count Montorio, he bestowed the dukedom of Palliano; and on the second he conferred the government of Rome, with the title of marquis de Montebello; and the youngest, who had hitherto served as a soldier of fortune in the armies of Spain and France, he created a cardinal, and nominated him to the important legation of Bologna. The ambition of Paul's nephews was too great to be satisfied with the dignities to which they had been appointed. Their aims were directed to sovereign and independent establishments, which they had no prospect of obtaining but by dispossessing the emperor of some of his Italian dominions, and to attempt such an undertaking both Paul and his nephews were incited by motives of resentment as well as interest. Paul proposed an alliance offensive and defensive with the French king against the emperor, in which Henry VIII. joined as a party. Scarcely, however, had the treaty between the pope and the king of France been signed two months, before Henry forgot the obligations under which it laid him, and agreed to a truce with the emperor, who was upon the point of resigning all his hereditary dominions to his son Philip, and of retiring from the world. When the news reached Rome, that this truce was actually concluded, and sworn to by Henry as well as the emperor and his son, in Feb. 1556, it excited in the pope and his nephews the utmost astonishment and consternation. They now began to dread the vengeance, which, they were aware, they fully merited. Paul had recourse to intrigue and negotiation. He affected, as father of the church, to approve highly of the truce, as a happy expedient for putting a stop to the effusion of Christian blood, and he exhorted the rival princes to embrace the favourable opportunity of setting on foot a negotiation for a definitive peace, offering himself to be a mediator between them. Under this pretext he nominated cardinal Rebiba his nuncio to the court of Brussels, and his nephew, cardinal Caraffa, to that of Paris. The real design of the latter was to solicit the French king to renounce the treaty of truce, and to renew his engagements with the holy see; and he was commanded by his uncle to spare neither intreaties, nor promises, nor bribes, to gain his point. By the

the infliction of the pope war was renewed, and the imperial forces soon made their way to the gates of Rome. The pope now gladly sought a truce, which was granted first for ten, and then for forty days; during which, various felicities of peace were proposed, without any sincerity on the part of the pope. He had but one object in view, *viz.* the destruction of his enemies; and on the arrival of the French troops, he became more arrogant than ever, and banished all thoughts from his mind but those of war and revenge. Hostilities were again renewed, and with so much success against the cause of the church, that Paul, proud and obstinate as he was, found it necessary to accommodate himself to the exigency of his situation. He accordingly employed the mediation of the Venetians, and of Cosmo de Medici, in order to obtain peace; and so reasonable was Philip in his expectations, that though he had the pope at his feet, yet he allowed him to finish the war, without any detriment to the papal see. The conqueror, owing to his superstitious attachment to the church, appeared in the abject character of a humble suppliant, and acknowledged his error; while he who had been the most arrogant hypocrite, though completely vanquished, retained his usual haughtiness, and was treated with every mark of superiority. Paul now had leisure, and he applied that leisure to render his favourite tribunal of the inquisition a more efficient instrument for the eradication of heresy. With this view, he directed the inquisitors to draw up a catalogue of such books as were thought proper to be condemned, as impious and heretical. This *Index Expurgatorius* was published two years afterwards, and all were prohibited, under pain of excommunication, perpetual infamy, and other arbitrary punishments, from possessing any of the books mentioned in that catalogue. The pope likewise ordered the tribunal of the inquisition to take cognizance of several crimes, which before had been under the jurisdiction of the other courts; and he deservedly incurred universal odium, by being so active and diligent in his inquiry after criminals, that he quickly filled all the prisons of the inquisition. In the year 1558, the college of the electors of the empire having been assembled at Frankfort, the prince of Orange laid before them the instrument with which he had been entrusted by Charles V., containing his resignation of the imperial crown, and the transfer of it to Ferdinand, king of the Romans, which the college accepted and approved, and put Ferdinand in possession of all the ensigns of imperial dignity. When the new emperor sent his chancellor to acquaint the pope with this transaction, Paul declared all the proceedings at Frankfort illegal and invalid, as transacted without his authority, and refused to acknowledge Ferdinand as emperor so long as he lived. The same pretensions were maintained by him in the instance of queen Elizabeth of England, who announced to him by her ambassador that she had acceded to the throne: he haughtily declared that the kingdom was a fief of the holy see, and that she had no right to assume the crown without his leave. She nobly despised his claims, threw off the papal yoke, and, after the example of her father and brother, assumed, with the concurrence of parliament, the supremacy in all matters, ecclesiastical as well as temporal, within her dominions. The mortification which this event occasioned to Paul was increased by the intelligence which he received from his nuncio in Germany, that at the diet of Augsburg, in 1558, Ferdinand had confirmed the treaty of Passau, which established the peace of religion, and also the decrees of the subsequent diets. He was equally displeased with the peace concluded between France and Spain, since, by one of the articles, the respective sovereigns bound themselves to labour in concert for

procuring the convocation of a general council, in order to promote the reformation of the church, and to devise expedients for establishing unity and concord in the religious world. Shortly after this, the pope was very desirous of convincing the world, that he had sincerely at heart a correction of abuses in the church; and with this view, he ordered all bishops to proceed to their own dioceses, and all who had embraced a monastic life to return to their monasteries, admitting of no excuse whatever with regard to the last; and he executed his mandate with such severity, that many of the vagrant monks were imprisoned, and some of them sent to the galleys. Toward the close of life, he exhibited his impartiality in the punishment of crimes, by directing his severity against his nephews, who had, in many instances, abused the trusts reposed in them. He also suppressed some new and very unpopular taxes, which he pretended had been imposed without his knowledge. It was now almost too late to act upon a new course of practice; he was unable to remedy the evils of his administration, as he died in August 1559, in the 84th year of his age, and after a pontificate of little more than four years. Such had been his arrogance, tyranny, and oppressions, and he had rendered himself so universally the object of hatred, that when he was upon his death-bed, the Romans rose tumultuously, cursed his name and family, and then flying to the Capitol, struck off the head of a statue erected to him but three months before, which they dragged with a thousand insults through the public streets of the city, and at last threw it into the Tiber. The populace then crowded to the prison of the inquisition, forced open the doors, released several hundred prisoners, then set fire to the building, which was soon reduced to ashes, with all the papers and records of that court. An edict was then published for abolishing the arms of the Caraffa family, and in a single day there was not in all the city a memorial of them left. Paul was the author of a treatise, "*De Symbolo*;" another, "*De emendanda Ecclesia ad Paulum III.*;" besides the rules which his monastery was governed, entitled "*Regulæ Theatinorum*." Moreri. Bower. Robertson's Hist. of Charles V. Mod. Un. Hist.

PAUL V. pope, formerly called *Camillo Borghese*, was descended from a family of distinction at Sienna, and born at Rome in 1552. He was educated to the profession of the law, took the degree of doctor, and acquired such reputation for his knowledge of it, that he was made referendary of both signets. In 1588 pope Gregory XIV. appointed him to fill the important office of auditor of the chamber. By Clement VIII. he was promoted to the college of cardinals, and sent unccio to Spain; and on his return, the same pontiff nominated him his vicar, which is one of the four principal dignities in the Roman church. Upon the death of Leo XI. in 1605, he was unanimously elected pope, his vigorous age of fifty-three being the only objection brought forwards against him. At his coronation he took the name of Paul V., and almost immediately afterwards discovered his spirit of nepotism, by bestowing the cardinal's hat on Scipio Caffarelli, his sister's son; and by appointing his two brothers, Francis and John Baptist, to the important offices of governor of the Vatican, and governor of St. Angelo. No one of his predecessors exceeded this pontiff in zeal for advancing the ecclesiastical authority and jurisdiction of the papal see, or shewed himself more violent in endeavouring to execute his vengeance upon such as encroached upon his pretended prerogatives. His zeal in defence of the pretended rights and powers of his see was particularly displayed in the rash and unsuccessful contest into which he entered with the republic of Venice, in the year

year 1606. The Venetians had published several laws for restraining the licentiousness of the clergy, and for other purposes necessary for the well-being of their state, which the pope ordered to be rescinded. This they refused, and justified their conduct with great spirit. When Paul found that they opposed his demands, his fury was inflamed to the highest pitch. Having suffered himself to be publicly styled "Vice-God upon earth, the monarch of Christendom, and the supporter of papal omnipotence," he was resolved to keep up his character, by pouring down upon the republic the full weight of his vengeance. It was, however, to no purpose: the Venetians resisted, and carried their point; and, at the same time, they banished the Jesuits and Capuchins, who had thought proper openly to break the laws of the state, by obeying the pope.

About this time, the form of the oath of allegiance, required to be taken by Popish recusants in England, having been submitted to the consideration of the college of cardinals, they were unanimously of opinion that no true Catholic could take it with a safe conscience; upon which the pope dispatched a brief to this kingdom, prohibiting all Papists from submitting to it, and exhorting them patiently to endure all manner of persecution rather than comply. During the year 1609, an ambassador arrived at Rome, from the king of Congo in Africa, to request that the pope would send with him, on his return, learned missionaries to propagate Christianity in that country; but the death of the ambassador, soon after his arrival, occasioned that design to be postponed to some future time. In the same year, the pope received letters from the king of Persia, which were soon afterwards followed by an ambassador from the prince. These letters and this minister were supposed to have been sent at the instigation of some of the king's Armenian subjects, who had embraced the Catholic creed, with a view to procure arrangements for their benefit. In the year 1610, Paul was earnestly solicited to enter into a defensive alliance with the king of France and the princes of Italy, which he declined, lest he should thereby be involved in war. While the subject was in agitation, intelligence arrived at Rome of the assassination of Henry IV., at which his holiness expressed great sorrow, and assisted personally at his obsequies, which were celebrated with much solemnity at Rome. In 1614 the pope received information that a treaty was negotiating between the king of Great Britain and the queen-regent of France, for a marriage between the prince of Wales and her second daughter, Christina: he ordered his nuncio at the French court to remonstrate against the proposed alliance, as prejudicial to the church. Another subject on which he ordered his nuncio to remonstrate was a decree of the parliament of Paris, condemning a treatise of Suarez, a Jesuit, which justified the murder of Henry IV., and of heretical kings in general, of which, to his disgrace, the pope had declared his approbation, to be burnt by the hands of the common hangman. This decree he complained of, as an infringement on the privileges of the holy see, which reserved to itself the power of judging and determining concerning the tendency of such works; and he demanded satisfaction, by the formal annulling of the decree: but he could obtain no other satisfaction than the suspension of its execution. He met with a similar mortification, in an unsuccessful endeavour which he made to prevail with the states of France to order the publication of the decrees of the council of Trent. In the course of the following year, Paul's attention was chiefly engaged by the old controversy between the Franciscans and Dominicans, concerning the *immaculate conception of the Virgin Mary*. Shortly after this, he was involved in a dispute with the

court of France, which demanded the estates of the marshal d'Ancre at Rome, for the use of the French king. A compromise was agreed upon between the contending parties: more than half was given to Lewis XIII., and the remainder was allowed to the pope towards the building of St. Peter's church. In the year 1619 the pope published an universal jubilee, in order to implore the assistance of the Almighty for the defence of the church, which was endangered by a general insurrection of the Protestants of Bohemia, and other countries under the Austrian dominions, who had been provoked to fly to arms by the oppressions with which they were harassed. The pope sent assistance in money to the emperor, who, in the course of the following year, gained a decisive victory, which obliged the insurgents to submit. Paul survived the news of this victory only a few months, and died at Rome in January 1621, in the 60th year of his age, after a pontificate of nearly 16 years. Paul V. was distinguished for talents and learning, and would have appeared to great advantage in the page of history, had he not suffered his ambition and furious zeal for the authority of the holy see to lead him into measures which he could not support, and had he not sacrificed the wealth of the state to the aggrandizement of his nephew, cardinal Borghese. As a friend to literature, he published a bull, commanding all the religious orders to maintain professors in the Hebrew, Arabic, Greek, and Latin languages. In adorning and beautifying the city with magnificent buildings, he is said to have rivalled Sixtus V. He extended and improved the Vatican palace and library. He built two magnificent palaces for his relations, one in the city, and the other without the walls; and in both he collected the most valuable works in sculpture and painting, and the finest monuments of antiquity that he could purchase. He brought water to several parts of the city, by aqueducts and subterraneous channels, some from places at nearly 40 miles distance; and he embellished the streets with a great number of fountains. He was likewise liberal in his charitable donations, and in his alms to the poor.

PAUL, *Father*, whose name, before he entered into monastic life, was Peter Sarpi, was born at Venice, August 14, 1552. His father followed trade, but with so little success, that on his death his family were extremely ill provided for. Peter was taken under the care of a maternal uncle, who, being himself a schoolmaster, cultivated the talents of his nephew with unwearied application. He soon shewed, by the turn of his mind, that he had a capacity adequate to the most difficult departments in literature, and having, at the age of thirteen, made himself master of school learning, he turned his studies to philosophy and the mathematics. He entered also on the study of logic under Capella of Cremona, who was of the order of the Servites, and in this order Peter Sarpi, notwithstanding the remonstrances of his friends, determined to enter himself. In 1566 he took the habit of the order, though at that time only fourteen years of age, a period of life in most persons very improper for engagements of this nature, but in him attended with such maturity of thought, and in such a settled temper, that he never seemed to regret the choice he then made, and which he confirmed by a solemn public profession in 1572. At a general chapter of the Servites, held at Mantua, Paul, for he had now assumed that name, being but twenty years of age, distinguished himself so much in a public disputation by his genius and learning, that William, duke of Mantua, a great patron of letters, solicited the consent of his superiors to retain him at his court, and not only made him public professor of divinity in the cathedral, and reader of divinity and the canon law in that city,

city, but honoured him with many proofs of his esteem. The honours and bustle of a court did not accord with his temper and disposition; he quitted it two years afterwards, and retired to his beloved privacy. He was at this period but twenty-two years of age, and was intimately acquainted not only with the Latin, Greek, Hebrew, and Chaldee languages, but with philosophy, the mathematics, canon and civil law, and all parts of natural philosophy and chemistry that were then pursued by men of science. He now took priest's orders, and was distinguished by the illustrious cardinal Borromeo with his confidence, and employed by him on many occasions, which excited the enmity of his contemporaries, who, jealous of his celebrity, and having nothing to urge against his conduct, charged him with denying that the Trinity could be proved from the first chapter of Genesis: the Inquisition, however, before whom the accusation was brought, thought the charge too ridiculous to be attended to for a moment. After this he passed successively through the dignities of his order, of which he was chosen provincial for the province of Venice at the age of twenty-six years; and he discharged this post with such honour, that in 1579 he was appointed, with two others, to draw up new regulations and statutes for his order. He performed this business with much success, and when his office of provincial was expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he made many important discoveries. Aquapendente, the famous anatomist, says that he was indebted to father Paul for his knowledge of the principles of vision, and there are pretty good proofs that he was not unacquainted with the circulation of the blood. He was now chosen procurator-general of his order, and during his residence at Rome was greatly esteemed by pope Sixtus V., and contracted an intimacy with cardinal Bellarmine and other eminent persons.

His enemies were still on the alert, and accused him of having written a letter in cyphers, which they explained, and said the true meaning was, that he hated the court of Rome, in which preferment was not to be obtained but by dishonest and corrupt means. This accusation was passed over, but not forgotten, and it made such impression on that court, that he was afterwards denied a bishopric by Clement VIII. He now retired from public life, and spent much of his time in studies devoted to practical piety. The most active scene of his life began about the year 1615, when pope Paul V. exasperated by some decrees of the senate of Venice, that appeared to him to interfere with the rights of the church, laid the whole state under an interdiction. Both parties having proceeded to extremities, employed their ablest writers to defend their measures. On the pope's side, among others, cardinal Bellarmine entered the lists, and with his confederate authors, defended the papal claims with great scurrility of language, and very sophistical reasonings. On this occasion father Paul was most eminently distinguished by his "Defence of the Rights of the Supreme Magistrate;" his "Treatise of Excommunication," and other writings; for which he was cited before the Inquisition at Rome, but he thought it prudent not to obey the summons. He was still pursued with unceasing activity by the agents of the pope, and one night, six months after a pretended accommodation had taken place, he was attacked by five ruffians armed with stilettoes, who gave him no less than fifteen stabs, three of which wounded him in such a manner, that he was left for dead. The assassins fled for refuge to the nuncio, and were afterwards received into the pope's dominions. It has been said, on good authority, that they were pursued by the

justice of heaven, and that all, except one man, who died in prison, perished by a violent death.

On his recovery he retired to his convent, where he employed himself in writing the "History of the Council of Trent," which bishop Burnet regards as the completest model of historical writing ever produced. Another writer considers it as equivalent to any production of antiquity, in which, he says, "the reader will find liberty without licentiousness, piety without hypocrisy, freedom of speech without neglect of decency, severity without rigour, and extensive learning without ostentation." In this and other works of less importance he spent the remainder of his life, till the beginning of the year 1622. when he died. As his end was evidently approaching, the brethren of his convent came to pronounce the last prayers, with which he could only join in his thoughts, being able to articulate no more than these words, "Esto perpetua," which were understood to be a prayer for the prosperity of his country. At his death he had attained to his 71st year, hated by the court of Rome and its adherents as their most formidable enemy, and honoured by all the learned for his abilities, and by the good for his integrity. His detestation of the corruption of the Roman church appears in all his writings; but there is a passage in one of his lectures frequently referred to on the subject, which we shall transcribe. "There is nothing more essential than to ruin the reputation of the Jesuits. By the ruin of the Jesuits, Rome will be ruined; and if Rome be ruined, religion will reform itself." Father Paul was buried with great pomp at the public charge, and a magnificent monument was erected to his memory.

PAUL, emperor of Russia, son of Peter III. and Catharine II. was born in 1754. He was brought up by his mother, and estranged by her from all public affairs. In 1773 he was married to the daughter of the landgrave of Hesse Darmstadt, who died two years afterwards. In 1776 he took for his second wife a princess of Wirtemberg Stutgard, niece to the king of Prussia, and in 1780 he made the grand tour of Europe. His desire of serving in the war of 1787 against the Turks was thwarted by his mother, and he continued to reside with his family at his palace with a few favourites. The sudden death of Catharine, in November 1796, made him master of a vast empire, for the government of which he was neither fitted by nature nor education. Catharine had never admitted him to any participation of power, and kept him in a state of almost total ignorance of the affairs of government. Although by birth he was generalissimo of the armies, president of the admiralty, and grand admiral of the Baltic, he was never permitted to head even a regiment, and was interdicted from visiting the fleet at Cronstadt. From these circumstances, it is evident that the empress either had conceived some jealousy of her son, or saw in him a mental imbecility that appeared to her to disqualify him for the arduous concerns of government. He was, however, not without qualities valuable in a sovereign. He had a strong attachment to justice, with an openness and frankness which rendered him accessible to truth when properly presented to him. His general intentions were good, though not unfrequently warped by prejudice and caprice.

It was commonly believed, that a short time before his death, Catharine had taken measures to exclude Paul from the succession, and to introduce Alexander in his stead. The plan, however, did not succeed, and Paul, on the day following his mother's death, made his public entry into St. Petersburg, amidst the acclamations of the people. Paul began his reign with breaking the power of the guards,

In many respects he shewed himself hostile to the memory of his mother, and it was probably in that spirit that he caused solemn obsequies to be performed for his unfortunate father, compelling the principal agents in his assassination to assist in the ceremonial. He abolished many of her institutions, and displayed the same restless desire of change that she herself had possessed. Trifling alterations in the dress and accoutrements of the soldiery, and the detail of military tactics, continued to occupy his attention. "Every day," said a bystander, "in the court of the palace, in a plain deep green uniform, great boots, and a large hat, he spends his morning in exercising his guards. Surrounded by his sons and aides-des-camps, stamping his heels on the pavement to keep himself warm, his bald head bare, his snuff nose cocked up to the wind, one hand behind his back, and with the other raising and falling his cane, in due time, and crying one, two; he prides himself in braving a cold of fifteen degrees of Reaumur without furs."

Soon after his accession, he gave an asylum to Lewis XVIII., and assigned him a large tract of land for his maintenance; and in order to prevent the spread of free inquiry, or, as he said, the spread of revolutionary principles, he laid the press under the most rigorous restrictions, and abolished the schools for the instruction of the lower classes, which Catharine had established. In 1798 he determined to employ his arms for the restoration of the ancient government of France, and in consequence of a treaty between him and the emperor of Germany, a Russian army of 45,000 men, under field-marshal Suvaroff, joined the Imperialists in the Austrian territories in Italy. They penetrated into Switzerland in 1799, and at first obtained great success, carrying all before them; but want of proper co-operation and plan at length defeated their purpose, and Suvaroff, in the autumn of the same year, led back the remainder of his army. Paul, in great rage, gave his faithful commander a very ungracious reception, and he threatened to withdraw from a confederacy, which he charged with failure in its engagements. The honour of grand master of Malta, conferred upon him, induced him, in the following year, to renew his exertions; but during the course of it his politics changed, he refused farther subsidies from England, and entirely seceded from the alliance. Scarcely had he deserted the allies, when he became out of humour with the British court, which had taken possession of Malta, and his next political object was to form a new maritime confederacy in the north, for the purpose of enforcing the claim of neutrals to a free navigation. He engaged Sweden and Denmark in the cause, and in the winter of 1800, he laid an embargo upon all British ships in his ports, confining the commanders, and sending the seamen to a distance up the country. At this period he seemed to have entered into the French interest; but despotic power, joining with strong passions and weak intellects, had now brought him to a state of capricious folly, little removed from insanity. He was perpetually making regulations of the most absurd and troublesome kind. Their general spirit was the maintenance of absolute authority in all its rigour, and the profoundest respect for the imperial dignity; but no one could less inspire it by his person and manners. Though not without a degree of generosity and good nature, the indulgence of his ungoverned caprice was daily converting him into a brutal tyrant, like some of the worst emperors of Rome. While accounts of his strange proceedings were circulating throughout Europe, he himself caused to be inserted in the Petersburg court gazette, "That the emperor of Russia, finding that the powers of Europe can-

not agree among themselves, and being desirous to put an end to a war which has desolated it for eleven years, intends to point out a spot, to which he will invite all the other sovereigns to repair and fight in single combat, bringing with them as seconds and equires, their most enlightened ministers and able generals, such as Thurgot, Pitt, Bernstorff, and that the emperor himself proposes being attended by generals count Pahlen and Khutof." This paragraph was immediately copied or translated into all the public papers, and it was said by many, that it was the composition of Paul himself, which has since been confirmed by Kotzebue, who was employed by the emperor of Russia to translate the original into the German language, for the express purpose of its being inserted in the Hamburg gazette. This folly was, in general, regarded as so decisive a proof of derangement, that the public was prepared to expect one of those revolutions to which the throne of Russia is peculiarly liable. Accordingly, on the night of March 22, 1801, Paul was found dead in his bed, and though it was currently reported that he was cut off by a stroke of apoplexy, it was soon generally known that he had been assassinated in the dead of the night, and that the perpetrators of the horrid deed had retired from the palace without the least molestation, and returned to their respective homes. As soon as the fact was discovered, medical assistance was called in, with the hope of restoring what might be only suspended animation; but these attempts proved fruitless. At seven o'clock, on the morning of the 23d, the intelligence of the death of Paul, and the succession of the grand duke Alexander, were announced to the people. By eight o'clock the principal nobility had paid their homage to the new emperor, who was solemnly proclaimed. Paul died in the 47th year of his age, and the fifth of his reign, leaving two sons, of whom Alexander, the eldest, succeeded him.

PAUL WARNEFRID, or, as he is often called, Paul the deacon, an eminent historian of the middle ages, was born of Lombard origin in the eighth century, at Ciudad del Friuli. He was educated in the court of Rachi, king of the Lombards, and afterwards ordained deacon of Aquileia. Desiderius, the last king of the Lombards, invited him to his court, employed him as a notary or secretary, and raised him to the posts of counsellor and chancellor. After the kingdom of Desiderius was overthrown, and the monarch made prisoner by Charlemagne in 774, the private history of Paul becomes obscure, and it is very differently related by different biographers. It is generally supposed that he first retired to his native country of Friuli, and that after the overthrow and death of Rodgauso, duke of that province in 776, he took the monastic habit. By some means his literary merit became known to Charlemagne, who took him into France, and perhaps employed him in his plans of promoting learning in his dominions. He was well acquainted with the Greek and Latin languages, and instructed in the former those clergymen who were selected to accompany the emperor's daughter, Rotrude, to Constantinople, where she was united to the son of the empress Irene. A remaining attachment to his sovereign Desiderius subjected Paul to the suspicions of some designs in his behalf, on which account he was banished; and he would probably have undergone the loss of his hands, or of his eyes, had not Charlemagne been unwilling to disable so eloquent a writer. It is farther supposed that he escaped from his banishment, and took refuge in the court of Arigiso, prince of Benevento; and that on the death of that prince in 787, he retired to the celebrated monastery of Monte Casino, where he ended his days, but at what time is

not known, though it is thought about the year 799. He was a considerable writer: his Latin poetry may rank with the best of that period: it consists chiefly of hymns, of panegyrics of saints and eminent personages, and other short pieces. One of the most interesting is an elegy addressed to Charlemagne, in order to obtain the liberty of a brother who was brought prisoner into France after the defeat of Desiderius. Of his prose writings the most valuable is entitled "De Gestis Longobardorum," in six books, which is the only history of that nation which we possess: and it contains facts that can no where else be found, and affords some curious views of rude society. Several editions of it have been published, and Muratori has inserted it in his great collection of the Italian historians. Paul likewise contributed to the Roman history entitled "Miscella," in which he was the continuator of Eutropius. He also wrote an abridged history of the first bishops of Metz, and other pieces of ecclesiastical biography, and made a collection of homilies by the order of Charlemagne. Gen. Biog.

PAUL, *St.*, in *Geography*, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Lavaur. The place contains 906, and the canton 6070 inhabitants, on a territory of 170 kilometres, in 14 communes.

PAUL, *St.*, a town of Brasil, in the captainship of St. Vincent. It is a kind of independent republic, composed of the banditti of several nations, who pay a tribute of gold to the king of Portugal. It is surrounded by inaccessible mountains and thick forests. S. lat. $23^{\circ} 25'$. W. long. $45^{\circ} 52'$.—Also, a government of the same name, situated to the W. of Rio Janeiro: the principal productions are grain and cotton. The population is computed at 11,100 whites, 32,170 Indians, and 9000 blacks or mulattoes. (See PAULISTS.)—Also, a town of New Mexico, situated at the confluence of the two main head branches of the Rio Bravo.—Also, the most southerly of the Pearl islands, in the gulf of Panama. In a safe channel on the N. side there is a place for careening of ships.

PAUL, *St.*, a town of France, and principal place of a district, in the department of the Var; 7 miles W. of Nice. N. lat. $43^{\circ} 41'$. E. long. $7^{\circ} 11'$.—Also, a town of France, in the department of the Upper Vienne; 9 miles S.E. of Limoges.—Also, a town of France, in the department of the Lemane lake, on the lake of Geneva; 10 miles E. of Thonon.—Also, a town of the island of Bourbon.—Also, a town of France, in the department of the Gard; 10 miles N.E. of Uzès.—Also, a town of the island of Malta; 6 miles N.W. of Malta.—Also, an island in the Indian sea, N. of Amsterdam. It is overspread with shrubs and trees, and is said to abound with fresh water, but affords no good anchorage, nor any place of easy landing. S. lat. $37^{\circ} 51'$. E. long. $61^{\circ} 2'$.—Also, an island in the gulf of St. Lawrence; 9 miles N.E. from the N. cape of the island of Cape Breton.—Also, a river of Guinea, which runs into the Atlantic; 5 miles N. of Cape Mesurada.

PAUL'S Bay, *St.*, a bay on the N.W. coast of Newfoundland. N. lat. $49^{\circ} 50'$. W. long. $57^{\circ} 35'$.—Also, a bay on the W. coast of Newfoundland; 10 miles N.E. of Bonne bay.—Also, a bay on the N.W. shore of the river St. Lawrence, about six leagues below Cape Torment, where a chain of mountains, 400 leagues in length, terminates from the westward.

PAUL-de-Fenouillet, *St.*, a town of France, in the department of the East Pyrenées, and chief place of a canton, in the district of Perpignan; 28 miles W.N.W. of Perpignan.

PAUL-de-Omaguas, *St.*, a town of Brasil, in the government of Para, on the river Amazons. S. lat. $3^{\circ} 35'$.

PAUL *Trois Chateaux, St.*, a town of France, in the department of the Drôme, before the revolution the see of a bishop; 12 miles S. of Montelimart.

PAUL, an Italian coin, worth almost sixpence English. See PAOLO.

PAUL, in *Sea Language*, is a short bar of wood, or iron, fixed close to the capstern or windlafs of a ship, to prevent those engines from rolling back, or giving way, when they are employed to heave in the cable, or otherwise charged with any great effort.

PAULA, in *Geography*, a town of Naples, in Calabria Citra, at a small distance from the sea; 12 miles N.W. of Cosenza.

PAULA, *St.*, a small island of Russia, in the Frozen ocean. N. lat. $76^{\circ} 54'$. E. long. $103^{\circ} 14'$.

PAULA Gumda, in *Natural History*, a name given by the people of the East Indies to a species of fossil of the osteocolla kind, found in some springs, the waters of which are loaded with spar. These people used it in medicine, giving it in milk for gonorrhœas, and that with good success.

PAULADADUM, a name given by some authors to the medicinal earth of the island of Malta, called *terra Melitensis*, and *gratia sancti Pauli*. Some have given this name also to a species of white bole found in some parts of Italy, which is made into cakes, and sealed, and serves in the place of this and other white earths.

PAULAR, *EL*, in *Geography*, a town of Spain, in Old Castile; 11 miles E.S.E. of Segovia.

PAULARAH, a town of Hindoostan, in Berar; 25 miles N.W. of Chanda.

PAULASTYA, in *Hindoo Mythology*, is one of "ten lords of created beings," frequently alluded to in their sacred books under the name of Brahmadikas, or children of Brahma. Their names are enumerated under the article MUNI of this work, where, and in the articles referred to, some particulars will be found respecting them. Paulastya, or Palastrya, is also a name of Ravana, the ten-headed tyrant of Lanka, or Ceylon, against whom the wars detailed in the Ramayana were waged. See RAVANA.

PAULEY'S, in *Geography*, a town of America, in South Carolina; 8 miles S. of Kington.

PAULHAGUET, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Brioude; 9 miles N.E. of Brioude. The place contains 982, and the canton 10,571 inhabitants, on a territory of 260 kilometres, in 22 communes.

PAULI, GREGORY, in *Biography*, a learned Polish divine, of the Protestant persuasion, was minister of the church of Wola, near Cracow, in the year 1555. He afterwards became pastor and senior minister of the church of Cracow, and was one of the earliest opponents of the doctrine of the Trinity in Poland, in behalf of the Arian hypothesis. For the freedom with which he avowed and defended his opinions in the pulpit, he was expelled from Cracow, when he retired to Racow, where he died at a great age, about the year 1591. He was author of "An Explanation of the difficult Passages of Scripture;" different treatises against the lawfulness of a Christian's undertaking offices of civil magistracy, or bearing arms; the first impression of the "Catechism of Racow," which was afterwards altered by Lælius Socinus, and Peter Statorius, and various pieces in the Trinitarian controversy.

PAULIANISTS, PAULIANISTÆ, in *Ecclesiastical History*, a sect of heretics, so called from their founder, Paulus Samosatenus, a native of Samosata, elected bishop of Antioch in 262.

His doctrine seems to have amounted to this: that the Son and the Holy Ghost exist in God in the same manner as the faculties of reason and activity do in man; that Christ was born a mere man; but that the reason or wisdom of the Father descended into him, and by him wrought miracles upon earth, and instructed the nations; and finally, that, on account of this union of the divine word with the man Jesus, Christ might, though improperly, be called God. It is also said, that he did not baptize in the name of the Father and the Son, &c. For which reason the council of Nice ordered those baptized by him to be re-baptized.

Being condemned by Dionysius Alexandrinus in a council, he abjured his errors, to avoid deposition; but soon after he resumed them, and was actually deposed by another council in 269.

PAULICIANS, a branch of the ancient Manichees, so called from their chieftain, one Paulus, an Armenian, in the seventh century: who with his brother John, both of Samofatena, formed this sect; though others are of opinion, that they were thus called from another Paul, an Armenian by birth, who lived under the reign of Justinian II. A certain zealot, called Constantine, revived, in the seventh century, under the government of Constans, this drooping faction, which had suffered much from the violence of its adversaries, and was ready to expire under the severity of the imperial edicts, and of those penal laws which were executed against its adherents with the utmost rigour. However, the Paulicians, by their number, and the countenance of the emperor Nicephorus, became formidable to all the East.

But the cruel rage of persecution, which had for some years been suspended, broke forth with redoubled violence under the reigns of Michael Curopalates, and Leo the Armenian, who inflicted capital punishment on such of the Paulicians as refused to return into the bosom of the church.

The empress Theodora, tutored by the emperor Michael, in 845, would oblige them either to be converted, or to quit the empire: upon which several of them were put to death, and more retired among the Saracens; but they were not all exterminated.

Upon this, they entered into a league with the Saracens, and, choosing for their chief an officer of the greatest resolution and valour, whose name was Carbeas, they declared against the Greeks a war which was carried on during this whole century, with the greatest vehemence and fury. During these commotions, some Paulicians, towards the conclusion of this century, spread abroad their doctrines among the Bulgarians: many of them, either from a principle of zeal for the propagation of their opinions, or from a desire of getting rid of the persecution and oppression they suffered under the Grecian yoke, retired, about the close of the eleventh century, from Bulgaria and Thrace, and formed settlements in other countries. The first migration was into Italy, from whence, in process of time, they sent colonies into almost all the other provinces of Europe, and formed gradually a considerable number of religious assemblies of persons, who adhered to their doctrine, and who were afterwards persecuted with the utmost vehemence by the Roman pontiffs. In Italy they were called Patarini, from a certain place called Pataria, being a part of the city of Milan, where they held their assemblies; and Cathari or Gazari, from Gazaria, or the Lesser Tartary. In France they were called Albigenes. The first religious assembly the Paulicians had formed in Europe, is said to have been discovered at Orleans, in 1017, under the reign of Robert; many of whom were condemned to be burnt alive.

The ancient Paulicians, according to Photius, expressed the utmost abhorrence of Manes and his doctrine. The Greek writers comprise their errors under the six following particulars. 1. They denied that this inferior and visible world is the production of the Supreme Being, and they distinguish the Creator of this world, and of human bodies, from the most high God, who dwells in the heavens: and hence some have been led to conceive, that they were a branch of the Gnostics rather than of the Manichæans. 2. They treated contemptuously the Virgin Mary, or, according to the usual manner of speaking among the Greeks, they refused to adore and worship her. 3. They refused to celebrate the institution of the Lord's supper. 4. They loaded the cross of Christ with contempt and reproach; by which we are only to understand, that they refused to follow the absurd and superstitious practice of the Greeks, who paid to the pretended wood of the cross a certain sort of religious homage. 5. They rejected, after the example of the greatest part of the Gnostics, the books of the Old Testament, and looked upon the writers of that sacred history, as inspired by the creator of this world, and not by the supreme God. 6. They excluded presbyters and elders from all part in the administration of the church. Mosheim's Eccl. Hist. vol. ii. 8vo.

PAULIEN, ST., in *Geography*, a town of France, in the department of the Upper Loire, and chief place of a canton, in the district of Le Puy. The place contains 2292, and the canton 5712 inhabitants, on a territory of 112½ kilometres, in 7 communes.

PAULINGSTOWN, or **PAWLING**, a township of America, in Dutchess county, New York, lying on the western boundary of Connecticut; containing 4269 inhabitants, of whom 34 are slaves.

PAULINSKILL, a river of America, in New Jersey, which runs into the Delaware, N. lat. 40° 54'. E. long. 75° 9'.

PAULINUS, PONTIUS MEROPIUS, or PAULINUS NOLANUS, in *Biography*, a celebrated prelate and ecclesiastical writer in the fifth century, was descended from a Roman patrician family, and born at the town now called Bourdeaux, in the year 353. He was a pupil of the celebrated Decius Ausonius, under whom he made a considerable progress in literature, and cultivated the study of rhetoric and poetry with success. Ausonius being called to Rome, Paulinus quitted his native place and followed him to that city, where he acquired much reputation as a pleader in the forum. He soon established for himself a character, and was raised while young to the consular dignity. Having married a Spanish lady named Therasia, he took leave of public affairs, and indulged his inclination for seeing foreign countries, visiting almost all the western provinces of the Roman empire. In the course of his travels he formed an intimacy with several Christians of high note, and was baptized by Delphinus, bishop of Bourdeaux, in the year 391. After this he went to Spain, and took up his residence at Barcelona; where he and his wife, having lost their only child, spent their time in devout contemplation and ascetic exercises, applying the greatest part of their property to benevolent and charitable purposes. In 393 he was ordained presbyter, having had the assurance that he should be allowed to go to Italy. During the following year he arrived at Rome, where he was treated with the utmost respect by all ranks, till perceiving the pope and clergy were growing jealous of his high reputation, he withdrew to a country house in the vicinity of Nola, in Campania. In 409, or perhaps sooner, he was ordained bishop of Nola. The early part of his episcopate was disturbed by the incursions of the Goths, who con-

quered and plundered the city of Nola; but he spent the remainder of his life in tranquillity, a bright example of piety, benevolence, and charity, and the object not only of veneration, but of delight, to persons of all ranks and parties. He died in 431, in the 78th year of his age. His works consist of "Letters" and "Poems," which are partly instructive, but chiefly of a lively and entertaining cast. They are correct, perspicuous, and elegant. The best edition of the works of Paulinus is that published at Paris in 1684, in two volumes 4to., the first of which contains his genuine pieces, the second such as are doubtful. Moreri. Gibbon, vol. v.

PAULINUS, an English bishop, who flourished in the early part of the seventh century, was called the apostle of Yorkshire, having been the first archbishop of York, a dignity that was probably conferred upon him about the year 626. He built a church at Almonbury, and dedicated it to St. Alban, where he preached to and converted the Brigantes. Camden mentions a cross at Dewborough, which had been erected to him, with this inscription, "Paulinus hic prædicavit et celebravit." At this period York was so small, that there was not so much as a church in it in which king Edwin could be baptized. Paulinus, it should seem, from Hume and others, was particularly patronized by Ethelburga, Edwin's queen. She is said to have made Christianity fashionable by her example; and her bishop, we are told, baptized 10,000 people in the river Swale. In Northumberland he baptized Segbert, king of the East Saxons. According to Bede, "Paulinus coming with the king and queen to the royal manor called Ad Gebrin, now Yevering, staid there 36 days, employed in the duties of catechizing and baptizing. In all this time he did nothing but instruct the people, who flocked to him from all the surrounding villages, in the doctrine of Christ and salvation; and after they were instructed, baptizing them in the neighbouring river Glen." He built some churches. See our articles LINCOLNSHIRE and NOTTINGHAMSHIRE.

PAULINUS, patriarch of Aquileia in the eighth century, and who is honoured by the Catholics with the title of saint, on account of his zeal in behalf of the doctrine of the Trinity, was a native of Germany. He is greatly distinguished by his laborious application, and zeal for the advancement of learning and science. By his erudition he recommended himself to the patronage of the emperor Charlemagne, who bestowed on him various substantial marks of his favour, and, towards the close of the year 776, promoted him to the patriarchate of Aquileia. From this time he became celebrated as a writer in defence of the Trinity. A complete edition of all his works, with learned notes and commentaries, was published at Venice in 1737, by John Francis Madrisi, a priest of the congregation of the Oratory. He died in the year 804.

PAULINZELLA, in *Geography*, a town of Germany, in the county of Schwartzburg-Rudolstadt; 8 miles W. of Rudolstadt.

PAULISTS, or as they are quaintly styled, *Mamelúcs*, a free-booting society of Brazil. Their town of *St. Paul* stands on a hill, about 150 paces in height, whence issue two rivulets, one to the S. the other to the W., which afterwards join, and fall into the Harcambu, that passes at the distance of a league to the N., a river full of fish, and capable of receiving large barks, but liable to inundations in the rainy season. On the N. of this river the mountains extend E. and W. for more than 40 leagues, while on the S.W. the chain seems to wind towards the mountains of Chiquitos in the Spanish possessions: the Parana passing with stupendous rapids of 12 leagues, the general breadth of the chain being

from 12 to 20. In the vicinity of St. Paul, the mountains present mines of gold of the purity of 22 carats, which is found in irregular masses, and in dust. The climate is benign, owing to the fresh air from the mountains, but the winter is cold and frosty. United by equal want of religion and morals, the first inhabitants of this town formed a republic, like that of robbers in a cavern. Malefactors of all nations and colours, Portuguese, Spaniards, Negroes, Indians, and all possible mixtures of mankind, formed about 100 families, which gradually rose to 1000. The Paulists declared themselves a free people; and they seemed to have merited the title in the worst sense of it, as they were completely free from all laws, morals, sentiments, and virtues: but they consented to pay the Portuguese a fifth part of the gold which they drew from the mines or scours (*lavaderos*). All strangers who did not bring certificates of having been regular thieves, were refused admittance into this hopeful colony; and there was a marked aversion from any multiplication of professions, as they rejected any robber who was at the same time a spy. The first trial of a new citizen, was to make an excursion, and bring in two Indians prisoners, to be employed in the mines, or in digging the grounds. Virtuous actions were carefully punished with death; and no citizen was permitted to retire from the society. Supplied with fire-arms from unknown quarters, they often descended the large rivers, carrying terror and destruction into the Spanish possessions in Paraguay; and an army would have been necessary ever to reduce them to the Portuguese domination. Where they suspected that force would not avail, they assumed the black gowns of the Jesuits, and preached with great fervour to the Indians, on the advantages of religion and civilization, and the heinous offences of robbery and murder, especially warning them against those devils the Paulists, who were accustomed to breakfast on nuns and little children. When they had catechized a sufficient number, they persuaded them to follow their teachers to a convenient spot, where they would find abundance of all the necessaries of life. The poor Indians, accustomed to the same procedure on the part of the Jesuits, allowed themselves to be conducted by these wolves in wool, who, when they had led them to the trap, seized and carried them off captives. This new mode of preaching began to disgust the savages; and the Jesuits found it difficult to avoid the total loss of their character, by the artifices of these new brethren, as the Indians could not possibly distinguish between a Jesuit and a Paulist. To the sword of the faith they were found to join that of the flesh, and to arm all their converts, not with patience but with fuses. The Paulists began to lose their advantages, both as preachers and as pirates; and the bonds of society having begun to be broken by the introduction of some virtues, the city was yielded to the Portuguese monarchy, which is still contented to receive a fifth part of the mines. Pinkerton's *Geog.* vol. iii.

PAULLINI, CHRISTIAN FRANCIS, in *Biography*, a physician and naturalist, was born at Eifenach, in Thuringia, in February 1643. He studied at the universities of Konigsberg, Copenhagen, Kiel, and Rostoch, was crowned poet at Hamburg, made master of arts at Wittemberg, and took the degree of doctor of physic at Leyden. After his graduation he pursued his travels, visiting Norway, Sweden, &c., and was prevented from extending his journey to Italy by sickness. He then settled in the practice of his profession, which he carried on at Hamburg, Altona, and in Holstein. He was honoured with the title of count palatine for his public services; and was appointed by the bishop of Munster to the offices of his first physician and historiographer. In 1689, however, he returned to Eifenach, where

he died in 1712, after having laboured under a palsy for seven years. He was a member of the academies Naturæ Curiosorum, and Ricovrati. He published a considerable number of works, chiefly monographs, or separate dissertations on subjects of natural history; such as his "Cynographia curiosa, seu Canis descriptio;" "Bufo breviter descriptus;" "Sacra herba, seu nobilis Salvia descripta;" "Tractatus de Anguilla;" "Talpa descripta;" "Lagographia curiosa;" "Lycographia;" "Onographia;" "De Jalappa, Liber singularis;" "Nucis Moscha:æ curiosa Descriptio," &c. He evinced in these papers an admiration of the marvellous, rather than of the useful; and the same may be said of his "Observationes Physico-Medicæ," which, however, contain some things worthy of attention. He likewise wrote "Theatrum illustrium Virorum Corbeizæ Saxonicæ," and some other works. Eloy Dict. Hist. Gen. Biog.

PAULLINIA, in Botany, so named by Linnæus in the first edition of his *Genera Plantarum*, in memory of the old Danish professor and physician Simon Paulli, who was born at Rostoch, in 1603, and died, if we mistake not, at Copenhagen, in 1680. He published in 1639, a Latin quarto, on Medicinal Plants, entitled *Quadripartitum Botanicum*; and in 1648 a thicker volume, in Danish, with wooden cuts, called *Flora Danica*, which however embraces the garden plants, as well as the native ones, known in Denmark at the time of its publication. He wrote also against Tobacco and Tea, and his work was translated into English by the late Dr. James, in 1746. The most remarkable circumstance attending it is his contending, with the positiveness usual to those who are in the wrong, that the Chinese Tea is no other than our European *Myrica Gale*; an error which Bartholin very cautiously and respectfully corrects, in his *Acta Medica*, v. 4. 1, where the true Tea is, not very accurately, figured.—Linn. Gen. 196. Schreb. 265. Willd. Sp. Pl. v. 2. 460. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 422. Juss. 247. Lamarck Illustr. t. 318. fig. 4, 5. Gærtner. t. 79. (Cururu; Plum. Gen. 34. t. 35.)—Clas and order, *Oleandria Trigynia*. Nat. Ord. *Tribilata*, Linn. *Sapindi*, Juss.

Gen. Ch. Cal. Perianth inferior, of five ovate, concave, spreading, permanent, unequal leaves. Cor. Petals four, obovate-oblong, twice as large as the calyx, furnished with claws; two of them more distant than the rest. Nectaries two; one of four oblong scales, inserted into the claws of the petals; the other of four glands at the base of the petals. Stam. Filaments eight, simple, shortish, connected at their base; anthers small. Pist. Germen superior, turbinate, three-sided, obtuse; styles three, thread-shaped, short; stigmas simple, spreading. Peric. Capsule large, turbinate, three-sided, of three cells and three keeled valves, the partitions from the central column. Seeds solitary, nearly ovate, each with a divided spongy tunic.

Ess. Ch. Calyx of five unequal leaves. Petals four. Nectaries of four scales and four glands. Capsule turbinate, of three cells, the partitions from the central column. Seeds solitary, with a cloven tunic.

Obf. Mr. Schumacher, in the third volume of the Copenhagen Transactions, has followed Plumier in making two genera of the Linnæan *Paullinia*, and he is followed by Willdenow. (See SERIANA.) He adopts the term *Samara* for the fruit of *Seriana*, which consists of three connected capsules, that do not burst, winged at their base, and whose nearly globose seeds do not seem to have any tunic. Such is the case in the true *Paullinia Seriana* of Linnæus, and several other species; but what Gærtner has figured for the last-named plant, is no other than the *barbadensis*, a true *Paullinia*. We know not whether Mr. Schumacher has found out this

mistake, as we have not seen his work, but must quote it on the authority of Willdenow, to whose fourteen species we add one hitherto non-descript, and two from Lamarck's Dictionary.

1. *P. nodosa*. Willd. n. 1. Jacq. Enum. Amer. 35. Obf. fasc. 3. 11. t. 62. f. 3.—Leaves ternate, obscurely toothed; the middle leaflet obovate. Footstalk without wings. Clusters longer than the leaves.—Native of South America. Jacquin never saw this but in a dried state, nor does it appear to have fallen in the way of any other botanist. He describes the stem as shrubby, climbing, round, unarmed, furrowed and smooth. Leaflets smooth on both sides, more or less unequally toothed, nearly sessile on their common stalk, which has no wing or border, obtuse, rather coriaceous, the middlemost nearly twice as large as the rest. Clusters six inches long, their common stalks woody, here and there tumid and knotty, the upper half bearing many scattered, branched, bracteated, many-flowered partial stalks; half an inch long.

2. *P. Cururu*. Linn. Sp. Pl. 524. Willd. n. 2. Jacq. ib. t. 61. f. 4. (Cururu scandens triphylla; Plum. Ic. 102. t. 111. f. 2.)—Leaves ternate, with tooth-like serratures. Footstalk winged. Clusters about as long as the leaves. Capsule pear-shaped.—Native of South America.—Stem climbing, with long, axillary, simple or divided tendrils. Footstalks two inches long, winged, entire, gradually dilated upwards. Leaflets longer, ovate, smooth, all nearly equal, with one central and many transverse ribs. Clusters axillary, many-flowered. Capsule with three blunt angles, and as many intermediate furrows.

3. *P. densiflora*.—Leaves ternate, obscurely serrated. Footstalk winged. Clusters aggregate, much branched, one-fourth as long as the footstalks.—Sent by Mutis from New Granada, to Linnæus, who never described it. The stem is triangular and furrowed. We perceive no tendrils. Leaves like the last, but broader and more elliptical, their lateral veins hairy on one side at their origin. Clusters hardly an inch long, downy, axillary, aggregate, repeatedly branched. Calyx hairy, as is likewise, in some degree, the obovate pointed capsule. Seeds large, polished, of a chestnut brown.

4. *P. caribagenensis*. Jacq. Obf. fasc. 3. 11. t. 62. f. 6. Willd. n. 3.—Leaves twice ternate, cut. Footstalks all winged. Stem without prickles.—Gathered by Jacquin about Carthage in South America. He describes the leaves as more deeply cut than in the rest, almost pinnatifid, and very thin, not at all coriaceous. The whole plant is without prickles.

5. *P. caribæa*. Jacq. ib. t. 62. f. 7. Willd. n. 4.—Leaves twice ternate, obtuse, slightly serrated. Partial footstalks winged; common one, like the branches, prickly.—Native of the Caribbee islands. Leaves smaller and blunter than those of the last, with slight and distant serratures; their common stalk beset with hooked prickles, which are also plentiful on the branches.

6. *P. curassavica*. Linn. Sp. Pl. 525. Willd. n. 5. Jacq. ib. 12. t. 61. f. 8. (Cururu scandens enneaphylla, fructu racemoso rubro; Plum. Ic. 101. t. 111. f. 1.)—Leaves twice ternate, pointed, bluntly serrated. Partial footstalks slightly winged. Valves of the capsules half-inversely-heart-shaped.—Native of Curaçoa.—The stem is unarmed, furrowed, with downy rusty angles, the furrows, in the upper part, as Schumacher well observes, marked with rusty dots. Leaves from four to six inches long, smooth, less coriaceous than usual, distant and coarsely serrated, the terminal leaflet large, tapering at each end. We have not seen the fruit.

7. *P. barbadensis*. Jacq. Enum. Amer. 36. Obf. fasc. 3. 12. t. 62. f. 9. Willd. n. 6. (P. Seriana; Gærtner. v. 1.

PAULLINIA.

381. t. 79.)—Leaves twice ternate, obtuse, coriaceous, nearly entire. Footstalks slightly winged. Valves of the capsule downy, half-ovate.—Native of the West Indies. The leaves are highly polished on their upper side, paler and opaque beneath, two or three inches long. Clusters on long stalks, each accompanied with a pair of tendrils. Capsules veiny, downy, of a rusty red, their valves much compressed, equally winged.

8. *P. polyphylla*. Linn. Sp. Pl. ed. 1. 366. (*P. foliis supra decompositis*; Linn. Hort. Cliff. 152. *Cordis indii folio et facie frutescens portoricensis*; Pluk. Phyt. t. 168. f. 5.)—Leaves doubly pinnate, ovate, cut. Footstalks winged, with hairy ribs. Angles of the stem fringed with spreading hairs. Flowers at the fork of the tendril.—Native of South America. The stem climbs by means of axillary tendrils, and has many angles, rough with dense spreading hairs, and separated by smooth furrows. The tendrils and footstalks are hairy in a similar manner, the latter all winged. Leaflets about half an inch long, ovate, more or less cut or lobed, sometimes tapering at the base, nearly smooth on both sides, with hairy ribs and edges. Tendrils about three inches long before they divide into two spiral smooth branches, at the base of which stands a small downy tuft of flowers. Of the fruit we can discover nothing, but Plukenet heard it was of a siliqueose kind, which term rather accords with *Paullinia* than with *Seriana*, and the close affinity of this species to the following, precludes all doubt of its genus. The great confusion which envelopes this species, could be dispelled only by the original specimen of Linnæus, who in the second edition of his Sp. Pl. confounded with it what is now properly called *Seriana tritenata*, Willd. Sp. Pl. v. 2. 466. A leaf of Plumier's figure, which belongs to this last, is actually copied by Jacquin, and cited by Willdenow, for *P. polyphylla*, of which Plukenet's plate above quoted is the only genuine representation we can discover.

9. *P. bipinnata*. Poiret in Lam. Dict. v. 5. 99. (*P. polyphylla*; Willd. n. 7?)—Leaves doubly pinnate, obovate, slightly notched at the summit. Footstalks downy, winged towards the end. Stem finely downy. Flowers at the fork of the tendril.—Gathered by Commerçon in Brasil. One of his specimens is before us, marked, with a doubt, *P. polyphylla*, Linn. and it appears to be what Schumacher, whom Willdenow copies, has actually described as such. This plant however differs essentially from the last, in the dense pubescence of its stem, as well as of its footstalks, and, though in a less degree, of the backs of its leaves, whose shape is obovate and obtuse, with two or three irregular shallow notches. The tendrils too are very much shorter and thicker, and their spiral branches are downy. Capsule near an inch long, downy, striated, its valves half-obovate, much compressed, abrupt and wavy at the summit.

10. *P. tetragona*. Aubl. Guian. v. 1. 355. Willd. n. 8.—Leaves once or twice pinnate, ovate, distantly serrated, smooth. Footstalks scarcely winged. Clusters compound, axillary, much shorter than the leaves. Valves of the capsule wedge-shaped, with a blunt terminal tooth.—Observed by Aublet at Cayenne. We have a specimen, gathered by Dr. Mærtner in the Caraccas, which accords as much as possible with our original one of Aublet, except that the former being in flower, the latter in fruit, with only one leaflet, an absolute decision can hardly be made. The leaves evidently appear by both specimens to be distantly toothed, though Aublet says they are entire, and he quotes Rumphius's *Funus quadrifidus*, v. 5. 4. t. 3, which is doubtless very different, except that the stem in both plants splits into four portions, serving to make baskets or cordage. The branches, tendrils, and common footstalk, in Mærtner's plant, are hispid with

prominent rigid hairs. The whole leaf is a foot long, of five pair of opposite leaflets, with an odd one; the lowest pair again pinnate, each of five leaflets, of which one is ternate; the second pair ternate, having small lateral leaflets; the rest all simple, full two inches long and one broad; the whole are reticulated with innumerable veins, and of a light green, smooth, except the midrib on the upper side. Flowers in compound, axillary, aggregate, slightly hairy clusters, three inches long, accompanied by many broad, ribbed, smooth, fringed bractes. Calyx downy at the edges and base, in both specimens. Capsule, in that of Aublet, near an inch long, narrower than in the last species, each valve crowned with a blunt tooth at the outer angle, the inside, and the central column, finely woolly.

11. *P. meliifolia* Poiret in Lam. Dict. v. 5. 99.—Leaves pinnate; leaflets ternate, pointed, toothed, downy beneath. Footstalks winged. Valves of the capsule slightly bordered.—Gathered by Commerçon at Brasil, according to Poiret. We find no specimen that answers to his description entirely. He compares the leaves to those of *Melia Azedarach*; but they are downy and rusty beneath. The clusters appear to spring from the division of the tendrils, as in N^o 8 and 9. The capsules are pear-shaped, a little rounded, stalked, marked at each suture with a short membrane "which originates from the upper part of the peduncle." This peduncle can only mean the stalk of the capsule or germen, not of the flower. M. Poiret contends that its border, or wing, is analogous to the remarkable one in *Seriana*, and hence he would keep the two genera united; but the valvular capsule is an important difference.

12. *P. Vespertilio*. Swartz Ind. Occ. v. 2. 695. Schumacher. Copenh. Transf. v. 3. p. 2. 122. t. 11. f. 1. Willd. n. 9.—Leaves pinnate, smooth, ovate, pointed, cut. Footstalk naked. Capsule with lanceolate horizontal wings.—Gathered by Mr. Masson in the island of St. Christopher. We have seen no specimen. Swartz says the stem is shrubby, round and smooth, climbing by means of axillary rigid tendrils, hardly so long as the leaves, which are pinnate, of two pair of leaflets with an odd one; their footstalks round, striated, without wings. Clusters axillary, simple, erect, shorter than the leaves, of many small whitish flowers. Capsules stalked, large, ovate, obtuse, three-sided, with three valves, terminated by three lanceolate, obtuse, thick, membranous, horizontal wings.

13. *P. pinnata*. Linn. Sp. Pl. 525. Willd. n. 10. Jacq. Obs. tasc. 3. 12. t. 62. f. 12. Gærtner. t. 79? (*Clematis pentaphylla*, pediculis alatis, fructu racemoso tricocco et cocineo; Plum. Amer. 76. t. 91. *Cururu scandens pentaphylla*; Plum. Gen. 34.)—Leaves pinnate, smooth, elliptic-lanceolate, pointed, bluntly serrated. Footstalk winged. Capsule pear-shaped, three-lobed.—Native of the West Indies, in dry sandy places, not unfrequent. The leaves are a span long, of two pair of shining veiny leaflets, with an odd one; their stalk rather broadly winged throughout. Clusters solitary between the branches of each tendril, downy; sometimes sessile and axillary, without a tendril. Fruit one inch and a half long, scarlet, with three furrows, according to Plumier, but no wings, the seeds black and polished, each with a white tender sweetish tunic. Gærtner represents it exactly obovate, without lobes or furrows, and the partitions opposite to the centre of each valve, which does not agree with Plumier, and we suspect he may have committed an error in this case, as well as with regard to *Seriana*; see our seventh species. Linnæus received from Browne's herbarium a Jamaica specimen, under the name of *P. pinnata*, which is certainly different from what we have described, having three pair of much smaller leaflets, the wing

of whose common stalk is greatly dilated at each side into a triangular form. For want of fructification, the genus is doubtful, but we take the plant to be a *Weinmannia*; perhaps a luxuriant branch of *W. pinnata*.

14. *P. tomentosa*. Jacq. Enum. Amer. 37. Obf. fasc. 1. 19. t. 10. fasc. 3. 12. t. 61. f. 13. Willd. n. 11.—Leaves pinnate, ovate, obtuse, wavy, downy on both sides. Footstalk winged. Capsules downy.—Native of South America, where it was discovered by Houffoun. The whole plant is clothed with short dense soft pubescence. Branches round. Leaflets broad-ovate, wavy or partly serrated, above an inch long, two pair, with a larger odd one, tapering at the base. Clusters from between the forks of the tendrils. Capsules turbinate, short, three-lobed. Linnæus had for this a totally different plant in the Upsal garden, with a large leaf, like a *Rhus*, to which his remark in both editions of Syst. Veg. refers. This has six pair of pointed serrated leaflets, with an odd one, and the upper half only of the common stalk is winged. Respecting the genus, nothing can be determined.

15. *P. cauliflora*. Jacq. Coll. v. 4. 176. Ic. Rar. t. 458. Willd. n. 12.—Leaves pinnate, ovate-lanceolate, entire, smooth; the lowermost pair ternate. Footstalk slightly winged. Flowers in dense axillary tufts.—Native of the Caraccas. It flowered at Vienna, in the stove, from October to January, but produced no fruit. The stem climbs, by means of tendrils, as in the other species. Leaves about six inches long, composed of one pair of ternate leaflets, two pair of simple, and an odd one, the latter near two inches long; all pale at the back. Flowers numerous, small, white, in sessile, round, dense tufts, either axillary, along with the cloven tendrils, or proceeding from various parts of the old leaflets stem.

16. *P. japonica*. Thunb. Japon. 170. Willd. n. 13.—Leaves pinnate, of four pair of three or five-cleft leaflets, with an odd one; the second pair ternate. Footstalks winged. Panicles opposite to the leaves. Stem herbaceous. Gathered by Thunberg in Japan, where it is called *Bak Ren*. "The stem is herbaceous, climbing, smooth, angular, without prickles, scarcely so thick as a straw. Leaves alternate, stalked, smooth; the lowest pair of leaflets nearly sessile, ovate, an inch long, cut into two or three entire segments; the next pair ternate, with a winged partial stalk, their lateral partial leaflets ovate, either undivided or cut, the middlemost three-cleft; the rest of the leaf pinnate, consisting of a bordered jointed stalk, two pair of oblong leaflets, in three or five segments, and a larger terminal one in three segments. The common footstalk resembles the stem, and is two inches long. Flowers paniced, opposite to the leaves. Common flower-stalks the length of the leaves; partial ones very short." Such is Thunberg's account, but as he says nothing of the fruit, and we have seen no specimen, the genus (whether *Paullinia* or *Seriana*) must remain in uncertainty.

17. *P. diversifolia*. Jacq. Enum. Amer. 36. Obf. fasc. 3. 12. t. 62. f. 14. Willd. n. 14.—Leaves doubly pinnate, obovate, obtuse, nearly entire. Footstalks winged. Stem round, nearly smooth.—Native of South America. As far as we can judge by Jacquin's description and figure, this ought to have been placed near *polyphylla* and *bipinnata*. The leaves are composed of obovate obtuse leaflets, about the size of the latter, (being scarcely, except the terminal ones, half an inch long.) but nearly smooth, almost always entire and undivided, and all their footstalks are winged, except the base of the general one. The first pair of divisions of the leaf are pinnate, of five leaflets, the second, third, and terminal ones are ternate, the last not larger than its neighbours. The stem is shrubby. Clusters accompanied by

tendrils, or rather, as we presume, springing from the latter at their division.

It appears to us that this genus, as well as its near relation *Seriana*, requires more accurate attention than either of them has yet received from botanical travellers. In our gardens they are now scarcely at all known, though some species of *Paullinia* were cultivated by Miller. S.

PAULMOW, in *Geography*, a town of Bengal; five miles N.W. of Curruckdeah.

PAULO, MARCO, in *Biography*, a celebrated traveller, son of Nicholas Paulo, a Venetian, who went with his brother Matthew, about the year 1225, to Constantinople, in the reign of Baudoin. While they were on this expedition Marco was born. On their return through the deserts, they arrived at the city where Kublai, grand khan of the Tartars, resided. This prince was highly entertained with the account which they gave him of the European manners and customs, and appointed them his ambassadors to the pope, in order to demand of his holiness a hundred missionaries. They accordingly came to Italy, obtained from the Roman pontiff two Dominicans, the one an Italian, and the other an Asiatic, and carried with them young Marco, for whom the Tartar prince expressed a singular affection. This youth was, at an early period, taught the different dialects of Tartary, and was afterwards employed in embassies which gave him the opportunity of traversing Tartary, China, and other eastern countries. After a residence of seventeen years at the court of the great khan, the three Venetians came back to their own country, in the year 1295, with immense wealth. A short time after his return, Marco served his country at sea against the Genoese, his galley in a naval engagement was sunk, and himself taken prisoner and carried to Genoa. He remained there many years in confinement; and, as well to amuse his melancholy, as to gratify those who desired it of him, sent for his notes from Venice, and composed the history of his own and his father's voyages in Italian, under this title, "Delle maraviglie del mondo da lui vidute," &c., of which the first edition appeared at Venice in 8vo. 1496. This work has been translated into several foreign languages, and has been inserted in various collections. The best editions are one in Latin, published by Andrew Müller at Cologne in 1671, and one in French, to be found in the collection of voyages published by Bergeron, at the Hague in 1735, in two vols. In the narrative there are many things not easily believed, but the greater part of his accounts has been verified by succeeding travellers. He not only gave better accounts of China than had been before received; but likewise furnished a description of Japan, of several islands of the East Indies, of Madagascar, and the coasts of Africa, so that from his work it might be easily collected that a direct passage by sea to the East Indies was not only possible, but practicable.

PAULO, in *Geography*, a town of South America, in New Granada; 25 miles E.N.E. of Tunja.

PAVLOGRAD, a town of Russia, in the government of Ekaterinoslav; 32 miles E. of Ekaterinoslav. N. lat. 47° 10'. E. long. 35° 54'.

PAVLOSK, a Russian fortress, in the province of Tauris, constructed for defending the straits of Taman, between the Black sea and the sea of Azoph; six miles S. of Kerch.

PAVLOV, a town of Russia, on the N. coast of the Tehudskoe lake; 20 miles S. of Narva.

PAVLOVA, a town of Russia, in the government of Irkutsk, on the Lena; 16 miles N. of Orlenga.

PAVLOVSK, a town of Russia, in the government of Voronez,

Voronez, on the Don; 68 miles S.S.E. of Voronez. N. lat. 50° 24'. E. long. 40 14'.

PAVLOVSKAIA, a town of Russia, in the government of Ekaterinoflav, on the Dnieper; 32 miles E. of Ekaterinoflav.

PAULUN, a town of Hindoostan, in the circar of Kitchwara; six miles S.E. of Raajegur.

PAULUS, CYRUS FLORUS, called *Paul the Silentiary*, because he was at the head of the royal silentaries, officers whose business it was to prevent noises in the palace, flourished in the sixth century, under the emperor Justinian. He is said to have been of an illustrious family, and possessed of hereditary opulence, but to have been still more distinguished for learning and eloquence. He was author of poems in the Greek language, among which was one giving the history and description of the church of St. Sophia in Constantinople in more than a thousand hexameter lines. This has come down to our times, and was published in the collection of Byzantine historians, with a translation and notes by Ducange. He also composed a poem on the Pythian Thermenæ, and some epigrams in the Anthology. See Gibbon, vol. vii. in which is a fine description of St. Sophia, taken partly from the work of Paulus.

PAULUS Hook, in *Geography*, a fortified post of North America, in Bergen county, state of New Jersey, on the North river, where the river is 2000 yards wide, opposite to the city of New York. In 1780 this river was so frozen, that carriages with heavy burdens passed over it.

PAUNCH, or PANCH, on *Ship-board*, a sort of thick and strong mat, formed by interweaving twists of rope-yarn as close as possible. See MATTS.

PAUNCHWAY, a small boat in Bengal, attendant on the *Budgerows*, which see. The paunchways move more expeditiously than the budgerows; but they are nearly of the same construction, with this difference, that the greatest breadth is somewhat further aft and the stern lower. We shall here add that another boat of this country, called "Moorpunkay," is curiously constructed; these boats are very long and narrow, sometimes extending to upwards of 100 feet in length, and not more than eight feet in breadth; they are always paddled, sometimes by 40 men, and are steered by a large paddle from the stern, which rises either in the shape of a peacock, a snake, or some other animal; the paddlers are directed by a man who stands up, and sometimes makes use of a branch of a plant, to regulate their motions, using much gesticulation, and telling his story to excite either laughter, or exertion. In one part of the stern is a canopy supported by pillars, in which are seated the owner and his friends, who partake of the refreshing breezes of the evening. These boats are very expensive, owing to the beautiful decorations of painted and gilt ornaments, which are highly varnished, and exhibit a considerable degree of taste.

PAUNDURA, in *Geography*, a town of Hindoostan, in Oude; 12 miles S.W. of Gazypour.

PAUNGARTENBERG, a town of Austria; six miles S.W. of Grein.

PAUNRAN, a town of Hindoostan, in Mohurbunge; 20 miles N. of Harriopour.

PAVO, PEACOCK, in *Astronomy*, a constellation of the southern hemisphere, unknown to the ancients, and not visible in our northern parts of the world, containing fourteen stars. See CONSTELLATION.

PAVO, in *Ichthyology*, a species of *Chatodon*, and also of *Labrus*; which see respectively.

PAVO, the Peacock, in *Ornithology*, a genus of birds of the order Gallinæ, of which there are four species, according

to Linnæus. The generic character is, bill convex, robust; the head is covered with feathers turned back; the nostrils are large; the feathers of the rump long, broad, expansile, and covered with rich eye-like spots.

Species.

CRISTATUS; Crest Peacock. Of this species there are three varieties, viz. 1. Head with a compressed crest; spurs solitary. 2. Cheeks, throat, belly, and wing-coverts, white. 3. Body entirely white. This species inhabits Asia and Africa, and is domesticated every where; is three feet eight inches long; sleeps on the highest places, and utters a loud and harsh cry; it is proud and vindictive, and feeds chiefly on grain and insects; it lays five or six eggs in some private place, which are grey-white: the young do not attain all their elegance till the third year. The bill and legs of this beautiful bird are brown; irids yellow; crest gold-green of twenty-four feathers, barbed at the tip, and with white shafts; the line above and beneath the eyes white; head, neck, breast, back and rump green-gold; feathers of the rump, usually called tail-feathers, sometimes five feet long; the real tail-feathers are eighteen in number, grey-brown, about 18 inches long; scapulars and lesser wing-coverts reddish-brown, varied with black, middle ones blue, with a gloss of green-gold, greater and spurious wings rufous; quill-feathers rufous, some of them varied with rufous, blackish and green; belly and vent greenish-black; thighs yellowish. The female has a shorter crest, and has no spur; the feathers of the rump not so long or elegant; the irids are of a lead colour, the bill and fringe on the breast white; the neck is green, the rest of the body and wings brown-ash.

The crest peacock exhibits in India, in its wild state, all the maturity of growth, and glow of colouring. It was an article of importation from that country to Palestine, in the reign of Solomon, in those fleets which conveyed, once in three years, to the court of that monarch invaluable treasures of art and nature. The female of this species is particularly solicitous to conceal her eggs from the male, which not unfrequently destroys them. They both feed chiefly on insects and grain, and prefer elevated situations for roosting, choosing the tops of houses and the highest trees for this purpose. Among the Romans they were regarded as great luxuries, and the young ones are now esteemed as a delicacy. Their voice is extremely harsh and dissonant, and in perfect contrast to that beauty exhibited in their plumage, which seems to combine all that delights the eye in the soft and delicate tints of the finest flowers, all that dazzles in the sparkling lustre of the gem, and all that astonishes in the grand display of the rainbow. See Plate III. Gallinæ of ORNITHOLOGY.

BICALCARATUS; Iris Peacock. Brown; head sub-crested; spurs two. This is found in China, and is larger than a pheasant. The bill is blackish, the upper mandible from the nostrils to the tip red; irids yellow; crown black; face naked; temples white; neck shining brown, with black lines; upper part of the back, shoulders, and wing-coverts brown, with yellowish stripes, the feathers near the tip with a large purple-gold spot; lower part of the back and rump spotted with white; body beneath brown, with transverse black streaks; quill-feathers dusky; legs brown. Individuals of this species have occasionally been brought to England, but they have not found the climate congenial to their habits.

TIBETANUS; Thibet Peacock, is about the size of a pinnado, or more than two feet in length. The specific character is cinereous streaked with blackish; head sub-crested,

and two spurs. The head, neck, and under parts, are ash-coloured, marked with blackish lines; the wing-coverts, back and rump are grey, with small white dots; besides which, on the wing-coverts and back, are large round spots of a fine blue, changing in different lights to violet and green-gold. This bird, as its specific name denotes, inhabits the kingdom of Thibet. The Chinese give it the name of Chinchien-khi.

MUTICUS; Japan Peacock. Head with a subulate crest, and it has no spurs. It is found in the Japan islands, and is of the size of the *P. cristatus*. The bill of this species is large; legs cinereous; area of the eyes red; irids yellow; body blue, mixed with green; head and neck greenish, with blue spots, and a white streak down the middle; belly, wing-coverts, secondary quill-feathers, and thighs cinereous, with black spots, the belly with white streaks; primary quill-feathers green, with transverse black lines, and yellowish towards the tip, which is black; feathers of the rump bay, with white shafts. The belly of the female is black.

PAVOASSAN, in *Geography*, a town of Africa, and capital of the island of St. Thomas, with a good harbour; the residence of the governor, and of the bishop.

PAVOISES. See **PAVAIS**.

PAVONIA, in *Botany*, received that appellation from Cavanilles, in honour of his countryman Joseph Pavon, who shared the labour of various botanical excursions, through Chili and Peru, with Dombey and Ruiz, and who is named, in conjunction with the latter, as author of the splendid *Flora Peruviana*. Mutis had destined for the same purpose the beautiful flower, figured long ago in various old books, under the denomination of *Flos Tigris*, which has but recently become known in the gardens of Europe. This however Linnæus referred to *Ferraria*; and his son, in publishing it, seems to have thought the specific name alluded to the peacock-like spots of the corolla; for he prints it as an adjective, *pavonia*. Many persons have so understood it. This plant is since restored to the rank of a genus; see **TIGRIDIA**.—Cavan. Diff. 132. Schreb. 469. Willd. Sp. Pl. v. 3. 833. Swartz Ind. Occ. v. 2. 1215. Juss. 272. Lamarck Illustr. t. 585.—Class and order. *Monadelphica Polyandria*. Nat. Ord. *Columnifera*, Linn. *Malvacea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, permanent, double; the outer of many linear-lanceolate leaves, rarely combined at the base; inner of one leaf, cup-shaped, divided half way down, rarely more, into five segments. *Cor.* Petals five, roundish, tapering at the base, a little oblique, spreading, united below to the tube of the filaments. *Stam.* Filaments numerous, combined in the form of a tube, about whose apex and surface they become separate; anthers kidney-shaped. *Pist.* Germen globose, furrowed; style thread-shaped, longer than the stamens, in ten segments at the top; stigmas globose. *Peric.* Capsules five, angular at the inner side, convex at the outer, of one cell and two valves, bursting in the upper part. *Seeds* solitary, ovate-oblong, acute.

Ess. Ch. Calyx double; the outer of many leaves or segments. Stigmas ten. Capsules five, of two valves. Seeds solitary.

This genus, separated by Cavanilles from *Hibiscus*, see that article, is rather artificial, there being no difference whatever in habit, and the technical marks of distinction not of the most decisive kind. These are the ten stigmas, which, in *Hibiscus*, are only five, and the finally distinct bivalve capsules, with solitary seeds. In *Hibiscus* the seeds are commonly numerous, in each cell of a five-valved five-celled capsule. This last-named genus being over-burthened with species, it is commodious to lessen their number by any allowable means, and as we presume the Hortus Kewensis,

which so generally follows Willdenow, will adopt *Pavonia*, we do not scruple to admit it. This author reckons up fifteen species.

1. *P. præmorfa* (*P. cuneifolia*; Cav. Diff. 139. t. 45. f. 1. *Hibiscus præmorfus*; Linn. Suppl. 309. Jacq. Ic. Rar. t. 141.)—Leaves roundish-wedge-shaped, abrupt, toothed, downy. Native of the Cape of Good Hope, cultivated in green-houses. The peculiar shape of the leaves at once distinguishes this species. The stem is shrubby, as in every other, except the 7th and 15th. Flowers lemon-coloured, one inch and a half wide; the segments of their outer calyx numerous and setaceous.

2. *P. leptocarpa*. Cav. Diff. 351. (*P. Typhalæa*; Cav. Diff. t. 197. *Urena leptocarpa*; Linn. Suppl. 308.)—Leaves lanceolate, ferrated. Outer calyx of five ovate leaves. Flowers capitate.—Native of Surinam. It is the *Hibiscus salicifolius* of the Pl. Surinam. in *Amœn. Acad.* v. 8. 260, and is known by the Linnæan herbarium only. The leaves are from three to five inches long, pointed, closely ferrated. Flowers yellow, in terminal heads. The inner calyx, smaller than the outer, is rather deeply divided, but not to the base, and the latter has but five leaves, which is a smaller number than the character requires. The capsules are those of a true *Pavonia*, but each is tipped with three points, half its own length, barbed with numerous recurved prickles. This species is very nearly related to the next, for which Cavanilles has figured it, not very correctly as to the calyx, whose divisions he makes not sufficiently deep, at least in the outer one, whereas Linnæus, on the other hand, errs in saying the inner calyx is of five leaves.

3. *P. Typhalæa*. Cav. Diff. 134. (*Urena Typhalæa*; Linn. Mant. 258.)—Leaves oblong-lanceolate, ferrated. Outer calyx of about seven linear leaves. Stem panicled. Flowers somewhat umbellate.—Native of the West Indies. This species, of which a specimen is preserved in the herbarium of the younger Linnæus, has not been well distinguished from the last, which has been generally mistaken for it. The present differs essentially in its panicled many-flowered stem, but especially in having the outer calyx of six or seven narrow linear leaves, or deep segments; whereas the former has five ovate ones. The barbed points are moreover as long as the capsules themselves, and the corolla is said to be white. The calyx of the true *Typhalæa* answers exactly to the generic character, but the preceding species is so closely allied to this, that they cannot be generically disjoined, though the latter has but five segments in its outer calyx.

4. *P. hastata*. Cav. Diff. 138. t. 47. f. 2.—Leaves oblong, hastate, bluntly toothed; densely downy beneath. Stalks axillary, single-flowered.—Gathered by Commerfon at Monte Video. Branches round, subdivided. Leaves dependent, about an inch long; besprinkled with starry hairs above; densely clothed with similar white pubescence beneath, as is the inner calyx especially. The outer calyx is of six, rarely only five, ovate leaves, shorter than the inner. Capsules reticulated, downy, without points or appendages.

5. *P. spinifex*. Cav. Diff. 133. t. 45. f. 2; and *aristata*, t. 45. f. 3. (*Hibiscus spinifex*; Linn. Sp. Pl. 978. Jacq. Hort. Vind. v. 2. 46. t. 103.)—Leaves broad-ovate, doubly crenate. Stalks axillary, single-flowered. Capsules with spreading smooth spines.—Native of South America. The leaves are two or three inches long, and half as broad, roughish to the touch. Flowers large, yellow. Capsules each tipped with three or four spreading, smooth, not barbed, awns or spines.

6. *P. papilionacea*. Cav. Diff. 140. t. 49. f. 2.—Leaves heart-shaped, ferrated. Stalks axillary, single-flowered.

Stamens

Stamens and style declining.—Gathered in Otaheite by Sir Joseph Banks, who communicated it to Cavanilles. *Flowers* large, yellow. Segments of the outer *calyx* very narrow, and longer than in the last.

7. *P. cancellata*. Cav. Diff. 135. (*Hibiscus cancellatus*; Linn. Suppl. 311. Am. Acad. v. 8. 260.)—Leaves heart-shaped, serrated. Outer calyx of twenty bristle-shaped, very hairy leaves. Stem decumbent.—Native of Surinam. The *stem* is herbaceous and trailing, clothed, like the rest of the plant, with prominent bristles. *Leaves* nettle-like. *Stalks* axillary, single-flowered. *Calyx* very remarkable for its numerous narrow segments, whose bristly hairs form a sort of net-work.

8. *P. racemosa*. Swartz Ind. Occ. v. 2. 1215. (*P. spicata*; Cav. Diff. 135. t. 46. f. 1. Malache scabra; Trew. Ehret. 50. t. 90.)—Leaves ovate, pointed, nearly entire. Flowers in a terminal cluster. Outer calyx of eight lanceolate leaves.—Native of bogs, among other shrubs and trees, in Jamaica. The nearly entire, naked *leaves*, roughish to the touch only, and the long terminal solitary *clusters*, of pale yellow, not very large, *flowers*, readily distinguish this species. The *leaves* in our specimens are very nearly entire; Ehret represents them serrated pretty copiously.

9. *P. corymbosa*. Willd. n. 9. (*Althæa corymbosa*; Swartz Ind. Occ. v. 2. 1213.)—Leaves heart-shaped, sometimes angular, smoothish. Flowers corymbose. Stalks and calyx hairy.—Found about the banks of rivers in Hispaniola and Jamaica. The habit is compared by Swartz to *Althæa hirsuta* of Linnæus. *Leaves* not quite smooth, serrated, sometimes almost sinuated as well as angular. *Flowers* yellow, rather large. Outer *calyx* of ten or twelve linear hairy leaves. *Capsules* rough. We have seen neither specimen nor figure.

10. *P. paniculata*. Cav. Diff. 135. t. 46. f. 2.—Leaves roundish-heart-shaped, serrated, with one or three points. Clusters compound, hairy. Stamens and style declining.—Native of Peru, near the source of the river Maragnon. *Dombey*. It seems, as Willdenow remarks, nearly akin to the last. The *flowers* are yellow, very numerous. *Stamens* drooping. *Style* ascending at the extremity.

11. *P. odorata*. Willd. n. 11.—Leaves ovate, somewhat heart-shaped, with three points, slightly toothed. Stalks axillary, single-flowered. Outer calyx of about twelve leaves.—Native of the East Indies.—The whole *plant* is hairy and viscid. *Leaves* oblong, slightly heart-shaped at the base. *Flower-stalks* long, sometimes assembled into a sort of *cluster* at the top of the *stem*. *Calyx* fringed. *Corolla* rather small, apparently red. *Willd.*

12. *P. coccinea*. Cav. Diff. 140. t. 47. f. 1. (*Malva folio hederaceo, flore coccineo*; Plum. Ic. 162. t. 169. f. 2.)—Leaves heart-shaped, three-lobed, serrated. Stalks axillary, single-flowered, ascending. Outer calyx of five linear-lanceolate leaves.—Native of Hispaniola, not of Dominica. Linnæus misquotes the figure of Plumier, for *Hibiscus* (or rather *Achæmia Malvaviscus*). The *flowers* appear to be large, standing erect in an elegant manner, the lower part of the *petals* cohering in the form of a tube, the extremities drooping. Plumier represents more than five leaves to the outer *calyx*, but Cavanilles examined a specimen.

13. *P. Columelka*. Cav. Diff. 138. t. 48. f. 3.—Leaves with five angles, serrated, nearly smooth; the uppermost oblong and undivided. Stalks axillary, single-flowered, shorter than the footstalks. Outer calyx of five linear-lanceolate leaves.—Found by Commerçon in the isle of Bourbon, growing abundantly by the sides of the roads cut through the woods. The *leaves* are shaped somewhat like

those of a vine. *Flowers* small, purplish, not unlike a common Mallow.

14. *P. urens*. Cav. Diff. 137. t. 49. f. 1. Jacq. Ic. Rar. t. 552.—Leaves with seven angles, hairy, cut and serrated. Flowers axillary, clustered, nearly sessile.—Native of the island of Mauritius. The *flowers* are of an elegant rose-colour, deeper in the centre, much resembling a common Mallow. *Capsules* with three barbed points, or beaks. *Leaves* and *stems* rough with pungent hairs.

15. *P. zeylanica*. Cav. Diff. 134. t. 48. f. 2. (*Hibiscus zeylanica*; Linn. Sp. Pl. 981. Burm. Ind. t. 48. f. 3.)—Leaves roundish-heart-shaped, cut, lobed, or deeply divided, bluntly toothed. Stalks axillary, single-flowered, equal to the footstalks. Outer calyx of ten linear bristly leaves.—Native of Ceylon. *Root* annual. *Stem* herbaceous, downy, somewhat branched. The *leaves* vary greatly as to their divisions, being sometimes divided to the very base into five oblong blunt segments. *Flowers* small, red. This species is now and then seen in gardens, but valued rather for the sake of rarity than beauty. Scopoli has figured the deeply divided variety, under the name of *Hibiscus arenarius*, Delic. Infubr. fasc. 3. t. 2, which we do not find quoted.

16. *P. spiralis*. Cav. Ic. v. 5. 20. t. 434.—Leaves heart-shaped, serrated, pointed, somewhat lobed. Stalks axillary, single-flowered. Outer calyx of many linear fringed leaves. Petals convoluted, each with a lateral tooth.—Gathered by Louis Née, in the island of Tobago, five leagues from Panama, flowering and fruiting in November. The *stem* is shrubby, six feet high. *Leaves* most like those of the tenth species, but it is not said whether they are smooth or otherwise. Outer *calyx* of nine linear hairy leaves. *Petals* scarlet, rolled together like those of *Achæmia Malvaviscus*, but larger, the *stamens* and *style* projecting far beyond them. This species is unnoticed by Willdenow, and might perhaps be introduced between the tenth and eleventh. S.

PAVONIA, or *Pavonina*, in *Ornithology*, a species of *Ardea*. See HERON.

PAVONIUS LAPIS, the *peacock-stone*, a name given by Ludovicus Dulcis, and other writers of his time, to a stone of which they say many idle things, such as its having the virtue of gaining a person's love to another, and the like. They have left us no description of it, but probably it was one of the variegated agates.

PAVOOR, in *Geography*, a town of Hindoostan; 15 miles N.W. of Tinevelly.

PAUPAKELLY, a town of Hindoostan, in Golconda; 20 miles S. of Byarem.

PAUPANASSUM, a town of Hindoostan; 20 miles W.S.W. of Tinevelly.

PAUPANASSY, a town of Hindoostan, in the Carnatic; 12 miles N.E. of Tanjore.

PAUPER, in *Law*. See *FORMA Pauperis*, and POOR.

PAURÆDRASTYLÆ, in *Natural History*, the name of a genus of crystals. The word is derived from the Greek *παυρος*, a few, *εδρα*, a side, or plane, the privative particle *α*, not, and *συλος*, a column, and expresses a fossil composed of but a few sides or planes, and having no column.

The bodies of this genus are crystals, composed of two pyramids joined base to base, without the intervention of a column; these being both hexangular, and consequently the whole body composed only of twelve planes; the others of the same structure being composed of sixteen. Of this genus there are only four known species.

PAUREY, in *Geography*, a town of Africa, on the Slave coast. N. lat. 6° 10'. E. long. 0° 15'.

PAURWITZ. See BAUERWITZ.

PAUSA, a town of Saxony, in the Vogtland; 72 miles W.S.W. of Dresden. N. lat. $50^{\circ} 31'$. E. long. $11^{\circ} 58'$.

PAUSANIA, Παιωνία, in *Antiquity*, a festival in which were solemn games, wherein freeborn Spartans only contended. It had its name from Pausanias, the Spartan general, under whose conduct the Grecians overcame Mardonius, in the famous battle at Platæa, there being always an oration in praise of him.

PAUSANIAS, in *Biography*, a celebrated Lacedæmonian commander, who fell at the famous straits of Thermopylæ, was the son of Cleombrotus, and nephew of Leonidas. He obtained a high rank in the magistracy of his country, and when Mardonius, the Persian general, invaded Greece with a mighty host, Pausanias was appointed commander-in-chief of the allied army raised to oppose him. He brought on a general engagement at Platæa, in the year 479 B.C., in which Mardonius was killed, and his army defeated with great slaughter. With the assistance of the Athenians, the camp of Mardonius was taken with an immense booty. Pausanias exhibited a greatness of mind in rejecting the proposal of one of the leaders, that the body of the Persian general should be fought for, in order that it might be treated with the same indignity that had been offered to that of Leonidas. He proceeded to punish the traitors to the cause of Greece, and marching to Thebes, obliged that city to deliver up the heads of the Persian party, whom he put to death. The effect of success upon his own mind was to nourish a spirit of pride and arrogance, and inspire ambitious designs. He assumed to himself all the honour of the victory of Platæa, and upon a golden tripod, which he presented to the temple of Delphi, he put an inscription that was honourable to himself alone. In the command of the united fleet, which had been given him for the purpose of freeing the Grecian cities from Persian garrisons, he behaved with great partiality to his own countrymen, and created many enemies; while the justice of Aristides, and the affability of Cimon, gained all hearts, and restored to the Athenians the naval supremacy of Greece. Suspensions were entertained that he meant to assume the full controul of Greece, and to get the power of the country in his own hands, and on this account he was recalled to Sparta, and underwent a trial for his life, but as the evidence was inconclusive, he was fined and liberated. When he returned to the army, he openly adopted the Persian habit and manners, and went into all the excesses of that luxury which he had formerly decried. It was supposed that his mind was deranged, owing to the following tragical incident. Having been captivated by the charms of Cleonice, a young woman of good family at Byzantium, her parents not daring to refuse his solicitations, obliged her to comply with his desires. To save her blushes, it was agreed that the lights should be extinguished when she entered his chamber. In the dark she unfortunately stumbled over one of the lamps; the noise of which suddenly awakening Pausanias, he fancied an assassin was coming to murder him, and, starting up, plunged a dagger into her breast. When he discovered the fatal error, he was almost distracted, and from that moment imagined that the blood of Cleonice was perpetually crying out for vengeance. He left Byzantium, and repaired to Heraclea, where he found persons who pretended to evoke and pacify the spirits of the deceased. That of Cleonice was called up before him, and made to say to him, "When you come to Sparta, you will find a termination to your sufferings." He went thither, still occupied with the thought of betraying his country to the Persians. For this purpose, he carried on a correspondence with Artabazus, a satrap; and all the messengers he sent were put to death, that

they might not betray him on their return. It is said that he in vain attempted to engage Themistocles, who was at that time an exile, to concur in his measures, and being impatient, he wrote a peremptory letter to Artabazus, which he committed to one Argilius, his particular favourite. The young man, alarmed by the reflection, that none of the former messengers returned, unsealed the packet entrusted to his care, and finding a direction to put him to death, immediately disclosed the matter to the ephori. They resolved to apprehend him, but being apprized of their intention, he fled into the temple of Minerva, from whence he could not be taken. While they were hesitating as to what could be done, the mother of Pausanias brought a brick, and set it against the door of the temple: her example was followed, till he was completely immured. When he was dead with hunger, his body was brought out, and interred by his friends. Corn. Nep. Univer. Hist.

PAUSANIAS, a Greek topographical writer, who flourished in the second century, under Adrian, and the Antonines, was probably a native of Cæsarea, in Cappadocia, and studied under the celebrated Herodes Atticus. Though as a speaker defective in his pronunciation, he obtained a high reputation by his compositions. He declaimed both at Athens and Rome, in which last named city he died at an advanced age. He seems to have been a great traveller, and besides his work on Greece that is extant, he composed descriptions of Syria and Phœnicia. The "Description of Greece" is highly valuable to the antiquary, and contains much information no where else to be met with. It is a kind of itinerary through Greece, in ten books, in which the author notes every thing remarkable that fell under his observation, such as temples, theatres, sepulchres, statues, paintings, public monuments of all kinds, the scites and dimensions of ruined cities, and the scenes of important transactions. In some parts he gives historical details, and in those his style, which is frequently negligent, rises to a degree of dignity. His work abounds with fabulous narrations, but what he himself saw, there is no reason to suppose he misrepresented. His work was first published in 1516, at the press of Aldus. The best edition has been reckoned that of Kuhnus, Greek and Latin, 1696, but others give the preference to the modern one of I. F. Facius, Lips. 1794-7, in four volumes, 8vo. There is a French translation in high estimation, by the abbé Gedoyn. Mœri.

PAUSARY, PAUSARIUS, in ancient Rome, an officer who, in the solemn pomps or processions of the goddess Isis, directed the stops, or pauses.

In these ceremonies, there were frequent stands at places, prepared for the purpose, wherein the statues of Isis and Anubis were set down; much after the manner of resting-places in the procession of the holy sacrament in the Romish church.

These rests were called *mansiones*: the regulation of which was the office of these *pausarii*.

From an inscription quoted by Salmasius it appears, that the Romans had a kind of college or corporation of *pausarii*.

PAUSARY, *Pausarius*, was also a name given to an officer in the Roman galleys, who gave the signal to the rowers, and marked the times and pauses; to the end they might act in concert, and row all together.

This was always done with a musical instrument. Hyginus says, that, in the ship Argo, Orpheus did the office with his lyre.

PAUSE,

PAUSE.

PAUSE, a stop or cessation of speaking, singing, playing, or the like.

The word is formed from the Latin *pausa*, which we find used in Lucretius and Plautus in the same sense.

The use of pointing in grammar is, to make the proper pauses in certain places. See POINT and PUNCTUATION.

The use of these pauses is equally necessary to the speaker and to the hearer: to the speaker, that he may take breath, without which he cannot proceed far in his delivery, and that he may relieve the organs of speech by these temporary rests, which otherwise would be soon tired by continued and uninterrupted action; to the hearer, that the ear also may be relieved from the fatigue which it would otherwise endure from a continuity of sound, and that the understanding may have sufficient time to mark the distinction of sentences, and their several members.

Pauses in common discourse, and in most compositions in prose, have, besides the duration, marks of a surer kind annexed to them to point out their nature: and these are certain notes of the voice, which declare of what kind the pauses are, at the instant they are made; and inform the mind what it is to expect from them; whether the sense is still to be continued in the same sentence; whether the preceding one is to be the last member of the sentence; or whether the sentence is closed, and a new one is to begin. By means of these notes or tones, the speaker may proportion his pauses to the importance of the sense, and not merely to the grammatical structure of words in sentences. A proposition, or sentiment of peculiar moment, may be preceded or closed by a longer pause than usual: a pause may be also made before some very emphatical word, but this is a liberty that should be used with great caution. An ingenious writer on this subject observes, that pauses in general depend upon emphasis: words are sufficiently distinguished from each other by accent; but to point out their meaning, when ranged in sentences, emphases and pauses are necessary. Accent, says this writer, is the link which connects syllables together, and forms them into words: emphasis is the link which connects words together, and forms them into members of sentences; but that there may be no mistake to which emphasis the words belong, at the end of every such member of a sentence there ought to be a perceptible pause. Sheridan's Lectures, p. 75, &c. See COMMA, COLON, POINTS, &c.

Pauses are commonly distinguished into those that are emphatical, and those that mark the distinctions of sense. An emphatical pause is made, after something has been said of peculiar moment, and on which we want to fix the hearer's attention. Sometimes such a thing is introduced with a pause of this nature. Such pauses have the effect of a strong emphasis, and are subject to the same rules, especially to the caution of not repeating them too frequently: for as they excite uncommon attention, and of course raise expectation, they will occasion disappointment and disgust, if the importance of the matter be not fully answerable to such expectation. But the most frequent and the principal use of pause is to mark the divisions of the sense, and, as we have already said, to allow the speaker to draw his breath. The proper and graceful adjustment of such pauses is one of the most nice and difficult articles in delivery. The speaker, in order to avoid mangling his sentences, and totally losing the force of the emphasis, should be careful to provide a full supply of breath for what he is to utter. It is a great mistake, says Dr. Blair, to imagine that the breath must be drawn only at the end of a period, when the voice is allowed a fall. It may easily be gathered at the intervals of the period, when the voice is only suspended for a moment;

and, by this management, we may have always a sufficient stock for carrying on the longest sentences, without improper interruptions. If any one, as the same ingenious author observes, shall have formed to himself a certain melody or tune, which requires rests and pauses of its own, distinct from those of the sense, he has undoubtedly contracted one of the worst habits into which a public speaker can fall. It is the sense which should always rule the pauses of the voice; for whenever there is any sensible suspension of the voice, the hearer is always led to expect somewhat corresponding in the meaning. Pauses, in public discourse, must be formed on the manner in which we utter ourselves in ordinary, sensible conversation; and not upon the stiff artificial manner, which we acquire from reading books according to the common punctuation, which is often arbitrary, capricious, and false, and dictates an uniformity of tone in the pauses, that is extremely disagreeable. In order to render pauses graceful and expressive, they must not only be made in the right place, but also be accompanied with a proper tone of voice, by which the nature of these pauses is intimated, much more than by the length of them, which can never be exactly measured. Sometimes it is only a slight and simple suspension of voice that is proper; sometimes a degree of cadence in the voice is required; and sometimes that peculiar tone and cadence, which denote the sentence finished. In all these cases, we are to regulate ourselves, by attending to the manner in which Nature teaches us to speak, when engaged in real and earnest discourse with others.

In reading or reciting verse, there is a peculiar difficulty in making the pauses justly. The difficulty arises from the melody of verse, which dictates to the ear pauses or rests of its own; and to adjust and compound these properly with the pauses of the sense, so as neither to hurt the ear nor offend the understanding, is so very nice a matter, that it is no wonder we seldom meet with good readers of poetry. There are two kinds of pauses that belong to the music of verse: one is the pause at the end of the line; and the other, the caesural pause in the middle of it. With regard to the pause at the end of the line, which marks the strain or verse to be finished, rhyme renders this always sensible, and in some measure compels us to observe it in our pronunciation. In blank verse, where a greater liberty is allowed of running the lines into one another, sometimes without any suspension in the sense, it has been questioned, whether, in reading such verse with propriety, any regard at all should be had to the close of the line. On the stage, where the appearance of speaking in verse should always be avoided, there can be no doubt, in the opinion of Dr. Blair, that the close of such lines as make no pause in the sense should not be rendered perceptible to the ear. But on other occasions, this would be improper: for what is the use of melody, or for what end has the poet composed in verse, if, in reading his lines, we suppress his numbers; and degrade them, by our pronunciation, into mere prose? We ought, therefore, certainly to read blank verse so as to make every line sensible to the ear. At the same time, in doing so, every appearance of sing-song and tone must be carefully avoided. The close of the line, where it makes no pause in the meaning, ought to be marked not by such a tone as is used in finishing a sentence; but without either letting the voice fall, or elevating it, it should be marked only by such a slight suspension of sound, as may distinguish the passage from one line to another, without injuring the meaning.

The other kind of musical pause is that which falls somewhere about the middle of the verse, and divides it into two hemistichs; a pause not so great as that which belongs to
the

the close of the line, but still sensible to an ordinary ear. This, which is called the *cæsural pause*, falls uniformly, in the French laconic verse, on the middle of the line. In the English, it may fall after the fourth, fifth, sixth, or seventh syllables in the line, and no other. Where the verse is so constructed, that this *cæsural pause* coincides with the slightest pause or division in the sense, the line can be read easily; as in the two first verses of Mr. Pope's *Messiah*:

“Ye nymphs of Solyma! begin the song;
To heavenly themes, sublimer strains belong.”

But if it shall happen that words, which have such a strict and intimate connection, as not to bear even a momentary separation, are divided from one another by this *cæsural pause*, we then feel a sort of struggle between the sense and the sound, which renders it difficult to read such lines gracefully. The rule of proper pronunciation, in such cases, is to regard only the pause which the sense forms, and to read the line accordingly. The neglect of the *cæsural pause* may make the line sound somewhat unharmoniously; but the effect would be much worse, if the sense was sacrificed to the sound. For instance, in the following line of Milton:

“——— What in me is dark,
Illumine; what is low, raise and support.”

The sense clearly dictates the pause after “illumine,” at the end of the third syllable, which, in reading, ought to be made accordingly; though, if the melody only were to be regarded, “illumine” should be connected with what follows, and the pause not made till the fourth or sixth syllable. So, in the following line of Mr. Pope's (*Epistle to Arbuthnot*):

“I sit, with sad civility I read.”

The ear plainly points out the *cæsural pause* as falling after “sad,” the fourth syllable. But it would be very bad reading to make any pause there, so as to separate “sad” and “civility.” The sense admits of no other pause than after the second syllable “sit,” which, therefore, must be the only pause made in the reading.

It is a distinguishing advantage of our English verse, that it allows the pause to be varied through four different syllables in the line; for as the pause is placed after one or other of these syllables, the melody of the verse is much changed, its air and cadence are diversified. By these means, uncommon richness and variety are added to English versification. When the pause falls earliest, that is, after the fourth syllable, the briskest melody is thereby formed, and the most spirited air given to the line. In the following lines of the *Rape of the Lock*, Mr. Pope has, with exquisite propriety, suited the construction of the verse to the subject:

“On her white breast | a sparkling cross she wore,
Which Jews might kiss | and infidels adore;
Her lively locks | a sprightly mind disclose,
Quick as her eyes | and as unfix'd as those.
Favours to none | to all she smiles extends,
Oft she rejects | but never once offends.”

Where the pause falls after the fifth syllable, which divides the line into two equal portions, the melody is sensibly altered. The verse loses that brisk and sprightly air, which it had with the former pause, and becomes more smooth, gentle, and flowing.

“Eternal sunshine | of the spotless mind,
Each prayer accepted | and each wish resign'd.”

When the pause proceeds to follow the sixth syllable, the tenor of the music becomes solemn and grave. The verse marches now with a more slow and measured pace, than in either of the two former cases.

“The wrath of Peleus' son | the direful spring
Of all the Grecian woes | O goddesses sing!”

But the grave, solemn cadence becomes still more sensible, when the pause falls after the seventh syllable, which is the nearest place to the end of the line that it can occupy. This kind of verse occurs the seldomest, but has a happy effect in diversifying the melody. It produces that slow Alexandrian line, which is finely suited to a close; and for this reason, such lines almost never occur together, but are used in finishing the couplet.

“And in the smooth description | murmur still.
Long loved adored ideas! | all adieu.”

Blank verse, being of a freer kind than rhyme, and naturally read with less cadence or tone, its pauses, and the effect of them, are not always so sensible to the ear. It is, however, constructed upon the same principles, with respect to the place of the pause. Some, indeed, have maintained that heroic verse admits of musical pauses, not only after the four syllables to which their place is above assigned, but after any one syllable in the verse indifferently, where the sense directs it to be placed. But this, says Dr. Blair, is the same thing as to maintain that no pause at all belongs to the natural melody of the verse; since, according to this notion, the pause is formed entirely by the meaning, not by the music. But this, he apprehends, is contrary both to the nature of versification, and to the experience of every good ear. Blair's *Lectures*, vols. ii. and iii. See *PROSODY* and *VERSIFICATION*.

Pauses, or silences, are the same in poetry as the odd-rests in music, which serves to make the odd notes even ten. St. Austin instructs us how the pauses are to be made according to the laws of music.

PAUSE, in *Music*, is a cessation of sound, marked with a character commonly called in England a bull's eye, ◡; but by the Italians a *corona*, or crown. The pause used to be of an unlimited duration in the middle of a piece, different from common rests, all which represent the duration of some note in the time-table. Emanuel Bach was the first who measured pauses by a rest of one, two, or three bars; which method has been adopted by Haydn, Mozart, and others, a method which is very convenient in symphonies and full pieces; as, when it was left to the will or sagacity of the several performers, they never, after a pause, resumed the strain together. See *RESTS*, and *CORONA*.

For the signs and characters of pauses, see *CHARACTERS*.

PAUSEBASTOS, in *Natural History*, the name of a beautiful stone dedicated to Venus, and called also *paneros*. It seems to have been a beautiful agate.

PAUSICAPE, Παισικαπη, among the Athenians, a kind of punishment. A round engine was put about the neck in such a manner, that the sufferer could not lift his hand to his head.

PAUSILIPO, or *POSILIPO*, in *Geography*, a celebrated mountain and grotto, near the city of Naples. It took its name from a villa of Vedius Pollio, erected in the time of Augustus, and called “*Pausilypan*,” from the effect which its beauty was supposed to produce in suspending sorrow and anxiety. This mountain is said to be beautiful in the extreme, and to be justly honoured with its appellation, as no scene is better calculated to banish melancholy and exhilarate the mind. The grotto is nearly a mile in length, and

is made through the mountain. 20 feet in breadth and 30 in height. On the mountain Vedius Pollio had not only a villa, but a reservoir or pond, in which he kept a number of lampreys, to which he used to throw such of his slaves as had committed a fault. When he died, he bequeathed among other parts of his possession his villa to Augustus; but this monarch, abhorring a house where so many ill-fated creatures had lost their lives for very slight faults, caused it to be demolished, and the finest materials in it to be brought to Rome, and with them raised Julia's portico.

Virgil's tomb is said to be above the entrance of the grotto of Paullipo. A vaulted cell and two modern windows above present themselves to view: the poet's name is the only ornament of the place. No sarcophagus, no urn, and even no inscription, serve to feed the devotion of the classical pilgrim. The epitaph, though not genuine, is yet ancient; it was inscribed by order of the duke of Pescobrangiano, the proprietor of the place, on a marble slab placed in the side of the rock opposite to the entrance of the tomb, where it still remains. It is as follows:

“Mantua me genuit. Calabri rapuere, tenet nunc
Parthenope, cecini pascua, rura, duces.”

An Italian author, supposed to be Pietro de Steffano, assures us that he himself had seen, about the year 1526, the urn supposed to contain the poet's ashes, standing in the middle of the sepulchre, supported by nine little marble pillars, with the inscription just quoted on the frieze. He adds, that Robert of Anjou, apprehensive lest such a precious relic should be carried off or destroyed during the wars then raging in the kingdom, took the urn and pillars from the tomb, and deposited them in the Castel Nuovo. This extreme precaution eventually occasioned the loss which it was meant to prevent: for notwithstanding the most laborious search and frequent inquiries made by the orders of Alphonso of Arragon, they were never more discovered. Some, indeed, have asserted, that the tomb just mentioned is not the sepulchre of Virgil. Among these we may reckon Cluverius and Addison. The reader will learn with regret that Virgil's tomb, consecrated as it ought to have been to genius and meditation, is sometimes converted into the retreat of assassins, or the lurking-place of Sbirri. Few places, however, are in themselves more picturesque, and from the recollection inseparably interwoven with it, no spot is more interesting than the tomb of Virgil. The whole hill of Paullipo is covered with country seats and gardens, for summer resort, being protected from the hot south and west. In the middle of the passage is a church or chapel; but the dust raised by the horses and carriages is very offensive.

PAUSIS, a word used by the old physicians for a remission in acute diseases.

PAUSUS, in *Entomology*, a genus of insects of the order Coleoptera. The generic character is as follows; antennæ two-jointed, the upper joint very large, inflexed, hooked, pedicellate; head pointing forwards, with a convex jugular triangle; thorax narrow, unequal, scutellate; shells flexile, deflected, truncate; fore-feet placed at the fore-part of the breast, thighs with minute appendages, the tarsi four-jointed. Five species are enumerated in Gmelin's edition of Linnæus, of which the first and second are fully described in the 4th volume of the Transactions of the Linnæan Society. This genus was not known when the 12th edition of the *Systema Naturæ* first appeared; and it obtained its present rank in 1775, owing to a dissertation published by Linnæus at Upsal. At this period one species only was mentioned. The etymology of the generic term is thought to be from the Greek *παυσις*, signifying a pause, cessation, or rest, because Lin-

næus, now old and infirm, and sinking under the weight of age and infirmity, saw no probability of continuing any longer his career of glory. He might therefore be supposed to say, “*hic meta laborum*,” as it really proved, at least with regard to insects, Pausus being the last he ever described. Such is the account given by Dr. Afzelius in the work already referred to.

Species.

MICROCEPHALUS. The head of the species is unarmed; the club is an oblong; shells as long as the body, not punctured, shanks linear. This rare insect is a native of Sierra Leona, the Banana, and neighbouring islands. The body is of a dark chestnut-brown; the head is, as its name denotes, uncommonly small; the shield is two-parted; jugular triangle minute; pivots of the antennæ black, upper joint of the club much larger than the head; the thorax broader than the head, and the wings are footy.

SPHÆROCERUS. Head horned, club globular; shells shorter than the abdomen, punctured; shanks dilated at the tip. This is found at Sierra Leona; the body is polished, chestnut, a little narrower than the last; the horn between the eyes is straight, conical, tipped with a tuft of cartilaginous hairs; the eyes are larger; the thorax is of the same breadth as the head, the wings are of a shining changeable violet. We shall give part of Dr. Afzelius' description of this insect in his own words: “There was,” says he, “a house building for the governor, on an eminence called Thornton Hill, at the south end of Free-town, in Sierra Leona; and in the beginning of the year 1795, several apartments having been got ready, so as to be habitable, one of them was allotted to me, and I removed into it in the end of the month of January. I had not resided there many days, when one evening, having just lighted my candle and begun to write, I observed something dropping down from the ceiling before me upon the table; which from its singular appearance attracted my attention. It remained for a little while quite immovable, as if stunned or frightened, but began soon to crawl very slowly and steadily. I then caught it, and from the remembrance I had of the Linnæan species, I directly took it for a non-descript of this genus. Some days after, coming into my room from supper, with a light in my hand, and having put it upon the table, there instantly fell another down from the ceiling. The third I was favoured with by the then governor Mr. Dawes, who informed me that it had dropped down before him on the table, just when he had entered his room, and was going to write. The other three, which I afterwards collected, were also got upon similar occasions, and from thence I thought I had some reason to conclude that it was a nocturnal animal; that it becomes benumbed by candle-light; that it lives in wood, and prefers newly-built houses. After the end of February I never saw any more. The last which I caught I put into a box, and left confined there for a day or two. One evening going to look at it, and happening to stand between the light and the box, so that my shadow fell upon the insect, I observed, to my great astonishment, the globes of the antennæ like two lanterns, spreading a dim phosphoric light. This singular phenomenon raised my curiosity, and, after having examined it several times that night, I resolved to repeat my researches the following day. But the animal, being exhausted, died before morning, and the light disappeared.”

RUBER. Reddish; thorax jagged before. This and the next species inhabit the Cape of Good Hope.

LINEATUS. Reddish; shells with a brown line. This is supposed to be the *Cerocoma lineata* of Fabricius.

RUFICOLLIS. Black; thorax and streak on the shells ferruginous,

ferruginous, supposed to be the *Cerocoma ruficollis* of Fabricius.

PAUTE', in *Geography*, a town of South America, in the audience of Quito; 23 miles E. of Cuença.

PAUTÉ, or *St. Tago*, a river of Peru, which runs into the Maranon; five miles W. of St. Francisco de Borja.

PAUTO, a town of New Granada; 25 miles E. of Tunja.

PAUTRE, ANTONY LE, in *Biography*, an eminent French architect, was born at Paris in 1614. He distinguished himself by his taste in the decoration of buildings. Several edifices from his designs were erected in the capital and its neighbourhood, of which the most noted were the wings of St. Cloud; the church of the nunnery of Port-Royal, and the hotels of Gevres and Beauvais. He was appointed architect to the king's brother, and afterwards to the king himself. He was a member of the Academy of Architecture from its first institution, and published a work on that art, entitled "Les Œuvres d'Architecture d'Antoine le Pautre," of which the first edition appeared in 1652. He died in 1691. He had a brother an eminent engraver, who died in 1682; and his son, Peter, who was born in 1660, was eminent as a sculptor. He studied fourteen years at Rome, and on his return was employed in several public works, of which the most celebrated is a group of Eneas bearing Anchises on his shoulders, and holding Ascanius in his hand, which was placed in the garden of the Thuilleries. He died in 1744, at the age of eighty-four.

PAUTUCKE, in *Geography*, a town of America, in the state of Massachusetts; 33 miles S.S.W. of Boston.

PAUW, N. DE, in *Biography*, a German canon, distinguished himself by his philosophical writings, of which the principal were "Recherches Philosophiques sur les Américains, les Egyptiens, et les Chinois," in two vols. 1768; and "Recherches Philosophiques sur les Grecs," two vols. 1787, reprinted at Paris in seven vols. 8vo. "In these works," says his biographer, "there are much learning and ingenuity, but joined with a bold spirit of conjecture, and a disposition to contradict all received notions." They were very popular at the time of their appearance, but have lost a great part of their original reputation. The author was in high estimation with Frederick the Great, as one of the free speculators of the time, and was, of course, obnoxious to the clergy. His private character was excellent. He died at Xanton, near Aix-la-Chapelle, in 1799; a nephew of his was Anacharis Cloots, who was famous at the commencement of the French revolution.

PAUXI, in *Ornithology*, the name of an American bird described by Nieremberg. See CRAN *Pauxi*.

PAUXIS, in *Geography*, a fortress of Brasil, in the government of Para, on the N. side of the river Amazon. S. lat. 1 56'. W. long. 58 10'.

PAUZEN, a town of Bohemia, in the circle of Boleſlau; 10 miles E. of Jung Buntzel.

PAUZK, PAUTZK, or *Putzig*, a town of Prussian Pomerania; 24 miles N.E. of Dantzick. N. lat. 54 30'. E. long. 18 3'.

PAW, in the *Manege*. A horse is said to *paſw* the ground when his leg being either tired or painful, he does not rest it upon the ground, and fears to hurt himself as he walks.

PAW *Patté*, in *Heraldry*, the fore-foot of a beast cut off short. If the whole leg be cut off, it is called *gambé*. Lion's-paws are much used in armoury.

PAWAH, in *Geography*, a town of Hindoostan, in Bahar; 40 miles S.W. of Bahar.

PAWARAH, a town of Hindoostan; 43 miles N.W. of Benares.

PAWEN, a small island in the bay of Gunong Tellu, on the E. coast of the island of Celebes. S. lat. 0° 18'. E. long. 122° 2'.

PAWING, or POGUM, a town of East Friesland, near the Ems; 32 miles S. of Emden.

PAWLE, in a *Ship*. See PAUL.

PAWLET, in *Geography*, a township of America, in Rutland county, Vermont, containing 1938 inhabitants. It is watered by Pawlet river, which joins Wood creek, and the confluent stream falls into South bay at Fiddler's Elbow.

PAWLOCZ, a town of Russian Poland, in the palatinate of Kiev; 60 miles S.W. of Kiev.

PAWN, PIGNUS, a pledge or gage for surety of payment of money lent. It is said to be derived, a *pugno*, quia res quæ pignori dantur, pugno vel manu traduntur. (Lit. Dict.) The party that pawns goods hath a general property in them; they cannot be forfeited by the party that hath them in pawn, for any offence of his, nor be taken in execution for his debt; neither may they otherwise be put in execution till the debt for which they are pawned is satisfied. Litt. Rep. 332.

If the pawn is laid up, and the pawnee robbed, he is not answerable; though if the pawnee use the thing, as a jewel, watch, &c. that will not be the worse for wearing, which he may do, it is at his peril; and if he is robbed, he is answerable to the owner, as the using occasioned the loss, &c. Ibid. See BAILMENT.

If the pawn is of such a nature that the keeping is a charge to the pawnee, as a cow, or a horse, &c. he may milk the one, and ride the other, and this shall go in recompence for his keeping. Ibid.

Things which will grow the worse by using, as apparel, &c. he may not use. If a pawnbroker receives plate or jewels, as a pledge or security, for the repayment of money lent thereon at a day certain, he has them upon an express contract or condition, to restore them, if the pledger performs his part by redeeming them in due time (Cro. Jac. 245. Yelv 178.); for the due execution of which contract many useful regulations are made by statute 30 Geo. II. c. 24. See *Pawn-BROKERS*.

PAWN, among *Miners*, is a pledge of money put into the bar-matter's hand, at the time when the plaintiff causes the bar-master to arrest the mine.

PAWN-BROKERS. See *Pawn-BROKERS*, and 39 & 40 Geo. III. c. 99.

PAWNAGE. See PANNAGE.

PAWNEES, in *Geography*, the name of an Indian nation, inhabiting a part of Louisiana, consisting of three villages. The number of warriors is 1993, of women 2170, and of children 2060, according to the statement made in the "Exploratory Travels in North America."

PAWNGAW, a town of Hindoostan, in Dowlatabad; 20 miles E. of Perinda.

PAWTUCKET FALLS, a cataract of America, in Merrimack river, in the township of Dracut.

PAWFUXET, a village of America, in the township of Craniton, Providence county, Rhode island.

PAX, a small metallic plate, commonly of silver, with the representation of the crucifixion engraved upon it, which was kissed by the priest at a certain part of the mass, he repeating at the same time *Pax tecum*, Peace be to you, and afterwards by the assistants in token of fraternal charity.

PAX *Dei*. See PEACE of God.

PAX *Ecclesiaz*. See SANCTUARY.

PAX *Regis*. See PEACE of the King.

"Longe debet esse pax regis a parte sua, ubi residens fuerit, a quatuor partibus loci illius, hoc est quatuor milliaria & tres quarentenæ, & novem acra latitudine, & novem pedes, & novem palmæ, & novem grana hordei, &c." Leg. Edw. Confess.

Ad PACEM redire, to restore to the peace, is to reverse an outlawry; whereby a person is restored to the benefit of the king's peace.

"Rex potest dare quod suum est, hoc est, pacem suam quam utlagatus amisit." Bracton, lib. iii.

PAXAROS, or *Bird-Island*, in *Geography*, a small island near the S. coast of Cuba. N. lat. $19^{\circ} 56'$. W. long. $78^{\circ} 24'$.—Also, an island on the coast of California, in the North Pacific ocean. N. lat. $30^{\circ} 18'$. W. long. $120^{\circ} 45'$.—Also, small islands or rocks in the Pacific ocean, near the coast of Chili. S. lat. $29^{\circ} 40'$.

PAXIMADES, an island in the Mediterranean, near the S. coast of the island of Candia. N. lat. $34^{\circ} 54'$. E. long. $24^{\circ} 43'$.

PAXTON, *Upper, Lower, and Middle*, three townships in Dauphin county, Pennsylvania: the first contains 2274, the second 727, and the third, including Swatara, 3208 inhabitants.—Also, a township of Worcester county, Massachusetts; 8 miles W. of Worcester, incorporated in 1765, and containing 582 inhabitants.

PAY of the *Army and Navy*, is the stipend or salary allowed for each individual serving in the army or navy; for which we refer the reader to the Registers published annually, and in almost every body's hands.

In our ancient armies, there were, at all times, both before and after the conquest, besides the feudal tenants, stipendiary or mercenary soldiers, natives as well as foreigners. But our earliest information respecting military pay reaches no higher than the reign of king Henry II. Mr. Grose, in his "Military Antiquities," vol. i. has given an account of the amount of the pay of officers and soldiers at different periods; and from his account it appears, that the pay of the troops, as it was established at the Revolution, underwent very little change till after the commencement of the present war in 1793. But in the course of the present war, the pay and allowance of the officers and soldiers have received considerable augmentation. In 1795 his majesty issued a warrant for granting an addition of $2\frac{1}{4}d.$ per diem to the subsistence of the non-commissioned officers and men; to this was afterwards added $3\frac{1}{4}d.$ per diem, making the pay of the private soldier $1s.$ per diem. In 1797, the stoppages from all the officers' pay called arrears, were abolished; besides which $1s.$ per diem was added to the subsistence of each subaltern officer. The pay of the surgeon and his mate (now assistant,) was also raised, the former to $10s.$ and the latter to $3s.$ a day. In our ancient armies there were, in addition to the regular stipend of the troops, certain allowances, called "regards" (rewards, Ducange.) Such there are, though under different appellations, at present. Among these we may notice the *non-effective* and *contingent* allowances to the captains of troops and companies. Formerly the captains received and kept the subsistence of the non-effective, or men wanting to complete their companies; but this becoming an enormous abuse, has been since restricted to $20l.$ for each captain per annum. The contingent allowance is proportioned to the strength of the company. There are besides other allowances to officers in general, such as bat, baggage, and forage money in camp, and lodging money in garrison, when there are no barracks. These allowances vary according to circumstances. For particulars, see Grose, ubi supra.

VOL. XXVI.

Full Pay denotes the pecuniary allowance which is made to officers and non-commissioned officers, without any deduction whatsoever. Since the abolition of arrears in 1797, commissioned and warrant officers, &c. (those belonging to the guards excepted,) receive their full pay, or daily subsistence. The private soldiers are subject to temporary deductions, for the purpose of appropriating part of their pay and allowances to the expence of their messes, including vegetables, &c. and to a stoppage not exceeding $1s. 6d.$ per week, for necessaries, which stoppage is to be accounted for every month; and the remainder being $1s. 6d.$ must be paid weekly to each soldier, subject to the accustomed deduction, for washing, and for articles to clean his clothing and appointments. The full pay of the British army is given in advance on the 25th of every month, and accounted for to government by the several district and regimental paymasters, through army agents appointed for that purpose. Non-commissioned officers and private soldiers, serving as marines, are not liable to any deduction whatever from their full pay, on account of provisions. Although the army is now paid its full pay, in consequence of the abolition of the distinction between subsistence and arrears, that pay is nevertheless subject to the usual deductions on account of poundage, hospital, and agency.

Half Pay is a compensation, or retaining fee, given to officers who have retired from the service through age, inability, &c. or who have been placed upon that list in consequence of a general reduction of the force, or a partial drafting, &c. of the particular corps to which they belonged. The half-pay becomes due on the 25th of June, and on the 25th of December in each year, but it is seldom issued until three months after the expiration of each of those periods. The only deduction from the half-pay is the poundage, $2\frac{1}{2} \text{ per cent.}$ The first time when this allowance occurs, is in a vote of the house of commons, January 18, 1697. As the officer when disbanded is rewarded with half-pay, so the private soldier in the cavalry has his horse, and an allowance for his sword given him, with fourteen days' pay to carry him home to any part of England: to any part of Scotland the allowance is twenty-one days' pay: and to any part of Ireland twenty-eight days' subsistence. The infantry likewise have the same allowance of pay for subsistence.

PAY-Master, is the person intrusted with the money, and that has the charge of paying it to the regiment. The payment of the land-forces is under the direction of an office, the business of which is conducted by the pay-master general, his deputy, cashiers, clerks, &c. The payment of the navy is under the direction of the treasurer of the navy, a pay-master, and accomptant, clerks, &c. There is also a pay-master of the pensions, &c. a pay-master of the marines, &c. district pay-master, &c. The army pay-office is at Whitehall: and the navy pay-office at Somerset-house.

PAY-Bills, bills belonging to the military department, which are distinguished according to the nature of the service for which they are given. Every captain of a troop or company receives a regular weekly account from his serjeant, of money to be advanced for the effectives of such troop or company; and on the 24th day in each month he makes out a monthly one for the pay-master, who makes out a general abstract for the agent. The pay-master-general's estimate is likewise called the pay-bill.

PAY-Lists, the monthly accounts which are transmitted by the several regimental and district pay-masters to their agents on the 25th of each month.

PAY-Serjeant. See SERJEANT.

To *PAY*, in *Sea Language*, is to daub or anoint the surface of any body, in order to preserve it from the injuries of the water, weather, &c. Thus the bottom of a ship is paid with a composition of tallow, sulphur, resin, &c. The sides of a ship are usually paid with tar, turpentine, or resin, or with a composition of tar and oil, to which is sometimes added red ochre, &c. in order to protect the planks from being split by the sun or wind. The lower masts are, for the same reasons, paid with the materials of the same sort, if we except those along which their respective sails are frequently hoisted and lowered; such are the masts of sloops and schooners, which are always paid with tallow for this purpose: for the same reason, all top-masts and top-gallant-masts are also paid with hog's-lard, butter, or tallow. Falconer. See SHIP and WOOD.

PAYA, in *Geography*, a town of South America, in the province of Darien; 30 miles E. of St. Marie de Darien.

PAYEE, in *Commerce*, the person to whom a bill is made payable.

PAYERNE, in *Geography*, a town of Switzerland, in the canton of Berne, formerly an imperial town, under the protection of the dukes of Savoy. It is governed by its own magistrates; 22 miles S.W. of Berne. N. lat. $46^{\circ} 51'$. E. long. $6^{\circ} 44'$.

PAYERSDORFF, a town of Germany, in the margraviate of Bayreuth, near which is a decayed castle; both which were taken by the Swedes under Gustavus Adolphus.

PAY-HO, or *PEI-HO*, a river of China, which rises in the north part of the province of Pe-tcheli, and runs into the gulf of Leao-tong. N. lat. $30^{\circ} 3'$.

PAY-HOU, a lake of China, in Pe-tcheli; 140 miles S. of Pe-king.

PAYJAN, a town of Peru, in the diocese of Truxillo; 15 miles N. of Truxillo.

PAYING-OFF, in *Sea Language*, denotes the movement by which a ship's head falls to leeward of the point where it was previously directed: particularly when, by neglect of the helmsman, she had inclined to windward of her course, so as to make the head-falls shiver in the wind, and retard her velocity.

PAYING-Off is likewise used to signify the payment of the ship's officers and crew, and the discharge of the ship from service, in order to be laid up at the moorings.

PAYING-Out, or *Paying-away*, is the act of slackening a cable, or other rope, so as to let it run out of the vessel for some particular purpose. See CABLE.

PAYMENT, the discharge of a debt, either by money really told, or by bills of exchange, &c. See DEBT, &c.

PAYMENT, *Prompt*, a popular term in England and Amsterdam. It is when a debtor acquits what he owes, before the expiration of the term granted by the creditor. The ordinary discount for prompt payment on most merchandizes, is one per cent.

PAYMENTS, *Equation of*. See EQUATION of Payments.

PAYMOGO, in *Geography*, a town of Spain, in the province of Seville, on the frontiers of Portugal; 35 miles N. of Ayanonte.

PAYNESVILLE, a town of America, in Trumbull county, state of Ohio, on lake Erie, near the mouth of Grand river; in 1802 it had about 150 inhabitants.

PAYO, Sr., a town of Portugal, in the province of Tras los Montes; 18 miles W. of Mirand-de-Duero.

PAYRA, a town of South America, in the province of Quito; 12 miles N.W. of Macas.

PAYRAC, a town of France, in the department of the Lot, and chief place of a canton, in the district of Gourdon. The place contains 902, and the canton 5171 inhabitants, on a territory of 140 kilometres, in 12 communes.

PAYROLA, in *Botany*, a name contracted by Jussieu from *Paypayrola* of Aublet, its Caribbean name.—Juss. 427. Lamarck Dict. v. 5. 118. Illustr. t. 125. (*Paypayrola*; Aubl. Guian. v. 1. 249. t. 99.)—Class and order, *Pentandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven into five, roundish, acute segments. *Cor.* Petals five, oblong, narrow, erect, united together, so as to resemble a tube, their tops reflexed; one larger, emarginate, inserted into the disk beneath the germen. *Stam.* Filaments five, erect, inserted into the disk; anthers oblong, combined, two-celled. *Pist.* Germen superior, placed on the disk; style elongated, stigma two-lobed. *Peric.* and *Seeds* unknown.

Obf. Aublet remarks that he never saw the fruit of this plant in its perfect state, but from an imperfect one, which he cut in halves, it appeared to have two cells.

Ess. Ch. Calyx inferior, five-cleft. Petals five, forming a tube, reflexed at their summit. Stigma two-lobed.

1. *P. guianensis*. Aubl. Guian. t. 99.—Native of woods in Guiana, about Sinemari, upwards of twenty miles from the sea. It flowers in October.—This is a shrub from twelve to fifteen feet in height, whose stem is upright and branched. *Leaves* alternate, stalked, large, ovate, acute, smooth, entire. *Stipulas* two, short, acute, deciduous. *Flowers* spiked, axillary, terminal, yellow, each furnished with three glands at its base.

PAYS, RENE LE, in *Biography*, a writer of celebrity, born at Nantz in 1636, was brought up to business, and obtained the post of director-general of the gabelles in Dauphiné and Provence. He was first known in the literary world in 1685, by a little production in verse and prose, entitled "Amitiés, Amours, et Amourettes," which was read with great avidity at Paris. It is said that in answer to some enquiries made by ladies as to his person, he addressed to the duchess of Nemours a "Portrait" of himself, written in the same style. He professed to imitate Vouture, but was severely criticised by Boileau as a very inferior writer. Le Pays, however, instead of being offended with the satire, paid a visit to the poet, and obtained his friendship. He published letters, which prove that he had visited England and Holland. He was honoured by the duke of Savoy with the knighthood of St. Michael, and was an associate of the academy of Arles. He died in 1690, at the age of fifty-four.

PAYTA, or *PAITA*, or *St. Michel de Payta*, in *Geography*, a town of Peru, in the diocese of Truxillo, founded by Francis Pizarro, in the year 1531. It is small, consisting of houses that are constructed of split canes and mud, covered with leaves, and one story high; the only exception being that of the governor, which is built of stone. It has a parish-church and chapel, dedicated to our Lady of Mercy. The inhabitants are chiefly Spaniards, Mulattoes, and Mestizoes, who live chiefly by passengers going or returning from Panama to Lima, the number of whites being inconsiderable; all of them constituting about one street, and about 172 houses, and 35 or 40 families. The port, though little more than a bay, is esteemed the best on the coast, and affords a secure anchoring-place. This is the only place where ships from Acapulco, Sonsonate, Panama, &c. can touch in their passage to Callao. The voyage is long and tedious, on account of contrary winds, rains, and shifting

ing currents : so that, though the distance, according to the latitude of these ports, is only 140 leagues, a ship is very fortunate in performing it in 40 or 50 days, and in not being obliged to return to Païta. Southward of the town is a mountain, called from its figure Silla de Païta, or the saddle of Païta. The soil round the town is wholly sandy, and very barren : for besides the total want of rain, it has not a single river for the conveyance of water, of which it would be entirely destitute, if it were not supplied every day with great fatigue from Colan, a town on the same bay, four leagues N. of Païta, near which runs the river Chera, which waters Amotape. The Indians of Colan are obliged to send daily to Païta one or two balzes, loaded with water, which is distributed in stated proportions among the inhabitants. Païta has also the greatest part of its provisions from the same town. The nature of the soil and the situation of the place render it extremely hot. The town owes its whole support to the harbour, which is the place, as we have already intimated, where the cargoes of goods sent from Panama are landed, together with those coming from Callao to the jurisdictions of Piara and Loja. In the bay of Païta, and also that of Sechura, little farther to the south, there is an ample fishery, in which the Indians of Colan, Sechura, and the small hamlets near the coast, are constantly employed. The whole defence of the town consists in a small fort encompassed by a brick wall, and mounted with about eight pieces of cannon, but it has neither ditch, nor outwork. It has been often taken by the English, and particularly in 1741 by the squadron of commodore Anson, when it was pillaged and burnt. S. lat. 5° 10'. W. long. 81° 6'.

PAYTOLLEE, a town of Hindoostan, in Rohilcund ; 7 miles E. of Biffowie.

PAZ, LA, a province and diocese of Peru, belonging however to the viceroyalty of Buenos Ayres. This diocese contains six jurisdictions, viz. La Paz, Omasuyos, Pacajas, Laricaxa, Chucuito, and Paucar-colla, which see respectively. The jurisdiction of La Paz is of no great extent ; and the city is almost the only place in it that is worthy of any notice. In the adjacent cordillera is a high mountain, called Illimani, which is supposed to contain immense riches ; but its summit being perpetually covered with ice and snow, no mine has been opened in this mountain. This province was formerly known by the name of Chuquiyapu, which in the idiom of that country, is commonly thought to signify Chacra, or an inheritance of gold, and is there corruptly called Chuquiabo.

PAZ, La, a considerable city, and capital of the above province, having, according to Helms, more than 4000 hearths, or 20,000 inhabitants. It is an elegant and clean town, chiefly trading in the noted tea of Paraguay. The province was first conquered by Mayta-Capac, the 4th Inca ; and the Spaniards having afterwards taken possession of it, this city was founded by Pedro de la Gasca, in order to secure a settlement of Spaniards, in the extensive interval of 170 leagues between Arequipa and Plata, for the improvement of commerce, and the convenience and safety of the traders. Its situation was selected in a valley called Las Pacafas, in October 1548, as a place abounding in grain and cattle, and full of Indians. Along the valley of La Paz flows a pretty large river, occasionally much increased by torrents from the Cordillera, about 12 leagues distant from the city ; but from its vicinity, a great part of the country is exposed to so cold an air, that hard frosts, snow, and hail are not uncommon ; but the city itself is secured from them by its happy situation. Other parts are so well sheltered, that they pro-

duce all the vegetables of a hot climate, as sugar-canes, cocoa, maize, and the like. In the mountainous parts are large woods of valuable timber, but infested with bears, tigers, and leopards, with a few deer ; while on the heaths are found guanacos, vicunas, and blamas, with a great number of cattle of the European species. The city stands on unequal ground, among the branches of the Cordillera, and is surrounded by mountains. When the river in its vicinity is increased, either by rains or by the melting of the snow on the mountain, its current forces along large masses of rocks, with some grains of gold, which are found after the flood has subsided, and from which some idea may be formed of the riches inclosed in the bowels of these mountains. In the year 1730, an Indian accidentally discovered a lump of gold of so large a size, that the marquis de Castel Fuerte gave 12,000 pieces of eight for it, and sent it to Spain, as a present worthy of his sovereign. This city is governed by a corregidor, under whom are regidores, and ordinary alcaldes, as in all other towns. Besides the cathedral and the parish church, there are three others ; and also religious fraternities of Franciscans, Dominicans, Augustines, the fathers of Mercy, a college of Jesuits, and a convent and hospital, together with two nunneries. Here is also a college of St. Jerom, for the education of youth, whether designed for civil or ecclesiastical employments ; 120 miles E.S.E. of Arequipa. S. lat. 17° 15'. W. long. 68° 36'.

PAZARO, a cape of North America, on the W. side of the peninsula of California, near to the south end of it, in about N. lat. 24°, and W. long. 113°.

PAZMANI, PETER, in *Biography*, a celebrated cardinal, who flourished in the 17th century, was descended from a noble Transylvanian family. The time of his birth is not known, but he entered the order of Jesuits in the year 1587, and distinguished himself by the progress which he made in the different branches of literature, sacred and profane. In the year 1607, he was appointed professor of philosophy, and afterwards of divinity at the college of Gratz, in Styria, in which posts he acquitted himself with universal satisfaction. He afterwards devoted himself to missions in different parts of the kingdom, and was thought to have laboured very successfully in opposing the progress of the reformed opinions. By his zeal he recommended himself to the emperor Matthias, and the principal Hungarian nobility, and was appointed to the archbishopric of Gran, or Strigonia, an office that he did honour to by the establishment of strict discipline, and correcting the relaxed manners of the Hungarian clergy. He founded colleges at Presburg, Posen, and other places, for the encouragement of literature. In 1629 he was promoted to the high dignity of cardinal, by pope Urban VIII., at the solicitation of the emperor Ferdinand II. By the same prince he was afterwards sent ambassador to the court of Rome. He died at Posen in 1637, while on his journey towards Vienna, to attend on the councils of the emperor Ferdinand III. He was author of "Acta et Decreta Synodi Diocesanæ Strygoniensis, celebratæ Tyrnauiz." "Sermons on the Gospels for all the Sundays, and several of the Festivals, throughout the Year," in the Hungarian language. "A Collection of Prayers," in the same language, which has undergone numerous impressions ; and a great number of doctrinal, practical, and controversial treatises, in Hungarian and Latin. Moreri.

PAZZANO, in *Geography*, a town of Naples, in Calabria Ultra ; 19 miles N.N.E. of Gierace.

PEA, in *Botany*, &c. See LATHYRUS, LOTUS, and PISUM.

PEA, in *Agriculture*, a sort of plant or pulse generally cultivated

cultivated as a field crop. It is a sort of crop which is often supposed to be less advantageous to the farmer than several others; but in many situations and circumstances of land, it will be found highly beneficial to the cultivator, from its ameliorating and cleaning properties.

The species and varieties of pease are very numerous; but those employed in field culture are distinguished into two kinds, the early and late; the chief of the former of which are the *early charlton*, the *golden hotspur*, and the *common white forts*; and of the latter the various kinds of grey pease, as the *marleborough grey*, the *horn grey*, and the *purple grey*; but the marleborough is the most commonly made use of by most farmers.

Soil.—Pease are a crop that are grown upon almost any sort of soil, but which answer best on those that are dry, and free from stagnant moisture, and which are in a good state of mellowness, and impregnated with calcareous materials. But “all the sorts of early pease should, according to Mr. Young, be cultivated on dry soils only. They will grow on moist, and even wet ones; but the crop is seldom beneficial. Upon sands, dry sandy loams, gravels, and chalks, they succeed well. They are not, however, to be much recommended on land in tith. Great success is rarely commanded, especially in a wet season, if they be not on a layer.”

It is a sort of crop cultivated after many different kinds, as almost all those of the grain description, as well as clover, sainfoin, and on old lays newly broken up from sward. But Mr. A. Young has well remarked, that “a farmer desirous of keeping his land always in good and clean order, should, in the arrangement of his crops, take great care not to be too free with wheat, barley, and oats, which are all exhausting plants. He should sow beans and pease enough, because they are ameliorating ones, and admit hand-hoeing, to kill the weeds. In those fields in which the common husbandmen sow oats or barley, after wheat, or after each other, let the good cultivator substitute pease or beans, or some other ameliorating crop, which will pay him better than white corn, under such circumstances, and at the same time keep his land clean. Pease may be sown, like black oats, on turf ploughed up before winter, and harrowed in.” He further remarks, “on the culture of pease, that bad farmers are too apt to sow this pulse when the land will yield nothing else. They have a proverb among them, which signifies, that the season does as much for pease as good husbandry; and they from thence take care that good crops shall be owing to season alone. Hence arises the general idea of pease being the most uncertain crop of all others. This is owing to their being scarcely ever sown on land that is in good order. Let the good husbandman lay it down as a maxim, that he should sow no crop on land that is not in good order; not merely in respect of fine tith at the time of sowing, but also of the soil’s being in good heart, and clear of weeds. He would not, however, here be understood to rank all these crops together, because beans and pease will admit of cleaning while they grow. On that account, if a farmer comes to a field which his predecessor has filled with weeds, a horse-hoed crop of beans will be expedient, when a barley crop would be utterly improper, and, after land has yielded one crop of barley, certainly another should not be sown, but one of pulse substituted. If these ideas are well executed, the pease and beans, in every course, will find the land in heart enough for barley, the soil will always be clean, and the crop good. Pease, when managed in a spirited manner, will not have the reputation of being so very uncertain a crop,

which character has, in some measure, been owing to ill conduct.”

And the same writer thinks, that the following courses do well for them:

- | | |
|-----------------------|---|
| “ 1. Turnips, | Also, 1. Turnips, |
| 2. Barley, | 2. Barley, |
| 3. Clover, | 3. Seeds for two, three, or more years, |
| 4. Pease and turnips, | 4. Pease and turnips, |
| 5. Barley, | 5. Barley, |
| 6. Carrots, | 6. Beans, |
| 7. Barley, | 7. Wheat.” |
| 8. Clover, | |
| 9. Wheat. | |

It is stated, that “there is a remarkable circumstance observed by that excellent husbandman, Mr. Overman of Norfolk, relative to pease, which should be in the mind of every farmer fond of a pea crop. It is, that they do not succeed well, if sown oftener than once in ten or eleven years; and he has heard it more generally observed by others, that pease should not be sown so often.”

In regard to manuring for this crop, it is observed, that “it is the practice with some farmers to manure for them. But he must confess that he has been always so much against it, that he never did it himself, and therefore can only state his reasons for avoiding it. If land is in heart, and they are put in on a layer, they do not want manure. A very good crop may be gained without it. He has had five, and even five and a half quarters an acre, without any manure applied for this crop. Dung makes them run to long straw, and that is not favourable for podding productively. Dung encourages weeds; and pease, except in the early stage of their growth, do not admit of such hoeing as a farmer would wish to give. Beans cannot have too much dung, but with pease the case is different. There are few situations in which the farmer can have such a command of manure to give him a sufficiency. It is, therefore, of much consequence to him, never to spread a load but where it will be sure to answer best. Every man complains of a want of dung; how very careful, therefore, ought all to be, to give it to the crops that will pay best for the expence.” But notwithstanding these useful remarks, manure may in many cases be employed with advantage for crops of this kind, and in some they cannot probably be grown without it to advantage.

Time of Sowing, and Quantity of Seed.—The time of putting this sort of crops into the ground differs considerably, according to the intentions of the cultivator. When they are grown for podding early for sale green, they should be sown at different times, from January to the end of March, beginning with the driest and most reduced sorts of land. And in this intention, in some southern counties, they are put in in the autumn. But for the general crops, from February to April, as soon as the lands can be brought into proper order, is the proper season; the grey forts being employed in the early sowings, and the white forts in the later. Mr. Young says, that where the crops cannot be put in in February, they should always be completed in the following month. And that, in sowing on layers, that “the white boiling pea, of many sorts, and under various names, is more tender than the greys, and various kinds of hog pease; but he has many times put them into the ground in February, and though very smart frosts followed, they received no injury. He has uniformly found, that the earlier they were sown the better. There is also a particular motive for being as early as possible; that is, to get them

on in June for turnips. This is most profitable husbandry, and should never be neglected. If they are sown in this month, and a right sort chosen, they will be off the land in June, so that turnips may follow at the common time of sowing that crop."

It is evident that the quantity of seed must be different in different cases and circumstances, and according to the time and manner in which the crop is put into the ground; but in general, it may be from two and a half to three bushels, the early sowings having the largest proportion of seed. In planting every flag, Mr. Young says, two bushels and a half is the usual proportion; but when drilled at greater distances, six or seven pecks will answer in most cases.

Methods of Sowing.—There are different practices pursued in putting this sort of crop into the soil: Mr. Young remarks, that in common management they are sometimes ploughed, and at others harrowed in, circumstances which often make a difference in the crops, as where the land is apt to bind with rain, and the pease are ploughed in, they sometimes do not come up at all, not having strength to pierce the plastered surface. But this is an evil that attends only the very binding soils with late sowing. On the other hand, when the seed is only harrowed in, where the land is not very well guarded, much devastation will be committed by the pigeons, and other birds, for which allowances should be made. It is supposed, that where the lands harrow well, all should be harrowed in, except on the lightest lands. But on these, such as loose sands, and other very porous and dry soils, it is a preferable practice to plough them in, as they have a greater depth, and are of course less liable to burn in hot summers.

It has been remarked, that it is usual, in these cases, in many districts, to put the seed into the ground in the broad-cast method; but the drill, or row system, is mostly to be preferred, as being more regular, saving considerably in the proportion of seed, and admitting of cultivation afterwards with more ease and advantage. And that different implements have been contrived for this use, but the most convenient is probably a small light sort of wheel-plough, to the body of which a sort of seed-box is attached, through the bottom of which the axis of a light wheel passes, by which the sowing is regulated, and which is pulled up and prevented from letting the pease be deposited at the ends of the ridges, or other places, as in turning, by a string attached to the handle. It may be conveniently employed with one or two horses. In regard to the rows, it is observed, that the proper distance of drilling this kind of crop is mostly about twelve or sixteen inches for hand-hoeing; but where the horse-hoe is employed, from two to three feet; and the depth to which the seed is deposited from two to three inches. And that, in some districts, the seed is put by the hand into drills mostly made crossways of the ridges, but occasionally in the direction of them at the distance of about fifteen inches from each other, and afterwards covered in by means of hoes. In some instances, also, a bush-harrow is drawn over the surface, by which the land is rendered smooth and even. But where this sort of crop is cultivated on a lay preparation, the best method is probably to dibble the seed in. This is the practice constantly followed by the best cultivators in some districts in Middlesex. Mr. Young, however, advises, that broad-cast pease should be utterly rejected in every case. The only question that can arise in their culture, is between drilling and dibbling. If the former is determined on, the land should have been ploughed late in autumn, with Duckett's skin coulter, into lands adapted to the drill-machine and scarifiers. The surface

being then worked shallow, in this month drilling should directly follow. If dibbling is determined on, the land should not be ploughed till the time of planting, and a heavy roller follow the plough. On lighter soils, if the frost has worked the surface, after ploughing, the ground will be in too friable a state, the holes will moulder in, and the seed will be laid too shallow. Dibbling pease on a layer cannot be too much commended. It is an excellent practice in most cases.

But in respect to the rows, the practice of various farmers differs exceedingly. Equi-distant rows, from nine to eighteen inches, are common. He has seen them at two feet, and even three. In dibbling, it is common in Norfolk and Suffolk to put in three rows, on every flag of nine or ten inches breadth; some farmers one row on such a furrow: and he has known very good crops in most of these distances. If horse-hoeing is intended, double rows at nine inches, with intervals of eighteen, do well: but the greatest crops have been from planting every flag.

It has been suggested, that, though the practice of steeping this sort of seed is seldom had recourse to by the cultivators of pease, it is probable that the later sown crops may be greatly benefited by it, as the vegetation of the plants may be rendered more quick, regular, and uniform. And in the *Maifons Rustiques*, the same practice is approved of, not only to separate the bad and faulty, but to enable the crop to rise sooner.

It is the custom in Hertfordshire, and some other districts, to sow beans, or even oats, sometimes with the pease, with a view of keeping them up. These mixtures should, however, never be adopted, as the different crops, from their being of an unequal growth, must constantly be liable to injure each other while they are growing on the land.

Culture while Growing.—There can be no doubt but that the use of the hoe in stirring the intervals, and earthing up the young plants where the crop has been put in in rows by the drill or dibble, is of essential advantage in promoting their growth, and protecting them from the injuries of the season. Where the method of hand-culture prevails, it is the general custom to have recourse to two hoeings; the first, when the plants are about two or three inches in height, and again just before the period in which they come into blossom. In this way the vigorous vegetation of the young crop is secured, and a fresh supply of nourishment afforded for the setting of the pods and the filling of the pease. At the last of these operations, the rows should be laid down, and the earth well placed up to them, the weeds being previously extirpated by hand-labour. In some parts of Kent, where this sort of crop is much grown, it is the practice, when the distance of the rows is sufficiently great, to prevent the vegetation of weeds, and forward the growth of the pea crops, by occasionally hedge-hoeing, and the use of the break-arrow, the mould being laid up to the roots of the plants at the last operation, by fixing a piece of wood to the arrow. This should, however, only be laid up on one side, the pease being always placed up to that which is the most fully exposed to the effects of the sun. The hedge-hoeing is performed at the rate of from two to three shillings the acre, according to the nature of the land. These sorts of crops can never be kept too clean, therefore the greatest attention should be paid to them.

It has been stated that there are many inducements to the cultivation of this crop, on suitable soils in the vicinity of large towns, where the demand for green pease is considerable; such as the ready supply of money, that is thus provided for the other expensive operations during the summer

mer months, the facility of thus rendering the land proper for the growth of turnips, and the large supply of fodder that is afforded by the stems of the plants when properly secured; notwithstanding the danger of such crops during the winter, and even in the spring months, when the season proves unfavourable, and the heavy expences incurred in the gathering and disposal of them. And that it is frequently a practice with the large cultivators of early green pea crops, in the neighbourhood of London, to dispose of them by the acre to inferior persons, who procure the podders; but the smaller farmers for the most part provide this description of people themselves, who generally apply at the proper season for the purpose. The business of picking or podding the pease is usually performed by the labourers at a fixed price for the sack, of four heaped bushels. The number of this sort of persons is generally in the proportion of about four to the acre, the labour proceeding on the Sundays as well as other days. It is sometimes the custom to pick the crops over twice, after which the rest are suffered to stand till they become ripe for the purpose of feed. This, however, mostly arises from the want of pickers, as it is considered as a loss, from the pease being less profitable in their ripe state than when green. Besides, they are often improper for the purpose of feed, as being the worst part of the crop. It is therefore better to have them clear picked, when the hands can be procured. After this they are loaded into carts, and sent off at suitable times, according to the distance of the situation, so as to be delivered to the salesmen in the different markets from about three to five o'clock in the morning. In many cases in other parts the early gatherings are, however, sent to the markets in half-bushel sieves, and are frequently disposed of at the high price of five shillings the sieve; but at the after periods they are usually conveyed in sacks of a narrow form, made for the purpose, which contain about three bushels each, which, in the more early parts of the season, often fetch twelve or fourteen shillings the sack, but afterwards mostly decline considerably, in some seasons so much as scarcely to repay the expences. This sort of crop affords the most profit in such pea seasons as are inclined to be cool, as under such circumstances the pease are most retarded in their maturation or ripening, and of course the markets are kept from being over abundantly supplied. With respect to the expence attending the gathering of green pease, it is different according to the difficulty of procuring podders, the bulk or abundance of the crops, and the kind of pea, or size of the pods. Those of the larger sorts, such as the marrowfats, being in the county of Middlesex about one shilling, and those of the smaller kinds, as the charlton, from fifteen to eighteen pence the sack. In Kent, the usual price is about fourteen-pence the sack for podding, one shilling for conveying them to the market, and three-pence the sack for the salesman. It is obviously only in the vicinities of large towns, that the system of green pea management can be carried on with the prospect of much profit; in other cases it will be better to take regular field crops in the usual way. These prices stand much higher at present.

It is further stated, that the quantity of produce of both the early and late pea crops varies much according to the nature of the season, and many other circumstances. The average of the early crops in Middlesex is supposed to be from about twenty-five to thirty sacks the acre. The author of the Synopsis of Husbandry, however, states the produce about Dartford, in the county of Kent, at about forty sacks the acre, though fifty have sometimes been gathered from that space of land.

In the county of Middlesex, Mr. Middleton has stated the expences and produce in cultivating a field of six acres in the year 1796 to stand as below, though it was not remarkable for more than a common crop.

The advantage in this case ten pounds.

And in the latter crops, that stand to ripen, it is supposed by some to be from three and a half to four quarters the acre; others, however, as Mr. Donaldson, imagine the average of any two crops together not more than about twelve bushels. And that on the whole, if the value of the produce be merely attended to, it may be considered as a less profitable crop than most others. But as a means of ameliorating and improving the soil, at the same time, it is however to be esteemed as of great value.

The greatest danger to the early pea crops is to be apprehended, when the weather during the more early spring months is hot and sunny in the day-time, attended with sharp frosts in the night, as in this way great mischief is often done; the crops becoming attacked with the mildew, and not ripening in a proper manner. And, while the pease are proceeding in their growth, and still more particularly at the periods when they come into blossom and begin to set their pods, it is of great importance to have rather moist weather, as by that means the vegetation of the crop is promoted in a more perfect manner, and there is a greater chance of the peas being well podded. The chief signs of the healthy and vigorous vegetation of pea crops are those of their leaves possessing a fine bloom of a bluish cast, and having the outermost large leaves of the blossom extending backwards in some degree.

As the pea crops become ripe, they wither and turn brown in the haulm or straw, and the pods begin to open. In this state they should be cut as soon as possible, in order that there may be the least loss sustained by their shedding. In the late or general crops, after they are reaped, or rather cut up by means of a hook, it is the usual practice to put them up into small heaps, termed wads, which are formed by setting small parcels against each other, in order that they may be more perfectly dried both in the seed and stem, and be kept from being injured by the moisture of the ground. But in the early crops the haulm is hooked up into loose open heaps, which, as soon as they are perfectly dry, are removed from the ground and put into stacks for the purpose of being converted to the food of animals, on which

which they are said to thrive nearly as well as on hay. When intended for horses, the best method would seem to be that of having them cut into chaff and mixed with their other food. Mr. Young asserts, that forward white peas will be fit to cut early in July; if the crop is very great, they must be hooked; but if small, or only middling, mowing will be sufficient. The stalks and leaves of peas being very succulent, they should be taken good care of in wet weather: the tufts, called wads or heaps, should be turned, or they will sell but indifferently, as the brightness and plumpness of the grain are considered at market more than with hog-peas. The straw also, if well harrowed, is very good fodder for all sorts of cattle and for sheep; but if it receives much wet, or if the heaps are not turned, it can be used only to litter the farm-yard with.

It is the practice in some districts to remove the haulm, as soon as it has been cut up by hooks, constructed with sharp edges for the purpose, to every fifth ridge, or even into an adjoining grass field, in order that it may be the better cured for use as cattle food, and at the same time allow of the land being immediately prepared for the succeeding crop. What are usually termed winter peas, or such crops as have been sown in the autumn, generally afford the largest proportion of cattle fodder, when properly managed in the securing of it.

Mr. Bannister states, that if wet weather happens whilst the peas lie in wads, it occasions a considerable loss, many of them being shed in the field, and of those that remain, a great part will be so considerably injured, as to render the sample of little value. This inability in peas to resist a wet harvest, together with the great uncertainty throughout their growth, and the frequent inadequate return in proportion to the length of haulm, has discouraged many farmers from sowing so large a season of this pulse as of other grain; though on light lands which are in tolerable heart, the profit, in a good year, is far from inconsiderable.

It is thought by some of considerable importance in the economy of a farm, when the nature of the soil is suitable, to have recourse to the early sorts; as by such means, the crops may in many cases be cut and secured, while there is leisure, before the commencement of the wheat harvest. And, that where the nature of the soil is dry and warm, and the pea crop of a sufficiently forward kind, it may be easy to obtain a crop of turnips from the same land in the same year, as has been suggested above. But in this view it is the best practice to put the crops in in the row method, and keep them perfectly clean by means of attentive hand and horse-hoeing; as in that way the land will be in such a state of preparation for the turnips, as only to require a slight ploughing, which may be done as fast as the pea crop is removed, and the turnip seed harrowed in as quickly as possible upon the newly turned up earth. In some particular districts a third crop is even put into the same land, the turnips being sold off in the autumn and replaced by collards, for the purpose of greens in the following spring. This, according to Mr. Middleton, is the practice in some places in Middlesex. But it is obviously a method of cultivation that can only be attempted on the warm and fertile kinds of turnip soil, and where the pea crops are early; on the cold heavy and wet descriptions of land, it is obviously impracticable, and wholly improper.

It is stated by a practical writer, that with the marrowfat and other late sorts of peas, the usual practice is either to prepare the land for wheat, or to put in crops of favours or other late sorts of cabbages, which are the methods of husbandry that may often be had recourse to, even on the more heavy sorts of land, with success. And that from pea

crops rendering the lands, on which they are cultivated, more light, open, and porous, they are supposed to be less proper for preceding wheat, than those of beans; on the more stiff sorts of ground, this cannot, however, be an objection of any great consequence, and even on the lighter kinds it may often be obviated, by giving the seed earth early, so that the crop may be put in upon a stale furrow, by the use of the sheep-fold, either immediately before or after the grain is deposited in the soil, and by repeating the same practice occasionally afterwards, as well as by rolling.

Application of Crops.—It is stated, that the portion of peas, that is not consumed as human food, is mostly appropriated to the purposes of fattening hogs and other sorts of domestic animals; and, in particular instances, supplies the place of beans as the provender of labouring horses; but that care should be taken, when used in this way, that they be sufficiently dry, as, when given in their green state, they are said to be apt to produce the gripes and other bowel complaints in these animals. And Mr. Bannister, after observing that the straw is a very wholesome food for cattle of every kind, suggests, that there is generally a considerable demand for peas of every denomination in the market, the uses to which they may be applied being so many and so various. The boilers, or yellow peas, always go off briskly; and the hog peas usually sell for sixpence or a shilling per quarter more than beans. For feeding swine the pea is much better adapted than the bean, it having been demonstrated by experience, that hogs fat more kindly when fed with this grain than on beans; and, what is not easy to be accounted for, the flesh of swine, which have been fed on peas, it is said, will swell in boiling, and be well tasted; whilst the flesh of the bean-fed hog will shrink in the pot, the fat will boil out, and the meat be less delicate in flavour. It has, therefore, now become a practice with those farmers who are curious in their pork, to feed their hogs on peas and barley-meal, and if they have no peas of their own growth, they rather choose to be at the expence of buying them, than suffer their hogs to eat beans. Nay, so far do some of them carry their prejudice in this particular, as to reject the grey peas for this use, as bearing too great an affinity to the bean, and therefore reserve their growths of white peas solely for hog-fattening.

Peas, if the ground is kindly for their growth, and the summer moist, generally produce a great abundance of haulm, which takes up a large space in the barn, and for this reason the mow ought always to be trodden with hogs or horses, or in some better way, which will close down the haulm into one-sixth part of the compass it would otherwise have occupied. In Leicestershire they set all their peas abroad in stacks, being persuaded that they thence acquire a much better colour than when housed in the barn.

Malted peas have been found to answer well in the fattening of hogs and turkeys, as well as in the feeding of horses in some cases.

Sowing of Seed-peas.—In the sowing of any particular sorts of peas for feed, they should be carefully looked over while in flower, in order to draw out all such plants as are not of the right sort; as there will always be, in every sort, some roughish plants, which, if left to mix, will degenerate the kind. As many rows as may be thought sufficient to furnish the desired quantity of seed should then be marked out, and left till their pods turn brown, and begin to split, when they should immediately be gathered up with the haulm; and if the farmer has not room to stack them till winter, they may be threshed out, as soon as they are dry,
and

and put up in sacks for use: but particular care should be taken not to let them remain too long abroad, after they are ripe; as wet would rot them; and heat, after a shower of rain, make their pods burst in such a manner that the greater part of their seeds would be lost.

PEA, *Chich*. See CICERO.

The chich pea is much cultivated in Spain, being an ingredient in their dyes, and is there called *garavance*. It is cultivated in France also, but in England it is rarely sown; and unless the season proves warm and dry, the plants decay before the seeds ripen. Miller.

The ancient Hebrews made use of chich peas as their common provisions, when they took the field. They parched them to eat. At this day in Egypt, when people undertake a journey, they lay in a good stock of chich peas, parched in a frying-pan. Bellonius assures us, that at Grand Cairo, and Damascus, there are abundance of shops, where people do nothing else but fry peas, it being a sort of provisions with which they furnish travellers. In Ethiopia they take barley with them, roasted in the same manner. In Turkey they lay in a stock of rice on these occasions, which they prepare and shell. The Hebrew term *שן*, signifies properly any thing roasted in general, and by it is understood roasted peas, rice, or barley; some will have even coffee to be meant by it. Bellon. lib. ii. cap. 53. Calm. Dict. Bibl.

PEA, *Everlasting*, or earth-nut pea, names sometimes given to the lathyrus. See LATHYRUS.

PEA, *Everlasting*, in *Agriculture*, a plant of the vetch kind, that may be sometimes cultivated. This is probably another plant of the pea kind that may be cultivated with great advantage as green food for animals.

Mr. Weston has observed, that tares and vetches are plants of which horses are very fond, and are cultivated with great advantage for that purpose. The everlasting peas belong to the same class of plants; are much more luxuriant in their growth, and yet are not cultivated, except for ornament. These plants are well known, and may be found in the gardens of almost every village in the kingdom. The luxuriance of their growth is so great, that the narrow-leaved, lathyrus sylvetris, grows to the height of five or six feet, the other, lathyrus latifolius, to eight, ten, or more. They begin to vegetate early in the spring, and continue growing until severe frosts stop them. Another peculiar advantage belonging to them is, that they are perennial-rooted plants, and when once sown, improve in their vigour and growth after the first year, and continue increasing for several successive ones, as may readily be proved by examining the gardens in which they are to be found, where seed may be had, and tried at first upon a small scale, with very little trouble and expence, and afterwards increased. A rood of land, light, and but poor in quality, was sowed with it early in the spring; the land prepared as for barley. A slight furrow was drawn with a light plough, and the seed thinly dropped into it. Another was drawn at a foot distance, and the seed dropped in like manner. An interval was then left at least two feet wide; then two more rows, till the whole was sown. The seed was afterwards covered by drawing a light harrow, with wooden tines, backwards and forwards across the land. When the plants came up and grew a little strong, they were thinned with a hoe to a foot distance, that they might have room to spread and branch. The first year they made no great quantity of fodder, but have since made ample amends.

The second spring they came up very strong and vigorous, branching out very much. A couple of horses were turned into feed, who were very fond of them, eating them very

greedily, though they were taken out of a good natural upland pasture. The third year the land was almost entirely covered, and it yielded a great deal of food. For experiment a few rods were mowed just before it flowered, which made good hay, sweet without being sticky.

It is noticed, that this experiment is not described longer than the three first years. Instead of destroying the plants by hoeing them where too thick, he would recommend them to be drawn out, and a fresh plantation made with them. In gardens, they are generally transplanted from the seed beds the second spring. And instead of turning horses into feed, he would prefer cutting them either with a scythe or sickle, and have them given to the horses. It would certainly by that method produce more fodder, and you could find how many times in the summer they would bear cutting, and at what height it is the most advantageous to cut them. If the intervals be left three feet wide, instead of two, there would be room to plant in September and October a winter crop, when the peas cease growing, as borecole, cabbage plants, &c. which would occupy the ground till March, at which time they begin to vegetate.

Others have found much advantage from this plant in the fattening of cattle in some of the western counties.

PEACE, PAX, in its general signification, stands in opposition to *war*. The right of making war and peace is one of the prerogatives of the king. In order to make a war completely effectual, it is necessary with us in England, that it be publicly declared, and duly proclaimed by the king's authority; and then all parts of both the contending nations, from the highest to the lowest, are bound by it. And wherever the right resides of beginning a national war, there also must reside the right of ending it, or the power of making peace. And the same check of parliamentary impeachment, for improper or inglorious conduct, in beginning, conducting, or concluding a national war, is in general sufficient to restrain the ministers of the crown from a wanton or injurious exertion of this great prerogative.

PEACE, in our *Law Books*, &c. is restrained to a quiet and inoffensive carriage towards the king, and his people. Lamb. Eirenarch.

Offences against the public peace are either such as are an actual breach of the peace; or constructively so, by tending to make others break it. Both of these species are either felonious, or not felonious. The felonious breaches of the peace, are strained up to that degree of malignity by virtue of several modern statutes; and, particularly, the "riotous assembling" of 12 persons or more, and not dispersing upon proclamation; "unlawful hunting" in any legal forest, park, or warren, not being the king's property, by night, or with painted faces, 1 Hen. VII. c. 7, or appearing with the face blacked, or with other disguise, and being armed with offensive weapons, to the breach of the public peace, and the

terror

terror of his majesty's subjects, 9 Geo. I. c. 22:—sending any letter without a name, or with a fictitious name, *demanding* money, &c. or *threatening* to kill any of his majesty's subjects, or to fire their houses, &c., 9 Geo. I. c. 22. 27 Geo. II. c. 15:—destroying any *lock*, *sluice*, or *floodgate*, &c. *turnpike-gate*, &c. The above-mentioned offences are felonies. Those that remain to be enumerated are merely misdemeanors; *viz. affrays*, *riots*, *routs*, and *unlawful assemblies*, consisting of at least three persons; *tumultuous petitioning*; *forcible entry or detainer*; *riding or going armed*, with dangerous or unusual weapons; *spreading false news*; *false and pretended prophecies*. Besides actual breaches of the peace, any thing that tends to provoke or excite others to break it, is an offence of the same denomination; such are *challenges to fight*, either by word or letter, or *bearing such challenge*; and *libels*. See each article.

The English laws have provided various means for preventing offences against the public peace. Where any man stands in danger of harm from another, and makes oath thereof before a justice of the peace, he must be secured by good bond, which is called *binding to the peace*. Any justice of the peace may, *ex officio*, bind all those to keep the peace, who, in his presence, make any affray; or threaten to kill or beat another; or contend together with hot and angry words; or go about with unusual weapons or attendance, to the terror of the people; and all such as he knows to be common barretors; and such as are brought before him by the constable for a breach of the peace in his presence, and all such persons, as, having been before bound to the peace, have broken it and forfeited their recognizances. (1 Hawk. P.C. 136.) Also, wherever any private man hath just cause to fear that another will burn his house, or do him a corporal injury, by killing, imprisoning, or beating him; or that he will procure others so to do; he may demand surety of the peace against such person; and every justice of the peace is bound to grant it, if he who demands it will make oath, that he is actually under fear of death or bodily harm; and will shew that he has just cause to be so, by reason of the other's menaces, attempts, or having lain in wait for him; and will also farther swear that he does not require such surety out of malice or mere vexation. (Ibid. 127.) This is called *swearing the peace* against another; and if the party does not find such sureties, as the justice in his discretion shall require, he may immediately be committed till he does. (Ibid. 128.) A recognizance for keeping the peace, when given, may be forfeited by any actual violence, or even an assault, or menace, to the person of him who demanded it, if it be a special recognizance; or, if the recognizance be general, by any unlawful action whatsoever, that either is or tends to a breach of the peace. Blackst. Com. b. iv. See *GOOD-BEARING*.

PEACE, Time of, is when the courts of justice are open, and the judges and ministers of the same may by law protect men from wrong and violence, and distribute justice to all. See *Coke on Litt.*

PEACE of the King, pax regis, mentioned in the stat. 6 Ric. II. &c. is that security which the king promises his subjects, and others taken into his protection, both for life and goods.

PEACE of God and the Church, pax Dei & ecclesie, mentioned in our *Ancient Law Books*, is that rest and cessation which the king's subjects had from trouble and suit of law, between the terms.

PEACE of the Plough, that whereby the plough, plough-tackle, and plough-cattle, are secured from distresses.

Thus fairs may be said to have their peace, because no
XXVI.

man may be troubled in them for any debt contracted elsewhere.

PEACE, Clerk of the. See *CLERK of the Peace*.

PEACE, Commission and Justice of. See *JUSTICES of Peace*.

PEACE, Conservator of the. See *CONSERVATOR*.

PEACE, Homage of the. See *HOMAGE*.

PEACE, in *Mythology*, a goddess among the Romans, to whom they erected a variety of magnificent temples. The temple, which was begun by Claudius, and finished by Vespasian, was not inferior to any in Rome. If we may believe Suetonius, Josephus, and St. Jerom, the emperor deposited there the precious and rich spoil of the temple of Jerusalem. In this temple those who professed the fine arts assembled, in order to dispute about their prerogatives, that in the presence of the goddess of peace, all heats might be banished from their debates. This goddess had also in the same city an altar, which was very much frequented. Monuments represent to us peace under the figure of a woman crowned with laurel, olive, or chaplets of roses, holding in one hand the caduceus, and in the other ears of corn, the symbol of plenty, which she procures. Aristophanes gives her Venus and the Graces for her companions. See *CONCORD* and *TRANQUILLITY*.

PEACE, in *Geography*, an island on the coast of Nova Scotia, S. of Mirachi point.

PEACE River, a large river of North America, which runs north-easterly into the Lake of the Hills. In the driest season, it is a quarter of a mile wide. The lands on this river are inhabited by the Beaver and Rocky Mountain Indians, who are an uninformed and barbarous race of beings. Polygamy is practised among them, and the women are in the lowest state of debasement. At their funerals, among other extravagant tokens of sorrow, the women, if the deceased be a favourite son or husband, cut off a finger at the first joint. Some of the old women have not a whole finger left. The men think it below their dignity to shew any mark of grief. These persons are great gamesters, and pursue this as their employment for several days and nights. Their habitations are formed by setting up a number of poles, united at the top, and expanded at the bottom in a circle of 12 or 15 feet diameter. These are covered with dressed skins sewed together. This business, and other drudgeries, are performed by the women, while the men sit smoking at their ease.

PEACEE, a town of Hindoostan, in Oude; 40 miles S. of Goorackpour.

PEACH-TREE, in *Botany and Gardening*. See *AMYGDALUS*.

PEACH-Tree, in the *Materia Medica*. The fruit of the peach is known to be grateful and wholesome, seldom disagreeing with the stomach, unless this organ is not in a healthy state, or the fruit has been eaten to excess. The flowers, including the calyx as well as the corolla, are the parts of the perica used for medicinal purposes. These have an agreeable but weak smell, and a bitterish taste. They are used as a purge for children made into a syrup, and are by some recommended as great destroyers of worms; but there is a circumstance attending them which is little taken notice of, and yet greatly alters their virtue. The custom of gardeners is, to graft the peach upon the almond or the plum-tree, and the flowers partake of the nature of the stock; those which are produced on peach-trees grafted on plum-stocks being much more purgative than those from almonds; the reason of which seems plainly, that the plum is a purgative fruit, the almond not at all so. The flowers of the least esteemed sorts of peaches are also usually found to be the best for medicinal use.

In examining these flowers, they are found to contain more than three-fourths of a superfluous humidity. The buds contain a little less than the blown flowers; which is very natural to be supposed, because it is their being afterwards charged with a larger portion of humidity which makes them open. The buttons, or buds of the flowers, are found on experiment, however, to be somewhat more purgative than the flowers when open.

If four pounds of these flowers are distilled in a balneum Mariæ, they yield twelve or thirteen ounces of a whitish liquor, sweet to the taste, and of an agreeable smell, resembling that of bruised peach kernels; and this is so strong in the water, that a few drops of it will very agreeably scent a larger quantity of any thing. If the buds are used to this purpose, instead of the open flowers, the same sort of liquor is drawn over; but it is of a somewhat coarser and more earthy smell. The residuum of these distillations put into a retort, and distilled by a reverberatory fire, gradually raised to its several degrees, yields both acid and alkaline substances; and, finally, a red spirit comes over, full of fuliginous particles, and containing some oil, part of which swims at the top of the liquor, and the other part, which is heavier, sinks to the bottom. This is what a chemical analysis shews in these flowers, different from other vegetable matters. Spirits of wine draw a very weak tincture from these flowers; it is indeed much weaker than an infusion of them in common water. An infusion in water of half an ounce of fresh peach-flowers, or of a dram of dry ones, (for, as before observed, they contain three-fourths of superfluous moisture) is a very gentle and agreeable purge, and it is said, when sweetened with sugar, to prove an useful purgative and anthelmintic for children.

This method of infusion is much better for these and all other purgative flowers, than the taking of the expressed juice; for in that case there is always a large quantity of purgative matter remaining in the residuum; which water in a warm infusion is able to take out. The infusion of rose or peach-flowers keeps also better than their expressed juice.

The juice always turns sour very soon; but the infusion, with the common caution of pouring a little oil on the surface, will keep good even for years.

When oil is used for this purpose, there should always be care taken that it be such as does not freeze easily; for in that case, the air gets in between the cake of frozen oil and the sides of the vessel, and spoils the liquor. Oil of almonds is greatly to be preferred to oil of olives on these occasions; as it freezes with much more difficulty. Another way of preserving the infusions is, the evaporating about half the liquor; and thus they will often keep a long time: as infusions keep better than the juices of plants, this seems to shew, that the former contain more of the principles than the latter.

The young leaves of the peach, made into an infusion in the same manner as the flowers, are more purgative than they, but less agreeable: they are to be taken in the same manner. Mem. Acad. Par. 1714.

These leaves are found to possess an anthelmintic power, and, from a great number of experiments, appear to have been given with invariable success to children and adults. However, as the leaves and flowers of the persea manifest in some degree the quality of those of the lauro-cerasus, they ought to be used with caution.

PEACH-Colour, the pale red colour of the blossoms of the peach-tree.

To give this beautiful colour to glass, add at different times, and in small quantities, the powder of prepared manganese to the mass for the making of lattimo, or milk-white

glass, while in fusion. This alone gives the peach-colour; but the metal must be immediately worked when of a right tinge, for the colour is very apt to go off.

PEACH-Colour, in the *Manège*. See BLOSSOM.

PEACH Gall-Insect, in *Natural History*, a small gall-insect, found in great plenty on the peach-tree. It is of an oblong figure, flat at the belly, and prominent on the back; pointed, and not unaptly resembling in miniature a small boat turned bottom upwards: their longer diameter is usually extended in the same direction with the length of the branch; sometimes a little obliquely, but scarcely ever perpendicular to that direction.

Their colour is usually a faint brown, sometimes it approaches to a coffee-colour, sometimes to a bright chestnut, but more frequently it has something reddish in it. This insect lives but a little while after it has laid its eggs, and its dried body makes an excellent covering and defence for them; and what is very remarkable is, that as this insect is now immoveable, and cannot draw itself over its eggs, they are not thrown out behind its body, as the eggs of other animals; but as they are laid, are drawn under the belly, and evenly arranged there.

The eggs are ten or twelve days before they hatch, and when hatched, the young animals remain quiet under the cover of their mother's carcase for several days.

It is usually about the beginning of June that the young insects get at liberty from under the body of their parent; they may then be found running very nimbly all over the branches of the tree, but are not distinguishable otherwise than by examining the branches with a microscope. The branches, thus covered with these young animals, are in a few days cleared again, and the insects found in form of small scales, covering the leaves, and now large enough to be seen by the naked eye.

Not only the gall-insects of the peach, but all the other species, after a certain time, become immoveably fixed to the place where they are, and no longer able to use their legs. Their growth is very slow from the time of their hatching, through the months of July, August, September, and October: at the beginning of November they are found somewhat enlarged in breadth, but they are yet no thicker, and at this time they are all become of the same colour, which is somewhat reddish. In the beginning of March they begin to swell and be filled with the growing eggs; their backs become a little convex, and, viewed with a microscope, appear covered with little tubercles; and one may, at this time, perceive seven or eight long threads, which run from several parts of their bodies: these fasten themselves to the branch at a distance from the creature, and fix it immoveably in its place. In the beginning of April they become much more convex, and though they can no longer walk about, they yet have at this time sufficient motion to shew an animal life. At this time, by very slow motions, they change their skin; and it is after this change that they assume so exactly the figure of galls, and grow so very quickly to their full size. Seven or eight days now make such a change in them, that they are not to be known for the same animal; but it is not till the beginning of May that they arrive at their utmost size. About the 15th of May they are in a condition to lay, and as the eggs are discharged, the belly is pushed closer and closer to the back; and when all are laid, becomes the shell before described, and the young ones are hatched under it, and become full of eggs, and do the same office afterwards to their young.

In the end of April the branches of the peach and other trees, covered with these insects, will be found to be greatly frequented by a sort of small flies, beautiful enough to demand

mand attention; their head, breast, body, and legs, are all of a deep red; they have only two wings, but those very large, being nearly twice as long as their bodies: these, in the fly's common posture, are crossed on the back, and the upper almost entirely hides the under one; they are less transparent than those of the common flies, and are of a dusky white, bordered with an edge of a fine bright and beautiful red: but what chiefly distinguishes them from all other species is, that they have two long white threads which run from their hinder part, and are of twice the length of their wings; between these there is also a remarkable part, a sort of tail made like a piercer, and of a third or fourth part of the length of these threads. This is, like all other stings, thicker at its base than at its point, and is bent a little downwards. The antennæ of this fly are adorned with long bodies, hairy, and larger at their extremities than at their insertions on the antennæ. It is easy at first sight to conceive, that these are the flies that had been produced of worms fed in the bodies of the gall-insects of a former year, and that they were now searching an opportunity to deposit their eggs in the bodies of these little creatures, to be hatched into worms there, and thence to come out in flies, as they themselves before had done.

The flies examined on the branches with a glass will also be found to introduce this seeming piercer always at the same place into the body of the gall-insect, and this is that cleft in the hinder part of the body, out of which the young ones, when hatched, afterwards find their way. The flies, which lodge their eggs or young worms in the bodies of other insects, if crushed at that season, will be always found to contain such eggs or small worms; and the microscope never fails to discover them in the matter crushed out of flies even smaller than these, but in these no observation ever shews any such. See *GALL-Insect-Fly*.

Notwithstanding that the peach gall-insect is the only species in which the male fly has been observed, there is no room to doubt but that the other species all have males of the same kind.

The orange gall-insect has been observed not universally fecundated, but that there is only a part of the animals that lays eggs; probably the others are those which hatch into the male flies; and the kermes, the noblest and most valuable of all the gall-insects, is known often to produce a white winged fly, very like that of the peach gall-insect. And Brennius, who gave some time since a history of the scarlet grain of Poland, the *coccus Polonicus*, a kind of pro-gall-insect; though in the first account, he gave into the opinion of both sexes being included in each of these animals, and that each was in itself sufficient for the propagation of its species: yet afterwards, to his very great honour, added an account of his having discovered the male of this species, which he describes to be a small fly, with a red body and white wings bordered with red; a fly in all respects like the male of the peach gall-insect. Reaumur's Hist. Inf. tom. iv. p. 1, to 44.

PEACH of the Cornish Miners, in *Mineralogy*. See *CHLORITE*. N. B. Under that article, read *peach* for *pearls*.

PEACH Water. See *WATER*.

PEACH, Wolf's. See *LYCOPERSICON*.

PEACH Island, in *Geography*, an island of Upper Canada, in lake St. Clair, about seven miles higher up than Detroit, nearly opposite to the communication of the Grand Marais with that lake. It contains from 60 to 100 acres of land fit for tillage; the other parts being meadow and marsh. There is little wood in this island; nor is it improved.

PEACHAM, HENRY, in *Biography*, author of a book, entitled "The complete Gentleman," published in the reign

of James I. It treats of "nobilitie in generall; of dignitie and necessitie of learning in princes and nobilitie; the time of learning; the dutie of parents in their children's education; of a gentleman's carriage in the univeritie; of stile in speaking, writing, and reading history; of cosmography; of memorable observation in the survey of the earth; of geometry; of poetry; of musicke; of statues and medalls; of drawing and painting in cyle; of sundry blazonnes both ancient and modern; of armory or blazing armes; of exercise of body; of reputation and carriage; of travaile; of warre; of fishing."

He was certainly a man of general knowledge, good taste, and acute observation. He resided a considerable time in Italy, where he learnt music of Orazio Vecchi. He was intimate with all the great masters of the time at home; has characterized their several styles, as well as those of many on the continent. His opinions concerning their works are very accurate, and manifest great knowledge of all that was understood at the time respecting practical music. He seems to have been a travelling tutor, for which office he appears to have been particularly well qualified. But with all his accomplishments, he is said to have been reduced to poverty in his old age, and chiefly to have subsisted by writing little penny books, which are the common amusement of children.

PEACIAM, in *Geography*, a post-town of America, in Caledonia county, Vermont, west of Barnet, on Connecticut river; containing 873 inhabitants.

PEACOCK, in *Astronomy*. See *PAVO*.

PEACOCK, REGINALD, in *Biography*, a worthy prelate, was successively bishop of St. Asaph and Chichester, by favour of Humphrey, the good duke of Gloucester; but he was deposed for resisting the papal authority, and denying the doctrine of transubstantiation, with other articles of the Roman Catholic faith. He was not equal to suffering in a righteous cause, but recanted his notions, and his books were publicly burnt. He then retired to an abbey, probably mortified and ashamed of his timidity, where he died about the year 1486.

PEACOCK, in *Ornithology*. See *PAVO*.

Peacocks were first brought from India, where they are still found, in the wild state, in vast flocks, in the islands of Ceylon and Java. From India they were removed to Greece, and being the birds sacred to Juno, were preserved about the temple of this deity at Samos: it is therefore probable, that they were brought here originally for the purposes of superstition, and afterwards cultivated for the uses of luxury. The peacock frequently accompanies the statues of Juno, and it was from her superior love to it, that she placed in its tail the eyes of Argus, after Mercury had put him to death.

Peacock's crests were anciently worn among the ornaments of the kings of England.

PEACOCK'S Tail. See *TAIL*.

PEACOCK-FISH, in *Ichthyology*, one of the larger species of the *turdus*, or *wrasse*, but of a middle nature between the long and the flat-bodied kinds; its usual standard, as to size, is about three pounds weight; and its colour on the back a mixture of blackish and a dusky blue; the blue is disposed in three or four longitudinal parallel lines, on a dusky blackish ground; about the head and gills the blue lines are more bright and numerous; its lower jaw is almost wholly blue, and its belly is of a fine saffron colour or reddish yellow; it has thick lips, and very sharp, though not very large teeth; its back-fin is, on the anterior part, of a fine deep blue, with an edge of purple, and sometimes of yellow; and the rest of the fin is red at the bottom and yellow at the top, and in

the middle is finely variegated with blue spots; the foremost nerves of the back-fin are rigid and prickly, and have soft and flexile rays accompanying them beyond the limb or edge of the fin, and of more than their own length; its gill-fins are a mixed red and yellow, and its belly-fin behind the anus of a pale flesh-colour, with a variegation of blue and yellow; the other belly-fins are of the same colour, and the tail is wholly blue. It is a most remarkably beautiful fish, and from the spots and variegations of its fins has obtained its name. See CHÆTODON and LABRUS.

PEAK, or PEEK, in *Sail-making*, the upper corner of triangular sails, and upper outer corner of fore and aft sails.

PEAK, in *Geography*, a mountain of England, giving name to a district in the county of Derby, between the Derwent and the Dove, which last river separates it from Staffordshire. It is mountainous, rocky, and barren, but abounds in mines of lead, iron, coal, and antimony: it also furnishes mill-stones and grind-stones.

PEAK *d'Etoile*. See *NEW HEBRIDES*.

PEAKS of *Ottor*, the highest part of the Blue Ridge, in the west part of Virginia, or perhaps any other in North America. From its base its height is about 4000 feet.

PEAKE BAY, a bay on the fourth coast of Jamaica. N. lat. $17^{\circ} 59'$. W. long. $76^{\circ} 38'$.

PEAN, in *Heraldry*, is when the field of a coat of arms is fable, and the powderings or.

PEANJEE, in *Geography*, a town of Pegu, on the Irrawaddy; 15 miles S. of Prone.

PEANTIDES, the name of a stone to which the ancients attributed great virtues for promoting delivery.

These stones were found in Macedonia and other places; and all the description we have of them is, that they resembled water congealed by frost. Probably the ancients meant by this name the *stalactites*, or stony icicles, which, as they hang from the roofs of caverns, greatly resemble the droppings of water from the eaves of houses congealed in frosty weather.

PEAR, in *Orcharding*, a fine rich sort of fruit, which is obtained from an orchard-tree of the same name, and from the juice of which the liquor called perry is prepared. See PEAR-Tree, below.

PEAR-Tree, in *Botany and Gardening*. See PYRUS.

PEAR-Trees, a fruit tree of the orchard kind. There are many sorts of this tree; but for the purpose of perry, the squash is in much the highest esteem. It is an early fruit, remarkable for the tenderness of its flesh. If it drops ripe from the tree, it bursts to pieces with the fall. The liquor made from this fruit is pale, sweet, yet remarkably fine, and of a strong body; a most excellent liquor, if duly manufactured from a soil which suits it. The oldfield is a favourite old pear, remarkable for the elegant flavour of its liquor. The barland pear is in great repute, as producing a perry which is esteemed singularly beneficial in nephritic complaints; as is the red pear for producing liquor of singular strength. The huffcap and the sack are other pears which have been usually grafted: and besides these, and a variety of others, great numbers of kernel fruits are found among the pear-trees in Herefordshire and other countries. See ORCHARD and PERRY.

Sorts.—Mr. Knight states, in his valuable Treatise on the Culture of the Apple and Pear, that “the experiments he has made on the pear have not been nearly so numerous as those on the apple, and have been confined to a single variety, the Teinton squash; but they have been fully sufficient to convince him, that the diseases of both chiefly arise from the debility of old age, and will be found equally incurable.

Though the pear is more properly a naturalized than an indigenous fruit in this country, it is much more hardy than the apple, and may certainly be cultivated in almost every part of England with nearly as much success as in Herefordshire. Like the apple it grows with the greatest luxuriance in strong deep soils, and in these the finest liquors are at present obtained from it; but it will flourish in every variety, where it is not incommoded with water. Its culture differs so little from that of the apple, that the same rules are in general equally applicable to both. It is most successfully propagated on stocks of its own species, but it will succeed in some degree on those of the quince, the medlar, the whitebeam, the common service, and the hawthorn; and probably on many others. When grafted on its own feeding stocks, which alone he would recommend, the operation should always be performed near the ground, on account of the reclining top-heavy growth of the young stocks. In raising stocks from the seeds of this fruit, a light, soft, loamy soil should be chosen, which is naturally of good quality, but which has not been recently manured. In this the seeds, like those of the crab-tree, should be covered about an inch deep, as soon as they are taken from the fruit.” And “much attention must be paid to them during the early part of the first summer, or great numbers will perish. They must be kept clear from weeds, and be regularly watered in dry weather; and if the mould be frequently stirred between the plants, it will be of great advantage to them: after the middle of August, they become more hardy, and little care or attention will be required from the planter.

“A sufficient number of varieties of this fruit, in a good state of growth, are in cultivation; but few of them possess any high degree of merit. The greater part are extremely productive of juice, and require to be ground soon after they fall, or are blown from the trees. The produce of some of them, when it has been nicely manufactured from well ripened fruit, often possesses great excellence; but it is often at the same time sweet and acetous; and if, owing to an unfavourable season, the fruit has not been properly ripened, and an access of fermentation cannot be prevented, the liquor becomes sour and unpalatable, and scarcely good enough to answer the meanest purposes of the farm-house.” He is “much disposed to doubt whether a single perry-pear, possessing nearly the greatest degree of excellence of which this fruit is capable, has yet been in cultivation. It appears highly probable that firmer fruits, which might be kept some time, or left under the trees to attain a more perfect and regular maturity, are likely to afford a more permanent and generous liquor. One pear, which in some degree answers this description, has been much cultivated, the longland; and though its produce, being without the fine flavour which is found in some others, is little attended to by the merchant, it has qualities which render it extremely valuable to the farmer: the fruit may be kept some time without sustaining any great degree of injury, when business of more importance occupies his attention: the liquor obtained from it is never very fine, but it is rarely below mediocrity: it possesses more body than is generally found in perry, and retains many of its good qualities in every different soil and situation. It is a fruit he should strongly recommend for culture in cold and exposed situations, for which the hardness of its blossom renders it peculiarly well calculated; but he is afraid it is advancing nearly to that period when young trees can no longer be raised with advantage to the planter.”

It is noticed, that “the pear is an extremely long-lived tree, and the same variety may in consequence be very long kept

PEAR-TREE.

kept in cultivation. At what period the Teinton Squash first sprang from the seed, probably cannot now be ascertained; but he suspects from its present diseased and worn out state, that it existed at least as early as the beginning of the sixteenth century. For another kind, the barland, which was much cultivated in the early part of the seventeenth century, still retains a large share of health and vigour, and the identical trees which supplied the inhabitants of Herefordshire in the seventeenth century with liquor, are likely to do the same good office to those of the nineteenth. He suspects, however, that this variety naturally possessed a greater degree of durability than is common to the species; and that its lofty spiral growth, by rendering it difficult to get grafts from the extremities of the bearing branches, has, in cultivation, made it still more durable. It is yet capable of being propagated; but trees nearly of the same stature with those which now abound, must not again be expected. The tree, which is said to have been the original, grew, he says, in a field called the Barlands, in the parish of Bosbury, and was blown down a few years ago."

"But though he does not think very highly of any of the perry-pears which are now cultivated, he does not know that he can point out the means of acquiring better. Those which he has employed to obtain improved kinds of apple, appear to him to be wholly improper. Every variety of that fruit, which possesses colour and richness, is capable of making fine cider, but a good perry-pear requires an assemblage of qualities, which will be rarely found in the same fruit. It must contain a large proportion of sugar, or its juice can never possess sufficient strength; and unless it be at the same time extremely astringent, the liquor produced from it will be acetous whenever it ceases to be saccharine. In the latter state it will agree with few constitutions, in the former with none. The juice of the best perry-pears is so harsh and rough, as to occasion a long continued heat and irritation in the throat, when the fruit is attempted to be eaten; yet by being simply pressed from the pulp, it becomes rich and sweet, without more roughness than is agreeable to almost every palate. This circumstance appears extraordinary, but it does not stand alone in the vegetable world." There are many cases in which similar changes take place with acrid vegetable substances. It is stated that "the defects of the apple and pear, when raised from seed, are generally of opposite kinds: in the former the fruit is usually harsh and sour, in the latter it is apt to be, when thoroughly ripe, sweet and insipid. The mode of cultivation therefore, which would improve the one by bringing it nearer to the highly cultivated state, and lessening its harshness, would not improbably be injurious to the other by producing the same effects."

It is stated that "an estimate may be formed in the apple of the merit of the fruit by the leaf and growth of the seedling tree, but in the pear these scarcely afford the slightest indication of the future produce. The leaves of those plants which will afterwards afford large rich fruits for the desert are often small and thin, and the stems will be covered with thorns; whilst others, whose leaves and growth shew every mark of a high state of cultivation, will sometimes produce fruits that are small and worthless."

It is not known that "better means can be used in obtaining new varieties of this fruit, than sowing a large quantity of seeds from healthy trees of an orchard in which the best kinds only have been planted, and afterwards selecting the plants of the most luxuriant and vigorous growth. But as no estimate can be formed of the value of their future produce, it will be prudent to retain a considerable number

till their fruits be known: few of which, he is afraid, must be expected to answer the wishes of the planter.

"He has, during the last twelve years, examined a very large number of seedling pears, and has a considerable variety growing on a farm he occupies, but he has never discovered more than one kind which he thought capable of making fine perry. The greater part of these, however, appeared to him to have sprung from the seeds of rich eatable pears, and some of them bore a very close resemblance to the fruits of old grafted trees in the neighbouring orchards. There is little reason to believe that the resemblance would have been less between the parent and the seedling fruit, had the former been eminent for the production of fine perry; and it therefore appears probable, that good new kinds may readily be obtained from the seeds of the best now cultivated. But even if few should be found capable of affording fine perry, the produce of all will be valuable to the farmer to mix with crabs, or apples which have been blown prematurely from the tree. The rapid sweetness of the juice of the pear is corrected by the acidity of these, and the liquor produced by the mixture often produces much more merit, than could have been expected from the ingredients. It will perfectly supply the place of small beer, and may be brought into the market at less than half the price, with sufficient profit to the grower."

And it is said that "the time which seedling trees will require to attain sufficient maturity to produce fruit, appears to vary much in different varieties. He has one plant which produced fruit at sixteen years old, and another which, from the concurrent testimony of many old people, who remember its first blossoms, appears to have remained unproductive through the first seventy years of its existence. It has since borne tolerably well; but its fruit is always without seeds, or internal cavity; and it appears to set with difficulty, much the greater part of the blossoms being constantly unproductive. Possibly its long continued barrenness, and the defects in its fructification, may both have arisen from some incidental imperfection in the organization of the plant. The fruit is in other respects perfect, and possesses great merit as a pear for the table."

It is stated that the directions he has given for planting the apple, are in every respect applicable to the pear; except that this tree being of more luxuriant and lofty growth, will require wider intervals. See *APPLE-TREE* and *ORCHARD*.

Planting.—In the most closely planted orchards the rows should not "be put at less than eighteen yards distance, nor the trees nearer than eight or nine to each other; and when the ground is to remain in tillage, intervals of twenty-five, or thirty yards, should be allowed between the rows. Attention must also be paid to the forms and stature of the different varieties, and as the fruit of these is rarely mixed with a view to make fine perry, trees of one kind should occupy each row." And that as "in some kinds the fruit grows only on the outside of those branches which are exposed to the sun and air; while in others it occupies every part of the tree; the former will of course require to be planted at greater distances than the latter."

Farther, "as the produce of the pear-tree, though of the same variety, and growing on the same stock, ripens extremely irregularly; the planter must therefore have a considerable number of trees of each kind he plants, or he will rarely have a sufficient quantity ready to be ground at the same time. Even when the fruit has fallen spontaneously from the trees, a fourth at least of some kinds will be found immature, or decaying, and totally unfit to make fine perry;

and

and should be (though it rarely or never is) separated from the rest." It is to this want of perfect and regular maturity in the fruit that Mr. Knight ascribes a defect, which perry is seldom found wholly free from, which is that of a crude and harsh acid which dwells on the palate, and which disgusts the best judges of vinous liquors; and to the same cause it may be owing, that perry, when genuine, does not agree with so many constitutions as cider. It is noticed that "the pear requires a certain state of maturity to afford perry in the greatest state of perfection: it should be ripe without being mellow, or decaying; when it has not obtained the proper state of ripeness, an excess of fermentation cannot be prevented, and when it has exceeded it, the liquor rarely ferments kindly, and is extremely apt to become sour; probably by having lost too great a proportion of its astringency; hence few kinds are found to improve by being kept after they have fallen from the trees."

Pruning.—"This is not often wanted in the culture of the pear-tree, which is rarely much incumbered with superfluous branches; but in some kinds, whose form of growth resembles the apple-tree, it will sometimes be found beneficial. The directions in this case are the same as those for the apple. See APPLE and ORCHARD.

Pear-trees are subject to similar diseases with those of the apple; "the blights of the trees, like those of the apple, arise either from insects or unfavourable weather, or a combination of both. The blossoms are often rendered abortive, by a small brown beetle, precisely similar to that found on the apple-tree, and probably of the same species; and a considerable quantity of its fruit is frequently destroyed by the *larvæ* of a small green four-winged fly. Each fruit which contains the latter insects becomes in a few days rounder than those in the natural state; and grows with much greater rapidity; but it falls off early in the summer, and if it be examined whilst growing, it will be found full of small grubs." But "the pear-tree suffers more frequently from cold than from insects, and therefore those varieties whose blossoms are produced rather late in the spring, and are preceded by the leaves, are generally most productive of fruit; and some kinds of the pear, as of the apple, are much more subject to injury, both from insects and unfavourable weather, than others. He has one seedling tree whose blossoms appear capable of bearing the most unfavourable weather without injury, and which has not once failed to produce a good crop in the memory of the oldest inhabitant of the village in which it stands. The fruit is rather too sweet to make good perry, unless in mixture with other kinds; but it nevertheless forms a very valuable variety for cold and exposed situations, as it ripens somewhat early in the autumnal season of the year." In the Report of the State of Agriculture in Herefordshire, it is stated that the pear, though in common producing an inferior liquor, has many advantages over the apple for general use. It is capable of succeeding in a greater variety of soil, is more productive of fruit, and less liable, especially in the perry kinds, to depredations. Besides, it has a more ornamental effect, and is of course better calculated for particular situations. The produce of each full-grown tree, will mostly be in the proportion of about twenty gallons of liquor. See APPLE-Tree.

The particular methods of preparing pears in the manufacture of perry, will be considered hereafter under the proper head. See PERRY.

PEAR, *Bachelor's*, a species of the *Solanum*; which see.

PEAR, *Garlic*. See CRATEVA.

PEAR, *Prickly*, or *Indian Fig*, *Opuntia*. This, in the Linnæan system, is a species of *Cactus*; which see.

PEARCE, ZACHARY, in *Biography*, a learned prelate of the church of England, was born at London in the year 1690. The earlier part of his education he received in a private school at Great Ealing, whence, in 1704, he was removed to Westminster school, then under the management of Dr. Busby. Here he remained six years, and greatly distinguishing himself, he was elected one of the king's scholars. In 1710 he went to Trinity college, Cambridge. He pursued his academic studies with great diligence and success, and obtained a high reputation as a classical scholar. During the first years of his residence at Cambridge, he occasionally amused himself with the lighter species of composition, some of which he sent to the *Guardian* and *Spectator*. In 1716 he published, from the university press, an edition of "*Cicero de Oratore*," with notes and emendations; which, at the desire of a friend, he dedicated to lord chief justice Parker, a circumstance which laid the foundation of his future fortunes. He was first elected a fellow of Trinity college, and waiting on lord Parker, to thank him for his interest on that occasion, his lordship presented him with a purse containing fifty guineas. In the year 1717, Mr. Pearce entered into deacon's orders; and in the following year he was ordained priest. It had always been his wish to devote himself to the clerical profession; but as he himself has told us, he delayed to do so till he had attained his twenty-seventh year, in order that he might, by a due degree of preparation, attain to so much knowledge of that sacred office, as should be sufficient to answer all the good purposes for which it was designed. In 1718, lord Parker having been appointed lord chancellor, Mr. Pearce was invited to live with him in the capacity of domestic chaplain; which invitation he gratefully accepted. In 1719 he was presented to the rectory of Stapleford-Abbots, in Essex, to which preferment the lord chancellor added, in the following year, that of St. Bartholomew, behind the Royal Exchange, in London. Soon after this, Mr. Pearce had the honour of being appointed chaplain to his majesty. In the year 1721 he married a lady possessed of a considerable fortune, by whom he had several children, all of whom died very young. About a year after his marriage, he was presented with the vicarage of St. Martin's, and in this prominent situation it was thought right he should take his doctor's degree; but as he was not of sufficient standing at the university, application was made for him to Dr. Wake, archbishop of Canterbury, who granted him that title by his diploma. In 1724 Dr. Pearce dedicated to his patron, now the earl of Macclesfield, his edition of Longinus on the Sublime, with a new Latin version and notes; which, by the masterly manner of its execution, contributed greatly to the increase of his reputation as a scholar and critic. To the ruin of the earl of Macclesfield, which happened in 1725, it was in some measure owing that several years elapsed, from this period, before our author received any additional preferment; and for the next he was indebted to the patronage of queen Caroline, though he did not obtain it till after her decease. In the year 1739 he was nominated dean of Winchester by sir Robert Walpole, to whose favour he had been recommended by the late queen. In 1744 the dean was elected prolocutor of the lower house of convocation for the province of Canterbury; and in 1748 he was promoted to the bishopric of Bangor. It is generally believed that he was really averse from accepting the episcopal dignity, and he was still more reluctant to comply with the solicitations of his friends, by being promoted to the bishopric

bishopric of Rochester, together with the deanery of Westminster. Twice after this he might have been raised to the high dignity of the bishopric of London, but he declined the honour. In a short time after the second offer, being at the advanced age of seventy-three, and thinking himself unable properly to discharge the duties of his station, he informed his friend, lord Bath, of his determination to resign both his bishopric and deanery, and to retire from the active duties of life; at the same time soliciting his lordship to request for him the honour of a private audience from his majesty for that purpose. This favour was granted to him, and the king, after having taken some time to deliberate, and to consult his legal advisers on the subject, signified his consent, and the bishop actually kissed hands on the occasion. A dispute, however, occurred between lord Bath and his majesty's ministers with respect to a successor, which in a manner obliged the king to send again for Dr. Pearce, and tell him he must think no more about resigning his bishopric. In 1768 he did, however, obtain the king's consent to his resigning the deanery of Westminster, and from that time he discharged his episcopal functions, and pursued his private studies, with all his remaining vigour till the year 1773, when he was seized with paralytic affections, that continued to increase till his death, which took place in June 1774, when he had attained to the 84th year of his age. Having no children, and having lost his wife the year before his own death, he made his brother, William Pearce, esq. his heir and executor. He bequeathed his library to the dean and chapter of Westminster, excepting such books as they already had, and these, with his MSS., he gave to his chaplain the reverend John Derby. He left by his will several legacies to private persons, and to public charities; but his principal legacy was to a college at Bromley, in Kent, which had been founded by bishop Warner in 1666, for twenty widows of clergymen who stood in need of assistance. "The fabric is neat, the apartments are commodious, and the condition of the inhabitants such as infers no degradation of civil rank. The revenue assigned by the founder was, in his time, not only competent but liberal; yet, by the alterations which the last century has produced in the modes of life, and the system of expence, what was then ample is now become scanty, and bishop Pearce left 5000*l.*, not to increase the number, but to advance the happiness of the society, by such an augmentation of revenue as might rescue them from penury. In this charity there is no ostentation; his benefaction scarcely continues his name, but sinks silently into the ancient fund, and those who shall enjoy the plenty which it restores, will, in a few years, hardly know to whom they owe it."

Dr. Pearce was first known to the public by philological learning, which he continued to cultivate with advanced age. "Cicero de Oratore" was published by him when he was bachelor of arts, and "Cicero de Officiis" when he was dean of Winchester. He did not confine his attention to the learned languages: he was particularly studious of Milton's poetry; and when Dr. Bentley published his imaginary emendations of the "Paradise Lost," Dr. Pearce wrote a vindication of the established text. In domestic life he was quiet and placid, not at all difficult to be pleased, nor inclined to harass his attendants or inferiors by peevishness or caprice. In his parochial cure he was punctually diligent, and very seldom omitted to preach. He was author of several works besides those already mentioned: among these were "The Miracles of Jesus vindicated;" and "Two Letters to Dr. Waterland upon the Eucharist;" but his great work was not published till 1777, under the title of "A Commentary, with Notes, on the

Four Evangelists, and the Acts of the Apostles, together with a new Translation of St. Paul's first Epistle to the Corinthians, with a Paraphrase and Notes," in 2 vols. 4to. This work is unquestionably the result of many years' studious application, and it reflects lasting honour upon his learning, critical talents, and intimate knowledge of the sense and spirit of the sacred writings. It now ranks high among theological students; but either from the largeness of the number printed, or from some other cause, unknown to the writer of this article, the commentary was for many years almost a drag on the booksellers' shelves. The copy from whence the foregoing particulars have been chiefly extracted was purchased as low as twelve shillings. Its value at present is better appreciated. Mr. Derby, his lordship's chaplain, gave likewise to the public four volumes of his lordship's sermons, on subjects of high importance to the present and future welfare of mankind. Bishop Pearce was author of N 121 of the Guardian; and of 572 in vol. viii. of the Spectator, and also of N 633 in the same volume, "On the Eloquence of the Pulpit."

PEARCH, or PERCH, in *Ichthyology*. See PERCA.

PEARL, PERLA, or *Margarita*, in *Natural History*, a hard, white, smooth, shining body, usually roundish, found in a testaceous fish, of the oyster kind; and is ranked in the number of gems.

The fish in which the pearls are found, is three or four times the size of the common oysters; and is called by naturalists, the "concha margaritifera." The East India pearl-shell is the "matrix perlarum" (mother of pearl) of Rumphius, or the "mytilus margaritiferus" of Linnæus; and therefore the general term pearl-oyster must be erroneous. Some also are found in a species of mya, or muscle. That pearls are not peculiar to one kind of shell-fish, as many have believed, was known to Pliny, who says, "quo apparet, non uno conchæ genere nasci." Many very good pearls have been found in Colchester oysters: and real pearls are found under the shell of the sea-hare (*aplysia*).

This fish is common in the gulf of Persia, near Ormus and Bahrein island; about cape Comorin, on the coast of the island of Ceylon; in the Bornean islands; in Saxony, and in Scotland, and also in South America.

The ancients called these pearls *uniones*, apprehending that there never was but one in an oyster; but there have been sometimes found seven in a shell; and an author, who treats well of their production, pretends to have seen a hundred and fifty in the same fish, but those in different degrees of perfection. The most perfect drop out first; the rest remaining longer at the bottom of the shell.

An ingenious writer (Henry J. Le Beck, esq.) has, in the 5th volume of the Asiatic Researches, given a particular account of the pearl-fishery at Ceylon, and also of the animal inclosed in the *mytilus margaritiferus*, from which the pearl is obtained. "This animal," he says, "is fastened to the upper and lower shells by two white flat pieces of muscular substance, which are called by Houttuin *ears*, and extend about two inches from the thick part of the body, growing gradually thinner. The extremity of each ear lies loose, and is surrounded by a double brown fringed line. These lie almost the third of an inch from the outer part of the shell, and are continually moved by the animal. Next to these, above and below, are situated two other double fringed moveable substances, like the bronchiæ of a fish. These ears and fringes are joined to a cylindrical piece of flesh, of the size of a man's thumb, which is harder, and of a more muscular nature than the rest of the body. It lies about the centre of the shells, and is firmly attached to the middle of each. This, in fact, is that part of the pearl fish which serves

erves to open and shut the shells. Where this column is fastened, we find on the flesh deep impressions, and on the shell various nodes of round or oblong forms, like imperfect pearls. Between this part, and the hinge (*cardo*), lies the principal body of the animal, separated from the rest, and shaped like a bag. The mouth is near the hinge of the shell, enveloped in a veil, and has a double flap or lip on each side; from whence we observe the throat (*œsophagus*) descending like a thread to the stomach. Close to the mouth there is a carved brownish tongue, half an inch in length, with an obtuse point; on the concave side of this descends a furrow, which the animal opens and shuts, and probably uses to convey food to its mouth. The tongue is supposed to be used in the exercise of the locomotive power of the pearl-fish. That they have this power is well known to the divers, who observe that they alter their abode in search of food, and also when disturbed by an enemy. In the latter case, it is said, they commonly descend from the summit of the bank to its declivity. Near the middle of the tongue are two blueish spots, which seem to be the eyes. In a pretty deep hole near the base of the tongue, lies the beard (*byssus*), fastened by two fleshy roots, and consisting of almost one hundred fibres, each an inch long, of a dark green colour, with a metallic lustre; they are undivided, parallel, and flattened. In general the byssus is more than three quarters of an inch, without the cleft (*rima*); but if the animal is disturbed, it contracts it considerably. The top of each of these threads terminates in a circular gland or head, like the stigma of many plants. With this byssus they fasten themselves to rocks, corals, and other solid bodies; by it the young pearl fish cling to the old ones; and with it the animal procures its food, by extending and contracting it at pleasure. Small shell-fish, on which they partly live, are often found clinging to the former. The stomach lies close to the root of the beard, and has, on its lower side, a protruded obtuse point. Above the stomach are two small red bodies, like lungs; and from the stomach goes a long channel or gut, which takes a circuit round the muscular column above-mentioned, and ends in the anus, which lies opposite to the mouth, and is covered with a small thin leaf, like a flap. Though the natives pretend to distinguish the sexes by the appearance of the shell, I could not find any genitalia. The large flat ones they call males, and those that are thick, concave, and vaulted, they call females, or *pedoo-chippy*; but, on a close inspection, I could not observe any visible sexual difference.

“It is remarkable that some of these animals are as red as blood, and that the inside of the shell has the same colour, with the usual pearly lustre, though my servants found a reddish pearl in an oyster of this colour; yet such an event is very rare. The divers attribute this redness to the sickness of the pearl fish; though it is most probable that they had it from their first existence. In the shade they will live twenty-four hours after being taken out of the water. This animal is eaten by the lower class of Indians, either fresh in their curries, or cured by drying; in which state they are exported to the coast; though I do not think them by any means palatable.

“The pearls are only in the softer part of the animal, and never in that firm muscular column above-mentioned. We find them in general near the earth, and on both sides of the mouth.”

The formation of pearls has puzzled both ancient and modern naturalists, and given occasion to a great number of hypotheses, many of them wild and extravagant enough.

Pliny, and from him Solinus, &c. will have them to be formed of the dew: the fish, say they, rises every morning

to the surface of the water, and there opens its shell, to imbibe the dew of heaven; which, like a liquid pearl, insinuating into the body of the pearl-oyster, fixes by its salts, and there assumes the colour, hardness, and form of pearl; as some other liquors are converted into crystals in the earth, or the juice of flowers into honey and wax in the body of the bee; but the pearl-oysters grow fast to the rocks, and nobody ever yet saw any of them appear on the surface of the water.

The same absurd opinion is maintained by the natives of Ceylon, and very similar to it is the account of the formation of pearls recorded in one of the Sanscrit books of the Brahmans.

Others will have pearls to be the eggs of the fishes they are found in; but neither does this con- sult with the phenomena: for pearls are found throughout the whole substance of the oyster; in the head, the coat that covers it, the circular muscles that terminate in the stomach, and, in general, all the fleshy and muscular parts; so that there is no appearance that pearls should be in the oysters, what the eggs and spawn are in fowls and fishes. For besides that there is no particular place destined for their formation, anatomists have not been able to find any thing about them that bears any relation to what passes in this respect in other animals.

Mr. Chemnitz, a celebrated conchologist at Copenhagen, supposes that the pearl is formed by the oyster, in order to defend itself from the attacks of the *pholades* and *boreworms*. But we may be assured that in this supposition he mistakes; for although these animals often penetrate the lower layers of the pearl shell, and there occasion hollow nodes, yet on examination it will be found, that they are never able to pierce the firm layer with which the inside of the shell is lined. How then can the pearls be formed as a defence against exterior worms, when, even on shells that contain them, no worm-holes are to be seen? It is, therefore, more probable these worms take up their habitations in the nodes, in order to protect themselves from the attacks of an enemy, than that they are capable of preying on an animal so well defended as the pearl-fish is.

Others with M. Geoffroy the younger, rank pearls among the bezoars; as comprehending, under that class, all stones formed in layers or strata in the bodies of animals. See BEZOAR.

M. Reaumur has a very curious piece on the subject of the formation both of the shells and pearls, in the Memoirs of the French Academy, anno 1717. He observes that pearls are formed like other stones in the animals; as those, *c. gr.* in the bladder, kidneys, &c. and that they are apparently the effects of a disease of the fish. In effect, they are all formed of a juice extravasated out of some broken vessels, and detained, and fixed among the membranes.

To evince the possibility of this, he shews that the shells of sea-fish, as well as those of snails, &c. are wholly formed of a glutinous stony matter, oozing out of the body of the animal. Now it is no wonder that an animal, which has vessels wherein circulates a sufficient quantity of stony juice to build, thicken, and extend a shell, should have enough to form stones also, in case the juice, destined for the growth of the shell, shall chance to overflow, and burst forth in any cavity of the body, or among the membranes.

To confirm this system, he observes, that the inner surface of the common pearl-muscle, found on the coasts of Provence, is of a pearl, or mother of pearl colour, from one part of its extent, which he determines, to another; after which it becomes reddish: now there are pearls of two colours found in the shell; and the colours of the pearls

are precisely the same with those of the shell; nay, more, each kind of coloured pearl is found in the corresponding coloured part of the shell; which shews, that, in the same place wherein the transpiration of a certain juice had formed, and would have continued to form a coat or layer of shell of a certain colour; the vessels which conveyed that juice being broken, there is formed a little mass or collection of the juice, which, hardening, becomes a pearl of the same colour with the part of the shell to which it corresponds.

Add to this, that the silver, or pearl-coloured part of the shell, is formed of strata, or layers, over one another, like an onion; and the reddish part of little cylindrical short fibres applied against one another. The pearls of the two colours have also this difference of texture; not but they are both composed of concentric couches; but those of the reddish pearls are much less sensible; and, besides, they have threads, which, like radii, proceed from their centre to their circumference. These circumstances seem effectually to determine the formation of pearls, and to establish the new system beyond contradiction.

The extravasations above-mentioned may be caused by heterogeneous bodies, such as sand, coming in with the food, which the animal, to prevent disagreeable friction, covers with its glutinous matter, and which, as it is successively secreted, forms many regular lamellæ, in the manner of the coats of an onion, or like different strata of bezoars, only much thinner; this is probable, for if we cut through the centre of a pearl, we often find a foreign particle, which ought to be considered as the nucleus, or primary cause of its formation. The loose pearls may originally have been produced within the body, and on their increase may have separated and fallen into the cavity of the shell. Those compact ones, fixed to the shells, seem to be produced by similar extravasation, occasioned by the friction of some roughness on the inside of the shell. The frie and the pearl-like nodes have a different aspect from the pearls, and are of a darker and bluer colour. In one of the former we found a pretty large true oval pearl, of a very clear water, while the node itself was of a dark blueish colour. The yellow or gold-coloured pearl, is the most esteemed by the natives; some have a bright red lustre; others are grey or blackish, without any shining appearance, and of no value. Sometimes when the grey lamella of a pearl is taken off, under it is found a beautiful genuine one, but it oftener happens that after having separated the first coat, you find a worthless impure pearl. We tried several of them, taking one lamella off after another, and found clear and impure by turns; and in an impure pearl we met with one of a clear water, though in the centre of all we found a foreign particle. The largest and most perfect pearl which we saw during our stay at Condatchy, was about the size of a small pistol-bullet, though we have been told since our departure, many others of the same size have been found. The spotted and irregular ones are sold cheap, and are chiefly used by the native physicians as an ingredient in their medicines.

As to the formation of the pearl-fish, though it is the most natural opinion, that this fish, like all others, produces eggs or spawn, whose exterior surface at first is soft and viscous, but changes, and hardens, by degrees, into a shell; yet we must not leave unmentioned the popular, though erroneous hypothesis, of the Parawas; viz. that in rainy weather, the brooks of the neighbouring lands that empty themselves all along the coasts, run near two leagues on the surface of the sea without mixing therewith. For a while the suspended water, they say, retains its natural colour and sweetness: but at length, the heat of the sun, condensing

it, forms it into a kind of light transparent froth; this done, it presently divides into an infinity of parts, each of which appears as if animated; moving this way and that like insects. The fishes sometimes catch at them as they pass by; but they soon abandon them. By degrees their skin thickening and hardening, they at length become heavy enough to sink to the bottom, and assume the figure of pearl-oysters.

We may judge with greater or less probability by the appearance of the pearl-shells, whether they contain pearls or not. Those that have a thick calcareous crust upon them, to which zoophytes of various kinds are fastened, have arrived at their full growth, and commonly contain the best pearls; but those that appear smooth, contain either none, or only small ones.

The art of forcing shell-fish to produce pearls was known, in the first centuries of the Christian era, to the inhabitants of the coasts of the Red sea, as we are told by the philosopher Apollonius, (Philosrat. in Vita Apollon. lib. iii. c. 57, edit. Olearii, p. 139) who thought that circumstance worthy of particular notice. The Indians dived into the sea, after they had rendered it calm, and perhaps clearer, by pouring oil into it. They then enticed the fish by means of some bait to open their shells; and having pricked them with a sharp-pointed instrument, received the liquor that flowed from them, in small holes made in an iron vessel, in which they hardened into real pearls. Olearius says, that this account is to be found in no other author: but it has at least been copied by Tzetzes, whose words may in some measure serve as an explanation. Tzetzes Variorum, lib. ii. segm. 373.

We are as yet too little acquainted with shell-fish to be able to determine with certainty, how much truth there really may be in this relation: but we have great reason to conjecture from it, that the people who lived on the borders of the Red sea were then acquainted with the method of forcing shell-fish to produce pearls; and as the arts in general of the ancient Indians have been preserved without much variation, the process employed by the Chinese at present, to cause a certain kind of muscles to form pearls, seems to confirm the account given by Philostratus. In the beginning of the summer, at the time when the muscles repair to the surface of the water and open their shells, five or six small beads, made of mother of pearl, and strung on a thread, are thrown into each of them. At the end of a year, when the muscles are drawn up and opened, the beads are found covered with a pearly crust, in such a manner, that they have a perfect resemblance to real pearls. The truth of this information cannot be doubted, though some experiments made in Bohemia for the same purpose were not attended with success. It has been confirmed by various persons, and it is very probable, that some operations and secrets, without which the process would prove fruitless even in China, may be unknown to the Europeans. Besides, many observations are known, which seem to shew the possibility of such an effect being produced. Professor Fabricius says, that he saw in the possession of sir Joseph Banks, at London, large chamæ, brought from China, in which there were several bits of iron wire, incrustrated with a substance of a perfect pearly nature. These bits of wire, he said, had been sharp, and it appeared as if the muscles, to secure themselves against the points of the wire, had covered them with this substance, by which means they had been rendered blunt. May not therefore the process employed by the ancients be still practised? And may not these bits of wire have been the same as those spikes used by the people in the neighbourhood of the Red sea for pricking muscles, and which per-

haps slipped from the hands of the Chinese workmen and remained in the animals?

The invention therefore of Linnæus cannot be called altogether new. That great man informed the king and council in the year 1761, that he had discovered an art by which muscles might be made to produce pearls, and he offered to disclose the method for the benefit of the kingdom. This however was not done, but he disposed of his secret to one Bagge, a merchant at Gottenburg, for the sum of eighteen thousand copper dollars, which make about five hundred ducats. In the year 1780, the heirs of this merchant wished to sell to the highest bidder the sealed up receipt: but whether the paper was purchased, or who bought it, we do not know; for professor Retzius at Lund, of whom we enquired respecting it, could not inform us. Dr. Stover, in his Life of Linnæus, vol. i. p. 360, says that the manuscript containing this secret is in the possession of Dr. J. E. Smith, in England. In the year 1763, it was said in the German newspapers, that Linnæus was ennobled on account of this discovery, and that he bore a pearl in his coat of arms; but both these assertions are false, though professor Fabricius conjectures that the first may be true. Linnæus received his patent of nobility, which, together with his arms, we have seen, in the year 1756, consequently long before he said any thing respecting that discovery, of which the patent does not make the least mention. What in his arms has been taken for a pearl, is an egg, by which Mr. Tilas, whose business it then was to blazon the arms of ennobled families, meant to represent all nature, after the manner of the ancient Egyptians. The arms are divided into three fields, each of which, by the colour which forms the ground, expresses one of the kingdoms of nature; the red signifying the animal, and the green the vegetable, &c. Over the helmet, by way of crest, is placed the *linnaea*: that beautiful little moth, the *phalæna linneella*, shining with its silvery colours, is displayed around the border instead of festoons; and below is the following motto, "Famam extendere factis." Linnæus once shewed us, among his collection of shells, a small box filled with pearls, and said, "Hos unioes confecti artificio meo; sunt tantum quinque annorum, et tamen tam magni." "These pearls I made by my art, and though so large, they are only five years old." They were deposited near the *mya margaritifera*, from which most of the Swedish pearls are procured; and the son, who was however not acquainted with his father's secret, said the experiments were made only on this kind of muscle, though Linnæus himself assured us that they would succeed on all kinds.

We conjecture that Linnæus alluded to this art in his writings so early as the year 1746, or long before he ever thought of keeping it a secret. The passage we mean is in the sixth edition of his "Systema Naturæ," where he says "Margarita. Testæ excrecentia latere interiore, dum exterius latus perforatur." See the article LINNÆUS.

That pearls are produced when the shells have been pierced or injured in a certain manner, is highly probable, and has been in modern times often remarked. It appears also, that the animal has the power of sometimes filling up such openings with a calcareous substance, which it deposits in them. This substance assumes the figure of the orifice, and the animal particles it contains give it its brightness and lustre. Pearl-fishers have long known that muscles, the shells of which are rough and irregular, or which exhibit marks of violence, commonly contain pearls, though they are found also in others, in which the same appearances are not observed. We are perfectly aware that experiments which some have made by piercing the shells of muscles, have been unsuccessful; but this does not prove that it is impossible to

procure pearls in that manner. Those who made them did not perhaps pierce the proper part of the shell; perhaps they made the orifice so large that it weakened the animal; and they may not have chosen the properest season of the year. The strongest objection, however, which can be made on this subject, is the undeniable truth that the proper valuable pearls are not found adhering to the shell, but in the body only; and that therefore those calcareous balls which fill up holes, cannot be perfect pearls. But from the words of Linnæus above quoted, we are led to conjecture, that he only made a hole in the shell without piercing it quite through. Linnæus also may have done some injury to the animal itself, when it opened its shell; for it is certain that testaceous animals are strong-lived, and can easily sustain any violence. It appears by the Transactions of the Swedish Academy, that some have been of opinion that shell-fish might be made to produce pearls by a particular kind of nourishment; and Lister thinks that these excrescences would be more abundant, were the muscles placed in water impregnated with calcareous matter; but professor Linnæus seems certain that his father employed none of these methods. Beckmann's Hist. of Inventions, vol. ii.

The perfection of pearls, whether round, in form of pearls or olives, or irregular, consists chiefly in the lustre and clearness of the colour, which jewellers call the *water*. There are some whose water is white, which are those most esteemed in Europe; the waters of others border on the yellow, which some Indians and Arabs prefer to the white; others are of a lead colour; others border on black; and others are quite black. They are all liable to change with wearing: in eighty or a hundred years they usually become of little value, especially the white ones, which often turn yellow, and spoil in forty or fifty years' time.

The difference of colours, doubtless, arises from the different parts of the oyster in which they are formed. When the seed happens to be thrown into the mesentery or liver, or the parts corresponding thereto, it is no wonder if the impurities of the blood change the natural white.

The oriental pearls are the finest, on account of their largeness, colour, and beauty, being of a silver white; whereas the occidental pearls seldom exceed the colour of milk.

In Europe pearls are sold by the carat-weight, the carat containing four grains. In Asia, the weights used for pearls are different, in different states.

The value of pearls increases as the square of their weight: thus, the price of a pearl of one carat being settled at 8s. to find the price of a pearl weighing six carats; first find the square of 6, *viz.* 36: which multiplied by 8, gives 288 shillings, or 14*l.* 8s. the price required.

The term pearl is only properly applied to what grows independent of the shell. The shell itself is rather called *nacre of pearl*: those pieces which have grown thereto, and have since been separated by the address of the workman, are called *scabs of pearls*; which are, in effect, nothing but roundish excrescences, or pieces of the shell, though frequently used for real pearl.

Pearls, F. Bouhours observes, have this advantage over precious stones dug out of rocks, &c. that the latter owe their lustre to the industry of men; nature only, as it were, hews them out, and leaves the finishing of them to art: but the former are born with that beautiful water which gives them their value. They are found perfectly polished in the abysses of the sea; and nature has put the last hand to them before they are separated from their mother.

Pearls have been used as ornaments from the earliest ages.

PEARL-FISHERY.

In the time of Job pearls were accounted to be of great value. Job, ch. xxviii. v. 18.

Pearls of unusual figures, *i. e.* neither round, nor in the pear form, are called *barognas*, and our's *Scotch pearls*: those of unusual sizes are called *parangons*; such as were that of Cleopatra, valued by Pliny at centies HS, or 80,000*l.* sterling; that brought in 1574 to Philip II. of the size of a pigeon's egg, valued at 14,400 ducats; that of the emperor Rudolph, mentioned by Boetius, called *la peregrina*, or *the incomparable*, of the shape of a muscade pear, and weighing thirty carats; and that mentioned by Tavernier, in the hands of the emperor of Persia, in 1633, bought of an Arab for 32,000 tomans, which, at 3*l.* 9*s.* the toman, amounts to 110,400*l.* sterling.

That pearls are calcareous is inferred from Cleopatra's having been able to dissolve her's in vinegar, and by these means to gain a wager from her lover, as we are told by Pliny (lib. ix. cap. 35.), and Macrobius (Saturn. lib. ii. cap. 15.) She must, however, have employed stronger vinegar than that which we use for our tables, as the pearls, on account of their hardness and their natural enamel, cannot be easily dissolved by a weak acid. Cleopatra, perhaps, broke and pounded the pearls; and it is probable that she afterwards diluted the vinegar with water, that she might be able to drink it; though dissolved calx destroys acids and renders them imperceptible to the tongue. We are told that the dissipated Clodius gave to each of his guests a pearl dissolved in vinegar to drink; "ut experiretur in gloria palati," says Pliny, "quid saperent margaritæ; atque ut mirè placuere, ne solus hoc sciret, singulos uniones convivis absorbendos dedit." Horace (lib. ii. sat. 3.) says the same. Caligula, also, "margaritas pretiosissimas aceto liquefactas forbebat." Suet. cap. 37. That pearls are soluble in vinegar is remarked in Pausanias, l. viii. c. 18. and Vitruvius, l. viii. c. 3.

Pearls have been reckoned of some use in medicine; but they were only the smallest sort, called *seeds of pearls*, that were used. The quality required was, that they should be white, clear, and transparent; and truly oriental. They served to make cordial potions, formerly much valued, but now fallen from their ancient reputation; and scarcely ordered by any but charlatans.

The ladies also use certain preparations of pearls, as they are made to believe, for their complexions: such as the whites of pearls; flowers, essences, spirits, tinctures, &c. of pearl; but they are all apparently deceits.

PEARLS, Ounce. See OUNCE.

PEARL-FISHERY. Pearls are taken in the seas of the East Indies, in those of America, and in some parts of Europe.

PEARL-FISHERIES OF THE EAST ARE, 1. The island of Bahrein, or Baharem, in the Persian gulf; this the Portuguese were masters of while they held Ormus and Mascati; but it has been returned to the sopher of Persia, since the time that prince, with the assistance of the English, took from them Ormus, and the Arabs Mascati. The revenue arising from this fishery to the sopher of Busheer, has been diminished by the pretensions of the Houls, a strong Arabian tribe between Gombroon and Cape Burdistan, who refused to pay for the permission of fishing. See BAHREIN.

2. The fishery of Catifa, on the coast of Arabia Felix, over-against Bahrein.

3. That of Manaar, a sea-port in the isle of Ceylon. The pearls here fished are the finest in all the East for their water, and roundness; but they seldom exceed two carats. See *Manner of Fishing for PEARLS in the East Indies*, farther on.

Lastly, there are pearls fished on the coast of Japan; but they are coarse and irregular, and little valued.

The pearls of Bahrein and Catifa are those that were formerly sold in the Indies; they border a little on the yellow, but the Eastern people do not value them the less for it: they esteem it the sign of their being ripe, and mature; and are persuaded, that those which have this yellowish tincture naturally never change their colour; and that, on the contrary, those of the white water do not hold above thirty years before the pearl assumes a filthy yellow colour, by reason of the heat of the climate, and the sweat of the persons who wear them. Some of the pearls, taken near the isles of Bahrein on the Arabian side, weigh 50 grains, but those are esteemed large which weigh from 10 to 12 grains.

PEARL, American, Fisheries, are all in the great gulf of Mexico, along the coast of the Terra Firma. There are five of them.

1. The fishery of Cubagua, an island five leagues from New Andalusia, in 10½ deg. north lat.

2. That of the island Marguerites, or Pearl Island.

3. That of Comogote near the Terra Firma.

4. That of the river De la Hach, called La Reneheria.

5. That of St. Martha, sixty leagues from the river de la Hach.

The pearls of these three last fisheries are usually of a good weight, but ill formed and of a livid water. Those of Cubagua seldom exceed five carats, but are found in abundance. But the greatest quantity, and the finest, both with regard to weight and water, are those of the island of Marguerites.

PEARL-FISHERY, in Chinese Tartary, is near the city Nipehoa, situate on a lake of the same name: the pearls here are less beautiful than those of Baharem, and the fishery less plentiful. It was this fishery that occasioned the war between the Chinese and Muscovites, terminated towards the end of the 17th century, by the Jesuits Pereira and Gerbillon; when the lake, which is of great extent, was divided between the two nations, each of which had pretended to the whole.

The Turks or Tartars call this valued product "Margion," signifying a globe of light; from which, and the Persian name "Mervarid," *i. e.* the offspring of light, was derived "Marguerite," the appellation in southern Europe.

There are some pearl fisheries also in the South sea, but they are very inconsiderable. The fisheries of the Bornean islands were noted in the time of Magalhaens; Pigafetta, his companion, reporting, that a Bornean monarch possessed two pearls, found here, as large as pullets' eggs.

PEARL-FISHERIES OF EUROPE are in some places on the coast of Scotland, particularly in the rivers Teith and Ythan, which furnish a large kind of mya or muscle, and pearls, some of which are in the shape of a pear, and others pink on one side; and in a river of Saxony called Elster, where the shells are about six inches long, but the pearls found here are no ways comparable to those of the East Indies, or of America; though they serve for necklaces, which are sold sometimes for a thousand crowns, and upwards. See an account of pearl fishing, in the north of Ireland, Philos. Transl. N^o 198.

PEARLS, *Manner of fishing for, in the East Indies; particularly in the isle of Ceylon.* About 12 miles from Manaar, and in the gulf so called, lies the bay of Condatchy, where all the boats are collected for the pearl-fishery. At this time the bay is crowded with small vessels, and the beach presents an astonishing multitude of people from every quarter of India. Several thousands of people

PEARL-FISHERY.

of different colours, countries, casts, and occupations, continually passing and repassing; vast numbers of small tents and huts erected on the shore, with the bazar or market place before them; a multitude of boats returning in the afternoon from the pearl banks; the anxious countenances of the boat-owners, while the boats are approaching the shore, and the eagerness and avidity with which they run to them when arrived, in hopes of a rich cargo; the vast number of jewellers, brokers, merchants, of all colours and all descriptions, both natives and foreigners, who are occupied in some way or other with the pearls, some separating and assorting them, others weighing and ascertaining their number and value, while others are hawking them about, or drilling and boring them for future use:—all these circumstances tend to impress the mind with the value and importance of that object, which can of itself create this scene. The banks, where the fishery is carried on, extend several miles along the coast from Manaar southward of Arippe, Condatchy, and Pomparipo. The principal bank is opposite to Condatchy, and lies out at sea about 20 miles. The first business, previous to the commencement of the fishery, is to survey the different oyster banks, to ascertain the state of the oysters, and to make a report on the subject to government. If the quantity is found to be sufficient, and in a proper state of maturity, the particular banks to be fished that year are put up for sale to the highest bidder, and are usually purchased by a black merchant. Sometimes the government deems it more advantageous to fish the banks on its own account, and to dispose of the pearls afterwards to the merchants. When this plan is adopted, boats are hired for the season on account of government from different quarters, at a variable price, but usually from five to eight hundred pagodas for each boat. When this plan was pursued, as it generally was by the Dutch, the governor and council of Ceylon claimed a certain *per centage* on the value of the pearls:—or if the fishing of the banks was disposed of by public sale, they bargained for a stipulated sum to themselves over and above what was paid on account of government. This perquisite was claimed on account of their trouble in surveying and valuing the banks. As it would not be expedient to fish the whole of the banks in one year, they are divided into three or four different portions, one portion of which is fished annually in succession. By this contrivance a sufficient interval is allowed for the oysters to attain their proper growth; and as the portion first used generally recovers its maturity by the time the last portion has been fished, the fishery becomes almost regularly annual. The oysters are supposed to attain their completest state of maturity in seven years; for if they be left too long, the pearls become so large and so disagreeable to the fishes, that they vomit and throw them out of the shell.

The fishing season commences in February, and ends about the beginning of April. The period allowed the merchant for fishing the banks is six weeks, or at the most two months; but the interruptions that occur prevent the fishing days from exceeding more than about 30. In a bad season, the purchaser of the fishery is allowed a few days more as a favour. The number of holidays observed by persons of different nations and sects, is one principal cause of a considerable interruption. Many of the divers are of a black race, denominated Marawas and Parawas, that inhabit the opposite coast of Tutucoreen: these people, though of the Malabar cast, are Roman Catholics, and leave off work on Sundays to attend prayers at the chapel of Arippe. But if stormy days, or Hindoo and Mahometan festivals (which are never neglected on any account by the natives) occur to interrupt the regular course of fishing, the farmer is some-

times desirous that the Catholic Marawas should make up for lost time by working on Sundays; but he cannot compel them to do this without an order from the chief civil officer of the government, who is appointed to superintend the fishery. The boats and donies employed in the fishery do not belong to Ceylon, but are brought thither from different parts of the continent; particularly Tutucoreen, Caracal, and Negapatam, on the Coromandel coast; and Colang, a small place on the Malabar coast, between Cape Comorin and Anjanga. The divers from Colang are accounted the best, and are only rivalled by the Lubbahs, a tribe of Moors, who remain on the island of Manaar, in order to be trained in this art. Before the fishery begins all the boats rendezvous at Condatchy, and are here numbered and contracted for.

During the season, all the boats regularly sail out and return together. A signal gun is fired at Arippe about ten o'clock at night, when the whole fleet sets sail with the land-breeze. They reach the banks before day-break, and at sun-rise commence fishing. In this they continue busily occupied till the sea-breeze, which arises about noon, warns them to return to the bay. As soon as they appear within sight, another gun is fired, and the colours hoisted, to inform the anxious owners of their return. When the boats come to land, their cargoes are immediately taken out, as it is necessary to have them completely unloaded before night. Whatever may have been the success of their boats, the owners seldom wear the looks of disappointment; for, although they may have been unsuccessful one day, they look with the most complete assurance of better fortune to the next; as the Brahmins and conjurers, whom they implicitly trust in defiance of all experience, understand too well the liberality of a man in hopes of good fortune, not to promise them all they can desire.

Each of the boats carries twenty men, with a *Tindal* or chief boatmen, who acts as pilot. Ten of the men row and assist the divers in re-ascending. The other ten are divers; they go down into the sea by five at a time; when the first five come up the other five go down; and, by this method of alternately diving, they give each other time to recruit themselves for a fresh plunge.

In order to accelerate the descent of the divers, large stones are employed: five of these are brought in each boat for the purpose; they are of a reddish granite, common in this country, and of a pyramidal shape, round at top and bottom, with a hole perforated through the smaller end sufficient to admit a rope. Some of the divers use a stone shaped like a half moon, which they fasten round the belly when they mean to descend, and thus keep their feet free.

These people are accustomed to dive from their very infancy, and fearlessly descend to the bottom in from four to ten fathoms water, in search of the oysters. The diver, when he is about to plunge, seizes the rope, to which one of the stones we have described is attached, with the toes of his right foot, while he takes hold of a bag of net-work with those of his left; it being customary among all the Indians to use their toes in working or holding as well as their fingers; and such is the power of habit, that they can pick up even the smallest thing from the ground with their toes almost as nimbly as an European could with his fingers. The diver, thus prepared, seizes another rope with his right hand, and holding his nostrils shut with the left, plunges into the water, and by the assistance of the stone speedily reaches the bottom. He then hangs the net round his neck, and with much dexterity, and all possible dispatch, collects as many oysters as he can while he is able to remain under water, which is usually about two minutes. He then resumes his former position, makes a signal to those above by pulling

PEARL-FISHERY.

the rope in his right hand, and is immediately by this means drawn up and brought into the boat, leaving the stone to be pulled up afterwards by the rope attached to it.

The exertion undergone during this process is so violent, that, upon being brought into the boat, the divers discharge water from their mouths, ears, and nostrils, and frequently even blood. But this does not hinder them from going down again in their turn. They will often make from forty to fifty plunges in one day; and at each plunge bring up about a hundred oysters. Some rub their bodies over with oil, and stuff their ears and noses to prevent the water from entering; while others use no precautions whatever. Although the usual time of remaining under water does not much exceed two minutes, yet there are instances known of divers who could remain four and even five minutes, which was the case with a Caffre boy the last year we visited the fishery. The longest instance ever known was that of a diver who came from Anjanga in 1797, and who absolutely remained under water full six minutes.

This business of a diver, which appears so extraordinary and full of danger to an European, becomes quite familiar to an Indian, owing to the natural suppleness of his limbs, and his habits from his infancy. His chief terror and risk arise from falling in with the ground-shark while at the bottom. This animal is a common and terrible inhabitant of all the seas in these latitudes, and is a source of perpetual uneasiness to the adventurous Indian. Some of the divers, however, are so skilful as to avoid the shark even when they remain under water for a considerable time. But the terrors of this foe are so continually before their eyes, and the uncertainty of escaping him so great, that these superstitious people seek for safety in supernatural means. Before they begin diving, the priest, or conjurer, is always consulted, and whatever he says to them is received with the most implicit confidence. The preparation which he enjoins them consists of certain ceremonies according to the cast and sect to which they belong, and on the exact performance of these they lay the greatest stress. Their belief in the efficacy of these superstitious rites can never be removed, however different the event may be from the predictions of their deluders: government therefore wisely gives way to their prejudices, and always keeps in pay some conjurers to attend the divers and remove their fears. For though these people are so skilful and so much masters of their art, yet they will not on any account descend till the conjurer has performed his ceremonies. His advices are religiously observed, and generally have a tendency to preserve the health of the devotee. The diver is usually enjoined to abstain from eating before he goes to plunge, and to bathe himself in fresh water immediately after his return from the labours of the day.

The conjurers are known in the Malabar language by the name of *Pillal Karras*, or *binders of sharks*. During the time of the fishery, they stand on the shore from the morning till the boats return in the afternoon, all the while muttering prayers, distorting their bodies into various strange attitudes, and performing ceremonies to which no one, not even themselves we believe, can attach any meaning. All this while it is necessary for them to abstain from food or drink, otherwise their prayers would be of no avail. These acts of abstinence, however, they sometimes dispense with, and regale themselves with *toddy*, a species of liquor distilled from the palm tree, till they are no longer able to stand at their devotions.

Some of the conjurers frequently go in the boats with the divers, who are greatly delighted at the idea of having their protectors along with them; but in our opinion, this fancied protection renders the divers more liable to accidents, as it

induces them to venture too much and without proper precautions, in full confidence of the infallible power of their guardians. It must not however be imagined that these conjurers are altogether the dupes of their own arts, or that they accompany their votaries to the fishery merely from an anxious care of their safety; their principal purpose in going thither is, if possible, to fish a valuable pearl. As this is the case, it is evident that the superintendent of the fishery must look upon their voyages with a jealous eye; such, however, is the devoted attachment of their votaries, that he is obliged to pass it over in silence, or at least to conceal his suspicions of their real intentions. He must also never hint a doubt of their power over the sharks, as this might render the divers scrupulous of committing themselves to the deep, or indeed deter them from fishing at all. The conjurers reap here a rich harvest; for, besides being paid by the government, they get money and presents of all sorts from the black merchants and those successful in fishing up the oysters.

The appearance of a single shark is sufficient to spread dismay among the whole body of divers; for as soon as one of them sees a shark he instantly gives the alarm to his companions, who as quickly communicate it to the other boats; a panic speedily seizes the whole, and they often return to the bay without fishing any more for that day. The sharks which create all this alarm sometimes turn out to be nothing more than a sharp stone on which the divers happen to alight. As false alarms excited in this manner prove very injurious to the progress of the fishery, every means is employed to ascertain whether they are well or ill founded; and if the latter be the case, the authors of them are punished. These false alarms occurred more than once in the course of the last two or three seasons.

The divers are paid differently according to their private agreement with the boat-owners. They are paid either in money, or with a proportion of the oysters caught, which they take the chance of opening on their own account; the latter is the method most commonly adopted. The agreements with the people who hire out the boats are conducted much in the same manner. They contract either to receive a certain sum for the use of their boats, or pay the chief farmer of the banks a certain sum for permission to fish on their own account. Some of those who pursue the latter plan are very successful and become rich; while others are great losers by the speculation. Oyster lotteries are carried on here to a great extent; they consist of purchasing a quantity of the oysters unopened, and running the chance of either finding or not finding pearls in them. The European officers and gentlemen, who attend here upon duty or through curiosity, are particularly fond of these lotteries, and very frequently make purchases of this sort.

The boat-owners and merchants are very apt to lose many of the best pearls while the boats are on their return to the bay from the banks, as the oysters, when alive and left for some time undisturbed, frequently open their shells of their own accord: a pearl may then be easily discovered, and the oyster prevented by means of a bit of grass or soft wood from again closing its shell, till an opportunity offers of picking out the pearl. Those fellows who are employed to search among the fish also commit many depredations, and even swallow the pearls to conceal them; when this is suspected, the plan followed by the merchants is to lock the fellows up, and give them strong emetics and purgatives, which have frequently the effect of discovering the stolen goods.

As soon as the oysters are taken out of the boats, they are carried by the different people to whom they belong, and placed

placed in holes or pits dug in the ground to the depth of about two feet, or in small square places cleared and fenced round for the purpose; each person having his own separate division. Mats are spread below them to prevent the oysters from touching the earth; and here they are left to die and rot. As soon as they have passed through a state of putrefaction, and have become dry, they are easily opened without any danger of injuring the pearls, which might not be the case if they were opened fresh, as at that time to do so requires great force. On the shell being opened, the oyster is minutely examined for the pearls; it is usual even to boil the oyster, as the pearl, though commonly found in the shell, is not unfrequently contained in the body of the fish itself.

The stench occasioned by the oysters being left to putrefy is intolerable; and remains for a long while after the fishery is over. It corrupts the atmosphere for several miles round Condatchy, and renders the neighbourhood of that country extremely unpleasant till the monsoons and violent south-west winds set in and purify the air. The nauseous smell, however, is not able to overcome the hopes of gain: for months after the fishing season, numbers of people are to be seen earnestly searching and poring over the sands and places where the oysters had been laid to putrefy; and some are now and then fortunate enough to find a pearl that amply compensates their trouble in searching after them. In 1797 while Mr. Andrews was collector, a Cooly, or common fellow of the lowest class, got by accident the most valuable pearl seen that season, and sold it to Mr. Andrews for a large sum.

The pearls found at this fishery are of a whiter colour than those got in the gulf of Ormus, on the Arabian coast, but in other respects are not accounted so pure, or of such an excellent quality; for though the white pearls are more esteemed in Europe, the natives prefer those of a yellowish or golden cast. Off Tutucoreen, which lies on the Coromandel coast, nearly opposite to Condatchy, there is another fishery; but the pearls found there are much inferior to those two species we have mentioned, being tainted with a blue or greyish tinge.

In preparing the pearls, particularly in drilling and stringing them, the black people are wonderfully expert. We were very much struck with the instrument they employ in drilling, as well as the dexterity with which they use it. A machine made of wood, and of a shape resembling an obtuse inverted cone, about six inches in length, and four in breadth, is supported upon three feet, each twelve inches long. In the upper flat surface of this machine holes or pits are formed to receive the larger pearls, the smaller ones being beat in with a little wooden hammer. The drilling instruments are spindles of various sizes according to that of the pearls; they are turned round in a wooden head by means of a bow handle to which they are attached. The pearls being placed in the pits which we have already mentioned, and the point of the spindle adjusted to them, the workman presses on the wooden head of the machine with his left hand, while his right is employed in turning round the bow handle. During the process of drilling, he occasionally moistens the pearl by dipping the little finger of his right hand in a cocoa-nut filled with water, which is placed by him for that purpose; this he does with a dexterity and quickness which scarcely impedes the operation, and can only be acquired by much practice.

They have also a variety of other instruments both for cutting and drilling the pearls. To clean, round, and polish them to that state in which we see them, a powder made of the pearls themselves is employed. These different opera-

tions in preparing the pearls occupy a great number of the black men in various parts of the island. In the black town or pettah of Columbo in particular, many of them may every day be seen at this work, which is well worth the attention of any European who is not already acquainted with it.

As the pearl fishery has been formerly, without due consideration, exhausted by the avarice of the Dutch, it is not perhaps at present so productive as it once was. However, the revenue which government derives from it is still considerable, and may by good management be increased. Pearls are considered as the next staple of the island to cinnamon; the concourse of people attracted by it affords a facility for disposing of the other produce; and by proper management, advantage might be taken of the opportunity here offered to introduce British manufactures into various parts of India. Percival's Account of Ceylon. Asiatic Researches, vol. v. p. 393, &c.

PEARL, *Manner of fishing for, in the West Indies.* The season for fishing there is usually from October to March. In this time there set out from Carthagena ten or twelve barks, under the convoy of a man of war called l'Armada. Each bark has two or three slaves for divers.

Among the barks there is one called Capitana; to which all the rest are obliged to bring at night what they have caught in the day, to prevent frauds. The divers never live long, by reason of the great hardships they sustain; continuing sometimes under water above a quarter of an hour. The method is the same as in the East Indian fisheries.

The Indians esteemed pearls before the discovery of America; and when the Spaniards arrived there, they found great quantities stored up, which the Americans set great value on. But they were almost all imperfect, and their water yellow and smoky, because they used fire in opening the fishes.

As to pearls in form of pears, though equally perfect, and of equal weight with the round ones, their value is much inferior: however, when two are found that match well, their value is less but by one-third.

PEARLS, *To blanch and cleanse.* First soak and cleanse them in bran-water, then in milk-warm water, and last of all steep them in mercurial water, then string and hang them in a glass, close it well, and set them in the sun to dry.

The bran-water is made thus: boil two good handfuls of wheaten bran, in a quart of water, till all the strength of the bran is drawn out, which use thus: take a new glazed earthen pan, in which put your pearls on a string, and pour the third part of the bran-water upon it: when they have soaked, and the water is just warm, rub your pearls gently with your hands, to clean them the better, and continue this till the water is cold; throw off that, and pour on another third part of the bran-water, that is boiling, proceed with this as you did before, and when cold, throw it away, and pour on the remainder of the water, still proceeding as before. After this, heat fair water, and pour it on your pearls, to refresh them, and to wash away the remains of the bran, by shifting them, and pouring on fresh warm water: this do thrice, without handling your pearls; then lay them on a sheet of clean white paper, and dry them in a shade; after which dip them into mercurial water, to bring them to perfection. *Postl. Dict. Com.*

Other Methods in blanching of Pearls.—Pound alabaster to an impalpable powder, rub the pearls therewith, very gently: this will not only cleanse them, but if you let them remain in this powder twenty-four hours afterwards, they will still
be

be the better for it. White coral has the same effect, used in the like manner. White tartar, calcined and divested of all its moisture, is very good for the same purpose.

Salt dissolved, filtered, coagulated, well dried, and ground, is as effectual as any of the former things for cleansing of pearls, by rubbing them therewith; and if afterward you lay them up in some coarse ground millet, it will contribute to their brightness.

PEARLS, *False or Artificial*, are counterfeit or fictitious pearls, resembling the true ones in shape, lustre, colour, and polish; popularly called beads.

These anciently were only made of glass, incruited on the inside with a pearl-coloured varnish, which was first pursued by some artists at Murano; or with a kind of amalgam or coating of quicksilver withinside; afterwards they used small balls of wax or gum, covered with a pearl-coloured enamel. These were praised on account of their lustre; but as their beauty was destroyed by moisture, they did not continue long in use.

There has since been invented in France another manner of making them, so near the natural ones in lustre and water, that they deceive a good eye. These are what the ladies now generally wear in defect of true pearl; small necklaces whereof they despise, and the large ones are generally too dear.

PEARLS, *False, Method of making*. Take of thrice distilled vinegar two pounds; Venice turpentine, one pound; mix them together into a mass, and put them into a cucurbit; fit a head and receiver to it, and after you have luted the joints, set it, when dry, on a sand furnace, to distil the vinegar from it; do not give it too much heat, lest the stuff swell up: after this put the vinegar into another glass cucurbit, in which there is a quantity of seed pearl, wrapped in a piece of thin silk, but so as not to touch the vinegar; put a cover or head upon the cucurbit, lute it well, and put it in bal. Mariæ, where you may let it remain a fortnight. The heat of the balneum will raise the fumes of the vinegar, and they will soften the pearls in the silk, and bring them to the consistence of a paste; which being done, take them out, and mould them to what bigness, form, and shape you please. Your mould must be of fine silver, the inside gilt; you must also refrain from touching the paste with your fingers, but use silver gilt utensils, with which fill your moulds. When they are moulded, bore them through with a hog's bristle or gold wire, and let them dry a little; then thread them again on gold wire, and put them into a glass; close it up and set them in the sun to dry: after they are thoroughly dry, put them in a glass matras into a stream of running water, and leave them there twenty days; by that time they will contract the natural hardness and solidity of pearls: then take them out of the matras, and hang them in mercurial water, where they will moisten, swell, and assume their oriental beauty; after which shift them into a matras hermetically closed up, to prevent any water coming to them, and let it down into a well, to continue there about eight days: then draw the matras up, and in opening it, you will find pearls exactly resembling oriental ones.

The mercurial water is thus prepared: take plate-tin of Cornwall, calcine it, and let the calx be pure and fine; then, with one ounce of the calx and two ounces of prepared mercury, make an amalgam; wash it with fair water, till the water remains insipid and clear; then dry the amalgam thoroughly, put it into a matras over the furnace, giving it such a heat as is requisite for sublimation. When the matter is well sublimated, take off the matras, and let it cool.

Take out that sublimate, add one ounce of Venice sublimate to it, and grind them together on a marble; put this into another matras, close it well, and set it upside down in a pail of water, and the whole mass will dissolve itself, in a little time, into mercurial water: this done, filter it into a glass receiver, set it on a gentle ash fire to coagulate, and it will turn into a crystalline substance: beat this in a glass mortar, with a glass pestle, to a fine powder; strain it through a fine sieve, and put it into a matras, stop it close up, and place it in balneo Mariæ; there let it remain till it resolves again into water, which will be fit for the above mentioned use. *Postl. Dict. Com.*

The sieur Janin, or Jaquin, having observed, that the scales of a little fish called the *bleak*, found plentifully in the river Marne, had not only all the lustre of the real pearl, but that, after beating them to powder in water, they returned to their former brilliance upon drying; bethought himself of setting a piece, or little mass thereof, in the cavity of a bead, or grain of girasol, which is a kind of counterfeit opal made of glass, and bordering much on the colour of pearl. The difficulty was to get it there, and when it was within, to spread it equally throughout the bead.

A little glass tube, six or seven inches long, and a line and half in diameter, but very sharp at one end, and a little crooked, served for the introducing of the matter, by blowing it with the mouth, after having taken up a drop of this mixture with the pointed extremity of the tube; and to spread it throughout the inner circumference, he contented himself to shake it gently a long time, in a little osier basket lined with paper.

The pulverized scales, fastened by this motion in the inside of the bead, resume their lustre as they dry. To increase this lustre, in winter, they lay the beads in a hair sieve, or a bolting cloth, which they suspend to the ceiling, and under it, at six feet distance, they lay heaps of hot ashes. In summer they suspend them in the same manner, but without any fire.

The pearls, thus well dried, become very brilliant; and nothing remains but to stop up the aperture, which is done by melting wax, conveyed into it with a tube like that used in introducing the powdered scales.

After clearing off the superfluous wax, they perforate the pearls with a needle, and string them; and thus they form a necklace.

PEARL, *Mother of*, is the shell not of the pearl oyster, but of another sea-fish of the oyster kind.

The shell withinside is very smooth and polished, and of the whiteness and water of pearl itself; and it has the same lustre withoutside, after the first laminae or leaves, which make the outer coat of this rich shell-fish, have been cleared off with aqua fortis, and the lapidary's mill. It is used in inlaid works, and in several toys, as snuff-boxes, &c.

PEARL, *Wens of*, are certain excrescences, or prominent places, in form of half-pearls; sometimes found in the bottoms of pearl shells.

The lapidaries have the address to saw off these protuberances, to join them together, and to use them in several works of jewellery, as if they were real pearls.

PEARL, in *Heraldry*, is used by such as blazon with precious stones instead of colour and metals, for argent, or white.

PEARL, in *Ichthyology*, a name given by us in the parts about London, to that fish which is called in Cornwall, and other parts of the west of England, *lug-a-leaf*: it is the rhombus lævis of the generality of authors. See PLEURO-NECTES *Rhombus*.

PEARL Keys, in *Geography*, islets or rocks in the Spanish main, on the Mosquito shore. N. lat. $12^{\circ} 26'$. W. long. $82^{\circ} 45'$.

PEARL Key Lagoon, a bay on the Mosquito shore. N. lat. $11^{\circ} 15'$. W. long. $83^{\circ} 12'$.

PEARL Islands, a cluster of small islands in the Atlantic, near the coast of Nicaragua. N. lat. $12^{\circ} 35'$. W. long. $83^{\circ} 50'$.

PEARL Islands, or *King's Islands*, small islands in the bay of Panama; 12 leagues from the city of Panama. They are low, and produce wax, water, fruit, fowls, and hogs, and they afford good harbours for ships. N. lat. $7^{\circ} 12'$. W. long. $81^{\circ} 45'$.

PEARL Island, a small island in the gulf of Mexico, at the mouth of the Mississippi.—Also, a small island in the West Indies. N. lat. $14^{\circ} 53'$. W. long. $79^{\circ} 13'$.

PEARL River, a river of America, which rises in the Chactaw country in the W. part of the Mississippi territory, and pursuing a southerly course to the gulf of Mexico, is navigable upwards of 150 miles. Its principal mouths are near the entrance at the E. end of the Regulets, through which is the passage to lake Pontchartrain; it has seven feet at its entrance, and deep water afterwards. In 1769 there were some settlements on this river, where were raised tobacco, indigo, cotton, rice, Indian corn, and all sorts of vegetables. The land produces a variety of timber, fit for pipe and hoghead staves, masts, yards, and all kinds of planks for ship-building.—Also, a river of Chiampa, which runs into the Chinese sea, N. lat. $10^{\circ} 54'$. E. long. $107^{\circ} 33'$.

PEARL Rocks, a group of low and dangerous rocks in the North Pacific ocean, near the S. extremity of Calvert's island. N. lat. $51^{\circ} 54'$. E. long. $231^{\circ} 52'$.

PEARL-Ash, in *Chemistry, Arts, and Manufactures*. The crude potash, when first obtained by the combustion of vegetable matter, abounds with a great variety of impurities, consisting of neutral salts, sulphur, charcoal, and some earthy matter.

When this substance is washed with clean water, and the insoluble matter allowed to subside, the clear liquor is evaporated in large shallow iron pans. The residuum consists of potash properly so called, still containing some neutral salts, but free from its other impurities. It is a mass of a white colour, from which it is called pearl-ash. In this state it is used by bleachers, glass-makers, dyers, and others. The real potash it contains, for which it is valued, is combined with carbonic acid in the proportion of 19 of acid to 42 potash. The remainder consists of sulphat and muriat of potash. See *CARBONAT of Potash*.

The goodness of pearl-ashes must be distinguished by the uniform and white appearance of them: they are subject, however, to a common adulteration, not easily distinguishable by the appearance, which is done by the addition of common salt. In order to discover this fraud, take a small quantity of the suspected salt, and after it has been softened by lying in the air, put it over the fire in a shovel: if it contains any common salt, a crackling and kind of slight explosion will take place, as the salt grows hot.

The pearl-ashes are much used in the manufacture of glass, and require no preparation; except where very great transparency is required, as in the case of looking-glass, and the best window-glass. For this purpose dissolve them in four times their weight of boiling water: when they are dissolved, let the solution be put into a clean tub, and suffered to remain there twenty-four hours, or longer. Let the clear part of the fluid be then decanted off from the sediment, and put back into the iron pot in which the solu-

tion was made: in this let the water be evaporated away till the salts be left perfectly dry again. Keep those that are not designed for immediate use in stone jars, well secured from moisture and air.

To those who buy large quantities of this article, it may not be unuseful to know the means of assaying it. Weigh 100 grains of it before it has been exposed to the air; then lay out a known weight of sulphuric acid, of the specific gravity of 1.8, or such as boils at the temperature of 460° . Dissolve the pearl-ash in its own weight of distilled water. With a small sucking tube add sulphuric acid by a small portion at once, till no more effervescence takes place. The weight of the remainder of the sulphuric acid will shew how much has been added to the solution. Then for every grain of sulphuric acid of the above strength taken up, allow .82 of a grain of pure potash. Thus, if 100 grains of the pearl-ash take up 40 grains of sulphuric acid, of the specific gravity 1.8, the pure potash contained in the 100 will be 32.8 grains. See *POTASH*.

PEARL-Barley. (See *BARLEY*.) This affords, to a microscopic observer, a peculiar kind of mite worthy of attention, and very different from the common species. The bodies of these have some brown marks upon them, and have not such long hairs as the common mites have; the hinder part of the body also is of a different make. They have eight legs; and before the head there stand two weapons twice as thick as the legs, and of about half their length: these are divided towards their ends with joints like fingers, and those have at their ends a sort of nails formed with sharp and crooked claws; and one of the longest joints is serrated at the edge like a saw. These weapons serve not only as arms and hands to seize hold of things, but they also serve as a defence; for as soon as any danger threatens the creature's head, it erects them both, and makes them meet and fold into one another over the head, as we can join our hands and fingers together in the same erect posture. Phil. Trans. No. 222.

PEARL Colour, in *Glass*. This beautiful colour is given to glass in the following manner: put tartar calcined to a whiteness into purified crystal, while in fusion, at several times, in small quantities, mixing it well every time, till the glass is become of the desired colour; and when it is, work it as quick as can be, for it is a colour that is quickly gone. See *GLASS*.

PEARL Shell or Gaper. See *MYA*.

PEARL, Pin, or Web, in *Medicine*, an unnatural speck, or thick film over the eye. See *PANNUS*.

PEARL, White, is the powder of pearls, or the finer parts of oyster-shells, much used in miniature paintings. The method of preparing it is to take the oysters, as they are found on the sea-coast, calcined by the sun, or otherwise to dry fresh ones by the fire, till they may be easily powdered; to scrape off from these shells all the external or other parts that are not of the most perfect whiteness; and to levigate them well with water on the stone, and wash the powder over till it is thoroughly fine.

PEARL, White, as a cosmetic, or magistry of bismuth, see *BISMUTH*.

PEARLED CROWNS. See *CROWN*.

PEARLSTONE, so called by Jameson, and *Perlstein* of Werner, in *Mineralogy*. Its colours are pearl and smoke-grey, yellowish-grey, flesh-red, and reddish-brown, also greyish-black. It occurs in round and longish vesicles; its lustre is shining and pearly; its fracture is small, and imperfectly conchoidal. It is composed of thin concentric lamellar concretions; translucent on the edges, easily frangible.

gible and soft. According to Klaproth, it is composed of

75.25	Silex.
12.	Alumine.
1.6	Oxyd of iron.
4.5	Potash.
2.5	Lime.
2.5	Water.

98.35

It occurs in porphyry, and often contains balls of obsidian; and is found near Tokay in Hungary.

PEARL'S POINT, in *Geography*, a cape on the W. coast of the island of Antigua.

PEARSON, JOHN, in *Biography*, a learned prelate of the church of England, son of a clergyman, who was rector of Creak and Snoring, in Norfolk, was born in the year 1612 or 1613. When he was eleven years old he was sent to E'on school, from whence, in 1631 or 1632, he was elected to King's college, Cambridge. Having taken his degree, he was, in 1635, chosen a fellow of his college. In 1639 he entered into holy orders, and in the following year bishop Davenant collated him to a prebend in the church of Sarum, and about the same time he was appointed chaplain to the lord-keeper Finch, who presented him to a living in Suffolk. On the commencement of the civil wars Mr. Pearson was made chaplain to lord Goring, and attended him when he went in the king's service into the west of England. Here he preached a series of sermons, which he afterwards published in a different form, under the title of "An Exposition on the Creed, &c." It was reprinted with additions and improvements in folio, and has been so well received and highly applauded by the learned and judicious, as to have gone through at least twelve or fourteen editions. Soon after the restoration of Charles II. preferment and honours flowed in rapidly on Mr. Pearson. In 1660 he was presented to the rectory of St. Christopher's in London; created a doctor of divinity at Cambridge by a mandamus from the king; installed a prebend in the cathedral of Ely; nominated archdeacon of Surrey; and appointed master of Jesus college, in Cambridge. In the following year he was one of the assistant managers on the part of the establishment at the Savoy Conference, on which occasion he conducted himself in a manner highly reputable to his character and talents. Mr. Baxter says, that "Dr. Pearson was their true logician and disputant, without whom, as far as I could discern, we should have had nothing from them but Dr. Gunning's passionate invectives, mixed with some argumentations. He disputed accurately, soberly, and calmly, being but once in any passion, breeding in us a great respect for him, and a persuasion, that if he had been independent, he would have been for peace, and that if it were in his power, it would have gone well. He was the strength and honour of that cause, which we doubted whether he heartily maintained." In June 1661, he was appointed lady Margaret's professor of divinity at Cambridge; and he filled that chair with distinguished credit and applause. In 1662 he was elected to the mastership of Trinity college, Cambridge, which led him to resign his other preferments in the church. In 1672 he was raised to the episcopal bench, being nominated the successor of the celebrated Dr. Wilkins in the see of Chester, with which he was permitted to hold the arch deaconry of Surrey, and the rectory of Wigan, in Lancashire. He had previously to this prepared for publication a learned work, which was published in 1672, entitled "Vindiciæ Epistolæ S. Ignatii—Accefferunt Isaaci Vossii Epistolæ duæ adversus

David Blondellum." The work owed its origin to the dispute then agitating concerning episcopacy, and was intended to support the arguments in its favour drawn from the epistles attributed to Ignatius, in opposition to those who did not admit the authenticity of those epistles. On this point Dr. Pearson so far concedes to his opponents as to admit, that of the three Latin and twelve Greek epistles published in Ignatius' name, the former are spurious, and five of the latter are of doubtful authority; but he maintains the authenticity and genuineness of the seven other Greek epistles, which are mentioned by Eusebius. Dr. Pearson held the bishopric of Chester upwards of thirteen years, but was, for several of those years previously to his death, disqualified for all public service by his infirmities. He died in 1686, when he was in the seventy-fifth year of his age.

He left behind him a number of works, which were creditable to his learning and industry. He was author of a preface to the Golden Remains of the ever-memorable Mr. John Hales of Eton; of "No Necessity of Reformation of the public Doctrine of the Church of England &c." of the preface to J. Field's edition of "The Septuagint;" and of "Annales Cyprianici, five tredecim annorum, quibus S. Cyprianus inter Christianos versatus est, Historia Chronologica." He was one of the editors of the "Critici Sacri," or collection of critics and commentators upon the bible, in nine volumes folio; and from his MSS. were published, after his death, "V. Cl. Joannis Pearsoni S. T. P. Cestriensis nuper Episcopi, opera Posthuma Chronologica, &c."

Bishop Pearson was a man of profound and general learning, an exact chronologist, and intimately acquainted with the writings of the fathers and ecclesiastical history. He is described by bishop Burnet, as in all respects the greatest divine of the age, a man of great learning, strong reason, and of a clear judgment. He was a judicious and grave preacher, more instructing than affecting; and a man of a spotless life, and of an excellent character. The same worthy prelate says, that Dr. Pearson's "work on the Creed is among the best that our church has produced." But he adds, that "he was not active in his diocese; too remiss and easy in his episcopal function; and was a much better divine than a bishop." He was a melancholy instance of what a great man can fall to; for his memory went from him so entirely, that he became a child some years before he died.

PEASE, in *Botany*, &c. See PEA.

PEASE-bloom-damp, in *Natural History*. See DAMP.

PEASE-bolt, a provincial term applied to pease-haulm.

PEAT, in *Rural Economy*, a sort of earth dug out and used in many countries for fuel. It is found in moist low grounds that lie betwixt hills, especially if timber has formerly stood upon the spot. It lies at various depths, being often near the surface, and sometimes from six, eight, or ten feet, to twelve or fifteen yards deep, having a stratum of black moory earth over it, such as the soil of many of our low meadows near the banks of rivers; it sometimes lies under a bed of gravel. It is moderately compact, and capable of being cut with a sharp thin spade into solid masses, like bricks. Exposed to the air, it dries slowly, and becomes somewhat hard, and very inflammable. The best kind burns in an open grate with a yellowish-blue flame, resembling that of charcoal, and with a less quantity of smoke than wood affords. Some varieties are considerably charged with pyrites, and some also with sulphates of soda and magnesia; and they are thus deteriorated as combustibles. By digestion in boiling water, peat affords a deep brown solution, slightly bitter to the taste, and containing an uncombined vegetable acid, similar to the suberic, with a portion of extract, and a little sulphur. By dry distillation, there comes over a watery ammoniacal liquor, and empyreumatic

oil, and carburetted hydrogen; a considerable quantity of charcoal remaining in the retort.

Peat is a sort of material which is found to exist in large tracts in different parts of the kingdom, and was formerly supposed to be useless in improving the lands in its neighbourhood; but later experiments have sufficiently shewn, it is a vegetable substance that, when properly mixed with other materials and applied, is capable of affording vast advantages in different cases. It should therefore not be neglected or overlooked where the farmer has an opportunity of making use of it. Lord Dundonald has well remarked, that peat, or vegetable matter, should be carried from the peat-moss to the poor soil, and the surface mould from the poor soil to the peat moss. By these means two beneficial purposes may, at the same time, be effected. The quantity of such like or other earthy matter necessary to be added to a peat soil, to alter the mechanical arrangement of its parts, is to be ascertained by proper trials; and, on the other hand, the quantity of peat requisite to be applied to poor soils will be regulated by the quantity of vegetable matter which such soils may already contain. And, the most efficacious method of applying peat to poor barren soils, is to mix it with the urine and dung of cattle; on failure of these articles, with alkaline and other salts; and lastly, with lime. He observes that experience can only determine the number of loads or weight of these different preparations, which should be given to an acre of ground. From such experiments as have already been made with the preparations of alkaline and some other salts, there is reason to believe that the quantity necessary to be given at one time would not exceed that of a proper dunging, and that equally beneficial effects would be produced. If this, on general experience, should be proved, the peat mosses in Great Britain and Ireland will not only afford an inexhaustible supply of manure for the poor lands in their vicinity, but may themselves, by the application of alkaline and other salts, be brought to the highest state of fertility.

Peat-mosses and fens have, hitherto, generally been considered either as nuisances, when in an unimproved state, or as soils of the greatest fertility, when cultivated. These different states regard only the peat-moss or fen itself, and have no reference to any consequences that might arise by the application of peat or of any preparation of it to the neighbouring lands. But as peat has been discovered to be capable of being converted into the most valuable of all manures, the importance of the peat-mosses in Great Britain and Ireland cannot, therefore, be too much impressed on the minds of the land-owners and occupiers of these countries. It is further stated, that from experiments made with alkaline salts and peat, it can be ascertained, that the effects of such mixture, weight for weight, are equal, if not superior, to those of dung. The usual quantity of dung given to an acre of ground, when it is intended to manure it effectually, is about eighteen tons. This it may, perhaps, receive once in five years. It will require a farm to be well managed and in high cultivation, to admit of one-fifth of it to be annually so manured. He supposes, that the best cultivated land, by the return of its own manure, unless when a quantity of vegetable matter has been accumulated, cannot do more than keep itself in heart; of course, nothing can be spared for the amelioration or improvement of poor or waste lands. The rendering the inert vegetable matter of peat-mosses and fens serviceable to this purpose, though effected at a greater expence than is at present incurred by any application or dressing to ground, could not fail to answer the expectation of the farmer, and must be considered as one of the most valuable improvements that has hitherto occurred in the annals of husbandry.

It is the opinion of some that it may be laid on land in the most effectual manner, by having it mixed up or blended with lime newly slaked in the proportion of one part of the lime to five or six of the peat; but later trials lead to the conclusion that it may be used more successfully by having it incorporated with some sort of manure, such as that of dung. In this state of combination very great effects have been produced by it, as suggested above, in numerous instances where it has been employed.

States of Peaty Matter.—The earl of Dundonald states the different preparations of peat, or states of mixture, in which it may be applied to lands, with good effects in counteracting particular defects, or in rendering them generally more fertile, to be these:

“ Peat, unmixed,
 —, ditto - - - oxygenated,
 —, oxygenated, mixed with dung and urine,
 —, ditto - - - alkaline salts,
 —, ditto - - - alkaline hepar,
 —, ditto - - - Glauber salt and lime,
 —, mixed - - - newly slaked lime,
 — and lime, mixed with peat ashes.”

It is supposed that all these preparations may, according to circumstances, be used to advantage. The consuming peat to ashes by fire, is always to be considered as the least productive, and most uneconomical. The most beneficial and productive of these preparations will be found to be:

Peat with dung and urine;
 — alkaline salts;
 — alkaline hepar;
 — Glauber salt and lime: and
 — lime.

In cases where the soil does not contain a due proportion of calcareous matter, a preference should always be given to the last or the two last of the above preparations, until it shall have received a sufficient supply of an article so indispensably necessary as calcareous matter to the production of sweet herbage, leguminous plants, and grain. It is farther supposed that by the above method of mixing peat with lime in the proportion of five or six times the weight of the former to that of the latter, no injury can possibly arise from the over proportion of the lime. As the lime, when thus mixed with the peat, will meet with proper matter for it to combine with, or act upon; and the small proportion necessary to be used, when put in comparison to the weight of the peat, will be much less than the quantity of lime only, frequently applied at once to land; it is conceived that the bulk, weight, and the expence of the preparation, may direct the farmer in respect to the proportion that may be requisite to effect his purpose in most cases.

And in an ingenious pamphlet lately published by lord Meadowbank, the following directions are given for forming peat into a manure to be applied to ground.

Let the peat-moss, of which compost is to be formed, be thrown out of the pit for some weeks or months, in order to lose its redundant moisture. By this means, it is rendered the lighter to carry, and less compact and weighty, when made up with fresh dung for fermentation; and, accordingly, less dung is required for the purpose, than if the preparation is made with peat taken recently from the pit. The peat taken from near the surface, or at a considerable depth, answers equally well. Then take the peat-moss to a dry spot, convenient for constructing a dunghill to serve the field to be manured. Lay the cart-loads of it in two rows, and the dung in a row betwixt them. The dung thus lies nearly on the area of the future compost dunghill, and the rows of peat should be near enough each other, that workmen, in making

making up the compost, may be able to throw them together by the spade. In making up, let the workmen begin at one end; and at the extremity of the row of dung, (which should not extend quite so far at that end as the rows of peat on each side of it do,) let them lay a bottom of peat, six inches deep and fifteen wide, if the grounds admit of it; then throw forward, and lay on about ten inches of dung above the bottom of peat; then add from the side-rows about six inches of peat; then another thin layer of dung; and then cover it over with peat at the end where it was begun, at the two sides, and above. The compost should not be raised above four feet, or four feet and a half high; otherwise it is apt to press too heavily on the under parts, and check the fermentation. When a beginning is thus made, the workmen will proceed working backwards, and adding to the column of compost, as they are furnished with the three rows of materials directed to be laid down for them. They must take care not to tread on the compost, or render it too compact; and, of consequence, in proportion as the peat is wet, it should be made up in lumps, and not much broken. And that, in mild weather, seven cart-loads of common farm-dung, tolerably fresh made, is sufficient for twenty-one cart-loads of peat-moss: but, in cold weather, a large proportion of dung is desirable. To every twenty-eight carts of the compost, when made up, it is of use to throw on, above it, a cart-load of ashes, either made from coal, peat, or wood; or if these cannot be had, half the quantity of slaked lime may be used; the more finely powdered the better. But these additions are no-wise essential to the general success of the compost. It is farther stated that the dung to be used should either have been recently made or kept fresh by compression; as, by the treading of cattle or swine, or by carts passing over it. And if there is little or no litter in it, a smaller quantity will serve, provided any spongy vegetable matter is added at making up the compost, as fresh weeds, the rubbish of a stack-yard, potatoe-shaws, sawings of timber, &c. And as some sorts of dung, even when fresh, are much more advanced in decomposition than others, it is material to attend to this, for a much less proportion of such dung as is less advanced will serve for the compost, provided care is taken to keep the mass sufficiently open either by a mixture of the above-mentioned substances, or, if these are wanting, by adding the peat piece-meal; that is, first making it up in the usual proportion of three to one of dung; and then, after a time, adding an equal quantity, more or less, of moss or peat. The dung of this character, of greatest quality, is shamble-dung, with which, under the above precautions, six times the quantity of peat, or more, may be prepared. The same holds as to pigeon dung, and other fowl dung; and, to a certain extent also, as to that which is collected from towns, and made by animals that feed on grains, refuse of distilleries, &c. It is still further observed, that the compost, after it is made up, gets into a general heat sooner or later, according to the weather, and the condition of the dung; in summer in ten days or sooner; in winter, not perhaps for many weeks, if the cold is severe. It always, however, has been found to come on at last. In order to bring on the heat more expeditiously in a compost made up in frost, a narrow addition of dung and peat has, sometimes after the frost has gone off, been laid along the sides of the compost, scraping down a little the coating of peat upon it, and, in summer, it sometimes rises so high, as to be mischievous, by consuming the materials (fire fanging). In that season a stick should be kept in it in different parts, to pull out and feel now and then; for if it approaches to blood heat, it should either be watered, or turned over; and on such an occasion, advantage may be taken to mix it with a little fresh moss. In

June 1796, a compost was formed, only 2½ peat to one dung; it heated in July beyond the measure of a thermometer graduated to 110°. Part was allowed to stand, part turned with a half more moss. Three weeks after, (18th August), the heat of the former had descended to 84°, while that of the latter had got up again to above 110°. The heat subsides, after a time, and, with great variety, according to the weather, the dung, and the perfection of the making up of the compost; which then should be allowed to remain untouched, till within three weeks of using, when it should be turned over, upside down, and outside in, and all lumps broken; then it comes into a second heat; but soon cools, and should be taken out for use. In this state, the whole, except bits of the old decayed wood, appears a black free mass, and spreads like garden mould. Use it weight for weight, as farm-yard dung; and it will be found, in a course of cropping, fully to stand the comparison. Let it be observed that the object, in making up the compost, is to form as large a hot-bed as the quantity of dung employed admits of, and then to surround it on all sides, so as to have the whole benefit of the heat and effluvia. Peat, nearly as dry as garden-mould in feed-time, may be mixed with the dung, so as to double the volume and more of it. Workmen must begin with using layers; but, when accustomed to the just proportions, if they are furnished with peat moderately dry, and dung not lost in litter, they throw it up together as a mixed mass; and they improve in the art, so as to make a less proportion of dung serve for the preparation. The addition, recommended, of ashes or lime to the compost, is thought to favour the general perfection of the preparation, and to hasten the second heat. The lime laid on above the dung-hill, as directed, is rendered mild by the vapours that escape during the first heat. It is added that such compost as is made up before January, has hitherto been in good order for the spring crops; but this may not happen in a long frost. In summer, it is ready in eight or ten weeks; and if there is an anxiety to have it soon prepared, the addition of ashes, or of a little lime rubbish of old buildings, or of lime slaked with foul water, applied to the dung used in making it up, will quicken the process considerably. Lime has been mixed previously with the peat; but the compost prepared with that mixture, or with the simple peat, seemed to produce equally good crops. All the land, however, that it has been tried on, has been limed more or less within these twenty-five years.

It is said, farther, that the rich coarse earth, which is frequently found on the surface of peat, is too heavy to be admitted into this compost; but it makes an excellent top-dressing, if previously mixed and turned over with lime. And peat, prepared with the lime alone, has not been found to answer as a good manure. In one instance, viz. on a bit of fallow, sown with wheat, it was manifestly pernicious to the land.

In some of these modes, this substance may be rendered capable of extensive application as a manure to land. See MANURE and MOSS.

PEAT-Ashes, in *Agriculture*, the ashes that remain after the combustion of this sort of vegetable material. This is, however, a very wasteful and dissipating process, as there is seldom one-twentieth part of its weight afforded in ashes. The rest is thus forced off into the air and lost, which by other means might be saved, and contribute to the vegetation and growth of plants. Where, however, the practice of converting it into ashes is had recourse to, it is observed that the peat may be burnt all the summer season: as soon as it is dug, some of it is mixed in a heap regularly disposed with faggot-wood, or other ready burning fuel: after a layer or two of it is mixed in this manner, peat alone is piled up to compleat the heap. A heap will consist of from four hundred

dred to a thousand loads. After setting fire to it at a proper place, before on purpose prepared, it is watched in the burning, and the great art is to keep in as much of the smoke as possible, provided that as much vent is left as will feed the fire. Whenever a crack appears, out of which the smoke escapes, the labourer in that place lays on more peat; and if the fire slackens too much within, which may be easily known by the heat on the outside, the workman must run a strong pole into the heap, in as many places as is necessary to supply it with a quantity of fresh air. When managed in this manner, the work goes on as it should do. It is to be noticed that when once the fire is well kindled, the heaviest rains do it no harm whilst it is burning.

And after having procured a sufficient quantity of ashes, the farmer's next care should be to apply them properly to use; and to do this, he must be well acquainted with the nature of the manure he is to lay on his land. With respect to peat-ashes, almost the only danger proceeds from laying them on in too great quantities at improper seasons. Nothing can be better, it is asserted, than peat-ashes for dressing low damp meadows, laying on to the quantity of from fifteen to twenty Winchester bushels on an acre; it is best to sow them by hand, as they will then be more regularly spread. And this work should be done in January or February at latest, that the ashes may be washed in towards the roots of the grass by the first rains that fall in the spring. If they were spread more forward in the year, and a speedy rain should not succeed, being hot in their nature, they would be apt to burn up the grass, instead of doing it any service. In regard to the quantity, it must be remembered, that the damper and stiffer the soil, the more peat-ashes should be laid on it; but on grass-land, the quantity should never exceed thirty Winchester bushels, and on light warm lands less than half that quantity is fully sufficient.

Also, on wheat crops these ashes are of the greatest service, but they must be laid on with the utmost discretion. Were they to be spread in any quantity before the winter, after sowing the corn, they would make the wheat too rank, and do more harm than good: was the spreading of this manure, on the contrary, deferred till the spring, the corn could not possibly during the winter season be benefited by it. After due reflection and repeated experience, the method of management was as follows: About the beginning of November, before the hard frosts set in, the writer sows on every acre of his heavy clayey wheat land, about eight Winchester bushels of these ashes; on his lighter warmer lands in wheat, he sows only four bushels at this season. The winter dressing is, he imagines, of great service: trifling as the quantity may seem, it warms the roots of the plants, brings the crop moderately forward, preserves its verdure, and disposes it to get into a growing state the first fine weather after Christmas. About the latter end of February, or the beginning of March, on the above-mentioned heavy lands in wheat, he bestows another dressing of ashes, by sowing of them on every acre eight bushels more; on light lands, in the second dressing, he allows only six bushels. These ashes laid on in the spring are of the greatest service, without any probability of danger; if rain falls within a few days after the dressing is laid on, it is washed in, and has a happy effect on the succeeding crop, co-operating with the manure that was laid on in November: if, on the contrary, dry weather for a long continuance succeeds, the first winter dressing has its full effect, and the quantity laid on in the spring is in fact so small, that there is very little probability of its burning or hurting the crop. This method has succeeded very well with him, and he has no reason to think it can fail with others. It is likewise stated as an useful fact, that this excellent manure is of great use in the turnip hus-

bandry, on many accounts, particularly as it much contributes to preserve the young crop from being devoured by the fly. When the writer sows his turnips before he harrows in the seed, he has eight bushels of these ashes strewed by hand on every acre; and when the plants shew their first leaves above ground, he sows on every acre four bushels more: by this management his crops seldom fail, when at the same time some of his neighbours sow their turnip-land three or four times over. This hint deserves attention, as pared and burnt land is said to have the same effect in preserving turnip-crops from the dreadful ravages of the fly.

It is further stated, that one of the principal advantages derived from these ashes is, however, the very great service they are of to every kind of artificial pasture. Sainfoin receives great benefit from this manure, and so do clover, ray-grass, and trefoil, provided it is laid on with discretion: the proper season is about the month of February: the quantity must be regulated by the nature of the crop and soil; but, in his opinion, it ought scarcely in any instance to exceed thirty Winchester bushels. Clover, with the help of this manure, grows with great luxuriance, inasmuch that he has often had two large crops of hay from the same field in a year, and good autumn feed afterwards.

But the effect of it is most seen in tares and vetches, and on them it is he bestows most of this manure, as they will bear it, being a very succulent plant. The writer had, last summer, a crop of tare-hay that was astonishing, by the help of these ashes, being above three large loads on an acre. The field contained six acres. It was a dryish loam, and not very rich. In the beginning of February he caused ten bushels, Winchester measure, to be strewed on each acre: immediately after the first rains had washed them in, the same quantity was in like manner spread, and about the middle of March he bestowed on each acre six bushels more for the last dressing. He is fond of dividing his entire quantities, thinking his crops are thereby less exposed to the danger of being burned, and the manure is besides more gradual and lasting in its effects. His tares came on amazingly; but they ran chiefly to haulm, which was what he wished, not having any desire of saving the seed, but intending to make the crop in hay: his only fear was, that it would rot on the ground before it was in proper condition to cut; but this he luckily escaped, by the soil being tolerably dry, and by the fineness of the weather. It was so heavy in the swath, that he was obliged to pay an extraordinary price for mowing it. He thinks the luxuriance of his crop was owing entirely to the invigorating quality of the ashes, which by their salts, &c. promoted the growth of the plants even to luxuriance.

Before he well knew the great fertilizing quality of these ashes, he lost, by improper management, a fine three-acre piece of hog-pease. He laid on this field, soon after the pease came up, threecore Winchester bushels of these ashes at one dressing: this brought them forward a great pace; but at harvest, he found to his grief, he had scarcely any corn, for he had overdone it in laying on so much, and the pease were run all to haulm. Ever since this accident he has declined using them as a common dressing for his pease, and this he has been the more induced to do, as, in several little experiments he has since made, he has found it extremely difficult to apportion the several quantities which ought to be laid on various soils when sown with pease; for the quantity that has one year succeeded very well with him, has, the next, owing to the difference of seasons, on the same soil, in another part of the same field, totally disappointed him; so that, for pease, he esteems it a very critical manure, therefore to be used very cautiously. And he says that the effects of this manure will be visible at least three years, and it does not, like

like some others, leave the land in such an impoverished state when its virtues are exhausted. It is supposed that peat-ashes are not so certain a manure for barley and oats as for winter corn; for as these are quick growers, and occupy the land but a few months, this warm manure is often apt to push them forward too fast, and make them run too much to coarse straw, yielding only a lean immature grain. Oats, however, are not so apt to be damaged by it as barley.

And he adds, that peat-ashes approach, in their effects on the several crops on which they are laid, to coal-foot; but two-thirds of the quantity that is used of foot will be sufficient of the ashes, as they are, in a much stronger degree, impregnated with a vegetative power; and they are, besides, in most places, easier procured in quantities, and at a cheaper rate.

But though this sort of dressing has been found useful on different sorts of land, it has by much the best effects on those of the light chalky kind, being often uselessly applied on such as are of a wet nature. And the full quantity is usually about forty bushels to the acre, and the time of applying them in improved husbandry in the spring months, as about March or earlier. See ASHES.

PEAT-Moss, in *Rural Economy*, a term applied to the earthy material which is dug up for fuel in some districts. It is of very different qualities and properties. See Moss and PEAT.

PEATRA, in *Geography*, a town of European Turkey, in Moldavia; 16 miles S.S.W. of Niemeetz.

PEATY-EARTH, in *Agriculture*, that sort of land which is of a peaty quality, or which contains much vegetable peaty matter. It is generally considered of a good quality. See PEAT.

PEATY-Land, that sort of ground which is of a peaty nature, or which abounds in the peaty material. There are many varieties of this sort of land, some being constituted of this substance to several yards depth, while others have it only in a very superficial manner. The former are frequently denominated peat-mosses or bogs, and the latter fens. Some of the different modes of bringing peaty-lands into cultivation, have been already noticed under Moss and Moor, but others may be introduced here with propriety. According to the earl of Dundonald, the primary step towards improving land of this sort, is to take off by proper channels the great feeder of water. This is to be effected by conducting one or more principal drains through them, and by water-courses on the solid or dry land, immediately above the level of them, so that they shall not be inundated by the surface-water or springs of the surrounding higher lands, and shall afterwards only require to be freed from the water that shall fall on their superficies. This being accomplished, the intermediate parts of the bogs should be drained, partly by open and partly by covered drains; care being taken that they are not made so deep as to lay the bog too dry: by which the peat, becoming oxygenated, and thence insoluble, would be incapable of yielding food to vegetables.

By the opposite extreme, unprofitable grasses and aquatic vegetables are produced. It is therefore an object of great importance, in effecting the drainage, to preserve a full command of the water, that it may be regulated at pleasure by the operation. The practical modes of management that are necessary in those cases, are explained more fully in speaking of the nature of moss. See Moss.

It is farther observed, that should a moss or bog be so circumstanced, as to admit of its being drained through a country which might be improved by a supply of vegetable matter, it would be prudent, previously to making the great or leading drains through the adjacent country or moss, to concert measures for making a proper communica-

tion by a canal, so that the remote lands might be supplied with peat from the moss, and the moss supplied with lime, marle, clay, earth, sand, shells, and other materials, from the distant country. And that as shell-marle is frequently found under peat-mosses, they should be bored in different places, to ascertain if they possess this valuable substance; or if they contain under the moss a rich clay or limestone gravel: for, in the event of these being found at a moderate depth, the moss or bog may be improved at a much less expence, as the distant carriage of these necessary articles, and the difficulty of carting and laying them on so loose and spongy a surface, would thereby be diminished. It is also suggested that the burning a part of the upper surface may, in some cases, be requisite, to afford, when it is otherwise too difficult to be procured, a due proportion of earthy matter. Peat-ashes will, in such cases, act in making a different mechanical arrangement in the soil; but, near the sides of the bogs where surface mould is to be had, a preference should be given to it in most cases. And the alteration in the mechanical arrangement of the soil being thus effected, the next object is the application of such substances as will bring the peat, or inert vegetable matter, into action. These substances are lime and alkaline salts, which contribute in different ways to the proposed improvement. Improved peat-mosses, bogs, or reclaimed fen-lands, are the soils the most productive of luxuriant vegetation, although from this cause they do not in general yield, in this northern and humid climate, heavy and well-filled grain. Such soils should be principally dedicated to pasture, and should only be ploughed when, notwithstanding the utmost endeavours, the ground produces coarse or rank grass; but this is in a great measure, or perhaps entirely, to be prevented by the due attention to the following directions: to keeping the water in the ditches at a proper level: to stocking the ground with a due proportion of neat cattle, sheep, and horses; as the one animal will eat the grass which springs up on the dung of the other, and which otherwise would produce tufts of coarse grass: to folding of cattle on different parts of each field: to using heavy rollers: and to top-dressings of alkaline salts, and other saline substances: and also to top-dressings of lime, either by itself, or well mixed with peat or fen mould, in the manner that has been directed above.

And it is advised, that the pasture should always be eaten quite close before winter, excepting such portions of it as are intended for winter food, which likewise should be eaten close off, before the spring vegetation commences; after which time it should not be depastured until the grass be sufficiently advanced to allow of a good bite. As all plants receive nourishment two ways, by their stems and leaves, as well as by their roots, the growth of young vegetables must necessarily be much retarded, when deprived, by being constantly eaten down, of one of their sources of subsistence. And as the consolidating the soil of peat-lands is an object of the first consideration, it is obvious, both on chemical and mechanical principles, that much cropping, and the consequent exposure of fresh surfaces to the action of air, are improper; and that after a few crops are obtained, the ground should be laid down with meadow grasses and white clover, and depastured with as much stock as it will carry. By these means, not only the soil will be consolidated and compressed, and particular grasses or herbage promoted according to the cattle so depastured, but the urine and dung of the cattle, by carefully folding them, will be laid on in such quantities, as will perform rapidly and at once the effect required; whereas, if the same quantity were divided over fifty or a hundred times the surface so folded upon, its operation would scarcely be perceptible, and the application

of each year's manure so subdivided, would either be washed away, or its beneficial effects lost, before the further quantity necessary could, in a series of fifty or a hundred years, be added to it. Hence a system of under-dunging, or manuring land, may be said to be nearly equal to no dunging at all: on which account the preference, with great reason, has been given, under all circumstances, to the ancient mode of cultivating the infield lands of Scotland. Folding in a proper manner, is particularly recommended for fen-lands and peat-lands, as the immediate effect produced by urine, is that of dissolving into mucilaginous saponaceous matter the oxygenated peat. Indeed in all businesses, it is well known, that what is once well done is not to be done again. By this judicious mode of proceeding, the chemical qualities and mechanical arrangement of the soil are so altered, that, without the grossest mismanagement, it is impossible it should return again to its former unproductive state. If this be properly attended to, the pasture will never grow coarse, or require breaking up, but will continue to improve the longer it is suffered to remain in that state. There are other reasons for continuing such lands in pasture, *viz.* the difficulty, from the softness of the soil, of conveying dung from the farm-yard to the fields; and likewise the tendency such soils have, by exposure to air, to become oxygenated, and consequently incapable of yielding the food requisite for the support of vegetables. And in the mode of stocking such pastures, it is further recommended to keep the fat, the half fed cattle, and the lean or young stock, in different inclosures, as is the practice in Ireland, and where grazing is well understood in England. The fat cattle should only top the grass, the half fed should succeed those, and lastly, the lean or store cattle should follow on the same pasture, and eat the herbage close down; repeating this practice as often as the fresh growth of grass will permit its being done with propriety. It is probable that under the above circumstances, the best sort of stock is that of sheep, as eating the herbage down in a more regular and equal manner; and at the same time contributing more to the improvement of the land, without doing any injury by their treading or otherways. See Moss.

PEATY-Soil, that sort of soil which is constituted chiefly of the peaty material. See SOIL.

PEAUCIER, in *Anatomy*, a name given by Winslow in his "Treatise on the Head," and by other of the French writers, to the muscle, called by Albinus *latissimus colli*; and the others *detrahens quadratus*, and *quadratus genæ*. Santorini has called the part of this which arises from the cheek, *musculus risorius novus*; and some call the whole *platysma myoides*.

PEBBLES, CALCULI, in *Natural History*, the name of a genus of fossils, distinguished from the flints and homochroa, by their having a variety of colours. These are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition which the motion of the fluid they were formed in gave their differently coloured substances.

The variety of pebbles, of England alone, is so great, that a hasty describer would be apt to make almost as many species as he saw specimens. A careful examination will teach us, however, to distinguish them into a certain number of essentially different species, to which all the rest may be referred, as accidental variations. When we find the same substances and the same colours, or those resulting from a mixture of the same, such as nature frequently

makes in a number of stones, we shall easily be able to determine that these are all of the same species, though in different appearances; and that, whether the matter be disposed in one or two, or in twenty crusts laid regularly round a central nucleus, or thrown without a nucleus into irregular lines, or finally blended into a sort of uniform mass.

These are the three states in which we are liable to find every species of pebble; for if it hath been most naturally and regularly formed by incrustation round a central nucleus, we find that ever the same in the same species, and the crusts not less regular and certain. If the whole has been more hastily formed, and has been the result only of one simple concretion, if that has happened while its different substances were all moist and thin, they have blended together and made a mixed mass of the joint colour of them all; but if they have been something harder when this has happened, and too far concreted to diffuse wholly among one another, they are found thrown together into irregular veins. These are the natural differences of all the pebbles; and having regard to these in the several variegations, all the known pebbles may be reduced to thirty-four species. Hill's Hist. of Foss. p. 512, seq.

In all the strata of pebbles there are constantly found some which are broken, and whose pieces lie very near one another; but as bodies of such hardness could not be broken without some considerable violence, their present situation seems to imply, that they have suffered that great violence in or near the places where they now lie. Besides these, there are others also found which have as plainly had pieces broken off from them, though those pieces are no where to be found; whence it seems equally plain, that whatever has been the cause of their fracture, they have been brought broken, as we find them, from some other place, or else that the pieces broken from them must at some time or other have been carried from this place to some other distant one.

Several of these broken pebbles have their edges and corners so sharp and even, that it seems evident they never can have been tossed about or removed since the breaking; and others have their sides and corners so rounded, blunted, and worn away, that they seem to have been roughly moved and rolled about among other hard bodies, and that too either with great violence, or for a very long continuance; since such hard bodies could not have been reduced to the condition we now see them in without long friction.

It may be supposed by some that these stones never were broken, but have been naturally formed of this shape; but it will be easily seen, by any one who accurately surveys their veins or coats, which surround the nucleus like the annular circles of a tree, that they must have been originally entire; and this will be the more plain if they are compared with a stone broken by art. Such pebbles as are found in strata, that lie near the surface of the earth, are much more brittle than those which lie in deeper strata.

The more clear and transparent the sand is which is found among pebbles, the more beautiful the pebbles are generally observed to be.

The use of these stones, and their disposition in the earth, is a subject of great admiration; and may serve as one of the numerous proofs of an over-ruling Providence in the disposition of all natural bodies. The surface of the earth is composed of vegetable mould, made up of different earth mixed with the putrid remains of animal and vegetable bodies; and is of the proper texture and compages for conducting the moisture to the roots of trees and plants: and under this are laid the sands and pebbles which

which serve as a sort of drain to carry off the redundant moisture deeper into the earth, where it may be ready to supply the place of what is constantly rising in exhalations; and lest the strata of sand should be too thick, it is common to find thin ones of clay between, which serve to put a stop to the descent of the moisture, and keep it from passing off too soon; and lest these thin strata of clay should yield and give way, and by their softness when wetted, give leave to the particles of sand to blend themselves with, and even force their way through them, there are found in many places thin coats of a poor iron ore, placed regularly above and below the clay; and by that means not only strengthening and supporting the clay, but effectually keeping the sand from making its way into it. Phil. Trans. N^o 483.

PEBBLES, Ridged. It is not uncommon to meet with pebbles in our gravel-pits, which have one or more ridges, or white lines, standing above the surface of the rest of the stone, in the form of a rib or zone, laid on the stone after its formation. This, however, is not the case; but the line or zone always goes through the whole body of the pebble: the matter forming this ridge is always harder than the rest of the stone; and it seems probable, that at first it was not elevated, but level with the rest of the surface; but being not so easily worn away by accidents, and when the whole pebble came in the way of rubbing among harder bodies, this would be less rubbed away, and consequently would be left more elevated than the rest. We daily see on the sea-shores numbers of stones rounded by the continual rolling and tossing among the waves, and in these the softer parts have given way first and been worn into holes, while the harder have been left prominent. It seems probably to have been the case with these pebbles also; but they are not found on the shores; but in our gravel-pits, at a great distance from the sea: and it is evident, that these have had their surfaces thus ground and worn down between the time of their being formed by concretion, and their being deposited where we now find them. The smoothness of the surfaces of some pebbles and flints, which we find with their natural coats or crusts worn off, is another proof of the same thing. These pebbles, in this unnatural naked state, as well as the ribbed and lined ones, are found in our pits, under the strata of earth; and yet they are exactly in the same condition with those which have been tossed about and rounded on the sea-shores.

PEBBLES, Swallowing of.—There are many people of opinion, that the swallowing of pebbles is very beneficial to health, in helping the stomach to digest its food, and a pebble-posslet is an old woman's medicine in the colic, in many parts of England. They usually order the small white stones to be picked out of gravel-walks for this purpose, and eat them in large quantities in some sorts of spoon meat, of which milk is an ingredient.

The thing that has given occasion to this practice seems to have been, that people observe the birds to pick up the gravel, and that they are never well unless they have frequent recourse to this to help their digestion: but this is no similar case at all, for the gizzard or stomach of a bird is made very strong, because the creature hath no teeth to chew its food; and this gizzard is lined with a rough coat, by the help of which and these stones, the food they swallow whole is so ground, as to yield its juices to the nourishment of the animal. But the stomach of man is formed so very differently, that it can never require those assistances to the comminution of food. Many people have, however, accustomed themselves to swallow not only these small white stones, but large pebbles, even to the size of a walnut each: these will often pass safely, and people who have long accustomed themselves to swallow them, boast of receiving

no injury from them: we can never know, however, that the death of such persons is not owing to them at last; and as they can do no good, it is best always to avoid them. There is one instance on record, of much mischief done by them, in our Philosophical Transactions, N^o 253. p. 190.

PEBBLE, Egyptian, constitutes the second family of the Siliceous genus in the mineralogical arrangement of Kirwan. This stone presents various colours together in the same specimen, either in regular or irregular concentric and alternating stripes or layers, or in dots and dendritical figures. The most usual colours are the yellowish and liver-brown, reddish-brown, isabella yellow, yellowish-grey, greyish, or reddish-white, milk-white, leek-green, and black, which last is only in dots and dendritical figures. It is found in spheroidal, or flat rounded masses, which are enveloped in a coarse rough crust. Its internal lustre, 1; external, 0; its transparency, 0; its fracture conchoidal; its hardness, 10; its sp. gr. 2.564, Brisson. Found principally in Egypt, sometimes in Europe, particularly in Lorraine. Kirwan's *El. of Mineralogy*, vol. i.

PECAQUE, ST., in *Geography*, a town of Mexico, in the province of Xalisco; 45 miles N. of Compostella. N. lat. 22°. W. long. 101° 30'.

PECARI, or TAJACU, in *Zoology*. See *Sus Tajassu*.

PECCANT, in *Medicine*, an obsolete term, which was much used by the humoral pathologists to denote every sort of morbid condition of the humours of the body, to which alone they ascribed almost all diseases. Hence their principal efforts were directed to the correction of the peccant matter, or to its evacuation. See *HUMORAL Pathology*.

PECETA, in *Commerce*, a Spanish silver coin. In 1772 the peccetas and reals were reduced to 9½ dineros fine: the mark being divided into 12 dineros, and the dinero into 24 grains. The old Mexican peceta of two Mexican reals (1736) is by the assay worse than the English standard, 4½ dwt.; its weight is 4 dwt. 7¼ gr.; its content in pure silver grains 93.6; and its value 1s. 1d. sterling. The peceta of two reals of plate (1721) is worse 1 oz. 7 dwt.; its weight 3 dwt. 16½ gr.; its content in pure silver grains 71.9; and its value 10d. sterling. The Mexican peceta (1774) worse 8 dwt.; its weight 4 dwt. 7½ gr.; its content 92.3; and value 1s. 0¾d. sterling. The peceta provincial of two reals of new plate (1775) worse 1 oz. 9½ dwt.; weight 3 dwt. 18 gr.; content 72.2; and value 10d. sterling.

PECETO, in *Geography*, a town of France, in the department of the Po; 3 miles S.W. of Chieri.

PECHANTRE, NICHOLAS DE, in *Biography*, a French poet, was born at Toulouse in 1638. He gained the poetical prize from the academy des Jeux Floraux three times. His tragedy of Geta was performed at Paris in 1687, with great applause. This was followed by Jugurtha, the Death of Nero, and some others. Pechantre died in the year 1708. Moreri.

PECHAREE, in *Geography*, a town of Hindoostan, in the circar of Chandaree; 35 miles W.S.W. of Chandaree.

PECHBLENDE, in *Mineralogy*. See *URANIUM*.

PE-CHE-LEE, in *Geography*. See *PE-TCHELI*.

PECHEM, in the *Materia Medica*, a name given by the modern Greek writers to the root called *behem* by Avicenna and Serapion. Many have been at a loss to know what this root pechem was; but the virtues ascribed to it are the same with those of the *behem* of the Arabians; its description the same, and the division of it into white and red, is also the same as that of the *behem*. Nay, the word pechem is only formed of *behem*, by changing the *b* into a *p*, which is very common,

common, and the aspirate into χ , or *ch*, which is as common.

Myrepsus, who treats of this root, says the same thing that the Arabian Avicenna says of *behem*, namely, that it was the fragments of a woody root, much corrugated and wrinkled on the surface, which was owing to its being so moist whilst fresh, that it always shrunk greatly in the drying.

PECHIA, in *Geography*, a town of Servia, on the Drino; 35 miles N.E. of Ragufa. N. lat. $43^{\circ} 14'$. E. long. $19^{\circ} 15'$.

PECHLARN, or POCHLARN, a town of Austria, on the right bank of the Danube. The river is very wide, and here the Romans had a harbour for their navy. They called it "Præclara," and it was considered as one of the strongest places in the country. It was formerly the residence of the margraaves of Austria. It was given by the emperor Otho to the bishop of Ratibon; 45 miles W. of Vienna. N. lat. $48^{\circ} 14'$. E. long. $15^{\circ} 20'$.

PECHLIN, JOHN NICHOLAS, in *Biography*, an ingenious physician, was born at Leyden in the year 1646. He was educated exclusively in his native city, until he received the degree of doctor in 1667; after which he travelled into Italy, and visited the principal universities of that country. He did not remain long without an opportunity of communicating the extensive knowledge which he had obtained; for in 1673 he was appointed to a professorship at Kiel, in Holstein, where he soon attained a high reputation. In 1678 he was elected a member of the academy "Naturæ Curiosorum;" and in 1691, a fellow of the Royal Society of London. He gained the favour and patronage of the court, and in 1680 was appointed first physician to the duke of Holstein-Gottorp, and subsequently his librarian and counsellor. In 1698 he accompanied that prince in a journey to Stockholm; and again, in 1704, he visited that capital with the hereditary prince, to whom he was appointed tutor, and died there in February, 1706.

Pechlin was author of several works, some of which evince a great degree of good taste and eloquence of style, especially his essay, entitled "Metamorphosis Æsculapii et Apollinis Pancreatici;" which was a satire against Sylvius de la Boë and De Graaf, and was published under the fictitious name of Janus Leonicerius Veronensis. His other tracts were entitled "De Purgantium Medicamentorum Facultatibus," Leyden, 1672; "De Vulneribus Sclopetorum," Kiel, 1764; "De Aëris et Alimenti Defectu, et Vitâ sub Aquis," *ibid.* 1676; "De Habitu et Colore Æthiopum," *ibid.* 1677. The feat of the colour of Negroes he pointed out in the *rete mucosum*, and imagined it was occasioned by bile. "Theophilus Bibaculus, sive de Potu Theæ," Francfort, 1684, a poetical eulogium on the virtues of tea; and "Observationum Physico-Medicarum Libri tres," Hamburg, 1691,—a collection containing some curious cases, but also evincing a considerable share of credulity in the author. Eloy Dict. Hist. de la Med.

PECHMEJA, JOHN, a French writer, was born at Villa Franca in 1741. He became professor of elocution in the college of La Flèche, and died in 1785. His eulogy on the celebrated Colbert was crowned with the approbation of the academy in 1773; but he is principally known by a work in poetic prose, called "Telephe," 2 vols.

PECHOR, in *Geography*, a town of Hindooistan, in the circar of Gohud; 25 miles S.S.E. of Gwalior.

PECHOWLY, a town of Hindooistan, in the circar of Chandaree; 40 miles N.W. of Chandaree.

PECHSTEIN, in *Mineralogy*. See PITCHSTONE.

PECHYAGRA, in *Medicine*, a name given by authors to the gout affecting the elbow.

PECHYS, a name used by some anatomical writers for the elbow.

PECHYTYRBE, an epithet used by some medical writers for the scurvy.

PECK, a measure, or vessel used in measuring grain, pulse, and the like dry substances.

The standard, or Winchester peck, contains two gallons; each gallon of corn measuring 268 $\frac{2}{3}$ cubic inches, and weighing about eight pounds troy.

Four pecks make a bushel; four bushels a comb, coom, or carnock.

Besides the general, or Winchester pecks, there are local pecks, containing some more, some less; as the Lancaster peck, containing six gallons, &c. See MEASURE and WEIGHT.

PECK, FRANCIS, in *Biography*, was born at Stamford, in Lincolnshire. He was educated at Cambridge, where he took his degree of M.A. He entered holy orders, and became curate of King's Clifton, in Northamptonshire; after which he obtained the rectory of Godeby, in Leicestershire, which was the only preferment he ever obtained. In 1721 he published proposals for printing the history and antiquities of his native town; and in 1727 he published the work, entitled "Academia tertia Anglicana. or the Antiquarian Annals of Stamford, in Lincoln, Rutland, and Northampton-shires." His inquiries relative to this single object led him to extend his researches; and in 1729 he printed a sheet of "Queries concerning the Natural History and Antiquities of Leicestershire and Rutland." Though he made considerable progress in collecting materials for a work on those subjects, it never made its appearance. In 1732 he published the first volume of his "Desiderata Curiosa," or collection of divers scarce and curious pieces, relating chiefly to matters of English history; consisting of choice tracts, memoirs, letters, wills, epitaphs, &c. A second volume followed in 1735, and the whole was reprinted in one volume, quarto, in 1779. In the year 1735 he displayed his industry in "A complete Catalogue of all the Discourses written both for and against Popery, in the Time of King James II.;" and in 1739 he edited nineteen letters of Dr. Henry Hammond. In the following year he published two volumes, quarto; one entitled "Memoirs of the Life and Actions of Oliver Cromwell, as delivered in three Panegyrics of him written in the Latin Language; with a Collection of divers curious historical Pieces, relating to Oliver Cromwell, and a great Number of other remarkable Persons." The other was entitled "New Memoirs of the Life and poetical Works of Mr. John Milton," with critical illustrations. This was the last of his publications. He died in 1743, leaving behind him materials for nine different works, which he had in contemplation. Of his MSS. the greater part came into the possession of sir Thomas Cove, of which the most valuable were five volumes, quarto, written fairly for the press, entitled "Monasticon Anglicanum; Supplementis novis adauctum." These were presented to the British Museum in 1779.

PECKELSHEIM, in *Geography*, a town of Westphalia, in the bishopric of Paderborn; 15 miles S.E. of Paderborn. N. lat. $51^{\circ} 34'$. E. long. $9^{\circ} 15'$.

PECKHAM, a hamlet in the parish of Camberwell, hundred of Brixton, and county of Surrey, England, is situated on the road from London to Greenwich, at the distance of $4\frac{1}{2}$ miles from St. Paul's cathedral. In Domesday book the manor is mentioned as belonging to Battersea, and being the property of Odo, bishop of Baienx, half-brother to the Conqueror. At a later period it appears to have been divided into two manors, called Bredinghurst and

Bafynges,

Basynges, from persons of that name who possessed them, in the reigns of king John and Edward I. The manor of Bredinghurst is now vested in the widow of William Shard, esq.; but the manor-house has been lately demolished, and the site let on building-leases. At Peckham are meeting-houses for the Anabaptists and Presbyterians. Here is annually held a large show fair, similar to that of St. Bartholomew in Smithfield, London.

The parish of *Camberwell* having been inadvertently omitted in its proper place, we deem it advisable to state a few particulars under this head. It is bounded by the parish of Newington-Butts, St. George's Southwark, and Rotherhithe, on the east; by Deptford and Beekenhurst, in Kent, on the south; by Croydon, and a detached part of Battersea, on the west; and by Lambeth on the north. At the time of the Domesday survey it comprehended one manor only, which was held of the Conqueror by Haimo, the sheriff; but it was soon afterwards divided, and eventually became several distinct manors, called Camberwell-Buckingham, Milkwell Camberwell-Ferne or Fryen, Dowdale or Uredale, and Deptford Strond. There were also two inferior manors, Camberwell and Cold-Abbey, both of them held of Camberwell-Buckingham. The land in this parish is mostly possessed of great fertility, and, exclusive of the sites of the houses, is laid out "in nearly an equal proportion between arable, pasture, and gardens."

Camberwell village is distant about three miles and a quarter from St. Paul's cathedral in London. The church here was erected about the commencement of the reign of Henry VIII., and consists of a nave, chancel, and two aisles, with a small embattled tower at the west end; the whole composed of flints and rough stone, except the south-west part, which is of brick. The chancel is of a very singular shape, being the section of a hexagon. In the east window of the north aisle are several full-length figures painted upon glass. These are now much mutilated, as well as the inscription beneath, which, however, is sufficiently entire to inform us, that they were intended to represent some members of the Muscamp family, who had their burying-place in this aisle. There are, besides, in the same window, two imperfect representations of female saints. This church contains many monuments of the Scotts, Bowyers, and others who have been interred within its walls. In the parish register here are several very curious entries: one of which records an instance of a woman bearing a child at the age of sixty-three.

In this parish are several charity-schools, which are supported chiefly by subscription, except the free grammar-school. This was founded and endowed by the Rev. Edward Wilson, in the reign of James I., and now affords education to twelve boys. But the chief charitable foundation of which it has to boast is Dulwich-College, situated in the hamlet whence it derives its name. Camberwell parish contains, according to the population returns of 1811, 2060 houses, and 11,309 inhabitants. See DULWICH. Lyfons's Environs of London.

PECORA, in the Linnæan system of *Zoology*, a term, comprehending a whole order of quadrupeds, in the class of mammalia. The characters of this order are, that the creatures have no fore-teeth in the upper jaw; the lower jaw has six or eight fore-teeth, which are placed at a considerable distance from the molars or grinders. The paps of this order of animals are situated in the groin, and their feet have hoofs. Of this order Linnæus enumerates eight genera; the *camel*, *moschus*, *cervus* or *stag*, the *camelopardalis*,

the *antilope*, the *capra* or *goat*, the *ovis* or *sheep*, and *bos* or *ox*.

PECQUET, JOHN, in *Biography*, a distinguished anatomist, was a native of Dieppe, and a graduate of the university of Montpellier. He was endowed with an active and intelligent mind, and pursued the study of anatomy with great ardour and ingenuity, which he evinced by the discovery of the thoracic duct and the receptaculum chyli, in 1647, while yet a student; by which the hitherto imperfectly known system of the lacteals was completed. After this happy indication of his skill, he settled, with a view to practise his profession, in his native town; but soon afterwards going to Paris, he recommenced his anatomical researches, for the purpose of demonstrating completely the important vessels which he had discovered; and he became acquainted with the most able anatomists in that metropolis. He succeeded completely in this demonstration, and traced the progress of the chyle, which is taken up from the intestines, by the lacteal vessels, into his receptacle, and by the thoracic duct to the left subclavian vein. This discovery soon gave his name a celebrity throughout Europe; and, as has generally happened in cases of important discoveries, it was doubted and denied by some, while others contended that it was not new. The work in which he published the discovery was entitled "Experimenta nova Anatomica, quibus incognitum hactenus Chyli Receptaculum, et ab eo per Thoracem in Ramos usque subclavios Vasa lactea deleguntur;" to which was subjoined a dissertation, "De Circulatione Sanguinis et Chyli Motu," 1651. It was reprinted in 1654, together with an essay "De Thoracis lacteis," in answer to Riolan; and many subsequent editions have appeared. Pecquet was a man of considerable acquirements, in addition to his anatomical skill, and was a member of the Royal Academy of Sciences from the year 1666. He is said, however, to have shortened his days by an unfortunate attachment to the use of spirituous liquors. He died at Paris in February, 1674. Eloy Dict. Hist. de la Med.

PECQUET, ANTHONY, a French writer, was born in 1704. He attained the rank of grand master of the water-works and forests of Rouen, and superintendent of the military school. The works by which he is principally known are "An Analysis of the Spirit of Laws, and the Spirit of Political Maxims," 3 vols.; "The Forest Laws of France," 2 vols.; "Thoughts on Man." He also translated the Pastor Fido of Guarini, and other Italian works into French. He died in 1762.

PECQUETI RECEPTACULUM, in *Anatomy*, a dilated portion just at the beginning of the thoracic duct, discovered by Pecquet. (See ABSORBENTS.) It is often called receptaculum chyli.

PECTEN *of the Pubes*, the prominent ridge of the os innominatum, situated over the foramen ovale, and giving origin to the pectinalis muscle. See EXTREMITIES.

PECTEN, in *Natural History*, the name of a tribe of shell-fish, the characters of which are these: it is a bivalve shell, shutting close in all parts, of a flattened shape, striated in the manner of a comb, and often auriculated, sometimes only semi-auriculated, and in some species not auriculated at all. There are also some few species which are elate, not flat, as the others, classed in the Linnæan system with the *ostrea*; which see. See also CONCHOLOGY (*Ostrea*).

This tribe of shells has had its name, pecten, from the longitudinal striæ with which its surface is covered, which resemble the teeth of a comb. According to the general character of this shell, it will be easy to perceive that it is

meant to include the cockles as well as the scollops; these being the pectens without ears, and with lefs flat or elated shells. These are called by all authors by a name which is only diminutive of pecten, *pedunculus*. And though the having ears is the common mark of distinction between the pectens and the cockles, which last usually have none, yet the genera are not distinct, as some have supposed; for there are shells allowed to be pectens, or scollops, which have yet no ears, and others universally allowed to be pectuncles, or cockles, which have ears. Hence appears the error of Lister, who made these two distinct genera, and gave the ears and the equal convexity of both shells as the great characters of them: these, though good marks to distinguish the species by, are by no means unalterable enough to found different genera upon.

The genus of pectuncles, or cockles, has been made by all authors a very extensive one, but the reader will find all the supposed species of it very aptly received into the genus of the *cardiformis*, or heart-shell, (see *CORDIUM*.) and the pectens.

According to this establishment of the genus of the pecten, the species are to be enumerated under several distinct heads.

Thus, some pectens are auriculated on both sides: of these we have seventeen species.

Of those pectens which are semi-auriculated, we have five species.

Of those pectens which have no ears at all, we have seven species.

This shell-fish is one of the spinners of the sea, having power of spinning or forming threads like the muscle; but they are much shorter and coarser even than those of that fish, so that they can never be wrought into any sort of work, in the manner of the longer and finer threads of the *pinna marina*. The use of these threads, which the pecten or scollop spins, is to fix the creature to any other body that is near, whether it be a stone, a piece of coral, or another shell. All these threads proceed, as in the muscle, from one common trunk; they make their way out of the shell in those pectens which have only one ear, a little below that ear; in the others, probably they issue out on both sides. It is an evident proof, that the fish has a power of fixing itself at pleasure, to any solid body, by means of these threads, that after storms the scollops are often found tossed upon rocks, where there were none the day before; and yet these are fixed by their threads, as well as those which had remained ever so long in their place. They form their threads in the very same manner with the muscle, only their organ which serves for spinning is shorter, and has a wider hollow, whence the threads are necessarily thicker and shorter. See *MUSCLE*.

PECTEN Veneris, in *Botany*, Venus' Comb, so called because the long parallel beaks of the seeds assume something of the aspect of a long-toothed comb. See *SCANDIX*.

PECTINALIS, or *PECTINEUS*, (le peigné, le pubo-fémoral,) in *Anatomy*, a muscle of the thigh, placed at the upper and front part of the limb, and extending from the horizontal portion of the pubes to the upper part of the linea aspera of the femur. It is flattened, elongated, and measures about three finger-breadths above, rather less below. The fascia lata and the crural vessels cover its anterior surface above, the sartorius lower down. It covers the pubes, the hip joint, the obturator externus, the obturator vessels and nerve, and the second head of the triceps. Its inner edge is parallel to the outer margin of the first head of the triceps, by which it is a little covered; the outer edge is

parallel to the psoas magnus. Its upper extremity is fixed to the upper and posterior edge of the pubes, chiefly by fleshy fibres, from the spine or tuberosity of that bone, to the beginning of the linea ileopectinea: thence it descends obliquely outwards and backwards, and, arriving opposite to the little trochanter, is twisted on itself, so that the anterior surface is turned outwards, the posterior inwards: it is then inserted in the line, which descends from the basis of the little trochanter to the beginning of the linea aspera.

The lower part of the pectinalis consists of a flattened tendon, extending upwards on the front of the muscle. The fleshy fibres arise from the pubes by very short aponeuroses, and terminate on the back of the tendon.

It bends the thigh on the pelvis, or *vice versa*: it contributes to maintain the pelvis in equilibrio on the lower limbs, when we stand. It will draw the thigh inwards, or towards the opposite limb, and carry it across the other. It rotates the thigh-bone outwards.

PECTINATI MUSCULI, the muscular fibres of the right auricle of the heart, so called because they are arranged in parallel fasciculi, somewhat resembling the teeth of a comb. See *HEART*.

PECTINATION, *Combing of the Head*. Frequent pectination is recommended by many physicians to women, and men who wear their hair, as an exercise; and, at the same time, a kind of friction.

PECTINATUM FOLIUM, in *Botany*, a simple leaf, whose numerous, deep, parallel segments, resemble the teeth of a comb. See *LEAF*.

PECTIS, might be so called perhaps, as professor Martyn says, from πᾶσις, *neatly combed or trimmed*. From looking at the original specimen of *P. ciliaris*, we are disposed to think that Linnaeus, the author of the name, had more particularly in his mind the idea of *pecten*, a comb, as applicable to the fringed bases of the leaves.—Linn. Gen. 430. Schreb. 564. Willd. Sp. Pl. v. 3. 2130. Mart. Mill. Dict. v. 3. Juss. 182. Lamarck Illustr. t. 684. Gært. t. 171. Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositae oppositifoliae*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common calyx* cylindrical, of five oblong, obtuse, nearly equal leaves. *Cor.* compound, radiated; perfect florets about six, rarely fewer or more, in the disk, funnel-shaped, equally five-cleft; female ones in the radius five, rarely fewer, ligulate, ovate, rather longer than the calyx. *Stam.* in the perfect florets, filaments five, short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, germen linear; style thread-shaped; stigma cloven; in the female, germen linear; style thread-shaped; stigmas two, revolute. *Peric.* none, except the unchanged spreading calyx. *Seeds*, in all the florets, solitary, linear. Down of three or five chaffy bristles, various in length and breadth. *Recept.* naked.

Eff. Ch. Receptacle naked. Seed-down of various chaffy bristles. Calyx of five leaves, cylindrical. Florets of the radius five.

1. *P. humifusa*. Swartz Ind. Occ. v. 3. 1362. Willd. n. 1. (*Jacobaea humifusa*, *hyperici foliis*; Plum. Ic. 84. t. 95. f. 2.)—Leaves spatulate, obtuse, fringed at the base. Flowers stalked. Calyx-leaves elliptical. Stem procumbent.—Native of various islands in the West Indies, in open barren spots, communicated by Dr. Swartz. *Root* annual, tapering, with many fibres. *Stems* herbaceous, procumbent, three or four inches long, much branched, square, smooth, leafy. *Leaves* crowded, opposite, each pair crossing the others, sessile, about half an inch long, spreading, spatulate, obtuse, entire, thickened, and sometimes roughish, at the

the edge, tipped with a very minute point; their under side paler, besprinkled with glandular dots; the base linear, elongated, clasping the stem, fringed with four or five bristly coarse teeth at each side. *Flowers* scarcely more than one on each branch, towards the extremity, axillary, on a simple, naked, sometimes downy, stalk, half an inch or more in length. *Calyx-leaves* elliptical, folding over each other, hardly half an inch long, strongly keeled, obscurely dotted, obtuse, emarginate, and minutely downy at the summit. *Florets* yellowish; those of the disk, according to Swartz, ten, rather unequally five-cleft; those of the radius five, short, oblong, entire. *Seeds* all linear-oblong, angular, black, those of the disk often abortive. *Down* of five chaffy bristles, lacinated at the base, ferrated at the edge.

2. *P. prostrata*. Cav. Ic. v. 4. t. 324. Willd. n. 2. —Leaves oblong, fringed at the base. Flowers sessile. Calyx-leaves elliptic-oblong. Stem procumbent.—Native of New Spain. It flowered at Madrid in the autumn of 1795. This seems, as Willdenow remarks, very near the former, from which it differs in having longer leaves, but especially in the want of stalks to the flowers, which are quite sessile, either at the ends of the branches, or in the fork between them. The calyx-leaves moreover appear to be much narrower, and scarcely folding over each other, but we have only Cavanilles's plate to judge by. *Down* of five awl-shaped chaffy scales. The leaves are an inch or more in length; glaucous and dotted, as in the foregoing, underneath.

3. *P. ciliaris*. Linn. Sp. Pl. 1250. Am. Acad. v. 5. 407. (Jacobæa foliis falcis, ad margines villosis; Plum. Ic. 145. t. 151. f. 2?)—Leaves linear-lanceolate; tapering, and strongly fringed, at the base. Flowers axillary, sessile. Stem erect.—Native of Jamaica. *Browne* in *Herb. Linn.* *Root* annual. *Stem* erect, hardly a span high, divided, or slightly branched, leafy for the most part, obscurely marked with a narrow, downy, intrafoliaceous line at each side. *Leaves* opposite, clasping the stem, above an inch long, linear, or somewhat lanceolate, obtuse with a small point; smooth on both sides; copiously and irregularly dotted, but not glaucous, beneath; entire, but rough at the edge with minute teeth; tapering at the base, and fringed in that part, usually for the space of half an inch, with numerous, distant, coarse, long, tawny, bristly hairs, directed upwards in a parallel manner. We can find no flowers on either of Browne's two specimens, but in the *Amœn. Acad.* they are described as "axillary and sessile; the corolla yellow and small; the seeds of the disk crowned with five bristles, membranous at the base, those of the radius with two only." Such are all the particulars which we can positively ascertain respecting this plant, whose history is remarkably confused, especially in Willdenow. The only synonym cited by Linnaeus in *Sp. Pl.* is Plumier's, which we dare not admit without a query. Its greater size may be no objection, but the fringe of the leaves extends much too far, and there is a representation of a short external calyx to one flower, which cannot agree with any *Pectis*. The latter may be an error of the copier or engraver. We see no other exception to make, but on the contrary the shape and situation of the flowers answer perfectly to the above description, which cannot have been made from this plate, because the colour of the corolla, and structure of the seed-down, could not have been learned from thence. But what can be the *P. ciliaris* of Swartz's *Obf. 307*? He describes the stem and branches as diffuse, the leaves perforated, as it were, at the margin; the flowers stalked, solitary, either in the summits or forks of the branches. He says his plant inhabits barren places in Hispaniola, flowering in June, and the leaves are

eaten fresh with bread, having a sweet smell like livery. He quotes *Hieracium minimum*, longis integris et angustis foliis; Sloane *Jam. v. 1. 255*; by mistake changing *angustis* to *argenteis*, and omitting the figure, which is t. 150. f. 1. Willdenow copies him implicitly of course. Now this figure, though bad, is not unlike our first species, with which however Swartz's description will not agree, nor do we know any plant that exactly answers to it. The leaves in Plumier's t. 86. f. 1. come the nearest as to the dots. See *P. punctata*.

4. *P. linifolia*. Linn. Sp. Pl. 1250. Am. Acad. v. 5. 407. (*P. punctata*; Jacq. *Amer.* 216. t. 128. Swartz *Obf.* 308. *Tagetes*? minor, caule subdiviso diffuso, foliis linearibus integris; Browne *Jam.* 319. *Hieracium* fruticosum, angustissimis gramineis foliis, capitulis parvis; Sloane *Jam. v. 1. 255. t. 149. f. 3*, very imperfect.)—Leaves linear, acute, with two or four setaceous teeth at the base. Stem forked, many-flowered. Seed-down of a few spreading awl-shaped bristles.—Native of Jamaica, Hispaniola, and Carthage, flowering from June to October. The root is annual. *Stem* two or three feet high, much branched and repeatedly forked, erect according to Jacquin, but diffuse according to Browne; the branches angular and smooth. *Leaves* about an inch and a half long, linear and very narrow, tapering at each end, entire, somewhat revolute when dry, smooth, besprinkled with dots beneath, even in Browne's own specimen which is described in *Am. Acad.*, though they are there said to be *levia*, (as opposed to dotted,) nor are the dots wanting in two other specimens now before us. Jacquin's figure however represents them rather too minute and copious. At the base of the leaf, on each side, is one or two pair of spreading, bristle-shaped teeth. *Flower-stalks* numerous, solitary from the forks of the stem, single-flowered, half an inch long, slender, angular, smooth, often bearing one or two setaceous bristles. *Flowers* small, yellow, with more or less of a purple tinge; florets of the disk three, rarely but two, their seed crowned with two spreading, smooth, awl-shaped bristles, about the length of their own corolla; those of the radius five, with three similar bristles to their seed. In these respects all our specimens answer to the Linnaean description; as also to that of Jacquin, so that there can be no doubt of his plant, though we are obliged to prefer the Linnaean specific name, of nearly the same date.

5. *P. punctata*. Linn. Sp. Pl. 1250, excluding Jacquin's synonym. (*P. ciliaris*; Swartz *Obf.* 307? *Chondrilla* foliis angustis et ad oras punctatis; Plum. Ic. 74. t. 86. f. 1.)—Leaves oblong, acute, with two or four minute bristles at the base. Stem forked, many-flowered. Seed-down of several short lacerated scales.—Native of the West Indies. We have specimens in the herbarium of the younger Linnaeus, marked *P. patula*, apparently a manuscript name, every body having considered the foregoing as the Linnaean *punctata*. But that being certainly *linifolia*, and the synonym of Plumier answering well to the present, even in the parts of fructification, though the dots of the leaves are rather too marginal and regular, we retain for it the name of *punctata*; an appellation by no means discriminative indeed, as every known species is dotted. The size and habit of the plant are like the last; the stem angular, purplish, repeatedly forked, and finally somewhat panicled. The leaves however are scarcely more than half as long, and nearly twice as broad, strongly dotted beneath, frequently rough-edged; their base furnished with one or two pair of extremely small bristles, not half the size of what are observable in *linifolia*. *Flower-stalks* much the same, but with more numerous, smaller, more chaffy bristles. *Florets* of the disk about six; those of the radius five. *Seed-down* in each of from three to

five small, chaffy, fringed and jagged, brown scales, smallest, and perhaps fewest, in the marginal florets. In three instances we find one of these scales, in the disk, elongated into a hispid bristle, extending rather beyond the *corolla*; a conclusive proof of the variableness of the *seed-down* in *Pectis*, which is notwithstanding a most natural genus. Is it possible that this species can be *P. ciliaris* of Swartz? Perhaps the bristles of the *seeds* may be sometimes more numerous than we have found them, and then his otherwise unintelligible description of the *sete* and *pappus* will be accounted for. We cannot ascertain what this author intends by *P. linifolia*, for which he has merely a reference to Petiver, (*Rapunculus Jamaicensis, folio tenuiflora*.) without page or plate, a citation we are unable to verify. That reference may belong to the real *linifolia*, though the latter should seem to be Swartz's *punctata*.

6. *P. pinnata*. Lamarck Journ. d'Hist. Nat. v. 2. 150. t. 31. Cav. Leccion. 203. (Schkubria abrotanoides; Roth. Catal. v. 1. 117. v. 2. 116. Willd. Sp. Pl. v. 3. 2130.)—Leaves deeply pinnatifid, thread-shaped. Stem panicled. Seed-down of several jagged scales, as long as the florets.—Frequent in New Spain. It has been cultivated for twenty-five years past in the gardens of Spain and France. We obtained it in 1792, from that of Dr. Bellardi at Turin, by the name of *P. trifida*. Roth says the *root* is annual, which we believe to be the case; Lamarck makes it perennial. Stem erect, two feet high, leafy, angular, deeply furrowed, smooth, alternately branched, panicled, many-flowered. Leaves alternate, pinnatifid, a most capillary and obtuse, like some of the finer kinds of *Artemisia*, one inch and a half or two inches long, smooth, very bitter, besprinkled all over with minute glandular dots. Flower-stalks scattered and terminal, aogular, roughish, slender, single-flowered, with one linear *bractea*. Calyx turbinate; its leaves obovate, besprinkled with minute shining dots, and beautifully tinged with violet. Corolla yellow; the radiant florets but one or two, ovate; those of the disk about six. Seeds square, with bristly angles. Down of five or more very beautiful, rather unequal, lanceolate, acute, membranous, glittering scales, all streaked with purple, their edges more or less deeply jagged or fringed. These scales are about as long as the *corolla* of each floret, and we do not find them ever accompanied with any bristles. A comparison of the *seed-down* with that of the last, will sufficiently shew, that the present plant is not authorized to rank as a distinct genus on that account. As to the habit, the *leaves* being alternate is more material than their division, to which last character the fringes of the other species may be considered as an approach. That they are full of glandular dots we readily perceive; though Lamarck indicates the contrary, as a difference between this plant and *Pectis*, all whose species, he rightly says, have dotted leaves. Roth appears to have known nothing of *Pectis*, at least on his first establishment of his genus *Schkubria*; nor was he perhaps sufficiently aware of the perils of such an undertaking, in this intricate class. The name of Schkuhr, notwithstanding its unfortunate orthography, is richly entitled to botanical commemoration, and we trust that some stable genus will, hereafter, be honoured with the charge of conveying it down to posterity. S.

PECTIS, an ancient musical instrument, of the form or use of which we are not very certain. Athenæus says, that the *pectis*, *magadis*, and *barbiton*, were the same instrument. It has been supposed to have been a dicord, a small instrument of two strings, with a neck, or finger-board, by which they were shortened with the pressure of the fingers, and a complete scale produced.

PECTORAL, something relating to the breast, *pectus*. In the Romish church, bishops, and regular abbots, wear a pectoral cross, *i. e.* a little cross of gold, hanging from the neck down to the breast.

PECTORAL Medicines, in the language of the older physicians, were all those medicines which were appropriated to the relief of the disorders of the breast or lungs. The epithet, however, was indefinite, inasmuch as it included demulcents, attenuants, astringents, and even anodynes, or whatever contributed to ease the breathing and cough. It has, therefore, been discarded. The more limited term, *expectorants*, is preferable.

PECTORAL Syrup. See SYRUP.

PECTORAL Wine. See WINE.

PECTORALE, or PECTORAL, in the Jewish Law. See RATIONALE.

PECTORALES, in Anatomy, two muscles placed on the front of the chest.

The *pectoralis major* (sterno-humerien) is the largest of the two, covers the front of the chest and of the axilla, and extends from the clavicle, the sternum, and the cartilages of the true ribs, to the front edge of the bicipital groove of the humerus. It is broad, and approaches to the triangular figure.

Its anterior surface is covered by the skin, the fibres of the latissimus colli being interposed between them above, and the mammary gland about the middle. The posterior surface covers, towards the inner side, the front of the sternum, to which it is attached; more externally, the cartilages of the true ribs, to which it is also attached, excepting the first and sometimes the last. This attachment is observed towards the sternal ends of the cartilages, and occupies a broader space in the lower than in the upper ones: it extends through the whole length of the sixth. Below the latter, it covers the rectus and obliquus externus abdominis. It also covers, in succession, beginning from the sternum, the true ribs, the external intercostal muscles, the subclavius, the pectoralis minor, the serratus magnus, the axillary vessels, the brachial plexus, and the coraco-brachialis and biceps muscles. The surface of the muscle is united to the parts just enumerated by loose cellular tissue, the quantity of which increases as we approach the axilla.

The internal edge is somewhat femicircular in its outline, and is fixed to the middle of the front of the sternum from its upper part, to the articulation of the cartilage of the sixth rib. In front of the ensiform cartilage it is confounded with the edge of the opposite muscle, and has a connection with the upper end of the linea alba; a small slip of its fibres is also connected to the upper edge of the aponeurosis of the obliquus externus abdominis, and generally covers the upper slip of that muscle.

The upper edge may be divided into two parts; the first, which is properly superior, is attached to the inner half of the front edge of the clavicle: the second is rather external, and is stretched obliquely from the clavicle to the humerus. The latter is directed downwards and outwards, and is nearly parallel to the inner edge of the deltoid, from which it is separated by a cellular line, broader above than below, and containing the cephalic vein. Sometimes the edges of the two muscles are confounded.

The lower edge is connected to the aponeurosis of the obliquus externus, goes obliquely outwards and backwards in front of the chest, then before the axilla, of which it forms the front edge; it then descends a little, and terminates on the humerus. This edge is thin towards the chest, and thicker at the axilla, where the skin turns in a little on its posterior edge.

The

The superior and inferior margins of the great pectoral muscle are united at a truncated angle, about two inches broad, attached to the front edge of the bicipital groove.

The sternal and the clavicular portions of the muscle may be more or less distinct from each other: they can sometimes be separated throughout.

The attachments to the clavicle and sternum are by no means of very short aponeuroses: those of the right and left muscles decussate in the front of the sternum. Towards the lower part of the chest, and upper part of the abdomen, a broader aponeurosis is seen, united to that of the obliquus externus. To the humerus the pectoralis major is attached by a broad tendon, from which productions are continued to line the bicipital groove, united to the tendons of the latissimus dorsi, teres major, and supra spinatus, and to form a connection with the aponeurosis covering the muscles of the arm. This tendinous insertion, and the muscular fibres connected to it, are twisted on themselves: the fibres of the clavicular portion are on the outside, and pass downwards: those of the pectoral are behind the former, and pass upwards.

The muscular fibres are not all alike in length or direction. Those which come from the clavicle are the shortest, descend from within outwards, and terminate on the front of the tendon. The fibres from the upper part of the sternum are rather longer, go horizontally outwards, and end on the front of the tendon, externally to the former. The remaining fibres go from below upwards, and increase in length and obliquity from above downwards: they end on the posterior surface of the tendon, and are turned in successively, one under the other, as they reach the tendon, so that the lower ones are fixed to the upper part of the tendon.

This muscle executes the reciprocal motions of the chest and arm. If the latter be hanging by the side of the body, the pectoralis major will move it forwards and inwards, so as to carry it across the front of the chest: when the arm has been elevated, it will draw the limb down again: it will also retract the humerus inwards, particularly if it has been turned out. The clavicular portion will co-operate with the deltoid in elevating the humerus. Acting in conjunction with the latissimus dorsi and teres major, it will draw the limb close to the side. When the arm is fixed, as in seizing any body before or above us, this muscle brings the trunk to the arm: hence it is an important agent in climbing.

The *pectoralis minor* (*ferratus minor anticus*, *collo-coracoidien*) lies on the front and upper part of the chest, and extends from the third, fourth, and fifth ribs to the coracoid process: it is flattened and triangular, with the basis of the triangle turned downwards and inwards, the apex upwards and outwards. The anterior surface is covered by the pectoralis major; the posterior covers the ribs, the intercostal muscles, the *ferratus magnus*, axillary vessels, and brachial plexus. The upper and lower edges are unattached, and present nothing remarkable: the former is the shortest. The basis of the muscle, turned downwards and inwards, is fixed to the upper edge and external surface of the ribs mentioned above, or to the second, third and fourth, by broad and thin aponeuroses. Thence it is continued backwards and outwards, growing at the same time narrower, and is fixed to the coracoid process, where it is connected to the coracobrachialis.

The aponeuroses, by which it is fixed to the ribs, have been mentioned: a flattened tendon connects it to the coracoid process: the fleshy fibres are continued obliquely between these, slanting from below upwards, backwards, and outwards: the upper are the shortest.

By drawing the coracoid process downwards and forwards, this muscle rotates the scapula, so that the anterior angle is depressed, and the inferior goes backwards. The rhomboidei and levator scapulae assist in producing the same effect. When it concurs with the *ferratus magnus*, the scapula is carried directly forwards. Supposing the shoulder to be firmly fixed, it may elevate the ribs, and thus assist in inspiration: the same remark will hold good of the pectoralis major also: hence, in asthmatic persons, and all those who breathe difficultly, the shoulders are habitually elevated, to bring these muscles into play, and they are more forcibly drawn up in the paroxysms of obstructed respiration.

PECTOREL, in our old writers, armour for the breast, a breast-plate, or petral for a horse. It is mentioned stat. 14 Car. II. cap. 3.

PECTORIS Os, in *Anatomy*, the same as sternum.

PECTORIS *Hydrops*. See *DROPSY of the Breast*.

PECTORIS *Osse*, in fish. The bones of the breast and belly are best sought after in the cetaceous and spinose kinds. In the spinose kinds they are these; the clavicles, the sternum, the scapulæ, or bones to which the pinnæ pectorales are affixed at their basis, the bones at the roots of the pinnæ ventrales.

The number, situation, and figure of these differ greatly in the several kinds of fish, and make very essential characters. See *FISH, Anatomy of*.

PECTORIS *Triangularis*. See TRIANGULARIS and PECTORALES.

PECUARI, among the Romans, those who farmed the public pastures, in order to let them to advantage.

PECUL, or PICUL, in *Commerce*, a weight used in some parts of the East Indies. The bahar of three peculs, or 300 catties, in Bantam weighs 396 lb. avoirdupois. The pecul of 100 catties at Cheribon weighs 125 lb. Dutch troy weight, or 132 lb. avoirdupois. Heavy goods are weighed in Malacca by the pecul of 100 catties, or 1600 taels. The pecul is = 135 lb. avoirdupois, and three peculs make a bahar. But what is called the China pecul at Malacca weighs 125 lb. avoirdupois. Rice is sold by the coyang of 40 peculs, or 5400 lb. avoirdupois. A coyang of rice in the isle of Amboyna contains 25 peculs. The pecul of pepper at Banjarmasin is 100 catties, or 125 lb. Dutch troy, or 135 lb. 10 oz. avoirdupois. The pecul and catty at Macassar are the same. In the isle of Ternate, the pecul and catty are the same as at Amboyna. The pecul in Siam is 50 catties, and the catty 20 taels, or 80 ticals. The Siam pecul weighs 129 lb. avoirdupois, and the catty 41 oz. 4½ dr. avoirdupois. The common weight in Trangania, on the farther peninsula, is the China pecul, which answers to 132 lb. 8 oz. 9 dr. avoirdupois.

PECULATE, PECULATUS, in the *Civil Law*, the crime of embezzling the public money, by a person who has the management, receipt, or custody thereof: so called *quasi pecunie ablatio*.

Civil lawyers use peculate for any theft of a thing, either sacred, religious, public, or fiscal. Peculate in the case of public money, is prosecuted even on the criminal's heir.

The Julian law, among the Romans, punished this crime with death in a magistrate; and with deportation, or banishment, in a private person. With us it is not a capital crime, but subjects the committer of it to a discretionary fine and imprisonment.

PECULIAR, in the *Canon Law*, a particular parish, or church, which hath jurisdiction within itself, for probate of wills, &c. exempt from the ordinary of the diocese, and the bishops' courts.

There are *royal peculiars*, and *archbishops' peculiars*.

The

The king's chapel is a royal peculiar, exempt from all spiritual jurisdiction, and reserved to the visitation and immediate government of the king himself, who is supreme ordinary.

Peculiar of the archbishops are exclusive of the bishops and archdeacons.

It is an ancient privilege of the see at Canterbury, that wherefoever any manors or advowsons do belong to it, they forthwith become exempt from the ordinary, and are reputed peculiar. In the province of Canterbury, there are more than a hundred such peculiar. In these peculiar jurisdiction is administered by several commissaries; the chief of whom is the dean of the arches for the thirteen peculiar within the city of London. See ARCHES.

There are also peculiar of bishops, exclusive of the jurisdiction of the bishop of the diocese in which they are situated: of these the bishop of London hath four parishes within the diocese of Lincoln; and every bishop, who hath a house in the diocese of another bishop, may therein exercise episcopal jurisdiction.

There are also peculiar of bishops in their own diocese, exclusive of archidiaconal jurisdiction.

The peculiar of dean, deans and chapters, prebendaries, &c. are places in which, by ancient compositions, the bishops have parted with their jurisdiction, as ordinaries to those societies. See COURT of Peculiar.

PECULIUM, the stock which a person in the power or property of another, as a slave, minor, or the like, may acquire by his own industry, without any advance or assistance from his father or master; but merely by their permission.

The word is usually derived *a pecunia et pecoribus*; because the whole estate anciently consisted in money and cattle.

PECULIUM is also used, among the Romanists, for what each monk or religious reserves, and possesses to himself.

Some say, that the peculium of a religious, when preferred to a cure, does not cease to belong to the monastery; and that the property thereof never absolutely resides in the religious himself.

PECUNIA, MONEY. See MONEY.

PECUNIA, in our old law-books, is sometimes used for cattle, and sometimes for other goods, as well as money.

In the emendation of the laws of Edward the Confessor, by William I., it is ordered, that no *viva pecunia, living money, i. e. cattle*, be bought or sold, except within cities, and that before three sufficient witnesses.

So in Domesday book, pecunia is frequently used, *pro pecude*; as pasture *ad pecuniam villa*.

PECUNIA *Ecclesia*, was anciently used for the estate of the church.

PECUNIA *Sepulchralis* was money formerly paid to the priest at the opening of the grave, for the good and behoof of the deceased's soul; and which our Saxon ancestors called *soul-fee*, and *animæ symbolum*.

PECUNIA, in *Mythology*, a goddess among the Romans, whom they invoked with a view of procuring money in abundance. But as the specie was coined of different metals, especially of gold, silver, and brass, and as one divinity would have too much occupation in taking care of the different coinages a particular one was appointed for each. Three goddesses represented upon some medals of the emperor Commodus and his successors, with a pair of scales, the cornucopia, and a heap of money by them, prove that there was at least that number, and the antiquaries agree that they presided over the coinage of three metals. Besides

these three divinities, there was also "Æs," or "Æsculanus," for the brass coin.

PEDACE, in *Geography*, a town of Naples, in Calabria Citra; 6 miles S. of Cosenza.

PEDACONDA, a town of Hindoostan, in Mysore; 15 miles E. of Chinna-Balabarum.

PEDAGE, PEDAGIUM, toll, or a local due exacted on persons, goods, and carriages, passing through certain places.

Pedage is usually levied for the repairing of roads, bridges, and causeways, the paving of streets, &c.—Anciently, those who had the right of pedage, were to keep the roads secure, and answer for all robberies committed on the passengers between sun and sun; which is still observed in some parts of England and in Italy, where there were guards, called *stationarii*, established for the security of merchants, particularly at Terracina, on the road between Rome and Naples.

PEDAGOGUE, or PEDAGOGUE, παιδαγωγός, formed from παιδων αγωγός, *puerorum duñor, leader of boys*, a tutor or master, to whom is committed the discipline and direction of a scholar, to be instructed in grammar and other arts.

M. Fleury observes, that the Greeks gave the name pedagogues to slaves appointed to tend their children, lead them, teach them to walk, conduct them to school, &c. The Romans also give the same denomination to the slaves who were entrusted with the care and instruction of their children.

PEDALE, as *à pedale*, implies a long note in the *basso continuo*, or thorough-bass, to be played or sustained without chords. See TARTO Solo.

PEDALES. See ABBOT.

PEDALINÆ, in *Botany*, a natural order of plants, established by Mr. R. Brown, Prodr. Nov. Holl. v. 1. 519, and named from *Pedaliium*, which belongs to it; see the next article. The characters are these.

Calyx in five, nearly equal, divisions.

Corolla of one petal, below the germen, irregular; its throat inflated; limb two-lipped.

Stamens four, two longer than the rest, included within the tube, and accompanied by the rudiment of a fifth.

Germen surrounded at the base with a glandular disk, of several cells, with one or two seeds in each. *Style* one. *Stigma* divided.

Drupa dry, armed with spines, of several cells.

Seeds with a paper-like skin. *Albumen* none.

Embryo straight.

Herbs with opposite leaves, and axillary flowers accompanied by a pair of bractæas.

PEDALIUM, a Greek name, chosen for this plant by professor David Van Royen, in allusion, as it seems, to the shape of the fruit. Πηδαλιον is, as professor Martyn says, the *rudder of a ship*, which each dilated angle, or wing, of the part in question somewhat resembles; but the Greek word also means a *stud, button, or head of a nail*, and the regular, or artificial figure of the whole fruit, reticulated like *lillagrec*, might well suggest such an application of it here.—Linn. Gen. 327. Schreb. 430. Willd. Sp. Pl. v. 3. 401. Mart. Mill. Dict. v. 3. Juss. 140. Lamarck Illustr. t. 538. Gærtn. t. 58.—Class and order, *Didynamia Angiospermia*. Nat. Ord. "*Luride, Perfonate, or perhaps Aggregated,*" Linn. *Bignonia*, Juss. *Pedalina*, Brown.

Gen. Ch. *Cal.* Perianth inferior, minute, in five deep segments; the lower ones longest. *Cor.* of one petal, slightly ringent; tube triangular, flat in front; limb flat, spreading, in five deep, rounded segments, the upper ones smallest, the

lower

lower one largest of all. *Stam.* Filaments four, shorter than the tube, hairy at the base, two of them shortest; anthers heart-shaped, two-lobed, terminated by a gland, and cohering in the form of a cross. There is, according to Rottböll, between the shorter stamens, the rudiment of a fifth filament, with a minute anther. *Pist.* Germin conical; style the length of the stamens; stigma cloven, its upper segment reflexed, the lower revolute. *Peric.* Drupa dry, fibrous, stalked, ovate, somewhat pyramidal, with four furrows, and as many angles, each of which bears a horizontal spine at its base. *Seed.* Nut of two cells, with four wings, and clothed with the rigid, permanent, branched and entangled fibres of the drupa. Kernels two in each cell, oblong, one above the other, each clothed with a dry membranous bivalve tunic.

Ess. Ch. Calyx in five deep segments. Corolla slightly ringent; its limb in five flat segments. Stigma two-lobed. Drupa dry, fibrous, with four spines. Nut of two cells, with four tunicated seeds.

Obs. This genus is thought to differ from JOSEPHINIA, see that article, in having but two lobes to the stigma instead of four, fewer cells in the fruit, and solitary seeds. Perhaps the genera are not naturally distinct, but we have not compared them in a sufficiently perfect state to decide. In habit they are very similar. We have corrected the original generic character; not only from the remarks of Rottböll and Gärtner, but from the manuscript emendations of Linnæus himself, annexing his own various conjectures, as to the natural order. What Gärtner terms an empty cell, appears merely a hollow stalk to the fruit.

1. *P. Murex.* Linn. Sp. Pl. 892. Burm. Ind. 139. t. 45. f. 2. (Murex; Linn. Zeyl. 205. Caka Mullu; Rheede Malab. v. 10. 143. t. 72. *Gartn.*)—Native of maritime situations, in Ceylon, and on the Malabar coast. *Root* annual. *Herb* very various as to luxuriance, of a somewhat fleshy and glutinous or greasy habit, like *Chenopodium album*, or Fat Hen. *Leaves* imperfectly opposite, sometimes all alternate, stalked, simple, obovate, obtuse, abrupt, coarsely toothed. *Flowers* axillary, solitary, stalked, the tube of the corolla about an inch long; their colour apparently white, or pale reddish. *Fruit* drooping, singularly elegant at an advanced period, when the branched entangled fibres become visible.

Rottböll says the smell of musk is very powerful in the flowering plant. We are told that the herb infused in water gives out an abundant colourless and insipid mucilage, and that it is used on the coast of Coromandel to turn water into a clear jelly, for what particular use is not mentioned. We find no such result from pouring boiling water on the dried leaves.

PEDALS, keys for the feet in almost all the large organs on the continent of Europe. The invention is recorded by Prætorius, Syntag. Mus. and ascribed to Bernard, a German organist at Venice, so early as the year 1470. (See ORGAN.) This discovery manifested great progress in the construction and performance of that noble instrument at so early a period; and seems to imply ideas of harmony and effects, beyond the power of human hands.

PEDANEUS, in the *Civil Law*, a petty judge who has no formal seat of justice, but hears causes standing, and without any tribunal.

The word seems formed from *stans in pedibus*: and is used among the ancients by way of opposition to those magistrates who were seated in the curule chair, in *sella curuli*, or had a tribunal or bench raised on high.

The Roman pedanei therefore, were such as had no tri-

bunal, nor pretorium; but rendered justice *de plano*, or *plano pede*.

From the eighty-second Novel, it appears that the emperor Zeno established these pedanei in the see of every province; and that Justinian erected seven of them at Constantinople, in manner of an office: granting them power to judge in any sum as high as three hundred crowns.

PEDANT, a schoolmaster, or pedagogue, who professes to instruct and govern youth, and teach them the literæ humaniores and the arts.

PEDANT is also used for a rough unpolished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations.

Dacier defines a pedant, a person who has more reading than good sense.

Pedants are people ever armed with quibbles and syllogisms; they breathe nothing but disputation and chicanery, and pursue a proposition to the last limits of logic.

Malebranche describes a pedant as a man full of false erudition, who makes a parade of his knowledge, and is ever quoting some Greek or Latin author, or hunting back to a remote etymology.

St. Evremont says that to paint the folly of a pedant, we must represent him as turning all conversation to some one science or subject with which he is best acquainted.

There are pedants of all conditions, and of all robes. Wicquefort says, an ambassador, always attentive to formalities and decorums, is nothing else but a political pedant.

PEDANTRY, or PEDANTISM, the quality or manner of a pedant.

To swell up little and low things, to make a vain show of science, to heap up Greek and Latin without judgment, to tear those to pieces who differ from us about a passage in Suetonius, or the etymology of a word, to stir up all the world against a man for not admiring Cicero enough, to be interested for the reputation of an ancient as if he were our next of kin, form what we properly call pedantry.

PEDARIAN, in *Antiquity*, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the senate.

The origin of the word Dr. Middleton thinks owing to this, that though the magistrates of Rome had a right to a place and vote in the senate, as well during their office as after it, and before they were put upon the roll by the censors, yet they had not probably a right to speak or debate there on any question, at least in the earlier times of the republic. For this seems to have been the original distinction between them and the ancient senators, as it is plainly intimated in the formule of the consular edict, sent abroad to summon the senate, which was addressed to all senators, as those who had a right to vote in the senate. From which distinction, these last, who had only a right to vote, were called, by way of ridicule, pedarian; because they signified their votes by their feet, not their tongues, and, upon every division of the senate, went over to the side of those whose opinions they approved. It was in allusion to this old custom, which seems, however, to have been wholly dropt in the later ages of the republic, that the mute part of the senate continued still to be called by the name of pedarians, as we learn from Cicero, who, in giving an account to Atticus of a certain debate and decree of the senate upon it, says, that

that it was made with the eager and general concurrence of the pedarians, though against the authority of all the confulars. Vide Festus in voc. Senatores, A. Gell. lib. iii. 18. Felt in Pedarius. Cicero ad Attic. 1. 19. Middleton. of Rom. Sen. p. 86. seq.

PEDATUM FOLIUM, in *Botany*, a foot-like leaf, is so called rather by way of contrast to a palmate or hand-like one, than from any very precise resemblance to the foot of any animal. It is compound, being in the first instance ternate, and the two lateral leaflets are each, more or less numerously, subdivided in front. *Helleborus fatidus* and *niger* have this sort of foliage.

PEDATURA, in *Roman Antiquity*, was used for a space or proportion of a certain number of feet set out.

The word occurs frequently in writers about military affairs; thus in Hyginus, de Castrametatione, we meet with "meminerimus itaque ad computationem cohortis equitatus milliaria pedaturam ad mille trecentos sexaginta dari debere;" which is to be thus explained: the pedatura, or space allowed for a cohort equitata or provincial cohort, consisting of both horse and foot, could not be the same as the pedatura of a uniform body of infantry, of the same number, but must exceed it by 360 feet; for the proportion of the room of one horseman to one foot soldier, he assigns as two and a half to one. Vide Phil. Trans. N^o 482. sect. 3.

PEDDAGUDAMY, in *Geography*, a town of Hindoostan, in the circar of Ellore; 10 miles N.W. of Ellore.

PEDDAPOUR, a town of Hindoostan, in the circar of Rajamundry; 22 miles E.N.E. of Rajamundry.

PEDDI-BALABARUM, a town of Hindoostan, in Mysore; 16 miles N. of Bangalore.

PEDEE, GREAT, a river of America, which rises in the Appalachian mountains, in North Carolina, where it is called Yadkin river. In South Carolina it takes the name of Pedee, and after receiving the waters of Lynche's creek, Little Pedee, and Black river, joins the Wakkamaw river, near George-town. These united streams, with the accession of a small creek, on which George-town stands, form Win-yaw bay, which, about 12 miles below, communicates with the ocean. It is navigable for boats of 60 or 70 tons, about 200 miles.

PEDEE, Little, a river that rises in several branches, in North Carolina, and unites with the Great Pedee in South Carolina, about 32 miles from the ocean.

PEDEMONTE D'ALISI, a town of Naples, in Lavora; 20 miles N.N.E. of Capua.

PEDENA, or **BIBEN**, a town of Iltria, the see of a bishop; 25 miles S.S.E. of Trieste. N. lat. 45° 22'. E. long 14° 16'.

PEDERNEIRA, a sea-port town on the W. coast of Portugal, in the province of Estremadura, containing about 1300 inhabitants; 18 miles S.W. of Leyria. N. lat. 39° 31'. W. long 8° 56'.

PEDERSORE, a town of Sweden, in the government of Wafa; three miles S. of Jacobstad.

PEDESTAL, formed from *pes, pedis, foot*, and *σῦλος, column*, in *Architecture*, the lowest part of an order of columns; being that which sustains the column, and serves it as a foot to stand on.

The pedestal, called by the Greeks *stylobates*, and *stereobates*, consists of three principal parts; viz. a square trunk, or dye, which makes the body; a cornice, the head; and a base, the foot of the pedestal.

The pedestal is properly an appendage to a column; not an essential part thereof; though M. le Clerc thinks it is essential to a complete order.

The proportions or ornaments of the pedestal are different

in the different orders: Vignola, indeed, and most of the moderns, make the pedestal, and its ornaments, in all the orders, one-third of the height of the column, including the base and capital: but some deviate from this rule.

M. Perrault makes the proportion of the three constituent parts of pedestals, the same in all the orders; viz. the base one-fourth of the pedestal; the cornice an eighth part; and the socle, or plinth, of the base, two-thirds of the base itself. The height of the dye is, what remains of the whole height of the pedestal.

PEDESTAL, Tuscan, is the simplest and the lowest of all. Palladio and Scamozzi make it three modules high; Vignola five. Its members, in Vignola, are only a plinth, for a base; the dye; and a talon crowned, for a cornice. This has rarely any base.

PEDESTAL, Doric, Palladio makes four modules five minutes high; and Vignola five modules four minutes.

In the antique, we not only do not meet with any pedestals; but even not with any base, in the Doric order.

The members in Vignola's Doric pedestal, are the same with those in the Tuscan, with the addition of a mouchette in its cornice.

PEDESTAL, Ionic, in Vignola and Serlio, is six modules high; in Scamozzi five; in the temple of Fortuna Virilis it is seven modules two minutes. Its members and ornaments are mostly the same with those of the Doric, only a little richer. The pedestal now usually followed, is that of Vitruvius, though we do not find it in any work of the antique. Some, in lieu hereof, use the Attic base, in imitation of the ancient.

PEDESTAL, Corinthian, is the richest and most delicate of all. In Vignola it is seven modules high; in Palladio, five modules one minute; in Serlio, six modules fifteen minutes; in the coliseum, four modules two minutes.

Its members, in Vignola, are as follow; in the base are a plinth, for a socle: over that a tore carved; then a reglet, a gula inverted and enriched, and an astragal. In the dye are a reglet, with a conge over it; and near the cornice a reglet, with a conge underneath. In the cornice is an astragal, a frieze, fillet, astragal, gorge, and a talon. See each under its proper article.

PEDESTAL, Composite, in Vignola, is of the same height with the Corinthian, viz. seven modules; in Scamozzi, six modules two minutes; in Palladio six modules seven minutes; in the Goldsmith's arch, seven modules eight minutes.

Its members, in Vignola, are the same with those of the Corinthian; with this difference, that, whereas these are most of them enriched with carvings in the Corinthian, they are all plain in the Composite. Nor must it be omitted, that there is a difference in the profiles of the base and cornice, in the two orders.

The generality of architects, Daviler observes, use tables or panels, either in relieve, or creux, in the dyes of pedestals, without any regard to the character of the order. Those, in relieve, he observes, only fit the Tuscan and Doric; the three others must be indented: but this, he adds, is a thing the ancients never practised, as being contrary to the rules of solidity and strength.

PEDESTAL, Square, is that whose height and width are equal; as that of the arch of the lions at Verona, of the Corinthian order; and such some followers of Vitruvius, as Serlio, Philander, &c. have given to their Tuscan orders.

PEDESTAL, Double, is that which supports two columns, and is larger in width than height.

PEDESTAL, Continued, is that which supports a row of columns without any break or interruption; such is that which sustains

sustains the fluted Ionic columns of the palace of the Thuileries on the side of the garden.

PEDESTALS of Statues, are those serving to support figures or statues.

Vinci observes, there is no part of architecture more arbitrary, and in which more liberty may be taken, than in the pedestals of statues; there being no laws prescribed for them by antiquity; nor any even settled by the moderns.

There is no settled proportion for these pedestals; but the height depends on the situation, and the figure they sustain. Yet, when on the ground, the pedestal is usually two-thirds, or two-fifths, of that of the statue; but always the more massive the statue, the stronger must be the pedestal.

Their form, character, &c. are to be extraordinary and ingenious, far from the regularity and simplicity of the pedestals of columns. The same author gives us a great variety of forms, oval, triangular, multangular, &c.

PEDESTRIAN STATUE. See **STATUE.**

PEDIÆAN, πεδῖαιος, in *Antiquity*. The city of Athens was anciently divided into three different quarters; one on the descent of a hill; another on the sea-shore; and a third in a plain between the other two.

The inhabitants of the middle region were called Πεδῖαιος, *Pediæans*, formed from πεδῖον, *plain* or *flat*: or, according to Aristotle, *Pediaci*: those of the hill, *Diacrians*: and those of the shore, *Paraliens*.

These quarters usually composed so many different factions. Pisistratus made use of the *Pediæans* against the *Diacrians*.

In the time of Solon, when a form of government was to be chosen, the *Diacrians* would have it democratic: the *Pediæans* demanded an aristocracy; and the *Paraliens* a mixed government.

PEDICELLARIA, in *Natural History*, a genus of the class and order Vermes Mollusca: the generic character is, that it has a body soft and seated on a rigid fixed peduncle; the aperture is single. There are three

Species.

GLOBIFERA. This is described as having a spherical head. It inhabits the Northern seas, among the spines of the Echini. The body is minute, and resembling a mucor; the head is reddish, having the appearance of a small cherry; the stem is tawny, and covered with a gelatinous hyaline skin.

TRIPHYLLA. The head of this is three-lobed; the lobes are nearly square and unarmed; the neck is round. It is found in the Northern seas, among the spines of Echini. The head has reddish or hyaline lobes, sometimes ovate; the neck is flexuous and blue; the peduncle or stem is of a chestnut-brown.

TRIDENS. Head three-lobed, the lobes are oval and awned; the neck is round. It inhabits also the Northern seas, and likewise among the spines of Echini. The neck is smooth and hyaline, though sometimes it is reddish; the lobes of the head are sometimes four, and thrice as long as the neck, rarely unarmed with awns; the peduncle is reddish, and three times as long as the neck.

PEDICELLUS, in *Botany*, a partial flower-stalk, or the ultimate subdivision of a general one. See **PEDUNCULUS.**

PEDICLE, **PEDICELLUS**, a diminutive of *pes*, *foot*, *footstalk*; that little stalk whereby the leaf, fruit, or flower, is sustained, and connected to its branch or stem. (See the preceding article.) Flowers will keep fresh a long time after gathering, by immersing their pedicles in water. The great secret of preserving fruits for the winter is to

seal up their pedicles with wax. Cherries with the shortest pedicle are esteemed the best. The pistil of the flower sometimes becomes the pedicle of the fruit.

PEDICULARES, in *Botany*, a natural order of plants, so denominated by Jussieu, from *Pedicularis*, which is one of them; see the next article. It is the second of the eighth class in that author's system, and comprises about a third part of the *Personatæ* of Linnæus; see **PERSONATÆ**. For the characters of Jussieu's eighth class, see **GENTIANÆ**. He thus defines the present order.

Calyx divided, permanent, often tubular. *Corolla* for the most part irregular. *Stamens* definite in number. *Style* one; with a simple, or rarely two-lobed, stigma. *Fruit* capsular, of two cells, with many seeds, and two valves which are connected by a central projection, forming a partition bearing seeds on both sides, and scarcely separable, the edges of the valves unconnected with the partition, and finally separating. The *stem* is mostly herbaceous. *Leaves* either opposite or alternate, each with a single *bractea*.

The first section, distinguished by having the stamens not didynamous, their number two or more, consists of *Polygala*, *Veronica*, *Sibthorpia*, and *Difandra*.

The second section, with four didynamous stamens, that is, two long and two short, has *Ourisia* of Commerson, and *Piriipa* of Aublet, with the Linnæan *Erinus*, *Manulea*, *Castilleja*, *Euphrasia*, *Buchnera*, *Bartsia*, *Pedicularis*, *Rhinanthus* and *Melampyrum*.

A third section consists of four genera akin to true *Pediculares*. These are *Hyobanche*, *Obolaria*, *Orobanche* and *Lathræa*; parasitical plants, about whose germination nothing is, or perhaps can be, known. Their fruit is in a manner unilocular.

The *Pediculares* in general are remarkable for turning black in drying; but this quality does not belong to *Polygala*. That indeed is a genus whose natural affinity is enveloped in much uncertainty, and it seems to us that Linnæus, who refers it to his *Lomentaceæ*, comes nearer the truth than Jussieu.

PEDICULARIS, Loufe-wort, a very noble and beautiful genus of plants; notwithstanding its unpromising name, derived from *pediculus*, a louse, which alludes to a quality attributed to some of the species, of making sheep lousy that feed upon them. This report might perhaps arise, as with respect to the *Drosera* and *Hydrocotyle*, from their growing in watery pastures, where sheep become unhealthy and scabby, whether they feed on any of these herbs, which is very doubtful, or no.—Linn. Gen. 307. Schreb. 403. Willd. Sp. Pl. v. 3. 202. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 655. Prodr. Fl. Græc. Sibth. v. 1. 429. Juss. 101. Lamarck illustr. t. 517. Michaux Boreal-Amer. v. 2. 18. Gærtn. t. 53.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personatæ*, Linn. *Pediculares*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ovate-oblong, tumid, unequally five-cleft, permanent. *Cor.* of one petal, ringent; tube oblong, gibbous; upper lip helmet-shaped, erect, compressed, emarginate, narrowest; lower spreading, flat, divided about half-way into three obtuse segments, the middle one usually narrowest. *Stam.* Filaments four, the length of the upper lip, under which they are concealed, two of them shortest; anthers incumbent, roundish, compressed. *Pist.* Germen roundish, superior; style thread-shaped, situated like the stamens but longer; stigma obtuse, inflexed. *Peric.* Capsule roundish, pointed, oblique, of two cells, bursting at the top; the partitions narrow, from the centre of each valve. *Seeds* several, ovate, angular, pointed, compressed, with a minute membranous appendage.

PEDICULARIS.

appendage. *Receptacle* roundish, at the bottom of the capsule.

Eff. Ch. Calyx swelling, unequally five-cleft. Upper lip of the corolla notched, compressed. Capsule of two cells, pointed, oblique. Seeds few, angular, pointed.

Very few species of *Pedicularis* were known to the old botanists. Linnæus discovered several in Lapland, as Haller has done in Switzerland, and Jacquin in Austria; but the most numerous acquisitions of this kind have been made in Siberia, by Gmelin, Pallas and others. The second edition of Sp. Pl. contains but 14 species; the 14th of Syst. Veg. 17; Willdenow has 34, having received some new Siberian ones from his friend Stephan. Five of the whole have branched stems, the rest are unbranched, though leafy and many-flowered. All are herbaceous, and perhaps perennial, though authors have marked some as annual. This is certainly erroneous with regard to *incarnata* of Jacquin, and our *sylvatica*, whether the *palustris* be annual, as Ray says, or not. They are with difficulty preserved in a garden, being mostly inhabitants of boggy alpine places, protected by a thick coat of snow throughout a long winter, and very susceptible of any recurrence of cold after they begin to vegetate in the spring. The *foliage* of the whole genus is simply or doubly pinnatifid, with minute, cartilaginous teeth, and remarkable for an elegantly crisped aspect, with rich shining green or purplish hues. The inodorous *flowers* form leafy spikes, and are either crimson or yellowish, but in every case richly variegated with contrasted tints.

The species are well made out in Willdenow, nor do we find it requisite to give detailed descriptions or synonyms of them all. A few examples will suffice, with the addition of two species which appear to be new. Only two are natives of Britain, with which our list commences.

P. palustris. Marsh Loufe-wort, or Tall Red-rattle. Linn. Sp. Pl. 845. Engl. Bot. t. 399. (*Pedicularis*; Riv. Monop. Irr. t. 92.)—Stem solitary, branched. Calyx ovate, hairy, ribbed, in two principal notched divisions. Lower lip of the corolla largest.—Native of boggy meadows, chiefly in the north of Europe; by no means unfrequent in England, flowering in June and July. The *root* is small and tapering, whether annual or perennial remains a doubt, *Stem* solitary, twelve to fifteen inches high, angular, with many opposite, lateral, leafy branches; the angles more or less hairy. *Leaves* scattered, stalked, doubly pinnatifid, smooth; the segments obtuse, notched, very various in breadth. *Flowers* numerous, large, rose-coloured, axillary, about the summits of the stem and branches. *Calyx* ovate, compressed, hairy, pale green or purplish, with a darker-green leafy border in two principal lateral divisions, which are strongly crenate and variously lobed, but the whole, taken together, can scarcely be called five-cleft. The lower lip of the *corolla* is longer and much broader than the upper, in three rounded, dilated, flat segments, minutely fringed. *Seeds* about five or six in each cell. This is an acrid usefess weed, untouched by horses or cows.

P. sylvatica. Pasture Loufe-wort, or Heath Red-rattle. Linn. Sp. Pl. 845. Engl. Bot. t. 400. Fl. Dan. t. 225. (*Pedicularis*; Ger. em. 1071. *P. minor*; Riv. Monop. Irr. t. 92.)—Stem branched at the base, spreading. Calyx oblong, angular, smooth, unequally five-lobed, cut. Radical leaves ovate.—Common with us in moist heathy pastures, among grass and moss, flowering in June and July. In Switzerland this species is very rare, nor does it seem to be well known on the continent, since Willdenow could express a doubt whether it were distinct from the former, and quote the excellent figure in the *Flora Danica* with hesitation.

The *root* is strong and thick, certainly perennial, crowned with a numerous row of sessile, pale, ovate, undivided *leaves*, notched and crisped at their edges, but totally different from the doubly pinnatifid superior *leaves*. These radical *leaves* seem characteristic of the species. The *stem* is divided to the very base into several short, spreading, or decumbent, simple, leafy branches. *Flowers* rose-coloured, very elegant; their *calyx* tubular, mostly smooth, five-lobed; their lower lip in nearly equal segments.—The marquis of Stafford met with a few regular *flowers*, which had five or six *stamens*, on some wild plants near his castle of Dunrobin, North Britain, in 1808.

P. euphrasioides. Willd. n. 3. (P. n. 15; Gmel. Sib. v. 3. 203. t. 43.)—Stem much branched. Calyx oblong, smooth, in two abrupt even segments. Upper lip of the corolla toothed.—Native of Siberia.—We have it also from Labrador, communicated by the late R. Molesworth, esq.—The *stem* is a span high, purplish, polished, with numerous branches from top to bottom. *Leaves* pinnatifid, toothed. *Calyx* with an entire, even border, not cut, crisped, or leafy. *Corolla* yellow, with a purplish upper lip, whose edge is sharply toothed.

P. parviflora.—Stem branched, angular. Calyx ovate, its border leafy, unequally lobed and notched. Upper lip of the corolla without teeth, larger than the lower.—Gathered by Mr. Menzies, on the west coast of North America. The habit is most like that of *P. palustris*, but every part is much smaller, nor does it answer to the description in Willdenow of a supposed variety of that species from Kamtschatka, for the upper *leaves* in ours are all doubly and deeply pinnatifid. The *calyx* is ovate, ribbed, smooth, with an elegant, broad, leafy, lobed and notched border. We find no teeth whatever on the upper lip of the *corolla*, which is longer than the lower; the latter is in three small, rounded, nearly equal lobes. The *flowers* seem to have been red, but the whole herb turns very black in drying. Its height is nearly equal to *P. palustris*.

All the following have simple stems.

P. Sceptrum Carolinum. Linn. Sp. Pl. 845. Willd. n. 7. Fl. Dan. t. 26. Ehrh. Phytoph. 55. (*P. alpina*, folio ceterach; Helw. Fl. 39. t. 39. *Sceptrum Carolinum*; Rudb. Lapp. t. 1. Linn. Lapp. ed. 2. 206. t. 4. f. 4, 5.)—Leaves pinnatifid; their segments broad, lobed, finely notched. Lower flowers whorled. Bractæas ovate, undivided. Calyx crested. Corolla closed.—Found in boggy woods in Hungary, Prussia, Mecklenburg, &c. but especially in Lapland, of which last country it is the most celebrated botanical treasure, being the largest and most stately of this whole genus. We do not find that it has yet been cultivated with success in any garden. The *stem* is a yard high, erect, straight, naked, except a whorl of *leaves* near the bottom. Radical *leaves* most numerous and largest, stalked, a span long, deeply pinnatifid, smooth, finely reticulated, the segments more or less pinnatifid, rounded, broad, with minute cartilaginous teeth. *Flowers* several, in a long, upright spike, the lower ones whorled, the rest chiefly alternate. *Bractæas* large, ovate, concave, crenate, tinged, like the leaves and stem, with purple. *Corolla* an inch and a half long, cream-coloured or pale yellow; the lips closed, elegantly tipped with crimson, the segments of the lower one equal, concave; the upper without teeth.—Rudbeck's wooden cut is truly magnificent.

P. auriculata.—Leaves pinnatifid; their segments oblong, notched. Lower flowers opposite. Bractæas leafy, pinnatifid. Calyx deeply cleft, with two rounded, leafy, crenate lobes. Corolla slightly gaping.—Sent by the Rev. Dr. Muhlenberg, from the neighbourhood of Lancaster in Pennsylvania.

PEDICULARIS.

sylvana. We find no description answerable to this species. The *stem* is simple, little more than a foot high, leafy. *Leaves* all nearly opposite, two inches in length, oblong, mostly smooth and naked, cut, but not deeply, into numerous, parallel, obtuse segments, with a cartilaginous notched edge. *Bractes* similar to the leaves, but gradually smaller. *Calyx* ovate, very smooth, two-lobed, each lobe crowned with a rounded, leafy, notched appendage. *Corolla* an inch long, nearly closed, pale or yellowish, with a tinge of red. The habit of the *leaves*, and the general appearance of the *flowers*, bring this plant near the *Sceptrum Carolinum*, from which nevertheless it is abundantly distinct, as well as from *P. triflis*, whose *corolla* is full as large, but downy at the edges, and whose *leaves* are more finely and deeply divided.

P. recutita. Linn. Sp. Pl. ed. 1. 608. ed. 2. 846. Willd. n. 14? Jacq. Austr. t. 258? (*P. caule simplicis, foliis pinnatis, floribus spicatis, staminibus eminentibus*: Hall. Helvet. v. 1. 138. n. 316. t. 8. f. 2)—*Leaves* deeply pinnatifid; their segments lanceolate, pinnatifid, acutely notched. *Spike* compact, leafy. Upper lip of the corolla crenate, obtuse. *Stamens* prominent.—Native of lofty mountains in Switzerland. We have Haller's plant, on which this species in Linnæus entirely depends. That of Jacquin, sent by himself, which Willdenow appears to have had in view, seems somewhat different, the *corolla* being smaller, its upper lip singularly oblong, rectilinear, and obtuse; nor do the *stamens* seem to project. This last character, however, to which the specific name, such as it is, alludes, is not very obvious at all times. We must leave the final determination of these two plants to those who can compare them fresh. Willdenow has very properly established, by the name of *P. elata*, n. 15, a tall Siberian species, with a long pale-purple *corolla*, which Linnæus confounded with *recutita*.

P. foliosa. Linn. Mant. 86. Willd. n. 16. Jacq. Austr. t. 139. (*P. alpina, flore luteo, radice nigra*; Bauh. Hist. v. 3. 439.)—*Leaves* doubly pinnatifid, in linear segments; the floral ones much longer than the flowers. *Calyx* five-cleft; its upper segment much larger than the rest. Upper lip of the corolla rounded, woolly, very obtuse.—This very fine species is not rare on the alps of Switzerland, Dauphiny, Savoy, Hungary, and Austria. The *root* is tapering, described by Jacquin as perennial, of a pale yellow. Willdenow marks it biennial, but erroneously. John Bauhin calls it black, but otherwise his synonym is the only certain and correct one to be found among the old writers. The plant is readily known by the ample finely divided foliage, which accompanies and envelopes its dense *spike* of pale yellow, numerous, woolly *flowers*, whose prominent palate is of a deeper hue than the rest.—Seeds of this *Pedicularis*, sent by the late Mr. Davall, are said to have vegetated at Kew; but we know not that the plants survived to blossom, nor have we met with this or any other, in perfection, in any garden.

P. acaulis. Scop. Carn. v. 1. 439. t. 31. Wulf. in Jacq. Coll. v. 1. 207. t. 14. Willd. n. 23.—*Stem* none. *Leaves* doubly pinnatifid. *Flower-stalks* radical, single-flowered.—Native of the less elevated mountains of Carniola and Carinthia, where it blossoms early in May, before the snow has disappeared from the more alpine tracts. The *root* is perennial. *Leaves* several, three or four inches long, with hairy stalks. The *flowers* are large, of a pale bluish-colour, springing immediately from the crown of the root, each on a simple hairy stalk, about as long as the *calyx*, which is hairy with a five-cleft leafy border, and scarcely half so long as the *corolla*.

P. flammea. Linn. Sp. Pl. 846. Fl. Lapp. ed. 2. 210 t. 4. f. 2. Tour in Lapland, v. 1. 296. Willd. n. 24, excluding the synonym of Fl. Dan. which rather belongs to *P. hirsuta*.—*Leaves* pinnate; leaflets imbricated, ovate, obtuse, doubly crenate. *Calyx* oblong, five-toothed. Upper lip of the corolla obtuse.—Native of the alps of Lapland, Norway, and Dauria; more sparingly of Switzerland. The *root* is perennial, with many oblong knobs. *Stem* three or four inches high, cylindrical, rather stout. *Leaves* scattered, stalked, of numerous, crowded, small, dark-shining-green leaflets. *Spike* somewhat leafy. *Calyx* oblong, angular, smooth, its teeth scarcely leafy. *Corolla* slender, deep yellow, its upper lip obtuse and brownish or purplish.—This is Haller's n. 315, a rare Swiss species, under which it is remarkable that, both in his *Historia* and *Nomenclator*, he copies from the Sp. Pl. of Linnæus an erroneous citation of Fl. Lapp. t. 11, instead of t. 4; a sign of his not having turned to the plate he quoted. Willdenow has here been more attentive.—Linnæus judged this species to be *P. alpina, folio ceterach*, Bauh. Pin. 163, a plant taken up from Gefner, who but imperfectly describes it. Helwing took the plant of Gefner to be *P. Sceptrum Carolinum*, which indeed answers much better to the idea of the leaves of *Ceterach* than the *flammea*.

P. rosea. Jacq. Misc. v. 2. 57. Ic. Rar. t. 115. Willd. n. 26. (*P. hirsuta*; Allion. Pedem. v. 1. 63. t. 3. f. 1.)—*Stem* nearly naked. *Leaves* deeply pinnatifid; segments linear, sharply pinnatifid. *Flowers* crowded. *Calyx* hairy. Upper lip of the corolla obtuse.—Native of the alps of Carinthia and the north of Italy. The *root* is composed of long fleshy cylindrical branches, running deep into the ground. *Stem* three or four inches high, simple, round, purplish, hairy, almost leafless, except at the top. *Leaves* mostly radical, stalked, finely divided, and acutely toothed. *Flowers* numerous, of an elegant rose-colour, crowded into a short dense spike or head accompanied by two or three leaves, which are rather smaller, and more sessile, than the rest. *Calyx* very hairy, in five unequal segments. Upper lip of the *corolla* oblong, rounded and obtuse; lower in three broad rounded segments, the middle one rather smallest.—Allioni mistook this for the Linnæan *hirsuta*, which is very different, having a leafy *stem*, much broader and ovate segments to the *leaves*, and yellow *flowers*. We believe the latter to be Fl. Dan. t. 30.—It must also be observed that Willdenow cites under *rosea*, Allioni's Specimen, t. 11. f. 1; whereas it is t. 12. f. 1, the other being *comosa*.

P. rostrata. Linn. Sp. Pl. 845. Willd. n. 27. Jacq. Austr. t. 205. (*P. n. 322*; Hall. Helvet. v. 1. 140. t. 8. f. 1, not f. 3, as he himself quotes it!)—*Stem* ascending, slightly leafy. *Leaves* doubly and deeply pinnatifid and toothed. *Flowers* scattered, stalked. Segments of the calyx pinnatifid. Upper lip of the corolla beaked.—Native of Switzerland, Austria, Carniola, Italy, and Dauphiny, on the most lofty mountains. The segments of the *leaves* are shorter and broader than in the last. *Stems* several, less erect. *Flowers* fewer, more distant, on longish partial stalks. *Calyx* much less hairy, with leafy pinnatifid segments. *Corolla* distinguished by the long inflexed beaked upper lip, which is of a deep crimson, the under being rose-coloured, with very broad lateral segments.—Linnæus unaccountably places this species among such as have branched stems.

P. tuberosa. Linn. Sp. Pl. 847. Willd. n. 28. (*P. n. 323*; Hall. Helvet. v. 1. 140. t. 10.)—*Stem* ascending, slightly leafy. *Leaves* doubly and deeply pinnatifid and toothed. *Flowers* crowded, nearly sessile. Segments of the

the calyx pinnatifid. Upper lip of the corolla beaked.—Native of the alps of Switzerland, Italy, and the south of France. Differs from the last in being larger, with more subdivided leaves, and yellow flowers, which are nearly sessile, being crowded into a dense leafy spike. The stem is not more erect, nor more leafy, in one than the other. The floral leaves of both are palmate and bipinnate, and the corolla distinguished by its long beak, which has sometimes a notch at the end in the *tuberosa*, as well as, if we mistake not, in the *rostrata*.

P. gyroflexa. Villars Dauph. v. 2. 426. t. 9. Willd. n. 29. (P. n. 324; Hall. Helvet. v. 1. 140. t. 11. f. 2.)—Stem ascending, slightly leafy. Leaves doubly and very deeply pinnatifid, notched, hairy, somewhat revolute. Upper flowers crowded; lower stalked. Segments of the calyx pinnatifid. Upper lip of the corolla arched, with a short notched beak.—Native of the alps of Switzerland, Italy, and Dauphiny. Most like the last in habit, but the segments of the leaves being slightly revolute, give them a more obtuse and crisped aspect. The corolla is rose-coloured, with a much shorter and blunter beak than either of the two last. These species are all nearly akin, and so similar in a dried state, that it is no wonder botanists in general have not well understood them. *P. fasciculata* of Bellardi, Willd. 30, is confessedly very like them all; but as no authentic specimen has fallen in our way, we can throw no light upon its history. The corolla is said to be in colour like the last; its upper lip not beaked, though approaching to that shape, terminating in three teeth, of which the intermediate one is very short.—These are followed in Willdenow by three Siberian species, called *rubens*, *compacta*, and *achilleifolia*, of which we have seen neither specimen nor figure. The genus concludes with

P. comosa. Linn. Sp. Pl. 847. Willd. n. 34. Allion. Ped. v. 1. 64. t. 4. f. 1. Spec. t. 11. f. 1.—Stem and spike leafy. Leaves doubly and deeply pinnatifid, rough, with bristly teeth. Calyx with five small downy teeth. Upper lip of the corolla cloven, with two small acute points.—Native of mountains in the south of France and north of Italy, but not abundantly; more frequent in the meadows of Russia and Siberia. This is a fine species, approaching to *P. foliosa* in size, habit, and colour, as well as abundance, of flowers; but the floral leaves are smaller and less prominent, and the corolla is smooth, with a round sinus at the extremity of its upper lip, accompanied by a pair of taper teeth. The division of the foliage is very similar in these two species, as also the short downy teeth of the calyx, and they ought to be placed next to each other in a natural disposition of the genus. We have a specimen from Allion himself, as well as others from Siberia.

Besides the two new species which we have added above to Willdenow's list, there are two in Michaux, Boreal-Amer. v. 2. 18, not referrible to any that he enumerates, nor do we know any thing more of them than the following very insufficient characters.

P. lanceolata.—Unbranched. Leaves lanceolate, deeply toothed. Spike leafless. Calyx smooth. Capsules short.—Native of Canada, in the country of the Illinois.

P. gladiata.—Unbranched. Spike leafy. Flowers alternate. Capsule protracted into a sword-shaped point, exceeding its own length. Flowers yellowish.—Native of Pennsylvania.

Our *P. auriculata* is certainly not referrible to either of these.

PEDICULARIS Morbus, from *pediculus*, louse, in *Medicine*, a morbid condition of the habit, and especially of the skin, in which lice are generated in multitudes, and with diffi-

culty destroyed. This disease has been said even to be fatal. See **PHTHIRIASIS**.

PEDICULUS, the Louse, in *Entomology*, a genus of insects of the order Aptera. The generic character is, mouth with a retractile recurved sucker without proboscis; without feelers; the antennæ are as long as the thorax; it has two eyes; the abdomen is depressed; it has six legs formed for running. The insects of this genus live by extracting animal juices; the larvæ and pupæ are six-footed and nimble, resembling the perfect insect. Of these strange and unpleasing animals, some infest the bodies of quadrupeds, others of birds, and some even of insects themselves. It must, however, be observed, that many small insects, infesting other animals, have often been referred to the genus *Pediculus*, which, in reality, belong to those of *Acarus*, *Monoculus*, &c. There are sixty-six species of the genus enumerated by Gmelin.

Species.

* **HUMANUS**. The specific character is, abdomen lobed, cinereous. The *pediculus humanus*, or common louse, is distinguished by its pale livid colour; it is produced from a small oval egg, popularly called by the name of a nit, which is agglutinated by its smaller end to the hair on which it is deposited: from this egg proceeds the insect, complete in all its parts, only much smaller in size. These specimens are far preferable for microscopic observation to the full grown insects, shewing, in a more distinct manner, the disposition of the viscera, muscles, &c. In this state it has such a transparent skin, that we are able to discover more of what passes within its body than in most living creatures. See **LOUSE**.

PUBIS; Crab-Louse. Abdomen emarginate behind; legs cheliform, hence its trivial name. In the antennæ are five articulations. It is found about the hairs of the groin, and sometimes, though very rarely, on the eye-brows of persons who are not attentive to habits of cleanliness.

RICINOIDES. The abdomen is orbicular, marked with a white line; the scutellum is composed of three lobes; the snout is white. It is a native of America. It gets into the legs of the naked inhabitants, where it draws blood, and depositing its eggs in the wound occasions very alarming ulcers.

SUIS. Found on the body of swine.

PORCELLI. Found on the body of the *Cavia cobaya*, or Guinea pig.

CAMELI. Head projecting and pointed; body ferruginous; abdomen ovate. It is found on the camel.

* **OVIS**. This infests the body of the sheep.

BUBALI. Yellowish, with dusky-brown streaks; the abdomen has ten conic marginal tubercles. It is found on the buffalo.

* **BOVIS**. Abdomen with eight transverse ferruginous lines. It inhabits the bodies of oxen, and cattle in general.

* **VITULI**. The abdomen is of a lead colour, and pointed at the end. Found on the bodies of heifers and cattle.

* **EQUI**. Found on the body of the horse.

* **ASINI**. Head projecting, obtuse; abdomen ovate, brown; legs cheliform. Found on the body of the ass.

VULTURIS. Oblong; abdomen brown, with two yellowish lines. It is found in the East Indies on the vulture, and is a large insect. It is farther characterized as having a flat head, yellowish, with black margins; the thorax is yellowish, with a black margin and dorsal line.

* **TINNUNCULI**. Head arrow-shaped, and mucronate on each side behind. Found on the *Falco tinnunculus*, or kestrel.

* **BUTEONIS**.

* **BUTEONIS.** Abdomen margined; the segments with two impressed dots on each side. It infests the Falco buteo, or buzzard.

* **STRIGIS.** Abdomen ovate, white, edged with red; legs red. Found infesting various species of the strix and falco.

* **CORVI.** Abdomen ovate, with a striate margin. Found on various species of the crow.

* **CORNICIS.** Abdomen ovate, pale, with lateral black spots, in which is a white pupil. Found on the common crow.

* **INFAUSTI.** Thorax narrow; abdomen ovate, pale, diaphanous. It infests the Corvus infauti.

* **PICÆ.** Head obtuse, brown, with four black dots. This is found on the Corvus pica, or magpie.

* **ORIOLE.** White, with a brown line on the abdomen. Found on the roller and oriole.

* **CUCULI.** Abdomen oblong, whitish, with brown bands. It infests the Cuculus canorus, or cuckoo.

* **CYGNI.** Head emarginate; abdomen ovate; the margin striate with black. It is found on the swan.

* **ANSERIS.** Filiform, pale; the margin dotted with black. It is found on the wild and tame goose.

* **MOSCHATÆ.** This is found on the Anas moschata, or Muscovy duck.

* **QUERQUEDULÆ.** This infests the Anas querquedula, or garganey.

* **MERGI.** White, with a yellowish head; body long. Found on the Mergus ferrator.

* **PROCELLARIÆ.** Long, filiform, brown; with pale legs. It inhabits Brasil, on the procellaria, or petrel.

* **VAGELLI.** Ovate, pale; thorax with two brown lines. Found on the Procellaria glacialis.

* **DIOMEDEÆ.** Head obtuse; body white; sides of the abdomen black. It inhabits Brasil; on the diomedea, or albatros.

* **STERNÆ.** Head triangular; abdomen ovate, pale; the back longitudinally blackish. Found on various species of the tern and gull.

* **PLATALEÆ.** This species is found on the Platalea leucorodia, or spoon-bill.

* **ARDEÆ.** This is found on several species of the ardea, or crane.

* **GRUIS.** Abdomen sub-clavate, pale, with snowy spiracles. It is found on storks and herons.

* **CICONIÆ.** Long, filiform; abdomen white; the sides dotted with black. It infests storks.

* **CHARADRII.** This species is found on the Charadrius pluvialis, or golden plover.

* **FULICÆ.** This infests the Fulica atra, or common coot.

* **RECURVIROSTRÆ.** This species is oblong, with a triangular grooved head. It is found on the recurvirostra, or avocet.

* **HÆMATOPI.** Glaucous; thorax very narrow; abdomen ovate; with pale incisures. Found on the Hæmatopus ostralegus, or sea-pie.

* **PAVONIS.** Head globular, and very large; body striate, with pale and brown. Found on the peacock.

* **MELEAGRIS.** Head triangular, obtuse; abdomen ovate, grey. This infests the turkey.

* **GALLINÆ.** Thorax and head mucronate on each side. This species infests poultry, and is destroyed by pepper.

* **PHASIANI.** Head ovate and large; abdomen globular, obtuse. It is found on the pheasant.

* **CAPONIS.** Abdomen edged with black. Found on common poultry.

* **TETRAONIS.** This species is found on the Tetrao tetrix, or black game.

* **LAGOPI.** On the Tetrao lagopus, or ptarmigan.

* **COLUMBÆ.** Body filiform, ferruginous, and clavate behind. Found on common pigeons.

* **EMBERIZÆ.** Pale brown; abdomen whitish, with lateral brown spots; head triangular. Found on the bunting.

* **PARI.** Body ovate; tail ending in four bristles. Found on various species of the parus, or titmouse.

* **MOTACILLÆ.** Head heart-shaped, rufous; abdomen white and tapering at the base. It is found on the wag-tail.

* **HIRUNDINIS.** Palish; abdomen black, spotted with white. Found infesting the Hirundo apus, or swift. The abdomen is bristly on both sides.

* **GRYLLOTALPÆ.** Blood-red, with white legs. Found on the mole cricket. The sucker is long, inflected, black; body red, immaculate.

* **APIS.** Body filiform, ferruginous. Inhabits Europe, on bees.

* **FARIONIS.** This is found on the Salmo fario, or trout.

* **ANATIS.** Whitish; first segment of the thorax round, truncate on each side; the abdomen linear and long. On the wild duck.

* **ORTYOMETRÆ.** Oblong; with a heart-shaped head; thorax narrow; segments of the abdomen bristly, with large spotted spiracles on each side. This infests the land-rail.

* **ALAUDÆ.** On the Alauda arvensis, or sky-lark.

* **STURNI.** On the Sturnus vulgaris, or starling.

* **CURVIROSTRÆ.** This is found on the Loxia curvirostra, or grosbeak.

* **PYRRHULÆ.** This infests the Loxia pyrrhula or bull-finch.

* **CLORIDIS.** This is found on the Loxia chloris, or green-finch.

* **CITRINELLÆ.** This infests the Emberiza citrinella, or yellow-hammer.

* **CURRUCÆ.** This is found on the Motacilla curruca, or babbling warbler.

* **RUBECULÆ.** On the Motacilla rubecula, or red-breast.

* **PEDIEUS,** in *Anatomy*, a name given by Riclan to the extensor brevis digitorum pedis communis. Some of the French anatomists still call it le pédieux.

* **PEDIGREE,** a descent, or genealogy.

* **PEDILUVIUM.** See *Bathing of the Feet*, art. FOOT.

* **PEDIMENT,** in *Architecture*, a kind of low pinnacle; serving to crown porticos, or finish a frontispiece; and placed as an ornament over gates, doors, windows, niches, altars, &c.

The pinnacles of the ancient houses, Vitruvius observes, gave architects the first idea of this noble part; which still retains the appearance of its original.

The parts of the pediment are, the tympanum and its cornice. The first is the pannel naked, or area of the pediment, inclosed between the cornice, which crowns it, and the entablature, which serves it as a base, or socle.

Architects have taken a great deal of liberty in the form of this member; nor do they vary less as to the proportion of the pediment. The most beautiful, according to Daviler, is that where its height is about one-fifth of the length of its base.

It is described thus: divide the line *ab* (*Plate XXIII. Miscellany, fig. 12.*) which is the length of the base, into two equal parts, in the point *c*, by means of the perpendicular *fd*; in this perpendicular take the part *ed* equal to *ac*; and from the point *d*, as a centre, describe the arch *aeb*. The point

point of the perpendicular, cut in *e*, will be the top of the pediment *aeb*; and the cornice, and the triangular space included therein, the tympanum.

The pediment is usually triangular, and sometimes an equilateral triangle: this is also called a *pointed* pediment. Sometimes it is circular; though Felibien observes, that we have no instances of round pediments in the antique, beside those in the chapels of the Rotundo. Sometimes its upper cornice is divided into three or four sides, or right lines; sometimes the cornice is cut, or open a top, which is an abuse introduced by the moderns, particularly by Michael Angelo. For the design of this part, at least over doors, windows, &c. being chiefly to shelter those underneath from the rain, to leave it open in the middle is to frustrate its end.

Sometimes the pediment is formed of a couple of scrolls, or wreaths, like two consoles joined together. See CONSOLE.

Sometimes, again, the pediment is without base, or its lower cornice is cut out, all but what is bestowed on two columns, or pilasters, and on these an arch or sweep, raised in lieu of an entablature; of which Serlio gives an instance in the antique, in a Corinthian gate at Foligny in Umbria; and Daviler a more modern one, in the church of St. Peter at Rome.

Under this kind of pediments do also come those little arched cornices which form pediments over doors and windows, supported by two consoles, in lieu either of entablature or columns.

Sometimes the pediment is made double, *i. e.* a less pediment is made in the tympanum of the larger, on account of some projecture in the middle; as in the frontispiece of the church of the Great Jesus at Rome: but this repetition is an abuse in architecture, though authorized by some very good buildings; as the large pavilion of the Louvre, where the caryatides support three pediments, one in another.

Sometimes the tympanum of the pediment is cut out, or left open, to let in light; as we see under the portico of the Capitol at Rome. Lastly, this open pediment is sometimes triangular, and enriched with sculpture, as roses, leaves, &c. as we find in most of the Gothic churches.

M. le Clerc observes, that the modillions in the cornice of the pediment should always answer exactly over those of the entablature. Indeed Vitruvius says, the ancients did not allow any modillions at all in pediments.

The same M. le Clerc observes, that the cornice which serves the pediment as a base, should have no cymatium; by reason the cymatium of the rest of the entablature, when it meets the pediment, passes over it.

This change of determination occasions a considerable difficulty; the cymatium, in this case, appearing too broad in the turn of the angle; to remedy which, the architects have recourse to several expedients.

A pointed pediment may crown three arches; but a circular pediment can only crown one agreeably.

One would never use above two pediments over each other in the same frontispiece; and even where there are two, it would be proper to have the lower circular, and the upper pointed.

PEDINABARUM, in *Geography*, a town of Hindoostan; 60 miles S.E. of Travancore.

PEDINAIG-DURGAM, a town of Hindoostan, in Mysore; 10 miles S.E. of Vencatighery.

PEDIR, a town on the N. coast of the island of Su-

matra; 20 miles E. of Acheen. N. lat. 5° 13'. E. long. 96° 5'.

PEDIS ABSCESSIO, *Cutting off a foot*, a punishment anciently inflicted among us; as appears by the laws of William the Conqueror. "Interdicimus ne quis occidatur, vel suspendatur, pro aliqua culpa, sed eruantur oculi, abscindantur pedes, vel testiculi, vel manus, &c." Leg. Will. cap. 1. So Ingulphus, "sub pena perditionis dexteri sui pedis, &c."

PEDIS minimi digiti abductor, in *Anatomy*. See ABDUCTOR.

PEDIS, abductor pollicis. See ABDUCTOR.

PEDIS, dorsum. See DORSUM.

PEDIS, flexor pollicis. See FLEXOR.

PEDIS interossei, perforans, perforatus, and transversalis. See the respective articles.

Transcriptio PEDIS finis. See TRANSCRIPTIO.

PEDITUM ARRAIATIO. See ARRAIATIO.

PEDLAR. See HAWKER.

PEDMAN, in *Geography*, a town of Hindoostan, in the circar of Guntoor; 10 miles S.S.W. of Guntoor.

PEDN-BOAR POINT, a cape on the S. coast of England, and county of Cornwall; six miles S.E. of Lizard Point. N. lat. 50° 6'. W. long. 5° 8'.

PEDO, in *Natural History*, a name given by some writers to the tipula, or father-long-legs; called also by others grüna, or the crane-fly.

PEDOMETER, or PODOMETER, formed from *πῆδος*, *pes*, *foot*, and *μέτρον*, *measure*, way-wiser; a mechanical instrument, in the form of a watch, consisting of various wheels, with teeth catching in one another, all disposed in the same plane; which by means of a chain or string, fastened to a man's foot, or to the wheel of a chariot, advance a notch each step, or each revolution of the wheel; so that the number being marked on the edge of each wheel, one may number the paces, or measure exactly the distance from one place to another.

An instrument of this kind has been lately invented and improved by Mr. Ralph Gout of Bunhill Row.

The pedometers of Mr. Ralph Gout have an advantage hitherto unknown, *viz.* the hour being attached to them, if required, which makes this instrument doubly useful. Thus, on the same dial is exhibited, at one view, time and distance by means of different hands.

Their internal construction is so very simple, as not to endanger their being put out of order, and if required to be cleaned, a person of the smallest capacity may do it, the wheels being all marked for that purpose.

The patentee has been induced to make various trials with his pedometers in public, one in the right, and one in the left side pocket, in order to establish more effectually their high state of perfection, not only in point of accuracy of the machinery, but to shew the nicety of man's walking.

The same pedometer will, by a proper application to the fiddle, ascertain every pace a horse takes, either in walk, trot, or gallop, and may be made to stop performance in a second, should the horse, in the course of measuring, go from one pace to another. In short, we do not feel the least difficulty in recommending this invention, as the best of the kind ever offered to the public.

PEDOMETER is sometimes also used for the common surveying wheel, an instrument chiefly used in measuring roads; popularly called the *way-wiser*. See PERAMBULATOR.

PEDRA, in *Geography*, a river of Africa, in the kingdom

dom of Adcl, which runs into the Arabian sea, N. lat. 11° 25'.

PEDRA Branca, a large white rock in the Chinese sea. N. lat. 22 19'. E. long. 114° 57'.

PEDRA da Gala, a small island in the Atlantic, near the coast of Africa. N. lat. 21° 48'.

PEDRA da Sureira, a rock or small island in the Atlantic, near the coast of Portugal, at the mouth of the Gopalha; four miles S. of the bay of Oporto. N. lat. 41° 6'. W. long. 8° 23'.

PEDRAÇA, a town of South America, in the government of Caraccas; 25 miles S.S.W. of Varinas.

PEDRAGAO, a town of Portugal, in the province of Elremadura; 30 miles S.E. of Coimbra.

PEDRAPALORE, a town of Hindoostan, in the Carnatic; 20 miles S. of Wandiwash.

PEDRAS, a river on the N.W. side of Punta des Padras, at the southern extremity of Amazon river.

PEDRAZA, a town of Spain, in Old Castile; the birth-place of the emperor Trajan; 21 miles N.E. of Segovia.

PEDRERO, PETERERO, or *Paterero*, a small piece of ordnance, used on board ships, for the discharging of nails, broken iron, or partridge shot, on an enemy attempting to board.

They are generally open at the breech, and their chamber made to take out, to be loaded that way, instead of at the muzzle.

PEDRO, in *Geography*, a town on the N.W. coast of the island of Ternate. N. lat. 0° 50'. E. long. 127 10'.—Also, a small island in the Indian sea, near the W. coast of Madagascar. S. lat. 14° 50'. E. long. 47° 48'.

PEDRO Bay, *Great*, a bay on the S. coast of Jamaica. N. lat. 17° 53'. W. long. 77° 41'. East of it lies Little Pedro point.

PEDRO Bluff, a cape on the S. coast of Jamaica. N. lat. 17° 52'. W. long. 77° 39'.

PEDRO Munoz, a town of Spain, in New Castile; 48 miles S.E. of Toledo.

PEDRO Point, a cape on the N. coast of Jamaica. N. lat. 18° 28'. W. long. 78° 12'.

PEDRO, *St.*, a river of Africa, on the Ivory coast, which runs into the Atlantic, N. lat. 4° 50'. W. long. 6° 50'.

—Also, a town of South America, in the province of Carthagena; 50 miles S. of Mompox.—Also, a town of S. America, in the province of Venezuela, on the S. coast of lake Maracaybo; 100 miles S. of Maracaybo.—Also, a town of Brasil, in the government of Para, on the river Amazons; 440 miles W. of Port Rio Negro.—Also, a town of S. America, in the province of Moxes, on the Mamora; 50 miles S. of Trinidad.—Also, a town of South America, in the audience of Quito; 20 miles N.W. of St. Josef de Huales.—Also, a town of Mexico, in the province of Mechoacan; 15 miles N. of St. Luis de Potosi.

—Also, a small island in the Pacific ocean, near the coast of Terra Firma. N. lat. 4 2'.—Also, a sea-port of Mexico, in the province of Guaxaca; 75 miles S. of Guaxaca. N. lat. 16 . W. long. 99° 1'.—Also, one of the Marquesas islands, called by the natives "Onateya," about three leagues in circuit. S. lat. 9 55'. E. long. 138° 55'.—Also, a town of the bishopric of Truxillo, and jurisdiction of Sana, situated in a fertile soil, near the coast of the Pacific ocean; 50 miles N. of Truxillo. S. lat. 7 26'.—Also, a town of East Florida; 44 miles E.S.E. of St. Mark.—Also, a small island near the coast of Spain, situated S.E. of the city of Cadiz, from which it is separated by a narrow strait, called "St. Pedro's Channel."—Also, a town of

the island of Cuba; 31 miles S.W. of Bayamo.—Also, a town of S. America, in the province of Cordova; 96 miles N. of Cordova.—Also, a town of New Navarre; 180 miles W. of Cata Grandé.—Also, a town of Mexico, in the province of Honduras; 15 miles W.N.W. of Naco.—Also, a bay of the Pacific ocean, on the coast of New Albion, between point Fermin and point Lafuen.

PEDRO Novo, *St.*, a town of Brasil, on a river which runs into the bay of All-Saints; 50 miles N.W. of St. Salvador.

PEDRO e Pablo, *St.*, a river of Mexico, which rises in Tabasco, and runs into the bay of Campeachy, N. lat. 18 20'. W. long. 93° 26'.

PEDRO, *St.* and *St. Pablo*, a river of Mexico, which rises near Zacatlan, in the province of Tlascala, and runs into the gulf of Mexico. N. lat. 10° 52'. W. long. 93° 26'.

PEDRO Nolusco, *St.*, a town of Brasil, on the Urubui; 70 miles N.N.E. of Fort Rio Negro.

PEDRO de Sul, *St.*, a town of Portugal, in the province of Beira; nine miles N.W. of Vifeu.

PEDRO de Taberna, *St.*, a town of Spain, in Aragon; 12 miles N. of Ainsa.

PEDRO de Porco. See *Hog* BEZOAR.

PEDROAS, Os, in *Geography*, a town of Portugal, in Alentejo; nine miles S.W. of Moura.

PEDROAS de Perceveira, rocks near the W. coast of Portugal; two miles S.S.W. of Sines. N. lat. 37° 40'. W. long. 8 52'.

PEDROGAON, a town of Portugal, in Estremadura; 21 miles N.E. of Thomar.

PEDROSA, a town of Spain, in the province of Leon, between Salamanca and Medina del Rio Seco; five leagues from the former.

PEDRUSI, or PEDRUZZI, PAUL, in *Biography*, was born of a noble family at Mantua in 1646. He entered himself among the Jesuits, and became distinguished for his deep knowledge of history and antiquities. He was chosen by Rannuncio, duke of Parma, to arrange his rich and curious cabinet of medals, and to give explanations of them. In 1694 he began to publish an account of this collection, under the title of "I Cæsari in oro raccolti nel Farnese Museo o publicati colle loro congrue interpretazioni," and he continued his labours till his death in 1721. This work, in its complete form, consists of ten volumes, and bears the title of "Museo Farnese;" of these he published seven volumes; and the eighth was edited by Peter Piovene, a brother Jesuit.

PEDUNCLE, in *Botany*. See PEDUNCULUS.

PEDUNCULARIA, a name by which some authors have called the *staphisagria*, or stavesacre: a plant whose seeds are used to kill vermin.

PEDUNCULUS, the flower-stalk, or, as some call it, *peduncle*, springs from the stem, and bears the flowers and fruit, but not the leaves. A flower-stalk originating immediately from the root, has an appropriate name, SCAPUS; see that article; though some prefer *pedunculus radicalis*.

The flower-stalk is either simple or compound; in the first instance it commonly bears a solitary flower, though it may bear a number of completely sessile ones, constituting a spike, as in *Potamogeton*. When compound, the ultimate divisions of this part are called partial flower-stalks. See PEDICELLUS.

Flower-stalks differ in situation, as well as in degree or mode of subdivision.

Pedunculus caulinus springs immediately out of the main stem or trunk, as in *Averrhoa Bilimbi*, and *Cynometra cauliflora*.

P. ramtus grows out of a principal branch, as in *Averrhoa Carambola*, and many other plants.

P. axillaris, an axillary flower-stalk, is very common, and indeed almost general, when the inflorescence is lateral. It proceeds from the bosom of each leaf; that is, immediately above the insertion of the leaf, or its footstalk. The same term is applied to a flower-stalk situated in the fork of a stem, or above the origin of a branch.

P. oppositifolius is inserted opposite to a leaf, of which several species of *Geranium* afford examples.

P. internodis, of more rare occurrence, grows from the intermediate part of a branch between two leaves, as in some species of *Solanum*.

P. interpetiolaris is placed laterally between the insertion of two leaf-stalks, as in some of the *Convolv.*

P. gemmaceus grows out of a leaf-bud, as in the Barberry, and some kinds of Willow; while in others of the last-mentioned genus, some buds are entirely destined to produce leaves, others flowers.

P. terminalis springs from the extremity of a stem or branch, which is very common. It always puts a period to the growth of such part, though the branch may, and usually does in trees and shrubs, put forth fresh shoots from, or below, the point of insertion of the flower-stalk.

P. lateralis is a general term for a flower-stalk that originates from the side of a stem or branch, whether it be axillary or otherwise.

P. solitarius is either single on a plant, as in the Snowdrop, or only one in the same place, as in the Violet, Thorn-apple, and many common plants.

Pedunculi aggregati, clustered flower-stalks, are such as grow several together from one point, in whatever situation.

P. sparsi are scattered over the plant or branches, in a solitary manner.

P. uniflori, *biflori*, *triflori*, are such as bear each one, two or three flowers.

P. pauciflori bear few, *multiflori* many, flowers.

When there is no flower-stalk at all, the flowers are said to be sessile, *stipes sessiles*.

Various particulars belonging to flower-stalks may be found at INFLORESCENCE, or under various articles there indicated.

The physiology of the PEDUNCULUS is in many instances curious. Its evident use is to sustain the flower and fruit, and to transmit their requisite matter of nourishment, till the seed is perfected. Hence the part in question, though sometimes curved during the growth of the flower, that the organs of impregnation may be sheltered from rain, often becomes erect for the better support of the seed-vessel, lest the seeds should be prematurely, or too suddenly, dropped. The slender and weak stalk of a flower, not unfrequently acquires additional increase and strength, for the support of a weighty fruit. Nevertheless, when its final purpose is answered, that very stalk separates at some destined spot, where a solution of continuity spontaneously takes place, in parts originally so firmly united that no trace of disunion could be perceived.

PEE, in *Geography*. See PROME.

PEE, in *Mining*, is used for the place where two veins meet and cross one another, thus +.

PEEAYE-MEW, in *Geography*. See PROME.

PEEBLES, a royal burgh, and the county town of Peebles-shire, or Tweeddale, Scotland, is situated at the distance of twenty-one miles south from Edinburgh, at the confluence of the Eddlestone, or Peebles Water, with the Tweed. It is of great antiquity, and was probably a town even in the time of the Gadens. At all events there were

undoubtedly a considerable village, and a church here, before the commencement of the Scoto-Saxon period; "and there was here also as early, perhaps, a royal castle, with a chapel and other accommodations, which a town only can supply." This opinion derives much support from the fact, that Peebles is mentioned in the earliest Scottish records, "as a town of the royal demesne, which yielded a firm into the royal exchequer." According to Dr. Pennycuik, it was occasionally honoured by the residence of the Scottish monarchs, till the death of Alexander III., who conferred on it many special marks of his munificence and favour. In the contents for the succession to the throne which ensued, the inhabitants espoused the cause of Baliol, and were afterwards compelled to submit to the usurpation of Edward I. of England. At this period the town appears to have been governed by a bailiff; and a certain number of burgesses, as we find them mentioned to have sworn fealty to the English king at Berwick, on the 28th of August 1296. In 1304, it was granted by that prince to Adomar de Valence, the warden of Scotland, and his heirs. When it became a royal burgh, with special privileges, is uncertain; but it is known to have sent two representatives to the parliament, called in 1357 to ratify and provide the ransom of David II. This monarch afterwards granted Peebles a charter, dated September 20, 1367, in which it is styled a royal burgh; and the same was subsequently confirmed by king James II. and king James VI with additional privileges. By virtue of these charters the corporation of the town now consists of seventeen members, a provost, two bailies, a dean of guild, a treasurer, eleven counsellors, and one deacon. Its revenue is very considerable, most of the lands in the vicinity being the property of the public. These lands were granted to the borough in the year 1560, in consideration of "the loyalty, fidelity, and good services" of the inhabitants.

The town of Peebles was much more extensive formerly than at present, and occupied a somewhat different site, extending from Eddlestone Water westward, to the Meadowwell-strand. Of its buildings at this period little is known, but they were probably of a comparatively superior cast, as many of the houses were occupied by the nobility attending the court, when the monarch resided in the castle. Peebles in fact was to Edinburgh what Windsor now is with respect to London. Previous to the reformation it had three churches, besides several chapels. The high church, which was dedicated to the Virgin Mary, is supposed to have been erected in the eleventh century, on the site of some more ancient fabric. Its ruins still remain at the western extremity of the old town. This church was destroyed at the time of the reformation; when the Cross-church was converted into the parochial place of worship; and continued to be such till the present handsome structure was erected in 1784. Peebles is now divided into two parts, called the Old and New Town. The latter is situated on the eastern bank of the Peebles Water, and appears to have been strongly fortified, both by nature and by art. Over the Tweed is an ancient bridge of five arches; and there are two smaller ones over the Eddlestone, to connect the new town with the old. The chief support of the town is its manufacture of carpets, serges, and linen and cotton cloths; but it is likewise much indebted to its market, which has been long celebrated for oat-meal. The market day is on Tuesday, weekly, and there are besides seven annual fairs.

The chief remains of antiquity in Peebles, are the ruins of the Cross-church, and of that which was dedicated to St. Andrew. The former was part of the conventual church of a monastery founded, according to Bœcius Major, and others, by king Alexander III. Some say it was erected

erected on the spot where the relics of St. Nicholas the Martyr were discovered in 1261, an event which is particularly noticed by Fordun. This convent was filled with Red or Trinitarian friars, which order was instituted for the redemption of Christian slaves from the Turks; a third part of their annual income being appropriated to that purpose. Its buildings constituted a square, having the church on the southern side. This edifice measured 102 feet in length, and 32 in width, and was, as well as the houses and cloisters, entirely built with whin-stone, except the angles, doors, windows, cornices, &c. which were of a white free-stone. After the suppression the convent was suffered gradually to go to decay, but part of the church, as already mentioned, was fitted up for divine service, and the remainder was walled off and converted into a public school. In this state it remained till the building of the new church, when the interior was stripped of its seats and furniture, but the walls, by a praiseworthy act of council, were ordered to be protected, as a venerable monument of ancient art.

The church of St. Andrew is of greater antiquity than the Cross-church. The exact period of its construction is not recorded; but as it is stated to have been consecrated by Josceline, bishop of Glasgow, who died A.D. 1199, its date may be fixed a few years previous to that event. Judging from its remains, it seems to have been a large and capacious structure, and is certainly of great age, as all its doors and windows display semi-circular arches, or at least some segment of a circle. This church was the most ancient parish church in Peebles. After it lost that rank, in favour of the Cross-church, it was allowed to fall into ruin. A party of Cromwell's soldiers used it for some time as a stable, and at their departure demolished the roof. The only portions of this structure now standing are the square tower, and some fragments of the side walls. The church-yard is still used as a burial ground. Of the royal castle of Peebles no vestiges can be traced, but its site yet retains the name of Castle-hill. For an account of the antiquities in the vicinity, see the next article.

According to the parliamentary returns of 1811, the burgh and parish of Peebles contain 422 houses, and a population of 2485 persons.

Beauties of Scotland, vol. ii. Caledonia, vol. ii. by George Chalmers, F.R.S. and S.A. 4to. 1810.

PEEBLES-SHIRE, or TWEEDALE, one of the southern counties of Scotland, is situated between $55^{\circ} 25'$ and $55^{\circ} 50'$ of N. latitude, and from $2^{\circ} 58'$ to $3^{\circ} 34'$ of W. longitude from Greenwich. It is bounded on the south by Dumfriesshire, on the north and north-east by Edinburghshire, on the west by Lanarkshire, and on the east by the county of Selkirk. According to Armstrong's map, it measures in length from north to south about 28 miles, and varies in breadth from 10 to 18 miles; the mean length being 27 miles, and the average breadth $13\frac{1}{2}$. Of consequence, the superficial area ought to be 364 square miles, and its contents 232,960 English acres; but from a minute calculation, made by Mr. Chalmers, the real superficies is estimated at 338 square miles, or 216,320 acres; of which about 20,000 acres are arable, or under tillage. According to the parliamentary returns of 1811, this shire contains 1820 houses, and 9935 inhabitants.

General Aspect of the County.—Tweeddale, when viewed from a distance, seems to form one continued chain of mountains, and may perhaps be generally described as a mountainous country. Upon a narrow investigation, however, it is found to possess many rich and fertile vallies or straths of arable land, lying along the banks of its numerous rivers. Of these the dale of the Tweed is the principal, intersecting

the centre of the county throughout its whole extent. Hence many vales branch off, following the channels of the several streams which increase that majestic river. These, as may be conjectured, are various in size, as well as diversified in appearance. The most considerable and the most fruitful are the vallies of the Lyne and Eddlestone waters. In general, the dales and the dingles are most fertile, and the hills most pleasant in the north and west divisions of the county; while, in the south and east, the vales are more barren, and the hills more bleak.

Mountains.—The surface of Peebles-shire rises on both sides of the great central valley of the Tweed, to a very considerable elevation. The highest hills are situated towards the extremities of the county; and, indeed, those bordering on Annandale are the loftiest in southern Scotland. On the boundary with Selkirkshire, Blackhouse hills measure 2360 feet in height above the level of the German ocean; and Seamed Law, about two miles further to the north, mounts to 2120 feet above the same level. Minchmoor, on the south-east of Peebles-shire, rises 2285 feet; and Windlestraw Law, on the north-east of the county, 2295 feet above the sea. In the parish of Manor are two very high hills, called Scrape and Dollarburn, the latter of which is calculated to reach an elevation of 2840 feet. Cardon, or Cadow-hill, in the parish of Kilbucko, is about 1400 feet above the level of the Tweed, or 2200 feet above the level of the ocean. This is the highest hill on the western side of the shire, but there are many others very little inferior in altitude. In the parish of Kirkurd is a hill called Hell's Cleugh, the summit of which is distinguished by a small cairn, called the Pyked-stane, whence is a view of the county beyond the Forth, and of a chain of hills stretching from the east part of Fife, as far as Dunbartonshire. South of the Forth, the view extends as far east as North Berwick, likewise to the Eildon hills near Melrose, and Cheviot hills in Northumberland. Dundreigh, or Druids' hill, in the parish of Eddleston, also commands a most extensive and diversified prospect over Teviotdale, Annandale, Clydesdale, Perthshire, Fifeshire, and the three Lothians. This hill is computed to rise 2100 feet above the level of the ocean. Near the source of the Tweed the hills are in general extremely beautiful, being covered with grass to their very summits: some of them are of a great height, particularly Hartfield and Broadlaw, which are stated to reach the altitude of 2800 feet from the level of the Forth. Between Minchmoor and Hinderland the hills are more black, craggy, and precipitous, than in any other district of the county, and are frequently intersected by deep and tremendous chasms. One of these openings, called Grimcleugh, is upwards of half a mile in length, and not less than 300 feet in depth.

Rivers and Lakes.—The rivers of this county are numerous; but all of them, with the exception of the Megget and the North and South Esk, discharge their waters into the Tweed, as the common receiver. This celebrated river, whence the familiar name of the shire is derived, has its source on the mountainous ridge which separates Tweeddale from Annandale, and can boast of giving rise to the three first rivers in the south of Scotland: the Annan, which flows southwards into the Solway-frith; the Clyde, which runs north-west into the Clyde-frith; and the Tweed, which directs its course to the German ocean at Berwick. The last-mentioned river flows above 40 miles within the county, in a curvilinear and serpentine direction, dividing it nearly into two equal parts. Its current, particularly in that part of its course above Peebles, during which it descends from a height of 1550 feet, is extremely rapid, as indeed are all the streams in the county. The Tweed is the longest river in

PEEBLES-SHIRE.

Scotland, the distance from its source to its confluence with the ocean being upwards of 100 miles. It abounds with salmon, as well as with trout. Among the rivers which fall into it, belonging to Peebles-shire, the most considerable are the Lyne, the Eddlelton, and the Leithen, on the north; and the Manor and the Quair on the south. The Lyne rises in the northern confines of the county, at a place called Cauldstaneflap; and after a course of 21 miles, reaches the Tweed three miles above Peebles. Eddlelton water has its source from King-Seat-hill in Eddlelton parish, and joins the Tweed at the county town. Leithen water runs a course of 12 miles from Water-Head to about a mile below Inverleithen church, which derives its Celtic name from that influx, or *inver*. Manor stream originates at Foulbrig, in the southern end of Manor parish, through which it runs a course of 12 miles; and which it drains, as it courses, with other streamlets to the common channel. The Quair issues from a spring at Glendean banks, and, after watering the magnificent pleasure grounds, falls into the Tweed near the noble seat of Traquair.

The lakes in Peebles-shire are neither numerous nor extensive. The most considerable of them, the Water loch in Eddlelton parish, scarcely exceeds three quarters of a mile in length, and half a mile in breadth. It is, however, a very beautiful sheet of water, and gives birth to the South Esk, which falls into the river Forth, along with the North Esk, at Musselburgh, in Midlothian. The other lakes within the county are Gameshope loch, and Slipperfield loch; the former of which occupies an uninhabited glen in Tweedsmuir parish, and is emptied by Gameshope rivulet, one of the sources of the Talla water. St. Mary loch, though it bounds this county for more than a mile, and is hence claimed by some Peebles-shire topographers, is, properly speaking, a Selkirkshire lake, as it extends several miles into that county. The Megget pours its waters into this lake, whence they pass on to the Yarrow and the Ettrick, two of the most celebrated rivers in Scottish song.

Mineral Products.—Peebles-shire, as the mountainous nature of its surface would promise, is fertile in minerals. If credit may be given to our ancient historians, Boece and Buchanan, gold was formerly found in Glen-Gaber water, which traverses the parish of Megget. In Lead-Law, a hill above Linton, several lead mines were formerly wrought, which also produced a considerable supply of silver. The sinks of these mines are still apparent, and are distinguished by the appropriate name of Silver-holes. About 60 years ago they were again tried, but the attempt proved unsuccessful; the quantity of ore obtained being scarcely adequate to defray the expences of the work. In Traquair parish several attempts have been made to discover lead veins, and much ore has been found, but not sufficiently rich in silver to induce any adventurer to open mines.

A specimen of galena ore was discovered, a few years ago, in one of the streams that fall into the Quair. Coal is plentiful, particularly in the north-eastern district of the county, where limestone is also equally abundant. Beds of marle are frequent in the parishes of Linton and Newland. They are apparently formed by oozeings and springs from limestone, which encrust or petrify moss by depositions of limestone. In these beds the shells of the common snails are observed rotten and friable. Near the lime rocks of Carlops and Spittlehaugh is a bed of blue marle, of a mixed consistency between stone and clay. The prevailing stone under-stratum in the county is whinstone, but there are likewise numerous quarries of white and red freestone in different parishes. The slate quarries here have long been celebrated.

In Tramore hill, within Stobo parish, are two seams of excellent blue slate, which has been manufactured for various purposes during several years. In the lands of Lamancha there is a vast variety of clays, and in particular a very thick bed of fire clay, like the Stourbridge clay. In the same lands are many veins of iron ore; one of them is entirely grain ore, and the remainder is mixed with the same ore. Manganese is also found here, both by itself and incorporated with the iron ores; and there are likewise here some masses or beds of iron-stone, but there are no iron-works yet established. White marble, according to Penny-cuick, was formerly dug up at Whitfield, in Linton parish.

Several mineral springs are found within Peebles-shire, but none of them are particularly distinguished. North from the village of Linton is a spring, called "Heaven-aqua water," which bears some affinity to that at Tunbridge. Another spring, similar to the Harrowgate waters, appears in the parish of Inverleithen. There is also a copious sulphureous well in the parish of Kirkurd. The water here was analysed by the late celebrated Dr. Black of Edinburgh, and found to be stronger than the sulphureous water at Moffat. At Lamancha, in Newland parish, is a chalybeate spring, called the "Vertue Well," which contains a large quantity of fixed air, that holds the iron in solution.

Soil and Climate.—The prevailing soil on the haughs, or flat grounds nearest the waters, is generally a sandy loam, or a composition of fine earth deposited by the water after floods. The level land, lying a little above the haughs, is of a rich loam soil, on a gravelly, rocky, or till bottom. Near the sources of the several rivers, the soil is frequently of a mossy or moorish nature, particularly in the northern district of the county, where, as already mentioned, the land is the least elevated.

The climate of Peebles-shire is various. In the valley of the Tweed, which may be called the body of the county, it is often mild and warm, while in the higher and more remote parts the cold is extremely intense. Showers of rain are frequent, but the average quantity which falls in this county is much less than in the adjoining counties to the east and west, seldom exceeding twenty-eight inches annually. Many of the hills are covered with snow as early as the commencement of October; and in the autumn months some of the vales suffer greatly from the prevalence of hoar-frosts or frosty mists, which blast vegetation of every kind, and are especially pernicious to potatoes, clover, and peas.

Agriculture.—From the termination of the eleventh, to the beginning of the fourteenth century, the husbandry of this county is said to have been in a much more forward state than in most of the other counties in Scotland. The system, as at present, was then a mixture of farming with grazing. The four centuries which succeeded, however, were unprosperous in the highest degree; and it was not till after the union that any amelioration began to take place, and that prejudice was forced, in some measure, to yield to the influence of more rational ideas. Among those who have promoted agricultural improvement since that period, were "the far famed" Archibald, duke of Argyle, sir Alexander Murray of Stanhope, Dr. Penny-cuick, and James M'Daigal, a farmer near Linton. The exertions of the individual last mentioned were particularly useful in their consequences. He introduced the Norfolk rotation of crops, and several other practices before unknown here; and by his success in their application, roused in his neighbours a similar spirit of enterprise and improvement. Dairy farming was revived by Thomas Stevenfon; and the turnip husbandry was first attempted in 1764 by George Dalzel, innkeeper

PEEBLES-SHIRE.

inkeeper at Linton, who was likewise the first to cultivate the potatoe on an extensive plan, by the plough. But the greatest spring to the farming prosperity of the county was fixed about the year 1788, when the lord of Neidpath granted to all his tenants leases for fifty-five years, in consideration of certain fines, which his wants or his rapacity induced him to demand. The idea of property for so long a period stimulated the farmers to erect commodious houses, to make inclosures, and to lay out their capitals in various improvements. Inclosing and planting has since proceeded rapidly; and the best practices in husbandry are adopted. Oats are the favourite grain, but barley is likewise pretty extensively cultivated on the best soils. The turnip husbandry is carried on to a great extent, and has almost entirely exploded the practice of summer fallowing. Artificial grasses are raised on the arable lands in every district of the shire. These, however, bear but a small proportion, in point of extent, to the natural pasturage lands, which perhaps occupy nine-tenths of the whole area of the county, and are still chiefly appropriated to the rearing and feeding of sheep. The average extent of sheep farms here is 1500 acres; but there are many which reach so high as 3000 acres, and few fall short of 800. Each of them have a portion of arable land attached to them, some more and some less, according to their distance from the vallies. The common breed of sheep here is "the short-tailed compact-bodied sheep, with black faces and legs." The practice of smearing sheep with a mixture of tar or train oil, or Orkney butter, is still continued in this county, though the reasons alleged for the custom do not seem very satisfactory. Some say it improves the wool, but others doubt it, and think its only advantage is, that it keeps the sheep warm in winter; and certain it is that Tweedale wool is both coarse and low priced, and fit only for making carpets, shalloons, and such like articles of woollen manufacture.

Civil Government and Divisions.—Peebles-shire, like every other county in Scotland, is subjected to the jurisdiction of a lord lieutenant, and a sheriff depute, the latter of whom nominates a substitute to hold courts in his absence. When it was first elevated to the rank of a sheriffdom is not precisely fixed by record, but we find mention of two sheriffs in Tweedale, one in Traquair, and the other at Peebles, about the year 1184. These two sheriffdoms merged into one before the close of the fourteenth century, under the title of the latter, and have remained in the same condition ever since. The parishes within this shire are sixteen in number; and besides the royal burgh of Peebles, there are five very considerable villages that have markets and annual fairs for sheep, horses, and cows. These are Linton, Eddleston, Skirling, Broughton, and Inverleithen.

The situation of Inverleithen is most beautiful; and it has lately acquired some degree of activity by a woollen manufacture established there.

Roads.—The improvement in roads within the last fifty years has been very great in this county. The public roads indeed are excellent. One from Edinburgh towards Moffat traverses the whole length of the shire, from north-east to south-west. Another traverses it in like manner from west to east, from Biggar, by Peebles and Inverleithen, towards Galla-shiels and Kelfo. This road affords the means of conveying towards Glasgow all the superfluous grain of this district. A road also runs from Inverleithen towards Middleton, which supplies a great part of Peebles-shire with coal. It was made in 1794, and shortened the line of communication no less than fourteen miles.

Manufactures.—Tweedale cannot be called a manufacturing county, for though a considerable quantity of linen

is made by the inhabitants, none of it comes to sale, the whole being consumed by their own families. Woollen and cotton weavers, however, are said to be increasing about Peebles and its vicinity; where are likewise a few stocking looms. A woollen manufactory has been lately established at Inverleithen, which from its congenial situation is calculated to flourish. It is surprising that no woollen manufactory has hitherto been fixed at Linton, considering its favourable position on the turnpike road to Edinburgh, and the numerous advantages it possesses with respect to coal, lime, freestone, water, and sheep-walks.

Antiquities.—The remains of antiquity in Peebles-shire are at once numerous and various. Traces of the ancient Britons can still be discovered here in the names of places; as also in their religious, sepulchral, and military monuments. At Hairflanes, in Kirkcud parish, are the remains of a Druid temple, consisting of a number of large stones standing in a circular form. Another curious druidical temple is situated on the remarkable peninsula called Sheriffmuir. From each of two standing stones there run out to the east, in a curvature, two rows of smaller stones, which also stand upright. A third monument of a similar kind is seen near Tweedsmuir church, and a fourth, smaller one, on the borders between Peebles and Selkirk. Several tumuli or barrows are spread over Kirkcud, Glenholm, and Linton parishes. In a cairn upon King's Muir, in Peebles parish, were lately discovered an inverted urn, containing the ashes of some British warrior, with the blade of his dagger. In Eddleston parish, near the Ship-Law, there is a barrow called the "Ship-horns," because resembling the inverted hull of a ship. A number of sepulchral cairns are also discovered in the vale of the Tweed, and on Sheriffmuir. These, however, all yield in interest to the grave of Merlin, which is pointed out under a thorn tree, near the influx of Powfail with the Tweed. In that sacred spot, according to tradition, lie the remains of the prophet, to whom so many wonderful feats and predictions are attributed in the writings of the ancient bards.

In Peebles-shire are many hill-forts, undoubtedly of British construction, and several standing stones, supposed to be memorials of battles. The forts are generally of a circular shape, but sometimes deviate from that figure to suit the summit, or the ground whereon they are placed. On the hill called Cademuir are four British encampments, one of which is surrounded by a rampart of stones without cement. This rampart is in some places double; but in other parts it is single and of prodigious thickness. Janet's brae in Peebles parish is also distinguished by two entrenchments, which are each surrounded by a single ditch and vallum. In the same parish are several other similar works; particularly one on the summit of Meldum, another on the hill above Hutchinfield, a third near Hayton Craig, a fourth on the hill above Wham, and a fifth on the hill called Ew-hill-rig. In Manor parish are likewise many strengths, on Hound-hill, Caverhill, and on a small eminence called the *Ring-know*. On a height near Inverleithen, are the remains of a British fortress, which appears to have had three ramparts and ditches. The other principal British military works, are at Milkington-Rings, and North-Shield-Rings, in the parish of Eddleston; on Terrace-hill, in Newlands parish; on the rising ground above Linton, and on the top of Lead-Law. Besides these, however, there are numerous others which our limits will not permit us to particularize.

The Romans, who were unquestionably the first people that encroached upon the British aborigines, have left few traces of their residence here, and those few are confined to military posts or encampments. Of these the principal one

is situated on the eastern side of the Lyne, about ten miles to the eastward of the Watling-street, which traverses the country within half a mile of the western extremity of the shire. This entrenchment is called by the common people Randal's Walls, from a tradition that Randolph, earl of Murray, had a house within its area. According to Armstrong it contains six acres and two roods of ground, which has been frequently ploughed, when many Roman coins have been turned up. Another Roman encampment is situated on the northern side of Upper Whitfield, in the parish of Linton. It is in the form of a parallelogram, and is surrounded by a single fosse and rampart, which are now nearly obliterated. A third entrenchment, in the parish of Manor, is also generally represented to be of Roman construction.

Among the other antiquities of this county, the most prominent are its terraces and castles. Respecting the origin and uses of the former much difficulty prevails; indeed all that has been advanced concerning them is merely conjectural. The opinion of Chalmers, however, that they were intended for the accommodation of large bodies of spectators to witness some sport, carries with it considerable plausibility; and it likewise seems probable that several of them were subsequently appropriated for the administration of justice. Of such works the most considerable are those on a beautiful green mount, called Terrace-hill, above Newlands. Along the whole face of this hill there are eleven or twelve terraces, from fifteen to twenty feet broad, which rise by a regular gradation to the top. About half a mile to the north is another eminence, called "Moot Hill," which has likewise several tiers of terraces. Similar terraces are to be seen at Kirkurd, at Skirling, and at Smithfield.

The remains of the castles and fortified towers of this county, are principally seated on the banks of the Tweed, and alternately on both sides of that river, and in sight of each other, as happens in Selkirkshire and Berwickshire. The object of this arrangement was the defence of the country from the incursions of the border chiefs. On the approach of an enemy, a fire was immediately lighted on the top of the nearest castle, and thus notice of the aggression was spread over a district of at least seventy miles in length in the course of a few hours. These castles were built of stone and lime, usually in a turretted form, and for the most part occupied an eminence of difficult access. Those situated within ten miles above and below Peebles were at least twenty-six in number, and much resembled each other, except in the circumstance of greater or less magnitude. At Traquair the Scottish kings had a castle in the twelfth century, where they occasionally resided for the purpose of hunting in the forest. This castle is now completely demolished, as well as that at Peebles, which is likewise said to have been a royal residence. On Woodhill are some remains of an ancient building, which is called Macbeth's castle; and in Broughton parish is another, bearing the same name, which is traditionally said to have belonged to the celebrated Macbeth. The remains of Oliver castle, the seat of the Frasers, are seen in Tweedsmuir parish; and on Fruid water are the remains of Fruid castle, another baronial mansion, which also belonged to that powerful family. Drummelzier castle is situated close to the river Tweed, and about a mile from it is Thaness castle, or Tinnis castle, formerly occupied as a sort of redoubt by the Tweedies, the lords of Drummelzier, who dominated here during several ages of anarchy. But these, and indeed almost all the ancient castles in this shire, are completely ruinous, with the exception of that of Niedpath, in the vicinity of Peebles, which being of vast strength, still continues in tolerable preservation, and consequently affords an excellent specimen of similar building. This castle stands

on a rock, projecting over the north bank of the Tweed, which here runs through a deep narrow glen well wooded on both sides. Towards the land it commands an important pass. The walls are eleven feet in thickness, and cemented with lime almost as hard as the strong whinstone of which they are built. Niedpath was anciently the chief residence of the Frasers above-mentioned, and was most probably the birth-place of the brave sir Simon Fraser, the last of the family in the male line, who, in 1303, with only ten thousand men, repulsed and defeated the English, thirty thousand strong, in three successive battles, fought in one day on Roslyn moor. In the reign of Charles I. it was garrisoned for the king, and held out against Cromwell longer than any place in Scotland, south of the Forth. The situation of this castle is extremely beautiful and commanding. Penny-cuick, who says it was of old called the "Castle of Peebles," celebrated it thus:

"The noble Niedpath Peebles overlooks
With its fair bridge and Tweed's meand'ring brooks,
Upon a rock it proud and stately stands,
And to the fields about gives forth commands."

Caledonia, or An Account of Historical and Topographic of North Britain, by George Chalmers, F.R.S. 4to. edit. 1810. Beauties of Scotland, vol. ii. Sinclair's Statistical Account of Scotland, vols. iii. iv. xii. xvii. Armstrong's Companion to the Map of Tweedale.

PEEING-GHIE, a town of the Birman empire, situated on the Irawaddy, from which a great quantity of teak timber is carried to Rangoon. The forests extend along on the western mountains: the trees are felled in the dry season, and when the monsoon sets in are borne by the torrents to this town and Sahlhadam, a little above it. Peking-ghie is about 20 miles N.W. of Mayadoun.

PEEK, in the *Sea Language*, a term used in various senses; *e. g.* an anchor is said to be *a-peek*, when the ship, being about to weigh, comes over her anchor, so that the cable hangs perpendicularly between the hawse and the anchor; the bringing of a ship into which position they call *heaving a-peek*.

A ship is said to ride *a-peek*, when, lying with her main and fore-yards hoisted up, one end of her yards is brought down to the shrouds, and the other raised up on end; which is chiefly done when she lies at rest in rivers, lest other ships, falling foul of her, should break her yards.

PEEK, *to ride a broad*, denotes much the same, excepting that the yards here are only raised to half the height.

To PEEK the mizzen, is to put the mizzen yard perpendicular by the mast.

PEEK is a name given to the upper corner of all those sails which are extended by a gaff, or by a yard which crosses the mast obliquely, as the mizzen yard of a ship, the main yard of a bylander, &c. The upper extremity of those yards and gaffs is also called the *peek* or peak.

PEEK is also used for the room in the hold, from the bits forward to the stem: in this place men of war keep their powder, and merchantmen their victuals.

PEEK-haliards, are the ropes or tackles by which the outer end of the gaff is hoisted as opposed to the throat haliards, which are applied to the inner end.

PEEK's Hill, in *Geography*, a small post-town of America, in West Chester county, New York, on the E. side of Hudson river, and N. side of the creek of its name, five miles from its mouth; 50 miles N. of New York.

PEELAS, a small island in the Sooloo Archipelago. N. lat. 6 32'. E. long. 121 45'.

PEELE, GEORGE, in *Biography*, a dramatic writer in the

the reign of queen Elizabeth, was a native of Devonshire, and a student of Christ-church college, Oxford, where he took his degree of M.A. in 1579. He was a good pastoral poet, and his plays were acted with great applause in the university.

PEELE, in *Geography*, a small sea-port town, situated on the western coast of the Isle of Man, in the Irish channel, was formerly denominated Holm, and appears, from its remains, to have been a place of considerable importance in the times of Manish independence. The annexation of Man to the British crown, and the subsequent destruction of the smuggling trade, however, have reduced it greatly. The harbour, indeed, is now almost entirely neglected, notwithstanding it is an excellent resort for shipping, and the pier is completely destroyed. In short, this town offers to the present traveller an appearance of decayed grandeur; and is consequently more an object of interest and curiosity than inviting as a place of residence, for the man of business or of pleasure. Woods, in his account of the Isle of Man, computes the population of Peele at about twelve hundred persons. The only church in the town, now used for divine service, is that dedicated to St. Peter, but there are besides the ruins of other two dedicated to St. Patrick and St. Germain. These stand within the castle, on a small rocky island, which is separated from the western extremity of the town by a narrow channel, scarcely a foot deep at low water. This island and castle are connected with the mainland by a strong wall, shelving to the top, which was built many years ago to secure the harbour. The entrance is on the eastern side, by a flight of steps now so ruinous as to be dangerous of access. The walls of this fortress measure about four feet in thickness, and are flanked with towers; the whole inclosing a space of somewhat more than two acres of ground. Before the sale of the Royalty of Man to the British government, a garrison of troops, in the pay of the lord of the island, was stationed here; but since that event the castle has been altogether neglected, and the entire area is occupied by the ruins of various buildings, walls, and dwelling houses. About the centre of it is a square pyramidal mound of earth, terminating obtusely, and having each of its sides directed to one of the cardinal points. This tumulus is surrounded by a ditch five feet and a half broad, and is supposed either to have been an eminence whence an officer might harangue his troops, or the burial place of some great personage. Near this mound stand the ruined churches above-mentioned, both of which are of considerable antiquity. Patrick's, however, is by far the older of the two, and is probably of earlier date than the era of the Norman conquest. St. Germain's was built about the year 1245, and is the cathedral of the island, but has not, for many years, been used for any other purpose than a burying-place. Its dimensions are seventy-six feet by twenty; and beneath one part of it is the ecclesiastical prison or dungeon, where such persons were confined as were so unfortunate as to incur the spiritual censure. The length of this vault is thirty-four feet, and its breadth sixteen. The bottom is of earth, and at one corner are the remains of an uncovered well, which must have rendered the place damp in the extreme. The only light or air is admitted through a small hole in the wall.

Three miles from Peele is the Tinwald mount, where the Manx parliaments and great councils were convened, and where also the superior courts held judicial proceedings at stated periods. It is an artificial eminence of very singular appearance, and of unknown antiquity. According to some etymologists, its name is a compound of the Danish word *tin* or *ting*, signifying an assembly or meeting, and *wald*, a field or

fenced place. Several modern authors, however, derive it from the British words *tyng* and *wal*, signifying "the juridical hill." The approach to the summit of this mount is by a flight of turf steps on the eastern side. The diameter at the top is about seven feet, and three feet below it is an annular plot four feet wide, which is succeeded by another six feet broad, and this by a third still wider. The circumference of the outer circle is nearly eighty yards; all the angles are rounded, and almost the whole surface is of turf.

At a short distance from the Tinwald is a small chapel dedicated to St. John, rebuilt about fourteen years ago, after the model of the former chapel, which had fallen completely to ruin. It has no pews, never being used for divine service except on the day of the promulgation of the laws. An Account of the Past and Present State of the Isle of Man, by George Woods, 8vo. 1811.

PEELING, a town of America, in Grafton county, New Hampshire, containing 83 inhabitants.

PEEM, a town of the duchy of Holstein; 9 miles W. of Eutyn.

PEEMDAHATTA, a town of Hindoostan, in the circar of Ruttunpour; 25 miles N.N.E. of Dumdah.

PEENANG, or *Prince of Wales's Island*. See PINANG.

PEENE, a river which runs into the Baltic, W. of the island of Usedom; separating in part of its course Hinder Pomerania from Anterior Pomerania. N. lat. $54^{\circ} 10'$. E. long. $13^{\circ} 50'$.

PEENEMUNDE SCHANZ, a town and fort in the island of Usedom, which it commands, as well as the entrance and mouth of the Peene, near which it stands; 6 miles N. of Wolgast. N. lat. $54^{\circ} 10'$. E. long. $13^{\circ} 48'$.

PEENPACK, a town of New York, in Orange county; 25 miles W. of Newburgh.

PEEPAROO, a town of Bengal; 6 miles from Natore.—Also, a town of Hindoostan, in Rohilcund; 15 miles W.S.W. of Budayoon.

PEEPLY, a town of Hindoostan, in Cattaek; 5 miles S. of Cattaek.

PEER, PAR, primarily denotes an equal, or one of the same rank and condition. Hence, in some councils, or assemblies, we find, "with the consent of our peers, bishops, abbots, &c."

PEER, afterwards, was applied to the vassals, or tenants of the same lord, who were obliged to serve and attend him in his courts.

They were called peers, *pares*, because equal in function; and *peers in fees*, or *fees*, because holding fees of the lord; or because their business in court was to sit and judge, under their lord, of disputes arising concerning fees.

The number of peers required to sit in a court was at least four; and when there happened to be too many peers in the same lordship, the lord usually chose out twelve, who had the titles of peers, by way of distinction and eminence.

There are also instances of women who have assisted at judgment, on account of their tenements, not of their being wives of peers. The origin of these peers of fees is as ancient as that of the fees they were appointed to judge of: from these we derive our common juries, and our peers of the realm.

PEER of the Realm, denotes a noble lord, or person who has a seat and vote in the upper house of parliament; which is hence called the *house of peers*. See NOBILITY.

The right of peerage seems to have been originally territorial; that is, annexed to lands, honors, castles, manors, and the like; the proprietors and possessors of which were (in right of those estates) allowed to be peers of the realm,

realm, and were summoned to parliament to do suit and service to the king: and when the land was alienated, the dignity passed with it as an appendant.

Thus, the bishops sit in the house of lords, in right of succession to certain ancient baronies annexed, or supposed to be annexed, to their episcopal lands: and though they are lords of parliament, they are not properly of the degree of nobility, their blood is not ennobled, nor their peerage hereditary: and, therefore, they are tried not by peers, but by a common jury: and when one of the nobility is tried by his peers in parliament, the spiritual lords must withdraw, and make their proxies. See BISHOP.

But afterwards, when alienations became frequent, the dignity of peerage was confined to the lineage of the party ennobled, and instead of territorial, became personal. Peers are now created by writ or patent. The creation by writ, or the king's letter, is a summons to attend the house of peers, by the style or title of that barony which the king is pleased to confer; that by patent, is a royal grant to a subject of any dignity and degree of peerage. The creation by writ is the more ancient, but a man is not ennobled thereby, unless he takes his seat in the house of lords; and some are of opinion, that there must be at least two writs of summons, and a sitting in two distinct parliaments, to evidence an hereditary barony (Whitelocke of Parl. p. 114.); and, therefore, the most usual, because the surest way is to grant the dignity by patent, which enures to a man and his heirs, according to the limitation thereof, though he never makes use of it. Creation by writ, however, has one advantage over that by patent; for a person created by writ holds the dignity to him and his heirs, without any words to that purport in the writ: but in letters patent, there must be words to direct the inheritance; or else the dignity enures only to the grantee for life. For a man or woman may be created noble for their own lives, and the dignity not descend to their heirs at all, or descend only to some particular heirs; as where a peerage is limited to a man, and the heirs male of his body by Elizabeth his present lady, and not to such heirs of any former or future wife. Co. Litt. 9. 16.

Peers of the realm are by their birth hereditary counsellors of the crown, and may be called together by the king, to impart their advice in all matters of importance to the realm, either in time of parliament, or when there is no parliament in being (Co. Lit. 110.): accordingly Bracton, (l. i. c. 8.) speaking of the nobility of his time, says, they might properly be called "consules, a consulendo; reges enim tales sibi associant ad consulendum." And in our law-books (7 Rep. 34. 9 Rep. 49. 12 Rep. 96.) it is laid down, that peers are created for two reasons; "1, ad consulendum; 2, ad defendendum regem;" on which account the law gives them certain great and high privileges: such as freedom from arrests, &c. even when no parliament is sitting; because it intends, that they are always assisting the king with their counsel for the commonwealth; or keeping the realm in safety by their prowess and valour. Instances of the peers to advise the king, have been in former times very frequent; though now fallen into disuse, by reason of the more regular meetings of parliament. In cases of emergency, our princes have at several times, in a later period, thought proper to call for and consult as many of the nobility as could be easily got together; such was particularly the case with king James II., after the landing of the prince of Orange; and with the prince of Orange himself, before he summoned that convention parliament, which afterwards called him to the throne. Besides, it is usually considered as the right of each particular peer of the realm to de-

mand an audience of the king, and to lay before him, with decency and respect, such matters as he shall judge of importance to the public weal. The claims of peerage may be hereafter easily settled, since by a standing order of the house of lords, May 1767, the heralds are directed to take exact accounts, and preserve regular entries of all peers and peeresses of England, and their respective descendants; and it is required that an exact pedigree of each peer and his family, shall, on the day of his first admission, be delivered to the house by Garter, the principal king at arms.

As to the privileges of peers, see NOBILITY and PARLIAMENT. See also CLERGY, *Benefit of*.

The house of lords have a right to take cognizances originally of all public accounts, and to enquire into any misapplication, or default in the distribution of public monies; or of any other mismanagement whatsoever.

Towards the latter end of the reign of king Charles I., the house of lords asserted their jurisdiction of hearing appeals from the chancery, which they do upon a paper petition, without any writ directed from the king; and for this their foundation is, that they are the great court of the king, and that therefore the chancery is derived out of it, and by consequence that a petition will bring the cause and record before them. This was much controverted by the commons in the reign of Charles II., but is now pretty well submitted to, because it has been thought too much, that the chancellor should bind the whole property of the kingdom without appeal.

PEERS, *Pairs of France*, were, before the revolution, the twelve grand lords of that kingdom. The institution of these peers is very uncertain; some refer it to Hugh Capet, at the time when the dukes and counts changed the offices they then held of the king into perpetual fiefs: but this is impossible; Champagne, one of the titles, not being then erected into a county. Indeed, Pasquier observes, that it is an old tradition, that there have been twelve peers in all ages. Of these peers, six were dukes, and six counts, *comtes*; of these, again, six were ecclesiastics, and six laymen.

The archbishops of Rheims and the bishops of Laon, and Langres, were dukes and peers; and the bishops of Noyons, Chalons on the Marne, and Beauvais, were counts and peers.

The dukes of Burgundy, Normandy, and Aquitaine, were lay peers and dukes; and the counts of Flanders, Champagne, and Thoulouze, lay peers and counts.

These lay peers assisted at the coronation of the kings in ceremony, and by way of representatives; where each performed the functions attached to his respective dignity: though their peerships were in reality all, except that of Flanders, reunited to the crown. Six lords of the first quality were chosen to represent them. The ecclesiastical peers usually assisted in person. At a later period, the title peer, in France, was bestowed, as in England, on every lord, or person, whose fee was erected into a lordship or peership.

The word peer, according to Pasquier, is derived from *patricius*, the first dignity in the eastern empire; on the model whereof he supposes these peers to have been instituted. But others, with more probability, derive the title from the *pares curie*, or *peers of fees*, because of their being equal to each other.

These *pares curie*, on whose model they suppose the peers of realms to have been erected, were a kind of vassals, depending all on the same lord, whom they were obliged to attend and assist in court.

All feudal matters, or disputes, among vassals, relating to their fees or dependencies, were terminated by the superior

rior lord of the two contending parties, and by their peers in fee.

If the procefs were between the lord and the vassal, the lord took no cognizance of it, and the peers alone judged it.

Hence all lords or nobles, being *pares nobilitate, i. e.* all equally intitled to the privileges of nobility, are denominated *pares regni, peers of the realm.*

Some authors attribute the first institution of peers of the realm to Charlemagne, but with little probability; since most of the siefs, which bear the names of duchies, &c. or give titles to the peers, were not erected into duchies, &c. till long after: the dukes, &c. in those days, being no more than simple governors of provinces, without any other title or privileges.

The more probable opinion is, that peers were first instituted by Philip the Young of France, about the year 1179, and that they first acted in capacity of peers at the coronation of his son.

PEER, in *Building.* See PIER.

PEER, in *Geography,* a town of France, in the department of the Lower Meuse, and chief place of a canton, in the district of Hasselt; 30 miles N. of Liege. The place contains 1005, and the canton 5351 inhabitants, on a territory of $187\frac{1}{2}$ kilometres, in 8 communes.—Also, a small island in the East Indian sea. S. lat. $5^{\circ} 18'$. E. long $118^{\circ} 20'$.

PEERAGE, the dignity of a peer attached to a duchy, earldom, barony, or the like.

The king of England confers peerage at pleasure. King George I. offered his parliament to resign that branch of his prerogative, and to have the number of peers limited.

The reason insisted on, was the inconvenience accruing to the state from an arbitrary and immoderate use thereof; the prince having it in his power to throw what number of his creatures he pleases into the upper house of parliament.

The twelve peers created at once in the reign of queen Anne, was a main argument in behalf of the peerage bill. But though a bill for this purpose passed the house of lords, it miscarried in the house of commons, whose leading members were then desirous to keep the avenues to the other house as open and easy as possible. It is recorded as a saying of king Charles, that if his friends could but secure him a house of commons, he would put his whole troop of guards into the upper house, but he would have the peers.

PEERAGE, to hold land in, in the *Ancient Customs,* was a tenure which obliged the person to assist the lord's bailiff in his judgments; as all the ancient vassals, called peers, did.

PEERESS. As we have noblemen of several ranks, so we may have noblewomen, and these may be by creation, descent, or marriage; and first, king Henry VIII. made Anne Bullen marchioness of Pembroke; king James I. created the lady Compton, wife to sir Thomas Compton, countess of Buckingham, in the life-time of her husband, without any addition of honour to him; and also the same king made the lady Finch viscountess of Maidstone, and afterwards countess of Winchelsea, to her and the heirs of her body: and king George I. made the lady Schulenberg duchess of Kendal.

A woman noble by creation or descent, marrying one under the degree of nobility, still remaineth noble, but if she be noble by marriage only, she loseth her dignity if she marry afterward a commoner; though not if the second husband is noble, and inferior in dignity to the first husband;

and by the courtesy of England, women noble by marriage, always retain their nobility. 1 Inst. 16. 1 Inst. 50. 6 Rep. 53

A countess or baroness (either in her own right, or by marriage) may not be arrested for debt or trespass; for though, in respect of their sex, they cannot sit in parliament, they are nevertheless peers of the realm, and shall be tried by their peers, &c. 20 Hen. VI. c. 9.

PEERGAOW, in *Geography,* a town of Hindoostan, in Dowlatabad; 35 miles S. of Amednagar.

PEERGOTCHY, a town of Bengal; 28 miles W. of Dinagepour.

PEERGUNGE, a town of Bengal; 39 miles N.E. of Purneah.

PEERNAGUR, a town of Hindoostan, in Oude; 17 miles of Manickpour.

PEERPAR, a town of Bengal; 5 miles N. of Rajamal.

PEER-PUNCHEL, mountains which form the southern boundary of Cachemire.

PEERWALTH, a town of Austria; 13 miles S. of Ips.

PEESKEN, a town of Prussian Pomerelia; 17 miles S.S.W. of Marienburg.

PEEVIT, or PEWIT, in *Ornithology,* a bird of the larus kind, with a black head, and a grey-coloured body. See *Larus Ridibundus.*

PEGANELÆON, a word used by the ancients to express oil, in which the leaves and flowers of rue had been infused and insolated.

PEGANERON, a name given by some old authors to a plaster in which rue was a principal ingredient, from *peganon,* the Greek name of rue.

PEGANUM, in *Botany,* a Greek name adopted by Linnæus for this genus, on account of its affinity to Rue; (see *RUTA.*) Πηγανον is the general name for Rue in Dioscorides; and this very plant, which is the *Harmel* of the Arabians, and thence called *Harmala* by some of the earlier modern botanists, is the Πηγανον αγριον, or Wild Rue, of that old Greek writer.—Linn. Gen. 239. Schreb. 322. Willd. Sp. Pl. v. 2. 856. Mart. Mill. Dict. v. 3. Sm. Prodr. Fl. Græc. Sibth v. 1. 319. Ait. Hort. Kew. ed. 2. v. 3. 146. Juss. 297. Lamarck Illustr. t. 401. Gærtn. t. 95. (Harmala; Tournef. t. 133.)—Class and order, *Dodecandria Monogynia.* Nat. Ord. *Multifloræ,* Linn. *Rutaceæ,* Juss.

Gen. Ch. *Cal.* Perianth inferior, of five linear, straight, acute, permanent, often toothed leaves, the length of the corolla. *Cor.* Petals five, oblong-ovate, slightly spreading. *Stam.* Filaments fifteen, awl-shaped, not half so long as the corolla, dilated at the base into a cup-like nectary under the germen; anthers oblong, terminal, erect. *Pist.* Germen roundish, three-lobed, elevated on a short stalk; style thread-shaped, erect, equal to the stamens; stigma oblong, triangular. *Peric.* Capsule roundish, with three blunt angles, of three cells and three valves, with partitions from the centre of each valve. *Seeds* several, obovate, acute, roughish.

Ess. Ch. Petals five. Calyx of five leaves. Capsule with three cells and three valves; the partitions contrary to the valves. Seed many.

Obs. Linnæus remarks that *Peganum* differs from *Ruta* as *Celastrus* from *Euonymus*; whatever is deducted in number from the pistil, being added to the stamens, and *vice versa.*

1. *P. Harmala.* Syrian Rue. Linn. Sp. Pl. 638. Bulliard Herb. de la Fr. t. 343. Sm. Fl. Græc. Sibth.

t. 456, unpublished. (Harmala; Ger. em. 1255. *Ruta sylvestris*, armala; Matth. Valgr. v. 2. 97.)—Leaves many-cleft. Stem herbaceous.—Native of open sandy heaths in Portugal, Spain, and various parts of the Levant. The dreary plains which separate France and Spain, beyond the Pyrenees, are clothed for the most part with this plant, far as the eye can reach. It is hardy with us, but not common, flowering in July and August. The root is perennial. *Herb* very bushy, repeatedly branched and leafy, of a glaucous hue, smooth. *Leaves* scattered, sessile, deeply three-cleft, pinnatifid, in linear, acute, entire segments. *Flowers* terminal, solitary, about an inch wide. *Calyx* widely spreading or deflexed while in flower, then erect; its leaves sometimes, but not always, three-cleft. *Petals* white, with green streaks. *Antbers* yellow. The whole plant has a strong scent, and bitter acrid flavour, of the rue kind.

2. *P. crithmifolium*. Retz. Obs. fasc. 3. 34. Willd. n. 2.—Leaves many-cleft. Stem shrubby.—Gathered near the Caspian sea, by Pallas, who sent seeds to Retzius. The latter distinguishes this, as a species, from *P. Harmala*, on account of its shrubby perennial stem, which is three or four feet high, whereas the other is scarcely half so tall, and the smaller size of its flowers. As to the calyx, whose leaves he says are divided in the *Harmala*, this is but rarely the case, and chiefly, as it seems to us, in garden specimens.

3. *P. retusum*, Forsk. Ægypt-Arab. 211. Vahl. Symb. v. 3. 63. Willd. n. 3.—Leaves wedge-shaped, abrupt. Stem shrubby.—Gathered by Forskall in Egypt, near Alexandria. The Arabians call it *Gharghed*.—This is a shrub, with spinous downy branches. *Leaves* sessile, somewhat fleshy, wedge-shaped, undivided, abrupt. We have seen no specimen, nor figure.

4. *P. dauricum*. Linn. Sp. Pl. 638. (*Harmala montana*, daurica, perennis, multicaulis, polygalæ folio, albo flore; Amm. Ruth. 70. *Ruta foliis simplicibus alternis*; Gmel. Sib. v. 4. 176. t. 68. f. 1.)—Leaves lanceolate, slightly crenate. Stem herbaceous.—Native of gravelly places in Siberia.—We have a wild specimen from the barons d'Itzenplitz. This has a thick, woody, perennial root. *Stems* numerous, erect, slender, mostly simple, leafy, round, smooth, scarcely a foot high. *Leaves* scattered, sessile, lanceolate, acute, half an inch long, slightly crenate towards the end, glaucous, besprinkled with glandular dots. *Flowers* few, somewhat corymbose, at the summit of each stem, white, not half the size of the first species, and differing widely from that in the form of the calyx-leaves, which are very short and ovate. The capsule is described by Ammann as of three, rarely four, cells, with two or three seeds in each.

Linnaeus seems to have been led by Gmelin's plate to suppose this had no calyx, and therefore he says, in the short generic character, "calyx five-leaved, or none," which Willdenow copies. The calyx however, though small, is present, and resembles in shape, though not in hairiness, that of *Ruta fruticulosa*, Labill. Syr. fasc. 1. t. 4. Willd. Sp. Pl. v. 2. 545, to which *P. dauricum* has a considerable general resemblance. The plants nevertheless are specifically, and as it appears by Labillardiere's figure of the fruit, generically, distinct.

Harmala montana, polygalæ foliis, floribus luteis; Amm. Ruth. 71, is thought by that author to be a mere variety of *P. dauricum*, with yellow flowers. To us it seems to merit further enquiry. May it not be still nearer akin to the *Ruta fruticulosa*, as the flowers of that are yellow? They cannot indeed be the same; as Ammann's plant, by the description of the fruit, is a true *Peganum*.

PEGASUS, in *Astronomy*, the name of a constellation of the northern hemisphere, figured in form of a flying horse. The stars in this constellation, in Ptolemy's Catalogue, are twenty, in Tycho's nineteen, in Hevelius's thirty-eight, in the Britannic Catalogue eighty-nine. See CONSTELLATION.

PEGASUS, in *Ichthyology*, a genus of fishes of the order Branchiostegous, according to the Linnæan system, but of the Cartilaginous order in more modern arrangements. The generic character is this: the mouth is beneath; the snout retractile; the upper jaw is elongated, denticulate, ensiform, and linear; aperture of the gills single, before the pectoral fins; body compressed downwards, articulate with bony incisions, and mailed; ventral fins behind the pectoral. There are three species, which are all natives of the Indian seas, and which are characterized by the shape of the snout.

Species.

DRACONIS. This species has a conical snout; it is a small fish, three or four inches in length, and is remarkable for the size of its pectoral fins, which are supposed to enable it, like the exocoeti, and some other fishes, to support itself for a few seconds in the air, while it springs occasionally over the surface of the water. The thorax, or superior part of the body, is of a broad, slightly flattened, squarish form, and is marked, both above and beneath by several radiated shields, or bony tubercles of considerable size; from each side of the abdomen springs a lengthened cirrus, which may be considered as supplying the place of a ventral fin; from the thorax the body suddenly decreases in diameter, and is marked into several divisions or transverse segments; the tail is small and slightly rounded; the pectoral fins are, as it has been already observed, large in proportion to the size of the animal, and of a rounder shape, with a kind of scalloped or indented outline; the eyes are large and protuberant, and the snout of a subconical form, but with a slight dilatation towards the tip, so as to appear spatule-shaped when viewed from above; the colour of the whole animal is whitish, with a slight cast of pale brown.

VOLANS. Snout ensiform, and denticulate. The length of this fish is about three inches; the snout is much elongated, flattened, rounded, and slightly dilated at the tip; marked by a longitudinal channel, and crenated or denticulated on the edges; on the head is a rhomboidal depression, and behind it are two deep sub-pentagonal cavities; the last joints of the body next the tail are pointed on each side.

NATANS. The snout of this species is ensiform and unarmed. It is about the length of the Volans, but much more slender: in respect to colour it is yellowish-brown, whitish beneath; snout slender, slightly dilated and rounded at the tip; marked above and beneath by a middle furrow; pectoral fins rounded and of a moderate size; the dorsal fin is situated on the middle of the back; segments of the abdomen about eleven or twelve in number; the tail is small and slightly rounded; the ventral cirri slender and flexible.

PEGASUS, in *Mythology*, a winged horse, whose origin is thus related by Hesiod: Perseus, it is said, cut off the head of Medusa, one of the Gorgons, and from the blood that issued from it sprung the hero Chrysaor, and the horse Pegasus: Chrysaor derived his name from a golden sword which he had in his hand at his birth. He fell afterwards in love with Callirhoe, the daughter of the Ocean, and had by her Geryon, the famous giant with three heads. Pegasus was so named, because he was born near the sources

of the ocean: he instantly left the earth, and winged his way to the mansions of the gods. There he now resides, in the palace of Jupiter himself, whose thunder and lightning he bears. According to Pindar, the horse Pegasus, who is represented by Hesiod as having taken flight to the mansions of the gods, was afterwards broke by Minerva, and given to Bellerophon, who mounted him to combat the Chimæra; but that hero having attempted to ascend to heaven on the wings of that horse, was thrown down to the earth, and Pegasus was placed among the stars. Ovid, among other fictions, says, that Pegasus, flying through the airy regions, went into Mauritania, where he transformed Atlas, who had given him a bad reception, into that mountain which has since borne his name. From thence, continues he, he went into Ethiopia, where he rescued Andromeda from the monster that was ready to devour her, and punished Phineus his rival, together with all those who had sided with him, by shewing them the Gorgon's head, which turned them all into stones. For an explanation of the fable of the Gorgons, see GORGONS. Under that article the reader will find that the three Gorgons were ships, called by the names which they bore, that Perseus's expedition was a sea voyage, and that Pegasus was a ship with sails, which Perseus carried into Greece, after having made use of it to rescue Andromeda. Virgil gives the epithet nine wings to a ship, "remigio alarum." If Hesiod, and after him the other poets, say that Pegasus sprung from the blood of Medusa, the reason is, says Banier, that Perseus did not carry off the ship which was so called, till after a sharp engagement, in which much blood was shed. Pegasus was, in a manner, the offspring of that Gorgon, because he belonged to her father Phorcys' fleet. When Pausanias says that Pegasus was broke by Minerva, we may suppose him to mean, that Perseus found occasion for a great share of prudence in managing to advantage a ship with sails, the use of which was then unknown to him. If, according to Ovid, Perseus mounted Pegasus for his Mauritanian expedition, it is unnecessary to say that it was meant of a ship, and not of a horse. It may however be alleged, that, according to Hesiod, Pegasus, as soon as he was born, left the earth and flew away to the mansions of the gods. A plausible meaning may be given to this circumstance by saying that Perseus, upon his return into Greece, as an acknowledgment to the gods for his happy voyage, consecrated the prow of the ship Pegasus in Jupiter's temple, according to usual custom; and if this temple stood upon mount Olympus, which was accounted heaven, and the mansion of the immortal gods, nothing more would be wanting for developing this part of the fable. As for the poets that are later than Hesiod, who make Pegasus to have taken flight upon mount Parnassus, where, with a blow of his foot, he made the fountain Hippocrene to spring up, and which became so famous afterwards for the feat of Apollo and the Muses, we may suppose, that Perseus consecrated likewise in the temple of Apollo, which was in that mountain, some other part of his ship. Chrysaor, who issued at the same time with Pegasus from the blood of Medusa, with a golden sword in his hand, was some ingenious artist who wrought in gold and ivory; an explanation corresponding both to his name and the sword in his hand. Phorcys employed him to work the elephants' teeth, and the horns of the other animals which his ships brought home; and the meaning of his marrying the beautiful Calirrhoe was, that Phorcys, in order to engage so great an artist to remain in his dominions, procured for him a considerable match. Banier's Mythology, vol. iii.

VOL. XXVI.

PEGASUS, in *Ornithology*, the grey-bellied humming-bird of Latham, a species of *Trochilus*, which see.

PEGAU, in *Geography*, a town of Saxony, in the circle of Leipzig, on the Elster, containing two churches and a convent; 10 miles S.S.W. of Leipzig. N. lat. 51° 12'. E. long. 12 12'.—Also, a town of Lower Stiria; seven miles N. of Gratz.

PEGERSK, a town of Russia, in the government of Pskov, near the lake Tchudskoe; 20 miles W.N.W. of Pskov. N. lat. 57° 55'. E. long. 27° 32'.

PEGMA, among the Romans, a wooden machine, used in theatrical entertainments, which was raised and let down by secret engines, whence it was said to grow. See PEGMATES.

PEGMATES, or rather PEGMARES, in *Antiquity*, a name given to certain gladiators, as well as artificers among the Romans.

The ancients sometimes exhibited shows of a sort of moving machine, called *pegmata*: these were scaffolds variously adorned, somewhat after the manner of those now raised for fire-works.

These scaffolds, being made to play, and rise aloft, either threw up into the air the matters with which they were charged; and, among the rest, men, who were thus sacrificed to afford the people diversion; or else they precipitated them into holes dug in the ground, where they lighted their funeral piles; or finally into the dens of wild beasts.

Both the miserable people thus sacrificed, and the workmen that made and played the machines, were called *pegmates*, or *pegmares*.

According to Casaubon, fire was set to the scaffold: and the pegmates were to save themselves through the flames, and the wreck of the machine.

Lipsius only says, that the pegmates were such gladiators as fought on scaffolds erected for that purpose. They were also called *petauriske*, q. d. *fliers in the air*.

PEGNA COVA, in *Geography*, a town of Portugal, in the province of Beira; seven miles N.E. of Coimbra.

PEGNA *da Francia*, a town of Spain, in the province of Leon, anciently called Lancia; 24 miles S.S.E. of Ciudad Rodrigo.

PEGNA *Garcia*, a town of Portugal, in Beira, on the confines of Spain; 26 miles E. of Castel Branco. N. lat. 39° 50'. W. long. 6° 39'.

PEGNA *Macor*, a fortified town of Portugal, in Beira, on the confines of Spain, containing three churches, a convent, and hospital, and about 2000 houses; 30 miles N.E. of Castel Branco. N. lat. 39° 59'. W. long. 6° 40'.

PEGNA *Mayor*, a town of Spain, in Galicia; 12 miles E.S.E. of Lugo.

PEGNAFEL, a town of Spain, in Old Castile, situated at the foot of a mountain, and defended with a castle; 25 miles S.E. of Valladolid.

PEGNA-FIRMA, a town on the W. coast of Portugal, at the mouth of the river Mongole; nine miles S. of Peniche.

PEGNAFLOR, a town of Spain, in Aituria, on the W. side of the Pravia; seven miles N.W. of Oviedo.—Also, a town of Spain, in the province of Cordova, on the Guadalquivir; 32 miles S.W. of Cordova.

PEGNARANDA, a town of Spain, in Old Castile; 18 miles W. of Osma.—Also, a town of Spain, in the province of Leon; 30 miles S.E. of Salamanca.

PEGNITZ, a river of Germany, which runs into the Rednitz, at Furth.—Also, a town of Germany, in the principality of Culmbach; on a river of the same name; 10 miles S. of Bayreuth. N. lat. 49° 45'. E. long. 11 33'.

PEGOMANTIA, Πηγομαντία, in *Antiquity*, a species of divination, which was performed with fountain water, by throwing into it a kind of dice. When they sunk to the bottom they drew happy presages; but if they remained on the surface of the water, it was a bad omen. See HYDROMANCY.

PEGONGMEW, in *Geography*. See PAGAIM.

PEGORELLA, in *Ichthyology*, a name by which some have called a fish of the truttaceous kind, caught in the Mediterranean, and more usually called *callarias*; which is a species of *Gadus*.

PEGUE, or BAGOO, in *Geography*, a country of Asia, the southern part of which was the Golden Chersonese of the ancients, is bounded on the N. by Arracan and Ava, on the E. and S. by Siam and the sea, and on the W. by part of Arracan and the bay of Bengal. This country occupies the sea-coast as far as Martaban; Prome and its northern frontier and Siam subjoined on the east. It is for the most part a level country, surrounded by mountains, which serve as a frontier on the land side, but towards the sea it is liable to invasion, and also in its interior parts by means of the rivers which pass through the mountains. These rivers, the chief of which are that of Pegu (or Syriam), and that of Ava (or Irrawaddy), so called from the capitals situated on their banks, still continue to roll down particles of gold; and it is probable, that their sands must in ancient time have yielded this precious metal in greater abundance. Hence it is not unlikely that the practice of gilding the roofs and spires of temples and palaces may have been derived from a remote period, more especially as we are informed, that Shoemadoo was built about 500 years before the Christian era, and this splendid appearance might naturally give rise to the classical appellation of the country. We learn from colonel Symes, that gold is discovered in the sandy beds of streams which descend from the mountains. Between the Keen Duam and the Irrawaddy to the northward, there is a small river called Sho Lien Kioup, or the stream of golden sand. The air of this kingdom is very healthy; the soil is very rich, and productive of corn, fruit, and roots; and it produces various kinds of timber, particularly the teak. The animals that principally abound in Pegu are elephants. Besides the mines of the richer metals which are found in this country, it abounds with inferior minerals. But the most singular product of Pegu is the ruby, which is found in a mountain between Syriam and Pegu, and which exceeds in value that of any other country. The gem called the Syriam is also found only in Pegu. But for a further account of the productions and inhabitants of this country, as well as of the various revolutions which it has undergone, we refer to the article BIRMAN empire. See also ARRACAN and AVA.

PEGUE, a city of Asia, and formerly capital of the kingdom of the same name, distant by water from Rangoon about 90 miles, mostly in a northward direction, but on account of the windings of the river, by land in a straight line much less. This city, in the year 1600, was one of the most splendid, large, and populous, in the whole of Asia; and is described by those who saw it in its prosperity as spacious, beautiful, and strong, surrounded with stone walls and very wide ditches. The extent of the ancient city may still be accurately traced by the ruins of the ditch and wall that encompassed it; from these it appears to have been a quadrangle, each side measuring nearly one mile and a half; the ditch, which was once no contemptible defence, is about 60 yards, and its depth 10 or 12 feet. The fragments of the wall evince that it was a large and laborious structure,

about 30 feet high, and at the base not less than 40 feet broad, composed of brick, badly cemented with clay mortar. Small equidistant bastions, about 300 yards asunder, are still discoverable, and there had been a parapet of masonry; but in its present ruinous state, it is so covered with weeds and briars, as to exhibit very imperfect vestiges of its former strength. In the centre of each face of the fort, there was a gateway about 30 feet wide; and these gateways were the principal entrances. The passage across the ditch is over a causeway raised on a mound of earth, that serves as a bridge, and was formerly defended by a retrenchment, of which there are now no traces. It is impossible to conceive, says colonel Symes, a more striking picture of fallen grandeur, and the desolating hand of war, than the inside of these walls displays. Alompra, when he got possession of the city in the year 1757, razed every dwelling to the ground, and dispersed or led into captivity all the inhabitants. The temples, or praws, which are very numerous, were the only buildings that escaped the fury of the conqueror; and of these the great pyramid of Shoemadoo has alone been revered and kept in repair. The present king of the Birmans has abrogated some severe penal laws imposed by his predecessors upon the Taliens, or native Peguers; and the only distinction subsisting at present between a Birman and a Talien, consists in the exclusion of the latter from places of public trust and power. Nothing has contributed more to reconcile the Peguers to the Birman yoke, than the restoration of their ancient place of abode, and the preservation and embellishment of the temple of Shoemadoo. Accordingly the king some time ago issued orders to rebuild Pegue, encouraged settlers by grants of ground, and invited the scattered families of former inhabitants to return and repeople their deserted city. His Birman majesty, on the death of the late Maywoon, or viceroy, directed his successor, the present governor, to quit Rangoon, and to make Pegue the place of his future residence, and the seat of provincial government of the 32 districts of Henzawuddy, the Sanscrit name given by the Birmans to the province of Pegu. The success of these measures has been such, that a new town has been built within the site of the ancient city; but Rangoon possesses so many advantages over Pegu, in a commercial point of view, that persons of property in business, will not easily be prevailed upon to leave one of the finest seaports in the world, to encounter the difficulties of a new settlement, where commerce, if any can subsist, must be very confined for the want of commodious navigation. The present inhabitants who have been induced to return, consist chiefly of Rhahaans, or priests, and poor Talien families, who were glad to gain a settlement in their once magnificent metropolis. Their number all together does not, perhaps, exceed six or seven thousand; those who dwell in Pegu, during its former days of splendour, are now nearly extinct, and their descendants and relatives scattered over the provinces of Tongho, Martaban, and Talowmeou; and many also live under the protection of the Siamese. It is apprehended, however, that respect for their favourite temple of worship, and the encouragement, as well as security, held out to those who venture to return, will, in time, accomplish the wife and humane intentions of the Birman monarch.

Pegue, in its renovated and contracted state, seems to be built on the plan of the former city, and occupies about one half of its area. It is fenced round by a stockade from ten to twelve feet high; on the north and east sides it borders on the old wall. The plane of the town is not yet filled with houses, but a number of new ones are building. There is one main street running east and west, crossed at right angles

by two smaller streets not yet finished. At each extremity of the principal street, there is a gate in the stockade, which is shut early in the evening; and after that time entrance during the night is confined to a wicket. Each of these gates is defended by a wretched piece of ordnance, and a few musqueteers, who never post sentinels, and are usually asleep in an adjoining shed. There are two inferior gates on the north and south side of the stockade. The streets of Pegue are spacious.

The new town is well paved with brick, which the ruins of the old plentifully supply; and on each side of the way there is a drain to carry off the water. The houses of the meanest peasants of Pegue, and throughout the Birman empire, possess manifest advantage over Indian dwellings, by being raised from the ground either on wooden posts or bamboos, according to the size of the building. The kioums or monasteries of the Rhahaans, and the habitations of the higher ranks, are usually elevated six or eight, those of the lower classes from two to four feet.

There are no brick buildings either in Pegue or Rangoon, except such as belong to the king, or are dedicated to their divinity Gaudma: his majesty having prohibited the use of brick or stone in private buildings, from the apprehension, as we were informed, (says Col. Symes,) that if people got leave to build brick houses, they might erect brick fortifications, dangerous to the security of the state. The houses, therefore, are all made of mats, or sheathing boards, supported on bamboos or posts; but from their being composed of such combustible materials, the inhabitants are under continual dread of fire, against which they take every precaution. The roofs are lightly covered, and at each door stands a long bamboo, with an iron hook at the end, to pull down the thatch: there is also another pole, with a grating of iron at the extremity, about three feet square, to suppress flame by pressure. Almost every house has earthen pots, filled with water, on the roof: and a particular class of people, whose business it is to prevent and extinguish fires, perambulate the streets during the night.

These people are called Pagwaat; they are slaves of government; men who have been found guilty of theft, and, through mercy, had their lives spared. They are distinguished by a black circle on each cheek, caused by gunpowder and punctuation; as well as by having on their breast, in Birman characters, the word *thief*, and the name of the article stolen, as, on one that we asked to be explained to us, Putchoo Khoo, *cloth thief*. These men patrol the streets at night, to put out all fires and lights after a certain hour. They act as constables, and are the public executioners.

The Maywoon's habitation, though not at all a magnificent mansion for the representative of royalty, is, notwithstanding, a building of much respectability, compared to the other houses of Pegue. From an outside view, we judged it to be roomy, and to contain several apartments, exclusive of that in which he gives audience: it possesses, however, but few ornaments. Gilding is forbidden to all subjects of the Birman empire; liberty even to lacker and paint the pillars of their houses is granted to very few: the naked wood gave an unfinished appearance to the dwelling of the Maywoon, which, in other respects, seemed well adapted for the accommodation of a Birman family.

The object in Pegue that most attracts and most merits notice, is the noble edifice of Shoemadoo, or the Golden Supreme. This extraordinary pile of buildings is erected on a double terrace, one raised upon another. The lower and greater terrace is about ten feet above the natural level of the ground, forming an exact parallelogram: the upper and lesser terrace is similar in shape, and rises about twenty

feet above the lower terrace, or thirty above the level of the country. We judged a side of the lower terrace to be 1391 feet; of the upper, 684. The walls that sustained the sides of the terrace, both upper and lower, are in a ruinous state; they were formerly covered with plaster, wrought into various figures; the area of the lower is strewed with the fragments of small decayed buildings, but the upper is kept free from filth, and is in tolerably good order. There is reason to conclude that this building and the fortrefs are coeval, as the earth of which the terraces are composed appears to have been taken from the ditch; there being no other excavation in the city, or in its neighbourhood, that could have afforded a tenth part of the quantity.

The terraces are ascended by flights of stone steps, which are now broken and neglected. On each side are dwellings of the Rhahaans, raised on timbers four or five feet from the ground; these houses consist only of a large hall; the wooden pillars that support them are turned with neatness; the roofs are covered with tiles, and the sides are made of boards; and there are a number of bare benches in every house, on which the Rhahaans sleep; but we saw no other furniture.

Shoemadoo is a pyramidal building, composed of brick and mortar, without excavation or aperture of any fort; octagonal at the base, and spiral at top; each side of the base measures 162 feet; this immense breadth diminishes abruptly, and a similar binding has not unaptly been compared in shape to a large speaking trumpet.

Six feet from the ground there is a wide projection that surrounds the base, on the plane of which are fifty-seven small spires of equal size, and equidistant; one of them measured twenty-seven feet in height, and forty in circumference at the bottom. On a higher ledge there is another row, consisting of fifty-three spires of similar shape and measurement.

A great variety of mouldings encircle the building; and ornaments somewhat resembling the fleur-de-lis surround the lower part of the spire; circular mouldings likewise girt it to a considerable height, above which there are ornaments in stucco not unlike the leaves of a Corinthian capital; and the whole is crowned by a *tee*, or umbrella, of open iron-work, from which rises a rod with a gilded pennant.

The tee or umbrella is to be seen on every sacred building that is of a spiral form: the raising and consecration of this last and indispensable appendage, is an act of high religious solemnity, and a season of festivity and relaxation. The present king bestowed the tee that covers Shoemadoo. It was made at the capital; and many of the principal nobility came down from Ummerapoora to be present at the ceremony of its elevation.

The circumference of the tee is fifty-six feet; it rests on an iron axis fixed in the building, and is farther secured by large chains strongly rivetted to the spire. Round the lower rim of the tee are appended a number of bells, which, agitated by the wind, make a continual jingling.

The tee is gilt, and it is said to be the intention of the king to gild the whole of the spire. All the lesser pagodas are ornamented with proportionable umbrellas of similar workmanship, which are likewise encircled by small bells.

The extreme height of the edifice, from the level of the country, is 361 feet, and above the interior terrace, 331 feet.

On the south-east angle of the upper terrace there are two handsome saloons, or kioums, lately erected, the roofs composed of different stages, supported by pillars; we judged the length of each to be about sixty feet, and the breadth thirty: the ceiling of one is already embellished with gold leaf, and the pillars are lackered; the decoration of the other is not yet completed. They are made entirely of

wood: the carving on the outside is laborious and minute: we saw several unfinished figures of animals and men in grotesque attitudes, which were designed as ornaments for different parts of the building. Some images of Gaudma, the supreme object of Birman adoration, lay scattered around.

At each angle of the interior and higher terrace there is a temple sixty-seven feet high, resembling, in miniature, the great temple: in front of that, in the south-west corner, are four gigantic representations, in masonry, of Palloo, or the evil genius, half beast half human, seated on their hams, each with a large club on the right shoulder. The Pundit who accompanied us, said that they resembled the Rakuls of the Hindoos. These are guardians of the temple.

Nearly in the centre of the east face of the area are two human figures in stucco, beneath a gilded umbrella; one, standing, represents a man with a book before him and a pen in his hand; he is called Thasiamee, the recorder of mortal merits and mortal misdeeds; the other, a female figure kneeling, is Mahafumdera, the protectress of the universe, so long as the universe is doomed to last; but when the time of general dissolution arrives, by her hand the world is to be overwhelmed and everlastingly destroyed.

A small brick building near the north-east angle contains an upright marble slab, four feet high, and three feet wide; there is a long legible inscription on it. We were told it was an account of the donations of pilgrims of only a recent date.

Along the whole extent of the north face of the upper terrace there is a wooden shed for the convenience of devotees who come from a distant part of the country. On the north side of the temple are three large bells of good workmanship, suspended high the ground, between pillars; several deers horns lie strewn around; those who come to pay their devotions first take up one of the horns, and strike the bell three times, giving an alternate stroke to the ground: this act, we were told, is to announce to the spirit of Gaudma the approach of a suppliant. There are several low benches near the foot of the temple, on which the person who comes to pray places his offering, commonly consisting of boiled rice, a plate of sweetmeats, or cocoa-nut fried in oil; when it is given, the devotee cares not what becomes of it; the crows and wild dogs often devour it in presence of the donor, who never attempts to disturb the animals. We saw several plates of victuals disposed of in this manner, and understood it to be the case with all that was brought.

There are many small temples on the areas of both terraces, which are neglected, and suffered to fall into decay. Numberless images of Gaudma lie indiscriminately scattered. A pious Birman who purchases an idol, first procures the ceremony of consecration to be performed by the Rhahaans; he then takes his purchase to whatever sacred building is most convenient, and there places it within the shelter of a kioum, or on the open ground before the temple; nor does he ever again seem to have any anxiety about its preservation, but leaves the divinity to shift for itself. Some of those idols are made of marble that is found in the neighbourhood of the capital of the Birman dominions, and admits of a very fine polish, many are formed of wood, and gilded, and a few are of silver; the latter, however, are not usually exposed and neglected like the others. Silver and gold are rarely used, except in the composition of household gods.

On both the terraces are a number of white cylindrical flags, raised on bamboo poles; these flags are peculiar to the Rhahaans, and are considered as emblematic of purity, and of their sacred function. On the top of the staff there is a heuza, or goose, the symbol both of the Birman and Pegue nations.

From the upper projection that furrounds the base of Shoemadoo, the prospect of the circumjacent country is extensive and picturesque; but it is a prospect of nature in her rudest state; there are few inhabitants, and scarcely any cultivation. The hills of Martaban rise to the eastward, and the Sitang river, winding along the plains, gives an interrupted view of its waters. To the north-west, about forty miles, are the Galladzet hills, whence the Pegue river takes its rise; hills remarkable only for the noisome effects of their atmosphere. In every other direction the eye looks over a boundless plain, chequered by a wild intermixture of wood and water.

Tradition reports that the temple of Shoemadoo was founded 2300 years ago by two merchants, who were brothers, and who came to Pegue from Tallowmeou, a district of one day's journey E. of Martaban. These pious traders at first raised a temple one Birman cubit (22 inches) in height: a cubit was miraculously added in one night; the merchants added another cubit, which was again miraculously doubled; and thus the building attained the altitude of 12 cubits: and the temple was afterwards gradually augmented by successive monarchs of Pegue.

The cows in the vicinity of Pegue are of a diminutive size, resembling the breed on the coast of Coromandel, but the buffaloes are noble animals, superior to those of any other part of India. These are used both for draft and agriculture. The only article of consequence manufactured at Pegue is silk and cotton cloth; it is well wrought, but they make no more than what suffices for their own consumption.

In the town of Pegue there are only three persons, besides the Maywoon or viceroy, whose rank entitles them to distinction. These officers exercise the function of magistrates, and hold separate courts at their own houses, for the determination of petty suits; but all causes of importance relating to property, and matters of an high criminal nature, are solemnly tried in open court, in which the three officers unite, and form a tribunal which sits at the "Rhoom," or public hall of justice, and the ultimate decision rests with the Maywoon. N. lat. 17° 40'. E. long. 96° 11' 15". Symes's Ava, vol. ii. Asiatic Researches, vol. v.

PEGUE, a river of Asia, in the vicinity of the city of the same name. It is called by the natives "Bagoo Kioup," or Pegue rivulet, to distinguish it from Mioup, or river. This river is navigable but a very few miles to the northward of the city of Pegue, and for this it is indebted wholly to the action of the tide. It has no communication with the sea, except by the Rangoon river, and, in the fair season, at low water, is almost dry. This stream has been sometimes mistaken for the Sitang river, about 15 miles E. of Pegue, which is a large and independent body of water, that partly describes the course that in the map is given to what is called the Pegue river.

PEGUNNOCK, a N.W. branch of Passaik river, in New Jersey, North America, which rises in Suffex county. The town of its name lies between it and Rockaway, another branch S. of this river, N.W. of Morrilown.

PEHL, a town of Aultria; 6 miles W. of Wells.

PEI, a city of China, of the second rank, in Se-tchuen, on the Kincha river; 720 miles S.S.W. of Peking. N. lat. 29° 50'. E. long. 107°.

PEICHELSTEIN, a town of Tyrol; 5 miles S.S.W. of Reutten.

PEJEND, or PAJANA, the most considerable lake of Finland, about 80 miles in length by 15 in breadth, which gives source to the river Kymmen.

PEJEPSCOL, or PEGYPSKEAG, a township of America,

rica, in Cumberland county, Maine, adjoining Poland, Durham, &c. on the westerly bank of Great Ameriskoggen river, about 30 miles N. of Portland.

PEI-HO, or *White River*, a river formed by several streams in the province of Pe-tche-li, and which runs into the gulf of Pe-tche-li. The mouth of the river is traversed by a bar, stretching N.N.E. and S.S.W., over which, at low water, the depth is not more than three or four feet, and in many places it is almost dry. The tides rise and fall six or seven feet at the mouth of the river: the time of high water, at the full and change of the moon, is about half after three; and five or six miles outside of the mouth of the river a large bamboo beam is placed upon the bar, together with some of a smaller size, continued nearly in a straight line to the shore, intended as marks to direct vessels entering into the river. The town of Ta-coo lies within the Pei-ho, and is the first place of any note in this part of the N.E. frontier of China. Yachts, or large covered barges, and boats of burthen, calculated to pass over the shallows of the Pei-ho, may be obtained here, in order to enable persons to proceed as far as this river leads, towards Peking, the capital of the empire. The progress upon the Pei-ho is necessarily very slow, as the course of the river is remarkably serpentine. The fields on each side exhibit a high state of cultivation, and are generally covered with the holcus sorghum, or the tallest of the vegetables producing esculent grain, commonly called Barbadoes millet; it grows to 10 or 12 feet high, and the lowest calculation of its increase is one hundred-fold. The houses in the villages near the river are constructed of bricks ill-burnt, or baked in the sun, which, as well as the tiled roofs, are plastered over with a muddy coloured substance, unmixed with lime. Near some of the towns and villages are pyramids about 15 feet high, but of different dimensions as to both length and thickness. They consisted of bags of salt, heaped together in that form, and covered merely with common matting. As soon as night comes on, the banks of this river are illuminated with variegated lights, from lanterns whose transparent sides were made of different coloured paper. The different numbers of lanterns hoisted on the masts' head of the various vessels in the river denote the ranks of the passengers they hold; all which, together with the lights from the cabins of the junks, reflected from the water, produce a moving and parti-coloured illumination. The salt, already mentioned, brought from Quan-tong and Fo-chien into the Pei-ho, is sufficient to load annually nearly 2000 vessels of 200 tons burden each.

At *Tien-sing* (which see) two rivers unite; one of which retains the name of Pei-ho; and the other is called "Yun-leang-ho," or grain-bearing river, from the quantities of wheat conveyed upon it from the province of Shen-see, and sent up by the Pei-ho to the neighbourhood of Peking. About 30 miles beyond Tien-sing, towards Peking, the tide of the Pei-ho ceases, and the progress of the yachts, &c. is effected by rowing with oars, or towing with ropes, and their advance is very slow against the current of the river. Large junks, to the number of 1000, each of which contains not less than 50 persons, and therefore in the whole amount to 50,000, are passing between Tong-choo-foo and Tien-sing; and as many more of other kinds of craft; so that upon a branch of a single river, the population of its moveable habitations amounts to 100,000 persons. Tong-choo-foo, where the water becomes too shallow for the navigation of yachts of any burden, is 90 miles distant from Tien-sing, and 12 miles from the city of Peking. The mouth of the river Pei-ho, in the gulf of Pe-tche-li, is in N. lat. 39°.

PEILLAC, a town of France, in the department of the Morbihan; 16 miles E. of Rochefort.

PEILSTEIN, a town of Austria; 4 miles S. of Aigen.

PEINA, a town of Westphalia, in the bishopric of Hildesheim, in a marshy country, on the Fufe, formerly reckoned among the fortresses. The inhabitants are chiefly Lutherans. It has an episcopal palace, a Capuchin convent, and a suburb called the "Damon," which is mostly inhabited by shopkeepers and Jews; 15 miles N.N.E. of Hildesheim. N. lat. 52° 10'. E. long. 10 18'.

PEINT, a town of Hindoostan, in Baglana; 28 miles N.W. of Nafuck.—Also, a town of Hindoostan, in Guzerat; 20 miles S. of Dungepour.

PEINTADE, in *Ornithology*. See *NUMIDA Meleagris*.

PEIPUS LAKE, or *Tchudskoe*, in *Geography*, a lake of Russia, which lies between the governments of Pfcove, Reval, Riga, and St. Petersburg, extending in length to about 80 and in breadth to 60 versts. By means of a very broad strait it is connected with the Pfcove lake, the length of which is stated to be 50, and the breadth, which is always decreasing, 40 versts. This latter receives the river Velikaia. Out of the Peipus comes the Narova, which through the Embach has communication with the Vertz-erb lake; out of this, on the other hand, flows the Fellin into the gulf of Riga; and consequently a very beneficial water-passage might be made between Riga and some of the inland provinces, by way of the Peipus lake. In this lake there are a few small islands, none of which are sufficiently important to deserve notice except Perka or Bork, called by the Esthonians Porkafaar, which is not only inhabited, but furnished with forests, and has no less than three villages upon it. Among the several brooks and rivers that flow into the Peipus, the Embach is the most considerable. The exit is through the Narva river into the gulf of Finland. The multitude of fish that breed in this lake afford a lucrative occupation to the boors of these parts, and increase the revenues of the adjoining estates, the owners of which let out the parts on which their lands abut at a certain rent. The fish are principally rebfe, a species of herring, and barbel. Besides these, here are pike, perch, a species of carp, whiting, quebb, korushki, gudgeons, &c. The pike and some others are dried in the air and exported: the rebfe are sometimes smoked. N. lat. 58° to 59° 10'. E. long. 27° to 27 28'.

PEIRA, a town of Malacca, on the W. coast; 100 miles N.W. of Malacca. N. lat. 3° 40'.

PEIRCE, JAMES, in *Biography*, was born in London in the year 1673. He had the misfortune in early life to lose both his father and mother, and was placed under the care of his guardian, Mr. Matthew Mead, a celebrated minister at Stepney, in whose house he was instructed in the rudiments of learning by a private tutor. After this he spent some years in different grammar schools, till he was prepared for entering upon a course of academical studies, when he was sent to Utrecht. Here he attended the lectures of the most celebrated professors, among whom were Witflus, Leydecker, Grævius, and Leusden: he cultivated a strict friendship with some of the most distinguished of his fellow students, particularly with Adrian Reland. From Utrecht he removed to Leyden, where he had the opportunity of hearing Gronovius, Spanheim, and other professors of the highest character in the republic of letters. Having spent several years in these seminaries he returned to England, and lived for some time with his relations at London, and then took apartments at Oxford, where he had constant access to the Bodleian library. After this, at the request

request of his friends, he preached a Sunday evening lecture at Miles' Lane, London, but he does not appear to have interested himself in the dispute then subsisting between the Independents and Presbyterians. With the ministers of the latter denomination he became well acquainted, and at their solicitation he settled at Cambridge, where he acquired the respect and esteem of many members of the university. From Cambridge he removed to Newbury, in Berkshire, where he appeared to great advantage, in the year 1707, in a controversy with Dr. Wells, a clergyman of Leicestershire, who had attacked the principles and practice of the Dissenters, and whose mistakes and misrepresentations he ably exposed. Mr. Peirce after this published, at different periods, various able controversial tracts, relating to the rites imposed under the establishment; the validity of the dissenting ministry, and presbyterian ordination; and the imputed sin of schism.

The next work of our author was called for by the appearance of "A Defence of the Doctrine and Discipline of the Church of England," written in the Latin tongue, and submitted to the judgment of foreign divines, by Dr. Nichols, Latin secretary to the Society for the Propagation of the Gospel. In this work the author had given such a view of the controversy between the Church and Dissenters, as was intended to expose the latter to the censure and condemnation of their foreign brethren, on which account Mr. Peirce was earnestly solicited to undertake their vindication in the same language, for the purpose of counteracting the effects of Dr. Nichols' performance. He accordingly published his "*Vindiciæ Fratrum Dissidentium*," in which he gave a full and very satisfactory answer to his antagonist. This work was published in 1717 in the English language, with the title of "A Vindication of the Dissenters, &c." It consisted of three parts: the first contains the history of nonconformity; the second treats of the doctrine of the church of England; and the third contains all the heads relating to discipline and worship. It, in fact, presents the reader with a view of almost the whole controversy between the established church and the Dissenters. In 1718, Mr. Peirce took part in the controversy relating to the Test Act, and published "Letters" on the subject to a friend, and to Dr. Snape. He had previously to this removed from Newbury to Exeter, having had a general and most unanimous invitation from the three united congregations of the Dissenters in that city. In this situation he gave the greatest satisfaction in the discharge of the pastoral duties, till there arose a controversy concerning the explication of the Trinity, which was productive of very disgraceful consequences. He had been educated in the trammels of orthodoxy as it was called, but had, during his ministry, learnt to shake off all those unscriptural phrases, which then, as well as now, were looked on as a kind of test of a man's religious opinions. He considered the scriptures as the only rule of faith, and from a very early period he took care to use their language in his sermons, when he introduced any doctrinal topic, and as he advanced in years he grew more careful in his adherence to this practice. The doctrine of the Trinity he looked upon as a *mystery*, and was averse from speaking or even thinking upon it. But his attention was unavoidably drawn to it by the clamour which was raised concerning his friend Mr. Whiston, for whom he had a high esteem, and at first he was exceedingly hurt to learn that Mr. Whiston had declared against the current doctrines of the day. He expostulated with his friend, but instead of convincing him of his error, he himself became a convert to the heresy that he had been ready to condemn.

"The reader," says Mr. Peirce, "will easily imagine

that this must have been a terrible shock to me, and that I must have had a great concern upon my mind, when I found myself at a loss about a doctrine, of which I had been all along fond, to a great degree of uncharitableness. However, this caused me to read the bible with more care, and make it more my prayer to God, that I might be led into the truth." It was not long before he was fully satisfied that the common opinion was not accordant with the doctrines held forth in scriptures. Being suspected of holding heretical opinions, he was attacked in the most hostile manner, and there can be no doubt that had his opponents possessed the power, they would most cheerfully have burnt him at the stake.

They required him to subscribe a test he refused, because he believed that the worst mischief had been done to the church of God by imposing unscriptural creeds and tests upon men, and he said he would never tamely surrender the liberty with which he had been made free. They turned him out of his meeting, and excited the clamour of the mob against him, by stigmatizing him and his friends with the then opprobrious epithet of *Arians*. Under these circumstances, Mr. Peirce found it necessary, for the vindication of his own character, and that of his friends, to lay a true state of the affair before the public, and accordingly published "The Case of the Ministers ejected at Exon." In 1720 he gave the world a much larger work, entitled "The Western Inquisition, or a Relation of the Controversy which has been lately among the Dissenters in the West of England," which contains a full account of the origin, progress, and issue of the nefarious and cruel persecution with which our author was harassed. To this a reply was published, entitled "An Answer to Mr. Peirce's Western Inquisition, &c." Mr. Peirce now took leave of the controversy by a very able and satisfactory piece, entitled "Inquisition Honestly displayed, or the Western Inquisition defended against the pretended Answer, &c."

From this period Mr. Peirce applied himself to the diligent discharge of his pastoral duties among a respectable people, by whom he was highly honoured and beloved, and to the completion of some explanations of the sacred writings, in which he had made considerable progress. The first fruits of his learned studies were given to the world in 1725, but without his name, in "A Paraphrase and Notes on the Epistle of St. Paul to the Colossians," 4to.; in which he endeavoured to follow the admirable rules and example of Mr. Locke, whom he considered as having done more than any other writer towards rendering St. Paul's epistles easy and intelligible. This publication was well received; and in the same year he gave the world "A Paraphrase and Notes on the Epistle of St. Paul to the Philippians." He intended to proceed with similar commentaries on all the other Epistles attributed to this apostle, excepting those that had been before paraphrased by Mr. Locke. His next attempt was on "The Epistle to the Hebrews," which he did not live to finish, for while he was engaged in it, he was attacked by a disorder which put an end to his life, on the 30th of March 1726, in the 53d year of his age.

The persecution which he had met with during his life pursued him even to the grave: for his relations having directed that a Latin inscription, containing an encomium on his learning and virtues, should be cut on a tomb-stone, the rector of the church in which his remains were deposited would not permit it to be placed in his church-yard; stating that he could not, in conscience, suffer a person so notorious for heresy to be warmly recommended to posterity in any place under his care and inspection. When it was afterwards requested that these words might be inscribed on his

his tomb, "Here lies the reverend, learned, and pious Mr. James Peirce," but it was refused, the rector assuming that Mr. Peirce could not be *reverend*, because he was not lawfully ordained, and that he was not pious, because he taught errors, so that the only inscription allowed, was "Mr. James Peirce's tomb." On a monument erected to his memory in the meeting-house in which he latterly officiated, he is held out to the veneration of posterity, as a rational, judicious, and affectionate preacher; a very laborious and sagacious interpreter of the Holy Scriptures; a sincere lover and strenuous defender of the truth; and a courageous sufferer for maintaining the doctrines of the gospel of Christ, and for asserting the liberties of Christians.

After the death of this excellent man, his "Paraphrase and Notes on the Epistle of St. Paul to the Hebrews, with Dissertations on several Texts of Scripture," were published in 1727, though evidently left in an unfinished state. The work was afterwards completed by Mr. Joseph Hallet. From Mr. Peirce's MSS. were also published "An Essay in favour of the ancient Practice of giving the Eucharist to Children" and other tracts.

PEIRESC, NICHOLAS-CLAUDE FABRI DE, a considerable promoter of literature, descended from the ancient family of Fabri of Pisa in Italy, was born in Provence in 1580. At ten years of age he was sent, with his younger brother, to the Jesuits' college at Avignon, where he continued five years. At the early age of seven he was appointed to the sole superintendance of his brother's education, who was about a year and a half younger than himself. In 1595 he removed to Aix, where he commenced the study of philosophy. At this time he became passionately fond of the medallic science, and the remains of antiquity. In 1596 he finished his course of philosophy and mathematics in the Jesuits' college at Tournon, and he afterwards studied the law at Aix. He was sent, in 1599, with his brother and a tutor to travel in Italy, and further prosecute his legal studies at Padua. He paid frequent visits to Venice, and became acquainted with several distinguished persons, particularly with father Paul, and the procurator Fred. Contarini. The fine cabinet of medals possessed by the latter was a peculiar object of attention to Peiresc, who gave the owner explanations of the Greek inscriptions. Rome was the next object of our youthful traveller's curiosity, and it gave ample gratification to his love of antiquities, and his desire of forming acquaintances among the learned. In 1601 he proceeded to Naples, and having thoroughly surveyed every thing worthy of observation in that city and its vicinity, he completed the tour of Italy, by returning along the coast of the Adriatic to Padua. He there resumed the study of the law, and likewise, at the same time, acquired a knowledge of the oriental languages, in which he was assisted by a learned rabbi named Solomon. Returning to France in 1602, he continued his studies at Montpeier, and in 1604 he took the degree of doctor of laws at Aix, after sustaining disputations for three days with great applause. In the following year he went to Paris, and in 1606 he visited England, where he was graciously received by king James. Of the learned men in this country, Camden, on account of his antiquarian knowledge, was particularly acceptable to him. On his return by Holland, he became personally acquainted with Joseph Scaliger and Grotius. After he had finished his travels, he was made counsellor to the parliament of Aix, which office he held, though in 1618 he entered into the ecclesiastical state, and was presented to an abbacy of the Benedictine order.

The great occupation of Peiresc during his whole life was the acquisition of knowledge, and the encouragement of

learned men, and no person of his time maintained such an extensive correspondence with the literati of different classes and countries. The chief objects of his enquiries and communications embraced philosophical experiments, natural history, rare products of art, antiquities, history, and philology. He formed for himself a museum of valuable curiosities, and a copious library, and then liberally opened his stores to authors and students. He has been characterized as a true citizen of the republic of letters, and a kind of general agent of learning throughout civilized Europe. He died in 1637, in the 57th year of his age. His funeral at Aix was conducted with great solemnity, and a collection of eulogies to his memory was printed in a variety of languages. The vast variety of objects which his studies comprehended prevented him from finishing any thing, so as, in his own opinion, to be fit for the public eye, but he left behind him a great number of MSS. on local history and antiquities, mathematics and astronomy, the medallic science, languages, &c. Of the writings of this scholar there have been published 48 Italian letters, addressed to Paolo and Giambattista Gualdo, in the "Lettere d'uomini illustri;" a considerable number of letters among those of Camden, and a long and learned dissertation on an ancient tripod found at Frejus, in the *Mém. de Literature et de l'Histoire*, by Desmalets, in 1731.

PEISDORF, in *Geography*, a town of Bohemia, in the circle of Königgratz; 14 miles N.E. of Gitschin.

PEISKREITSCHAM, or PYSLOWICE, a town of Silesia, in the principality of Oppeln; 12 miles W.N.W. of Beuthen.

PEITSCHENDORF, a town of Prussia, in Bartenland; 22 miles S. of Rastenburg.

PEITZ, a town of Brandenburg, in the Ucker Mark, on a small river which runs into the Spreke. In its vicinity are iron mines, and manufactures of pitch and turpentine; 20 miles E.S.E. of Luben. At the peace of Tilsit, this town was ceded to Saxony. N. lat. $51^{\circ} 53'$. E. long. $14^{\circ} 40'$.

PEIXE, in *Ichthyology*. See *ZEUS Gallus*, and *CENTRISCUS Scutatus*.

PEKAN, in *Zoology*. See *MUSTELA Canadensis*.

PEKEA, in *Botany*, a West Indian name for a tree of Cayenne, which bears an excellent nut, sometimes sold in the fruit-shops of London, by the name of Suwarrow nut. Aublet figures this species in his t. 239, and another in t. 238. See *RHIZOBOLUS*.

PEKENEN, in *Geography*, a town of Africa, on the Grain coast; 15 miles S. of Sanguin.

PEKET, a town on the N. coast of the island of Cumbava. S. lat. $8^{\circ} 15'$. E. long. $117^{\circ} 36'$.

PE-KIANG, a river of China, which rises near Nan-yang, in the north part of the province of Quan-tong, and runs into the river Canton, 30 miles below Canton. This river continues its course through an extent of about 260 miles, to the city of Canton; from thence it falls, after a further course of about 80 miles, into the southern sea of China, near which it takes, among foreigners, the name of Bocca Tigris. For a great part of its course to the northward of Canton, it lies between two ranges of calcareous hills, consisting of rugged eminences with intervening plains between them, on which are erected small neat houses, surrounded by patches of land under cultivation, and apparently accessible only by the river. In its bed frequently occur heaps of stones, with stakes of wood, forming dams, with sluices, through which the water runs, and in these are placed baskets of wicker-work, which allow the fish to pass, but prevent their regrefs; thus rendering them a prey to the proprietors of these snares. As soon as the hills opposite to each other begin

begin to be less rugged, tobacco is planted on their flanking sides; but some of the mountains are barren and of a horrid aspect, and formed of rocks piled upon rocks in a variety of fantastic forms, and threatening passengers sailing on the river under their over-hanging heads. Other hills consist chiefly of mines of coal rising directly from the river, and opening into day; the contents of which are loaded immediately on barges from the mouth of an horizontal shaft. This is a pulverizable kind of coal, usually called culm coals. As the river becomes sufficiently deep and wide, the passage barges are changed for larger and more commodious yachts. The volume of water is increased by the junction with another considerable stream proceeding from the N.W. At their confluence stands the city of "Chau-coo-foo," the environs of which are pleasant and romantic. The plains are sown with rice and tobacco, whilst the rising grounds produce cotton and the sesanqua. On one side of the river is an immense rock of grey coarse marble, estimated to be about 600 feet in height; and in a fissure close to the water's edge, and accessible only by boats, is a temple, inhabited by Ho-shaung, or priests of Fo, who worship in it a variety of deified heroes, and of virtues and passions personified. This temple consists of several apartments, one over the other, of considerable height, consisting chiefly of excavations made into the rocks; and above them is an immense mass of stalactites, not less, in appearance, than a ton in weight, out of which proceed a vast number of ramifications. A plain, terminated only in the horizon, at length succeeds to the double range of heights through which the river had flowed mostly from its source. The stream is here widened, and soon meets the tide flowing from the southward. The adjoining country is intersected by large canals for the purposes of navigation, and others of a smaller size for occasionally watering the grounds. The whole exhibits every mark of fertility, industry, and populousness. The principal cultivation is that of rice, with some groves of mulberry trees. Along this river, as it approaches Canton, are nurseries of curious plants and country houses belonging to the principal native merchants of that city. The city and suburbs of Canton are situated mostly on the eastern bank of the Pe-kiang river. See CANTON.

PE-KING, or PEKIN, the capital of the province of Petcheli, and of the whole empire of China proper. Its name is said to signify the "Northern court," and it is so called by way of distinction from the city of Nan-king, denominated the "Southern court." Pekin was the Cambalu, or city of the Chan, in writings of the middle ages, the capital of Cathay, as Nan-king was of Mangé. It is situated in a fertile plain, 20 leagues distant from the great wall. The road to it from Tong-choo-foo forms a magnificent avenue, for persons and commodities bound for that capital from the east and from the south. It is perfectly level; the central part, to the width of about 20 feet, is paved with slabs of granite, brought from a considerable distance, and of a size from six to sixteen feet in length, and about four feet broad. On each side of this granite pavement is a road unpaved, wide enough for carriages to cross upon it; the road is bordered in many places with trees, particularly willows of a very uncommon girth. The passage lies over a marble bridge, very wide, and substantially built, which traverses a rivulet, not subject to inundations; and is little elevated above the level of the roads, which it connects together. Those who enter the city in this direction, arrive at length at one of the eastern suburbs, along a street that is paved, and that exhibits a busy scene of manufacturers, shop-keepers, and buyers. We shall first trace the progress of the embassy under lord Macartney through this city, and

then more particularly describe the city itself. To traverse the suburb, required about 15 minutes, when the party arrived before the walls of Pekin. Near the gate of entrance the walls were faced with stone, but elsewhere with brick; over the gate was a watch-tower several stories high. In each story were painted port-holes for cannon. Round the gate, on the outside, was a semi-circular wall, with a lateral gate. The city walls were about 40 feet high; the parapet was deeply crenated, but had no regular embrasures, nor did any cannon appear upon the walls; but in the merlons were loop-holes for archery. The thickness of the walls at the base was about 20 feet, and 12 across the terre-pleine, upon which the parapet was erected. The outside of the city wall, though not perfectly perpendicular, was smooth, but the inside was upon a considerable level; the rows of bricks which form it being placed, like steps, one above and behind the other, such as are described to be the faces of the Egyptian pyramids. The walls were flanked on the outside by square towers, at about 60 yards distance from each other, and projecting from the curtain between them 40 or 50 feet. Several horsemen might ride abreast upon the ramparts, ascending to them upon slopes of earth raised on the inside.

Few of the houses in Pekin were higher than one story; none more than two: while the width of the street which divided them was considerably above 100 feet: so that it was airy, gay, and lightsome. The street was unpaved, and water sprinkled on it to lay the dust. A light handsome building was erected across it, called by the Chinese "Pei-loo," translated so as to signify a triumphal arch, though no part of it resembles an arch. The whole was built of wood, and consisted of three handsome gate-ways, of which the middle is the highest and largest. Over these were constructed three roofs above each other, richly decorated. Large characters painted or gilt upon the uprights or transoms, indicated the purpose for which the pei-loo was erected. They are meant to compliment particular persons, or to perpetuate the memory of some interesting event.

The first street extended in a line directly to the westward, until it was interrupted by the eastern wall of the imperial palace, called the Yellow wall, from the colour of the small roof of varnished tiles, with which the top of it is covered. Various public buildings, seen at the same time, and considered as belonging to the emperor, were covered in the same manner. These roofs, uninterrupted by chimnies, and indented in the sides and ridges into gentle curves, which heightened the effect, were adorned with a variety of figures, either in imitation of real objects, or more commonly as mere works of fancy: the whole shining like gold under a brilliant sun, immediately caught the eye with an appearance of grandeur in that part of buildings where it was not usual to seek for it. Immense magazines of rice were seen near the gate: and looking from it to the left, along the city wall, was perceived an elevated edifice, described as an observatory, erected, in a former dynasty, by the emperor Yong-loo, to whom the chief embellishments of Pekin are said to be owing. In front of most of the houses in this main street were shops, painted, gilt, and decorated, in a grand style. Over some of them were broad terraces, covered with shrubs and flowers. Before the doors were hung several lanterns of horn, muslin, silk, and paper, fixed to frames, in varying the form of which the Chinese seemed to have exercised their fancy to the utmost. Outside of the shops, as well as within them, was displayed a variety of goods for sale.

As soon as the persons belonging to the embassy had arrived

rived at the eastern side of the Yellow wall, they turned along it to the right, and found on its northern side much less bulle than in the former street. Instead of shops all were private houses, not conspicuous in the front. Before each house was a wall or curtain, to prevent passengers from seeing into the court into which the street-door opened. This is called the wall of "respect." A halt was made opposite to the treble gates, which are nearly in the centre of this northern side of the palace-wall. It appeared to inclose a large quantity of ground. It was not level like all the lands without the wall: some of it was raised into hills of steep ascent: the earth taken to form them left broad and deep hollows, now filled with water. Out of these artificial lakes, of which the margins were diversified and irregular, small islands arose with a variety of fanciful edifices, interspersed with trees. On the hills of different heights the principal palaces for the emperor were erected. The whole had somewhat the appearance of enchantment. On the summit of the highest eminences were lofty trees surrounding summer-houses, and cabinets contrived for retreat and pleasure. From the spot whence an opportunity thus offered to take a glance through the gates of the palace-wall, of part of what was inclosed within it, the eye, turning to the north, observed through a street extending to the city wall, the great palace, of considerable height, which includes a bell of prodigious size and cylindric form, that, struck on the outside with a wooden mallet, emits a sound distinctly heard throughout the capital. Beyond it, but more to the westward, was one of the northern gates, the watch-tower over which rendered it visible above the intermediate buildings. Proceeding on beyond the palace-gates directly to the westward, between the Yellow wall and the northern buildings of the city, is a lake of some acres in extent, which in autumn was almost entirely overspread with the peltated leaf of the nymphæa nelumbo, or lien-wah of the Chinese.

The route was continued westerly through the city. Among other buildings was seen a library of foreign MSS. one of which was said to be an Arabic copy of the Koran. Some Mahometans were observed distinguished by red caps; and also natives of Tartary, or females of a Tartar race. Their feet were not cramped, like those of the Chinese; and their shoes with broad toes, and soles above an inch in thickness, were as clumsy as those of the original Chinese ladies were diminutive. Some few of the former were well-dressed, with delicate features, and their complexions heightened by the aid of art. A thick patch of vermilion in the middle of the lower lip, seemed to be a favourite mode of using paint. Some of them were sitting in covered carriages, of which, as well as of horses, there are several to be found for hire in various parts of the town. A few of the Tartar ladies were on horseback, and rode astride like men. Several of the streets were narrow, and at the entrance of them gates were erected, near which guards were stationed, for quieting any occasional disturbance in the neighbourhood. These gates are shut at night, and opened only in cases of exigence. The train of the embassy crossed a street which extended N. and S. the whole length of the Tartar city, almost four miles, and is interrupted only by several pei-loos, or triumphal fabrics; and passing by many temples and other spacious buildings and magazines, they reached, in little more than two hours from their entrance on the eastern side, to one of the western city gates. Near this gate, and along the outside of the western wall, ran the small rivulet, (here widened into a considerable ditch,) which, after almost surrounding Peking, runs towards Tong-choo-foo, and falls into the Pei-ho: the suburb beginning at this western gate, being more extensive

than that through which they had entered into the city, took for traversing it upwards of twenty minutes.

The embassy found, in proceeding N.W. from Peking, the same kind of granite pavement over which they had travelled to that city from Tong-choo-foo. It led them to the open town of Hai-tien, containing few other buildings besides those intended for the sale of goods, and for the accommodation of artificers, near the autumnal palace of Yuen-min-yuen, which lies a little way beyond it. The shops of Hai-tien, besides necessaries, abounded in toys and trifles, calculated to amuse the rich and idle of both sexes. Between Hai-tien and Yuen-min-yuen, was the villa intended for the ambassador and his suite, which was an inclosure of twelve acres. It contained a garden laid out in serpentine walks, a rivulet winding round an island, a grove of various trees, interspersed with patches of grass ground, and diversified with artificial inequalities, and rocks rudely heaped upon each other. The building in this place consisted of several separate pavilions, erected round small courts. The apartments were handsome, and not ill contrived. Several of them were adorned with landscapes, painted in water-colours.

The capital of Peking bears not in size the same proportion to the rest of China that London does to Britain. The principal part of it is called the Tartar city, from the circumstance of its having been laid out anew in the 13th century, in the time of the first Tartar dynasty, or as Du Halde says, because the houses were allotted to the Mandshurs, in the beginning of the present dynasty. It is in the form of a parallelogram, of which the four walls face the four cardinal points. They include an area of about fourteen square miles, in the centre of which is the imperial palace, occupying within the Yellow wall at least one square mile, the whole being about one-third larger than London, on its present extended scale; whereas the fifteen ancient provinces of China, independently of the vast accession of territory from the great wall to the neighbourhood of the Caspian sea, bear a proportion to Great Britain of about 15 to 1. Adjoining, indeed, to the southern wall of the Tartar city, is another, called, by way of distinction, the Chinese city. Here most of the people lodge, who come occasionally upon business from the provinces to the capital. Its walls, which are greatly in decay, include likewise a very considerable space, about nine square miles. A small part only, however, is occupied by buildings, which are indifferent, crowded, and irregular; the rest is empty, and part of it is in cultivation. Within this compass has been raised the "Sien-nong-tan," or eminence of venerable agriculturists. Thither the emperor repairs every spring, and in compliance with ancient usages, goes through the ceremony of directing with his own hand the plough through a small field, by way of doing honour to the profession of a husbandman. When this part of the ceremony is finished, a group of peasants chaunt round him hymns in praise of husbandry, following his example, and making several furrows with the plough in his presence. The produce of the ground he has ploughed is carefully collected, and solemnly announced to surpass, in quality and quantity, what any other spot of equal dimensions had yielded in the year. The celebration of this festival is made known as far as the remotest village of the empire. Within the walls of the Chinese city has likewise been erected the "Tien-tan," or eminence of heaven. The single character "tien," or heaven, is inscribed upon the principal building in this eminence. Its form is round, in allusion to the vault of the heavenly firmament, as it strikes the eye; in like manner the "Tee-lan," a temple dedicated to the earth, which the ancient Chinese supposed to be a perfect

PE-KING.

fect square, is of a square form. In the summer solstice, when the heat and power of the sun are at the highest, the emperor comes in solemn procession to pay obedience, and offer thanks for its benign influence, and in the winter solstice similar ceremonies are performed in the temple of the earth. This solemn adoration of heaven and earth is confined to the person of the emperor; and for his convenience is performed at Peking, where he likewise appears abroad, in a variety of other grand processions, suggested by the mixed views of policy and religion. There are few other ceremonies performed in Peking.

Peking is merely the seat of the government of the empire. It is not a port, nor a place of inland trade nor manufacture. No representative diet, nor general states, with numerous retainers, assemble there to assist, or check, or examine, the measures of the crown. It forms no rendezvous for pleasure and dissipation. Peking owes little of its extent and populousness to the various circumstances that contribute to aggrandize and enlarge European cities. Most men there have stations regularly allotted them, or are occupied in attending or providing for those who have. From the operation of a variety of causes in China, there is a constant tendency to level wealth; as there is no right of primogeniture, nor any hereditary dignity, the extremes of wealth and poverty are equally unknown. There are properly but three classes of men in China, men of letters, from whom the mandarins are taken, cultivators of the ground, and mechanics, including merchants. To these we might add a fourth class, *viz.* the military. In Peking alone is conferred the highest degree of literature, upon those who, in public examinations, are found most able in the sciences of morality and government, as taught by the ancient Chinese writers; with which studies the history of their country is intimately blended. Among such graduates, all the civil offices in the state are distributed by the emperor; and they compose all the great tribunals of the empire. The candidates for these degrees are such as have succeeded in similar examinations in the principal city of each province. Those who have been chosen in the cities of the second order, or chief town of every district in the province, are the candidates in the provincial capital. They who fail in the first and second classes have still a claim on subordinate offices, proportioned to the class in which they had succeeded. These examinations are carried on with great solemnity, and apparent fairness. Military rank is likewise given to those who are found, upon competition, to excel in the military art, and in warlike exercises. The great tribunals are situated, for the sake of convenience, near the southern gate of the imperial palace at Peking. To them all the transactions of the empire are regularly transmitted. They are councils of reference from the emperor, to whom they report every business of moment, with the motives for the advice which they offer on the occasion. His imperial majesty generally conforms to the suggestions of these tribunals, of which there are several, superior and subordinate.

The estimated population of Peking was supposed, in the last century, by the Jesuit Grimaldi, to amount to sixteen millions. Another missionary reduces, at least that of the Tartar city, to one million and a quarter. According to the best information given to the embassy, the whole was about three millions. The low houses of Peking seem scarcely sufficient for so vast a population; but very little room is occupied by a Chinese family, at least in the middling and lower classes of life. In their houses they have no superfluous apartments. A Chinese dwelling is generally surrounded by a wall, six or seven feet high. Within this inclosure a whole

family, of three generations, with all their respective wives and children, will frequently be found. One small room is made to serve for the individuals of each branch of the family, sleeping in different beds, divided only by mats hanging from the ceiling. One common room is used for eating. This arrangement renders the younger orderly and temperate in their conduct, under the authority and example of the older; and it enables the whole to subsist, like soldiers in a mess, with more economy and advantage.

The streets of Peking are thronged with people, the multitude of whom is increased by the mandarins of rank, appearing always with numerous attendants; and still more by circles of the populace round auctioneers, vendors of medicines, fortune-tellers, singers, jugglers, and story-tellers. The nobility of the court and princes of the blood never appear in public, without being surrounded by a large body of cavalry; and as their presence is required at the palace every day, their train alone would be sufficient to create confusion in the city. Besides, as there is a continual influx of the riches and merchandize of the whole empire into this city, the number of strangers that resort hither is immense. These are carried in chairs, or ride on horseback; and they are always attended by a guide acquainted with the streets, and with the houses of the nobility, and principal people of the city. In summer there are to be seen small temporary shops, where people are served with water cooled by means of ice; and eating-houses are every where to be met with, with refreshments of tea and fruits. Each kind of provision has a certain day and place appointed for its being exposed to sale. Nevertheless, the crowds of people at Peking do not prevent it from being healthy. The Chinese, indeed, live much in the open air, increasing or diminishing the quantity of their apparel according to the weather. The atmosphere is dry, and does not engender putrid disorders; and excesses productive of them are seldom committed. Great order is preserved among such multitudes; and the commission of crimes is rare. The police of the capital is so well regulated, that the safety and tranquillity of the inhabitants are seldom disturbed. At the end of every cross street, and at certain distances in it, there is a kind of cross bars, with sentry boxes, in each of which is placed a soldier; and few of these streets are without a guard-house. Besides, the proprietor or inhabitant of every tenth house, like the ancient tythingmen of England, takes it in turn to keep the peace, and be responsible for the good conduct of his nine neighbours. If any riotous company should assemble, or any disturbances happen within his district, he is to give immediate information of it to the nearest guard-house. The soldiers also go their rounds, and instead of crying the hour like our watchmen, strike upon a short tube of bamboo, which gives a dull hollow sound, that prevents those unaccustomed to it from sleeping. The viceroy of Peking is of the Tartar race, and is styled governor of the nine gates, that being the number of gates belonging to the city. His jurisdiction extends not only over the soldiers, but also over the people in every thing that concerns the police. In the suburbs only public women are registered and licensed: they are not very numerous, being proportioned to the small number of single men, and of husbands absent from their families to be found in the metropolis. In Peking, as well as in other parts of China, parents are less frequently neglected than infants are exposed. Female infants are, for the most part, chosen for this cruel sacrifice, because daughters are considered more properly to belong to the families into which they pass by marriage; while the sons continue to be the support and comfort of their own.

Notwith-

Notwithstanding all the means adopted for restraining this barbarous practice, a missionary, who was not inclined to exaggerate the evil, has reported that in Pekin about 2000 infants were every year exposed, of whom a considerable number perished. The missionaries, to their honour it must be acknowledged, have contributed to preserve many, and afterwards to maintain and educate them.

The principal building in Pekin is the imperial palace already mentioned: it stands in the middle of the Tartar city, at a little distance from the south gate; and the entrance to it is through a spacious court, to which there is a descent by a marble staircase, ornamented with two large copper lions, and a balustrade of white marble, which runs in the form of a horse-shoe, along the banks of a rivulet, that winds across the palace with a serpentine sweep: the bridges over it are of marble. At the bottom of this first court arises a façade with three doors: that in the middle is for the emperor only; the mandarins and nobles pass through those on the sides. These doors conduct to a second court, which is the largest in the palace; it is about 300 feet long, and 50 broad; an immense gallery runs round it, in which are magazines, containing rich effects, belonging to the emperor as his private property; for the public treasure is entrusted to a sovereign tribunal, called "Hou-pon." In this second court is the royal hall, called "Teintotien," or the hall of the grand union: it is built upon a terrace about 18 feet high, incrufted with white marble, and ornamented with balustrades of excellent workmanship. Here the mandarins arrange themselves, when they come, on certain days, to renew their homage, and perform those ceremonies that are appointed by the laws of the empire. This hall is almost square, and about 130 feet long; the ceiling is carved, varnished green, and loaded with gilt dragons. The pillars which support the roof within are six feet in circumference towards the base, and are coated with a kind of malthick varnished red; the floor is partly covered with coarse carpets, after the Turkish manner; but the walls have no kind of ornament, neither tapestry, lustres, nor paintings. The throne, which is in the middle of the hall, consists of a pretty high and very neat alcove. It has no inscription but the character "ching," which denotes excellent and perfect, as well as most wise and holy. It is ascended by steps in the front and on each side. Tripods and vessels of incense are placed on the sides, and before it is a small table, as an altar, on which are laid offerings of tea and fruit to the spirit of the absent emperor. As the Chinese attribute to their emperor perfections belonging to the deity, they conceive his dominion as virtually extending over the whole world. Believing the majesty of the emperor to be ubiquitous, they sacrifice to him when absent; and it is not therefore surprising that they should adore him when present. The adoration, or "Koteou," they pay him consists in nine prostrations of the body, the forehead being each time made to touch the floor; which is not only a token of the deepest humility and submission, but implies a conviction of the omnipotence of the personage to whom this act of veneration is performed. These abject prostrations are required not only from the subjects and tributary princes of the empire, but also from all strangers, however exalted. Upon the platform, opposite to the hall just mentioned, stand large vessels of bronze, in which incense is burnt, when any ceremony is performing. There are also chandeliers shaped like birds, and painted of different colours, as well as the wax candles that are lighted up in them. This platform is extended towards the north, and has upon it two lesser halls; one of them is a rotunda, that glitters with varnish, and is lighted by a number of windows. Here the emperor changes his

dress before or after any ceremony. The other is a saloon which opens to the north: through this door the emperor must pass, when he goes from his apartment to receive on his throne the homage of the nobility: he is then carried in a chair by officers dressed in long red robes bordered with silk, and caps ornamented with plumes of feathers. We may here observe, that the temples of Pekin have no claim to elegance, when compared to its palaces. The religion of the emperor is performed with great magnificence in Tartary, but in China it is new. The mandarins and men of letters venerate Confucius, and assemble in halls of simple construction; and the lower classes of the people are unable to contribute to the erection of splendid edifices for public worship. Besides, their attention is much taken up with their household gods. Every house has its altar and its deities. (See CHINA.) The imperial palace, which presents an assemblage of vast buildings, extensive courts, and magnificent gardens, is shut up on all sides by a double wall; the intervening space being occupied by houses belonging to the officers of the court and eunuchs, and by different tribunals. The exterior circumference of this palace is reckoned to be $1\frac{1}{2}$ league. The extent, grandeur, regular disposition of apartments, and singular structure of the pavilion roofs (already noticed), cannot fail to strike beholders with surprise. N. lat. $39^{\circ} 55'$. E. long. $116^{\circ} 28'$. Earl of Macartney's Embassy, by Sir G. Staunton, vol. ii. Barrow's China. Grofier's China, vol. i.

PELADA, a kind of alopecia, or distempered state of the body, occasioning the shedding of the hair, arising from a venereal cause.

PELÆAS, Πελαιας, in *Ornithology*, the name by which the ancients called that species of pigeon now known by the name of the *livia*, and *saffarolla*; a grey pigeon, of a very small size, and with some variegations of purple and green. See LIVIA.

PELAGIA, in *Natural History*, the name by which Pliny, and other of the ancient naturalists, have usually called the *purpura*.

PELAGIA, *St.*, in *Geography*, a town of Naples, in the province of Otranto; 3 miles N. of Tarento.

PELAGIÆ, formed of *πελαγος*, *marine*, or belonging to the sea, in *Natural History*, a term used to express such sea shells and fishes, as never, or very rarely, are found near the shores; but always reside in the deep, or in those parts of the bottom of the sea which are most remote from land.

PELAGIANS, PELAGIANI, in *Ecclesiastical History*, the denomination of a sect, well known in the church by the writings of St. Augustine.

The author of this sect, Pelagius, properly called Morgan, was a monk of Bangor: but the learned are at a loss whether it was of the monastery of Bangor in Wales, or that of the same name and order in Ireland. But he was a contemporary with St. Jerom and St. Augustine; and quitted his country to go and live in the East, according to the custom of the monks of those days, who were attached to particular houses like those of our own time.

Cœlestius, as some say, a native of Ireland, according to others, of Scotland, and again, as others say, of Campania, in Italy, was the colleague of Pelagius, in forming this sect. They both lived at Rome in great reputation, and were universally esteemed on account of their extraordinary piety and virtue. About the year 410 they published their doctrine, first in Sicily, and afterwards in Africa. From Africa Pelagius passed into Palestine, and Cœlestius remained at Carthage, whence, his errors being condemned in a council, A.D. 412, he went into the East. The former, under the protection of John, bishop of Jerusalem, made a public

profession of his opinions, and formed disciples in several places. In the year 415 he was accused by Orosius, a Spanish presbyter, whom Augustine had sent into Palestine for that purpose, before an assembly of bishops who met at Jerusalem, but was dismissed without the least censure, and was soon after fully acquitted of all errors by the council of Diospolis, a city of Palestine, known in Scripture by the name of Lydda. However, after this council, Pelagius and Cœlestius were condemned again, A.D. 416, by the African bishops assembled at Carthage, and those of Numidia assembled at Milevum. Soon after the controversy was brought to Rome, and referred by Pelagius and Cœlestius to the decision of Zosimus, who was raised to the pontificate, A.D. 417; and he pronounced in their favour, declared them sound in the faith, and unjustly persecuted by their adversaries. However, he was prevailed upon by the remonstrance of the Africans to change his mind, and he severely condemned those two persons, whom he had honoured with his approbation, and covered with his protection. They were also condemned by the council of Ephesus, A.D. 431; and, in short, the Gauls, Britons, and Africans, by their councils, and emperors, by their edicts and penal laws, demolished this sect in its infancy.

Pelagius absolutely denied all original sin, which he held to be the mere invention of St. Augustine; and taught that men are entire masters of their actions, and perfectly free creatures; in opposition to all predestination, reprobation, election, &c.

He owned, indeed, that the natural power of man needed to be assisted by the grace of God, to enable him to work out his own salvation; but, by this grace, he only meant outward assistance, *viz.* the doctrines of the law, and of the gospel.

Though, when pressed by those words of St. Paul, "Deus est enim, qui operatur in nobis," &c. he owned that it is God, in effect, that makes us will what is good, when he warns and excites us by the greatness of the glory we are to obtain, and by the promises of rewards; when he makes us love him by revealing his wisdom, &c.

These are Pelagius's own words, as cited by St. Augustine; who confutes him, and shews, that, besides these exterior graces, there are required other real and interior ones.

He owned, that the will of man is indeed aided by a real grace; but he added, that this grace is not absolutely necessary in order to live well; but that it only helps us to do well with the more ease.

Julian, one of his adherents, went farther yet; and owned that the assistance of grace was absolutely necessary to enable us to do perfect works.

In effect, the grand doctrine of the Pelagians was, that a man might accomplish all the commands of God by the mere power of nature; and that the gifts of grace were only necessary to enable him to act well more easily, and more perfectly.

PELAGIE, in *Geography*, a river of Louisiana, which runs into the Missouri, N. lat. 38° 30'. W. long. 91° 30'.

PELAGIUS I. pope, in *Biography*, was a native of Rome, and became a deacon of the Roman church, and was employed in the capacity of nuncio at the court of Constantinople by several of the popes in succession. He was first sent to the imperial residence by pope Agapetus, in the year 535, where he rose into extraordinary favour with the emperor Justinian, the empress, and the leading persons at court. About the year 539 he was commissioned, together with Ephraim, patriarch of Antioch, and

Peter, patriarch of Jerusalem, to decide on the case of Paul, who had been banished to Gaza, on account of a deacon's death, to which he was said to have been privy. Having repaired to Gaza after the trial of the African prelate, sentence of deposition was pronounced upon him. While Pelagius was returning to Constantinople he met with some Palestine monks on their journey to that city, in order to prefer complaints to the emperor against the followers of Origen; and having promised them his interest at court, he succeeded in obtaining an edict from Justinian in 541, by which sentence of condemnation was passed upon the Origenists. In the mean time, he had betrayed the interests of pope Silverius at Constantinople, and, to ingratiate himself with the empress, became privy to the measures for securing the popedom to Vigilius, the usurper of the see. About the year 545 he returned to Rome, being either recalled by Vigilius, or, according to others, sent by Justinian with a large sum of money for the relief of that city, which was reduced to great distress by the incursions of the Goths. In 547 he was deputed by the citizens of Rome on an embassy to Totila, king of the Goths, for the purpose of dissuading that prince by his prayers from besieging the city, when, though he failed in the object of his mission, by his intercession he was the means of preserving the lives and liberties of numbers of the conquered Romans. In the same year Totila sent him in the character of ambassador to Constantinople, to negotiate a peace between the Goths and Romans. He adhered to Vigilius in all his disputes: in all his changes, condemning or approving those articles which the pope condemned or approved. With him he was banished for rejecting the fifth council; but recanting, when the pope recanted, he was with him released from his exile and recalled to Constantinople. He attended Vigilius on his return from the East; and upon the death of the pope in the island of Sicily, in the year 555, he hastened to Rome, the emperor having promised to raise him to that see if he survived Vigilius, upon his engaging to cause the fifth council to be universally received in the West. When Pelagius arrived at Rome, he found the people and clergy so highly enraged against him, that instead of electing him their bishop, they all with one consent separated themselves from his communion. What induced many to concur in this measure, was a strong report, that, in order to secure the object of his ambition, he had been accessory to the death of his predecessor. But Pelagius, relying on the support of the emperor, resolved to have himself ordained in defiance of the canons, as well as the electors. Having, therefore, engaged two Italian bishops to second his views, but these not being sufficient, he substituted in the room of a third a presbyter of Ostia, and by means of these three he was ordained a bishop. The Roman people still declared against his power, determining never to acknowledge him for their lawful bishop. Under these circumstances Pelagius applied to the emperor, and obtaining his interest and support, he was acknowledged the lawful bishop. No sooner was he settled in the quiet possession of his see, than he endeavoured to perform his engagement to the emperor, by persuading the western bishops to receive the fifth council. With this view he addressed letters to them, in which he attempted to prove, that the constitution of Vigilius was in no respect derogatory to the decrees of Chalcedon, and consequently that such as did not receive it ought to be deemed schismatics. So far, however, were his letters from producing the desired effect, that the bishops of Tuscany, Liguria, Venetia, Illyricum, Gaul, Spain, and Ireland, declared loudly against that constitution, and the fifth council, and

the Italian bishops, as well as the Irish, besides censuring the pope in the strongest terms, separated themselves from his communion.

Thus abandoned by almost all the bishops in the West, and finding his endeavours to satisfy them of his orthodoxy were ineffectual, he wrote to the emperor's chief general Narfes, exhorting him to restrain by his authority and power, those whom a reverence for St. Peter and his see could not restrain, or bring to a sense of duty. Narfes being of a mild and humane disposition, instead of acting as the pope desired, endeavoured by entreaties and persuasion to gain over those Italian bishops who were the subjects of the empire, and though he was at first not successful, by steadily adhering to the system of pacification, he in the end prevailed upon some of the bishops of Tuscany and Liguria to renew their communion with the see of Rome. About the year 557, a report was spread in Gaul, that the pope had departed from the genuine Catholic doctrine. Childebert, king of the Franks, sent an ambassador to Rome, for the purpose of examining into its truth, and of demanding of Pelagius a confession of his faith. In compliance with the king's demand, the pope transmitted to the monarch his confession, accompanied with solemn declarations, that he not only received, but was ready to defend, at the expence of his life, the holy faith of Chalcedon; yet maintaining, that nothing had been defined in the fifth council, but what was entirely agreeable to that faith and doctrine. Pelagius died in 560, after a pontificate of nearly five years, during which he had the mortification to see the authority claimed by the pretended successors of St. Peter almost universally disregarded by the western bishops, who persevered in condemning and rejecting a council which he had approved and received, and even suspected the orthodoxy of his creed because he received it. Sixteen letters which have been attributed to him, may be found in the fifth vol. of the Collect. Council. of which, however, the first is admitted by the editors of that work to be spurious.

PELAGIUS II. pope, was of Gothic extraction, and the son of Winigild, but a native of Rome. Upon the death of pope Benedict in 578, the see continued vacant four months, at the expiration of which Pelagius was chosen to fill that dignity. His election having taken place at a time when the Lombards were masters of the greatest part of Italy, and kept Rome itself closely besieged, it was judged expedient that he should be ordained before the emperor's confirmation could be received; but as soon as the siege was raised, he sent Gregory, then deacon in the Roman church, and afterwards his successor in the popedom, to excuse the informality, and to entreat the emperor's acquiescence in a proceeding which had been rendered necessary by the calamitous circumstances of the times. The Lombards, by their ravages, had now spread such devastation and terror in every part of Italy, that persons who had the character of holy men regarded them as the instruments of the divine vengeance to depopulate the country; and some of them fancied that they had revelations, which foretold them that the Lombards were the fore-runners of the last day, and that the end of the world was at hand. By the report of their visions the credulous multitude was terrified to such a degree, that instead of uniting against the common enemy, they abandoned themselves to despair, and suffered the barbarians to plunder and destroy without opposition. In this state of the empire in the West, the church continued to be divided by the schism which had been occasioned by the constitution of pope Vigilius, and not terminated by his successors. The talk of healing that schism, Pelagius considered to be one of the

first objects that merited his attention, and he determined to apply to it with the utmost zeal. The Lombards, however, occasioned the most serious alarms to the church, and obliged his holiness to pay more attention to the secular concerns of the state than to its spiritualities. They had conquered the important city of Pavia, and having made it the metropolis of their new kingdom, extended their conquests from thence over the adjacent provinces, threatening to advance a second time against Rome. This threat they were enabled to carry into execution without delay, since the exarch Longinus had not sufficient forces to meet them in the field. Under constant apprehensions, therefore, that they would speedily make their appearance at the gates of the city, Pelagius sent new legates to the emperor Tiberius, in the year 580, to lay before him an account of the defenceless state of Italy, and to solicit a supply of men and money, that the city of Rome itself might not fall into the hands of the barbarians. But the emperor, though wishing well to the cause, had it not in his power to send them any relief. Finding Italy thus abandoned by the emperor, in 581 the pope applied to Guntram, king of Burgundy, who was distinguished for his attachment to the bishops of Rome, and their see, exhorting and entreating him to renounce the alliance which he had lately concluded with the Lombards, and by turning his arms against them, prevent the entire subjugation of Italy. In this he was likewise unsuccessful. In 584, Pelagius sent three letters to the bishops of Istria, in which he intimated that the disputes which divided them were foolish and idle; enlarged on the evils attending a division among the Catholic prelates; exhorted them, with great tenderness, to return to the unity of the church; and proposed a conference, to be held at Rome, or, if more convenient for them, at Ravenna, which he hoped would end to their satisfaction and his. To these letters the Istrian bishops replied in the order in which they received them; but so far were they from making any impression on their minds, that these prelates came to a determination to decline all communication with Rome. Pelagius, finding that he could not succeed in his design by persuasion, resolved to have recourse to persecution. He accordingly wrote to the exarch, exciting his resentment against the Istrian prelates, by representing them to be incorrigible disturbers of the peace of the empire as well as the church. Zamaragdus, instead of following the prudent and humane example of his predecessor Narfes, in the pontificate of Pelagius I., suffered himself to be the tyrannical instrument of papal vengeance, and seized and imprisoned the refractory prelates.

From this period we meet with no farther particulars relating to Pelagius before the year 588, when a council was held at Constantinople, for the trial of Gregory, patriarch of Antioch, who had been accused of incest, and several other very serious crimes. After the patriarch had been honourably acquitted, the council, before it broke up its meeting, confirmed to John of Constantinople, on his own application, the title of œcumenical or universal bishop, to be enjoyed by him, and his successors in that see. Though it does not appear that this title was attended with any accession of power, yet Pelagius was alarmed lest the dignity of his bishopric should be eclipsed, and endeavoured to excite the whole Christian world against John, as if he intended to engross all ecclesiastical power to himself and his see. As much disturbed and concerned as if the council had condemned some fundamental article of the Christian religion, he immediately, by the authority, and in the name of St. Peter, declared all the acts of that assembly null and void, excepting their acquittal of Gregory. He also dispatched messengers

messengers to Constantinople with letters to the patriarch, and to his nuncio at the imperial court; the former he commanded to relinquish the anti-christian title which he had assumed, and the latter he enjoined not to communicate, nor assist in divine service on any occasion with the bishop of Constantinople, till he had renounced that distinction. Notwithstanding this, John probably continued the use of his title as long as he lived, though the pope was prevented, by death, from proceeding farther in this affair. In 589 the Catholic cause received an accession of strength by the conversion of the Gotlis in Spain, who, after having professed the doctrine of Arius during more than two centuries, were persuaded by their king Recaredus to renounce it, and to embrace the Catholic faith. This event gave great satisfaction to the Catholic party, though Pelagius survived but a short time to enjoy it. In consequence of an inundation of the Tiber, which laid the greater part of the city of Rome, and the adjacent country under water, a dreadful distemper broke out, which proved fatal to Pelagius in February 590, after he had presided over the Roman see eleven years and about a quarter. Ten "Letters," and six "Decrees" under his name, are inserted in the fifth vol. of the Collect. Concil.; some of them are, however, supposititious.

PELAGIUS, the distinguished leader of a Christian sect. See PELAGIANS.

PELAGNISI, in *Geography*, an island in the Grecian Archipelago, about eight miles in circumference. N. lat. 39° 30'. E. long. 24° 8'.

PELAGONIA, in *Ancient Geography*, a country of Macedonia, called also "Tripolitis," on account of its three cities, according to Strabo.—Also, a town of the same country.—Also, a town of the island of Sicily.

PELAGOSA, in *Geography*, an island in the Adriatic, near the coast of Dalmatia. This island, and the adjacent rocks, are the remains of an ancient volcano; and its present aspect, which is rugged and ruinous, indicates many violent eruptions; 16 miles S.W. of Agosta. N. lat. 42° 45'. E. long. 16° 10'.

PELAMYS, in *Ichthyology*, a name by which the ancients expressed the young brood of the *thynnus*, or tunny fish, at a certain age and size; but later writers have appropriated the word for the name of a distinct species of fish of the same genus, called by others *sarda*; and by some by the two names joined into one, *pelamys-sarda*. It is a sea-fish, of the shape of the tunny: but of a smooth skin, and free from scales every where, except about the gill-fins; its teeth are large, long, and crooked. These are the only external marks by which it is to be known from the young brood of the tunny; but when brought to the table, it is easily distinguished by the hardness of its flesh.

PELAMYS *Vera*, a name given by Rondeletius, and some other authors, to the fish more distinctly known by the name of *amia*.

PELANG, in *Geography*, a town of the Birman empire; 8 miles N.E. of Pagongmew.

PELANI, Πελανί, among the Athenians, a kind of cakes used in their libations.

PELARGONIUM, in *Botany*, so called from *πελαργός*, a *flork*, in allusion to the beak of the fruit, which resembles the bill of that bird; as well as to preserve an analogy with the *Geranium*, or Crane's bill. The name and the genus were first suggested by Dillenius, in Hort. Elth. 149, and subsequently adopted by Burmann and P'Heritier, as well as by the editors of the first edition of *Hortus Kewensis*. *Pelargonium* embraces what are commonly known by the appellation of African Geraniums, and which doubtless

constitute a most natural genus, clearly distinguished from GERANIUM, as well as from ERODIUM, (see those articles,) by the irregularity of the flower and its tubular neclary, to say nothing of number of stamens.—Burm Afr. 89. L'Herit. Geraniol. unpublished. Ait. Hort. Kew. ed. 1. v. 2. 417. Willd. Sp. Pl. v. 3. 641. Lamarck Illustr. t. 574. (Geranium; Linn. Gen. 350. Schreb. 458. Juss. 268.)—Class and order, *Monadelphica Heptandria*. Nat. Ord. *Gruinales*, Linn. *Gerania*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep, oblong, permanent segments, the uppermost protracted downwards into a honey-bearing tube, running along the flower-stalk, with which it is united. *Cor.* Petals five, oblong or roundish, spreading, longer than the calyx, irregular. *Stam.* Filaments ten, awl-shaped, flat, united at their base into a sort of cup, three of them, rarely five, abortive, and without anthers; anthers seven, rarely but five, oblong, versatile. *Pist.* Germen superior, oblong, with five furrows, beaked; style central, awl-shaped, spirally furrowed, as long as the stamens, permanent; stigmas five, reflexed. *Peric.* Capsules five, aggregate, membranous, obovate, vertical, separating at their inside, pointed at the base, each tipped at its summit with a long, linear, flat, pointed, rigid awn, hairy on its outside, and at length spirally twisted, adhering by its point to the summit of the style. *Seeds* solitary, erect, ovate.

Ess. Ch. Calyx in five deep segments, the uppermost elongated at the base into a nectariferous tube, running down the flower-stalk. Petals five, irregular. Filaments ten, unequal, three or five of them abortive. Fruit beaked, of five aggregate capsules, each tipped with a long spiral awn, bearded on the inside.

This vast and favourite genus, for which we are almost entirely indebted to the Cape of Good Hope, consists of a great number of well-marked species. But that number is greatly augmented, in almost every book, by the admission of spurious hybrid species or varieties, which continually start up from seed wherever many of the primary ones are cultivated, and are for a while propagated by cuttings, or even by seed. Sooner or later, however, they for the most part vanish, even before the eyes of those who witnessed their origin. Willdenow defines 120 species of *Pelargonium*, several of which we know to have been the production of European gardens. He arranges them in eight sections. We shall select examples of each, subjoining such remarks as seem to us necessary, but abstaining from the hazardous and unimportant undertaking of classing, or accounting for, every evanescent variety, with figures of which some authors, otherwise of good credit, have burthened and bewildered the science. All these plants have rather a fleshy habit, and more or less of a peculiar scent, in some instances exquisitely agreeable. Some are herbaceous, with a tuberous root, that supplies the place of the shrubby stem observable in most of the others. Their foliage is mostly downy, sometimes glaucous. Flowers more or less umbellate, rarely endowed with any scent, except what arises from the herbage, though some, whose colours are of the yellowish-green or lurid kind, are deliciously fragrant at night. The prevailing colour, throughout the greater part of the genus, is crimson, scarlet, or light purple, in various beautiful shades and combinations, often intermingled with white. Yellow and blue are both equally rare in this natural order, and the latter scarcely occurs at all in the genus of which we are treating.—Every known species, except perhaps one or two, is perennial. They are greenhouse plants in England, flowering at various seasons, and conducing greatly to the ornament of a collection. In some few instances the number of petals, as well

PELARGONIUM.

well as of the *stamens*, differs a little from the generic description.

Section 1. *Stem wanting. Root turnip-like. Umbel compound.* Twenty-two species in Willdenow.

P. longifolium. Long-leaved Stork's-bill. Willd. n. 1. Jacq. Ic. Rar. t. 518. (*Geranium longifolium*; Burm. Geran. 50. n. 67. t. 2. Cavan. Diff. 235. t. 102. f. 1. *G. prolificum*; Linn. Sp. Pl. 950.)—Stem none. Umbel compound, leafy. Leaves lanceolate, acute, entire, smooth; the older ones pinnatifid, linear. Petals linear-obovate. Anthers four.—Gathered first by Oldenland at the Cape of Good Hope. *Root* ovate-oblong. Radical *leaves* several, on longish stalks, spreading, above two inches long, and near one broad; mostly accompanied by some younger ones, that are deeply pinnatifid, and very narrow. *Flower-stalk* foliary, three or four inches high, bearing about three unequal, downy, partial stalks, accompanied by a leaf or two, each terminating in a downy *umbel*, of several rose-coloured *flowers*. Analogy shews the stalk of this plant to be but a *scapus*, not a true *caulis*, though it generally elevates a leaf or two from the root. It must however be confessed that, like many others in this genus, it forms an intermediate link between a stem and flower-stalk, or rather combines the two.

P. longiflorum. Long-flowered Stork's-bill. Willd. n. 2. Jacq. Ic. Rar. t. 521.—Stem none. Umbel compound, somewhat leafy. Leaves lanceolate, acute, entire. Petals linear. Anthers four.—Of this Jacquin's *depressum*, t. 520, is justly made a variety by Willdenow; and we would venture also to refer to it his *ciliatum*, t. 519, which Willdenow, on account of two little occasional appendages to the leaves, terms *auriculatum*, n. 7.—Perhaps they are all but varieties of *longifolium*, differing in their narrower *petals*, which are buff-coloured, with a deeper purple stain at the base of some of them. The *footstalks* of all are hairy, at least at their base, as are the *umbels* and partial *flower-stalks*. There is a general conformity in their foliage and aspect, which will scarcely allow us to trust to any apparent specific differences, but we offer our sentiments, on so obscure a tribe, in the way of conjecture only.

P. auritum. Eared Stork's-bill. Willd. n. 8. (*Geranium auritum*; Burm. Geran. 47. n. 61. *G. prolificum* δ ; Linn. Sp. Pl. 950. Mant. 433. *G. africanum*, foliis pleurumque auritis, floribus ex rubro purpurascens; Comm. Hort. v. 2. 121. t. 61.)—Stem none. Umbels simple or compound. Leaves ovate-oblong, obtuse, simple or ternate, slightly notched, hairy. Petals obovate, oblong. Anthers five.—Burmah says this is the rarest of all the Cape Geraniums. Linnæus had it in the Upsal garden, as appears by his herbarium. It is nearly allied to the foregoing, but seems altogether more hairy, and the *leaves* are most frequently truly ternate, and obtuse. The *petals* are of a deep crimson. We cannot ascertain the number of *anthers*, but Linnæus says they are five.

To this are nearly allied *hirsutum* of Burmann, n. 68. t. 2. Willd. n. 12, and *heterophyllum*, Jacq. Ic. Rar. t. 516. Willd. n. 15. Both vary much in the division of their *leaves*, but the segments always partake either of a wedge-like or obovate figure, and are by no means linear. They are also constantly hairy.

P. pinnatum. Pinnate Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 417. Willd. n. 18. Curt. Mag. t. 579. (*P. astragalifolium*; Jacq. Ic. Rar. t. 511. *Geranium pinnatum*; Linn. Sp. Pl. ed. 1. 677. *G. prolificum* γ ; Linn. Sp. Pl. 950. *G. africanum* astragali folio; Comm. Prælad. 53. t. 3.)—Stem none. Umbels simple or compound. Leaves pinnate; leaflets numerous, ovate, undivided, hairy

on both sides. Anthers five.—Commelin received seeds of this from the Cape about the year 1699. Whatever may be thought of the rest of this tribe, the present plant is certainly a very well marked species. The *leaves* are very like those of several *Astragali*. Sometimes the *leaflets* are placed in fours. The *flower-stalks* are hairy, sometimes simple, but mostly bearing three umbels, with a small leaf or two. The *petals* vary in breadth and colouring, but are generally obovate-oblong, pale buff, or cream-coloured, the two uppermost speckled with red. Anthers five.

P. lutcum. Dwarf Yellow Stork's-bill. (*Geranium lutcum*; Andr. Repof. t. 423.)—Stem none. Umbels mostly simple. Leaves pinnate; leaflets stalked, ovate, acute, divided. Anthers five.—This flowered in 1803, in the collection of Mr. G. Hibbert at Clapham, having been received by him, amongst many other rarities, from the Cape.

We know nothing of it but from Andrews's work, yet we have no doubt of its being distinct from all in Willdenow. The stalked and cloven *leaflets* are very peculiar. Whether they are smooth or hairy is not mentioned, but the figure expresses the former. The numerous *flower-stalks* are all drawn simple and smooth, nor does any pubescence appear on the *umbel* or *calyx*. The *petals* are linear-obovate, of a full yellow; the two uppermost streaked with red. Anthers five.

P. barbatum. Bearded-leaved Stork's-bill. Willd. n. 19. Jacq. Ic. Rar. t. 513. (*Geranium prolificum* β ; Linn. Sp. Pl. 949. *G. proliferum*; Burm. Geran. 51. n. 70. t. 2. Cavan. Diff. 259. t. 120. f. 3.)—Stem none. Umbel compound. Leaves pinnate; leaflets linear-lanceolate, acute, partly three-cleft, bearded at the tips. Anthers five.—This species appears to have been one of the first, of its tribe, brought from the Cape into the European gardens. Linnæus cultivated it with success at Upsal. The narrow, decurrent, frequently three-cleft *leaflets*, and especially the tuft of two or three bristly hairs at the point of each segment, afford its discriminative characters. The *umbels* and their stalks are downy. *Flowers* small and inconspicuous, flesh-coloured with some purple streaks.

P. rapaceum. Turnip-rooted Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 418. Willd. n. 22. Jacq. Ic. Rar. t. 510. (*Geranium rapaceum*; Linn. Syst. Nat. ed. 10. v. 2. 1141. *G. prolificum* α ; Linn. Sp. Pl. 949. *G. africanum*, myrrhidis folio, flore albicante, radice rapacæ; Comm. Hort. v. 2. 125. t. 63.)—Stem none. Umbel compound. Leaves pinnate; leaflets doubly pinnatifid, linear, downy. Corolla somewhat papilionaceous.—This used formerly to be known in gardens by the name of the Horfe's head Geranium, in allusion to the remarkable shape of the *flower*, by which alone it is clearly distinguished as a species. Three of the *petals*, much the broadest, cohere like the wings and keel of a papilionaceous flower, and are white or pale blush-coloured; the other two, narrower, rose-coloured and spotted, are reflexed, and look like a divided standard of the same kind of blossom. The *root* is very thick and tuberous, often divided. *Leaves* downy, pinnate; their leaflets doubly pinnatifid, in linear segments, which are variable in length and breadth.—If Linnæus had seen this alive, he could never have confounded it with any other.

Section 2.—*Stem very short. Root tuberous.* Four species.

P. lobatum. Lobe-leaved Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 418. Willd. n. 23. (*Geranium lobatum* α ; Linn. Sp. Pl. 950. Cavan. Diff. 250. t. 114. f. 2. *G. africanum*, noctu o'ens, tuberosum, vitis foliis hirsutis; Comm. Hort. v. 2. 123. t. 62.)—Stem scarcely any. Umbel compound. Leaves ternate or quinate; leaflets broad, roundly lobed, crenate, downy beneath. Anthers six.

PELARGONIUM.

fix.—An old plant in the European gardens, yet not very common, flowering in the greenhouse or conservatory in April and May, and highly desirable on account of the nocturnal fragrance of its *flowers*, which is like that of the bergamot pear, though far superior. The *petals* are obovate, and of that dull brownish or tawny green, appropriated to many night-scented flowers, as *Hesperis triflis*, *Cheiranthus triflis*, &c. The *leaves* are a span or more in breadth, soft and downy, acutely crenate. *Flower-stalks* hairy. *Umbels* downy. *Root* much like the last.

P. trifle. Night-scented Stork's-bill. Willd. n. 24. (*Geranium trifle*; Linn. Sp. Pl. 950. Cornut. Canad. 109. t. 110. Cavan. Diff. 261. t. 107. f. 1.)—Stem short. *Umbels* simple. *Leaves* hairy, pinnate; leaflets doubly pinnatifid, in oblong acute segments. *Root* of many jointed knobs—This is so like the last in its *flowers*, that it might be supposed a variety with deeply divided *leaves*, but it is more caulescent, and the *root* differs essentially in being composed of many elliptical jointed knobs, instead of consisting of one great solid body. Cornuti's plate, published in 1635, however misplaced in a work on Canada plants, is we believe the first that appeared of any African *Geranium*, or *Pelargonium*, and has also great merit in the execution. He says the *roots* are eatable.

P. flavum. Carrot-leaved Stork's-bill. Willd. n. 26. (*P. daucoides*; Jacq. Ic. Rar. t. 522. *Geranium flavum*; Linn. Mant. 257. *G. daucifolium*; Cavan. Diff. 260. t. 120. f. 2. *G. africanum, folio staphylini*; Riv. Pentap. Irr. t. 107.)—Stem short. *Umbels* simple. *Leaves* hairy, repeatedly subdivided, in linear-lanceolate segments. *Root* of many jointed knobs.—This we are persuaded is but a variety of the last, with more divided and narrower *leaves*, though Willdenow inserts, between the two, a most distinct species, which is the following.

P. appendiculatum. Broad Stipulaceous Stork's-bill. Willd. n. 25. (*Geranium appendiculatum*; Linn. Suppl. 304. Cavan. Diff. 262. t. 121. f. 2.)—Stem scarcely any. *Flower-stalks* angular. *Leaves* doubly pinnate, hairy. *Stipulas* dilated, rounded, coriaceous, ribbed, united with the base of the footstalks.—It does not appear from whom Linnæus received his wild African specimens of this very singular species, which we have not heard of in any garden. The remarkable *stipulas*, often an inch wide, at once distinguish the plant. Perhaps it ought to stand in the first section, as more akin to several there to be found, than to the *trifle* and its allies.—The *root* is nearly globose. *Leaves* nearly all radical, three or four inches long, extremely hairy, finely divided. *Flower-stalks* hairy, rather taller than the leaves, divided a little above the base into two angular, strongly furrowed branches, each bearing a hairy *umbel* of many smallish rose-coloured *flowers* on long stalks. The specimen figured by Cavanilles is the very counter-part of the Linnæan ones, and having been sent by Thunberg, we may presume they were all gathered by him, and that no other botanist has met with this remarkable plant.

Section 3. *Stem elongated, herbaceous, or somewhat shrubby.*
Twenty-six species.

P. anotheræ. Evening-primrose Stork's-bill. Willd. n. 27. Jacq. Ic. Rar. t. 525. (*Geranium anotheræ*; Linn. Suppl. 305.)—*Umbels* of about three flowers. *Leaves* opposite, lanceolate, obtuse, with tooth-like serratures, very finely downy on both sides. *Stem* ascending, herbaceous.—Jacquin at first mistook this for *G. ovatum* of Cavanilles; see our next-mentioned species. We have not seen it in any garden. The Linnæan specimen seems to be one of those brought from the Cape by Thunberg, which his venerable

preceptor was just able to contemplate with satisfaction, but not to describe. The *stem* is divided into several herbaceous branches, a span long, spreading, and partly decumbent. *Leaves* on long stalks, oblong-lanceolate, deeply and unequally serrated. Whole *plant* clothed with dense, soft pubescence, like some kinds of *Anothera*. *Flowers* two or three in each *umbel*, nearly regular, smallish, rose-coloured. *Fruit* large, with a downy beak.

P. ovale. Oval Hoary Stork's-bill. Willd. n. 29. L'Herit. Geran. t. 28. (*G. ovatum*; Cavan. Diff. 238. t. 103. f. 3.)—*Umbels* of about four flowers. *Leaves* ovate, acute, strongly serrated, hoary. *Stem* trailing. *Anthers* seven. Resembles the last in general habit, but differs in the shape of the *leaves*, and their much longer stalks. The *flowers* are much larger, and rather more numerous in each *umbel*; *fruit* smaller. *Anthers* seven, though Cavanilles says five; but as he saw only dried specimens, we presume he might easily mistake this point, and we rather refer his synonymy to this species, than to the *eriosleman*, under which Willdenow has doubtfully cited him.

P. eriosleman. Woolly-filament Stork's-bill. Willd. n. 32. Jacq. Hort. Schonbr. v. 2. 4. t. 132.—*Umbels* of about four flowers. *Leaves* elliptical, obtuse, crenate, finely downy. *Stem* erect. *Upper petals* notched. *Stamens* woolly. *Anthers* five.—This species has been much misunderstood. Burmann himself sent it to Linnæus, doubting whether it were distinct from his own *G. ovale*, Prodr. Cap. 19; and Linnæus, far more unaccountably, supposed it a variety of his *G. malacoides*, while his son guessed it to be *betulinum*! The specimen however is rightly marked as having but five anthers. The erect though humble *stem*, and obtuse closely crenate *leaves*, at once distinguish it from the last. The *petals* are white; the two uppermost broad, acutely notched, spotted with crimson at the base. *Anthers* and *style* red.

P. stipulaceum. Narrow Stipulaceous Stork's-bill. Willd. n. 34. (*Geranium stipulaceum*; Linn. Suppl. 306. Cavan. Diff. 254. t. 122. f. 3.)—*Umbels* of about three flowers. *Leaves* heart-shaped, cut and crenate, slightly hairy. *Stem* short, gibbous, somewhat jointed. *Stipulas* awl-shaped, rigid, permanent.—Thunberg found this at the Cape, and gave it to Linnæus, as well as to Cavanilles. The *stem* is very remarkably tumid, fleshy, and jointed, subdivided, though of humble growth, each joint beset with numerous, rigid, thorn-like, permanent *stipulas*. The *leaves* are few, stalked, heart-shaped, and obtuse, variously cut and lobed, paler beneath, clothed on both sides with short scattered hairs; their length about an inch. *Flower-stalks* three or four inches long, pale, nearly smooth, umbellate. *Flowers* three or four, small. *Fruit* with a hairy beak.

P. tabulare. Rough-stemmed Stork's-bill. Willd. n. 36. L'Herit. Geran. t. 9. (*Geranium tabulare*; Linn. Sp. Pl. 947. excluding Burmann's syn. *G. elongatum*; Cavan. Diff. 233. t. 101. f. 3.)—*Umbels* three-flowered. *Leaves* kidney-shaped, five-lobed, notched, slightly hairy. *Stem* ascending, rough with deflexed bristles.—Native of the Cape of Good Hope, but whether of the Table Mountain, as its name implies, is very doubtful, so many things having been confounded under this name. We are however certain of L'Heritier's plant, on his own authority, though his figure does not well express the peculiar character of the coarse bristles of the *stem*, inclined rather downwards. The original specimen of Linnæus is the same. But *G. tabulare* of Burmann and Cavanilles is extremely different, being Willdenow's *P. faniculifolium*, n. 75, and, if we mistake not, *variegatum*, n. 78.

The true *tabulare* is not one of the most ornamental kinds,
and

PELARGONIUM.

and therefore cultivators are apt to neglect it. The *root* is perennial and woody. *Stems* weak and tender, often dying down to the ground, distinguished by their peculiar hairiness. *Leaves* on long stalks, dull green, scarcely marked with any concentric shade or zone, but besprinkled with shining tawny hairs. *Umbels* of about three small, very pale flesh-coloured yellowish *flowers*, on very long smooth stalks, opposite to the leaves. *Calyx* hispid. *Petals* narrow. *Anthers* five. *Style* elongated beyond the beak, before it divides into *stigmas*.

P. alch. milloides. Lady's-mantle-leaved Stork's-bill. Willd. n. 37. (*Geranium alchemilloides*; Linn. Sp. Pl. 948. Cavan. Diff. 234. t. 98. f. 1. *G. africanum*, folio alchimillæ maculato; Riv. Pentap. Irr. t. 104.)—Umbels of about four flowers. Leaves kidney-shaped, deeply five-lobed, cut, very hairy. Stem diffuse, rough with deflexed bristles. *Stigmas* sessile.—Very near the last, but well distinguished in the Hortus Kewensis, by the *stigmas* being sessile, without any elongation of the *style* beyond the hairy beak. The *stem* is very hairy with deflexed bristles, the *flower-stalks* with spreading ones. *Leaves* more hairy than in *P. tabulare*, often marked with a purplish zone; their lobes more straight and deep, coarsely cut at the extremity.

The younger Linnæus confounded with this a very curious and little-known species, *P. articulatum*, Willd. n. 35, adopted by that writer from Cavanilles, who has correctly figured it, t. 122. f. 1. Willdenow has no less judiciously placed it between *P. stipulaceum* and *tabulare*. The base of the *stem* is jointed and swollen, clothed with permanent, membranous, somewhat spinous *stipulas*, resembling *stipulaceum*; but the rest of the *stem*, as well as the *foliage*, are nearly akin to *tabulare* and *alchemilloides*. The *flowers* are larger than in either, apparently yellowish, their two larger *petals* streaked with purple.

P. odoratissimum. Nutmeg-scented Stork's-bill. Willd. n. 38. (*Geranium odoratissimum*; Linn. Sp. Pl. 948. Cavan. Diff. 241. t. 103. f. 1. *G. africanum humile*, folio fragrantissimo molli; Dill. Elth. 157. t. 131.)—Umbels of about five flowers. Leaves roundish-heart-shaped, crenate, very softly downy.—This species is known by the delicate softness of its *leaves*, and their highly aromatic and powerful smell, which is renewed by rubbing, even after the plant has been dried twenty years or more. For this scent it is chiefly valued, the *flowers* being small, whitish and inconspicuous. The coarse engraving of Dillenius is more truly excellent, as expressing the soft habit of the plant, than many a fine coloured plate probably would have been.

We doubt much whether *G. africanum*, Cav. Diff. 242. t. 104. f. 1, can be a variety of this, though it is so considered by Willdenow. The *flowers* are five times as large, and *leaves* more hairy. The specific name is truly unfortunate, as applying equally to this whole genus.

P. alceoides. Musk-mallow-leaved Stork's-bill. (*P. columbinum*; Jacq. Hort. Schonbr. v. 2. 4. t. 133. Willd. n. 42. *Geranium alceoides*; Linn. Sp. Pl. 948. *G. folio alceæ tenuitè laciniato*, flore pentapetalo purpurascente, femine tenui; Marr. Cent. 16. t. 16.)—Umbels many-flowered. Leaves ternate, deeply three-cleft, lacinated. Stem herbaceous, decumbent, hairy. Nectary shorter than the segments of the calyx.—This has the aspect of an European rather than a Cape Geranium, and the shortness of its nectariferous tube combines with the habit, to bring it very near *Erodium*. As however that tube is present, no doubt can remain of the genus. Jacquin, who raised the

plant from Cape seeds, and kept it flowering throughout the winter in his stove, was not aware of its being a Linnæan species, concerning which the herbarium of Linnæus removes all doubt. We cannot therefore submit to the alteration of its very expressive specific name. The fertile *filaments* are usually five, though it seems one of them occasionally wants its *anther*. The *petals* are small, purple; the two uppermost prettily marked with an eye-like spot.

P. tricolor. Three-coloured Stork's-bill. Curt. Mag. t. 240. Willd. n. 45. (*P. violaceum*; Jacq. Ic. Rar. t. 527.)—Umbels three-flowered. Leaves oblong, bluntish, hoary, cut and somewhat pinnatifid, obscurely three-lobed. Two upper petals glandular at the base.—Seeds of this were sent by Mr. Masson from the Cape to Kew garden in 1792. It was first published by Mr. Curtis, and is a favourite plant in collections, though not one of the easiest to preserve. We notice it here chiefly for its singular beauty. The *petals* are roundish and nearly uniform in shape, but very different in colour. The three lowermost are usually milk-white, rarely striped slightly with red; the two uppermost of a most rich and deep blood red, darkly veined, with a velvet-like reflection, their base almost black, beset with shining glandular points. *Seeds* are rarely produced in England, yet the species is very distinct and permanent.

P. coriandrifolium. Coriander-leaved Stork's-bill. Willd. n. 50. Jacq. Ic. Rar. t. 528. (*Geranium coriandrifolium*; Linn. Sp. Pl. 949. Cavan. Diff. 263. t. 116. f. 1. *G. africanum*, foliis coriandri; Riv. Pentap. Irr. t. 108.)—Umbels of about three flowers. Leaves bipinnate; leaflets pinnatifid, linear. Anthers five. Petals usually four. Stem herbaceous, roughish.—An old inhabitant of greenhouses, whose *stem* is diffuse, herbaceous, and usually annual, though the *root*, if properly preserved, is, as at the Cape, its native country, perennial. The finely divided *leaves*, and the large *flowers*, make this worth cultivating for variety. The two upper *petals* are much the largest, obovate, and veined with purple; the three lower, of which the middlemost is generally wanting, are narrow, and pure white.

Section 4. *Stem shrubby. Leaves neither divided nor angular.* Four species.

P. glaucum. Glaucous Spear-leaved Stork's-bill. L'Herit. Geran. t. 29. Willd. n. 53. (*Geranium glaucum*; Linn. Suppl. 306. *G. lanceolatum*; Cavan. Diff. 235. t. 102. f. 2. Curt. Mag. t. 56.)—Stalks mostly single-flowered. Leaves lanceolate, entire, pointed, smooth, glaucous.—This, one of the most singular of its genus in foliage, was raised by the late Mr. Lee, from seeds picked out of Cape specimens at sir Joseph Banks's, about the year 1775. Great disputes have always existed concerning the specific name, *glaucum* as well as *lanceolatum* being each so strikingly opposite, that the first which is heard seems entitled to bear down all opposition. That given by Linnæus himself, and published by his son, has however prevailed. So glaucous are the *leaves*, even in a dry state, that they appear to have been white-washed. Their form is lanceolate, inclining to obovate, with a point; their length nearly two inches. The *stem* is shrubby and branched, angular, glaucous with a purple tinge. *Footstalks* stout, angular, from one to three inches long, connected with the *leaf* by a joint, and both together are nearly upright. *Stipulas* in pairs, lanceolate, acute. *Flower-stalks* axillary, bearing one, rarely two, elegant *flowers*, whose partial stalk is often longer than the general one, and accompanied, nearly all the way to its base, by the nectariferous tube. *Petals* obo-

PELARGONIUM.

vate, of a delicate blush-colour, with crimson veins. This species is increased readily by cuttings, like most of the shrubby kinds.

P. betulinum. Birch-leaved Stork's-bill. Willd. n. 55. Curt. Mag. t. 148. (*Geranium betulinum*; Linn. Sp. Pl. 946. *G. frutescens*, &c.; Burm. Afr. t. 33. f. 1, 2.)—Umbels of about three flowers, downy. Leaves ovate, unequally serrated, nearly smooth.—A handsome well-named species, of which both the varieties, figured by Burmann, are common in every collection, the larger one being preferred. The flowers are pale pink, their upper petals obovate, near an inch long, richly veined with purple. *Nectary* rather short.

P. acetosum. Sorrel-leaved Stork's-bill. Willd. n. 56. Curt. Mag. t. 103. (*Geranium acetosum*; Linn. Sp. Pl. 947. Cavan. Diff. 239. t. 104. f. 3.)—Umbels of about three flowers, smooth. Leaves roundish-obovate, crenate, smooth. Petals linear. The Dutch brought this very early from the Cape, and it has long been generally dispersed throughout Europe. Its perfect smoothness; the somewhat glaucous hue, rounded undivided shape, and acid flavour of the leaves; with the narrow petals, which are flesh-coloured, with straight pink veins, clearly distinguish the *P. acetosum*. Miller speaks of a variety with scarlet flowers, to which we have seen some near approaches.

Section 5. *Stem shrubby. Leaves either angular, lobed, or palmate.* Thirty-seven species.

P. hybridum. Hybrid Stork's-bill. Willd. n. 59. (*Geranium hybridum*; Linn. Mant. 97. Cavan. Diff. 239. t. 105. f. 2. *G. africanum arborescens*, *malvæ folio pingui*, varietas; Dill. Elth. 152. t. 125. f. 152.)—Umbels many-flowered. Leaves roundish, crenate, nearly smooth, slightly lobed, unspotted. Petals obovate-oblong, broader than the segments of the calyx. Dillenius says this was produced from seed of *P. inquinans*, hereafter mentioned, and he points out its resemblance, in many points, to the *acetosum*. Linnæus therefore called it *hybridum*. He might have applied a similar name to several others, had he lived to cultivate many of the new-discovered species. The present, whether a real mule, or a permanent intermediate species, has remained for a long course of years in the gardens, being chiefly, if not entirely, increased by cuttings. The stem is smooth. Leaves very like the *acetosum*, but broader, obscurely lobed, and in some degree downy. Flowers of a scarlet red, with much broader petals than the last, but longer than those of the *inquinans*.

P. zonale. Horse-shoe Stork's-bill. Willd. n. 60. (*Geranium zonale*; Linn. Sp. Pl. 947. Cavan. Diff. 230. t. 98. f. 2. *G. africanum arborescens*, *alchimillæ hirsuto folio*, floribus rubicundis; Comm. Præl. 51. t. 1.)—Umbels many-flowered. Leaves heart-shaped, rounded, slightly lobed, toothed, roughish, marked with a concentric zone.—The most popular of all the species, which the Dutch originally obtained from the Cape, in 1700, and whose many varieties are the ornament of every greenhouse and conservatory. Their copious rose-coloured flowers, produced in plentiful succession, are very showy; their leaves are always distinguished by a dark concentric transverse stripe, various in breadth and intensity, and there is a common, but less luxuriant kind, whose foliage is blotched with white or yellow, and whose petals are narrower than in some of the rest.

P. inquinans. Scarlet Stork's-bill. Willd. n. 61. (*Geranium inquinans*; Linn. Sp. Pl. 945. Cavan. Diff. 243. t. 106. f. 2. *G. africanum arborescens*, *malvæ folio pingui*, flore coccineo; Dill. Elth. 151. t. 125. f. 151. *G. afr. arbor. malvæ*

folio lucido, flore elegantissimo kermesino; Mart. Cent. 3. t. 3.)—Umbels many-flowered. Leaves orbicular-kidney-shaped, slightly lobed, crenate, downy and viscid.—Martyr says this splendid species was first brought into England about the year 1718. It soon became common, and is justly admired for the vivid scarlet of its copious flowers. The greatest peculiarity of this *Pelargonium* is that which its name expresses, of staining the finger with a greasy red moisture, exuding from the whole surface of its soft downy branches. There are several varieties, differing in the magnitude or splendour of their flowers. This is supposed to be the mother, *acetosum* the father, of *P. hybridum* above described.

P. heterogamum. Lady Coventry's Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 424. Willd. n. 62. L'Herit. Geran. t. 18.—Umbels many-flowered. Leaves orbicular-kidney-shaped, acutely lobed and toothed, hairy. Stem rough with deflexed bristles.—This should seem to have been produced between the last-mentioned and *P. alchemilloides*, Willd. n. 37. The pubescence and leaves much resemble the latter; the scarlet flowers, and upright shrubby stem, accord with the former. It is allowed on all hands to be a hybrid plant, and, as Mr. Lee informs us, originated in Lady Coventry's greenhouse. The anthers are six. Stigmas elevated on a short simple style, above the hairy beak; not sessile, as in *alchemilloides*.

P. peltatum. Ivy-leaved Stork's-bill. Willd. n. 65. (*Geranium peltatum*; Linn. Sp. Pl. 947. Mill. Ic. t. 140. Curt. Mag. t. 20.)—Umbels of few flowers. Leaves five-lobed, entire, fleshy, smooth, more or less peltate. A common plant in every greenhouse and window, having been early introduced from the Cape, nor can it be confounded with any other, on account of the five-lobed, dark, shining, ivy-like leaves. The flowers are rose-coloured and handsome. The insertion of the footstalk is usually peltate, or a little way from the base of each leaf. We are however convinced by our own observation, and the practical authority of Mr. Lee, that *P. lateripes*, Willd. n. 66. L'Herit. Geran. t. 24. which differs in this respect from the common *peltatum*, and has moreover less angular branches, is nevertheless but a variety, and not a very permanent one.

P. tetragonum. Square-stalked Stork's-bill. Willd. n. 67. L'Herit. Geran. t. 23. Curt. Mag. t. 136. (*Geranium tetragonum*; Linn. Suppl. 305. Jacq. Ic. Rar. t. 132. Cavan. Diff. 231. t. 99. f. 2. *G. trigonum*; Scop. Del. Infubr. v. 1. 12. t. 5.)—Stalks two-flowered. Branches fleshy; quadrangular. Petals four.—Sent from the Cape by Mr. Masson, in 1774. The smooth, fleshy, somewhat jointed stem, with three or four prominent angles; small, rounded, lobed, notched leaves, besprinkled with long hairs, and sometimes beautifully variegated with rose-colour and white, as in Curtis's figure, strikingly mark this species. The flowers are no less peculiar and very handsome; their two upper petals are near one inch and a half long, obovate, reflexed, pale pink with branched crimson veins; two lower small and white, the middle one being wanting. Stamens crimson, with seven anthers. Its succulent nature renders it rather more difficult of cultivation than some others.

P. cucullatum. Hollow-leaved Stork's-bill. Willd. n. 69. (*Geranium cucullatum*; Linn. Sp. Pl. 946. Cavan. Diff. 241. t. 106. f. 1. *G. africanum maximum*; Riv. Pentap. Irr. t. 98.)—Umbels many-flowered. Leaves kidney-shaped, hooded, slightly scolloped, finely toothed. A large and showy species, well known in gardens, remarkable for its greyish hoary aspect; rounded, tunnel-like, scarcely lobed leaves; and copious, hairy umbels, of large purple flowers, whole

PELARGONIUM.

whose two upper *petals* are finely pencilled, and marked with a dark central spot.

P. angulosum. Angular Hoary Stork's-bill. Ait. Hort. Kew. ed. 1. v. 2. 426. Willd. n. 70. (*Geranium acerifolium*; Cavan. Diff. 243. t. 112. f. 2. *G. africanum arborescens*, foliis cucullatis angulosis; Dill. Elth. 155. t. 129. *G. afr. arbor. ibisei folio anguloso, floribus amplis purpureis*; Mart. Cent. 28. t. 28.)—Umbels many-flowered. Leaves rounded, hooded, angular, toothed.—This perhaps is still more frequently met with in gardens than the last, of which we are disposed to think it a mere variety, differing only in the acute angles of the *leaves*, and their rather more coarse or unequal teeth. Some experienced cultivators are of our opinion. Linnæus did not even distinguish the present plant as a variety, but the former is the genuine *cucullatum* of his herbarium.

P. variegatum. Variegated Glauous Stork's-bill. Willd. n. 78. *P. lanculæfolium*; Willd. n. 75. *P. cortusæfolium*; Jacq. Ic. Rar. t. 539. *Geranium variegatum*; Linn. Suppl. 305. Cavan. Diff. 251. t. 118. f. 3? *G. tabulare*; Burm. Geran. 36. n. 44. t. 1. Cavan. Diff. 232. t. 100. f. 2.)—Umbels of about five flowers. Leaves palmate, five-lobed, flat, glaucous, smooth, sharply toothed. Stipulas heart-shaped. *Nectary* not longer than the calyx.—We feel little reluctance in combining all the above synonyms under one species. The Linnæan *G. variegatum* appears to have been little known to any body, and was rendered more obscure by the doubtful and imperfect figure in Cavanilles, which has only two flowers on a stalk, and shews nothing of the length of the nectariferous tube. The Linnæan specimen has four or five *flowers* in each *umbel*, and answers exactly to Jacquin's t. 539, except that the *leaves* are rather more deeply lobed, without any appearance of a zone, at least in a dried state. The *flowers* appear by Jacquin's figure to vary in size, and Burmann's *tabulare* exhibits them of still smaller dimensions, perhaps because his plate was taken from a dry specimen. This species therefore, known in our gardens by the name of *saniculæfolium*, but which ought to retain its original appellation, *variegatum*, is readily distinguished by being perfectly smooth and glaucous, with numerous round *branches*. *Leaves* on long spreading *stalks*, more or less deeply five-lobed, the middle lobe often three-cleft, and all of them sharply cut or serrated. Most generally, as it seems, the disk is marked with a brown or purplish, concentric, broken zone. The *stipulas* are of a broad-ovate or heart-shaped form, and vary in size. *Umbels* on very long stalks, opposite to the *leaves*, of four or five handsome *flowers*. *Calyx* with a few bristly hairs about the base, well expressed by Jacquin, its segments full as long as the nectariferous tube, whose termination is very evident. Two upper *petals* large, obovate, rose-coloured, with a purple central spot, and many dark veins; three lower ones linear and whitish.

Very possibly *P. fuscum*, Jacq. Ic. Rar. t. 540. Willd. n. 74, may be but a slight variety of *variegatum*. Its *branches* are said to be rough when young.

P. grandiflorum. Large-flowered Glauous Stork's-bill. Willd. n. 77. (*Geranium grandiflorum*; Andr. Repof. t. 12.)—Umbels of two or three flowers. Leaves palmate, five-lobed, flat, glaucous, smooth, sharply toothed. Stipulas ovate. *Nectary* thrice as long as the calyx.—Mr. Masson is said to have sent this species from the Cape in 1792. It is justly admired for the size and beauty of its *flowers*, which are only two or three on each stalk, and essentially distinguished from *variegatum* by the great length of their nectariferous tube, which is about two inches, being thrice that of the *calyx*. The *petals* are white; the two uppermost elegantly stained with rose-colour; the rest narrower,

and rather shorter. The *leaves*, and whole habit, exactly agree with our specimen of *variegatum*; but the *stipulas* are more rounded, or obovate, not heart-shaped. The plate of Cavanilles, done for the last, may very probably have been taken from a specimen of the present species. We suspect moreover that *P. patulum*, Jacq. Ic. Rar. t. 541. Willd. n. 76, is but too nearly related to this, though, having seen no specimen, we cannot speak with confidence.

P. cotyledonis. Peltate Downy Stork's-bill. Willd. n. 79. L'Herit. Geran. t. 27. (*Geranium cotyledonis*; Linn. Mant. 569.)—Umbels compound. Leaves heart-shaped, peltate, rugged, molt downy beneath. Stem fleshy, without thorns.—This is one of the very few species which do not readily blossom in gardens. We never saw the *flowers*, nor did Linnæus, Cavanilles, nor Willdenow. The plant was brought to England from Holland in 1768, according to Mr. Fairbairn, but the Hort. Kew. says it is a native of St. Helena, and was introduced in 1765, by Mr. John Bush. It is however allowed to be likewise a Cape species. The *stem* is peculiarly thick and fleshy, each branch crowned with a number of stalked, peltate, rounded, slightly lobed *leaves*; finely reticulated, corrugated, and minutely downy above; veiny, and clothed with soft, dense, hoary pubescence beneath. L'Heritier's fine plate represents the *flower-stalk* a foot high, hairy, repeatedly compound, bearing several *umbels*, of about four *flowers* each. The *petals* are roundish, and nearly uniform. *Nectary* very short.

P. cchinatum. Prickly-stalked Stork's-bill. Curt. Mag. t. 309. Willd. n. 80. (*P. hamatum*; Jacq. Hort. Schönbr. v. 2. 7. t. 138.)—Umbels many-flowered. Leaves roundish-heart-shaped, lobed, crenate, soft, densely downy beneath. Stem fleshy. Stipulas permanent, spinous.—Somewhat similar to the last, but abundantly distinct, having simple *umbels*; *leaves* softer, neither peltate nor rugose, and the *stem* armed with strong, conical, curved thorns, originating from the permanent *stipulas*. The *petals* are inversely heart-shaped, nearly regular, pure white, sometimes purple, two of them beautifully striped and spotted with that colour. *Nectary* running down almost to the very base of each partial flower-stalk. Curtis and Jacquin described this plant unknown to each other. It is not yet become common, though both singular and ornamental.
