CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

P

P A A

P, A labial consonant, formed by a slight compression of the anterior part of the lips, and retaining an uniform sound, and the fifteenth letter in the English alphabet.

When the P is followed with an H in the same word, it has the sound of an F; thus Philosophy is pronounced Filofophy: and this is generally the case in words derived from the Greek.

P and B are so like each other, that Quintilian declares, that in the word *obtinuit*, his reason required him to put a *b*, but that his ears could hear nothing but a *p*, *optinuit*: hence in ancient inscriptions, and old glossaries, it appears, that these two letters have often been confounded.

Several nations still pronounce one for the other, the Welsh and Germans particularly, who say, *ponum vinum* for *bonum vinum*.

Plutarch observes, it was usual for those of Delphi to say *βάλειν* for *πάλειν*, *βίκαρον* for *πίκαρον*; and among the Latins, as often as an *s* followed, the *b* was changed into a *p*, as *scribo*, *scripsi*.

P is sometimes mute before *t*, as *accompt*; but in modern orthography it is usually omitted.

P, in *Music*, is the initial of *piano*, soft, for which it stands; and *pp*, by abridgment, for *pianissimo*, very soft.

P. M. among *Astronomers*, is frequently used for *post meridiem*, or *afternoon*; and sometimes for *post mane*, *after the morning*, i. e. *after midnight*.

P was also used among the ancients as a numeral letter, signifying the same with the G, viz. a hundred; according to the verse of Uguccio.

“P similem cum G numerum monstratur habere.”

Though Baronius thinks, it rather stood for seven.

When a dash was added a-top of P̄, it stood for four hundred thousand.

St. Jerom observes, on Daniel, that the Hebrews had no P; but that the *ph* served them instead of it; adding,
VOL. XXVI.

that there is but one word in the whole bible read with a P, viz. *apadno*.

The Greek π signified 80. The Latins used P as an abbreviature. Thus P. stood for Publius, pondo, &c. in S. P. Q. R. or Senatus populusque Romanus, for populus; R. P. denoted respublica; P. C. patres conscripti; PR. S. prætoris sententia, &c. On the French coins, P denotes those that were struck at Dijon.

P. in *Medicinal Prescription*, is used for *pugil*, or the eighth part of a handful.

P. Æ signifies *paries æquales*, equal parts of any ingredient: otherwise denoted by *ā* or *anā*.

P P. signify *pulvis patrum*, i. e. Jesuit's powder, or the cortex Peruvianus in powder; which is so called, because first brought into Europe by those fathers; and *p. p. t. præparatus*, prepared.

PAA, in *Geography*, a town of Thibet, 450 miles E. of Lassa. N. lat. 28° 18'. E. long. 98° 34'.

PAA, a town of the island of Ceram, and capital of a district abounding in sago.

PAAKOLA, a town of Sweden, in the government of Ulea; six miles N. of Kemi.

PAALAVANKA, a town of Hindoostan, in Golconda; 30 miles N.W. of Damapetta.

PAARDEBERG, or the *Horse Mountain*, so called from the number of wild horses or zebras, that formerly frequented it, a mountain of the Drakenstein district, in Southern Africa, which is a continuation of Paarl mountain to the northward. The produce of the farms is chiefly confined to wheat, which, with a sprinkling of manure, or a couple of years' rest, or by fallowing, will yield from 15 to 20 fold. They cultivate, also, barley and pulse, but have few horses or cattle beyond what is necessary for the purposes of husbandry.

PAARL, a village in the district of Drakenstein, in Southern Africa, situated at the foot of a hill that shuts in

B

the

the valley of Drakenstein on the west side. It consists of about 30 habitations, disposed in a line, but so far detached from each other, with intermediate orchards, gardens, and vineyards, as to form a street from half a mile to a mile in length. About the middle of this street, on the east side, stands the church, a neat octagonal building, covered with thatch; and at the upper end is a parsonage-house, with garden, vineyard, and fruit groves; and a large tract of very fine land. The village is overhung by blocks of granite, the pearl, and the diamond. Barrow's Africa, vol. ii.

PAATIS, a town of Sweden, in the government of Abo; 10 miles N. of Abo.

PAATPASSER, a small cirar of Bengal, watered by the Ganges, between Dacca and Boofnah.

PAAVOLA, a town of Sweden, in the government of Ulea; 20 miles E. of Brahested.

PAAW, PETER, in *Biography*, a physician and anatomist, was born at Amsterdam in 1564. When he had finished his scholastic education, he was sent to Leyden at the age of sixteen, where he attended the medical courses for the space of four years, and thence proceeded to Paris for farther improvement. He afterwards commenced his travels for the purpose of visiting other celebrated schools; and after spending some time in Denmark, and at Rostock, where he received the degree of doctor in 1587, he repaired to Padua, and attended the dissections of Fabricius ab Aquapendente. Paaw was naturally of a grave and serious disposition, and possessed an acute and retentive memory, and was therefore well able to profit by these advantages of education; and accordingly his great acquirements were soon acknowledged, on his return to Leyden, by an appointment to a medical professorship in that university in 1589. His whole ambition was centered in the prospect of supporting the dignity and utility of this professorship, and he obtained the approbation and esteem both of the public and his colleagues. He died, universally regretted, in August 1617, at the age of fifty-four. Anatomy and botany were the departments which he most ardently cultivated, and Leyden owes to him the establishment of its botanic garden.

Paaw left the following works: 1. "Tractatus de Exercitiis, Laeticiis, et Bellariis." Rost. 2. "Notæ in Galenum, de cibis boni et mali fucci," *ibid.* These two pieces appear to have been his inaugural exercises. 3. "Hortus publicus Academicæ Lugduno-Batavæ, ejus Ichnographia, descriptio, usus, &c." Lugd. Bat. 1601. 4. "Primitiæ Anatomicæ de humani corporis ossibus," *ibid.* 1615. 5. "Succenturiatus Anatomicus, continens Commentaria in Hippocratem de Capitis Vulneribus. Additæ sunt Annotationes in aliquot Capita Libri 8vi. C. Celsi," *ibid.* 1616. 6. "Notæ et Commentarii in Epitomen Anatomicum Andree Vesalii," *ibid.* 1616. The following appeared after his death: 7. "De Valvulâ Intestini Epistolæ duæ," Oppenheim, 1619, together with the first century of the Epistles of Fabricius Hildanus. 8. "De Peste Tractatus, cum Henrici Florentii additamentis." Lug. Bat. 1636. 9. "Anatomicæ Observationes selectiores." Hafniæ, 1657, inserted in the third and fourth centuries of the anatomical and medical histories of T. Bartholin. He also left in MS. a "Methodus Anatomica," which was in the library of M. de Vick of Amsterdam. Eloy Dict. Hist. de la Med.

PABBAY, or PAPAY, in *Geography*, one of the Bishop's islands, among the Hebrides. N. lat. 56° 50'. W. long. 7° 32'.—Also, one of the small Hebrides, near the W. coast of Lewis. N. lat. 58° 11'. W. long. 6° 59'.—Also, one of the western islands of Scotland, about nine miles in circumference, and five miles N. from North Uist. N. lat. 57° 55'. W. long. 7° 12'.

PABIANICE, a town of the duchy of Warsaw; 32 miles E.N.E. of Siradia.

PABLO, ST., a lake in the jurisdiction of Otabalo, in the province of Quito, three leagues in length, and about half a league broad. Its waters are discharged into Rio Blanco.—Also, a town of Mexico, in New Navarre; 170 miles W. of Casa Grande.—Also, a town of New Mexico; 70 miles E. of Sumas.—Also, a town of South America, in the province of Moxas; 140 miles N.W. of Trinidad.—Also, a town of Mexico, in the province of New Biscay; 130 miles S.W. of Pairal.—Also, a town of Mexico, in the province of Veraguas; 22 miles S.W. of Remedios.

PABNEIKIRCHEN, a town of Austria; four miles N.W. of Grein.

PABO, in *Biography*, a British prince and warrior, who flourished in the fifth century, was defeated and sought refuge in Wales, where he was hospitably entertained by the king, who gave him lands. From the army he entered into the church, and by his devotions acquired the character and title of a saint. He founded a church in Mona, Anglesea, where his monument with an inscription is said still to exist. Owen's Camb. Biog.

PABOON, in *Geography*, an island of Africa, in the river Gambia, nine miles long, belonging to the kingdom of Yani.

PABOS, in *Botany*. See CAAMINI.

PABOU, in *Geography*, a town of Canada, on the N. coast of Chaleur bay; 20 miles S.W. of cape Goope.

PABULUM is sometimes used among naturalists for fuel, or that part in combustible bodies which the fire immediately feeds on, or is supported by.

PABULUM of Plants, in *Agriculture*, a term applied to that substance which nourishes them. See FOOD of PLANTS.

PACA, the Spotted Cavy, in *Zoology*. See CAVIA Paca.

PACAJES, or PACAXES, in *Geography*, a town of Peru, and capital of a jurisdiction in the diocese of La Paz, containing some rich silver mines, which are not much wrought. Here are also emeralds. The air is variable, sometimes cold, sometimes hot, and occasionally temperate. The pastures are good: and its principal source of commerce and wealth is cattle; 80 miles S.W. of La Paz.

PACALIA, a feast held among the ancient Romans, in honour of the goddess Pax, Peace.

Alnhelmus, de Laud. Virgin. speaking of the impure festivals and ceremonies of the heathens, calls one of them *Panalia*; which passage Gronovius charges as faulty, alleging, that there was no feast of that name, but that it should have been *Pacalia*, or perhaps *Palilia*.

The ancients, who personified, and even deified every thing, were not forgetful of Peace: she had an altar at Rome, and a stately temple; and religious rites were paid her with great solemnity.

PACAMARES, in *Geography*, a district of Peru, where the air is temperate, and which is said to abound with gold.—Also, an Indian nation occupying the banks of Amazon river.

PACATIANUS, TITUS JULIUS MARINUS, in *Biography*, an usurper, who excited the Gauls to revolt in his favour, in the reign of the emperor Philip; but he was defeated and put to death in the year 249 by the troops which raised Decius to the throne. There are medals of Pacatianus still existing. Moreri.

PACATUS, LATINUS DREPANIUS, who flourished in the fourth century, was a native of Drepanum, in Aquitania, and celebrated as a poet and orator. He was in habits of intimacy with Ausonius, who consulted him on his own writings, and has addressed several pieces to him.

When

When Theodosius the Great visited Rome in the year 388, after the defeat of Maximus, Pacatus was deputed from Gaul to congratulate him on his victory. On this occasion he pronounced a panegyric oration before the emperor and senate, which is extant, and in the course of which he said, if the elder Brutus could be permitted to revisit the earth, the stern republican would abjure, at the feet of Theodosius, his hatred of kings, and ingenuously confess that such a monarch was the most faithful guardian of the happiness and dignity of the Roman people. "Yet," says the historian of Rome, "the piercing eye of the founder of the republic must have discerned two essential imperfections, which might, perhaps, have abated his recent love of despotism. The virtuous mind of Theodosius was often relaxed by indolence, and it was sometimes inflamed by passion:" see THEODOSIUS. Pacatus was afterwards created a proconsul, and in 393 was appointed superintendent of the imperial domain. The orator Symmachus addressed several letters to him, and Sidonius Apollinaris mentioned him with applause. He was probably a Pagan. None of his poems remain: his panegyric on Theodosius was printed in 1651, separately, and it is contained in the "Panegyrici Veteres." It is reckoned eloquent for the age in which it was written, "more characterized by force of expression and imagination than by taste and purity of style, and, in its best passages, bearing some resemblance to the manner of Tacitus." Moreri. Gibbon.

PACAUDIE'RE, LA, in *Geography*, a town of France, in the department of the Loire, and chief place of a canton, in the district of Roanne; 12 miles N.W. of Roanne. The place contains 1426, and the canton 7326 inhabitants, on a territory of 245 kilometres, in eight communes.

PACCHIEROTTI, GASPARO, in *Biography*, one of the most scientific, expressive, and finished singers, which Italy ever produced, was born in the Roman state, and began his career in 1770, at Palermo in Sicily, where he continued during 1771. In 1772, he was the principal singer in the great theatre of San Carlo at Naples, with the De Amicis. In 1773, at Bologna; in 1774, at Naples again. In 1775, at Milan, with the Taiber; in 1776, at Forli; in 1777, at Genoa and Milan; and in 1778, at Lucca and Turin, previously to his arrival in England, where his reputation had penetrated a considerable time, and where signor Piozzi, who had heard him at Milan, sung several airs after his manner, in a style that excited great ideas of his pathetic powers. The travels of captain Brydone had likewise contributed to raise public expectation; indeed our own was excited so much, that we eagerly attended the first general rehearsal, in which, though he sung *sotto voce*, under a bad cold in extreme severe weather, and did not seem to exert himself, our pleasure was such as we had never before experienced. The natural tone of his voice was so interesting, sweet, and pathetic, that when he had a *mezza di voce*, or long note to swell, we never wished him to change it, or to do any thing but swell, diminish, or prolong it in whatever way he pleased, to the utmost limits of his lungs. A great compass of voice downwards, with an ascent up to B b, and sometimes to C in alt, with an unbounded fancy, and a power not only of executing the most refined and difficult passages of other singers, but of inventing new embellishments, which, as far as our musical reading and experience extended, had never then been on paper, made him, during his long residence here, a new singer every time we heard him. If the different degrees of sweetness in musical tones to the ear might be compared to the effects of different flavours on the palate, it would perhaps convey our idea of its perfection, by saying that it is as superior to

the generality of vocal sweetness, as that of the pine apple is, not only to other fruits, but to figar or treacle. Many voices, though clear and well in tune, are yet insipid and uninteresting, for want of piquancy and flavour. The voice of Pacchierotti, when at its best, was the *dolce piccante*. A more perfect shake on short notice, and in every degree of velocity, we never heard. His execution of rapid divisions was so true and distinct, that, with a loud and vulgar-toned voice, he would have been admired as a bravura singer; but the natural tone, and, if we may so call it, sentimental expression and character of his voice, is such, as to make many hearers lament his condescending to rival the lark, or ever, even in pathetic songs, quitting simplicity in order to change or embellish a passage in the most new, artful, or ingenious manner possible. But to lovers and judges of music, who constantly attend the opera, it seems desirable that the performers, during the run of a musical drama, should have the power of stimulating attention to an air often repeated, by a variety of new graces and ornaments, which, in some measure, renovate a song every time it is performed; yet, though Pacchierotti possessed this power far beyond any singer we had heard, the public, frequently poisoned by the shafts of envious professors, and perhaps dilettante, was always more inclined to censure than duly commend this talent; for which we can no otherways account, unless this seeming injustice still proceeded from the wishes of an audience to hear more of the sweet tones of his natural voice, undisturbed by art or science.

That Pacchierotti's feeling and sensibility are uncommon, is not only discoverable by his voice and performance, but countenance, in which, through a benign and benevolent general expression, there is a constant play of features, which manifests the sudden workings and agitations of his soul. He is an enthusiast in his art, and feels the merit of a composition and performance with true Italian energy. Nice and fastidious in criticising himself, he consequently does not gratify frivolous and doubtful claims upon his admiration or applause; but to real and intrinsic merit, we never met with more candour, or heard more judicious and zealous panegyric bestowed from one professor to another.

To hearers not accustomed to the refinements of singing, his extemporaneous flights and divisions were so new, that they at first were doubtful whether to blame or commend. But as the true criterion of merit in the arts, is to improve on examination, all persons of knowledge and feeling constantly experienced increasing pleasure at each performance, however frequent the opportunities may have been of gratifying their wish to hear him.

He is not gifted with a very robust constitution, nor was his chest proof against the rude and sudden attacks of our climate; so that though he was never obliged by indisposition to be absent from the stage when his duty called him thither, above once or twice during four years residence among us, yet his voice was sometimes affected by slight colds, from which the stoutest natives are not exempt; but when he was quite in order and obedient to his will, there was a perfection so exquisite in tone, taste, knowledge, sensibility, and expression, that our conceptions in the art could not imagine it possible to be surpassed.

The low notes of his voice were so full and flexible, that in private, among his particular friends and admirers, we have often heard him sing Anani's and David's tenor songs in their original pitch, in a most perfect and admirable manner, going down sometimes as low as B b on the second line in the base.

It appears that in his youth, when his chest was strong, while stimulated by a love of perfection and a determination

to execute every conquerable difficulty, he studied with such unremitting diligence and assiduity as have enabled him to execute, at sight, in all clefs, and in every style of composition, the most difficult songs that have been composed, with such facility, precision, and expression, as if he had long perused and prepared them for public performance. This we have often seen him do in original scores, that it was impossible for him ever to have seen before. He was the only modern singer that of late years we had found able to enter into the style of composers and performers of past times; but being an excellent mimic, he seems never to have heard a singer of great abilities without remembering the particular traits, inflexions, tone of voice, and expressions, which rendered him or her famous. Though he seemed to have a particular zeal for the success of his friend Bertoni's composition at the opera; yet we never perceived a want of ardour in his performance of Sacchini's music, particularly in "Rinaldo," where he sung with as much energy, taste, and expression, as ever it was possible for him to manifest on any occasion. And in concerts he treated the audience with a greater variety of matters, in the songs he selected, than any singer of our time had ever done. At the Haymarket he was usually obliged to lower his performance, particularly duets, to the level of a first woman of very moderate abilities: we except madame Le Brun, who was however so cold and instrumental in her manner of singing, that they did not well accord together. We know there were many frequenters of concerts, who called themselves lovers of music and judges of singing, and yet disliked both his voice and manner, and did not scruple to say, that he had never sung a note in tune during his residence in this country; which was such an insult upon the ears and feelings of his admirers, that they, in revenge, flatly denied their claims to superior knowledge, taste, or experience in such matters.

Almost every great singer unites himself in interest and friendship with some particular composer, who writes to his peculiar compass of voice, talents, and style of singing. Thus Manzoli and Pescetti, Guarducci and Sacchini, Millico and Gluck, the Agujari and Colla, and Pacchierotti and Bertoni, were closely connected.

In the summer of 1779, Pacchierotti returned to Italy for a year, when he was succeeded by Roncaglio, but returned again in 1780, and remained here till after the Commemoration, in 1784.

The airs in which the natural sweetness of his voice, taste, expression, and general powers of pleasing, seem to have made the deepest impression, were, "Misero pargolletto," by Monza, in Demosonte; "Non temer," by Bertoni, in the same opera; "Dolce speme," by Sacchini, in Rinaldo; and "Ti seguirò fedele," in Olimpiade, by Paisiello.

After retiring from England, Pacchierotti seldom sung in public, except at Venice, in which state, at Padua, he established himself in an elegant house, wholly fitted up with English furniture, and an excellent library of well-chosen English books, of which he was very fond, and was able to read with fluency and taste.

During the Revolution he was much harassed and plundered both by the French and Austrians; and, we fear, was a great loser by the breaking of the bank of Venice, and by other failures where he had invested or lent his property. He is, however, said still to retain the low notes of his voice, which is sunk into a full and rich counter-tenor, and in which he still sings to his friends with more strength and firmness than ever.

PACCHIONI, ANTONIO, a learned physician and ana-

tomist, was born at Reggio in 1664. His early education he obtained in his native place, but he repaired to Rome for the purpose of completing his medical studies, and attended the celebrated Malpighi, who subsequently introduced him into practice at Tivoli, where he resided six years, and obtained considerable reputation. He was therefore invited to return to Rome, where he obtained the friendship of Lancisi, who united him as an associate with himself in the work which he was prosecuting, an explanation of the plates of Eustachius. Pacchioni, from his connection with these two able anatomists, was led into similar pursuits, and now devoted himself to anatomical researches, occupying much of his time in dissection, particularly in the examination of the membranes of the brain. His first work, which obtained some temporary celebrity, was entitled "De Duræ Matris Fabricâ et Usu Disquisitio Anatomica," Romæ, 1701; but his observations were not confirmed by other anatomists. In this treatise, he advanced an opinion concerning the muscular and contractile nature of the dura mater, which he supposed, by means of its connection with the tentoria, to act by alternate compression upon the brain and cerebellum. This doctrine, however, was confuted by Bagliu Fantoni, and some other anatomists. His second publication was upon a similar subject, and entitled "Dissertatio Epistolaris de Glandulis conglobatis Duræ Meningis humanæ, indeque ortis Lymphaticis ad Piam Meningem productis, ad clariss. Virum Lucam Schroœckium," Romæ, 1705. The asserted discovery of glands in the neighbourhood of the longitudinal sinus, involved him in controversies with other anatomists, which produced other publications of his own. In his "Dissertationes binæ ad spectatissimum Virum Joannem Fantonium datæ, &c." Rome, 1713, he defended this hypothesis of the glandular structure of those parts; and in his "Dissertationes Physico-Anatomicæ de Dura Meninge humana, novis experimentis et lucubrationibus auctæ et illustratæ," ibid, 1721, he published his final notions on his favourite subject, and continued to maintain the muscular nature and action of the dura mater. Although his opinions have not been received by later anatomists, they were supported with ingenuity, and the investigations, to which the controversy led, contributed to a more accurate knowledge of the parts concerned. Pacchioni died at Rome in 1726. He was a member of the academies of Bologna and Sienna, and of the Society Naturæ Curiosorum. An edition of all his works, with figures, was published at Rome, in 4to., in 1741; in which, among other additions, were the following papers, viz. "Epistola ad Ludovicum Testi de novis circa solidorum et fluidorum Vim in viventibus, ac Duræ Meningis Structuram et Usu Observationibus;" "Vesicantium damna in Multis Morbis;" and "Prolapsi Cordis Historia." Eloy Dict. Hist. Gen. Biog.

PACCHIONI *Glandule*, in *Anatomy*, small white and rounded bodies, connected with the membranes of the brain, and named after an Italian anatomist, who described and delineated them. Bichat calls them *granulationes cerebrales*. See BRAIN, and NERVOUS *System*.

PACCIAUDI, PAOLO MARIA, in *Biography*, an historian and antiquary, was born at Turin in the early part of the eighteenth century. He entered into the order of Theatines, and became librarian to Philip, duke of Parma. He died in 1785. He had passed a studious and retired life, almost entirely occupied in the duties of his station. His principal works are, "De cultu S. Joannis Bapt. Antiquitates Christianæ," 1755; "Monumenta Peloponnesiaca," in two vols. 4to.; "Memorie de Gran Maestri dell ordine Gerofolimitano," three vols. 4to.; and several dissertations on particular objects of antiquity.

PACE,

PACE, or PAICE, RICHARD, a learned priest and considerable statesman, who flourished in the sixteenth century, was probably born at or near the city of Winchester, about the year 1482. He was educated at the expense of Thomas Langton, the bishop of that diocese, who employed him in early life as an amanuensis. His proficiency in learning, and his genius for music, recommended him strongly to his patron, who determined to afford him the best advantages in his power, for the acquirement and cultivation of literature. With this view he sent him to the university of Padua, at that time the most famous seminary of literature in Europe, with a handsome allowance to defray his expenses. Here he was assisted in his studies by Cuthbert Tunstall, afterwards bishop of Durham, and William Latimer. On his return to England he entered himself of Queen's college, Oxford, of which his patron, bishop Langton, who was now dead, had been provost. He was almost immediately taken into the service of Dr. Bainbridge, the new provost, who was soon promoted to the archbishopric of York, and afterwards being made a cardinal, Pace accompanied him to Italy. In this land of assassination Bainbridge was poisoned by a priest, out of revenge for having received a blow from him in the moment of passion. Of the manner of the cardinal's death, of the circumstances attending it, and the measures taken to discover those concerned in it, Pace transmitted an account to king Henry VIII. Upon his return home he was sent for to court, where his talents and accomplishments recommended him so powerfully to the king, that he appointed him secretary of state, and employed him in several important negotiations. His political character did not prevent him from entering into holy orders; and in the year 1514 he was made prebendary of the cathedral of York, and afterwards an archdeacon. In 1515, Henry VIII. being alarmed at the progress which the arms of Francis I., king of France, were making in Italy, sent the archdeacon on an embassy to the court of Vienna, for the purpose of engaging the emperor Maximilian to attempt the expulsion of the French from the duchy of Milan. Having succeeded in his mission, he next went into Switzerland, where he induced some of the cantons to furnish Maximilian with troops. In the year 1519, upon the death of the emperor, when the kings of France and Spain declared themselves candidates for the imperial throne, Henry determined to become their competitor, and sent Pace his ambassador into Germany, to watch over his interests at the diet of the empire. His services on this occasion, though not successful, were rewarded, in the same year, with the deanery of St. Paul's, London, as successor to Dr. Colet, and very soon after he was made dean of Exeter. In 1521 he was presented to a prebendal stall in the church of Sarum, and on the death of pope Leo X., in the same year, cardinal Wolsey sent him with proper instructions to Rome, for the express purpose of endeavouring to obtain for the cardinal the papal chair. The election had, however, taken place before he could arrive at Rome, and Adrian, bishop of Tortosa, had been chosen pope. On the death of Adrian, in 1523, Pace was employed a second time to negotiate on Wolsey's behalf, but with no better success than before. Unable to obtain the grand object of his ambition, the cardinal employed Pace in soliciting from the pope an enlargement of his powers as his holiness's legate, which he obtained. After this he was sent ambassador to Venice, where he acquitted himself with much talent; but notwithstanding the abilities by which he sustained his character as ambassador, Wolsey conceived a prejudice against him, of which he experienced the dire effects. For two years he received no instructions relative to the object of his appointment, nor any remittances for the support of his ex-

pences, notwithstanding the almost incessant applications which he made to England. At the same time intelligence was imparted to him, that the cardinal, who had been his friend, had become inveterately hostile to his interests. This usage had such an effect upon Pace, that he fell sick and lost his intellects. Information of his condition having been brought to the king, he instantly gave directions for his return home, where he was so carefully attended by physicians, at the king's command, that his faculties and health were so far restored, as to be able to direct his attention to literary pursuits. Soon after this, Pace was introduced to the presence of the king, who expressed much satisfaction and pleasure at his recovery, and admitted him to a private audience, in which he took the opportunity of remonstrating against the cardinal's unjust treatment. Wolsey was called upon by the king to vindicate himself against this charge: this he found no difficulty in performing, and in his turn attacked the complainant with such vigour, as to get him sent to the Tower, where he was detained a prisoner for the space of two years, till he was at length discharged by the king's command. The rigour of this treatment was more than Pace could sustain; he was again bereaved of his senses, and never recovered the use of them, except at short intervals, when he was able to read and to enjoy the conversation of his friends. He resigned his church preferments a little before his death, and retiring to Stepney, he died in 1532, before he had completed his fiftieth year. He had passed an active life, and devoted all his leisure from public business to study, the fruit of which he published in several learned works. Of these the first was entitled "De Fructu qui ex Doctrina percipitur Liber:" which was written while Mr. Pace was at Constance, and in the course of which the author took an opportunity of inveighing against drunkenness, a vice very general at that place. The inhabitants considered the attack as levelled against themselves, and an answer was written, apologizing for themselves, and their customs in drinking. Pace's next printed work was "Oratio Pace nuperrime composita et Fœdere percusso inter Henricum Angliæ Regem, et Francorum Regem Christianissimum in Æde Pauli Londini habita." He was author also of "De lapsu Hebraicorum Interpretum;" of "Epistles," and of several other pieces; and of some translations, one of which was a sermon of Fisher, bishop of Rochester, of which he gave a Latin version, which had been preached on the day when the writings of Luther were publicly burnt. Pace was held in high esteem by the learned men of his time. Erasmus denominates him "utriusque literaturæ calientissimus," and addressed to him more letters than to any one of his correspondents. He had an extraordinary facility in learning languages, and not only spoke several modern tongues, but understood the Latin, Greek, Hebrew, Chaldee, and Arabic. Erasmus was attached to him on account of his candour, the mildness of his temper, and his literary acquirements, and could never forgive the persons who had been the cause of his misfortunes.

PACE, *Passus*, *Step*, a measure taken from the space between the two feet of a man in walking.

The *ordinary* pace of a man is two feet and a half; though many reckon it a yard; the *geometrical* or *German* pace, called also the *greater* pace, is five feet.

The ancient Roman and modern Italic mile consists of a thousand paces, *mille passus*. The French league is 3000 paces, and the German 4000.

PACE of the *Horse*, in the *Manege*, a term signifying the particular manner of his going on the road, or when at work. It is also applied to the step or progression of other animals of different kinds. The most common paces, and those which are natural to the horse, are the walk, the trot, and the

the gallop. There is likewise another pace which is acquired by horses, called the amble, but which in some appears to be almost natural to them. In some cases it is not uncommon for horses to mix their different paces, and by this means to go in a sort of shuffle betwixt the walk, trot, amble, and gallop; but horses which make use of this kind of motion are rarely of any great utility or value to their owners.

This bad mode in the progression of the horse may proceed from different circumstances, as habit, a fretful disposition; and perhaps, in some instances, from debility in the back or loins, as well as in the legs or other parts.

Where the horse has a good and proper pace, he moves with steadiness in these several modes of progression without mixing them in any degree whatever.

PACES, in *Surgery*. See *FOOT-DRAWING*.

PACHA. See *BASHAW*.

PACHACAMA, or PACHACAMAC, in *Geography*, a pleasant and fruitful valley in the audience and jurisdiction of Lima, about 12 miles S. from Lima, and celebrated before the conquest of Peru, on account of a famous temple dedicated to the creator of the universe, called by the Incas "Pachacamac."

PACHACAMAC, in *Mythology*, the name which the idolaters of Peru gave to the Sovereign Being whom they worshipped, together with the sun and other imaginary deities. The principal temple of this deity was situated in the valley above-mentioned, and was founded by the Incas of Peru. This idol was held in the greatest veneration: and it is said that their kings and priests entered this temple with their backs towards this altar, and came out again without daring to turn about. Pizarro derived great riches from the temple of Pachacamac, to the amount of 900,000 ducats, although 400 Indians had taken away as much as they could carry, and the Spanish soldiers had pillaged it before he came. The ruins that still remain furnish a very high notion of its magnificence.

PACHAMACLI, in *Geography*, a town of European Turkey, in Romania; 40 miles S. of Filippopoli.

PACHAMAMA, in *Mythology*, the name of a Peruvian goddess.

PACHEA, in *Geography*, a small island in the bay of Panama. This is one of the Pearl or King's islands, low and woody, about 12 leagues from Panama.

PACHECO, JOHN DE, in *Biography*, marquis Villena, the favourite and prime minister of Henry IV., king of Castile. By his insinuating manners and talents he obtained so great an authority, that he disposed, at pleasure, of all places in the kingdom. Lewis XI. of France corrupted him by a pension, and he perfidiously betrayed his master's interests in the peace of 1443, by agreeing to many articles prejudicial to the kingdom of Castile. Henry, having discovered his treachery, reproached him with it, which so provoked Pacheco, that he actually conspired against the power of his sovereign, and proclaimed prince Alphonso king of Castile in 1465. Shortly after this, Alphonso displeased his minister, and fell a victim to his treachery. Pacheco caused the young king to be poisoned, and was reconciled to Henry, who continued him in his authority and favour till his death, in 1473.

PACHECO, FRANCISCO, a painter, who owes his celebrity more to the ingenuity and talents of his scholars Cano and Velasquez, and to his theory and writing, than to his superiority as an artist. He was the pupil of Luis Fernandez, but though partial to the great style, does not appear to have studied it in Italy. With sufficient correctness of outline, judgment in composition, dignity of

characters, propriety of costume, observance of chiaro-scuro, and perspective, Pacheco displeases by want of colour, timidity of execution, and dryness of style. Seville possesses the best of his historic performances; of his numerous portraits, those of his wife and Miguel Cervantes were the most praised. As a man of literature, he possesses considerable erudition; and wit and humour as a writer of epigrams. Fuseli's Pilkington.

PACHELBET. At the latter end of the last century there were several famous organists of this name in Germany: of these, John of Nuremberg, born 1651, is said to have been the first who introduced the overtone style into Germany. He was successively organist of the principal cities of the empire, and greatly improved both vocal and instrumental church music, by his numerous compositions; all which were still held in great esteem, according to Walther, in 1732, when he published his dictionary.

PACHEQUE, in *Geography*, a small island on the S.W. side of the bay of Panama, on the coast of the N. Pacific ocean, and one of the beautiful islands within the semicircular bay from Panama to point Mala. These islands yield wood, water, fruit, fowls, hogs, &c., and afford excellent harbour for shipping.

PACHERRY, a town of Meckley; 90 miles S.S.E. of Munnypour.

PACHETE, a circle of Bengal, bounded on the N. by Currackdeagh, on the E. by Burwan and Bissanpour, on the S. by Midnapour, and on the W. by Sillee, Tamar, and Rangur; about 70 miles long and from 12 to 40 broad. The capital is Rogonatpour. It derives its name from a fort, six miles N.E. from the capital.

PACHI, or PACH-HOUTOC, a town of Thibet; 70 miles S.E. of Hami.

PACHICA, a town of Peru, in the government of Buenos Ayres, seated on this coast, S. lat. 22°.

PACHIRA, in *Botany*, Aublet's name for the Cayenne tree which the French call *Cacao sauvage*, or Wild Chocolate. Nothing is to be discovered of its etymology or meaning. See *CAROLINEA*, which is indubitably the same plant.

PACHIRA, in *Geography*, a town of Peru, in the diocese of Truxillo; six miles N. of Payta.

PACHITEA, a river of South America, which joins the Maranon at 8° 26', and is esteemed the most beautiful of all its tributary streams. It rises in 10° 46', first running E., then N., and in the early part of its progress it is called the Pozuzu, especially at its confluence with the Mayro, where it forms a noted haven, from which there is an open navigation to the Maranon.

PACHODECARHOMBIS, in *Natural History*, the name of a genus of fossils, of the class of the selenitæ.

The word is derived from the Greek *παχυς*, thick, *δίζα*, ten, and *ρῶμβος*, a rhombus, and expresses a thick rhomboidal body, composed of ten planes.

The characters of this genus are, that the selenite of it consists of ten planes; but as the top and bottom in the leptodecarbombes, or most common kind of the selenitæ, are broader and larger planes than any of the rest, the great thickness of this genus, on the contrary, makes its four longer planes in all the bodies of it, meeting in an obtuse angle from its sides, its largest planes. Of this genus there are four species.

PACHOMIUS, in *Biography*, a saint in the calendars of the Greek and Latin churches, who flourished in the fourth century, was a native of Thebais or Upper Egypt, and born of Gentile parents, who brought him up in their religion. When he was twenty years of age, he was forced to bear arms in the war of Constantine against Maxentius, by which

which means he had the first opportunity of meeting with any Christians who shewed him hospitality and kindness, and to whose faith he avowed himself a convert, as soon as he was relieved from military service. He immediately began to practise all the austerities of that superstition of which St. Anthony had lately proved himself the parent. He now formed the design of establishing a community of persons subject to the same rules of an ascetic life, and fixed his abode at Tabenna in Upper Egypt, on the banks of the Nile, where he built a monastery, and established rules of discipline, which it was reported had been dictated to him by an angel. In a short time the fame of his sanctity drew to him such numbers of disciples, that his house overflowed, and he was obliged to erect new ones, from time to time, till the Upper Thebais was almost filled with monasteries of his order. He died in the year 350, or, according to others, in 360. In his life, written by an ancient Greek author, and translated into Latin by Dennis le Petit, many miracles are ascribed to him; and in Benedict of Aniana's "Codex Regularum," there are preserved eleven of his "Letters," written with great simplicity, and addressed to the superiors of the monasteries founded by him. In the life already referred to, are preserved the rules of discipline, pretended to have been divinely communicated to him, and in the fourth volume of the "Bibl. Patr." a larger collection of rules, concerning the diet, the habits, the employments, and the discipline of monks, which is said to have been translated from Pachomius' original in the Egyptian language into the Greek, and from Greek, into Latin by St. Jerome. Moreri.

PACHORE, in *Geography*, a town of Hindoostan, in the circar of Gohud; 10 miles N.N.E. of Ahar.

PACHUCO, a town of Mexico, famous for the silver mines in its vicinity. It is said, that of these there are not less than 1000. One of them, called Trinity, is supposed to be as rich as any in Mexico; 45 miles N.N.E. of Mexico. N. lat. 20° 45'. W. long. 100° 42'.

PACHUNTICA, formed from *παχυνη*, *I incrassate*, a term used by some medical writers to express incrassating medicines.

PACHYMER, or PACHYMERUS, GEORGE, in *Biography*, a Greek historian, was born at Nicæa, of a Constantinopolitan family, in the middle of the 13th century. He entered into the church, and was likewise employed in offices of importance in the state under Michael Paleologus and Andronicus. At the age of nineteen he accompanied the former, when he took possession of Constantinople in 1261. He died in the year 1310. He was author of a valuable portion of the history of the East, which is inserted in the collection of the Byzantine historians, and was published at Rome in 1669. It consisted of thirteen books, and contained an account of the reign of Michael, and that of Andronicus, down to his twenty-third year. The style is said to be harsh and obscure, yet it is not wholly deficient in eloquence, and the author displays a more free and enlightened spirit than most of his countrymen. This history was translated into French by the president Cousin. To Pachymer is attributed a paraphrase on the epistles of Dionysius the Areopagite, and a treatise on the procession of the Holy Ghost; a compendium of the Aristotelian philosophy was published from his MS. at Oxford in 1666. Moreri.

PACHYSANDRA, in *Botany*, a genus of Michaux, was thus named from *παχυς*, *thick or clumsy*, and *ανδρς*, *a man*, in allusion to the thickness of the stems. Michaux *Boreali-Amer.* v. 2. 177. Willd. *Sp. Pl.* v. 4. 339.—Clafs and order, *Monoclea Tetrandria*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of three oval, concave, upright leaves, one of them external, and rather the smallest. *Cor.* Petals two, oval, concave, rather larger than the calyx. *Stam.* Filaments four, erect, thrice as long as the petals, very thick, compressed, and somewhat club-shaped; anthers incumbent, oblong, of two cells, finally curved.

Female, *Cal.* Perianth of three close-pressed, oblong, acute leaves, one of them external. *Cor.* Petals four, oval, smaller than in the male, closely pressed to the germen. *Pist.* Germen superior, rather globose, with three furrows; styles three, recurved, with a longitudinal furrow above; stigmas linear, flattish. *Peric.* Capsule nearly globular, three-lobed, crowned with three spreading horns from the permanent styles, of three cells. *Seeds* two in each cell, oblong, smooth, pendulous from the summit of the cell.

Ess. Ch. Male, Calyx of three leaves. Petals two. Stamens thrice as long as the petals.

Female, Calyx of three leaves. Petals four. Styles three. Capsule with three horns, and three cells. Seeds two in each cell.

1. *P. procumbens*. Michaux v. 2. 178. t. 45.—Gathered by Michaux on the western side of the Alleghany mountains in North America. The root is fibrous and perennial. *Stem* herbaceous, procumbent in the lower part, then ascending, round, smooth, leafy above, about a span high, scarcely branched. *Leaves* alternate, stalked, ovate, about two inches long, smooth, veiny, and ribbed; entire at the base, bluntly and broadly toothed in the upper part. *Spike* simple, solitary? from the base of the stem, erect, rather lax, two inches long, composed of about two female flowers, and four times as many male ones above them. *Corolla* finely fringed. *Capsule* somewhat downy.—Michaux remarks, that the character of this genus is almost the same as that of *Buxus*, but the habit totally different. We have presumed to alter his description a little with the *Buxus* before us, in order to compare and contrast them, as well as we could without examining his plant.

PACIAN, in *Biography*, a saint in the Roman calendar, and bishop of Barcelona in the fourth century, was descended from a noble Spanish family, and flourished towards the close of the fourth century. He had been a married man previously to his entering the religious community of which he was a member. He died at an advanced age, leaving behind him a son, named Flavius Dexter, who was the person to whom Jerome inscribed his catalogue, and at whose request it was drawn up. Pacian wrote many books, among which, one was entitled "Cervus," or *The Stag*, a satirical piece, written against the Pagans, and abounding, it is said, in wit and eloquence; but no part of it has reached modern times. There are still extant, attributed to Pacian, "Three Letters to Sempronian, a Novatian," which are probably the treatises mentioned by Jerome; also "An Exhortation to Repentance," and "A Discourse concerning Baptism," addressed to the Catechumens. They were edited by John de Tilly, at Paris, in 1538; by Paul Manutius, at Rome, in 1564, and they are inserted in the fourth volume of the *Bibl. Patrum*. A more correct edition of the whole, excepting the "Discourse on Baptism," collated with a MS. of the year 800, was afterwards given by cardinal d'Aguirre, in the second volume of the Spanish Councils, illustrated with numerous learned notes. The writings of Pacian are panegyricized by Dupin: "His exhortations," says the ecclesiastical historian, "are lively and persuasive; his thoughts well weighed; his proofs solid; his manner of writing pleasant; his style elegant, and the periods short. In a word, these little tracts may pass for master-pieces in their kind, and the two exhortations, or discourses, may be looked upon

upon as perfect models of popular preaching." Dupin. Lardner, vol. iv. 8vo. edit. 1788.

PACIFIC, peaceful, or free from troubles, tumults, &c.

PACIFIC *Age* is a denomination given to that period in which our Saviour was born, on account of the general peace which then prevailed through the Roman empire.

PACIFIC *Letters, Literæ Pacificæ*, in the *Ancient Church*, was a denomination given to all sorts of letters testimonial, given by the bishop or chorepiscopus to their priests, when they had occasion to travel abroad; certifying that the bearer was a Catholic, and in communion with the church.

The life of pope Sixtus I. taken from the pontifical of pope Damasus, mentions that pope as the first who introduced those letters called *Formatæ, Canonice, Commendatitæ, Communicatorie, Ecclesiasticæ, & Pacificæ*.

PACIFIC *Ocean, or South Sea*, in *Geography*, that vast ocean which separates Asia from America: it is called *Pacific*, from the moderate weather which the first mariners, who sailed in it, met with, between the tropics; and it was called the *South Sea* because the Spaniards crossed the Isthmus of Darien from north to south. It is properly the western ocean, with regard to America.

Geographers call the South sea, *Mare Pacificum*, the *Pacific Ocean*, as being less infested with storms than the Atlantic. Mr. Frezier affirms, it does not deserve that appellation; and that he has seen as violent tempests therein as in any other sea: but Magellan happening to have a very favourable wind, and not meeting with any thing to ruffle him, when he first traversed this vast ocean, in 1520, gave it the name which it has retained ever since. Maty, however, adds, that the wind is so regular there, that the vessels would frequently go from Acapulco to the Philippine islands, without shifting a sail.

This ocean fills the grandest concavity of the globe, occupying nearly half of its surface from the eastern shores of New Holland to the western coast of America; and it is diversified with several groups of islands, which seem, as it were, the summits of vast mountains emerging from the waves. Separately considered, this immense concavity receives but few rivers; the chief being the Amur from Tartary, and the Hoan-ho and Kian-ku from China, while the principal American rivers run towards the east. This ocean, considered as the boundary of the Russian empire, washes the shores of the government of Irkutsk, from Tschukotskoy Nofs, or Cook's Straits, to the frontiers of China; or, in other words, from the mouth of the river Aimakan, that is, from 65° to 45° N. lat. It is divided into two great parts. That lying eastwards from Kamtschatka, between Siberia and America, is eminently styled the Eastern, or the Pacific ocean; that on the W. side from Kamtschatka, between Siberia, the Chinese Mongoley, and the Kurilly islands, is called the sea of Okhotsk. From the different places it touches, it assumes different names: *e. g.* from the place where the river Anadyr falls into it, it is called the sea of Anadyr; about Kamtschatka, the sea of Kamtschatka; and the bay between the districts of Okhotsk and Kamtschatka, is called the sea of Okhotsk, the upper part of which is termed Penjinskoye mare, that is, the Penjinskian sea, as it approaches the mouth of the river Penjina.

PACIFICATION, the act of restoring or re-establishing the public peace and tranquility.

The word is applied to many ordinances of the kings of France, designed to pacify the troubles that occurred in the kingdom, with regard to religion, during the 16th century, and particularly appropriated to the periods put to the religious broils raised in France in the year 1598, by the

edict of Nantz; and the civil commotions, between the English and Scots, ending in 1638.

PACIFICATOR is commonly understood in the same sense with mediator; *viz.* one who endeavours to reconcile princes or powers at variance.

Wicquefort makes a difference between mediator and pacificator. The peace being concluded between France and England in 1621, the instruments on each side were put in the hands of certain ambassadors, who had been employed as pacificators, not as mediators, to be kept till such time as the ratification had been exchanged. So the archbishop of Pisa, the duke of Tuscany's ambassador at Madrid, was never esteemed a mediator, though the French ambassadors allowed him to be present at the conferences held with the commissioners of Spain, to act as a pacificator of the differences between them. The grand duke had not offered his mediation, nor would France have accepted it. Wicquefort, part ii. sect. 11.

PACIFICATORS, in *Church History*, a name given to those who, in the sixth century, followed the Henoticon of Zeno.

PACIFICUS, in *Mythology*, an epithet of Jupiter, synonymous with Salamines among the Syrians, derived from the Hebrew "Salman," which generally signifies *pacatus fuit*.

PACIFICUS MAXIMUS, in *Biography*, a Latin poet, was born at Ascoli, of a noble family, in 1409: the time of his death is not known, but his poems were printed at Florence in 1489, under the title of "Heccateligiam sive Elegiæ:" this edition is now very scarce. That of Parma, with his other works, in 1691, is purged of many licentious passages that occur in the former. He mentions the venereal disease in his poems before the discovery of the new world by Columbus.

PACINISCO, in *Geography*, a town of Naples, in Lavora; 11 miles E.S.E. of Sofa.

PACIO, GIULIO, in *Biography*, a distinguished jurist and philosopher, was born at Vicenza in the year 1550. From an early age he was distinguished for his proficiency in letters, and being destined for the study of the law, he was sent to Padua, where he studied under the ablest masters that could be obtained. On his return to Vicenza, his propensity to enquiry led him to peruse the writings of the Reformers, for which he was accused to the bishop, who gave orders for his apprehension. He accordingly took refuge at Geneva, where, being destitute of other means of support, he opened a school for children. In 1578 he was chosen professor of jurisprudence in that city. He married a lady of Lucca, who was also a refugee, by whom he had ten children. In 1585 he was invited to a professorship at Heidelberg, and on his acceptance of that office he delivered an oration, "De juris civilis difficultate ac docendi Methodo," which he afterwards printed, signing himself Beriga, from a country-house belonging to his family. He remained at Heidelberg till 1595, when he quitted it for Sedan, where the duke of Bouillon had established a new academy. In this he held the logical chair till the war broke out, which obliged him to return to Geneva. Soon after he was elected principal of the college of Nismes, thence he removed to the professorship of civil law at Montpelier, where he had as a domestic pupil the celebrated Peirefc. It was the great object of the pupil to bring back his master to the Catholic faith; and for this purpose he wished to fix him, with a large stipend, at the university of Aix. But Pacio's wife, more zealous than himself for the new principles, could not be brought to reside in a Catholic city. At length, however, he refused a flattering invitation from the university of Leyden, because he had again become a Catholic. In 1616 he removed to Valence

in Dauphiné, where he occupied the chair of the celebrated Cujas, with a very high salary. About the year 1619, he published a work concerning the dominion of the Adriatic sea, on account of which he was honoured by the republic of Venice with the order of St. Mark; it also procured him a pressing invitation to a professorship at Padua, which he accepted for a very short time; after this, in 1621, he returned to Valence, where he continued his professional labours till his death, in 1635. The works of this writer are numerous, and chiefly on legal or philosophical topics, in both of which sciences he was profoundly versed. He published new and accurate versions of several of Aristotle's works, which have ranked as models of translations. The great honours and emoluments which he received, and the contests which subsisted among the most famous universities to obtain possession of him, sufficiently prove that he was one of the most considerable scholars of that period. The titles of his most important works are, "De Contractibus;" "Synopsis Juris;" "De Jure Maris Adriatici;" "Corpus Juris Civilis." He wrote a treatise on arithmetic at the age of thirteen.

PACK, in *Commerce*, denotes a quantity of goods, made up in loads, or bales, for carriage. A pack of wool is a horse's load, containing seventeen stone and two pounds, or 240 pounds weight. See *Wool*.

PACKAGE, a duty set and rated in a table taken of goods and merchandises; and all goods not specified in the table are to pay for package duties, after the rate of one penny in the pound, according as they are valued in the book of rates.

PACKERS are really, what their title expresses, packers as well as pressers of all sorts of bale goods (intended for exportation), for the great trading companies and merchants, for which they are answerable, if they should happen to receive any damage through bad package; besides this, several of them are considerable dealers.

PACKERSFIELD, in *Geography*, a township of New Hampshire, Cheshire county, E. of Keene, on the head branches of Ashuelot river, containing 977 inhabitants; 86 miles W. of Portsmouth.

PACKET, or PACKET-BOAT, a vessel appointed by government to carry the mails of letters, packets, and expresses, from one kingdom to another, by sea, in the most expeditious manner. Thus, the packet-boats under the direction of the post-master-general of Great Britain carry the mails from Dover to Calais, in time of peace; from Falmouth to Lisbon, Gibraltar, Malta, the West Indies, and America; from Harwich to Helvoetsluys, or Gottenburgh and Heligoland; from Weymouth to Guernsey and Jersey; from Parkgate and Holyhead to Dublin; and from Milford to Waterford. See *Post*.

PACK-HORSE, in *Agriculture*, such a horse as is employed in carrying heavy loads on the back in the manner of a pack.

For this use, horses should be close, well made, and strong.

PACKMOTE BAY, in *Geography*, a bay on the east coast of the island of Martinico.

PACO CAATINGA, in *Botany*, a coniferous species of Brazilian canna. Margr.

There is a second species of this plant, which is distinguished by the sweetness of its leaves underneath, and by its red flowers; and a third species, known by its ceruleous tetrapetalous flowers. Ray.

PACO *Seroca*, Marg. *piso*, a species of Brazilian canna, which bears its fruit in clusters at the bottom of the stalk. The fresh leaves, as well as the stalk and fruit, before it is ripe, being rubbed, give a smell like ginger, which is

VOL. XXVI.

very grateful, and therefore serves instead of spices. They are also used in hot-baths. Ray.

PACOLET, in *Geography*, a small river of America, in South Carolina, which unites with Broad river, 30 miles above Tyger river, and 24 S. of North Carolina line. On this river are the famous Pacolet springs; 17 miles above its confluence with Broad river.

PACORUS, in *Biography*, son of Orodes, king of Parthia, signalized himself by the defeat of Crassus, whose army he nearly cut to pieces, in the year 53 B. C., and whom he made prisoner. He took Syria from the Romans, supported the republican party of Pompey, and that of the murderers of Julius. After ravaging Syria and Judea, Ventidius defeated him, and Pacorus was slain in battle in the year 39 B. C.

PACOS, in *Zoology*. See *CAMELUS Paco*.

PACOURIA, in *Botany*, a genus in Aublet, t. 105, who names it thus from the Caribbean appellation *Pacouri-rana*, Jussieu retains it, Gen: 148, expressing a doubt of its being distinct from *Ambelania* of the same author, t. 104. Both are united by Schreber and Willdenow, under the name of *WILLUGHBEIA*; see that article.

PACOURII, De Laet. a vast tree growing in the island of Maragnan, belonging to Brazil; it bears leaves like those of the apple-tree, a white flower, and a fruit of the bigness of two filts. The rind or peel of this fruit, which is about an inch thick, being boiled or preserved in sugar, is reckoned a delicacy. Ray.

PACOURINA, one of Aublet's unexplained names. See *HAYNEA*.

PACQUING, in *Ornithology*, a name given by the people of the Philippine islands, to a small bird of the sparrow kind, but very beautifully variegated. It feeds on the seeds of grass.

PACK-RAG DAY, in *Rural Economy*, a provincial term, signifying the day after Martinmas-day, the time of changing farm-servants.

PACK-SADDLE, a saddle adapted to the carriage of heavy packs or burdens.

PACK-WAY, in *Rural Economy*, a provincial word, signifying a bridle-road, or horse-path.

PACT, PACTUM, or *Pactio*, in *Law*, a covenant or convention between two or more parties.

Ulpian derives the word from the Latin verb *pacisci*, to bargain, agree, contract: others, with more probability, from *paco*, I appease, or *pacify*: or from *pango*, I fix, establish.

The civil lawyers, after Ulpian, define the word pact, the consent of two or more parties to the same thing. "Duo-rum aut plurium in idem consensus," lib. iii. sect. 2. ff. de *pactis*.

There are two species of conventions, viz. the *pact*, and *contract*. A pact against good manners, against public or natural equity, is null. It is a maxim in law, *Ex nudo pacto non oritur lex*.

PACTA CONVENTA, in Poland, are the articles agreed on between the king and the republic, and which they mutually oblige each other to observe.

These stipulations were introduced after the demise of Sigismund Augustus, in 1572, when all title to the crown, from hereditary right, was formally abrogated, and absolute freedom of election established. At this era a charter of immunities was drawn up at a general diet, to be ratified by the new sovereign before his election. The groundwork of this charter, termed in the Polish law "pacta conventa," was the whole body of privileges obtained from Louis and his successors, with these additions: 1. The king to be elective, and his successor never to be appointed during his life:

2. The diets to be assembled every two years: 3. Every noble or gentleman in the whole realm to have a vote in the diet of election: 4. Should the king infringe the laws and privileges of the nation, his subjects were absolved from their oaths of allegiance. From this period, the "pacta conventa," occasionally enlarged, have been confirmed by every sovereign at his coronation.

PACTOLUS, in *Ancient Geography*, a river of Asia, which had its rise on mount Emolus, in Lydia, watered the plain adjoining to Sardis, traversed that town, and ran into the Hermus, which discharged itself into the gulf of Smyrna. This river is said to have contained a quantity of gold. As to the fable related concerning it, we refer to MIDAS. The kings of Persia obtained possession of the Pactolus and its treasures, by Cyrus's conquest of Lydia. Xerxes I. drew gold from the Pactolus, and this valuable metal was furnished by it in the time of Herodotus: but it afterwards failed long before the time of Strabo. The gold of the Pactolus was derived from the mines of mount Emolus; and when these were exhausted, the supply of the river was discontinued. This river was, according to Varro and Chrysostron, the chief source of the wealth of Cræsus.

PACUVIUS, MARCUS, in *Biography*, a Latin tragic poet, was a native of Brundisium, and is said to have been the sister's son of Ennius. He flourished about the year 154 B.C., and is renowned as the friend and guest of C. Lælius. In the rude state of the Roman theatre, he obtained a high reputation; and his tragedy of Orestes is mentioned by Cicero in his "De Amicitia," as having been heard with thunders of applause. He was the author of some satires, and had a talent for painting. In advanced life he retired from Rome to Tarentum, where he died, having nearly reached his ninetieth year. The fragments of his work, which still remain, have been published in the "Corpus Poetarum Latinorum" of Mattaire. Moreri.

PACY, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the district of Evreux, seated on the Eure, and formerly surrounded with walls; 11 miles E. of Evreux. The place contains 1750, and the canton 9930 inhabitants, on a territory of 165 kilometres, in 32 communes.

PACZANOW, a town of Poland, in the palatinate of Sandomirz; 28 miles E.S.E. of Sandomirz.

PAD, in *Rural Economy*, a term applied to a sort of stuffed cushion, a foot-path, and also to an easy paced horse.

PAD-Saddle. See **SADDLE**.

PADA, in *Geography*, a town of Hindoostan, in the circuit of Gangpour; 30 miles E. of Gangpour. N. lat. 21° 58'. E. long. 84° 39'.

PADANG, a sea-port town on the W. coast of the island of Sumatra. This was the principal settlement of the Dutch, who established themselves here because it was in the vicinity of Menayeabow, the richest seat of gold; and it was under the government of a director and council. The fort is situated within 40 yards of the north bank of the river, and is of a square form, having four bastions of stone, and walls about nine feet high. On the south side of the river are high mountains, which extend to the sea-coast. The water is very good; and both cattle and fruit are plentiful and cheap. Padang, before its capture by the English, in 1781, used to draw to itself about a third part of the whole quantity of gold procured at the several ports on the W. coast of Sumatra, which has been estimated at about 10000 ounces annually. In this place there has been a considerable manufacture of filagree. (See **FILIGRANE**.) S. lat. 0° 40'. E. long. 99° 48'.

PADANG, a small island in the East Indian sea, near the W. coast of Borneo. S. lat. 0° 33'. E. long. 109° 21'.

PADANG-Goochie, a river of Sumatra, which divides the Lampon country, or a portion of the southern extreme of the island, from Passumah, near the sea-coast.

PADASJOKI, a town of Sweden, in Tavastland; 36 miles N.E. of Tavasthus.

PADATO, a town of Mexico, in the province of Culiacan; 40 miles N.W. of Culiacan.

PADBERG, a town with a citadel, in the kingdom of Westphalia; 5 miles E. of Brilon.

PADDA, or **RICE-BIRD**, in *Ornithology*. See **LOXIA Oryzivora**.

PADDA. See **RICE**.

PADDINGTON, in *Geography*, a parish and village in the hundred of Ossulston, and county of Middlesex, England, is situated at the north-western extremity of London. The parish, which extends about two miles in length, is bounded by Kenfington, St. Margaret's, Westminster, and St. George's, Hanover-square, on the south; by Wilfson on the north; by Mary-le-Bone on the east; and by Kenfington, and a detached part of Chelsea, on the west. According to a survey, its area comprises 1197 acres, 3 roods, and 30 perches, of which about one hundred acres are laid out as garden-ground, and the remainder is occupied by houses, and appropriated to pasturage.

The village of Paddington stands about a mile to the north of Tyburn turnpike. Like most of the other villages connected with the metropolis, it has increased greatly in extent of late years, and, since the opening of the canal in 1801, has become a place of considerable commercial importance. This canal, which derives its name from the parish, branches off from the Grand Junction canal near Norwood, and passing through the parishes of Ealing, Northall, Greenford, Perivale, Harrow, Acton, Fulham, Twyford, and Wilfson, as well as the detached parts of Chelsea and Kenfington, terminates at this village in a large basin, on the sides of which are convenient wharfs and warehouses, belonging to the Paddington canal company. The advantages of this cut must be obvious to every one at all acquainted with the inland navigation of this country. By entering the Grand Junction canal, it affords to Paddington, directly or indirectly, a navigable communication with almost every trading or manufacturing town in the kingdom. The New, or Regent's canal, which is to connect the Paddington canal with the river Lea, and consequently with the Thames below London, is now in rapid progress of execution; and this may likewise be regarded as a measure which promises much commercial benefit, not only to the capital but to the country at large.

Paddington manor in ancient times constituted part of the possessions of Westminster Abbey; at the dissolution it was annexed to the bishopric of Westminster; and when that see was abolished, soon after its establishment, Edward VI. transferred it to Ridley, bishop of London, and his successors, along with the advowson of the church, which is supposed to have first become parochial about the same time. The church, since that period, has been twice erected; first by sir Joseph Sheldon, lessee of the manor, little more than a century ago, and again in 1791, by the parish, under the authority of an act of parliament. It is a square building, with a projecting wing on each side, and a portico of the Doric order, fronting the south. Several persons of note lie buried, both in the church and in the surrounding cemetery, among whom are John-Henry, marquis of Lansdown, Dr. Geddes, and the celebrated statuary Banks. In Lyfson-Green is a small chapel of ease, called the "Bentinck-chapel;"

chapel;" and close to the Mary-le-Bone turnpike is another place of worship, erected within the last few months, and denominated the "Paddington chapel."

In this parish are the hamlets of Baywater, and Tyburn. Contiguous to the former are large public tea-gardens, formerly appropriated as physic-gardens by the late sir John Hill. Here is also the Queen's Lying-in hospital, originally instituted in 1752, in St. George's Row, near Tyburn turnpike, but removed hither in 1791. It is an excellent establishment, and is much indebted for its present prosperity to the active exertions of their royal highnesses the dukes of Suffex and Cambridge. Tyburn is noted for having been the place of execution for the malefactors of London and Middlesex, till the year 1783. Here were likewise nine of the city conduits, and a banquetting-house, belonging to the lord mayor, which was demolished in 1737. None of the conduits now remain, but there is a large reservoir newly constructed, at a short distance to the westward of the canal basin, whence a considerable division of the west end of the town is supplied with water.

Paddington parish, according to the late parliamentary returns of 1811, contains 935 houses, and a population of 4609 persons. A charity-school, established here in 1802, for thirty boys and the same number of girls, is supported by voluntary contributions; and there are several alms-houses for the accommodation of the poor, the gifts of various benefactors. Lysons's *Enviours of London*, &c. vol. iii. edit. 1795. Supplement by the same author, 4to. 1811.

PADDLE, a term used for a small sluice; such are those that fill and empty the locks of a canal. See **LOCK**.

PADDLE-hole is the crooked arch *ee* (*Plate V. Canals*, fig. 36.) which gives a passage for the water from the upper pound to fill the lock.

PADDLE-Weirs. See **LOCK-Weirs**.

PADDLE, a sort of oar used by the natives of Africa, America, and some of the islands in the South Sea. They are made of light wood of various shapes, but mostly shorter and broader in the blade than our oars, and instead of rowing with them horizontally like an oar, they manage them very dextrously, in a perpendicular manner, either for rowing or steering.

PADDLE, in *Glass-making*, a name of an instrument with which the workman stirs about the sand and ashes in the calcar.

PADDLE-Staff, in *Agriculture*, an implement used by ploughmen to free the share from stubble, earth, clay, &c. which impede its action.

PADDOCK, or **PADDOCK Course**, a piece of ground, generally taken out of a park, ordinarily a mile long, and a quarter of a mile broad, encompassed with pales or a wall, for the exhibiting of races with greyhounds, for wagers, plates, or the like.

At one end of the paddock was a little house, where the dogs were to be entered; and whence they were slipped; near which were pens to enclose two or three deer for the sport.

The deer, when turned loose, ran all along by the pale; and the spectators were placed on the other side.

Along the course were several posts; *viz.* the law-post, 160 yards from the dog-house and pens; the quarter of a mile post; half-mile post; and pinching post; beside the ditch, a place made to receive the deer, and preserve them from farther pursuit. Near the ditch were placed judges, or triers. For further particulars, see the article **COURSING**.

PADDOCK, in *Agriculture*, a small field or inclosure. It also signifies a large toad.

PADENS, in *Commerce*, a sort of bitter almonds from Per-

sia, which are used at Surat for money, about 60 of which pass for one pice.

PADEPATNAM, in *Geography*, a town of Hindoostan, in the Carnatic; 35 miles S.S.E. of Tanjore.

PADER, a river of Westphalia, which rises near Paderborn, and about three miles from the town is joined by two other streams, and forms the Lippe.

PADERBORN, a city of Westphalia, and capital of a bishopric of the same name. The bishopric or principality is bounded on the N. by the county of Lippe, on the E. by Hesse and Calenberg, on the S. by the duchy of Westphalia and the principality of Waldeck; and on the W. by the counties of Reitberg and Lippe, in the duchy of Westphalia; its greatest length being about 44 miles, and its greatest breadth 36. The greatest part of it is fertile, and produces a good breed of cattle; but some part of it is an extensive heath. It has some good iron-mines, salt and medicinal springs, and several rivers that abound in fish: the principal of which are the Weser, Dimel, Nette, Lippe, Alm, and Pader. In 1802 this bishopric was given to the king of Prussia, and by the peace of Tilsit, it became a province of the new kingdom of Westphalia.

The city was chosen by Charlemagne as a place of abode, when he wished to put an end to the Saxon war of 30 years' duration; accordingly he fixed his camp here, and erected it into a bishopric, which was confirmed by pope Leo. Hence the town became considerable, and several diets were assembled here. It enjoyed imperial privileges, carried on a great trade, and was reckoned one of the Hanse-towns. At present it has much declined, and its trade is become insignificant. Besides the cathedral, it has a collegiate and two parish churches; 42 miles S. of Minden. N. lat. 51° 40'. E. long. 8° 54'.

PADERNA, a town of Portugal, in the province of Algarve; 9 miles N. of Silvas.

PADEW, a town of Poland, in the palatinate of Sandomirz; 32 miles W. of Sandomirz.

PADILLA, **DON JUAN DE**, in *Biography*, the leader of a popular insurrection in Castile against the ministers of Charles V., was the eldest son of the commendator of Castile. When the cortes, or parliament of Spain, assembled in Galicia, and had voted the emperor a free gift, without obtaining the redress of grievances under which the nation laboured, the citizens took up arms, gained possession of the castle, established a popular form of government, and chose Padilla as their leader. He was well qualified for the duties imposed upon him, and his zeal was animated by that of his wife, Maria de Pacheco, a lady of noble birth, great abilities, and unbounded ambition. The regent, cardinal Adrian, having sent a body of troops under Ronquillo for the reduction of the revolted citizens, Padilla came to their assistance with a considerable reinforcement, and gave Ronquillo a defeat. He then, in concurrence with the other leaders, appointed a general convention of the malcontents, to be held at Avilla. In this assembly, deputies appeared from almost all the cities entitled to representation in the cortes, and formed a solemn league of mutual defence, under the title of the junta. They placed the dowager queen Joanna, who was almost in a state of mental debility, at the head of the government, renounced the authority of the regent, and carried on all their operations in her name. Padilla next proceeded to Valladolid, where he reduced Adrian to the condition of a private person, and seized upon the archives and seals of the kingdom. The junta then drew up a remonstrance, containing a statement of grievances, with demands for redress, which struck no less at the privileges of the nobility than at the prerogatives of the crown; and thereby

thereby produced an union of the nobles with the royalists. The junta, at first, jealous of the popularity of Padilla, substituted at the head of a large army Don Pedro de Giron, a nobleman high in rank, but wholly unequal to the trust committed to him. Through his unskilfulness the person of the queen was recovered by the royalists, together with the seals and public archives, and several of the members of the junta were made prisoners. Padilla was now raised to the chief command, and to procure the necessary supplies of money, Donna Maria went with her train to the cathedral of Toledo, in which was contained a vast treasure of ecclesiastical wealth. She entered it in solemn procession, with all the marks of the deepest sorrow and contrition, and her train, after much ceremony, proceeded to the pillage which afforded a rich booty. Padilla was for a time successful in various small encounters, but at length the royal army advanced upon them, in April 1521, and put them to flight almost without resistance. Padilla attempted, but in vain, to rally them, and resolved not to survive the ruin of his party. He rushed among the thickest of the foe, was wounded and made prisoner, together with his principal officers. On the next day, without the form of trial, he was led to execution. He viewed the instruments of death without terror or dismay, and having written two manly and eloquent letters to his wife, and to the city of Toledo, he quietly submitted to his fate. When the sentence was read proclaiming them as traitors, one of his fellow sufferers betrayed emotions of indignation, but Padilla restrained him, observing, "that yesterday was the time to have acted with the spirit of gentlemen; to day that of dying with the meekness of Christians." After his death, his widow Donna Maria supported the sinking cause, and to revenge his fate, she raised fresh forces, and used every art to animate the citizens of Toledo to a vigorous resistance. She marched through the streets with her son, in deep mourning, seated on a mule, before whom a standard was borne representing his father's execution. At length, however, the city was invested by the victors, and though she defended the citadel, to which in an early period of the siege she retired, with great resolution for four months, she was at last under the necessity of escaping in disguise, and fled to her relations in Portugal, where she ended her days. Robertson's Hist. of Charles V.

PADILLA, LORENZO DE, one of the historiographers of Charles V., is celebrated on account of his great eminence as a Spanish antiquarian. He took great pains in preserving Roman inscriptions, and ascertaining the classical geography of Spain. Among other works, he left a general history of Spain, in four parts, a few sheets of which have been preserved, a proof that it had been committed to the press, though the impression was probably never completed. The manuscript is still in the Dominican library of St. Paul's at Cordova. Padilla was one of the earliest genealogical writers among the Spaniards. Gen. Biog.

PADLEE, in *Geography*, a town of Hindoostan, in Guzerat; 10 miles S. of Durrampour.

PADMA, or **PEDMA**, in *Mythology*, is an attribute of the Hindoo deity of Vishnu, and in pictures and statues is generally seen in one of his four hands, in the form of a lotos or lotus, for which lovely aquatic padma, or pedma, is a Sanscrit name. (See **LOTOS**.) As there noticed, Pedma is a name of Lakshmi, consort of Vishnu, as is also Pedmala, and Pedmalaya. Pedma-devi, meaning goddess of the lotos, or perhaps queen of beauty, is a name likewise given to Lakshmi, and sometimes to Parvati, the consort of Siva. Pedma-nabha, and Pedmaksha, denoting lord or possessor of the Pedma, or of Lakshmi, are other names of Vishnu. Kamala is another Sanscrit word for the lotos,

and for the goddesses named after it, similar to Pedma. (See **KAMALA** and **LAKSHMI**.) One of the eighteen sacred mythological poems is named Padma Purana. See **PURANA**.

PADOBE' of *Senegal*, in *Ornithology*. See **TURDUS Erythropterus**.

PADOGI, a species of punishment used in Russia. In this punishment the body of the criminal is stripped to the waist, and then laid upon the ground; one slave holds the head between his knees, and another the lower part of the body; then rods are applied to the back, till some person gives notice to desist, by crying out enough.—This punishment is considered in Russia merely as a correction of the police, exercised on the soldier by military discipline, by the nobility on their servants, and by persons in authority over all such as are under their command.

Ever since the accession of Elizabeth to the throne of Russia, the punishments were reduced to two kinds, *viz.* the padogi and knout.

PADOLA, in *Geography*, a town of Italy, in the Cadore; 12 miles N.N.E. of Cadore.

PADONGMEW, a town of the Birman empire, on the Irawaddy; 6 miles S.W. of Prone.

PADOR, a town of Africa, in *Damel*, on the Senegal. N. lat. 16° 40'. W. long. 14° 20'.

PADOUCAS, a western branch of the river Missouri. The inhabitants of its banks are called Padoucas, and are said to have been of Welsh origin.

PADRAMA, a small island near the coast of Sardinia. N. lat. 40° 38'. E. long. 9° 53'.

PADRAN BAY, a bay on the S.E. coast of Cochin-China. N. lat. 11° 24'. E. long. 108° 40'.

PADREAH, a town of Hindoostan, in Guzerat; 10 miles N. of Baroach.

PADROENS, a town of Portugal, in the province of Alentejo; 13 miles W. of Mertola.

PADRON, EL, a town of Spain, in Galicia, situated on the Ulla; anciently called "Iris Fluvia;" 15 miles S. of Santiago.

PADRON, Cape, a cape on the W. coast of Africa. S. lat. 6°. E. long. 12° 20'.

PADSHAWPOUR, a town of Hindoostan; 30 miles S. of Delhi.

PADSTOW, or **PETROCSTOW**, a market and sea-port town in the hundred of Pyder, and county of Cornwall, England, is situated on the west side of Padstow haven, near the mouth of the river Camel or Allan, which falls into the Bristol channel. It is distant 243 miles W.S.W. from London, and 30 miles W. by S. from Launceston. This town is of considerable antiquity, and is said to be the spot where St. Patrick founded the first religious house in Cornwall, when he arrived from Ireland in the year 432. It was first called Lodenick, and afterwards Adelstow, from king Athelstan, who, according to tradition, conferred many privileges on the inhabitants. The market-day here is on Saturday, weekly, and here are two fairs during the year. The harbour is among the best on the north coast, though much obstructed by sand, except in the middle channel, by which vessels of large burden may enter, and find a commodious anchorage. Padstow is governed by a portreeve, assisted by a certain number of the most respectable inhabitants. Its chief support is derived from the share it possesses in the pilchard fishery, and the custom of the numerous small vessels which resort to the harbour in the event of contrary winds, or strefts of weather. Humphrey Prideaux, the learned dean of Norwich, author of the "Connection of the Old and New Testaments," was a native of this town. According to the parliamentary returns of 1811, the parish of Padstow contains 237 houses, and a population of

1498 persons. Beauties of England and Wales, vol. ii. by E. W. Brayley, and John Britton, F.S.A.

PADUA, a city of Italy, and capital of the Paduan, on a small river, which runs into the Brenta. The right of citizens was granted to it by the Romans, and they allowed it to choose a senate. It was destroyed by Atila, repaired by Narses, and again destroyed by the Lombards; it was often ravaged, and as constantly re-established. In 1406, it was taken from the dukes of Milan by the Venetians, and the territory annexed to their republic. Padua is a place of considerable extent, containing 26 parishes, 4 hospitals, 41 convents, 7 gates, 7 stone bridges, 9 squares, and a great number of beautiful edifices or palaces: nevertheless it is poor, and the streets are in general narrow, dark, dirty, and ill paved. The university was founded by Charlemagne, and much enlarged by the emperor Frederic II, and pope Urban IV., but it has lately declined much from its former reputation. Padua is the see of a bishop, suffragan of Udina. The cathedral is well-built. The church of St. Antony, the patron of the city, is large and beautiful. The town-house was built on the ruins of the ancient senate-house, and is a grand structure. This city is fortified and governed by a podestat. The number of inhabitants is estimated at 38,000. This is an ancient town, and some have pretended that it was built by Antenor, after the destruction of Troy; 22 miles W. of Venice. N. lat. 45° 24'. E. long. 10° 52'.

PADUAKANS, in *Sea Language*, a name given by the Macassars to their proas. See **PROA**.

PADUAN, in *Geography*, a country of Italy, bounded on the N. by the Trevisan, on the E. by the Dogado of Venice, on the S. by the Polesino, and on the W. by the Vicentin; about 35 miles from N. to S., and 28 from E. to W.; being formerly a part of Lombardy. The air is salubrious, except in a few places situated near the salt marshes. The land is flat, and the eminences are hillocks rather than mountains, and produce grapes of excellent flavour, oranges, and other fruit, exclusively of corn, hemp, rice, various fruits, and all kinds of vegetables. The aspect of the country presents plantations of vines. Here are also commons for the rearing of cattle, and mulberries for the culture of silk, which yields a considerable trade. Upon the whole we may observe, that this country has been denominated a second paradise, and the garden of Europe. The number of inhabitants has been estimated at 300,000. The rivers Adige, Brenta, Bachiglione, and Musona, though they sometimes do injury by overflowing their banks, contribute to the enrichment of the country, particularly by promoting navigation and commerce, and by giving motion to a number of mills. This country, which in 1405 became subject to the dominion of Venice, followed its fate, under the new arrangement of the French revolution, in being annexed to the kingdom of Italy. The principal places are Padua, Anguilara, Arqua, Campo S. Pietro, Citradella, Este, and Montefelice.

PADUAN, among *Medalists*, a modern medal made in imitation of the antique; or a new medal struck with all the marks and characters of antiquity.

The name is taken from *Paduanus*, a famous Italian painter, who succeeded so well in the imposture, if it may be so called, that the best judges are at a loss to distinguish his medals from the genuine ones.

This Paduan was thus called from the place of his birth, Padua; his proper name was Giovanni Cavino; others say, Lewis Lee; he flourished in the seventeenth century. Gotheb Rink adds, that he had an associate in this forgery, called Alexander Bassianus. His son Octavian, though born at Rome, was also called the *Paduan*.

PADUAN is properly applicable to those medals only,

which are struck on the matrices of the elder Paduan; which are still preserved. Though it is frequently used in the general for all medals of this kind.

Joubert observes, that there have been a Paduan and Parmesan in Italy, and a Carteron in Holland, who had the knack of imitating the antique in perfection. The Parmesan was Laurentius Parmesanus. We may also add another Italian who excelled in this way, viz. Valerius Bellus Vicentinus; but his medals are not so common as those of the rest.

PADUANINO, **DARIO**, in *Biography*. His real name was Dario Varotorj, but he is better known under the one by which we have designated him. He was born at Verona in 1539, and at first attached himself to the study of architecture; but afterwards received instructions in painting from Paul Veronese, and became a very skilful artist. His fame rests principally upon the pictures he painted for the churches in Padua and in Venice, but there are many very graceful and agreeable productions of his upon a smaller scale scattered about, and some few are found in this country. They indicate a lively and brilliant, though not a profound genius, and exhibit the gay effect of the Venetian style, which he adopted in a pleasing manner.

He was renowned for his piety as well as for his ingenuity; and in the act of returning thanks at the shrine of the Virgin, in Padua, for having been miraculously preserved when a scaffolding had broken and fell with him, he was smitten with apoplexy, and died at the age of 57, anno 1596. He left a son, Alexander Varotori, called also Paduanino, who was not so successful as his father, though he was not without merit. He died in 1650, at the age of 60.

A daughter also of Dario's excelled in portraiture. Her name was Chiari, and she is highly praised by Rodolfi.

PADULA, in *Geography*, a town of Naples, in the province of Otranto; 4 miles N. of Nardo.—Also, a town of Naples, in Principato Citra; 14 miles N. of Policastro.

PADUS, in *Botany*, a name borrowed from Theophrastus, who gives no other account of his *παδος*, than that it greatly delights in a shady situation, like the Yew, and another plant which he denominates *θεραπευαλος*, and which some have guessed to be the Guelder-rose, *Viburnum Opulus*. *Padus* is now applied to the Bird Cherry, *Prunus Padus* of Linnæus; a tree to which the above account is hardly suitable, but which is nevertheless considered as the plant of Theophrastus by his recent commentator Mr. Stackhouse.

PADUS, in *Ancient Geography*, the *Po*, a river of Gallia Transpadana, commencing towards the W. at mount Vesalus and running eastwards, so as to discharge itself into the Adriatic gulf by many mouths, in which case the Greeks called it "Eridanos" or "Eridan." The origin of the name has been traced by etymologists to a corruption of the Celtic "boden," whose root is "bod" or "pot," and refers to its height and depth. According to Pliny the Po received 30 rivers; but Cluvier reckons as many as 40; under which number they must have comprehended many torrents, which become dry in summer.

PADUTI, in *Geography*, a town of Naples, in Calabria Citra; 4 miles E. of Rosano.

PÆAN, *παιων*, in *Antiquity*, a hymn in honour of Apollo, or some other of the gods; chiefly used on occasion of victory and triumph. They were sung in the procession at the Panathenaia.

Festus derives the word *απο του παιων*, *ferire, to smite, shoot*: but Hefychius rather takes Apollo to have been denominated *Pæan*, from *παιω, θεραπευω, I heal*; in allusion to his being the deity of medicine.

The

The Pæan took its name from Apollo himself; who was denominated *Pæon*; because in his combat with the serpent Python, his mother Latona encouraged him to make use of his arrows, by crying frequently, *ἦ παι, ἦ παι, do boy, bravely boy.*

PÆAN or *Pæon* is also a name of a foot in the ancient poetry; so called, as commonly supposed, because appropriated to the hymn Pæan; though Quintilian derives the name from its inventor *Pæon*, a physician. There were four kinds of feet called Pæans.

The first Pæan consists of four syllables, one of which is long, and the rest short, as *colligere*; the second is composed of a short, a long, and two shorts, as *resolvere*; the third of two long, a short, and a long, as *communicant*; and the fourth of three short and one long, as *temeritas*.

PÆCILIA, in *Ichthyology*, a name given by Schoneveldt, and some others, to the fish called by most authors the *mustela fossilis*. It is properly a species of *cobitis*, and is called by Artedi the *blucisb cobitis*, with five longitudinal black lines on the body. See *COBITIS Fossilis*.

PÆDARTHROCAE, from *παις*, a child, *αρθρον*, a joint, and *κακος*, an evil, in *Surgery*, a scrofulous swelling of a joint; a disease to which children are particularly subject.

PÆDERIA, in *Botany*, appears to have been so called by Linnæus from *Pæderos*, an opal, in allusion to the transparency and changeable colour of its berry. Linn. Mant. 7. Schreb. 161. Willd. Sp. Pl. v. 1. 1219. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 63. Juss. 205. Lamarck Illustr. t. 166.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, Juss.

Gen. Ch. Cal. Perianth superior, of one leaf, turbinate, with five teeth, permanent. Cor. of one petal, funnel-shaped, hairy internally; limb in five small segments. Stam. Filaments five, awl-shaped, various in length, from the middle of the tube; anthers oblong, incumbent. Pijl. Germen roundish, inferior; style capillary, cloven, the length of the corolla; stigmas simple. Peric. Berry small, ovate, inflated, brittle. Seeds two, ovate.

Ess. Ch. Corolla funnel-shaped, hairy within. Berry inflated, brittle, with two seeds. Style cloven.

1. *P. fatida*. Stinking Opal-berry. Linn. Mant. 52. Banks Icon. Kæmpf. t. 9. Lamarck f. 1. (*Convolvulus fœtidus*; Rumph. Ambon. v. 6. 436. t. 160.)—Leaves ovato-lanceolate, or somewhat heart-shaped. Panicles cymose. Germen smooth. Corolla externally downy.—Native of China, the East Indies, and the island of Mauritius. A climbing shrub, with long, smooth, slender, twining, compound, leafy branches, spreading to a great extent over the neighbouring bushes and trees. Leaves opposite, on long roughish stalks, lanceolate, pointed, entire, various in breadth, more or less ovate or rounded at the base, sometimes heart-shaped. Stipulas within the footstalks, short, triangular, deciduous. Panicles axillary, compound, forked, cymose, slender, more or less downy. Bractæas small, membranous, jagged. Germen and calyx smooth and shining, small. Corolla about half an inch long; externally downy and greyish, internally of a deep purplish brown, lined with hairs. Berry the size of a currant, globose or oblong, crowned with the calyx, smooth, shining, very brittle, pale green and semitransparent, finally yellowish. Rumphius says the leaves are very fœtid when rubbed, or when the sun shines upon them, inasmuch that those who pass by where the plant grows, are greatly annoyed with the smell. This odour is of a stercoraceous kind, like that of another plant of the same natural order, *Ernodea montana*, Sm. Prodr. Fl. Græc. Sibth. v. 1. 98. (See *ERNODEA*.) We have seen the *Pæderia* in the stoves at Paris in 1786, and have per-

ceived this smell. This plant is said to have been brought to Kew in 1806, but has not yet flowered. One of Linnæus's specimens from China, on which the shining berries though dried are very beautiful, has heart-shaped leaves, exactly like Kæmpfer's plate, with very downy stalks both to the leaves and flower. Most specimens accord with the figures of Rumphius and Lamarck; yet we do not see sufficient grounds to distinguish theirs as a species, from that of Kæmpfer.

2. *P. fragrans*. Fragrant Opal-berry. Lamarck Dict. v. 2. 260. Illustr. t. 166. f. 2. Willd. n. 2.—Leaves elliptical. Panicles corymbose. Germen downy. Tube of the corolla smooth. Gathered in woods in the island of Mauritius, by Commerçon, who taking it for a new genus, named it *Danais*, in allusion to the history of the *Danaïdes* who murdered their husbands, "because," says he, "where the flowers of this plant are luxuriant, the male or the female organs are rendered abortive." This is abundantly distinct from the first species, in its more elliptical and brighter-coloured leaves; but more especially in its corymbose downy panicles, downy germen and calyx, and longer, more slender, corolla, whose tube is quite smooth, even though the limb be sometimes slightly hairy at the back. The flowers are said to have the scent of a *Narcissus*, but even more delightful; their colour is red. Commerçon describes the fruit as globular.

PÆDEROTA. See *HEMIMERIS* and *WULFENIA*. The name is ancient, and has been applied by some to a species of *Teucrium*, by others to the *Acanthus spinosus*.

PÆDO-BAPTISM, a compound of *παις*, *παιδης*, infant, and *βαπτισμα*, baptism, infant baptism, or that conferred on children. See *BAPTISM*.

PÆDO-BAPTISTS, formed of *παις*, *παιδης*, infant, and *βαπτίζω*, I baptize, are those who maintain that baptism should be administered to infants. In support of this opinion, they plead, that if infants, under the Christian dispensation, were excluded from the privilege of baptism, the Christian institution must appear, in this respect, to be less complete and perfect than that of the Jews: and it is not likely, by arguing *à priori*, that God would appoint an external sign of peculiar distinction and benefit for children under the patriarchal and Jewish constitution, without any similar appointment under the Christian dispensation; more especially as the first profelytes to Christianity, and those in particular who were converted from among the Jews, would naturally expect some token of distinction and privilege, comprehending their children, and resembling in its design, though milder in its nature, that which Christianity had abrogated. This expectation was farther encouraged by the very condescending and affectionate manner in which our Lord expresses himself concerning infants; particularly when he says, Mark x. 14. "Of such is the kingdom of God;" which some understand to signify, that the rights and privileges of the Christian church belong to such. With these views, it is easy to conceive to what subjects they would apply the general charge to baptize profelytes, unless they had been directed and restricted by some express order.

An order of limitation was absolutely necessary to prevent their mistaking the proper subjects of baptism, and misapplying this ordinance, if infants were to be excluded. This would be the more likely, as they would explain the precepts of Christ, concerning baptism, by the custom prevailing among the Jews, in his time: and as it was the practice, when profelytes came over to the Jewish religion, to baptize the children with the parents, the apostles would naturally conclude, that children were included in the general commission. Matt. xxviii. 19.

Mr. Wall has endeavoured to shew, from the books of the Jews themselves, and those of others, that understood the Jewish customs, and have written concerning them, that it was the custom of the Jews before our Saviour's time, and, as they affirm, from the beginning of their law, to baptize as well as circumcise any proselyte that joined them from other nations, and with him, at his desire, his infant children likewise.

Moreover, the advocates for infant baptism urge more directly the argument from circumcision after this manner: the covenant made with Abraham was a covenant of grace, by which spiritual and eternal blessings were promised to him (see Matt. xxii. 31, 32. Heb. xi. 6. Rom. iv. 11—17. Gal. iii. 6.—18. 29.) and as such comprehended both Jews and Gentiles, and their seed. Circumcision was instituted by God as a token of that covenant, and as such, he commanded that it should be administered to the infant offspring of his covenant people. Gen. xvii. 1—4. And yet, though the covenant endureth, that ancient token of it is abolished; nor is there any external sign or seal of it, under the Christian dispensation, except baptism. We have, therefore, reason to think, that this ordinance was intended to succeed circumcision, as it resembles it in many respects, and seems to be called the circumcision of Christ, by the apostle Paul, Col. ii. 11, 12. And inasmuch as circumcision was administered to infants, in token of this covenant, baptism, being its substitute and antitype, ought to be administered to infants likewise. Consult Acts, ii. 39. Rom. xi. 17, &c.

Another argument for infant baptism is deduced from the words of the apostle, 1 Cor. vii. 14. which are supposed to have a direct reference to infant baptism; because *holy* often signifies those that might be admitted to sacred rites, and *unclean* such as were to be excluded from them. Doddr. in loc.

The Pædo-baptists acknowledge that there is no direct and express command to baptize infants; but appealing to the history of the administration of baptism, they argue, that the apostles are said to have baptized whole families, (Acts, xvi. 15. 33. 1 Cor. 1. 16.), and, therefore, probably infants, comprehended under this general denomination. And they apprehend, that they have been able to trace such intimations at least of infant baptism, in the earliest ages of the church, as may, to a high degree of probability, prove it to be an apostolic, and consequently divine institution.

Irenæus, who was born about the time of St. John's death, and probably of Christian parents, mentions infants among the regenerate, *i. e.* the baptized, as the word generally signifies in his writings.

Justin Martyr, about forty years after the time of the apostles, speaks of some who had been *made disciples* from their infancy.

Tertullian, about one hundred years after the apostles, though he advises parents to defer baptizing their children, except when their lives were in danger, speaks of the practice as generally received and observed in his time.

Cyprian, about one hundred and fifty years after the apostles, is allowed by all to speak expressly of infant baptism, as generally used in the church; and we learn, that, in his time, A. D. 253, a question being agitated among sixty-six bishops, in the council of Carthage, Whether an infant must be kept till he was eight days old before he be baptized, all unanimously gave their opinion to the contrary.

There are many passages that expressly refer to infant baptism in the works of Origen, who was born of Christian parents; and as his father was martyred in the year 202, when he was seventeen years old, the remoter Christians of

his family must have been nearly contemporary with the apostles.

In the Apostolic Constitutions, which are allowed to be very ancient, express mention occurs of infant baptism, as commanded by Christ. Matth. xix. 14.

The learned Wall, who took great pains in this inquiry, informs us, that, in the first four hundred years after the apostles, there appears to be only one, *viz.* Tertullian, who, in some cases, advised the delay of infant baptism; and another, *viz.* Gregory, who practised such delay in the case of his own children: but no society of men adopted this opinion, nor did any one person pretend to say it was unlawful to baptize infants: and in the next seven hundred years, there is not so much as one man to be found, that either spoke for or practised any such delay; and, if truth were to be determined by numbers, the general and uniform practice of the Christian church is very much in favour of infant baptism.

On the other hand, the Baptists plead, that infants are incapable of complying with the terms required in order to baptism, *i. e.* repentance and faith, and of receiving those instructions which Christ directed, as previous to it. Matt. xxviii. 19. compared with 1 Peter, iii. 21. But the Pædo-baptists reply, that those instructions and conditions were required only of those who were capable of them. Besides, the word *μαθητεύσατε*, which some understand of *teaching*, previous to baptism, may signify *make disciples*: and that infants may be comprehended under that name, some have argued from Acts, xv. 10. The word used by Justin Martyr, in the passage above cited, and applied to infants, is *εμαθητεύσαν*. And it has been farther alleged, that the penmen of scripture, and other Christian writers, have commonly used the word to signify the reception of any one to the number and degree of disciples, as preparatory to subsequent instruction; so that persons, thus received in order to be taught, were, before the instruction itself, denominated disciples. Compare Luke, ix. 57. and Matt. viii. 19, 20, 21. Eusebius Evang. Demonst. lib. iii. sect. 7. where he styles those who were desirous of learning of Christ, his disciples.

It is farther objected, that infants are incapable of receiving any benefit from baptism; and that, in this case, the ordinance is exposed to contempt. The Pædo-baptists reply to this objection, by maintaining, on the contrary, that there are many advantages resulting from baptism administered to infants, both to them and principally to their parents, whose immediate act it is; that an ordinance, as in the case of Christ, who was himself baptized, may sometimes be administered to those who are not capable of *all* the purposes for which it was originally instituted, and which it may subserve with regard to others; and still farther, that this argument against baptizing infants, by proving too much, proves nothing: for if infants are incapable of the ends of baptism, under the Christian dispensation, infants under former dispensations were equally incapable of the ends of circumcision; and, therefore, such an institution was useless and improperly enjoined.

The objection founded on the silence of the New Testament, with regard to infants as the subjects of baptism, is already answered, in the beginning of this article, and the objection retorted against the Baptists themselves. The history of the practice of baptizing infants has been already stated; and though it is urged, that Justin Martyr contends for a profession of faith as necessary in order to baptism, whence was derived the use of sponsors, in the case of infants, it is answered by the Pædo-baptists, that Justin speaks of the adult, or may consider the confession of the sponsor

as the child's, being made in his name: and this is the more probable, as the subsequent fathers use the same language long after infant baptism was the prevailing practice.

The Pædo-baptists also differ from the Baptists as to the mode of administering the Christian ordinance. The former perform it by sprinkling or pouring on water; the latter, by the immersion of the whole body, which they contend to be an essential circumstance. In favour of immersion it is pleaded, that the word βαπτίζω, being derived from βαπτίω, properly signifies *to plunge*: on the other hand it is urged, that in this diminutive and derivative form it may signify any method of washing, and is sometimes used in scripture for washing things which were not dipped in water, but on which it was poured. Compare Luke, xi. 38. Mark, vii. 4. and those passages in which the pouring out of the spirit is called baptism, Acts, i. 5. ch. xi. 15, 16; to which some add, 1 Cor. x. 2. observing that βαπτίω is never used for baptism.

Farther, the Baptists argue, that John performed his baptism by immersion, and that his practice is obligatory upon all Christians. To this some have replied, that John's baptism is distinguished from Christian baptism, and that some, who had received his baptism, were again baptized in the name of Christ. (Acts, xix. 3, 4, 5.) And, therefore, that his example does not bind Christians. However, it is at least doubtful whether John, who was of the line of the priests that had been always used to perform their purifications by sprinkling, did really baptize by immersion. On the affirmative it is urged, that we read of his baptizing (εἰς) in Jordan: but to this is answered, that εἰς signifies *by, at, or with*, and consequently furnishes no proof that John plunged his disciples into the river of Jordan. It is farther pleaded, that he chose a place for this purpose, where there was much water; and this he might have done, for the convenience of sprinkling as well as of plunging, considering the numbers that resorted to his baptism, Matt. iii. 5. It is improbable, that such multitudes of both sexes, and at a distance from their own habitations, should be baptized in any other mode.

Another argument, in favour of immersion, is drawn from the account of Philip and the eunuch, Acts, viii. 38, 39, who went down (εἰς) into the water; and, after the baptism, they are both said to come up (εἰς) out of the water. But many passages might be cited, where εἰς signifies *to or unto*, and ἐκ, *from*. Matt. xv. 24. chap. xvii. 27. chap. iii. 11. John, ix. 1. 2 Cor. v. 1. Rev. xix. 5.

It is farther argued, that plunging alone represents our being buried with Christ in baptism, and consequently that this ceremony is essential. Compare Rom. vi. 4. Col. ii. 2. The Pædo-baptists, though they allow that there is in these passages an allusion to the mode of baptism which then generally prevailed, maintain, that in the institution of the ordinance, there is no declaration that it was chiefly designed to represent this, and persons were baptized before it was generally known that Christ should die and arise from the dead. Our being cleansed from sin seems to be the thing primarily intended, which may well be represented by pouring on water; and as this more naturally represents the pouring out of the spirit, the sprinkling us with it, and the sprinkling of the blood of Jesus, it may answer as valuable purposes as that mode, which, more directly, represents death and a resurrection.

The most considerable argument in favour of immersion is, that it was practiced in the primitive ages. Several texts in the New Testament, say the Baptists, plainly declare this. (Matt. iii. 6. 16. John, iii. 23. Acts, viii. 36—39.) But from these passages, the Pædo-baptists reply, that no certain

conclusion in favour of immersion can be drawn; nor from the subsequent history of the Christian church. Though they allow that immersion might be used, there are some cases in which it is more probable that the mode of baptism was sprinkling; partly on account of the number baptized at once, and partly because many of them were strangers, and far from their own habitations, and therefore destitute of that change of raiment which decency, conveniency, and safety, would have required. We might add farther, that baptism by sprinkling is, in its nature and the circumstances attending it, more suitable to the mild and benign genius of Christianity, and to the designed extent of its spread through all the various climates of the earth, than baptism by immersion. See, on this subject, Wall's History of Infant Baptism, 4to. 1707. Wall's Defence of the History against Gale, &c. 8vo. 1702. Towgood's Baptism of Infants a reasonable Service. Fleming's Plea for Infants, &c. &c.

For a summary of the principal arguments in favour of baptizing adults, and by immersion, see BAPTISTS.

PÆDOPHLEBOTOMIA, from παις, and φλεβοτομία, *venesection*, in *Surgery*, the operation of venesection practiced on a child.

PÆDOTHYSIA, παιδοθυσία, in *Antiquity*, an inhuman custom, that prevailed amongst the ancient heathens, of sacrificing their children. Thus it is related in the scriptures, that the king of Moab, being besieged by the Israelites in his capital, and reduced to great straits, took his eldest son, that should have reigned in his stead, and offered him for a burnt offering upon the wall, on which the siege was raised. 2 Kings, iii. 27.

From Phœnicia this cruel practice passed into Europe and Africa, and spread itself far and wide; and it is reported, that the Mexicans are, at present, guilty of it.

PÆNA, in *Ancient Geography*, an island of the Atlantic ocean, west of the province of Tingitana. Ptolemy.

PÆNOE, in *Botany*, the name of a very large tree, which grows in Malabar.

The resin, discharged from the root, bark, fruit, and other parts of this tree, when boiled with oil, is used either for a hard or liquid pitch; and is, in the Indian sacrifices, sometimes burnt instead of incense.

The kernels of the fruit when bruised, and, in conjunction with warm water, levigated on a marble, corroborate the stomach, remove a nausea and vomiting, allay racking pains of the belly, and cure the cholera. The resin of this fruit, when melted with the oleum sesami, is an excellent vulnerary balsam; when reduced to a powder, and exhibited, it also powerfully cures a gonorrhœa, and other vulnerary symptoms. Ray.

PÆNULA, or PENULA, among the Romans, a thick short, close-bodied garment, fit for a defence against cold and rain.

PÆONES, in *Ancient Geography*, a people who inhabited the coast of Macedonia and mount Rhodope, according to Dion Cassius. Herodotus places them on the banks of the Strymon; and Ptolemy assigns to them for their habitation Macedonia, towards the sources of the river Haliacmon.

PÆONIA, a country of Macedonia, which, according to Pausanias, took its name from Pæon, the son of Endymion. Herodotus speaks of this country, as subject to Darius, son of Hytaspes. It was situated east of the Axius, and west of Strymon.

PÆONIA, in *Botany*, the Pæony, so named by the ancients, in memory of Pæon the physician, whom Homer records as having cured Pluto with this herb, when he was wounded by

by Hercules. We presume its virtues are altogether reserved for such august occasions, they having never been made manifest on any other, as far as we can learn. The *raison* of Dioscorides evidently appears, by his very particular description, to be our plant. What he distinguishes, by the gratuitous appellation of male and female, are now acknowledged to be two species; though Linnæus considered them as varieties of one, by the name of *P. officinalis*. Linn. Gen. 273. Schreb. 365. Willd. Sp. Pl. v. 2. 1221. Mart. Mill Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 3. 315. Sm. Prodr. Fl. Græc. Sibth. v. 1. 369. Juss. 234. Tourn. t. 146. Lamarek Illustr. t. 481. Gært. t. 65.—Class and order, *Polyandria Pentagynia*. Nat. Ord. *Multifloræ*, Linn. *Ranunculaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five small, roundish, concave, reflexed, permanent leaves, unequal both in size and insertion. *Cor.* Petals five, roundish, concave, contracted at the base, spreading, very large. *Stam.* Filaments very numerous, (about three hundred), capillary, short; anthers erect, large, oblong, quadrangular, of four cells. *Pist.* Germens two or more, ovate, erect; styles none; stigmas compressed, oblong, obtuse, coloured. *Peric.* Follicles as many as the germens, ovate-oblong, spreading widely, often downy, coriaceous, bursting lengthwise at their inner edge. *Seeds* numerous, oval, polished, coloured, ranged along each margin of the future.

Eff. Ch. Calyx of five leaves. Petals five. Styles none. Follicles superior, with many marginal seeds.

Obs. Linnæus remarks, that though the most natural number of the germens is, in his opinion at least, two, they are often more numerous; but he thinks they scarcely ever amount to five. Some newly discovered species however contradict this, and indeed most of the old ones afford reasons, at one time or other, for the union of the Linnæan orders from *Digynia* to *Pentagynia*, in the class *Polyandria*, into one; which is sanctioned also by *Delphinium*, *Aconitum*, and others. See Sm. *Introd. to Botany*.

1. *P. Moutan*. Chinese Tree Pæony, or Moutan. Ait. n. 1. Sims in Curt. Mag. t. 1154. (*P. suffruticosa*; Andr. Repof. t. 373 and t. 448.)—Stem woody, perennial. Leaflets oblong-ovate; glaucous and somewhat hairy beneath; the terminal one three-lobed. Germens numerous, distinct.—Native of China, where it is one of the most favourite objects of horticulture, as may be seen by the paper-hangings, screens, porcelain, and other ornamental productions of art, brought from that country. It is depicted on such with double blossoms, either of a rose-colour, crimson, purple, white, or even of a golden yellow. The first only has been introduced into this country, by Sir Joseph Banks, in 1789. Collectors who have had means of communication with China, particularly the late Right Hon. Charles Greville, and Sir Abraham Hume, have anxiously endeavoured to obtain some of the other varieties, but in vain; except that the gentleman last mentioned has procured a shrubby Pæony with a single flower, more beautiful than the double, of which we shall presently speak as a distinct species. The *Moutan* proves tolerably hardy in England, though, like many other plants from the same country, which blossom early in our spring, it requires the protection of a glass frame at that season. The shrubby *stem* is peculiar to this and the next species, among all those hitherto known, and forms a large bush, spreading several feet in diameter. *Leaves* on long stalks, alternate, large and spreading, twice or thrice ternate in an opposite manner, deciduous; their leaflets tapering at the base, acute, entire, occasionally lobed, veiny; glaucous and very sparingly hairy beneath;

the terminal ones three-lobed. The scales of the *leaf-buds* are pale crimson. *Flowers* terminating the branches, solitary, six or eight inches broad, known to us in a very double state only, consisting of innumerable jagged rose-coloured *petals*, with a few *stamens*, with yellow *anthers*, remaining unchanged, and a greater or less number of *germens*, all separate and distinct. The smell of the *flower* is generally unpleasant, but a sweet-scented variety, of the same colour, is cultivated by Messrs. Lee and Kennedy. It is strange, and scarcely credible, that Thunberg and Loureiro should have thought this shrub a mere variety of our common *P. officinalis*. The latter indeed suspects that some of the supposed varieties of this plant, which, for many hundred years, are said to have been cultivated in China, are probably species. We are as yet much in the dark respecting these, but they seem by the drawings of the Chinese, to differ only in the colour of their blossoms. That whimsical people are reported to take pleasure in budding the different colours on the same stem.

2. *P. papaveracea*. Poppy-fruited Pæony. Andr. Repof. t. 463.—Stem woody, perennial. Leaflets oblong-ovate; glaucous and slightly hairy beneath; the terminal one three-lobed. Germens about six, closely combined into a globe. This blossomed in 1808 in the fine collection of the late lady Amelia Hume, at Wormleybury, having been introduced a year or two before, from China. It differs in no respect, as to *stem* and *foliage*, from the preceding. The *flowers* however differ, in being nearly single, with scarcely more than five *petals* which are very large, white or blush-coloured, with a large purple spot, at the base of each, vying with the beauty of a Gum Cistus. The *stamens* also are copious and all perfect. But the most remarkable difference exists in the *pistil*, which consists of six *germens*, rarely more, all closely compressed together into a globe, like a Poppy-head, and even enveloped in one common integument. The appropriate number of *stigmas*, one to each germen or cell, crowns this globe. Whether this can possibly be a variety, is doubtful. Dr. Sims is induced to consider it, if natural, as amounting to a generic distinction. This the exact conformity of all the other parts forbids, especially as there are similar specific differences in other genera; see NIGELLA. The character in question is found constant in all the specimens of this fine plant, that, for several successive years, have fallen in our way.

3. *P. officinalis*. Common Pæony. Willd. n. 1. Ait. n. 2. Retz. Obs. fasc. 3. 35. Linn. Sp. Pl. α . 747. Buliard t. 101. (*P. fœmina*; Matth. Valgr. v. 2. 266. Fuchs. Hist. 202. Lob. Ic. 682. f. 2. Ger. em. 981.)—Leaves twice compound; leaflets with broadly-lanceolate lobes. Follicles downy, nearly upright.—Native of shady groves in Switzerland, as well as on the mountains of Crete and Greece. It has been as long cultivated in European gardens, as perhaps any other exotic, flowering in May and June. The *root* is perennial, with many fleshy, cylindrical, or elliptical knobs, black externally. *Stems* herbaceous, annual, two feet high, with large, spreading, compound, dark-green *leaves*, mostly smooth and naked underneath, as well as above. *Flowers* terminal, solitary, crimson, usually double in gardens. There is an elegant flesh-coloured variety, as well as a white one. This is certainly the *raison* *ϑηλια*, or female Pæony, of Dioscorides, so named, of course, without any idea of the real sexual distinctions, in the parts of fructification. He celebrates it as useful in promoting natural discharges when deficient, and restraining some of them when too abundant. The flavour of the root is acrid, bitter and fœtid, and its qualities are reported to be narcotic

PÆONIA.

and dangerous, which we can readily believe. Bulliard's plate seems intended for this, though he did not distinguish it from the following very distinct species.

4. *P. corallina*. Entire-leaved Pæony. Willd. n. 2. Ait. n. 3. Retz. Obf. fasc. 3. 34. Engl. Bot. t. 1513. (*P. officinalis*; Linn. Sp. Pl. β. 747. Mill. Illustr. t. 47. *P. mas*; Ger. em. 980. Lob. Ic. 684. Matth. Valgr. v. 2. 265).—Leaves twice ternate; leaflets ovate, undivided. Follicles downy, recurved.—Native of the south of Europe. Dr. Sibthorp had wild specimens communicated to him by an apothecary of Zante. It was also discovered, in a wild state, by Francis Bowcher Wright, esq. in the rocky clefts of the island called Steep Holmes, in the Severn, in August 1803, whence this species has found a place in *English Botany*. Gerarde says he found it at Southfleet, Kent, which his editor Johnson rudely denies. Rustic gardens often abound with this flower, in its proper single state; the seed-vessels being admired, and long preserved for the decoration of the cottage chimney-piece, on account of their shining pink inside, and black polished seeds, contrasted with the red remains of numerous abortive ones, ranged along the edges. This is the *παριον αρρυν*, or male Pæony, of Dioscorides, whose leaves he compares to those of a Walnut-tree, a sufficient indication of their ovate, undivided, simply pinnate form, by which the species is clearly distinguishable from the last. The qualities of the two plants probably differ but little. We find the leaves of the present sometimes downy beneath.

5. *P. peregrina*. Crimson-flowered Small Pæony. Ait. n. 4. Sims in Curt. Mag. t. 1050. (*P. promiscua*; Ger. em. 982. Lob. Ic. 683. *P. byzantina*; Ger. em. 982?)—Leaves twice ternate; leaflets elliptic-oblong, decurrent, lobed; glaucous and hairy beneath. Follicles erect, downy.—Native, probably, of the south of Europe. It is a plant of much humbler growth, and smaller dimensions, than any of this genus that we have hitherto mentioned, and is essentially distinguished, if we mistake not, by its decurrent leaflets, whose main ribs unite far above the base. The flowers are of an elegant, but not very deep or bright, crimson, scarcely three or four inches in diameter, often double, with linear internal petals, like a double anemone. Such is the plant we had from Mr. Loddige by the name of *P. humilis*, with whose figure and description it, as Dr. Sims well remarks, does not at all agree. But neither, in our judgment, does it accord with the *P. peregrina, flore coccineo*, Bell. Hort. Eyf. Vern. (not Ætiev.) ord. 6. t. 9, nor with *P. byzantina* of Gerarde, Parkinson and others, which is described by Parkinson as larger than the Male Pæony, *P. corallina*; whereas our *peregrina* is a great deal smaller, and exactly answers to the *promiscua* of old books. It appears to be rather of recent introduction among us, and we have some suspicion of its having been brought from Siberia. The flowers are produced in May or early in June, and the roots are quite hardy.

6. *P. daurica*. Glaucous Daurian Pæony. Ait. n. 10. Andr. Repof. t. 486.—Leaves pinnate; leaflets elliptical, obtuse, glaucous, somewhat wavy. Stem herbaceous.—Native of Siberia, from whence it was procured, in 1790, by the late Mr. Bell. This, like the rest, is a hardy perennial, flowering in May or June. Stem about two feet high. Leaves apparently all simply pinnate, glaucous on both sides, paler beneath; leaflets broadly elliptical, obtuse, concave, veiny, rather wavy at the edge. Flowers large and handsome, of a purplish rose-colour, with copious yellow stamens, and two pistils. Follicles ovate, divaricated, downy, about one inch and a half long. We know this species, which seems well worthy of general cultivation,

from Mr. Andrews's work only. Its affinity to the three preceding, has made us here swerve from the arrangement in the *Hortus Keavenfis*.

7. *P. albiflora*. White-flowered Pæony. Pallas. Ross. v. 2. 92. t. 84. Willd. n. 3. Ait. n. 5. Andr. Repof. t. 64. and t. 612.—Leaves twice ternate; leaflets elliptic-lanceolate, acute, entire, smooth. Capsules recurved, smooth. Calyx bracteated.—Native of Mongol Tartary, on grassy hills, and introduced into the British gardens by Pallas, its celebrated discoverer, in 1784. This flowers in May or June, and is hardy, but we do not find this species so easy of culture, nor so free in flowering, as some others. The inhabitants of its native country are said to eat the roots boiled in soups, and to mix the powdered seeds with the infusion or decoction of their tea. The stem is herbaceous, usually dark brown, smooth and polished. Leaves twice ternate, of a dark shining green above, paler beneath, quite smooth and naked. Flowers comparatively small, but peculiarly elegant in their native simplicity and snowy whiteness, with concave, partly closed, petals, and a brown calyx, accompanied by three green, leafy, sessile bractæas. Germens three or four, brown and smooth. These flowers have a sweet aromatic scent. There is a double variety, with a bluish-coloured tint, and yellowish inner petals, figured in Andrews's t. 612, which makes a very splendid appearance; but we have always admired the original plant, as one of the most desirable of its genus, nor are we singular in this opinion.

8. *P. humilis*. Dwarf Spanish Pæony. Retz. Obf. fasc. 3. 35. Willd. n. 4. Ait. n. 6. (*P. pumila fœmina*; Lob. Ic. 683. Ger. em. 982.)—Leaves twice ternate; leaflets in three deep linear segments, downy beneath. Follicles hairy, nearly erect. Clusius records this as a native of Spain. Gerarde speaks of it as known in the English gardens in his time. We have never met with a specimen, and should be very glad to see it well figured. Retzius describes the stem a foot and half high, simple, smooth, angular and green. Leaves in very narrow segments, acute; glaucous above; whiter and downy beneath. Petals of a deeper red than those of *P. corallina*, n. 4. Germens greenish, slightly hairy, as are also the short, nearly upright, follicles.

9. *P. anomala*. Jagged-leaved Siberian Pæony. Linn. Mant. 247. Willd. n. 5. Ait. n. 7. Andr. Repof. t. 514. (*P. laciniata*; Pallas. Ross. v. 2. 93. t. 85. *sibirica*. P. n. 14; Gmel. Sib. v. 4. 184. t. 72.)—Leaves twice ternate; leaflets with many lanceolate segments, smooth. Follicles depressed, smooth. Calyx bracteated. Frequent throughout most parts of Siberia, in grassy, shady, rather lilly spots. Mr. Bell introduced this first into England, and it flowered with him in July 1807. The calyx is accompanied with leafy bractæas, like those of *P. albiflora*, but longer and narrower, like the numerous lanceolate segments of the foliage, by which this species is distinguished at first sight from all we have hitherto described, except the last, but that has downy leaves, glaucous above, and hairy upright seed-vessels. The corolla of *P. anomala* is concave, of a full rose-colour. Germens usually five, spreading, smooth, as well as the follicles.

10. *P. hybrida*. Mule Pæony. Pallas. Ross. v. 2. 94. t. 86. Willd. n. 6. Ait. n. 8.—Leaves twice ternate; leaflets with numerous linear segments, smooth. Germens downy. Pallas mentions this as occurring now and then wild, in valleys on the banks of some of the larger Siberian rivers, but much smaller than the specimen delineated in his plate, which he says originated in the garden at Petersburg, and was supposed to be a hybrid production between the preceding species and the following, as it never produced seeds. Mr. Bell is recorded as having introduced *P. hybrida* into England,

PÆONIA.

England, in 1788. Like the last it is perennial, flowering in May, and like that, has the *leaflets* much divided, but with still narrower segments. The parts of fructification however more agree with *tenuifolia*, hereafter described. The *bracteas* are partly lacinated, as in that, not all undivided, as in *anomala* and *albiflora*. The *corolla* is of a deeper red, and the *germens*, instead of being smooth, are downy. It is very likely, though occasionally found wild, to be a mule plant, rather than a permanent intermediate species.

11. *P. tenuifolia*. Fine-leaved Pæony. Linn. Sp. Pl. 748. Linn. fil. Pl. Rar. fasc. 1. 9. t. 5. Pail. Ross. v. 2. 95. t. 87. Willd. n. 7. Ait. n. 9. Meerb. Ic. t. 25. Curt. Mag. t. 926. (P. n. 15; Gmel. Sib. v. 4. 185. t. 73.)—Leaves thrice ternate; leaflets in numerous linear-awl-shaped segments, smooth. Follicles hairy.—Native of Siberia, from whence the late Mr. Malcolm is said first to have obtained it alive in 1765. This is one of the most elegant species, and a highly desirable hardy herbaceous plant, flowering readily in the open border, about the end of May. The root creeps moderately. In a wild state the stem is said to be about a foot high; in a garden it is full two feet, erect, simple, or slightly branched, clothed with numerous, very compound and finely divided, dark-green, smooth leaves, spreading in a recurved direction. Flowers terminal, solitary, concave, rather above two inches wide, of a most vivid, deep, rich, shining blood-colour, with copious yellow stamens. The bracteas are partly divided like the leaves, partly entire. Germens densely covered with erect, close-set, plush-like, shining, brown, rigid hairs. We seldom see the seeds perfected in England, though they are said to ripen in Sweden. No wonder that Linnæus, who, when he first became acquainted with this beautiful Pæony, was full of his newly conceived ideas of hybrid generation in plants, immediately guessed it to be a mule between the common *Pæonia* and *Adonis apennina*. It does indeed look like a magnified *Adonis autumnalis*. Such resemblances are, nevertheless, fallacious, and there is no real foundation for believing the *P. tenuifolia* any other than a most distinct and permanent original species.

PÆONIA, in Gardening, comprises plants of the large, herbaceous, showery, perennial kind, of which the species are, the common pæony (*P. officinalis*), and the slender-leaved pæony (*P. tenuifolia*).

There are two principal varieties of the first species; the common female, and male pæony.

The former of these has the roots composed of several roundish thick knobs or tubers, which hang below each other, fastened with strings; the stalks are green, about two feet and a half high; the leaves are composed of several unequal lobes, which are variously cut into many segments; they are of a paler green than those of the latter sort, and hairy on their under side; the flowers are smaller, and of a deeper purple colour.

The latter has the roots composed of several oblong knobs hanging by strings fastened to the main head; the stems the same height with the preceding; the leaves are composed of several ovate lobes, some of which are cut into two or three segments; they are of a lucid green on their upper side, but are hoary on their under; the stems are terminated by large single flowers, composed of five or six large, roundish, red petals.

The flowers in both sorts appear in May, and are natives of several parts of Europe.

And Miller suggests, that it is scarcely necessary to observe that the old names of male and female have nothing to do here with sexes, the flowers of both being hermaphrodite.

Besides, there are several sub-varieties of the female pæony,

as with double flowers, differing in size and colour, cultivated in gardens. The male pæony also varies, with pale and white flowers, and with larger lobes to the leaves: they also vary much in different countries.

As there is the *Foreign Pæony*, with a deep red flower; the roots are composed of roundish knobs, like those of the female pæony; the leaves are also the same, but of a thicker substance; the stalks do not rise so high; the flowers have a greater number of petals, and appear a little later. This is a native of the Levant. The large double purple pæony is probably a sub-variety of this.

The *Hairy Pæony*, with a larger double red flower; the roots like the common female pæony; but the stalks taller, and of a purplish colour; the leaves much longer, with spear-shaped entire lobes; the flowers large, and of a deep red colour.

The *Tartarian Pæony*, with roots composed of oblong fleshy tubers of a pale colour; the stalks about two feet high, pale green; the leaves composed of several lobes, irregular in shape and size, some having six, others eight or ten spear-shaped lobes, some cut into two or three segments, and others entire; of a pale green, and downy on their under side; the stalks are terminated by one flower of a bright-red colour, a little less than that of the common female pæony, having fewer petals.

The *Portugal Pæony*, with a single sweet flower, has not roots composed of roundish tubers, but has two or three long taper-forked fangs like fingers; the stalk rises little more than a foot high; the leaves are composed of three or four oval lobes, of a pale colour on their upper side, and hoary underneath; the stalk is terminated by a single flower, which is of a bright red colour, smaller than the above, and of an agreeable sweet scent.

Method of Culture.—The single sorts are easily raised by seeds, and the double by parting the roots.

The seed should be sown in autumn, soon after it is perfectly ripened, or very early in the spring (but the former is the better season), on a bed or border in the open ground, where the soil is rather light, raking it in lightly. It may also be sown in small drills.

The plants should afterwards be properly thinned, kept perfectly free from weeds, and be occasionally watered when the weather is hot and dry.

As they should remain two seasons in the bed, it is necessary, in the second autumn, to spread some light mould over them, to the depth of an inch; and in the autumn following they may be removed where they are to remain. Plants of the double-flowered kinds are often produced from these.

The roots of the old double-flowered plants may be taken up in the beginning of the autumn, and divided so as to have one bud or eye, or more, to each part or crown, as without care in this respect, they never form good plants. And where regard is had to the flowering, they should not be too much divided, or the offsets made too small, as when that is the case they do not flower strong. But where a great increase is wanted, they may be divided more, being left longer in the nursery-beds.

They should be planted out as soon as possible after they are separated, though, when necessary, they may be kept some time out of the earth. The large offsets may be set out at once where they are to remain; but the small ones are best set in nursery-beds for a year, or till of proper strength for planting out.

The plants may afterwards be suffered to remain several years unremoved, till the roots are increased to very large branches, and then be taken up when the stalks decay, in autumn,

autumn, divided, and replanted in their allotted places in the manner directed above.

All the sorts are hardy plants, that are capable of flourishing in any common soil in almost any situation, either in open exposures, or under the shade of trees.

The Portugal variety, however, should have a warmer situation and lighter soil than the others.

They are proper ornamental flowery plants for large borders, and may be had at all the public nurseries. In planting, one should be put here and there in different parts, placing them with the crowns of the roots a little within the surface of the earth, and at a yard at least distant from other plants, as they extend themselves widely every way, assuming a large bushy growth; and, together with their conspicuous large flowers, exhibit a fine appearance, and are often planted at the terminating corners of large borders adjoining principal walls, displaying a bushy growth in their foliage and flowers. When the flowers are gone, the capsules opening lengthways discover their coloured seeds very ornamentally, especially in that called the male pæony and varieties. And to forward this, the capsules may be slit open on the inside at the proper valve; whereby they will expand much sooner, and display their beautiful red seed more conspicuously than would otherwise be the case.

PÆONITES, in *Natural History*, a name given by some writers to the stone called by others *paenites*, and esteemed of great use to women in labour. It seems to have been called pæonites, from Pæonia, in Macedonia, where it was found.

PAES, in *Geography*, a river of Lapland, which runs into the North sea, N. lat. 70°.

PAESIELLO, GIOVANNI, in *Biography*, a Neapolitan, and gifted with as much fertility of invention for dramatic compositions as nature ever bestowed on an Italian opera composer. He was thought, at the beginning of his career, not to have laboured sufficiently at the drier parts of counterpoint, upon which many great masters of Italy have established their fame.

From his early youth he gave way to the fire of his invention, which art could hardly restrain, much less confine to rule. His wildness, however, was never grotesque, ungraceful, crude, wild, or offensive to cultivated ears; but consisted of the most happy flights of fancy, pleasing melodies, and new effects of accompaniment. He at first worked at little dramas in the Neapolitan jargon, so different from good Italian, that it is totally unintelligible to the rest of Italy. This language, however, is allowed to be very poetical, and capable of receiving all the grace and refinements of melody.

He composed for the burletta a comic opera in Italian, as early as 1765, "Amore in Ballo;" and in 1766, "Le Nozze Turbate." In 1770 we heard at Naples his comic opera called "Le Trame per Amore," in which, though the singing was but indifferent, and out of nine characters there was not one good voice, yet the music pleased us extremely. The symphony, consisting of only one movement, was truly comic, and contained a perpetual succession of pleasing passages. The airs were full of fire and fancy, the ritornels abounding with new passages, and the vocal parts in elegant and simple melody, such as might be remembered and carried away after the first hearing, or be performed in private by a small band, or even without any other instrument than a harpsichord or pianoforte. The airs of this drama were much applauded when we heard it performed, though it was the fourteenth night of its run.

But since that time he has continued improving in his style, both in serious and comic operas, and the public all over Europe has not been insensible to his transcendent

merit, as he has justly been regarded at the head of vocal composition of the present time, as Haydn of instrumental. In 1770 he was the only composer in Naples who could make head against the high favour in which Piccini then stood, after his "Buona Figliuola." We were so happy as to hear him *improvise* in music at Sir William Hamilton's, where, having dined, he was begged to sing a scene of an opera; but there being none at hand which he liked to perform, he said "date mi un libretto," and the words of the first opera which could be found having been put on the harpsichord desk, he composed and sung extempore three or four scenes in so exquisite a manner to his own ingenious accompaniment, that no studied music and singing we ever heard of the greatest composers or performers ever pleased us so much. It was not written music, it was inspiration.

He passed three years at Petersburg in the service of the empress Catharine II., whose court was constantly in possession of the best composers and vocal performers of Italy, and there he established a great reputation, which since his return has been constantly increasing in his own country. He is now (1804) at Paris, and though a modern, is as much revered and respected as any of the most invaluable antiques among the spoils of Italy. A list of his works would astonish by the number, as much as they have delighted by their performance, every judge of feeling, who is able to discriminate good music from bad, or perfection from mediocrity.

PAEZ, PEDRO, a man deservedly celebrated in the history of the Jesuits, and of Abyssinia, was a Castilian, born at Toledo of a noble family. Having completed his studies in the company, he was sent to India in the year 1588. The Portuguese in Abyssinia were at this time without a patriarch, or any spiritual assistant, so difficult was it to introduce them into that kingdom, every entrance into which was in possession of the Turks or Moors. To this mission Pæz and P. Antonio de Montserrat were appointed. They were made prisoners on their way, and sent to the court of the king of Xael, by whom they were kindly treated; but being himself tributary to the pacha of Yemen, and bound by treaty to send him all the Portuguese who might fall into his hands, they were sent to Canaan, the capital where the pacha resided. At first their captivity was easy; but afterwards they were treated with great barbarity, in hopes that he might obtain a very large ransom for their liberty. At length the viceroy of India obtained their deliverance, upon the payment of a thousand crowns: they returned to India, where Montserrat soon afterwards died. Pæz was more successful in his second attempt; he entered Abyssinia very safely in 1603, and instead of busying himself with court intrigues, and seeking court favour, he remained quietly among his flock, translating into Abyssinian a compendium of the Christian doctrine, which had been written by Marcus George. He instructed some children in the dialogues of this work. The king of the country, hearing of their proficiency, sent for the master and his scholars to exhibit before him. He was delighted with their performance, and became himself a thorough convert to the Roman Catholic faith; but the zeal which he shewed in behalf of the new system of faith led to his deposition and untimely death. Other revolutions followed; when things, however, were become quiet, Pæz undertook to build a palace at Gorgora, a rocky peninsula, on the south side of the lake of Dembea. He was himself architect, mason, smith, and carpenter, and produced a building which was the astonishment of those who beheld it. A spring-lock, which he fixed upon one of the doors, saved the king's life, when an attempt was made to assassinate him. The last triumph which Pæz enjoyed was that

that of seeing the king put away all his wives but one, and receiving his general confession. He died in May 1622. Gen. Biog.

PAGÆ, in *Ancient Geography*, a town of the territory of Megara, situated towards the north, on a small gulf formed by an extension of the gulf of Corinth, and called "Mare Aleyonium."

PAGAHM, in *Geography*, once a magnificent city of the Birman empire, on the Irawaddy, but now its remains are merely numerous mouldering temples, and the vestiges of an old brick fort, the ramparts of which are still to be traced. The town of Neoundah, about four miles to the north, which may be called a continuation of Pagahm, has flourished in proportion as the latter has decayed. Pagahm is said to have been the residence of forty-five successive monarchs, and was abandoned 500 years ago, in consequence, as it is said, of a divine admonition; but whatever may be its true history it was certainly once a place of no ordinary splendour. The temple of Pagahm rises upwards with a heavy breadth almost to the top, and then terminates abruptly in a point, which give to the buildings a clumsy appearance. Many of the most ancient temples at this place are not solid at the bottom; a well arched dome supports a ponderous superb structure; within, an image of Gaudma sits enshrined; four Gothic door-ways open into the dome, in one of which was a human figure standing erect, said to have been Gaudma, and another of the same personage, lying on his right side asleep, both of gigantic structure. These, however, are not the usual attitudes of the divinity; as he is generally depicted sitting cross-legged on a pedestal, adorned with representations of the leaf of the sacred lotus carved upon the base; the left hand of the image rests upon his lap, and the right is pendent. Beyond the suburbs there is a part where the inhabitants are employed in expressing oil from the Sesamum seed: the grain is put into a deep wooden trough, in which it is pressed by an upright timber fixed in a frame; the force is increased by a long lever, on the extremity of which a man sits and guides a bullock that moves in a circle, thus turning and pressing the seed at the same time; the machine was simple, and effectually answered the purpose. Of these mills, there were not less than 200 within a very narrow compass. From the circumstance of the cattle being in good order, it was concluded that they were fed on the seed after the oil was extracted. The land about Pagahm scarcely yields sufficient vegetation to nourish goats. Symes' Embassy to Ava, vol. ii.

PAGALOAN, a town in the N.W. coast of Mindanao.

PAGAMEA, in *Botany*, Aubl. Guian. v. 1. 112. t. 44. Juss. 209. Lamarck Illustr. t. 88. A genus consisting of only one species, whose fruit was judged by Jussieu to be not sufficiently ascertained. It appears next akin to FARAMEA of the same authors, (see that article,) and likewise belongs to the *Rubiaceæ* of Jussieu. Aublet describes the berry as of two cells, with two seeds, convex on one side, flat on the other, one of them frequently abortive. Each of these seeds, when cut across, is found to have two cells, with a kernel in each cell.—The *Pagamea guianensis* is a shrub seven or eight feet high, growing on the top of the Serpent mountain, in Guiana, and bearing flowers, as well as fruit, in August. The branches spread every way, and are knotty, leafy at the extremities. Leaves opposite, in pairs crossing each other, stalked, lanceolate, pointed, entire, about three inches long, single-ribbed and veiny, smooth and pliant. Stipules sheathing, short, with two small points. Flowers in short, loose, axillary, stalked spikes. Corolla white, funnel-shaped, equally four-cleft, downy within.—No reason is given

for the name, nor any thing said about the qualities or uses of the plant, except that the wood is hard, and of a yellowish colour.—The trunk is only five inches in diameter.

PAGAN, PAGANUS, a heathen, gentile, or idolater, one who adores false gods.

Baronius derives the word *paganus*, a *pagis*, *villages*, because, when Christians became masters of the cities, the heathens were obliged, by the edicts of Constantine and his sons, to go and live in the country villages, &c. Salmastius will have the word come from *pagus*, considered as originally signifying *gens*, or *nation*: whence he observes, we say indifferently, pagans, or gentiles.

The abbot de Fleury gives another origin of pagan: he observes, that the emperor Constantine, going from Antioch, against Maxentius, in 350, assembled all his troops, and advised such as had not received baptism to receive it immediately; declaring withal, that such as should be found unbaptized should quit the service, and go home.

Hence, perhaps, says the abbot, the name pagan might be given to those who chose the latter; the Latin word *paganus* properly signifying a *person who does not bear arms*, in opposition to *miles*, a *soldier*.

And hence it might, in time, extend to all heathens; or, continues he, the word might come from *pagus*, *village*, in regard the peasants were those who adhered longest to the idolatry of the heathens.

PAGAN, BLAISE FRANÇOIS, *Compte de*, in *Biography*, an eminent military engineer, was born at Avignon in the year 1604. He entered into the army at twelve years of age, and distinguished himself in a variety of actions. He was patronized by his near relation, the constable de Luynes, whom he had the misfortune to lose at the siege of Montauban, at which he was also deprived of the sight of an eye by a musket-shot. At the passage of the Alps, and the barricades of Suza, he placed himself at the head of a determined band, and having gained the summit of a steep mountain, he cried out "This is the road to glory," and instantly slid down the mountain; and being imitated by his men, they arrived first at the barricades and carried them. When the king, Lewis XIII., laid siege to Nanci in 1633, Pagan had the honour to attend him in drawing the lines and forts of circumvallation. In 1642 he was sent to the service of Portugal, in the post of field-marshal, and there he had the misfortune to lose his eye. Though disabled from serving his country in the active duties of a warrior, he was intent upon augmenting its glory, by extending the boundaries of military science. Having from his youth closely applied to mathematical studies, with a particular view to the science of fortification, he now employed the whole force of his active mind in speculations of this kind, and in 1645 published his "Traité des Fortifications;" this was regarded as the best work that had ever been written on the subject, and it is said that whatever improvements have been made since, have been derived chiefly from this treatise, as conclusions from its principles. In 1651 he published his "Theoremes Geometriques," which shew an extensive and deep knowledge of all the parts of the mathematics. In 1655 he published an "Historical and Geographical Account of the River Amazons, extracted from different Writers," and we are assured, that though blind, he drew the chart of that river and the parts adjacent. His other works, published in 1657 and 1658, were "Theorie des Planetes;" and "Tables Astronomiques;" by the former he cleared the system from that multiplicity of eccentric circles and epicycles, which astronomers had invented to explain their motions. His astronomical tables are reckoned succinct, and very plain. Pagan died at Paris, November 18, 1685. He was devoted

to judicial astrology; but what he wrote on this subject is the only thing which detracts from his high character. He had an universal genius, and having applied himself entirely to the art of war, and particularly to the branch of fortification, he made much progress in it. He understood the deeper branches of the mathematics, and had so fine a genius for these abstruse speculations, that he read but little on the subject, his own fertile mind supplying him with almost every thing that he wanted. Lewis XIII. regarded him as one of the most adroit, and most valiant men in his kingdom. That branch of his family which removed from Naples to France in 1552, became extinct at his decease. All his works were collected and printed in 12mo. in the year 1669. Moreri.

PAGAN, PETER, a distinguished poet of the 16th century, was born at Wanfrid, in Hesse, and being educated with great care, he exhibited at an early age much literary taste, and a particular turn for poetry. In the year 1550 he received the degree of bachelor in philosophy, and he became poet to the emperor Ferdinand. To the study of poetry he joined that of history, and was elected professor of both in the university of Marburg. He died at Wanfrid, on the 29th of May, 1576. Besides many pieces in poetry on miscellaneous subjects, he left "Historia tergemorum Romanorum et Albanorum fratrum," in verse, which contained the history of the three Horatii, and the three Curatii. Moreri.

PAGAN Creek, in *Geography*, a river of Virginia, which runs into James river, N. lat. 37° 5'. W. long. 76° 37'.

PAGANALIA, an ancient rural feast thus called, because celebrated in the villages, *in pagis*.

In the paganalia, the peasants went in solemn procession all round the village, making lustrations to purify it. They had also their sacrifices, wherein they offered cakes on the altars of the gods.

Halicarnassus and St. Jerom refer the institution of the paganalia to Servius Tullus. They were held in the month of February.

PAGANELLUS, in *Ichthyology*, a species of *Gobius*; which see.

PAGANICA, in *Geography*, a town of Naples, in Abruzzo Ultra; 8 miles N.N.W. of Aquila.

PAGANINA, an Italian word, used by some authors to express the first excrements of children: these, dried and reduced to powder, are esteemed by some a very great and powerful medicine against epilepsies. It is to be taken in small doses, every day, for some time.

PAGANINI, LA, in *Biography*, an admirable singer and actress in the character of *prima buffa* in the burletta operas of "Il Mondo della Luna," and "Il Filosofo di Campagna," composed by Galuppi, when his genius was in full fire. The airs "Si l'Uomini sirpirano," and "Donne, donne, fiamo Nate," were sung in a way so piquant and agreeable by the Paganini, that the applause which she acquired by them amounted almost to acclamation. This last opera had an uninterrupted run of fifteen nights; and the Paganini, though not young when she came hither from Berlin, in 1760, increased in reputation so much during the run of this opera, that when it was her turn to have a benefit, such a crowd assembled as we never remember to have seen on a like occasion, before or since; indeed, not one-third of the company that presented themselves at the opera-house doors were able to obtain admission. Caps were lost, and gowns torn to pieces, without number or mercy, in the struggle to get in. Ladies in full dress, who had sent away their servants and carriages, were obliged to appear in the streets and walk home in great numbers without caps or

attendants. Luckily the weather was fine, and did not add to their distress by rain or wind; though their confusion was greatly augmented by its being broad daylight, and the streets full of spectators, who could neither refrain from looking or laughing at such splendid and uncommon street-walkers.

PAGANISM, the religious worship and discipline of pagans; or the adoration of idols and false gods.

The gods of paganism were either men, as Jupiter, Hercules, Bacchus, &c. or fictitious persons, as Victory, Fame, Fever, &c. or beasts, as in Egypt, crocodiles, cats, &c. or finally inanimate things, as onions, fire, and water, &c.

PAGAPATE, in *Botany*, Sonnerat Guian. 16. t. 10, 11. See SONNERATIA.

PAGARCHUS, *παρχος*, formed from *pagus*, *village*, and *αρχη*, *command*, among the ancients, a petty magistrate of a pagus, or little district, in the country.

PAGASA, or PAGASU, in *Ancient Geography*, a town of Magnesia, formerly a part of the town of Phœræ.

PAGE, formed from *παῖς*, *child*, *boy*, a youth of state, retained in the family of a prince, or great personage, as an honourable servant to attend in visits of ceremony, carry messages, bear up trains, robes, &c. and at the same time to have a genteel education, and learn his exercises.

The pages in the king's household are various, and have various provinces assigned them: as pages of honour, pages of the presence-chamber, pages of the back stairs, &c.

Pages were anciently distinguished from the other servants in livery, by their wearing drawers in lieu of breeches; and sleeves turned up with velvet.

Cujas and Gothofred observe, that pages in the emperor's families were called *pagagogiani pueri*. Fauchet says, the word page was first given to the little boys who attend tilers, to bring them their tiles, &c. that till the time of Charles IV. or VII. the name was common to the basest servants; and it is since then, that page is become a term of honour; and the meaner servants are distinguished from them by the name of lacqueys, valets, &c.

PAGE is particularly used in the Turkish seraglio, for the children of tribute, or slaves who wait on the grand signior.

They are commanded by the first aga, and constitute four classes, called odas.

PAGE of a Book. See PRINTING.

PAGEANS, in *Mythology*. See PYGMIES.

PAGEANT, a triumphal car, chariot, arch, or other the like pompous decoration, variously adorned with colours, flags, &c. carried about in public shows, processions, &c.

PAGEL, in *Ichthyology*, a name given by the Spaniards to that fish which authors in general called the *erythrinus*, or *rubellio*, and some the *xathus* and *pagrus*. It is properly a species of the *sparus*, and is distinguished by Artedi from the rest of that genus, by the name of the *silver-eyed red-bodied SPARUS*, which see.

PAGET'S PORT, in *Geography*, a small harbour within the great found in Bahama islands, and in the most easterly part of the found.

PAGHATAKAN, a town of New Jersey, on the Pa-pachton. N. lat. 42° 8'. W. long. 74° 40'.

PAGI, ANTHONY, in *Biography*, a celebrated Cordelier, and one of the ablest critics of his time, was born at Rogne, in Provence, in the year 1624. He embraced the monastic life, in the convent of Arles, in the year 1641, and obtained so high a reputation, that he became four times provincial of his order; but his religious duties did not prevent his application to the study of chronology and ecclesiastical history, in which he excelled. His most considerable work is a critique

critique upon the "Annales" of Baronius, in which, following the learned author year by year, he has rectified an infinite number of mistakes, both in chronology, and in the representation of facts. The first volume was published at Paris in 1689, and dedicated to the clergy of France, who allowed him a pension; the other three were not printed till after the death of the author: the publication of them was superintended by his nephew Francis. A new edition of the whole was published at Geneva in the year 1727. Father Pagi died at Aix in 1699. His nephew, already referred to, having finished the publication of his uncle, employed himself in writing a work of his own, which he published under the title of "Breviarium Historico-Chronologico-Criticum, Illustriora Pontificum Romanorum Gestæ, Conciliorum Generalium Acta, &c. complectens," forming in the whole four volumes, 4to. This work is said to display much curious research, and is drawn up in a correct and neat style. Francis Pagi died in 1721, in the sixty-seventh year of his age. He left a nephew, Anthony, on whom devolved the care of publishing the last volume of his uncle's "Breviarium." Moreri.

PAGIETTA, in *Geography*, a town of Naples, in Abruzzo Citra; 5 miles S. Langiano.

PAGIN, M., in *Biography*, a violinist at Paris in the year 1770, much admired for his taste, neatness, and delicacy, by judges of the violin,—not of the French school. He was a disciple of Tartini, and regarded by many at Paris as his best scholar. Having had the honour of being hissed at the Concert Spirituel for daring to play in the Italian style, he quitted music as a profession, and had a place conferred upon him under the count de Clermont, of about 250*l.* a-year.

PAGLIA, in *Geography*, a river of Italy, which runs into the Tiber, a few miles below Orvieto.

PAGLIANELLO, a town of Naples, in Lavora; 14 miles N.E. of Capua.

PAGLIANO, a town of Naples, in Abruzzo Ultra; 15 miles E.S.E. of Aquila.

PAGLIAPOLI, a town of Naples, in Calabria Ultra; 4 miles E. of Gierace.

PAGLION, a river of France, which runs into the Mediterranean, a little to the E. of Nice.

PAGNINUS, SANCTES, in *Biography*, an Italian Dominican monk in the fifteenth century, eminent for his skill in the oriental languages and biblical learning, was born at Lucca in 1466, but according to others, in the year 1470. At the age of sixteen he took the habit in a convent of the Dominican order, and applied with extraordinary diligence to the study of the learned languages, and of divinity. He became deeply and accurately skilled in Latin, Greek, Hebrew, Chaldee, and Arabic, but he was particularly celebrated for his knowledge of the Hebrew language. He spent the greater part of his life in a monastery at Lyons, was distinguished by his zeal in defending the Catholic church against the attacks of the reformers, and laboured to prevent the numerous Italian families which had settled in this city from being converted by the emissaries of the Waldenses and Lutherans. Pagninus is, however, chiefly known by his making the first modern translation into Latin of the Old Testament from the original Hebrew, and of the New Testament from the Greek. To this design he was led from a firm conviction that the Vulgate translation, as it has descended to modern times, is greatly corrupted from the state in which it was left by St. Jerome. It was his object, therefore, to produce a new translation, in which the Vulgate should be followed whenever fidelity to the originals permitted. Being patronized by Leo X. he began his great work in 1493, and having employed himself in it with the greatest

affiduity twenty-five years, finished it in 1518. He then applied to the translation of the apocryphal books and the New Testament, both of which he rendered from the original Greek before the year 1521. The whole was published at Lyons in 1528, under the title of "Veteris et Novi Testamenti nova Translatio, per Sanctum Pagninum nuper edita, approbante Clemente VII." Many high commendations have been bestowed upon this work by the most learned rabbis, who have given it the preference to all other translations of the sacred Hebrew writings, and likewise by many eminent Christian critics, Catholic and Protestant, and among others, by Leusden, Erpenius, Buxtorf, and Huet. But father Simon and others, though they admit that Pagninus has shewn great learning and talents, contest its claims to the superior excellence which the former attribute to it. Simon says it is obscure, barbarous, and full of solecisms, and he maintains that it sometimes changes the sense of the text. The version has gone through many editions. Huet, though he gives Simon credit for the general truth of his criticisms, yet proposes his manner as a model for all translators of the sacred books; "Scripturæ interpretandæ rationis utile nobis exemplar proposuit Sanctus Pagninus." This author published "Thesaurus Lingux Sanctæ," in folio, which was reprinted by Robert Stephens, under the title of "Thesaurus Lingux Sanctæ contractior et emendatior." Pagninus published many other works; he died at Lyons in 1536. Buxtorf, who made much use of his Thesaurus, in forming one of his own, calls him "Vir linguarum Orientalium peritissimus." Luther spoke of him with great applause.

PAGO, in *Geography*, an island in the Adriatic, near the coast of Dalmatia, or Morlachia, about 20 miles long and 6 broad containing several villages. It is subject to a stormy sea, so that neither wood, nor pasture, nor corn lands are found upon that part which is opposite to the continent, except in few places. The air is darkened by the salt mist that is raised by the collision of the waves in the narrow channel of Morlachia. The large lake itself is not calm in the stormy season, and so far from being a harbour, it is tempestuous and useless. The inhabitants of the city are not secure in their houses, without defending the roofs by large stones, nor can they leave them with safety during the violence of the wind. This island in winter is no less inhospitable than Siberia, always covered with snow and fire, and exposed to the cold north wind. The nakedness of the rocks, which form the surface of almost the whole island, the narrowness of the vallies, the reverberation of the water of the lake, which is generally quite calm in summer, increase the heat to such a degree among the stones, that the vines which are planted round the lake ripen the grapes before the beginning of August, and the few other productions of the spot anticipate the usual time of maturity. The part of the island under the jurisdiction of Pago, produces about 40,000 barrels of good wine, and about 2000 of Rakia, one year with another. The island is covered with sage and odoriferous herbs; which furnish food for the bees, inasmuch that honey forms no inconsiderable branch of trade. The pasture among barren rocks maintains also a large number of sheep and goats, so that the wool, which is very bad, and cheese, furnish small articles of export. The northern part of the island, called "Novaglia," and depending on the government of Arba, is well supplied with water, and has good pastures on its low grounds, by which its black cattle are larger and better than those on any of the neighbouring islands, or of litoral Dalmatia. The produce of corn and oil is very scanty, and not sufficient for two months sustenance of the inhabitants. The most considerable produce

duct of the island is salt : the salt-works belonging partly to the government, and partly to private proprietors. The northern extreme of the island, called "Punta di Loni," is abundantly supplied with wood for various purposes, though other parts are wholly destitute. The roots and trunks of old olive trees afford excellent materials for the cabinet-makers and sculptors. The soil of the island, that is, of the land lying on the declivity and at the bottom of the hills, is very gravelly and light; but on the northern extremity, where are plains, though stony, the land is better and stronger, and might be cultivated for all sorts of corn. The whole number of inhabitants amounts only to 3500, most of whom live in the city of Pago, which is supposed to contain 3000. N. lat. 44° 40'. E. long. 15° 10'.

PAGO, a town of the above island, built by the Venetians in the year 1468. This city has undergone various revolutions. The difficulty of access to it, and the bad accommodation it affords to strangers, render the intercourse with it very unfequent; and to this circumstance it is owing that the inhabitants are as wild and unpolished, as if they were ever so remote from the sea, and the commerce of polite people. Even the gentry exhibit grotesque figures, both in their drefs and behaviour; and the ignorance of the clergy is incredible.

PAGOD, or PAGODA, a name which the Portuguese have given to all the temples of the Indians, and all the idolaters of the East.

These pagods, or pagodas, are mostly square; they are stone buildings, which are not very lofty, and are crowned with a cupola. Within, they are very dark; for they have no windows, and only receive their light through the entrance. The image of the idol stands in the deepest and darkest recess of the temple; it is of a monstrous shape, and of uncouth dimensions, having many arms and hands. Some of these idols have eight, and others sixteen arms; with a human body, and the head of a dog, with drawn bows and instruments of war in their hands. Some of them are black, others of a yellowish hue. In some pagodas there are no images, but only a single black, polished stone, lying upon a round altar, covered with flowers and sandal-wood, which were strewed upon it. Greater veneration is manifested for these stones than for the idols themselves. Their worship of these divinities consists in throwing themselves upon the ground, and making their salam, or salutation, with their hands, and ejaculating their prayers in silence, in that posture. The offerings which they are accustomed to present to their gods consist of flowers, rice, pieces of silk and cotton, and sometimes gold and silver. Every thing is laid before the idols, and is taken care of by the Brahmins, who profit the most by it. They guard the pagodas both by day and night. The pagodas of China are lofty towers, which sometimes rise to the height of nine stories, of more than 20 feet each.

In order to give such an idea of these buildings as may enable the reader to judge with respect to the early state of arts in India, we shall briefly describe two, of which we have the most accurate accounts. The entry to the pagoda of Chillambrum near Porto Novo, on the Coromandel coast, held in high veneration on account of its antiquity, is by a stately gate under a pyramid, 122 feet in height, built with large stones above forty feet long, and more than five feet square, and all covered with plates of copper, adorned with an immense variety of figures, neatly executed. The whole structure extends 1332 feet in one direction, and 936 in another. Some of the ornamental parts are finished with an elegance entitled to the admiration of the most ingenious artists. The pagoda of Seringham, superior

in sanctity to that of Chillambrum, surpasses it as much in grandeur; and, fortunately, we can convey a more perfect idea of it by adopting the words of an elegant and accurate historian. This pagoda is situated about a mile from the western extremity of the island of Seringham, formed by the division of the great river Caveri into two channels. "It is composed of seven square inclosures, one within the other, the walls of which are twenty-five feet high, and four thick. These inclosures are 350 feet distant from one another, and each has four large gates with a high tower; which are placed, one in the middle of each side of the inclosure, and opposite to the four cardinal points. The outward wall is near four miles in circumference, and its gateway to the south is ornamented with pillars, several of which are single stones, thirty-three feet long, and nearly five in diameter; and those which form the roof are still larger; in the inmost inclosures are the chapels. About half a mile to the east of Seringham and nearer to the Caveri than the Coleroon, is another large pagoda, called Jembikisima; but this has only one inclosure. The extreme veneration in which Seringham is held, arises from a belief that it contains that identical image of the god Wischnu, which used to be worshipped by the god Brahma. Pilgrims from all parts of the peninsula come here to obtain absolution, and none come without an offering of money; and a large part of the revenue of the island is allotted for the maintenance of the Brahmins who inhabit the pagoda; and these, with their families, formerly composed a multitude not less than 40,000 souls, maintained, without labour, by the liberality of superstition. Here, as in all the other great pagodas of India, the Brahmins live in a subordination which knows no resistance, and slumber in a voluptuousness which knows no wants."

The pagods of the Chinese and Siamese are exceedingly magnificent.

The revenues of the pagod of Jamigrade are so great, as to furnish, every day, from fifteen to twenty thousand pilgrims.

PAGOD is also used for the idol adored in the temple.

Hence, many give the name pagod to those little porcelain images brought from China.

PAGOD, or *Pagoda*, is also the name of a gold coin, current in several parts of the Indies, on the footing of the piece of eight.

There are also silver pagods, struck at Narsingua, Bisnagur, &c. which usually bear the figure of some monstrous idol: whence their names. They are of various values.

Accounts are kept at Madras, or Fort St. George, on the Coromandel coast, in pagodas, fanams, and cash; 80 cash = 1 fanam, and 42 fanams = 1 pagoda. Such is the mode of reckoning used by the East India company, and other European merchants, but among the natives, the value of the pagoda varies from 44 to 46 fanams. The gold coins are star or current pagodas; and the silver coins, Arcot rupees. Double and single fanams are current here, and copper pieces of 20 cash, called pice. Also pieces of five and ten cash, called doodee, and single cash pieces: these copper coins are struck in England, bearing the date of 1803, and the value is marked upon each. The star pagoda weighs 52.56 English grains, and the gold is 19½ carats fine; it therefore contains 42.048 grams of fine gold, and is worth 7s. 5¼d. sterling; but it is commonly valued at 8s. In the company's books, 100 star pagodas are valued at 425 current rupees; and 10 star pagodas at 16 Spanish dollars. Many other coins circulate on the Coromandel coast, of which the most generally current are the following; viz. the old pagoda, with three swamy, or figures, coined at Madras and Negapatam, which is about 20¾ carats fine, and which generally

nerally bears a batta, *i. e.* an agio or discount of 10 *per cent.* against the new coins of the same places: the old pagoda of Negapatam and Tutocoryn, which is of the same value as the star pagoda: the new pagoda of Negapatam and Tutocoryn, which is 18½ carats fine; and is reckoned about 4 *per cent.* worse than the star pagoda: the Porto Nova pagoda, which is 17½ carats fine; and is about 20 *per cent.* worse than the star pagodas: the Pondicherry pagoda, originally equal in value to the star pagoda, but its standard has been lowered to 17 carats, and even less. All these different pagodas are nearly of the same weight. Mohurs, or gold rupees of Bengal, occasionally pass here for four star pagodas. There are also gold fanams, which are only 7½ carats fine, and are alloyed chiefly with silver; 24 of these are reckoned for an old Negapatam pagoda.

Gold and silver are weighed by the current or star pagoda weight, as above stated. At Mangalore, on the Malabar coast, accounts are kept in Sultanee pagodas, rupees, and annas; the pagoda being four rupees, and the rupee, 16 annas: others divide the pagoda into 10 hunas, and the huna into 16 parts, called likewise annas. At Masulipatam, on the Coromandel coast, accounts are kept in pagodas, rupees, and annas; the pagoda being 3½ silver rupees, and the rupee 16 annas. The coins, besides gold and silver rupees, are pagodas of nearly the value of the star pagoda of Madras.

In the Myfore country, and particularly at the capital, Seringapatam, accounts are kept in Canter'raia pagodas, and palams, called by the English Canter'raia pagodas and fanams. This pagoda is an imaginary money, and the fanam, which is a real coin, is the 10th part of the pagoda. The coins are gold mohurs, which pass for four pagodas; sultany pagodas, coined by Tippoo Sultan, and other pagodas, coined by Hyder Ally, and by the rajah of Myfore, all passing for 13 fanams: also, sultany rupees, and rajah rupees, 26 of which pass for 7 sultany pagodas; copper dudus, called by the English dubs, 260 of which are the market price for a sultany pagoda. The shroffs, when they exchange copper for gold or silver, pay at the rate of 234 dudus for a pagoda; but when they change gold and silver for copper, they receive 240; whilst the price fixed by government is 182 dudus *per pagoda*: and the other coins exchange in proportion. At Pondicherry, the coins are gold pagodas, and silver rupees and fanams. Gold and silver are weighed by the star pagoda, rupee, and fanam. A pagoda weighs 9 fanams, or 144 nellos; so that three rupees are equal in weight to 10 pagodas; 71½ pagodas weigh a French mark, or 3778 English grains.

The following table shews the assay, &c. of the several pagodas which it specifies, W. every where denoting worse than English standard, and the mint price of gold in England, that is 3*l.* 17*s.* 10½*d.* *per ounce*, being standard.

	Assay.	Weight.	Contents in pure Gold.	Value in Sterling.
	car. gr.	oz. dwt. gr.	grains.	£. s. d.
* Star pagoda - - - - -	W. 3 0	0 2 4¾	42.	0 7 5¼

* N. B. The fineness of the star pagodas varies from W. 2 car. 3 gr. to W. 3 car. 0½ gr.

The pagodas differ in shape from all European coins: they have a convex side, with prominent dots, and a flat side which generally bears a figure, and in some three figures, of Indian idols. The star pagoda is marked on the convex side with a star; other pagodas are marked with a crescent, or with an initial letter; the pagodas of Masulipatam and Pondicherry have nothing on the convex side but the dots. Tippoo's pagodas have no figure on the flat side, but a legend which is translated thus: "Mahomet, he is the authority of equity," with the date of the Hegira: on the convex side, the name of the place where it was coined, and generally the initial of Hyder. Kelly's Universal Cambiit.

PAGODA Bay, in *Geography*, a bay on the East coast of Cochinchina. N. lat. 12° 21'. E. long. 109° 4'.

PAGON, or ST. IGNATIUS, one of the Ladrone islands, about 36 miles in circumference; 30 miles N. of Amalagan.

PAGOOR, a town of Bootan; 16 miles S. of Tassafudon.

PAGOUA BAY, a bay on the east coast of the island of Dominica. N. lat. 15° 18'. W. long. 61° 19'.

PAGOYUM, a word used by Paracelsus and his followers, to express an imaginary being, which presides over, or is the occasion of diseases, whose causes are less known, and which have been supposed to arise from enchantment. Such is the doctrine of this strange writer, and on this subject he has written a treatise called *Pagoyus*.

PAGRUS, in *Ichthyology*, a species of *Sparus*; which see. See also SPARUS *Dentex*, and SPARUS *Erythrinus*.

PAGUL, in *Geography*, a town of Africa, in Whidah; six miles N.W. of Sabi.

PAHA-CACHON, a town of Thibet; 100 miles S.W. of Hara-Toubé.

PAHANG, PAHAN, or *Pán*, a sea-port town on the E. coast of Malacca, called by the Portuguese "Paon," and by the Arabs "Fân." It is situated about four leagues from the sea, and inhabited only by nobility, the people dwelling in the suburbs. It is inclosed by a wall, made of the trunks of trees joined close together, and about 24 feet in height, strengthened with a bastion. The streets are fenced on both sides with hedges of reeds, and planted with cocoa

and other trees; so that Pahang appears more like an assemblage of gardens than a regular town. The houses are constructed of reeds and straw, the king's palace only being of wood: for Pahang was formerly the capital of a kingdom, but it is now part of Johor. The adjacent country is low, but fertile, producing pepper, eagle and calambac woods, coarse gold, nutmegs, Sapan wood, diamonds, and hog-stones, deemed of superior efficacy to bezoar-stones. In the interior of the country elephants are numerous. N. lat. $3^{\circ} 40'$. E. long. $103^{\circ} 36'$.

PAHANG, or *Pulo-Pahang*, a small island near the coast of Malacca; five miles E. from the town of Pahang.

PAHARGUNGE, a town of Bengal; ten miles S.W. of Beyhar.

PAHAVENS, a town of Persia, in the province of Irak; 30 miles W. of Jedd.

PAHICH, a town of Arabia, in the province of Hedjaz; 60 miles S.E. of Medina.

PAHIE is one of the classes of canoes or boats used by the inhabitants of the islands in the South sea. The pahie is of different sizes, from sixty to thirty feet long, but very narrow; a transverse section of it resembles the spade of cards, the whole being much wider in proportion to its length. The largest pahies are used for fighting, in which case they are fitted with a stage or platform; but principally for long voyages. Hawkefworth's *Voy.* vol. ii. p. 222, &c. See *BOAT (Pahie.)*

PAHO, in *Geography*, a river on the W. coast of the isle of Celebes, which runs into the straits of Macassar. S. lat. $3^{\circ} 10'$. E. long. $119^{\circ} 52'$.

PAHVA, a small island on the coast of Finland, with a town upon it. N. lat. $60^{\circ} 29'$. E. long. $21^{\circ} 30'$.

PAHVITTRAM, a town of Hindoostan, in the Carnatic; 14 miles E.S.E. of Coveripurum.

PAJACK, in *Commerce*, a corn measure in Russia: thus, the chetwert or cool of corn is 2 ofmins, 4 pajacks, 8 chetwericks, or 64 garaitzy. A cool of flour is 9 poods, and a sack 5 poods. The chetwerick is $13\frac{1}{2}$ English inches in diameter, and $11\frac{1}{2}$ in depth; it therefore measures 1555,92 cubic inches, and contains $5\frac{1}{2}$ Winchester gallons nearly. In business the usual calculation is, that 100 chetwerts produce 72 quarters, and 1 chetwert $5\frac{3}{4}$ bushels, Winchester measure.

PAJANA, in *Geography*, a lake of Sweden, in the province of Tavaftland, about 100 miles in length.

PAJAS, a town of Asiatic Turkey, in the government of Marasch and bay of Alexandretta; five miles W. of Alexandretta.

PAJAUNNY, a town of Hindoostan, in Oude; 30 miles W. of Kairabad.

PAICHAM, a town of Chinese Tartary. N. lat. $42^{\circ} 42'$. E. long. $120^{\circ} 22'$.

PAIDORFF, a town of the duchy of Stiria; six miles N. of Muehrau.

PAIGLES, in *Botany*. See *PRIMULA*.

PAIJALA, in *Geography*, a town of Sweden, in West Bothnia; 86 miles N. of Tornea.

PAIL, in *Rural Economy*, a wooden vessel in which milk, water, or other fluids are commonly carried.

PAIL-Brush, in *Agriculture*, a sort of hard brush furnished with bristles at the end to clean out the angles of the vessels more fully. These ought to be in every dairy, though in many districts their use is scarcely known.

PAIL-Stake, in *Rural Economy*, a simple contrivance for drying dairy utensils upon, being merely a bough of a tree furnished with different small branches, which is fixed with its

thick end into the ground in the dairy-yard. The several small branches being lopped of proper lengths, the stumps afford pegs for hanging the pails upon, or for other utensils, by which they are not liable to be blown down and thereby burst or injured.

PAILLY, in *Geography*, a town of Hindoostan, in Vi-fiapour; five miles S.S.W. of Sattarah.

PAIMBŒUF, or PAINBŒUF, a town of France, and principal place of a district, in the department of the Lower Loire, situated at the mouth of the Loire, 21 miles W. of Nantes. The place contains 4220, and the canton 6047 inhabitants, on a territory of $72\frac{1}{2}$ kilometres, in three communes. N. lat. $47^{\circ} 17'$. W. long. $1^{\circ} 97'$.

PAIMPOL, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of St. Brienc; seven miles E. of Treguier. The place contains 1679, and the canton 16,319 inhabitants, on a territory of $127\frac{1}{2}$ kilometres, in 11 communes.

PAIN, DOLOR, $\alpha\lambda\gamma\eta$, in *Medicine*, an uneasy and distressing sensation, which is connected with various forms of disease, and with various species of injury, inflicted upon the living body.

As we are altogether unable to explain the nature of sensation, and the agency of the nervous system, as the organ of that faculty; so it is impossible to give any satisfactory account of the proximate cause of pain. As in all similar cases, we must content ourselves with considering it as an ultimate fact, and with observing the various circumstances under which it occurs, and the different phenomena which accompany it. All the attempts which have been made to explain its nature, being founded entirely upon hypothetical speculations that have been altogether gratuitous, are justly exploded.

The varieties of pain can only be described by referring to the common agents by which they are excited, to the parts of the body in which they are seated, or to the degree and duration of their occurrence. The external agents, which produce painful sensations, operate variously upon the living body; some by mechanical, and some by chemical action upon the animal fibre; while others act by a peculiar influence upon the nervous system, without deranging the structure of the sentient parts. The mechanical agents are all such as tend to produce a solution of continuity in the solid parts, to interrupt the circulation of the blood in them, and to produce an extravasation of the fluids from their proper vessels: whence pain is a consequence of blows, bruises, and continued pressure, of laceration from the bites of animals, of abrasion, of the cutting and stabbing of sharp instruments, &c. The chemical agents produce a solution of continuity, by inducing the parts of the living body, like dead matter, to enter into new combinations: whence pain is the consequence of the action of fire, or intense heat from any source, and of a number of acrid substances, which corrode the substance of the body, such as the strong mineral acids, the pure alkalies, &c. Again, the third class of external causes of pain consists of those agents, which act speedily upon the sentient system, injuring its functions, without lesion to any organic structure; namely, the venomous and narcotic secretions of animals and vegetables, which are called poisons. As the operation of these various exciting causes occasions many modifications of pain, which are probably very similar in different individuals, we are thus furnished with a language, by which the various painful sensations may be described to those who feel them not. Thus we speak of a burning, stinging, pricking, gnawing, cutting, or lacerating pain. Pains are also distinguished by other

PAIN.

other concomitant sensations, such as by being connected with a sense of weight, of throbbing or pulsation, of rawness or excoriation, of tension or contraction, of formication or the creeping of insects, of shooting or darting through particular parts, of coldness, of torpor or numbness, and so forth. Some pains, again, are characterized by remaining fixed and immovable; while others are flying or wandering pains, leaving one part and seizing upon others in succession; and others are periodic or intermittent, ceasing altogether for a certain number of days or hours, and recurring with great regularity, like the paroxysms of an ague.

Many of the causes above-mentioned, however, do not immediately excite pain, but indirectly, by producing one of two morbid conditions, which are invariably accompanied by pain; we mean *inflammation*, or *spasm*: whence pain frequently occurs, as a symptom of these diseases, arising from internal causes, and independently of the violent operation of the external agents above enumerated. The diagnosis between these two sources of pain, in many maladies, is of the utmost practical importance, as the indications of cure are nearly of an opposite nature in the two cases.

Before we come to these practical points, it may be proper to notice some pathological facts, which are worthy of observation. It is obvious, that the nervous system is the medium of sensation, or the communicating link between the parts receiving the impression, and the common sensorium, the brain, where the perception is produced. For if the nervous trunks are divided, and the communication cut off, the parts of the body, so insulated, may be cut or otherwise injured without pain, and even without the cognizance of the individual. Hence the pain cannot be said strictly to be seated in the part to which the sensation is referred. This is illustrated in a remarkable manner in case of the loss of limbs by amputation or accident. The patients, in these instances, often complain of pain in the fingers or toes of their lost arm or leg; a sensation, which can only arise from the impression which the wounded nerve makes upon the brain, being similar to that which it had been accustomed to convey from the extremity of its branches, while the limb remained perfect. In other cases, again, the pain is not even referred by the mind to the actual seat of the irritation which induces it, but to some other point, at a distance from it. Thus the part which is the seat of unceasing sensation, when the cells of the lungs are loaded with mucus, blood, or other matters, is the top of the larynx, or wind-pipe, which excites the effort of coughing, to expel the offending substance, and which subsides when the cells are unloaded. In a similar manner, in inflammation of the liver, the pain which is most complained of is not always seated in that organ, but is often referred to a small space at the top of the shoulder. And in all cases of irritation in the urinary bladder, whether from the presence of a stone or gravel in that sac, of acrid urine, of blood, pus, or other foreign matter, the most poignant irritation is often seated at the extremity of the urethra. The facts are not easily explained, but are necessarily referred to some peculiar communication of sympathy through the distribution of the nerves.

It is a curious fact, which has been attempted to be explained in various ways, that pain is much alleviated by certain exertions of the voluntary muscles; whence, in all cases of violent pain, persons are observed to resort to some species of exertion, such as grasping any thing strongly, fixing the teeth, exerting the voice in screams or moaning, &c. Dr. Darwin, with his accustomed acuteness, generalizes this observation to a great length. "The restlessness

in some fevers," he says, "is an almost perpetual exertion of this kind, excited to relieve some disagreeable sensations; the reciprocal opposite exertions of a wounded worm, the alternate emprosthotonos and opisthotonos of some spasmodic diseases; and the intervals of all convulsions, from whatever cause, seem to be owing to this circumstance of the laws of animation; that great or universal exertion cannot exist at the same time with great or universal sensation, though they can exist reciprocally; which is probably resolvable into the more general law, that the whole sensorial power being expended in one mode of exertion, there is none to spare for any other." *Zoonomia*, vol. i. sect. xxxiv. 1, 2.

This idea of the two great powers of motion, sensation and volition, in the animal machine, is, Dr. Darwin thinks, confirmed by the observation, that they never exist in a great degree or universally at the same time; and hence he would account for the fact, stated above, that we instinctively exert our voluntary motions, when suffering severe pain or uneasiness, and thus procure ourselves relief. The ingenuity with which he illustrates the modes of exertion, in cases of bodily suffering, is peculiarly his own.

"When any violent pain afflicts us, of which we can neither avoid nor remove the cause, we soon learn to endeavour to alleviate it, by exerting some violent voluntary effort, as mentioned above; and are naturally induced to use those muscles for this purpose, which have been in the early part of our lives most frequently, or most powerfully exerted. Now the first muscles, which infants use most frequently, are those of respiration; and on this account we gain a habit of holding our breath, at the same time that we use great efforts to exclude it, for this purpose of alleviating unavoidable pain; or we press out our breath through a small aperture of the larynx, and scream violently, when the pain is greater than is relievable by the former mode of exertion. Thus children scream to relieve any pain either of body or mind, as from anger, or fear of being beaten. Hence it is curious to observe, that those animals, who have more frequently exerted their muscles of respiration violently, as in talking, barking, or grunting, as children, dogs, hogs, scream much more, when they are in pain, than those other animals, who use little or no language in their common modes of life, as horses, sheep, and cows.

"The next most frequent or most powerful efforts, which infants are first tempted to produce, are those with the muscles in biting hard substances. Hence when a person is in great pain, the cause of which he cannot remove, he sets his teeth firmly together, or bites some substance between them with great vehemence, as another mode of violent exertion to produce a temporary relief. Thus we have a proverb, where no help can be had in pain, "to grin and abide;" and the tortures of hell are said to be attended with "gnashing of teeth." Hence in violent spasmodic pains, I have seen people bite not only their tongues, but their arms, or fingers, or any object which was near them, &c.

"If the efforts of our voluntary motions are exerted with still greater energy for the relief of some disagreeable sensation, convulsions are produced; as the various kinds of epilepsy, and some hysterical paroxysms. In all these diseases, a pain or disagreeable sensation is produced, frequently by worms, or acidity in the bowels, or by a diseased nerve in the side, or head, or by the pain of a diseased liver." *Loc. cit.*

To this view of the subject it might perhaps be objected, that the exertions and convulsive motions, if they were excited by the pain, should be proportionate to the violence of the pain; which is not the case. This objection, however,

PAIN.

is entirely obviated by the consideration, that the nervous system suffers a greater degree of irritation from many sensations, that are even in some degree pleasurable, than from intense pain. This is exemplified in respect to tickling. Children have been tickled into convulsions; and perhaps no pain is so intolerable as that of tickling, if the violent efforts of laughing and of moving the limbs were to be restrained. The writer of this article has been informed by a very intelligent gentleman, who is subject to constant and severe convulsive actions, of the nature of St. Vitus's dance, that they are clearly the result of disagreeable sensations, not always amounting to what may be called pain. In this way, it seems to happen, that the most violent and fatal convulsive malady with which we are acquainted, the *tetanus*, or locked jaw, is produced from the irritation of a wound, but not from a deep and open wound, but from a slight abrasion of the skin, or from a wound that is just healed.

Independently, then, of the suffering which pain occasions, its effects on the animal economy are sufficiently severe to induce us to search for the means of relieving it. It never exists long without exciting some degree of fever, and disturbing the functions of life, especially that of digestion; whence also debility and emaciation ultimately follow: frequently it brings on delirium, syncope, or fainting, and convulsions of every species, besides those already mentioned, and even occasions death itself. In many diseases, therefore, it is an important object to alleviate pain, even where such alleviation has no remedial effect upon the disease, of which it is a symptom.

With a view to the successful alleviation of painful diseases, it is necessary to establish a clear diagnosis with respect to the origin of the pain; for the treatment, which will cure one variety, will aggravate another, and even accelerate the fatal termination of the disease which it accompanies.

Violent or *acute pain* originates, in general, from acute inflammation of some organ, or from *spasm* in a muscular part. The former species of pain accompanies inflammation of all the viscera; occurring in the head, in phrenitis, or inflammation of the brain; in the chest, in pleurisy, and inflammation of the heart, or of the diaphragm; in the right side, in inflammation of the liver; in the abdomen, in enteritis and peritonitis; in the loins, in nephritis, and so on. The spasmodic pain occurs in the muscles of the limbs, in cramp; in the bowels, in colic; in the stomach, in gastrodyria; in the uterus, during the time of parturition; and in the muscles of the jaw and of the spine, in locked jaw and tetanus, &c. In some of these cases, the obvious appearance of rigid contraction, or spasm, in the muscles of the pained parts, as in the cramp, locked jaw, and tetanus, is sufficient to point out the nature of the pain. But in regard to the internal pains, the principal source of diagnosis is the presence or absence of a state of *fever*. Acute inflammation cannot exist, without an increased velocity of pulse, which is also commonly strong, or at least hard, and wiry, and not easily compressible under the finger: there will also be thirst, heat of skin, a dry and foul tongue, with failure of appetite, and some prostration of strength. When the pain arises from spasm, the symptoms of fever are generally absent; the pulse is often not altered in its beats, but remains moderate, soft, and compressible; the tongue continues moist, and without fur; there is no particular thirst, nor any sense of heat, succeeding chilliness; and the animal functions are not much disturbed. It is principally from these circumstances that the nature of pain, in any one seat, is ascertained: thus in inflammation of the bowels, and in spasmodic colic, the seat and the degree of severity of the

pain are often precisely similar, and can only be thus decidedly distinguished. Some other circumstances, however, require attention as auxiliary to the diagnosis: for instance, in inflammation, *pressure* upon the part pained aggravates the evil, and a sense of *soreness* is felt under the touch; while, in spasm, the parts are not generally tender, but the pain is often relieved by pressure, and even by *friction*. In inflammatory affections, again, the pain remains *fixed* in one spot, and regular in the degree of its intensity; whereas, in spasmodic ailments, the pain is commonly *moveable*, wandering from one point to another, as the spasm suddenly relaxes in one set of muscular fibres, and recurs in others; and it is commonly *sudden* in its attack, and *remittent* in its degree, being aggravated and alleviated by fits or paroxysms.

The progress of an internal inflammatory disease may often be ascertained, and the nature and period of its termination anticipated, by an attention to the variation of the pain, together with other symptoms. Thus if, after some continuance, an acute inflammatory pain gradually becomes more obtuse, is accompanied with a sense of weight and tension, and at length with a sensation of throbbing or pulsation, it is most probable that suppuration has commenced, and that the disease must terminate in abscess; and there will be no doubt of this, if at the same time the fever begins to remit, and paroxysms of rigour, followed by flushes of heat, come on daily: in other words, if the fever put on a hectic type. Again, if, during the continued severity of the pain and fever, the former should *suddenly cease* altogether, the practitioner is not to suppose his patient recovering: it is probably an indication that *gangrene* has come on, and that the life of his patient is near its close. This will be placed beyond a doubt, if, at the time of the cessation of pain, the pulse loses its sharpness, and becomes small and feeble, with a tendency to coldness in the extremities, and a sinking of strength.

Another material consideration, in estimating the probable event of a painful disease, is the importance of the organ in which it is seated. An inflammation in any of the viscera, immediately subservient to the great functions of the living body, is always attended with danger, especially in the brain, stomach, or bowels; because the functions of these organs cannot be interrupted with safety to the vital machine. But an inflammation, however violent, may occur in the external muscular or ligamentous parts, as in the joints and limbs, without much risk to the safety of the system. It is never to be forgotten, however, that what is called a *metastasis* of such external inflammation to an internal organ, (of which both gout and acute rheumatism afford many examples,) that is, the occurrence of inflammation in some internal viscus, immediately upon the spontaneous disappearance of external inflammation, is always an alarming circumstance, and leads to an unfavourable prognosis.

Of the more chronic varieties of pain, it is not necessary to treat at any length, as they are commonly accompanied by other symptoms of disease, which are equal objects of medical attention, and which contribute to point out the nature of the malady.

The diagnosis being once established, in cases of acute pain, according to the principles above stated, the selection of the proper *means of cure* will be perfectly easy: but if a mistake is committed in determining the first point, the misapplication of the remedies will be of serious injury. For if the expedients, which will presently alleviate spasmodic pain, be administered for the removal of that which is inflammatory, it is scarcely possible that aggravation should not follow; and

and in many cases, on the contrary, when the proper remedies for inflammation are applied for the relief of spasmodic pain, an injurious effect, scarcely less severe, may be expected to result. Yet in the popular practice, no mistake is so common as the former of these errors.

For the cure of violent inflammatory pain, such as occurs in phrensy, pleurisy, and inflammation of the stomach or bowels, evacuations by blood-letting, both general and local, by external vesication, and by the use of cathartics, are the means which must be adopted, and executed with expedition; while every stimulus, in the way of food, drink, and medicine, must be cautiously interdicted, and the whole antiphlogistic system rigidly pursued. But in the feeble and debilitated constitutions, in which spasmodic diseases often occur, such a plan might aggravate the malady, and reduce the constitutional powers to a dangerous state of imbecility. On the other hand, in the constitutions just described, and in most cases of spasmodic pain, the most effectual remedies are opiates, combined with stimulants of the most powerful and diffusible kind, such as alcohol, suspending the stimulant gums and essential oils, ammonia, preparations of ether, &c. Yet it is scarcely necessary to remark, how directly adverse to inflammatory affections such medicines must prove. It is, therefore, lamentable to reflect upon the indiscriminate resort, which is popularly made to spirituous and hot liquors, under all internal pains, especially in their commencement; and the necessity of attending to the marks of distinction above pointed out, or of delaying all remedies until proper medical assistance be procured, in cases of the attacks of such diseases, cannot be too strongly enforced.

PAINS, After, in Midwifery. See *AFTER Throes* or *Pains*.

PAIN-d'Abeiles, a word used by some to express what the ancients called *ambrosia*, or the yellow substance found concentered in lumps on the legs of bees, and supposed by the generality of the world to be real wax.

Experiments made by Mr. Reaumur and others, have sufficiently proved that this substance is not wax, nor has it any of the properties of wax; but it has been conjectured, that this is the matter out of which wax is finally made.

In tracing this substance up to its origin, we find that the bees collect the farina of flowers, which, when moulded by their feet into a lump, makes this matter. It is very probable, that they feed on this matter, and, as some imagine, after passing through certain changes in their bodies, it becomes wax. This was an opinion so old as the days of Pliny; some of the authors he quotes calling this substance *ambrosia*, or the food of these little deities; but later observations overthrew this opinion, till it again got credit under the more accurate examinations made by Mr. Reaumur, on the structure and parts of the bee. This is a food not only eaten occasionally by the bees, but necessary to their support, and is found stored up in their hives against a bad season. The combs have their different cells made for different purposes; and, beside that, some are destined for receiving honey, and some for the young worms which are hereafter to become bees; there are some also which serve to contain this yellow matter, collected on the legs of these insects. In fine weather, when more of this matter is collected than is eaten for immediate nourishment, the bees scrape off the lumps of it from their legs into some of the holes, or cells of the combs, where, others following their example, there finally become large reserves of it; which are eaten on such days when they cannot go out in search of more.

The bee collects this yellow matter, which, according to

Reaumur, is the prime constituent of the wax, from whatever flowers happen to be most plentiful about the hives; and though generally yellow, as the farina of most plants is so, yet it is sometimes seen in red or green lumps on their thighs; but whatever be its natural colour, it is always turned yellow before it is discharged from the body of the animal; and when the stomach of any of them is dissected, after feeding on a red substance collected from flowers, the farina of which is of that colour, the change is found to be made as to colour in this part, for the whole is found there in form of a yellow jelly. This matter, taken out of the stomachs of several bees, and dried, is found to be of a disagreeable smell, like fermented matter, and of a pungency somewhat resembling that of the volatile salts. Mr. Reaumur was hence induced to try the effect of the volatile salts in turning the bees bread, or rough wax, into perfect wax by digestions, continued a long time, but in vain. If we may give credit, however, to the German Ephemerides, there is a much more easy way of reducing this matter, while yet contained in the apices of the plant, into true wax; and that without the assistance of the work of the bees. Mr. David Maja gives an account, in those papers, that the persons he employed in beating roses into conserve, always observed in the pounding of the roses, before the sugar was put to them, that a piece of solid but soft matter was found adhering to the pestle of the mortar, which, on a strict examination, proved to be true and genuine wax. It appeared from this experiment that the juice of the petals or leaves of the roses, was able, by the assistance of beating, to convert into true wax the farina contained in the apices of that flower. Mr. Reaumur tried what effect the juice of roses would have on the yellow matter collected on the legs of the bees, and on the farina of plants, but no treatment he could give these substances was ever able to produce wax. Mr. Reaumur alleges as an absolute proof, that the bees eat the rough wax or bees bread; that, by observing the bees of a certain hive to come home loaded with it every day, several times over, during the month of April, and a great part of May; and after this, opening and examining the hive they belonged to, there were found no new combs, nor were the old bees enlarged in size; it is true, that there were some cells found filled with magazines of this matter, but as the far greater part was brought to no sort of account, it seems very plain that they had eat it. It is to be observed, that the bees have their several periods of going out in search of this matter and of honey: it would be too fatiguing for them to be always thus at work; and to avoid this there is always a very large part of them, even more than half the hive, found at rest within it; these are such as have worked till they are tired, and the others in turn take this manner of resting, and send these out to work again. Reaumur's Hist. Inf. vol. x. p. 68.

But it is necessary to add, that Butler, Purchas, Rusden, and Thorley, very accurate observers of the various operations of bees, have urged several arguments to disprove the identity of the substance now described, and wax. When the hives, they say, have been for a year or more filled with combs down to the floor, and there is no more room to build, the bees carry in this matter in the greatest plenty; and even when no more wax is wanting, besides the small quantity which is required for sealing up the honey and the breeding cells. They also urge, that this substance is very different from wax; as the particles of the former will separate from each other, and be crumbled to powder when examined between the fingers, whereas those of the latter will adhere, and cleave together; and if the one be carried to the fire, it will melt and dissolve, whereas the other will be converted into

into ashes and dust. The difference of the colours of this substance is an additional proof that it was not wax, which, when it is gathered and wrought into combs, is always white, and the change of its colour is owing merely to the age of the combs, and breath of the bees. Besides, it is observed, that new swarms for the first, second, or third day, carry in little or nothing of this matter; though in that space of time they have conveyed into the hive sufficient quantities of wax, formed into several large combs: on the contrary, when they carry in the greatest quantity of this matter, they collect the less wax: because the new swarms want the wax, and the old stocks want food and nourishment for their young. Moreover, Mr. Thorley found upon the belly of a bee, which he caught as it was entering the hive, within the plaits, no less than six pieces of solid wax, perfectly white and transparent: and he has also at other times found wax in the same situation. Thorley's Inquiry into the Nature, &c. of Bees, ed. 1774, p. 106. See WAX.

PAINÉ *Fort, & Dure, in Law*, an especial punishment, formerly inflicted on one, who, being arraigned of felony, refused to put himself upon the ordinary trial of God and his country, and thereby stood mute by the interpretation of law.

This is vulgarly called *pressing to death*. The process whereof is thus described:

"He shall be sent back to the prison, whence he came; and he laid in some low dark room, where he shall lie naked on the earth, without any litter, rushes, or other cloathing, and without any raiment about him, but only something to cover his privy members; and he shall lie upon his back with his head covered, and his feet; and one arm shall be drawn to one quarter of the room, with a cord, and the other arm to another quarter, and his legs in the same manner; then let there be laid upon his body iron, or stone, as much as he may bear, or more; and the next day following, he shall have three morsels of barley-bread without drink; and the second day he shall have drink three times, as much at each time as he can drink, of the water next unto the prison, except it be running water, without any bread; and this shall be his diet, till he dies."

This species of punishment is now discontinued by 12 G. III. cap. 20. See MUTE.

PAINIM, the same with Pagan.

PAINOM JEUNG, in *Geography*, a town of Thibet, on the Painom-tchieu; 122 miles S.S.W. of Lassa. N. lat. 29°. E. long. 89° 8'.

PAINOM-TCHIEU, a river of Thibet, which runs into the Burhampooter; 15 miles S. of Sgigatchee-Jeung.

PAINOUÇ, a town of Chinese Tartary. N. lat. 41° 56'. E. long. 119° 49'.

PAINSWICK, a small market-town in the hundred of Bisley, and county of Gloucester, England, is seated on the southern declivity of Sponebed-hill, at the distance of six miles S.S.E. from the city of Gloucester, and 101 miles W. by N. from London. It is a town of considerable antiquity, being mentioned in Domesday book under the name of Wiche. The manor then belonged to Roger de Laci, who, joining in the rebellion excited by Robert Curthose against his father, was deprived of all his possessions. On this event Painswick became the lordship of Pain Fitz-John, from whom it derived the former part of its present designation. Since that period it has been inherited by several noble personages, and among others by the lords Talbot, one of whom obtained a grant, in the year 1400, to recompense the widows of those persons who were slain in foreign wars, "it having been represented that eleven married men out of sixteen had

lost their lives beyond the sea; and the widows were allowed to marry with whom they list."

Painswick consists of several streets, very irregularly built. The church, dedicated to St. Mary, is the only edifice worthy of notice. This building has a nave, a chancel, and a north and south aisle, with a tower and spire at the west end, rising to the height of one hundred and seventy-four feet. Its style of architecture is mixed and incongruous; the south aisle, which is modern, is supported by Doric pillars, and the entrance is beneath an Ionic portico, while the body of the church is in the pointed style. The spouts under the battlements of the north aisle, represent singularly grotesque heads of demons. In the chancel are several monuments of the Jerningham family.

According to the parliamentary returns of 1811, this town and parish contains 674 houses, and a population of 3201 persons, a great proportion of whom are employed in the woollen trade.

Above the town, on the summit of Sponebed-hill, is an ancient entrenchment, designated by the different appellations of Kimsbury-castle, King's-Barrow, and Castle-Godwin. This fortification is of a square shape, and has a double ditch and vallum. The inner rampart incloses an area of about three acres, and as well as the outer one is still of considerable height, though both have of late years suffered great dilapidation for the sake of the stones employed in constructing them. This encampment is supposed to have been of Roman origin, as coins of that people are frequently dug up within its area. It was afterwards, however, occupied by earl Godwin during the insurrection made for the expulsion of all foreigners from the kingdom; and again by the royalist army after the siege of Gloucester, in the time of the grand rebellion. The position of this entrenchment, in a military view, is excellent, as from its loftiness it overlooks a large tract of the adjacent country.

Haresfield parish, to the westward of Painswick, contains some vestiges of antiquity. On the high ridge of hills, which shelter the village, is a very singular entrenchment, conjectured to have been a station of the Romanized Britons. It extends on one side 600 yards in length, and is defended by a single vallum fifteen feet high. Connected with this work is another, (partly in the parish of Standish,) which incloses the bold promontory, called Beacon-hill, by a "transverse vallation fifty feet deep, and containing fifteen acres." At Harescomb is the site of an ancient castle of the Bohuns. Beauties of England and Wales, vol. v. by E. W. Brayley and John Britton, F.S.A. Bigland's History of Gloucestershire, vol. ii.

PAINT, BLACK OIL, in the *Arts*, is prepared by grinding, with a proper quantity of oil, the charcoal or soot blacks, or the natural black earths, or the pit-coal, till they are united into a smooth, uniform, thick compound, which is occasionally diluted with more oil to a due consistence for being worked freely with the brush or pencil. The finest black colour is made with ivory black, ground before the addition of the oil, into an impalpable powder. The material most commonly made use of is lamp-black, the unctuousness of which disposes it to mix more easily and perfectly with oil than other pigments; but it derives hence the imperfection and disadvantage of drying slowly, which may be remedied by a due preparation of the oil; as by setting it on fire, and boiling it, as in the method of making printing-ink. An opaque deep black paint with water, is made by grinding ivory-black with gum water, or with the liquid which settles from white of eggs, after they have been beaten up and suffered to stand a little. Some use gum-water and the white of eggs together; and observe that a small addition

of the latter makes the mixture flow more freely from the pencil, and improves its glossiness. Lewis's Com. Phil. Techn. p. 356, &c.

PAINTED LADY, among the *Florists*, a term for a particular sort of carnations, the flowers of which have all their petals red or purple on the outside, and white underneath.

PAINTED Lady Pea, in *Gardening*, the common name of an ornamental pea. See LATHYRUS.

PAINTED Post, in *Geography*, a township of America, in Steuben county, New York, on Tioga river, between Bath and Newtown; containing 262 inhabitants.

PAINTEN, a town of Bavaria, in the principality of Neuburg; 11 miles W. of Ratibon.

PAINTER, in *Naval Language*, a rope employed to fasten a boat either alongside of the ship to which it belongs, or to some wharf, key, &c. as occasion requires. See SHANK-*Painter*.

PAINTER, in the *History of the Arts*, one who possesses and practises the art of painting.

PAINTER'S Harbour, in *Geography*, a port on the W. coast of Cape Breton. N. lat. 46° 22'. W. long. 61° 16'.

PAINTERS, House. The price of painters work is limited by statute, and they shall not take above 16*d.* a-day, for laying any flat colour, mingled with oil or size, upon timber, stone, &c. and plasterers are forbid using the trade of a painter in London, or to lay any colours of painting, unless they are servants to painters, &c. on pain of 5*l.* But they may use whiting, blacking, red lead, ochre, &c. mixed with size only, stat. 1 Jac. I. cap. 23.

Painting is measured by the square yard in the same manner as waincoting, the mouldings being measured by a thread; the sashes of windows are paid for by the piece; and it is usual to allow double measure for carved mouldings, &c.

PAINTING, the Art of, is the art of imitating the appearances of natural objects, by means of artificial colours spread over a surface; the colouring substances being used either dry, as in crayon painting; or compounded with some fluid vehicle, as oil, water, or solutions of different gums and resins in oil or spirits, &c.

The theory and practice of this ingenious and delightful art, are divided by its professors into five principal parts; *viz.* *invention*, or the power of conceiving the materials proper to be introduced into a picture; *composition*, that of arranging those materials; *design*, that of delineating them; *chiaro-scuro*, or the arrangement and management of the lights and shades, and of light and dark colours; and *colouring*, whose name sufficiently designates its end.

Each of these principles we have already amply discussed in separate articles; and our readers will also find the more minute, though not less useful, subdivisions of them explained and illustrated under their respective designations. (See EFFECT, ELEGANCE, EXPRESSION, &c.) We shall in this place, therefore, confine ourselves to the treatment of the subject generally, rather than technically; and trace its history from its first application as an arbitrary means employed to relate or record a mere fact, in a rude and formal manner, such as it was found practised among the Mexicans, (see Robertson's America,) to that high state of cultivation, when it was employed to soften and mould the heart, by impressing it with sentiments at once moral, lovely, and energetic.

Nature has denied to few the passions and feelings which are the basis of the imitative arts; and most men delight in beholding their productions. The desire of imitation appears to be so congenial to the mind, that one can scarcely

imagine there could have been any lengthened period of time when it was not called into action, as an agent, either of amusement, of information, or of instruction. Of drawing or painting more particularly, it appears reasonable to suppose, that it must have been adopted for either or all of these purposes, in the earliest stages of human society; though in its very simplest and rudest form.

It will be therefore a vain attempt, if we endeavour to trace the period when the art began its original essays, as an assistant towards communication between man and man; as a means of adorning their persons, or amusing their minds. A state of indolence and ignorance, such as that of savage nations whose sole occupation, dictated by necessity, consists in procuring the necessaries of life, by becoming acquainted with the productions of nature, never appears to have prevented the practice of the ruder elements of it; and it is not improbable that the waste of time between the active periods of exertion in the chase, might itself have been the cause of the first step towards imitation. In pure indolence of thought, or by accident, the first trace of form might have been made in the sand, or on the body; or resemblances observed in sticks or stones, have given rise to the idea of imitating by lines and colours the appearances of natural objects. Among the rudest, most uncultivated nations which our circumnavigators have within the two last centuries discovered, unless it be the natives of New Holland, and that may admit of a doubt, none are without the rudiments of art. Some exhibit it by carving what they consider as ornamental forms, &c. on their instruments of war, their idols, or their utensils. Others, in more refined attempts, adorn their persons by coloured lines and figures; puncturing their skins, and rubbing in powders of various colours, which become by that means indelible. All display the influence of natural principle in this particular; and from these rude employments of the inventive and imitative faculty, the progress appears neither unnatural nor difficult, till we find it adopted as a substitute for language; transmitting an image and record of events before the invention of writing; and even in a more universal, though in one view more confined manner, than that later invention is capable of.

Although thus early the art of painting may be supposed to have allured the attention of men, to have excited their inherent taste for imitation, and in this find the basis of a durable principle for itself whilst mankind exists; yet, when the mere object of conveying ideas was once completed, its advance towards that cultivation of which we now know it to be capable, was extremely slow. Being more an adjunct to the pleasures than the necessities of human life, it could not experience that attention which alone carries it forward, when time was occupied almost exclusively in procuring necessary food; and before intellectual education had made men acquainted with its true value. Painting may exist in a state of ignorance, but has never been known to flourish, except at the periods wherein human cultivation was most assiduously encouraged, and ardently pursued; and even in the highest stages of mental acquirement, and when that art was most devotedly admired, and industriously practised, it struggled with difficulties proportioned to its value, and the delight it is calculated to afford; and few have been the happy mortals who have enjoyed the blessing of shining pre-eminent in the exercise of it.

Such are the uncertainties attending the traditional history of the progress of the arts of design in the countries to the east of Syria, which relate to the probability of their having been first practised there, and thence travelled through

PAINTING.

Persia to Egypt, where they are said to have been domiciliated six thousand years before they were introduced into Greece; that we shall not scruple to lay them aside, and commence our history of painting from the time when we have the earliest actual account of its existence; *viz.* in the reign of Ninus and Semiramis, king and queen of Assyria; about 2000 years before the commencement of the Christian era. Of the art of painting at this period, we have but a glimpse, and are then immersed in the same obscurity as before, where nought but conjecture and arguments drawn from subsequent events are the guides.

Diodorus Siculus relates, lib. ii. "that Semiramis having thrown a bridge over the Euphrates at Babylon, erected a castle at each end of it, and enclosed them by three walls of considerable height, with towers upon them;" these were built of brick, painted and burnt. These paintings exhibit a very great advance in the arts for that early period; for he says, "the bricks were painted before they underwent the fire," (so that, if this account be correct, here was enamel as well as painting), and that not only there were single figures of animals represented in colours, but they were also combined in groups; one, a hunting piece of considerable length, wherein the queen herself was represented on horseback, throwing her dart at a panther; and near her Ninus striking a lion to the earth with his spear." They were of great extent, covering walls and towers attached to them. One other mention of painting is found in the same author, concerning the same period, and under the guidance of Semiramis; and that is, of paintings in the temple dedicated to Belus, and founded by her. In them were represented monstrous figures, exhibiting hermaphrodites and centaurs; or unnatural combinations, probably allusive to the idolatry of the time. Diodorus also mentions the situation of the arts in Egypt at about the same period, where probably they had attained nearly the same degree of cultivation: sculpture, as best serving religious purposes, being in both countries carried much farther than the sister art of painting.

From Egypt the arts were supposed to have been transplanted to Greece, where a more genial culture awaited them; where they had not to struggle with such impediments as arose from the government and habits of Egypt; and where alone, in the more early period of the world, they are found to have been fully brought into action. In other countries, where any trace is visible of them, wrought before the Greeks had exhibited their power, the best exemplars are little better than hieroglyphics; and most probably they never far exceeded the efforts of youthful learners of the present day.

It is, doubtless, to the Greeks alone we are indebted for the highest cultivation which the imitative arts have known. In sculpture they attained so high a pitch of excellence, as to remain unrivalled to this moment; and it is probable, that as far as relates to the perfect imitation of a single figure, in taste, in expression, and in execution, the same may be said of their painting: but there is much reason to conclude, that in many branches of that art they are surpassed by the best among the moderns. In Egypt, the knowledge of what is most desirable in art, selection, never appears to have operated far. When a specific form of character was once adopted, there it remained, and was repeated unchanged for generations. Little action was given to figures, and no attempt at all at expression. Pliny says, that the statues made by the Egyptians in his time, differed in no respect from those made by them 1000 years before. Of their painting, a few figures remain to us; but their date is by no means clear. Two of them, seen at Thebes,

and described by Bruce, are supposed by him to be of the time of Sesostris (about 700 years B.C.), who is said to have beautified and restored that city; but this is mere conjecture. Of these paintings, he remarks, that they may be compared with good sign-paintings of his day.

It appears very probable that the practice of improved art, improved in comparison with the very rudest periods, was very widely diffused. Pliny, besides mentioning the culture of it in Egypt, speaks of paintings at Ardea in Italy, older than the foundation of Rome. Unfortunately we cannot follow this author precisely, in his account of the rise of the art in that country, any more than in Greece. By his own statement, the only guides he had, except tradition, *viz.* the Greek writers, were extremely incorrect. But though we may not trust our judgments with him on the era of the rise of painting, yet the plan he offers us of its progress, the imperfection of its first essays, the gradual advance towards perfection by the addition of new and more valuable qualities, and the retrograde steps it fell into after it had reached its acme, present an order of things so precisely following the system of nature in every part, that we cannot hesitate to give complete faith to it.

After smiling at the claims of the Egyptians, who said that the art had been known and practised in Egypt 6000 years before it was introduced into Greece, he says, that it was not practised in Greece till after the siege of Troy; a circumstance certainly not credible, if the story above related of Semiramis be true; and if Homer be correct in imputing so much of sculpture as he does to the artists of that period; or the amusements of Penelope, of Andromache, and of Helen, at their looms, be at all founded in fact. It is not probable that so much of other arts, particularly of weaving coloured designs, should exist, without some advance being made at the only source whence it is natural to imagine they could arise. It is vain to discuss the point; nor is it of much consequence whether it were at Corinth or at Sicily that the practice of drawing first attracted particular notice. But, as Mr. Fuseli has beautifully observed in his first lecture, "if ever legend deferred our belief, the amorous tale of the Corinthian maid, who traced the shadow of her departing lover by the secret lamp, appeals to our sympathy to grant it."

The first essays, then, of this delightful art were merely outlines of a shade, such as are still made use of in that agent of the science of physiognomy, termed a *silhouette*; with no line within, no shade, or colour; and they were therefore called *skiagrams*. The next step was to the monogram, or lines within the outline; and afterwards to the monochrom, or outlines filled up with one single colour. This, by study, and a more scientific mode of proceeding, advanced to the polychrom, or picture of many colours; and at length was perfected by that harmony of tone, so exalted in the hands of Apelles and his contemporaries.

Pliny mentions the name of Saurias, as one who practised the earliest stage of the art, and of his drawing the figure of a horse; and of Philocles the Egyptian, Cleantes of Corinth, Ardices of the same place, and Telephanes of Sicily, who advanced to the monographic. Cleophantes of Corinth is said to have been the first who practised the monochromatic, and his colour to have been that of a pounded tile. In concurrence with him, or after him, wrought Hygiemon, Dinias, and Charmas; and probably one of these improved the monochromatic style, so as not to make a whole picture, containing many figures, of one colour in every part; but varied the colours, so as to characterise the different objects introduced. According to Quintilian, (lib. ii. c. 3.) "they could so manage the single colour, which they used in the monochro-

PAINTING.

monochromatic style, as to give every appearance of relief to parts;" but by what means, as light and shade appears not to have been observed, he does not say. After these came Eumarus the Athenian, and Cymon of Cleonea; to the latter of whom, Pliny gives the praise of having greatly advanced the art, by giving variety of attitudes to his figures, attending to the folds of draperies, and more discriminatingly marking the joints and veins of the body, than had been done by his predecessor.

To the existence of none of the above-mentioned artists does Pliny, or any other author, affix a date; but he contends, and with reason, for that of an established and important fact in the history of the art, *viz.* that about the 16th Olympiad, or little better than 700 years before the Christian era, Candaules, king of Lydia, purchased a picture, painted by Bularchus, called the battle of the Magnetes, and gave for it its weight in gold: a tolerably sufficient proof of the high esteem the art was held in at that time; though we ought by no means to deduce from it, that Bularchus had arrived at any other degree of perfection, than what placed him among the best of his day; and it tells but very little as to the actual state of the art at the time: since, in its infancy, the patron could only be guided in his judgment, by what had preceded; and the best, though moderate, has always received the highest eulogiums from those who, of necessity, are ignorant of superior exertions.

Whatever was the degree of excellence to which the immediate successors of this fortunate painter carried the art, we must be content to remain entirely ignorant of it. Possibly the confusions of civil anarchy and of foreign wars, which followed this period, and brought Athens, and indeed all Greece, near to destruction, prevented, in a great degree, the exercise of an art, which requires the fostering aid of peace, of science, and of patronage flowing from the hand of power.

When intestine commotion had subsided, and Xerxes had been driven out of Greece, then the depression under which her inhabitants had groaned was removed, and her spirit revived, exalted by a sense of its own dignity and importance. Genius then stepped forth from its retreat, encouraged and rewarded. The liberal arts, aided by the general cultivation of mind which then took place, were summoned to assist in erecting monuments to the heroic deeds of the national heroes; and again we are enabled to trace the steps of painting, still weak and tottering in her gait at first, but soon advancing with amazing rapidity towards the highest point she is supposed ever to have reached.

Sculpture was most probably practised with continued success, even during the times of distress and warfare. The necessities of the idolatrous religion, which so powerfully controuled the Greeks, might alone have required the exertion of all the talents the country could produce. We can no otherwise account for the immense advance which that art is found to have made before painting, at the period of which we are speaking. Phidias, who was the most renowned among sculptors, guided the hand of his brother Panæus, (the first painter whose name occurs after the re-appearance of the art,) in adorning the walls of the portico, called Pœcile, at Athens; where he painted the battle of Marathon, and introduced into it the portraits of the principal commanders, both Greek and Persian. But how great was the difference between their powers! The former, among other works, had produced those in the temple of Minerva, called the Parthenon, which to this day remain a source of admiration and of envy; while that of the latter, as described by Pausanias (*Atticæ*, lib. 1. c. 16.) exhibit

his art still in its infancy: although Pliny observes, that the painters were then supplied with colours better suited to their purpose; and thus proves, that the practice of it had continued in cultivation, however slow its progress. To Panæus, however, Greece was indebted for an anxious zeal to advance the art he practised, to a more equal station with sculpture; and in his time, prizes were instituted at Delphos, and at Corinth, for its encouragement; where he himself contended, but was excelled by Timagoras of Chalcis.

Just so far as to have become the partial and humble rival of sculpture in bas-relief, with the exception of colour, had painting at this period proceeded; and even Polygnotus of Thasos, who succeeded Panæus, advanced it no farther than a more vivid imagination, acting upon the same system, might rationally be supposed to have done. He also was employed to paint in the Pœcile at Athens, and in the Lesche, or public hall, at Delphos. Three of his pictures in the latter place are minutely described by Pausanias. (*Phœciæ*, c. 25. et seq.) The same imperfect elemental principle is their basis, as in that of his predecessor, or rather perhaps his contemporary; at least in part; for Pliny says, Polygnotus was prior to the 90th olympiad, and Phidias is known to have died in the first year of the 91st (432 years B.C.) The pictures by Polygnotus, which were at Delphos, were works of immense labour, from the number of figures introduced in each; but they were entirely without any idea of composition, perspective, or chiaro-scuro. Each figure had its appropriate action, consistent with its history and character; but no connection in lines with its neighbour: and that the observer might be at no loss of time in considering whom they represented, the painter had placed a name to every figure. They were arranged in rows, beside, or over, each other; and Pausanias, in describing them, begins at one end, and proceeds with an individual enumeration of them to the other, and then speaks of other figures over these; but whether they diminished in size, does not appear. Yet Polygnotus was a man endowed with uncommon talents, and certainly advanced his art very far in point of expression and action in his figures, and in ideal colouring. Of this, his figure of the demon Eurynomus in one of the pictures above-mentioned, *viz.* of Ulysses consulting the shade of Tiresias in Hades, is a sufficient proof. "His colour," says Pausanias, "is between black and azure, like that of flies who infest meat; he shews his teeth, and sits upon the skin of a vulture." Pliny also says of this artist, that he was the first who dressed his female portraits in gay colours, and he has been highly complimented by Lucian, who invokes his aid to accomplish his perfect woman. "Polygnotus," says he, "shall open and spread her eyebrows, and give her that fine glowing decent blush, which so inimitably beautifies his Cassandra. He likewise shall give her an easy flowing dress, with all its delicate wavings; partly clinging to her body, and partly fluttering in the wind."

It could not be many years after the time of Polygnotus, or perhaps it was even during his life, that another step in advance was made in the art of painting, by Apollodorus of Athens; whose name is particularly mentioned by Pliny as having discovered the principle of beauty, or rather having first adopted it in painting; for it had long been known and practised in sculpture. From this period, the art assumes its most essential character, and its most pleasing one; making man its object, not individual men; the genus, not the species; except in the more humble work of portraiture. By this sentiment, Pliny must himself have been actuated, when he says, that "before Apollodorus, none were worthy

PAINTING.

of record as artists; and that no picture had till then been produced, which a man might take pleasure in observing for any length of time."

The system of Apollodorus, to whatever height he bore it, was eagerly embraced by his pupil and successor Zeuxis of Heraclea; of whom his master did not deem it derogatory to himself to say, (in some verses which he wrote,) that "the art of painting had been stolen from its professors, and practised by Zeuxis alone." Uniting the simple but energetic style of Polygnotus, with the peculiar selection and taste of his master, he certainly appears to have surpassed both. It is the remark of Quintilian, that he considered the poetic unity of character adopted by Homer, in the descriptions of his heroes, as his model; and gave to each individual he painted, the peculiar distinction of a class. This must have been his object, at least in the picture of Juno, which he painted for her temple at Agrigentum, according to a vow which the inhabitants of that place had made. For before he began the picture, he desired to see all the most beautiful maidens of the city naked, and from them he chose five, whose form he most admired; intending to exhibit the most perfect combination of female forms, by selecting and adopting the most beautiful parts of each.

Timanthes, Eupompus, Androcydes, and Parrhasius the Ephesian, all flourished and were renowned together with Zeuxis; the first, and the two last, however, bore the sway of skill and of public favour. Among the principal productions of Zeuxis, are enumerated, a figure of Penelope, wherein he is said not only to have given her a becoming person, but also to have expressed the qualities and affections of her mind. Another of Jupiter on his throne, accompanied by the gods. Hercules strangling the serpents in his cradle, in the presence of Alcmena and Amphictyon: and of a wrestler, or champion; with which he himself was greatly delighted, and wrote underneath it, "that it would be more easily envied than imitated." Having acquired great riches, he refused to paint any longer for money, and gave away his pictures; declaring they were above all price. Of him and his rival Parrhasius, it is difficult to say which carried the art to the greatest extent, or was most vain-glorious. The story which Pliny relates of their contest, by no means settles the former; as both their pictures were mere matters of imitation, and could have little to do with their real excellencies, except in colouring. But if the fact be true, it is a wonderful instance of their perfection in that point; and totally excludes the possibility of belief in what he says concerning the colouring materials with which they were acquainted, and used, *viz.* only four; and those were impure and imperfect in themselves. A curtain might, indeed, be of a dull colour, and possibly such an one Parrhasius might have imitated, with such materials, and so perfectly, as to have deceived Zeuxis; but it is to be presumed the luscious transparency, colour, and brilliancy of the grape in those days, were not very widely different from what it now exhibits; and those pure qualities can only be imitated by the purest and most perfect of colours. Zeuxis, indeed, having himself mistaken the painted curtain of Parrhasius for a real one, was obliged to acknowledge himself surpassed; or must have submitted to the inference, that his penetration was not superior to that of the birds whom he had deceived. It was remarked, in favour of Parrhasius, that he had a purer eye to proportion and symmetry, which he is said to have reduced to rule; that he rounded the boundaries of his figures into their grounds, better than those who had preceded him; and that he superadded the charms of grace in the action of the body and features, and in the disposal of

hair and draperies. With these qualifications, if justly given him, he claims the pre-eminence; though perhaps in the compliment which Pliny pays him concerning the softness of his outline, he himself might have been deluded by the agreeable effect of such a procedure; whilst it may have been carried to a fault by Parrhasius. Such an inference may certainly be fairly drawn from the observation of Euphranor upon his picture of Theseus, which, in comparison with his own, he said, appeared to have been fed on roses: implying, probably, that it wasted substance as well as colour. As the vanity of Zeuxis led him to have his name embroidered in gold upon the border of his robe, when he attended at the Olympian games; that of Parrhasius induced him to wear a purple robe and a golden garland; to bear a staff wound round with tendrils of gold; and to have sandals tied to his feet and ankles with golden straps. He styled himself *Abroditus*, the dainty or delicate, and declared he was descended of Apollo; and that he had nightly visits by Hercules, while he was painting a picture of that divinity. The emperor Tiberius was so delighted with a picture of his, of an Archigallus, or chief priest of Cybele, that he kept it constantly in his own room, and valued it at 60,000 sesterces, 48*l.* 10*s.* Pliny mentions many of his works, and also that though he was thus skilful, he was excelled, according to the opinion of the Samians, by Timanthes, in a picture of Ajax at the award of the armour of Achilles to Ulysses: whereon he simply remarked, that his regret was only, that such a hero as Ajax should have been overcome a second time, by a man unworthy of the honour!

The quality for which Timanthes is renowned, is vigour of imagination. This aided him to fill the decided corporeal forms, now fixed as characteristic, with passion; and it is sufficiently illustrated by that well-known circumstance of the peculiar action given by him to his figure of Agamemnon, in the picture representing the sacrifice of Iphigenia; and by the mode in which he embodied the idea of grandeur in stature, in a small picture of a Cyclops; *viz.* by introducing some satyrs, supposed to be of the usual size of man, measuring the length of the giant's thumb with a thyrsus. One of his pictures remained at the time Pliny wrote, about 400 years afterwards, in the temple of Peace, at Rome. He calls it the portrait of a prince; and says, "it is so perfect, and so full of majesty, that it appears to comprise every thing desirable in the art of painting."

The art continued advancing by rapid degrees at this period. Nature, in form, in colour, and expression, was the guide; and to develop her beauties the sole object of the artists. Eupompus sufficiently displayed this basis, in his advice to Lyfippus, the sculptor, who enquired of him, whom among his predecessors he should make the objects of his imitation. "Behold," said the painter, shewing his friend a multitude of characters passing by, "behold my models! From nature, not from art, by whomsoever wrought, must the artist labour, who hopes to attain honour and extend the boundary of his art." (Pliny, lib. xxxiv. c. 8.) To such a pitch of excellence was painting at this time advanced among the Greeks, that it became highly esteemed; was thought worthy of being ranked at the head of the liberal arts; was ordered to be taught to the sons of the higher classes, in preference to all other things, according to Pliny, and forbidden to be practised by slaves. Such was the honour done to it, by the influence which the painter Pamphilus of Amphipolis had acquired. Of him it is remarked, that he was the first who proved the value which the art acquired, by an union with science and literature; and to him,

him, Apelles, the unrivalled hero of Grecian painting, was indebted for his initiation to its mysteries.

This extraordinary man (Apelles) appears, if we give full credit to the traditions concerning him, to have been endowed with a more perfect combination of rare talent and excellent qualities, than has, either before or since, fallen to the lot of any other. He had, besides, the peculiar felicity of being born at that period when his country was at its highest pinnacle of cultivation; so that mankind saw in him the happy union of a perfect mind, strengthened and guided by the best assistance education could possibly afford. Not only as an artist is he extolled above all others, but equally so as a man; for his gentleness, his amiability, generosity, and magnanimity. Pliny places the time when he flourished, in the 112th Olympiad, (328 years B.C.); and adds, that he became so consummate in the art, that he alone enriched it more than all his predecessors had done; and compiled several books upon it, wherein he illustrated its principles. It is agreed by all writers, who speak of him, that in him, the art of painting reached its acmé. He himself indeed acknowledged, that he was surpassed by several artists in different branches of its practice; by Amphion in disposition, by Asclepiodorus in proportion, &c.; but that in the combination of the whole, he excelled them all.

Yet it is not without some grains of indulgence, this most liberal praise is to be received. It is extremely difficult to know how far to attach real value to the language of praise, as given to works of art; so much depends upon the taste and judgment of him who bestows it. The highest terms of praise will always be given to the best works of their time: and therefore we find, that at all periods contemporary authors have expressed the same degrees of approbation, and in nearly the same terms, of the pictures they have seen produced; whilst we know, that as art was slow in its progress, it is impossible, that in all its varying stages, it would have merited equal praises. No doubt, however, can remain, but that Apelles was a most powerful and agreeable painter; and that he must have given a degree of taste, of grace, of life and effect to his figures, which had never till then been equalled in their union, is evident, since it is the general unvarying opinion of all writers who have mentioned him; and they are neither few nor weak. As many of his pictures were preserved at Rome in the time of Pliny, he had an opportunity of judging for himself; as far at least as their condition after such a lapse of time (nearly 400 years) would allow him; but the tribute which he pays to the excellence of his mind is of course deduced from the reports of others. There appears in the latter no extravagant hyperbole which leads to disbelief; and his generous conduct towards so powerful a rival as Protogenes, well deserves the honourable mention made of it. Being highly delighted with a picture of Jalyfus, painted by that artist, he sailed to Rhodes on purpose to visit him; where finding him neglected and in poverty, he purchased some of his works, and declared, that he intended to sell them as his own. Roused to a recognition of the talents of their fellow citizen by such powerful testimony as that of Apelles, they raised him from his humble situation to rank and fortune.

The well-known contest of these two friendly artists, in the lines they drew as designatory of themselves, exhibiting that taste and skill which they knew none but themselves possessed, stands upon well founded testimony as a fact. The tablet whereon they were drawn remained untouched, was taken to Rome, and was there seen by Pliny himself; who speaks of it, as having the appearance of a large blank

surface; the extreme delicacy of the lines rendering them invisible, except on a close inspection. They were drawn with different colours, one upon, or rather within, the other. To judge from his account of it, it might be supposed, that all the beauty lay in the extreme delicacy of the points which had been used, and of the hands which had applied them; but it is reasonable to suppose, that the first direction of the line might have some principle of beauty for its guide, by which, as well as by the neatness of its execution, Protogenes was instantly moved to the declaration, that none but Apelles could have drawn it!

Beloved, honoured, and employed by Alexander, Apelles had the happiness of enjoying that fullness of renown, to which he was so justly entitled. Alexander, the envy and admiration of the world, treated the painter with the familiarity of a friend; ordained that none other should presume to paint his likenesses; frequently visited him; and crowned his favours by a sacrifice to friendship of a most uncommon nature among men: depriving himself of a beloved object, his favourite Campaspe; and giving her to gratify the affection of one whom he so much esteemed.

The pictures produced by this exalted artist were numerous, and are mentioned pretty much at length by Pliny, lib. xxxv. cap. 10. But perhaps the best comment upon his talents as a painter, will be found in the character Mr. Fuseli has given of him. He places him in that rank where every thinking mind will be gratified to find him. "The name," he observes, "of Apelles in Pliny, is the synonyme of unrivalled and unattainable excellence; but the enumeration of his works points out the modification which we ought to apply to that superiority: it neither comprises exclusive sublimity of invention, the most acute discrimination of character, the widest sphere of comprehension, the most judicious and best balanced composition, nor the deepest pathos of expression: his great prerogative consisted more in the union than the extent of his powers; he knew better what he could do, what ought to be done; at what point he could arrive, and what lay beyond his reach, than any other artist. Grace of conception, and refinement of taste, were his elements, and went hand in hand with grace of execution, and taste in finish; powerful, and seldom possessed singly, irresistible when united."

That our readers may judge for themselves of the propriety of these remarks, we will enumerate from Pliny the pictures of which he speaks, and which of course may be supposed to convey a very just idea of the class of subjects generally chosen by Apelles. Of Alexander the Great, and his father Philip, the portraits he painted were very numerous; some single and some accompanied by other figures. One in the temple of Diana at Ephesus, of Alexander launching thunder, is highly extolled for its effect, and the boldness of its relief; "the hand which was raised appearing to come forward, and the lightning to be out of the picture:" in another of the same king, he was represented in a triumphal chariot, near him the figure of war, with his hands tied behind his back. This, and another Alexander, accompanied by Castor and Pollux, and a figure of Victory, were preserved by Augustus in the forum. Many other portraits are mentioned; viz. of Antiochus, king of Syria; of Antigonus; Archelaus with his wife and daughter; Abron, an effeminate debauchee; Clytus on horseback, armed, except his head, with an attendant delivering his helmet to him; and of Megabyfus, a priest of the temple of Diana at Ephesus, sacrificing, in his pontifical vestments. In subjects of fancy, are, a Diana surrounded by her nymphs, attending at a sacrifice; Neoptolemus, son of Achilles, on horseback, contending with Persians; Hercules with his

PAINTING.

back towards the observer, and his head turned round so as to shew his face; a horse painted in competition with other painters, and said to have excited living horses to neigh; and lastly, his renowned picture of Venus rising from the sea; which being taken to Rome was dedicated by Augustus in the temple of Julius Cæsar; and several Greek epigrams upon it, are preserved in the Anthologia. So great was its perfection, that no artist could be found who would undertake to restore the lower part of it, when by accident it had been injured: and of another of the same subject, begun for the inhabitants of his native island, (Cos,) and of which he had only finished the head and breasts when he died, Pliny says, that no painter would set his hand to complete it; through a fearful acknowledgment of this great master's superiority. Other pictures and designs of his are mentioned by different authors, but these are sufficient to shew the general tendency of the subject: on which he employed the extraordinary powers of imitation he was endowed with. The bare mention of them is sufficient to prove the critical acumen of our learned professor of painting; but doubtless they are fully capable of admitting, indeed they require, all that grace and taste in conception and execution, for which he was renowned, to compensate for their want of pathos.

What was omitted by Apelles, was supplied by his contemporary, Aristides of Thebes. Unable to rival him in harmony and grace of colour and execution, and qualified by nature to display the influence of the passions, Aristides followed in the steps of Timanthes. His was the power of impressing form with soul, of fixing upon, and representing with effect, those impassioned actions of the body, which are the result of the more amiable or violent emotions of the mind. So effective was the earnestness of a suppliant portrayed by him, that "his voice seemed to escape from the picture," and not only was he capable of representing the more simple emotions of the passions; but their most complex unions were also subject to his skill. An expression, in which are discoverable maternal affection, anxious for the benefit of its offspring, amidst the pangs of certain and approaching death, was produced in his picture of a woman who had received a mortal wound upon her breast, endeavouring to prevent her infant, eager for its nourishment, from sucking her blood instead of milk. (Pliny, lib. xxxv. c. 10.) The mind dwells with apprehensive commiseration on the bare relation of the image; and great, indeed, must have been the discriminative power of mind, and of hand, to execute justly, so difficult a task. Although Aristides appears to have most delighted in subjects which afforded him an opportunity of displaying his knowledge of the human mind, and its pathognomic influence upon the body; such are his pictures above mentioned, and those of a sister dying for love of her brother, and of one suffering under the languishments of illness; yet he sometimes ventured upon a more extended field, and in one instance painted a picture of a battle between the Greeks and Persians, in which were introduced 100 figures, and was paid by Mnason, king of Elatea, 10lbs. of silver for each of them. In another he represented a race of chariots with four horses; of which, Pliny observes, "you would almost think the wheels were in motion, such was the energy of action in the picture."

At this time, the art of painting was upheld in Greece by a great number of ingenious men renowned for their distinctive excellencies. Asclepiodorus for the beauty of symmetry; Protogenes, for exquisite skill in execution and finish; and in him the art received one of the highest tokens of regard it was ever favoured with; for when Demetrius Poliorcetes was besieging the city of Rhodes, and might have taken

it by assailing it on the part where Protogenes resided, he forbore, lest he should do an injury to his works; and when the Rhodians delivered the place to him, and requested him to spare the pictures of their admired artist, he replied, "that he would sooner destroy the images of his forefathers, than the productions of Protogenes."

With these artists, and a few others, as Nicias, Nicomachus, Mnason, Aristodemus, &c. all nearly contemporaries, this delightful art arrived at its utmost height; and though it continued to be practised by a succession of ingenious men, many of whose names are handed down to us, and who contended against the formidable difficulties presented by the scenes of luxury and confusion which opposed them, yet their efforts to uphold its dignity were in vain. When the country, weakened by domestic broils, became subjugated by the Romans, its arts and its energies expired with its liberties; the spirit which animated the arts in Greece being removed, they fell to rise no more, at least for ages. But the cycle of nature will have its course in the arts, as well as in governments, and in man himself. All sublunary things have within them the seeds of their own destruction; and having reached the acme of excellence in their kinds, their further progress in existence can only be retrograde.

In the means left to us for tracing the history of painting in Greece, many are the deficiencies we have to deplore; but in nothing more than the want of pictures, and the entire loss of the treatises written on the principles of the art, by Apelles, Parrhasius, Protogenes, and Perseus, a pupil of the former, to whom he dedicated his work. If, happily, these had been preserved, we might have been able to decide upon the state of the art and the merits of its professors, with much greater accuracy than from the remarks of mere critics, however acute and industrious; who are now our only resource. The liability to error and misguidance of such, none can be at a loss to determine, who have perused the extended labours of Winkelman, Du Bos, and others upon subjects of this nature; where, though surrounded with great ingenuity in antiquarian research, ignorance of the technical parts of the art is made apparent by affected allusions and frequent misapprehensions, which the mere tyro in practice would detect; and where a display of classical learning appears to have been more an object of the authors, and for which they were better qualified, than a just extension of the principles of art, or instruction in the practice of it.

From the information we still possess upon this subject, it is extremely difficult to decide upon the exact degree of cultivation the Greeks attained, in many branches of the art of painting, as now understood. We have sufficient data to ground a satisfactory belief, that in the most essential points, as fullness of invention, expression, grace, character, and design, they rivalled the sculptors of the best periods; and that they carried colouring to an equal degree of perfection, (though by some doubted,) appears to us not improbable. But whether they ever understood and employed composition, as it is now scientifically practised, as far as relates to the union or separation of groups, and effecting the distances of given objects according to the rules of linear or aerial perspective; or whether they at all comprehended and practised the science of chiaro-scuro, as employed by subsequent schools of art, we have yet to learn. On these points the descriptions of their productions afford no conclusive evidence.

It must be observed, that the criticisms employed by the ancient writers partake very little of technic information; nor appear to have arisen from any thing like technical knowledge; the

PAINING.

the only source from which any very satisfactory information was likely to ensue. Left, as we are, to deduce principles from imperfect materials, we are led to conclude, that the ancient painters of Greece never contemplated their art in many points of view, at which the moderns have successfully aimed: but that their prime object was, even in the most cultivated periods, to impress, undisturbed upon the mind, the whole force of one image; and for that purpose apposition, rather than composition, is the most effective mode; especially when aided by a select style of representation. It may, therefore, have been the effect rather of a precise scientific principle, than a want of intelligence, that we find, or conceive we do, an imperfection in the most engaging, though not the most useful parts of the art. It may rationally be doubted, whether, as applied by this polished nation to the worship of imaginary deities, or the exaltation of heroes, it would not have been deprived of a great portion of its influence, if more artifice had been introduced into their pictures; though there is no doubt at all, of the improvement the minor qualities produce in the art, as it is now employed; being an agent of pleasure rather than of instruction or emulation.

We occasionally meet in authors who speak of ancient art, with descriptions of pictures containing many figures, but in general its efforts were confined to subjects in which two or three only were required; and it is worthy of remark, that in none of them is there any observation on the contrasts employed in lines, in light and shade, or in colour: nor is there any mention of what is now understood by the term back-ground. To guess from these attempts at criticism, we should, at least we might conclude, that all pictures painted by the Greeks were similar in principle to those found at Herculaneum, of which the best have entirely plain grounds, and others very little variety; which evidently shews, that the writers were unacquainted with the art. Their remarks are too vague, too undetermined, appear not to flow from any feeling or knowledge of what art is, but only from common perceptions, alike felt by all of equal understanding. Yet every painter knows, that without some ingenious management of the ground, quite sufficient to form an object of particular remark, the land of Alexander would have still adhered to the canvas; and not, as Pliny remarks, have appeared to project before it, or "out of it."

That they discovered to a certain extent the effect of contrasting lights and shades, is evident from Plutarch's observation, that "painters increase the brilliancy of light colours by opposing them to dark ones, or to shades;" and Pliny has this remarkable general expression, when, having spoken of the painters in the monochromatic style, he adds, "in process of time the art assumed new powers, and discovered (or invented) light and shadow; by gradating which, the colours are alternately heightened or kept down. Afterwards *splendour* was added, which was different from light, and which, because it was a mean between light and shade, they called *tonon*; and the union of the colours, and the transition from one to another, they called *barmogen*," lib. xxxv. c. 5. Although we see in these passages, that the three grand requisites for the science of colouring and of chiaro-scuro, *viz.* contrast, tone, and harmony, were felt by the Greeks; that the degrees of light and shade in their own force, and in their approach towards each other, were fully understood; with the value of middle tints, the most difficult and important object of the painter's attention; and that one general hue in the whole work was considered and effected; yet we cannot agree with M. Du Bos and others, that we ought hence to conclude, that chiaro-scuro was

scientifically understood and practised by them to any extent, at all approaching that to which it has subsequently been carried by Rembrandt and the Flemish school, or the best among the Italians. All, which Pliny asserts, they knew upon this head, is requisite for the due execution of a single figure, upon a plain ground, and offered to view in the most simple style of composition. Unhappily very few of their pictures have remained to us, and those we have, we must suppose are the works of inferior artists. Among the twelve pictures, the best of those found at Herculaneum, and all possessed of infinite beauties in taste, in grace, and feeling; there is exhibited in one of them a more compound management of chiaro-scuro, in the reduction of tone on parts of the flesh and drapery, than is to be found in any other monument of ancient art; but it is not sufficient to prove that it proceeded from any thing like principle. We have, therefore, no satisfactory proof upon this subject; and it is most rational to conclude with sir Jos. Reynolds, that this, which makes so material a part of modern art, was unknown to the Greeks (as a science.) "If," he observes, and justly, "the great painters had possessed this excellence, some portion of it would infallibly have been diffused, and have been discovered in the works of inferior artists handed down to us."

The same may be said of their knowledge of perspective, at least of the application they made of it in pictures; notwithstanding Vitruvius says, that it was practised by Agatharchus, a contemporary of Æschylus and Polygnotus, in the theatre at Athens; and was soon afterwards reduced to principles, and treated as a science, by Anaxagoras and Democritus. The reasoning upon this subject stands precisely upon the same ground as that concerning their knowledge of chiaro-scuro, and we are naturally led to the same conclusion; though it is difficult to conceive, that when the general principles of a science so necessary to just delineation were understood, that they should not be put into practice. Perhaps, as we have before observed, it is possible that back-grounds were more simple than we are accustomed to see them in modern times; and therefore less of perspective would be required in them.

It certainly is not a little remarkable, that no mention of consequence, of any thing like a ground of relief, should be made in describing pictures, of whose beauties in the principal parts we have such enthusiastic encomiums; and so little of landscape, that it appears to have been almost entirely disregarded. The attempts at back-ground in two or three of the Herculaneum pictures, are puerile in the extreme; and the most beautiful productions of ancient art yet exhibited to modern times, are of figures relieved off plain grounds, or rather blended into them. If Apelles, or any other great and renowned master, had made it a study, to produce a beautiful combination of objects receding in due degrees to extreme distance, such as in these days is regarded as absolutely necessary in a picture, the scene of whose action is in the open air; it is hardly credible, that it would not so far have attracted the attention of the critic as to have become an object of remark. But in none of the criticisms or observations of ancient authors, (of Pliny more particularly,) is a secondary object ever even mentioned, as being on a separate line of ground, or distance; or indeed any thing, but the immediate subject of the picture; though many of those he describes are such, as to require the accompaniment of natural objects, as sky, rocks, trees, mountains, &c.

In Italy, as well as in Greece, it appears not improbable, that painting was practised at an early period, but in a rude and very imperfect mode: little, however, is known of its actual

PAINING.

actual progress there; and that little, partaking more of antiquarian curiosity, conjecture, and doubt, than of utility, or certainty. Pliny, indeed, says, that there were paintings exhibiting at Ardea in his time, executed before the foundation of Rome. But after a lapse of 800 years, how much of this may not be attributed to error in the tradition he recorded? The earliest traceable and satisfactory account of the art being practised in Rome, is in the year 450 of the city, or 303 years before our era; when Fabius, a noble patrician, painted the temple of Salus; and he and his family thence obtained the surname of *Pictor*. It is not improbable that Fabius had travelled in Greece, and there had the happiness to see the elevated station of the art at that time; he might even have seen Apelles himself, employed upon those works which brought honour upon his country, and secured immortality for himself. Yet the city does not appear to have much profited by this example; nor to have obtained renown for its artists, either in number or in quality. Pliny mentions none other after Fabius, till, on the lapse of 150 years, Pacuvius, the poet, amused his declining years with painting the temple of Hercules in the *Forum Boarium*. Although it is evident, that about this time Greek paintings were introduced into Rome, either to gratify curiosity, or adorn the triumphs of generals who had been engaged in Sicily, or Greece; yet no emulation to cope with the artists of those countries was exhibited by the Romans. That warlike people were too much occupied in schemes of aggrandisement and military fame, to devote much attention to the arts; and it was not till the time of the emperors, that they experienced any thing like encouragement in Italy.

After the reduction of Greece to the Roman power, the city of the conquerors became the emporium of honour, employment, and consequent profit to artists; but that only in a gradual advance. First of all, the plunder of the ancient residence of taste, (that country, where, of all the world, it had alone found a secure and honoured establishment and due regard for a great length of time; where its utility was proved, and its delights enjoyed;) satiated, as well as astonished, the uncultivated, comparatively uncultivated, inhabitants of Italy; and no employment might be found for domestic artists, when the views of all admirers of art, were directed to another country for a supply of their wants. Afterwards the men themselves, who had in vain laboured to continue the arts in that once favoured, but now unhappy country, quitted it, to ensure their own existence; till, by degrees, Rome, become the mistress of the world in policy, assumed the controul of the arts. Still its own native citizens were content to allow themselves an inferior share in its praise; since the principal part of the artists, either in painting or sculpture, who practised in Italy, are supposed to have been Greeks.

Antiquaries, under the influence of varying circumstances, have at different times attached priority of cultivation to different countries. Such is the case with the regions of Italy. Etruria has been, and is still, most generally considered as the nurse of the arts in that country; but the discovery of painted vases in the southern parts of Italy, and in Sicily, being more frequent than in Etruria, has led many to imagine, of late, that painting was practised in those countries previous to its cultivation in the more northern provinces. But very little argument can be derived from this circumstance; as it appears to us, that the designs and execution of those curious monuments of art, only testify the previous existence of some superior powers in the art; as the extension of taste in our own manufactories, or the attempts at it, proves the existence of the art of painting,

and its higher, or more direct cultivation in this country. The paintings upon those vases are, it is true, so inferior, as to the extent of art they exhibit, that they merit only to be classed among the productions of the earliest periods; but that perhaps is more owing to the artists who executed them, being desirous of proceeding only so far as would answer a specific purpose; and by no means aiming to attain the degree of perfection at which the art had actually arrived at the time. The slight degree of difference in point of excellence among the majority of them, affords an argument to prove, that it was not painting, or the cultivation of it, which was the object of those who supplied the initiated with these vases. Some few of them, in invention indeed, indicate a mental power superior to the system upon which they are executed; and the artists who painted them, only appear to have employed, in an imperfect manner, materials offered to their hands by others. For whatever purpose they pursued their labours, it was probably sufficient for them, that the hieroglyphics they marked were understood: that being effected, their object was completed. Some of them being rather more ingenious artificers than others, and guided by the learned or artful, multiplied combinations of figures, in order to create or explain deeper mysteries, and excite the zeal of the superstitious and enthusiastic. If these opinions are correct, there is no arguing concerning the state, or antiquity, of the art of painting from Etruscan vases. The use of their hieroglyphics, for so the figures employed upon them may be termed, like those of the Egyptians, or like letters, admit of little improvement, or indeed of alteration, in themselves; and allow only of being changed in effect, by new combinations. They may, therefore, or they may not, have been executed at a period comparatively late, when considered with regard to the history of painting properly so called; and certainly may be regarded, rather as an offset, than as attached to the main stems in its growth; or as an extraneous application of part of the art, rather than the art itself.

Where the Greeks first settled in Italy, or where the most free communication was held with the mother country, there it is most likely the arts transplanted, would be first cultivated; but they do not appear to have arrived at any great degree of excellence in any part of that country, previous to the conquest of Greece by the Romans; and it must still remain a doubt, whether Etruria or Calabria was the parental abode of the arts of Italy. They appear certainly to have received more cultivation in the former of those districts than in the latter, particularly sculpture; at least, there is something like evidence of the culture of it in Pliny, who mentions, "that the little brazen images, dispersed all over the country, were wrought in Tuscany in very ancient times."

Whencesoever it were that Rome acquired the little taste she felt for art, or rather the slight degree of emulation which animated her citizens to enter the paths of tasteful cultivation, it is certain, that during the period of her existence as a republic, the impetus was very weak, and the progress of course of little or no extent. The practice of painting after the days of Pacuvius, before mentioned, was held to be effeminate and disgraceful; and it was not subsequently engaged in by any respectable men. The result, of course, was a testimony to the wisdom of the Greeks; who, in order to enhance the merit of the art, ordained, that none but such as Roman pride excluded, should presume to practise it. From being regarded as contemptible, it actually became so; whereas in Greece, being raised in rank and esteem, it became truly worthy of both. But what this powerful city could not acquire by her own genius, she endeavoured, after her

PAINING.

her generals became acquainted with the riches of Greece and Sicily, to treasure up from the spoils of those countries. Some of those generals, to increase the splendour of their triumphs, and others, for private or for public ornament, carried pictures as well as statues to Rome, and exhibited them to the people; and others again caused pictures to be painted of their successful battles, to stimulate the admiration and applause of the people; and thus tacitly acknowledging the value of the art, upbraided their fellow citizens, for neglecting the cultivation of it.

It would be natural to suppose that when the fierceness and severity of republican independence gave way to the suavity and more refined manners of a court devoted to one person; when literature and science were highly cultivated, and the example of Greece was before them; that the Romans would not fail to blend the pursuit of the elegant arts, with the refined luxuries in which they indulged. But that does not appear to have been the case, to any great degree. Had it been so, Pliny, who does not easily lose sight of the honour of his country, would not have failed to mention it; particularly as it came so near the time in which he lived. He gives only the names of a few painters then practising, or who had practised, being native artists; and accompanies it with a lamentation, "that the art was dying." Lib. xxxv. cap. 5.

Even in the practice of the Greek painters of that period employed in Italy, the certain mark of decaying art is constantly referred to by contemporary authors; *viz.* brilliancy, rather than purity and truth in colouring; and ornament, adding affected beauty to forms, and taking place of simplicity, elegance, and expression.

As no preparation of art had previously taken place, powerful enough to aid the plans of the state, when Augustus understood the system of the Grecian leaders, and saw the use to be made of painting by a monarch; he very wisely endeavoured to adopt what was ready to his hands; and caused two pictures, painted by Apelles, of Alexander victorious, and triumphant, to be carried to Rome, and placed conspicuously in the forum. Images of his own power and exaltation, which Claudius Cæsar more openly proclaimed, when he ordered the heads of both pictures to be cut out, and Augustus's portrait placed in their stead. But the Romans, and Roman emperors, whatever subjects they may have created for the pencil, found little native talent able, or sufficiently interested, to convey them to posterity in an honourable manner by painting; and even in sculpture their best artists were low indeed in comparison with the Greeks, at least no Roman artists' names of great repute are handed down to us. Both arts were diverted to unworthy objects; they continued to fall in every valuable quality; and painting most of all; till at length the irruptions of the northern nations put an end to both Grecian and Roman efforts; and barbarism, from which Greece is not yet redeemed, usurped the stations of luxury and refinement. For near 1000 years, did the glorious title of the cultivator of intellectual power; the leader among nations, in whatever was most adapted to do honour to human nature, appertain to that highly favoured country; for a period approaching 2000, has she suffered degradation and depression, even almost to annihilation. Yet her present inhabitants are represented by travellers as still the same animated and ardent race, although bending to the strong hand of power, and unhappily under the influence of a government and religion, whose tenets forbid the extension of human knowledge; and whose power is upheld by ignorance.

Italy, overcome by the same wild anarchy with Greece,

groaned not under the weight of the despotic spoiler who had subdued her energies, more than half the time which her predecessor in the race of nations has bowed, ere the dawns of science beamed upon her, and roused her from the state of torpor to which she had been reduced.

Even then, Greeks had the honour of stimulating her to the cultivation of her native powers; till at length that flame was kindled, which, by a gradual accumulation of strength, warmed Italian breasts, and excited them to emulate in arts, those whom their forefathers had subdued in arms. But the country being then under the controul of a system of religion which forbade the introduction of images into her temples, the course and application of study was necessarily changed, and the art of painting became the principal object of attention; whereas that art, highly as it was prized and cultivated by the Grecians, in the latter periods of their existence as a ruling power, had remained, as we have seen, for a great length of time, nearly unemployed; whilst the sister art of sculpture, being most subservient to the purposes of an idolatrous religion, was cultivated in so extraordinary a manner, that the accumulation of its productions in statues, bas-reliefs, &c. both in bronze and marble, became prodigious; and not to be imagined by those unacquainted with the fact. Pausanias speaks of 2827 entire statues in the places which he travelled through, as remaining in his time, besides numerous other works of sculpture; and this was only in a part of Greece, and not till after the Romans had, for 300 years, been plundering the country of innumerable beautiful productions. Rhodes, it is said, could boast of 3000 statues of brass; and Nero took, from Delphos alone, 500 statues. The cause of this vast accumulation of sculpture is apparent; in the patronage that art derived from the government and the priesthood; who found it an useful instrument in moulding the people to their wishes. They were well acquainted with its influence upon the minds of men, when skilfully applied in exciting their sympathies, stimulating their emulation, or assisting in compelling their devotion. The foundation, therefore, of the superexcellence of this art among the Greeks, does not lie very deep for our research. What else could be the result of so much, and so constant an employment for a connected series of hundreds of years, the consequent emulation which must ensue, where so many competitors entered the field, and when, in addition to the influence of government, so many establishments of a religious order were anxious to become conspicuous by employing them? By its means the priesthood were enriched, and exalted in the eyes of their countrymen; adorers were drawn to their shrines; and their favourite divinities more generally worshipped.

The same sentiments and principles, always present to the ambitious and powerful, and which, under happy auspices, re-act for the benefit of the people, operated near 1000 years afterwards upon the government and church of Rome; when, by the revival of science and of art, these salutary means of strengthening themselves fell into their hands. But, as the second commandment of the decalogue by which they were, or rather ought to have been, controuled, prohibited the worship of images; their attention was directed to the use which might be made of painting, and sculpture was confined to monumental and ornamental purposes; or nearly so. Thus circumstanced, the result was precisely the reverse of what occurred in Greece. Sculpture, except in a few instances, made a progress only to mediocrity; whilst painting rose and expanded its beauties to the utmost perfection; and soon followed that period, when, as we have before observed, notwithstanding the high-flown panegyrics of ancient authors upon Grecian art, the

doubt

PAINING.

doubt is justified, whether its painters were not surpassed by those of Italy and Flanders, who flourished in this latter age of the world.

It was not at once, and by miracle, that painting re-appeared. Cherished, amidst the terrors of war and bigotry, by the Greek monks, in their silent seclusions, it was occasionally exhibited; and for two centuries at least before the acknowledged era of its rise, according to Malvasia, and perhaps more early, had been publicly practised, though humbly, in fresco, and in mosaic. He says that from 1115 to 1140, Guido, Ventura, and Orfon, were employed as painters in several churches at Bologna; and doubtless these practices prevailed in other places; for now the ecclesiastical power of the church of Rome was completely established in Italy, and felt the advantages to be derived from adding splendour to the buildings erected to its honour, and exciting the zeal of its devotees. The character, however, of the art, as exhibited in the works of the Greek agents universally employed at this time, was but ill calculated to answer the higher views of those who promoted the exercise of it; for it was now at its lowest ebb.

Pisa, Lucca, Florence, and other petty republics into which the kingdom of Italy was divided, began, about this period, to shake off the barbarism which had so long abused and controuled them, and to exhibit a taste for improvement. Artists were summoned from Greece to assist in adorning Pisa and Florence; and amongst other things to paint the chapel of the Gondi family, at the church of Sta. Maria Novella, in the latter place; whilst the Venetians employed Apollonius and others of the same country, on mosaics, in the church of St. Mark.

To the gratification enjoyed by Giovanni Cimabue at seeing the productions of the former of these artists, is Europe indebted, in a great measure, for whatever she has since beheld in the art. He, Andrea Taffi, who learned the art of working in mosaic from Apollonius; and Nicolo Pifano, instructed first in sculpture by Greeks, and afterwards by study from ancient bas reliefs, brought by his countryman from Greece; were the first Italians reported to have entered the lists with their masters: whose taste is allowed to have been hard and poor, and devoid of all spirit of imitation; either of nature or of ancient art. A state of debasement we might deem impossible to have occurred, after the extraordinary display of talents which those countries had witnessed; did we not know the rapidity with which the arts fall into decay, if not upheld by a constant succession of practice; and how slow their growth is in advance. And yet, doubtless, notwithstanding the horrors of destructive war, and the mad superstitious zeal of the Iconoclastes of the 8th century, many noble examples of sculpture, and architecture more particularly, must have remained to guide their taste. So it was, however, and Vafari and others speak of the arts at this period, as being utterly unworthy of the name. Such was their situation in Italy, when Cimabue, who was born at Florence, of a noble family, in 1240, having been initiated into the miserable practice of the Greek artists, conceived the desire of improving upon it; and succeeded so well in his attempt, that a picture of the Virgin, which he painted as large as life, for the church dedicated to her at Florence, excited enthusiastic delight in his fellow citizens. They treated the painter with almost divine honours; the picture was carried in procession, with the sound of trumpet, to the place of its destination; and the day was celebrated as a public feast.

Encouraged by this applause and admiration, Cimabue pursued the art with ardour; and though the utmost of his efforts were weak and inefficient, yet he made a very great

advance beyond his teachers. Vafari, 200 years afterwards, could not help expressing his surprize, that he had seen his way so far through the obscurity of the age he lived in: yet such was the Gothic barbarity in his picture of Christ crucified, in the cloister of St. Francis, at Pisa, that written labels are employed to convey the sentiments of the Saviour to his mother and St. John.

His pupil Giotto, whom from a shepherd he raised to be a painter, relieved the art infinitely more from the fetters of Greek imperfection. The extreme rapidity with which he advanced in design, we can only account for by supposing, that he left the trammels of the art, as then practised; and studied attentively the productions of the ancients which were to be found in Florence: and which then, doubtless, began to be in research. Giotto left off the use of labels; aimed at real expression, and obtained it; and, even in his own age, was acknowledged to be the pupil of nature. He may be said to have performed for the Italians what Polygnotus had done for the Grecians, by marking the line in which the art ought to be pursued; and though in both it was accompanied with great deficiencies, yet it was just in its object and direction.

To Giotto the world was indebted for the portraits of Dante, Brunetti, and others, amongst those who at that time shone conspicuous in literature, and with whom he lived upon terms of intimacy and friendship. His abilities procured him the patronage of pope Benedict IX., according to Vafari, (though Baldinucci says he is mistaken, and that it was Boniface VIII.), who employed him in St. Peter's; and highly honoured and remunerated him. Henceforth the art of painting became attached to the papal dignity, and few succeeding pontiffs disregarded the use of it.

An inclination to encourage the practice of painting in all the countries attached to, or dependent upon, the church, at this time became apparent; and the fame of Giotto having spread very widely, the advantage attending the exhibition of his powers was extended to numerous places where he was called to employ them. The king of Naples required him for a time of the pope; received him with honours, and employed him largely. At Avignon, where he attended the pope, at Milan, Lucca, Arezzo, and many other places, besides his own native city, Florence, was he engaged to adorn the churches, &c. with his paintings; and his great work at Assisi remains, though in a ruined state, to this day. (See the article GIOTTO.) The principal benefit the art gained by him was his having again returned to nature for the actions and expressions of his figures; and been very successful in attempting to imitate her effects.

The skill of this ingenious artist excited the emulation of many among his contemporaries throughout Italy; and the arts having now acquired an earnest of employment and reputation, of emolument and of honour, no longer wanted skilful professors, or illustrious patrons. A grand epoch of their establishment took place at Florence in 1350, fourteen years after the death of Giotto; when a disciple of his, Jacopo Cassentino, and nine other artists, founded the academy of St. Luke in that city: an institution from whence arose a large display of talent, increasing in worth, till at length, near 150 years after its foundation, it gave to the world three of the greatest luminaries in art which it has ever known; Lionardo da Vinci, Michael Angelo Bonarotti, and Raphael; besides Masaccio, and others of great repute.

About the same time, considerable advance was made in painting at Venice and Bologna. In the latter place, Franco Bolognese had practised, with great reputation, as a miniator or illuminator of books. He enjoyed with Giotto the friendship of Dante; and the language which that poet employed

employed in praise of their talents, is at once an argument and proof, how little reliance is to be placed upon the praises which authors so freely bestow upon the works of contemporary painters. For though in their time they well merited the rank he gives them, of being at the utmost height in the practice of art; yet we now know for certain, that they were very far indeed from having reached the extent of its possible career; and instead of being found to have offered a perfect sacrifice at the altar of taste, they had scarcely passed the threshold of her temple.

What they had done, however, was of sufficient excellence to operate powerfully in the establishment of the art, particularly by Giotto. But, unhappily, the taste of the time and of the country, was not in favour of that kind of study, by which the Greeks had obtained their exalted rank. The efforts of the art were confined, almost exclusively, to subjects drawn from the history of Christianity; or more frequently, from the legends of saints, and the sufferings of martyrs. The latter, indeed, required some knowledge of anatomy and form; but those drawn from the former sources, however engaging they might be to the heart, presented a field of exercise to the artist, comparatively narrow and confined, when placed in competition with the variety afforded from the wide irregularities of heathenism. Not that the history of the bible fails in presenting to the pencil scenes engaging and poetic, of the highest moral culture, and of sublime imagery; and not less delightful by their simplicity, than interesting and important in their consequences: but there is an alloy attached to them, which renders them not so engaging in vision, as in description; and, therefore, less fit subjects for the painter, than the poet. In the scenes of the New Testament, more particularly; the almost entire exclusion of the nude, or, when introduced, its being devoted to the exhibition of deformity or common life, confining the exertions of the artist to heads and draperies alone; would operate strongly to delay the progress of the art towards its legitimate object, when exclusively employed. And the general feelings of a superstitious age, but just emerging from barbarism, and under subjugation to a priesthood bigoted in the extreme; by no means gave room for that latitude of exertion, without which it is in vain to look for very high attainments. In such a period, whatever tended to make the pleasures of the world inviting, and to render man happy and contented with himself; counteracted the principles of those who hoped, by exciting his apprehensions, to keep him in subjection. Terror, therefore, the most powerful agent of superstition, was more employed than the sentiments of humanity, as the guide of those who selected subjects for the painters; to whom they offered scenes of martyrdom, of infernal punishments, or of hardships and severities to which devotees submitted themselves, in their mistaken zeal for purity and truth. We cannot wonder, therefore, if, under such trammels, the art languished in its progress; and if the ill direction given to the great employment it enjoyed, for a while withheld it from that perfection, to which, under more free indulgence, it aspired; when civil policy united her influence to that of religion, or rather of superstition, in its support.

After a lapse of near 100 years from the death of Giotto, Tomaso da San Giovanni, better known by the name of Masaccio, (from his total neglect of personal appearance,) exhibited a more exalted taste, and a grander style of execution than his contemporaries. The art under his hands may be said to have advanced from the weakness of infancy to the station of youth, verging towards the vigour of perfect manhood. He first composed with an eye to the whole; managed his groups and single figures upon the principles

of perspective, which had been taught him by the sculptor Brunelleschi; and by understanding the effect of those principles, first laid the feet of upright figures flat upon the ground, and foreshortened his heads and figures with truth and effect. In fact, it was to him future artists were indebted for a more sure and full direction of the line in which the art ought to be pursued. He studied nature with the greatest attention, gave breadth and simplicity to his draperies; and most admirable action, character, and expression to his figures; which are justly and appropriately employed, and wrought with admirable execution. Even Raphael did not scruple, 80 years afterwards, to study, and sometimes to adopt his actions; of which there is an extraordinary instance, in the figure of St. Paul preaching at Athens. Michael Angelo is also reported by Vasari, to have regarded his pictures with great respect and attention. His principal works in the chapel of the Brancacci, in the church del Carmine, at Florence, became the school of study for all those excellent artists who succeeded him; till at length Lionardo da Vinci, born near that city in 1445, two years after the death of Masaccio, came forth with superior lustre, and eclipsed all that had preceded. Endowed with uncommon genius, all arts and sciences seemed scarcely to offer a sufficient field for the exertion of his talents. He grasped at all, and succeeded in whatever he undertook; but by his versatility, wasted much of his time in experiment. Had he persevered with steadiness in pursuit of the art of painting, he probably would have carried it to the utmost perfection. As it was, whatever he painted came from his hand elevated and adorned, and presented a complete originality of effect and manner. To truth and precision of character, and whatever had been well done by Masaccio, Lionardo added new and most valuable qualities, by introducing the principles of chiaro-scuro, and depth of tone in colour. By the former of these, pictures were relieved from the tameness of mere imitation; and acquired an increase of power, in boldness and strength of relief, and force of effect. (See EFFECT.) He may be said to have given more than hints of improvement in all the various branches of the art; and to have left some examples, whence, others enjoying more steadiness, and less impetuosity of character, subsequently imbibed such instruction, as directed their course, and aided them in a nearer view of ideal perfection. Michael Angelo in design, Correggio in finish and chiaro-scuro, and Rubens in composition, are fully indebted to Da Vinci for the foundation of much of their perfections.

Before the time of this extraordinary man, the imitative arts had obtained a firm establishment in Italy, by the encouragement its professors enjoyed; and of course the number of artists increased very considerably. One circumstance which occurred at Florence in the year 1400, exhibits that growth very strikingly; and no less so, the true feeling of the citizens of that place towards it. It was the wish of the council, who formed the government, to have another door of bronze to the church of St. John, similar to the one already wrought by Pisano, from a design by Giotto; and for that purpose they invited artists, in various parts of Italy, to send models for competition. The works of seven were chosen for submission to the judges; who consisted, not of a committee of taste appointed from amongst men unpractised in art, but of thirty-four artists of distinguished talent; painters, sculptors, and chasers in gold and silver. Among the competitors, were Brunelleschi, Donatello, and Ghiberti; all men of extraordinary powers, and each worthy of the task. The election fell on Ghiberti, who so executed the work, that Michael Angelo, many years afterwards, said, the doors he had made were worthy to be the gates of heaven. And the

judgment of artists was thus itself justified; and by Vasari is declared to have been regarded, as manifesting not only soundness of sense, but also freedom from every unworthy feeling.

When such care was taken to select in sculpture, it is not probable that the art more immediately applicable to the purposes of the church, which participated in the governments, or rather controuled the sentiments of the whole community, should be neglected in cultivation, or studied vaguely. Accordingly we find, that painting advanced in rapid progress; and circumstances now combined, to render that advance just in its course. The general increase of mental civilization, of literature, and of science; the same causes which operated in the establishment of the first grand era of the arts among the Greeks; now again began to prevail in the world; and the country where they were found, by natural progress, in its turn became the nurse of art; and in time was remunerated in the honour and renown of supporting them, till they established a second epoch, scarcely less illustrious than the former.

The existence of Lionardo da Vinci was the immediate precursor of that exaltation; and the examples he left, and the lessons he inculcated in his writings, had no small share in producing it. (See VINCI DA.) In him, as we have seen in Pamphilus, the master of Apelles, the art enjoyed the advantage of an union with science and general cultivation; and the effect of that combination is evident in the history of both. It enabled Lionardo to embellish and diversify the general impression of character drawn by Masaccio; and to exhibit, with more variety and fullness, the latent feelings of the human heart. Of this, his picture of the last supper, at Milan, is a sufficient proof. And that this perfection was the result of deep reflection, is evident, by his having refrained from painting the head of the Saviour, till he could completely satisfy his mind, with what features and expression he ought to compose a representation of his divine character. By him the theory of design was perfected to a considerable degree. His book upon its principles is well known, and though confused, ill digested, and unequal in its parts; yet it is, beyond a doubt, the most scientific and useful, of all elementary books on the subject; and will alone testify the extraordinary power of his mind, and his activity in research. Many others of his writings are unfortunately lost; and some confined to libraries, where they are very rarely visible.

About the beginning of the century in which Lionardo was born, the use of oil was adopted as a vehicle for painting; and afforded the means of most extensive improvement; particularly in colour and effect. Distemper, or colours mixed with size and water, &c. appears to have been the first adopted practice; and afterwards, fresco; as more durable and better adapted to larger purposes. (See DISTEMPER and FRESCO.) But both of these modes are limited in the execution, more particularly the latter, in which no means being given to change or retouch the colours without evident disparagement of the work, the artist was obliged to adopt as simple a plan of conduct as possible in the management of his designs. But when a vehicle was discovered, or applied, the use of which permitted frequent changes in effect, and in arrangement of colours, with the assurance of perfect union at the conclusion; no means were wanting which he could desire for the indulgence of the utmost stretch of his imagination.

The event which gave rise to the exercise of painting with colours ground and mixed with oil, is supposed, with great reason, to have been varnishing over pictures painted with water colours: which, as they were wrought up to the full re-

semblance of natural objects when the colours were dry, were rendered by the varnish as deep in hue as when the materials were wetted to be employed; and thus a tone of effect was superadded to the natural and ordinary one, purely artificial, but very engaging; and the more so, when placed in opposition to the comparatively dull and tame effect of the former modes; which of necessity lacked lustre, as they always dried with a deadened surface.

The discovery of this very essential advantage to the art of painting, which so readily enabled it to outstep whatever had been previously done; has been, by most authors who have written upon the subject, attributed to John Van Eyck, of Brussels, in 1410. Though many doubt concerning the accuracy of this opinion, yet one thing remains clear, that till after the time in which he lived, oil, as a vehicle for colour, was not in general use. No doubt can remain, that if he did not actually first apply it to the purpose of his art, at least he first used it essentially and effectually. His application of it would not otherwise have made, as Vanmader says, "as much noise in the world as the discovery of gunpowder by Bertoldo Schwartz had done, near a century before!" nor would a native of Italy have taken the trouble of journeying to Flanders, and soliciting the friendship and instructions of Van Eyck, as, Vasari says, Antonello da Messina did, could he have obtained the knowledge he sought at the cost of less trouble and time.

Painting, according to Vanmader, the historian of the Flemish artists, had been carried into Flanders about the time of Giotto, by some Flemings who went for the express purpose of learning it; and he says that "the mode of painting brought from Italy was with gum and eggs; having been so practised at Florence, at its first commencement by Cimabue." It spread in practice among the Germans about the same time, and each of these countries established a mode of art, or style, for themselves. It was in Italy alone, however, that any true perception of what was the proper object of art appears to have been felt, and there it was first exhibited; and even there, it dates its principal exertions from one city and its dependencies, *viz.* Florence. In this place alone it remained pure in its object, the delineation of character and expression, with selection of form, and simplicity, and unmixed purity of effect. A style of design, which pursuing the first impulse of the art, *viz.* the representation of events at their most impressive moments, leaves minor objects out of consideration; and aims solely at fulfilling its purposes in an intuitive manner, upon the mind of an observer. That style, Giotto had founded; it was improved in effect by Masaccio, strengthened by Bartolomeo della Porta, and Lionardo da Vinci, and finally perfected by Raphael and Michael Angelo.

To this most important aim of the art, the introduction of oil in painting brought no efficient aid. What has been said of its benefits, applies only to the ornamental, or less important applications of it. The objects of the grand style, *viz.* beauty of design, and purity of expression, the weakest materials are capable of presenting to the imagination; and, therefore, notwithstanding the brilliancy of colour and effect, which was afforded by the use of oil, it was in great measure disregarded by the Florentines; or if employed by them, they carried into its practice, the defective hues of fresco: to the exception of Lionardo da Vinci, and Fra. Bartolomeo della Porta, (born at Florence in 1479,) who followed closely the line of colouring laid down by the former, his immediate predecessor. To him, the art is indebted for the first conception of the union of true grandeur of style in design, with a suitable dignity and depth of colouring. The subjects he chose were generally of a religious kind, which nearly ex-

cluded naked figures; but he amply compensated for that, by the mode in which he composed his draperies, and arranged his groups. Of him Raphael is supposed to have acquired more information than from any other source, till he had seen the works of M. Angelo in the Sistine chapel. It was Bartolomeo who changed the taste he had imbibed from his master Pietro Perugino, and directed it in the course wherein he afterwards surpassed all that the modern art of painting had effected.

This delightful art, supported by an illustrious patronage, derived, from its acknowledged ability to aid the purposes of state, the increase of riches and of intellectual cultivation; but most materially from religion, now attained its second era of glorious success. A constellation of ingenious men, endowed with uncommon talents, appeared to spread its light once more through the world; and painting was perfected, as far perhaps as human nature can carry it, in the works of Michael Angelo, Raphael, Titian, and Correggio.

Although no one of these four great men appear to have made the Grecian principle of select beauty a precise object of attention; yet in those branches of the art which they more immediately cultivated, they must be considered as having attained the very highest rank. The almost miraculous sublimity of invention, grandeur of design, and breadth of manner, with which the series of pictures adorning the chapel of Sixtus IV. in the Vatican, are planned and executed; sufficiently attest the power of the former. The truth, simplicity, grace, and propriety, exhibited in the historic and poetic compositions, which cover the walls of the pontifical palace itself, and which are also exhibited in the cartoons at Hampton Court; justify the praise bestowed on Raphael. The renown of Titian would be supported by the grandeur of conception, richness and truth of colour, and vigour of effect, which characterises his St. Peter Martyr, did no other work of his masterly hand exist. And Correggio will ever live in estimation, while the suavity and grace of arrangement, the perfect harmony of colour, and the concentrated and brilliant effects of chiaro-scuro, exhibited in the Duomo of Parma, the Notte at Dresden, and the St. Jerome at Paris, are preserved to the world. (See lives of M. Angelo, Titian, Raphael, and Correggio.) To behold the various excellencies of these great men united in one, is still "a consummation devoutly to be wished."

At the time in which they flourished, namely, about the end of the fifteenth and beginning of the sixteenth century, the immense patronage which the art was enjoying throughout Italy, stimulated numbers to the profession of it. In Rome, Naples, Florence, Bologna, Parma, Venice, Lucca, &c. abundance of artists were found ready to fulfil the commissions which individuals, convents, and churches, heaped upon them.

Whilst it was pursued at Florence in its higher principles, and thence transplanted pure to Rome, to adorn the pontifical palaces, &c. of the imperial city; its more alluring, though less solid charms, were cultivated at Venice; where colour occupied the attention of the artists, and repaid it with her most engaging fascinations. Among those artists, Giorgione del Castell Franco, born in 1477, has the reputation of having begun that system of colouring, which his early death alone prevented him from carrying to perfection. Had the period of his existence been lengthened, it is probable that Titian, who adopted his style, would not have stood so completely alone, as he now does, at the head of the Venetian school. In character, and in grace, Giorgione, in some of the few works which he has left, has evidently

surpassed him. Except in the adaptations of it to exalted subjects, and an admixture of a certain degree of grandeur and purity in design, which was effected by Titian, the Venetian style of art has an equal supporter in Giacomo Robusti, called il Tintoretto; who too free to be correct, and too daring to be chaste, held the pencil with a vigour of colour and execution, worthy of being added to the sublimity of Michael Angelo in design. Unfortunately, to the delights of execution and surface, he sacrificed character, expression, and propriety; and the world ought to regard him as the founder of the ornamental style, rather than Titian; whose best works hold a middle rank between Tintoretto and Michael Angelo, and are of too serious a character to merit that appellation. It was, however, his process of colouring, which guided the hand of Tintoretto, and also that of Paulo Veronese, in establishing the success of the Venetian school. Paduanino, the elder and younger Palma, Pordenone, the Bassans, and many others, upheld the system for a time, but not with equal powers.

Another aberration from the grander aim, and more solid original principles of the art, was effected at Parma by the talents of Correggio. Whether he had ever seen the works of Leonardo da Vinci, must remain a doubt. Certainly, the same feeling of arrangement in light and shade, and in the tones, or approaching tones, of colour, seems to have governed both; but Correggio first exhibited it in large works, with brilliancy, with richness, and with consummate harmony. To his principal object, grace of effect, he sacrificed forms and characters; but made amends for the treason, by the perfection to which he carried his own principles. Yet the peculiar grace which accompanied his designs, was too frequently of an artificial nature, and dangerous to follow; as it approaches the verge of affectation, and sometimes justly deserved that appellation.

That peculiar practice of the art, of which Correggio was the inventor, acquired from the district wherein he and his imitators resided, the title of the Lombard style; having chiaro-scuro, rather than colour, for its basis. So that we find the three great schools, into which the Italian practice of painting has been divided, were founded separately upon the three great principles of the art. The Florentine, upon design; the Venetian, upon colour; and the Lombard, upon the union of colour and chiaro-scuro, but principally upon the latter. The colouring of the Lombard school differs from that of the Venetian, in being less positive, or less prismatic; and more like the reduced effect of colours seen by twilight; their hues being rendered subservient to the principle which more immediately characterises that school. Whereas, in the Venetian style, the colours themselves form a part of the chiaro-scuro, and are wrought up to the highest degree of purity and brilliancy of which they are capable. The styles of both are completely artificial; and the result of science, deviating from the general appearances of nature; and are in great danger of becoming unnatural, except in the most skilful hands.

There are, indeed, two other schools spoken of in Italy, viz. the Roman and the Bolognese. But we can hardly separate the former from the Florentine; for the principal works done at Rome were by Florentines, or those educated amongst them, who of course brought the style of that school with them to Rome, and executed their pictures in it; and that of the Bolognese, being an attempt at combining the excellencies of the three principal ones, cannot be classed with those original styles; founded as they are on original principles of art. The Carracci, nearly 100 years after the time of Raphael, were the principal promoters of

this system of combination; which in no slight degree assisted in the ruin of the art, by distracting the attention of its professors. Agostino Carracci wrote a sonnet upon it, in which he inculcated his own ideas, of the qualities necessary to form a perfect painter; wherein he says, "whoever would be a great painter, must take the design of Rome; the shade and motion of Venice; the dignified tone of Lombardy's colour; the terrible manner of Michael Angelo; the just symmetry of Raphael; Titiano's truth of nature; and the sovereign purity of Correggio's style: add to these, the decorum and solidity of Tibaldi; the learned invention of Primaticcio; and a little of Parmigiano's grace." However laudable the attempt to unite these various excellencies may be, the difficulty has hitherto been found too great for any one successfully to combat; and the labours of its great founders, even of Annibal and Ludovico Carracci, powerful and able as they were, by no means served to prove the certainty of the system, in conducting the practice of art to perfection. Notwithstanding the plausible theory it held out, it was too vague in principle, and admitted of too much uncertainty and variety in practice; as each one who adopted it, was at liberty to take, or reject, as much of the peculiar qualities of the masters recommended, as his own taste might direct.

The exercise of painting, as pursued by the Florentine school, being founded upon the most original, most simple, and most valuable principle of the art, is, no doubt, most worthy of esteem. Its grand object, at its happiest period, was an undisguised address to the understanding; and its means, were grandeur of style and truth in design, and a simple unaffected colouring. In its practice there was an uniformity of pursuit, and the same ideas which governed and directed the attention of the earlier artists, were emulously and steadily cultivated; till at length, after a lapse of more than 300 years, from the time of Cimabue, if he may be called the founder, its triumph was completed by the talents of Michael Angelo Buonarrotti, who has been styled the Homer of modern painting. Raphael, however, must not be deprived of the share of applause due to him in tracing the line of its success; for though he was not strictly Florentine, yet the better part of his means were drawn from that school, whose principles he adopted as soon as he was acquainted with them. The praise, however, which is his due, does not arise from any extension of improvement upon the principles of the Florentine school, but from a more perfect application of them than had before been known. He therefore, in this respect, stands upon much lower ground than his great contemporary, who increased considerably the importance of its aims, and grandeur of the style in which they were displayed; and after whose death it gradually declined, till it was at length overpowered by the more specious attractions of the two other schools we have mentioned, the Venetian and the Lombard. In this elevation of the Florentine school, we would not be thought to fail in due respect for the others; from whence have proceeded so many men of great abilities, and so many works of superior excellence. The combination of the three, forms a mass of excellence, the productions of which, the world yet beholds with wonder and delight: but of which, the eclectic principle of the Bolognese school has failed to exhibit one highly effective instance. For further illustration of the peculiar varieties of these schools, see the articles COLOURING and COMPOSITION, most of the principal ones concerning the different parts of painting, and the lives of the painters most conspicuous in them.

At the time when the great masters of these schools were assiduously cultivating the art, and almost simultaneously

bringing it to perfection in all its various branches; it fortunately occurred, that there existed men possessed of affluence and power, conscious of its value, and sensible to its beauties; willing to aid the exertions of its professors, and to employ their talents in an exalted manner. Long held benumbed by the rigid severities of neglect, the germ of its growth, at first, had scarcely felt the genial warmth of encouragement applied to it; by degrees it slowly spread forth its leaves to catch the inspiring gale; then eagerly enjoyed the kind atmosphere which surrounded it; at length its beauties burst suddenly on the view with delightful perfection, and by the enchanting pleasure it afforded, more than repaid the hands which had cherished it. Even in its decay, it left a blessed odour upon the countries that had fostered it: a memento of their existence in the great scale of nations, far more estimable, than the melancholy details of artifice, (under the name of policy,) and of war with its attendant miseries, which so perpetually blacken the page of history.

If the circumstances which attended its progress in ancient Greece, be compared with those accompanying its more recent one in Italy, of which we now speak, they will be found most singularly to correspond; even to the periods of time occupied in its several stages. In both countries, it had risen under the influence of devotional feeling, to various degrees of improvement, as possessed by different masters. It had been enlarged, enlightened, and rendered more estimable by the elements of learning and science infused into its studies; in Greece by Pamphilus, and in Italy by Lionardo da Vinci; and during the latter periods of its progressive improvement, it was employed in both countries as an agent of state policy.

The patronage which we have seen the art enjoying in Italy from the commencement of its career, kept pace with its progress, till it was perfected by the family of the Medici at Florence, and by Julius II. and Leo X. at Rome. Cosmo di Medici in his superintendance over the political affairs of the former place, during the first part of the fifteenth century, did not neglect the interests of its academy, and of the arts in general. A great mass of reliques of ancient art, recovered from oblivion by industrious research throughout the country, of which they had once been the most conspicuous ornaments, adorned his magnificent mansion in that city. These he exhibited for the improvement of taste, and took under his peculiar care the academy of St. Luke, which had been formed in the preceding century. His grandson, Lorenzo, surnamed the Magnificent, who in 1464 succeeded to his power and influence, and was endowed with a far greater predilection for art, for science, and for literary pursuits; increased the collection in a very considerable degree. Being laudably desirous of exciting his countrymen to a successful rivalry with these treasures of beauty, or rather of encouraging the spirit and ability already exhibited by them, he opened his gardens where they were deposited as a school of study; and honouring the abilities of Michael Angelo, appointed him to the management of it. By his influence, and that of Piero Soderini, then Gonfaloniere, the council hall of the republic, which had been recently rebuilt, was ordered to be adorned with paintings by Lionardo da Vinci and Michael Angelo; each having one side of the hall appointed for the exertion of his abilities. This was the first example of any consequence, of public civil employment being given to the painters of Italy; for hitherto their greater exertions had been confined to religious subjects, and devoted to the service and benefit of religious establishments. The subjects chosen for these great competitors were of an heroic nature; and selected from the history of

of the wars of the republic. Unfortunately neither of them proceeded so far as to complete their pictures, although their preparatory cartoons were the theme of universal approbation; and whilst they were preserved, succeeding artists rushed with eagerness to study their excellencies.

The political disturbances which took place soon after prevented the further attention of the Florentines to the arts for some time. In the mean while that skilful, great, and ambitious successor to the papal chair, Julius II., informed of the high perfection in which painting was then practised, would not allow so useful an instrument to lie unemployed in his service. He summoned both Angelo and Raphael to attend him; and under his auspices those great works were begun in the Vatican, of which we have before spoken. His successor, Leo X., emulating the magnificence of his father, Lorenzo di Medici, and that of his immediate predecessor in the papal chair, continued to perfect the plans which the latter had laid down; and directed the efforts of the pencil, to the honour and service of the church over which he presided, the station which he more immediately held, and his own peculiar glory.

The recent discoveries of some of the most beautiful antique statues with which we are acquainted, and which were brought by the popes to assist in adorning the pontifical palace; together with the splendid and admirable works produced by the two great artists and others of lesser note; completely transferred the seat of the arts from Florence to that imperial residence of power, which had hitherto acted but a secondary part, or hardly that, in their cultivation. To this alluring mass of talent, the powers of Titian were also ultimately added; and so important and instructive an assemblage of excellencies was thus combined, that Rome became a kind of university of art, and the resort of all those who aspired at eminence in the practice of it; and more particularly in its most exalted qualities. Thus the second grand epoch of the art was completed in the age of Leo X.

It might have been expected that the effects of these brilliant examples of art would produce still greater excellencies; but, as if there were a boundary set to the intellectual exertions of man, beyond which he is not permitted to pass; the patronage of the highest powers, and the ardent ambition of ingenious artists failed, even to prolong these days of super-eminent success. The splendour of the talents exhibited by those great luminaries of the art, seem to have dazzled, whilst it illuminated, those who approached the hemisphere wherein it shone; and all attempts to reach its exaltation were in vain. After this favoured period, in which it appears that both patrons and artists, had arrived at the ultimatum of their greatness, the hand of destiny once more conducted the art of painting to its decline in Italy. Yet, as before, it lingered in its fall; and like a meteor approaching to dissolution, cast many brilliant emanations around.

Among the most skilful of those who continued to uphold the practice of art with ability, were Julio Romano, Francesco Parmigiano, Pellegrino Tibaldi, and Tintoretto. The former was the most successful of the pupils of Raphael; but though, like Raphael, struck with the grand aims and style of Michael Angelo, he had not his judgment and taste to guide him in the application of it. Endowed with a poetic imagination, and desirous of being original, he swerved from the course pointed out by his master, and lost sight of his purity and truth. Yet if there ever were one painter in the world, whose taste, whose feeling, and whose style, might be adopted with impunity, and imitated without apprehension of imbecility, it certainly was Raphael. Founded as it was upon nature, his taste in composition seems

to bid defiance to perversion. His invention was subservient to his subject, and was dictated by it; and yet, in his successors it not unfrequently took the lead; and the subject, gave way to the bewitching delights of contrast, grouping, and all the systematic arrangements of the art. The grandeur of style, and imposing power of Michael Angelo, was the misused source of this destroying evil. That style, emanating from a peculiar sympathetic feeling of his exalted mind, and correspondent to the poetic fervour which inspired it, though strong and boldly marked, was still under the guidance of nature; and by his perfect knowledge of her forms, was prevented from swerving to deformity. After him, men unable to fathom his principles of action, did not scruple to tread on the ground which he had hallowed; Pellegrino Tibaldi alone traced his steps with successful energy; and displayed his power in the frescoes which adorn the hall of the Institute at Bologna. But in the hands of most of his imitators, it became only a specious mode of imposing upon the unlearned; and contortion and grimace, under the appellation of *il Gusto Grande*, took place of style and character.

The principle of the Venetian style, being more loosely founded than those of the former two, and capable of application to all kinds of subjects, though not with equal propriety, was of course less likely to be so soon destroyed; and having the natural charm of colour for its support, it was practised with considerable success for a length of time. But that of Correggio being altogether imaginary, or arising from more abstract research, found no successful imitator. His expansive breadth of light, conducted with fullness of colour, perfect harmony, and depth of tone, has certainly never been repeated by any one, or but partially. Parmigiano, who probably saw him paint, and doubtless studied his works with great attention, imbibed more of his peculiar excellencies than any other; and in his best works adopted as much of the tone and style of Correggio, as he could blend with his more exalted attempts to reach the lofty design of Michael Angelo. One work, such as his picture of the vision of St. Jerome, now in England, makes more than ample amends for his mistaken adoption of the grace of Correggio; and its too frequent perversion to affectation, visible in his smaller designs. He, unfortunately, like Giorgione, was cut off in the early part of his career, (at the age of 37,) and perhaps before the fullness of his power had time, or opportunity, completely to develop itself. Had he been longer spared to the world, and his progress been equal to the promise afforded by the works he has left; it is more than probable, that we should have seen a more perfect combination of the superior excellencies of the art, than has hitherto been effected. See PARMIGIANO.

About the end of the 16th century, the Eclectic school of Bologna, of which we have before spoken, was founded under the auspices of the Carracci; and certainly, though they did not effectually complete the object they proposed, yet their exertions and abilities arrested, for a while, the retrograde progress of the art. Ludovico the senior, and teacher of the others, in a great measure restored the art once more to nature; and by the purity and simplicity of his taste in form and in colour, preserved his superiority over his nephews, Annibal and Agostino. The former of these, however, strongly contested that point, by his powerful and free execution, and his great academical acquirements; but his mistaken application of them, more than counterbalanced their value; and of this, his great work, the gallery of the Farnese palace is an abundant proof.

The school which they formed for the improvement of their art, and which was entitled *l'Accademia degli Desiderosi*, but

PAINING.

but is now better known as the *Academy of the Carracci*, proved a source of information whence sprung many artists deservedly renowned. Among them were Guido Reni, Domenichino, Lanfranco, Albano, and Guercino. Amid the varied works of these able men, may be seen the imperfection of the plan adopted by their master. Each following the dictates of his inclination, differed from his fellow student in the objects of imitation, as well as in manner; and yet the school attached in measure to all, inasmuch as the art, in preference to nature, was the main object of attention with them generally. In some few instances, indeed, the reverse took place; and Domenichino, in his pictures of the Communion of St. Jerome, and the Cure of the Demoniack, rivalled, in feeling and expression, the fame of Raphael; qualities which had languished, and been neglected after the death of that renowned artist. See lives of the artists mentioned.

After this period the art continued to decline in Italy. The great talents of Pietro da Cortona, and Luca Giordano, were abused by the too great facility with which they satisfied the perverted minds of their employers. Nicholas Poussin alone endeavoured to stem the torrent of corruption in taste, which now flowed over the classic ground of former ages; but though he reverted to the pure source of Grecian art for his models, yet in severe criticism, he is justly said "rather to have copied its reliques, than adopted its spirit." He indeed is by some denied to the Italian school; but as the chief part of his life was spent in that country, and all the valuable information he possessed derived from his residence there, we have attached him to the history of its art; and with him closes all record concerning it, worthy of particular distinction.

To Germany the art travelled from Italy: at what period is not exactly to be ascertained; but it is not improbable that it was soon after the time of Giotto. It was not, however, till towards the end of the 15th century, that its progress there claims our attention. At that time Albert Durer relieved it from little better than obscurity, by his ingenuity, his fertile invention, and his skilful attention to minute imitation of individual forms. He carefully studied the human figure, but wasted his time in fanciful schemes for regulating proportion; and never attained the art of selection, or a station in the rank of exalted artists. Yet sometimes his compositions are well worthy to have been treated in the greatest style in design, and the colour with which he executed them, often rivals the best among the Venetians. The bane of the style, if it may be called so, is meagreness and poverty of forms, mean expression, and capricious and often vulgar invention. Lucas Van Leyden was the best of those who attempted to rival the name of Albert Durer, unless we except Holbein; who, though he never equalled him in composition, infinitely surpassed him in portraiture. The taste of the Germans totally changed after they possessed the knowledge of the works of Michael Angelo; when, with the constant effect of the sudden transition of extremes, the newly imbibed principles burst all reasonable bound; and were employed, only to be abused. Unable to penetrate the depths of its mysteries, its surface was extravagantly imitated by Goltzius, by Spranger, and a host of ambitious contemporaries; but the folly of this misapplication soon acted to its destruction; and in its decay bore down with it the character of the German school of painting.

The history of the art in the neighbouring countries of Flanders and Holland, is merely the same with that of its progress in Germany, till about the middle of the 16th century. The extreme richness of colouring which had been effected by John Van Eyck, was maintained entire; and

seems almost exclusively to have occupied the attention of the Flemish artists. Their distance from Italy, and the consequent want of intercourse with that country, precluded any precise acquaintance with the peculiar beauties of ancient art; and having no model to guide them, or rival to contend with, they were at liberty to follow the suggestions of their own inclinations. It conducted them to as precise an imitation of the effects of natural objects immediately presented to their eyes, as lay in their power to produce. The system of religion here, as in Italy, found occupation for the artists in a considerable degree; but its exercise soon deviated into common life, and reached its ultimatum in the days of Rubens and Rembrandt. The former of these "meteors of the art" shining in a sphere completely his own, irradiated the world with a brilliant and uncommon lustre. Possessed of a mind as full of genius as of energy; he appears without difficulty to have embraced from contemporary artists, and the great masters of Italy, whose works he visited, those elements of which he composed his own system. The principal features of which are, an union of the splendours of the Venetian school, with a grandeur of outline drawn from the Florentine, without its correctness, not untinged with the natural imperfections of his countrymen, and guided by his own individual brilliancy of imagination, and a total disregard of the beauty of the antique. But whencesoever he drew the first rudiments of his style, his application of it was immediately to nature, with all her varieties. Never man was less the slave of a style than Rubens: although it does not cease to appear in all his productions, yet it was moulded to his subject, of whatever nature it were, with the greatest facility; and he certainly added a gradation to the scale of the art by a manner peculiarly his own, and totally diversified from all others. Its great object was to captivate, and no man more completely succeeded in his design, in spite of the numberless defects with which his works abound. To use the words of Sir J. D. Reynolds, "such is the fascination of his pencil, that it is only when we are removed from its influence, we are willing to acknowledge any inferiority in Rubens, to any other painter whatever." (See RUBENS.) He was truly the father of the Flemish art; and under the influence of his example and subsequently to his decease, so perfect a cultivation of the means of imitation, both in drawing and colouring, and also in arrangement, took place in Flanders and in Holland, that a new species of art was produced, unknown to any other part of the world; and during the course of the 17th century, furnished those countries wherein it arose, with innumerable works of the greatest perfection in their kind.

At the beginning of the century, that most extraordinary and original luminary of the art, Rembrandt, appeared; and aided the power of Rubens in completing the perfections of the Dutch and Flemish schools. In him the world possessed another of those men of powerful genius, who created an atmosphere of art for themselves, and moved within it uncontrolled, with a security that sets imitation at defiance. What Correggio had given to the Italians, Rembrandt bestowed upon the Dutch; chiaro-scuro concentrated, or expanded; rivalling the purity and brilliancy of nature. That, and colour, were his immediate agents; with which he played at will, in all the varieties which a vivid imagination and close observation of the more striking effects of nature, could possibly supply him; and not unfrequently by their means gave beauty even to deformity, at least robbed it of disgust, and rendered it engaging to the eye.

The characteristic features of the schools, at the head of which these two extraordinary men are duly placed, are, a perfect skill in combination and arrangement of chiaro-scuro,

scuro; great strength of natural and local character; and a precise truth of imitation, even almost to perfect deception in form, colour, and effect. These powerful qualities are, however, too constantly degraded by a low and vulgar application of them, particularly among the painters of the Dutch school. Among the Flemings, many of the pupils of Rubens adhered to his class of subjects, and exhibited a brilliancy of imagination, and power of execution, worthy of the source whence they proceeded. Vandyke more especially; who, in point of chastity of design, and purity of colouring, excelled even the power of his master, though he had not his capacious genius, to whom the representation of all things seemed equally facile, and whose abilities seem to have been enlarged according to the sphere he was called to act in, or the canvas he was employed to cover.

It would be useless to enter into a minute detail of the progress of the art in those countries. The lives of the various artists who maintained it for a time, supply the necessary information; and their names are, in general, familiar to our readers; we therefore refer to them for further information. See JORDAENS, CHAYER, DIEFENBECK, KONING, METZU, TENIERS, NETSCHER, &c. &c.

The history of the patronage of the art in Holland and Flanders, lies within a very short compass; as it rested almost entirely with the church, who called for altar-pieces, (and their chapels were filled with them,) and the munificence and taste of private individuals. Very few, indeed, of their public establishments were adorned with pictures, notwithstanding the immense fund of abilities the countries possessed; and it was left to find its own interests, by gratifying the taste for portraiture, among the rich merchants and burghers; or the execution of small pictures, within the scale of admission to private rooms, on subjects of ordinary interest, of landscape, or of vulgar amusement. Its practice in those countries failed completely soon after the commencement of the 18th century.

Very little of the progress of the art in Spain is known previous to the year 1500; though it is scarcely probable, considering the intercourse between that country and Italy, Naples more especially, that it had not much previous employment there. Soon after that time, the renown of Titian, and the favour in which he stood with the emperor Charles V. the example afforded by the portraits he drew of that monarch, with the high honour he received from his son Philip II., and his own residence for a few years (according to Palomino Velasco) in the country, roused a spirit of emulation among her natives. And as far as an excellent power of individual imitation, and of gentle, amiable feeling, in composition and expression, will bear a rank among the higher qualities of the art of painting, the Spanish nation may justly claim their share. But the best works of their best painters, give them no just title to any proportion of the homage due to the great masters of Italy, who exercised successfully the grand style. Nevertheless the style of the best Spanish artists is of no mean quality. Spagnoletto certainly selected for himself an original one; the principal foundation of which he had gathered in his studies from the Italian masters; and which, when properly adapted to subject, presented an air of grandeur, forcible, yet severe. But he stood alone in it. A milder and more amiable feeling characterises the manner of the historical painters of his country, as is testified in the works of Coello, Morales, (El Divino,) Murillio, Carrero, Herrera, and others; whilst the bold freedom, and mastery of hand acknowledged to have been possessed by Velasques, with the singular reality of his portraits, places him upon a level with Titian and Vandyke in that peculiar branch of

the art. The gay luxuriancy of the pencil, in the hands of Luca Jordano, employed to cover the ceilings and staircases of the Escorial, and other royal palaces; and the very high honours and emoluments bestowed upon him, and others of the like taste, assisted, no doubt, to hasten the downfall of the art in Spain; in which country it disappeared, as to any effective prosecution of it, about the same time that it did in Italy and in Flanders. The late turn of events in the Peninsula, has made us better acquainted with the productions of Spanish painting than we formerly were; and more intimate acquaintance serves to increase respect for the simplicity and suavity of the general taste of their best artists. But their productions were not very numerous, and are difficult to be obtained.

In France the adoption of Lionardo da Vinci by Francis I. after he had left Italy, (and in whose arms he died,) together with the powerful talents of Primaticcio, of Rosso, and of Nicolo Abbati, employed by the same monarch to paint in fresco the chambers of the royal palace of Fontainebleau; it might have been imagined, would have laid so strong a foundation of exalted taste in the country, where it came with all the charms of novelty, that it could not but have been pursued by a people eminent for their ingenuity, with a degree of success rivalling the neighbouring country of Italy; more especially as they had perpetual intercourse with it, and were under the influence of the same system of religion, which had there adopted painting as a portion of itself. Yet very little arose from these admirable examples; and the only French painters whose names have come down to us of any pretensions to excellence for the next 150 years, are Jean Cousin and Jacques Blanchard. The former lived towards the end of the sixteenth century, and was a skilful designer, though in a meagre taste. He painted principally on glass. (See COUSIN.) The latter was of somewhat later date; and having, by study at Venice, acquired a taste for Venetian design and colouring, he obtained the name of the French Titian, and his works were much esteemed. After these, the art did not rise in France, till Poussin, having imbibed a taste for its excellencies in Italy, returned to his native country, but with reluctance, at the invitation of Louis XIII. Although the treatment he received was handsome, and becoming both patron and painter, yet he found the taste of his country not formed to relish the simplicity of his style. The facile mediocrity of Simon Vouet received more admiration; and Poussin, disgusted, returned to his tranquil life at Rome; leaving the field to a competitor, who laid the foundation of that flutter and frivolity, which characterised the style of the French school previous to the revolution. Le Sueur, indeed, felt like a man of a pure and elevated mind; and spurned the trammels imposed by the style of Vouet. The chastity, the feeling, and purity of the soul of Raphael, seem to have been infused into his mind, and exhibited itself in the series of pictures painted for the convent of the Chartreux at Paris, and known as the life of St. Bruno; in the burning of the books of magic at Ephesus, &c. &c. But no preparation had been made to receive so pure a taste as Le Sueur's; and in a court where ostentation took place of magnificence, its suavity and gentleness were ill capable of withstanding the brilliant, but false glitter, which accompanied the exertions of his fellow student under Vouet, Charles le Brun. He sunk under the unjust abasement, and fell a victim to mortality at the early age of 37; not without leaving cause for a suspicion of his having been poisoned.

His fortunate competitor Le Brun, formed, by the great extent of his ability, an era in the history of the art in France; and stands unrivalled in his style, as the acknowledged head of the French school; the deity of its succeed-

ing

ing artists; and the theme of their eternal adoration, to the utter exclusion of all the real great painters of Italy, of Flanders, or of Spain. And if a vigorous imagination, and powerful execution of rich combinations, in forms, and colour; with an eye and a hand, which arranged with facility the various parts of extended compositions, and united them as a whole; will effectively weigh against the want of simplicity, natural expression, and purity in design; then he well merited the distinction given him by his countrymen. The splendid arrangement of the gallery of Versailles (now in danger of perishing by the neglect that palace experienced during the days of republican France) is a satisfactory proof of the extent of his abilities; and when his battles of Alexander are placed in conjunction with it, we can no longer wonder that such a display of talent, so congenial to the mind of that vain ambitious monarch, Louis XIV., completely overpowered all competitors. During his long reign, talent of all kinds shone conspicuous round his throne; and painting was consequently elevated and encouraged; the splendour of the court, and the dignity of the king, being made the principal objects of attention by its professors. An academy of painting, &c. was formed at Paris, under the immediate patronage of his majesty; and another at Rome, for the benefit of French students. Vander Meulen accompanied him in his campaigns, and painted the principal events that occurred, to perpetuate his renown. But a more classical tribute of homage was required of the art, in that age of learning. In imitation therefore of Cæsar, who had perverted the pictures of Alexander, painted by Apelles, to his own exaltation, by adopting them as symbolic of that power which he had created for himself; so, by the instrumentality of Le Brun, Louis XIV. contrived to make the victories of that immortal conqueror emblematic of his own restless ambition, and his love of false glory, on which he prided himself, but for which no real hero fights, when it must be purchased at the dread price of suffering humanity. The grand monarch, however, in this mistaken application of the art, acknowledged the utility of it, as an agent of glory to himself, through the medium of a more magnanimous prince, who conquering but to conquer, lightened a weight of execration by exhibiting many traits of real heroism. And the result has been, another proof added to the testimony of former ages, of the increased renown which may be acquired by a monarch and a country, from a cultivation of the arts which adorn human nature, above that derived from political causes.

If even the firm basis of nature, upon which the style of Michael Angelo was founded, did not preserve it from perversion by his imitators; it was not likely that Le Brun's, built as it was upon the sandy foundation of artifice, should share a happier fate. As it led the way in substituting theatrical for natural taste, in gesture and in expression, and had obtained such a commanding influence by its success; those who adopted it appear to have imagined that the former was the best prototype of the two; and accordingly the stage, and its artificial airs and graces, which were ready made to their hands, and prevented the difficulty and trouble of searching and selecting from the coy haunts of nature what was necessary for their works, was made the subject of their imitation. But no want of ability appears in the men who immediately succeeded Le Brun. The wonder is that men endowed with so much talent, could have submitted their understandings to so false a taste. Sebastian Bourdon, indeed, rushed from it, and with true poetic feeling endeavoured to imitate, and often very successfully did imitate, the purer taste of Poussin; but Pierre Mignard, Jouvenet, Champagne, and Rigaud, rushed into the system, till it became reduced to pompous no-meaning flutter; and in the hands of

Van Loo, Bouchet, &c. lost all trace of its masterly origin, and sunk into contempt, even in the country where it originated. In a more minute detail of the progress of the art than our limits will admit, the names of Watteau and of Vernet ought not to be overlooked, the former, particularly, who created a pleasing style of execution and colour, and exhibited it in sportive scenes of imagination drawn principally from the amusements of the higher circles; and the latter introduced a taste for landscape and views of sea-ports which had been unknown till his time, but was too artificial in his colouring.

When the terrors of the recent revolution had somewhat subsided, and in measure even during its course, it was thought proper in France to revolutionize the taste of its arts. But whether the fervour of hatred to royalty, the determination to exterminate all remnants of it, even to its bounties, or a real feeling of the indirect course which the taste of their school of art had taken, guided them in the choice of their present style of design, and was the cause or not of the change, certain it is, that in its vibration, it has gone as far beyond the true line of propriety on the one side, as it had before done on the other. In place of the pompous display of figures in affected attitudes, overloaded with draperies of rich stuffs flowing in all the parade of unmeaning magnificence, a dry and insipid imitation of Greek sculpture is adopted; and in spite of the immense mass of perfect exemplars, in the works of Raphael, of Titian, of Domenichino, and almost all the renowned masters of Italy and of Flanders, &c. with which the gallery of the Louvre abounds, and which, with a superior judgment, the government leave free to their study; the present rulers of taste in France have marked a line of conduct for the students, imitative of the condition of painting before those masters were born. Rejecting the efforts of the happy period of its maturity, they prefer resorting to the infancy of the art, with about as much propriety as a man who is desirous of walking might tie up his legs, and throw himself into the arms of his nurse. Whether the minute attention now given by the French school to drawing, and the peculiar taste in which it is directed, *viz.* to the adoption, in painting, of the forms which appear to belong exclusively to sculpture, be likely to produce, in any length of time, the end proposed, is extremely problematic. We rather suspect the system must be changed ere they will reach the object of their wishes; and then perhaps this preparatory attention to simple forms may have its due effect.

It has remained to our time, that it should be said of England, she had a school of art appropriately her own.

So very little is known of what occurred concerning the art of painting in this country, previous to the time when Henry VIII. encouraged the abilities of Holbein in portraiture, and invited Titian to come here; that it would be useless to endeavour to trace its history. Enough, however, is known to satisfy us that it was at a very low standard. It was but little before his time, that the people of England began to throw off the yoke of ignorance and barbarism; and to cultivate literature and science. The ambition of Henry to be renowned, and his spirit of rivalry to his great neighbour Francis I. of France, were quite sufficient motives to stimulate him to the proud aim of becoming a patron of the liberal arts; had not his theological discussions with Luther, and afterwards his more sublimary quarrel with the pope, so powerfully diverted his attention from them; and produced him so active an employment in deciding the course of the reformation in religion which consequently ensued. But however great be the cause that England has to rejoice in the general fruits of that change in religious principles and government; its effects were fatal to the cultivation of the

the arts of painting and sculpture. Those arts, particularly the latter, being then so thoroughly interwoven with the system of the church of Rome, were of consequence as thoroughly opposed by that of England, set up in defiance of its authority. Had the arts at this time, when the nation was new-modelling its character, been adopted by the reformed system of religion; and had they accompanied it with progressive steps in its course to our present state of cultivation; we might, together with our just privilege to boast of an exalted rank as a nation, in literature and science, have likewise heightened our importance by exhibiting a settled style of historical painting. But it was nipped in the bud, and to this day has not overcome the effect of the chilling blast of disappointment and neglect.

In the succeeding reigns of Edward VI., Mary, and Elizabeth, some few portrait painters, natives some, but principally foreigners, exerted themselves to gratify the desires of our nobility, and preserve their features to the admiration of posterity. St. Antonio More, Frederick Zuccheri, Isaac Oliver, Lucas de Heere, and others of less note, supported this branch of the art with varied success. But during the long and splendid reign of the latter of the three sovereigns, not only was encouragement denied to historical painting, but the very humble, and even graceful attempt made by the dean of her majesty's chapel, Dr. Symson, to afford her pleasure from the sight of prints upon religious subjects, met only with the severity of rebuke. (See Strype's Annals.) Whether it were natural bigotry, or political necessity, which incited the queen to the use of the repulsive air she assumed, it acted like a command upon the church. "Who," said she to the doctor, "engraved those prints?" A German. "It is well it was a foreigner, or we should have enquired into it," was the royal rejoinder, which gave the cue to the clergy, throughout the kingdom, for the "expunging of all paintings on the walls of churches, and the substitution of passages of scripture in their stead;" and from that time to the present hour, the prejudice, except in a very few instances, remains in full force. Thus was that channel through which alone the plastic arts had ever been introduced with success into any country, closed upon the efforts of the English; and by that hand which, if conducted with true and enlightened policy, ought to have fostered it. Nor can we be surprised if the people, ignorant and overheated as they were with religious zeal, should unite in the feelings of their governors.

Charles I. endeavoured to introduce a feeling for the art, which his father had almost entirely overlooked; but for which he appears to have had a very great affection. He employed Rubens during his short residence here, as envoy from the king of Spain, to paint the ceiling of the banquetting room, now the chapel of Whitehall; and procured a treasure of inestimable value to the country, by the countenance and encouragement he afforded to Vandyke; and also to other ingenious foreigners, who have enriched the country with their productions. He formed a very considerable collection of pictures, in addition to those already possessed by the crown, and at the suggestion of Rubens bought the cartoons; he employed an artist to copy the works of Titian in Spain, and purchased the cabinet of the duke of Mantua, at the cost of 20,000*l.* (see Walpole's Anecdotes, Car. I.) and some were sent him as presents. The whole were sold and dispersed by the parliament in 1643, who gave especial orders, "that all pictures which had the representation of the Saviour or the Virgin Mary in them, should be burnt." After the restoration many of them were returned to the Royal Collection, but only to meet utter annihilation by the fire which consumed the palace of Whitehall.

Of the natives of England, few caught the flame of desire to imitate them even in portraiture, not one in history. Of the former, W. Dobson took the lead, and succeeded in painting a head with great skill; but there his abilities rested. His exertions, and those of his contemporaries, were arrested, almost entirely, by the Gothic barbarity of the puritanical system which followed; and the taste of Charles II., whatever he might have acquired from his father, was only immersed in impurity and frivolity, by his long residence at the French court; where he acquired a taste for that parade and pompous display of magnificence which was the ruin of the French art.

Verrio, and Benedetto Gennaro, were the protégés of this monarch. The former was employed by him to decorate the ceilings and walls of the royal palace of Windsor; and received for the extravagant load of ingenious absurdities with which he covered them, to the amount (according to Walpole) of 5500*l.* and upwards. Of the latter, there are several pictures at Windsor, in a style of dull imitation of Guercino, of whom he was a nephew. In portraiture sir Peter Lely filled with very great ability the place which Vandyke had held; and in an original and very agreeable manner, he often rose to a station very nearly approaching that of his great predecessor. In the expression of beauty he frequently surpassed him; and was a far more agreeable painter to the ladies. Sir Godfrey Kneller, likewise, in this reign began his long career of portrait painting; he succeeded to Lely's fame upon his decease in 1680; and as an artist was utterly ruined by success. Had he been under the necessity of labouring with care to support the great name he enjoyed and abused, he had talents efficient to the purpose. Witness for him, the converted Chinese at Windsor, the portrait of Newton at Petworth, of Dr. Meade at Oxford, and many others. But he lived and practised painting for five successive reigns, almost without a rival, making gain rather than fame the object of his desire. Dahl, who was a Swede, was the only one who interfered with his practice, to any extent. Wissing, his countryman, threatened, by his carefulness in finishing, to have more effectually counteracted him; but he, unfortunately for Kneller's reputation, died young.

In historical painting, no English artist had appeared to rival the productions of foreigners introduced here, in any degree, till at length sir James Thornhill, born in 1677, arose to contest the honours of the palette with La Guerre, who had been employed to adorn the halls and staircases of many among our nobility. The style he adopted, like that of his rival, was but a lower imitation than Verrio's of the French school; and by no means served to elevate the taste of the country. However, the state did him the justice to employ him in the decorations of St. Paul's and at Greenwich, in which he was most materially assisted by a German of the name of André: but such was the humiliating nature of his engagement, that he was paid at the rate of 40*s.* per square yard. With him properly commences the history of English art, though portraiture, as we have noticed, had been practised by Dobson after Vandyke, also by Riley, and by Cooper, who was a very ingenious artist, in miniature. But after them, it sunk lower and lower, in the hands of Greenhill, Jervas, Richardson, (who, notwithstanding, has so admirably written upon the art, and exhibited in his essays a true feeling for those excellencies which he could never exemplify by manner;) and hundreds of others whose names it would be cruel to rescue from oblivion; for the mania for portraiture did not cease, though the ability of the artists was fast verging to utter decay. What sir James Thornhill had done in historical, or rather decorative art, found no very successful imitator; so that to use the words of Horace Walpole, "in the com-

PAINING.

mencement of the reign of George I. the arts of England were sunk almost to the lowest ebb;" and with the still greater authority of sir Joshua Reynolds we may add, "lower they could not well be."

That such should be our degraded condition in the art of painting, which from its value and importance, when properly applied, has been so justly considered as essentially useful in promoting the dignity of a state; and that, at a time when, in political importance, in science, in poetry, and philosophy, we held so high a station among the kingdoms of Europe, where it had been cultivated with success, must, at first sight, appear somewhat paradoxical. A little consideration upon the circumstances which have counteracted its growth among us, will, however, at once satisfactorily dispel the surprise it necessarily occasions. In no nation has the art been known to rise spontaneously to perfection. We have seen it in Greece and Italy gradually gaining strength through accumulated years, growing as it were with the people. "The artist and the age," Mr. Barry has observed, "were so fitted to the weakness of each other, that admiration was kept constantly alive during the whole successive progress from barbarism to perfection." When it was first introduced from the earliest sources of cultivation on the continent, this was the time to have encouraged it, and taught the nation to imbibe a taste for its beauties; and then, by degrees, it might also have reasonably been expected to have improved among us. Whereas the circumstances related above, exhibit it, on the contrary, rebuffed, before it had taken sufficient root, and what lighter branches had attached themselves to the soil, torn with violence from its nourishment. The earlier works of the artists, whether British or foreign, being expunged from the churches, and the seal of authority placed against their future admission; together with the breaking up of the monasteries, and the consequent dispersion of those bodies of men, to whom at least mankind are indebted for the maintenance of literature, and the arts during the dark ages, settled completely the fate of historical painting in England. The favourable moment for employing it in any other than a religious course elapsed; and the general tone of education among the people, not having fitted them to receive its influence, except as attached to religion, what little had been adopted was stifled in its growth. In the mean time an accumulation of pictures gradually took place; the produce of other countries, where the art had been more regularly attended to, and the habit of resorting to the continent for information gaining strength, the acquired ideas of our nobility and gentry rose above the power of the uncherished artists of the country, which those who guided public taste upon too just grounds decried; and thus an evil which to this day operates to depress our artists, commenced its preponderating influence.

The circumstance apparently most surprising in this matter, is, that when the powers of Vandyke were so long and so widely displayed in England, and portraiture so much encouraged, that so few of her artists should have followed in his track, or that taste should have swerved so completely from it. But the fact is, that British students were inclined to pursue it, witness Dobson and Riley; and Jamesone in Scotland; and they succeeded to a very considerable degree. It could not, however, be expected that when there had been so little food for nourishment offered to artists, that they should at once spring to perfection, unless endowed with genius in a higher degree than even the renowned master whom they emulated. No one was immediately found equal to that, and the allowances created by his exquisite abilities, had scarcely subsided into regular study, when Lely appeared to usurp his station, and spread the peculiar beauties of his own ready

pencil in the way; gratifying the court, and, consequently, guiding the taste of the country. Kneller succeeded rapidly to him; the English artists had not time to rise; and imitation of the reigning influence was alone left for them; as no one advanced with sufficient power of mind to steer successfully in a track of his own.

The period at length arrived, when England, exerting her native energy, advanced in her turn to enjoy a share of renown among the cultivators of the art of painting.

The principal difficulty in the outset of this event, was to rescue the art from the degrading influence of a vicious taste, to retrace the steps of our predecessors, or rather, to burst the bondage in which they had enthralled us, and resort at once to the original principle of imitation; which, when pure and select, is the only sound basis of the art. The first step towards it was the establishment of a school for drawing from the living figure. This had been begun by sir James Thornhill, in most inexplicable conjunction with sir Godfrey Kneller, who one would imagine, from his latter works, had left all consideration of the value of such a thing far behind. Thus, however, he assisted in laying the foundation of a remedy for the evil, which he more than any other had occasioned. This school, sir James continued at his own house in the Piazza for some years. His death, in 1734, obliged the artists to procure another situation, which was not effected without some difficulty; for the people were so unprepared to consider the study from the naked figure as necessary to the artists, that their meetings were even suspected to be held for immoral purposes. Another school was at length formed by Michael Moser, a native of Schaffhausen, and a chaser by profession, and six other artists, principally foreigners, the management resting with Moser. After a while they were visited by Hogarth and others, and a larger body was formed in consequence, who established themselves in Peter's-court, St. Martin's-lane, in the year 1739. Having acquired some property by combined exhibitions of their works, they solicited a charter of incorporation, and the scheme being sanctioned by the king, their charter was granted in 1765. But dissensions arising in the body, a secession of many of its principal members took place, and the result was the establishment of the Royal Academy in 1768, under the more immediate patronage of his majesty; sir Joshua Reynolds being nominated its first president. *Edwards's Anecdotes of Painters. Introduction.*

In conjunction with these more active exertions of the artists, there did also arise in the minds of many gentlemen of improved understanding, a wish to see the art of the country emancipated from the shackles of the artificial taste which was imposed upon it, and societies were formed, which made it an object of attention, and excited a more general regard for it. But this was not till after the time when the artists had forced their way into notice; more especially Reynolds, Hogarth, and Wilson.

Richardson, who died in 1745, at the advanced age of 80, unable by his pencil to rival the real beauties of Vandyke, of Raphael, or others whose names stand on high record, endeavoured to make amends by his pen, and in 1715, published a book full of high encomiums of the merits of those masters, and of useful observations on the theory of the art of painting; and in 1719 another, on criticism, and the science of a connoisseur; works of which nobody will be inclined to dispute the merit, who knows the value which sir Joshua Reynolds placed upon them; and particularly the former, which he declared confirmed him in his love of the art, and elevated his ideas of its professors. In it, Richardson contended for the propriety of painting portraits in the collume of their time; a dangerous symptom of feeling

PAINING.

ing for the continuation of the system of loose robes introduced by Kneller, when common sense began to resume her influence in the minds of artists. Hudson, the son-in-law of Richardson, with the help of Van Alken, (a Fleming,) and in rivalry with Van Loo, (a Frenchman and brother to Carlo Van Loo,) profited by the suggestion, and ventured to reject the nonsensical draperies in use at the time; and instead of loose unmeaning pieces of varied fluffs thrown in artificial folds over the shoulders of the gentlemen; and the affectation of grace and grandeur in which the ladies were represented *en chemise*, half exposed and half enveloped in one ill-contrived piece of silk, as if they had carelessly thrown on a mantle when rising from their beds, he dressed them in the formality of the day; and his Flemish assistant painted their silks and laces with great care and exactness. Hayman also, who had succeeded Sir James Thornhill as a historical painter, upon the same ground felt himself at liberty to preserve the uniforms proper to those whom he introduced into his pictures; and no longer by a senseless magic converted them into Roman centurions or Grecian heroes.

Thus, by the aid of the schools we have mentioned, and their own good sense, the attention of English painters was at last steadfastly attached to the first principle of their art, imitation, from whence they might rise; instead of being distracted by that which properly belongs only to its decay, ornament, from whence to proceed must be to fall. It was comparatively of no import, that the materials which they had to imitate were detestable in themselves; and nothing could be more repulsive to good taste than the toupees and stiff skirts of the men, and the starched ruffles, high heads, and hoop petticoats of the women. Attention to actual representation in the first instance, appears to have been the only means by which the vile spell that controuled them could be effectually dissolved. That once broken, and a cultivation of taste taking place on better grounds; and when a real knowledge of what was truly admirable in art, and attainable in its practice, had been assiduously cultivated by our artists in Italy, unshackled by any extraneous trammels, and exerting their judgments in a right unbiassed direction; it no longer appeared problematic, whether England might, or not, produce painters, as she had done poets and philosophers. The chains which had prevented her native exertions, had been forged imperceptibly by foreigners, who reviled her, aided by unfortunate political circumstances; and it is not a little striking, that when she rejected their influence, when all pretensions to art were sinking upon the continent, and those countries where it had most flourished, ceased to produce painters of eminence; that, at that very time, England should step at once from her obscurity, and illumine the deadened atmosphere of art, with an irradiation of no common lustre.

It were useless to trace the progress of the art in the hands of those who in minor degree assisted in this enfranchisement of it in our country; "or recount the stammering and babbling of its infancy;" for as such, its condition at the time of which we are speaking may be regarded. It scarcely enjoyed the period of youth, for when Reynolds and Wilson returned from Rome, they rushed at once with it to maturity in portraiture and in landscape. And when West, having by his British connections in America imbibed a true taste for its beauties, had also cultivated it in Italy, and came here to devote his life in its service, all that had been done in history, by Hayman, by Pine, by Wale, and others, was instantly sunk in oblivion.

Hogarth, however, demands a rescue from the mass of our earlier artists. With a marked originality of feeling,

he pursued the art as his own taste, or rather fortune, guided him; and traced a line for himself totally unknown to any other, though more in the application of the art than in itself. Yet in his latter pictures, particularly in his *Rake's Progress*, and the *Marriage-a-la-Mode*, he exhibited a thorough feeling for the beauties of the Dutch school; executed in a broad style of his own, and proving, that if his youth had been employed in painting pictures, instead of engraving silver tankards, he might have rivalled the best among them.

In landscape, Lambert had advanced beyond the steps of his contemporaries; and produced with some talent, a kind of union of the peculiarities of Gasper Pouffin, and Claude. But when Wilson expanded his brilliant, chaste, and glowing tints, in ample masses of light and shade, over the canvas; the art seemed to leap at once ages in advance; far too rapid, indeed, for the taste of the public; or the benefit of its (subsequently) adored professor. See *Life of Wilson*.

Whatever had been done here in portraiture, from the time of Vandyke and Lely till 1752, when Reynolds returned from Italy, was then utterly annihilated by the display of his splendid talents; the foundation of all, which this branch of the art boasts in the English school. Not but that there have been and are exhibited various deviations with original feeling, from his peculiar taste; but his is the acknowledged and undoubted claim of superiority, as of priority. His best portraits are inferior to none, for truth of character, and style of treatment; in many points they are superior to those of all the portrait painters who ever lived; and to his talents, exhibited in the various works collected by the British Institution, and opened to the public during this last summer, (1813,) the nation has, by acclamation, declared its homage, and acknowledged its obligations. See *Sir JOSHUA REYNOLDS*.

With respect to the practice of the higher style of historical painting in this country, the rank it merits is so much the almost exclusive privilege of artists now living, that it is not easy to know how to state the sentiments which liberal and candid criticism dictates concerning it. Partiality may blind, or true criticism, if given, may be misconstrued to flattery, or some principle of a meaner kind. It must be left, therefore, to posterity, to give the due meed of praise to those, who have exerted themselves against innumerable difficulties, and endeavoured to uphold the true spirit of the art in this, its most arduous application; and persevered, till at length something like an inclination to encourage their efforts appears to arise, where alone it can be effectual. No one can for an instant hesitate to declare their sense of the exalted abilities with which it has been, and is supported; or cease to wish to see them duly engaged.

Of those who have practised in this branch of the art, and are departed, Reynolds, Romney, Opie, and Barry, require to be particularly mentioned. The former with all the splendour of chiaro-scuro and colour, which no one since Rembrandt has wielded with so much authority, exhibited in his pictures of Hercules strangling the serpents, Macbeth, cardinal Beaufort, and Ugolino, a fund of historic power. Romney also had poetic imagination, feeling and expression; and in the little leisure allowed by his general practice of portraiture, indulged in the delights ideal subjects afforded him; while Opie presented "images new and striking, drawn directly from nature," and "what he wanted of academical or classical information, he compensated for, in great measure, by character, by force, and by a just and bold imitation." But of the four, Barry was the only one who had regularly educated himself for its practice, and undoubtedly had the

PAINTING.

highest and most enthusiastic feeling for its best qualities. With a generous zeal worthy of the highest encomium, he broke entirely from all consideration of the ordinary style of subject, or design; and contemplating his art in the most exalted manner, attempted to embody the elevated ideas he entertained. His most sincere admirers must, however, regret, that those excellent sentiments, which he so ably inculcated by his pen, were not more completely supported by his pencil; yet, his productions of the series of pictures upon the culture of man, in the great room of the society in the Adelphi, notwithstanding their imperfections in the executive part, must ever remain a marked event in the annals of historical painting in England.

For further illustrations on this subject, see PICTURE.

Colours employed by the Romans in Painting, in the time of Pliny. See Pliny, lib. xxxv. caps 6 and 7.

WHITES.

- Melinum.* A native white earth, from the island of Melos, used by Apelles before white lead prepared with vinegar was invented.
- Paratonium.* An Egyptian white earth, used in distemper; and similar probably to the white now called Cremnitz white, from Hungary. Pliny complains that paratonium was frequently adulterated with Cimolian earth, which was used by the fullers at Rome.
- Eretria.* An ashy white. It is named from a town of Eubœa, now Trocco.
- Cerussa.* White lead.
- Anulare.* Gypsum.
- Creta.* Chalk.

YELLOWS.

- Sil.* Ochre of four kinds; named Atticum, Lucidum, Syricum, and Marmorofum.
- Auripigmentum.* } Orpiment.
- Arsenicum.* }
- Cerussa usta.* Masticot, first discovered by the fire at the Piræus.

REDS.

- Minium.* Red lead, both natural and artificial. The best native minium was found in a quicksilver mine near Ephesus; and in endeavouring to extract gold from it, Callias, the Athenian, discovered vermilion.
- Vermilion.* The same as now used.
- Sinopis.* A red earth. The best was found near Lemnos, and was so valuable, as to be sold sealed up. It approached near in colour to minium.
- Rubrica.* A red earth.
- Cinnabar.* Native Indian name for dragon's blood.
- Sandaracha.* A red orpiment.
- Sandyx.* By some thought to be vegetable red, and obtained somewhat after the manner of our lakes, viz. absorbing the colouring matter of a decoction of the vegetable matter in chalk.
- Purpurissum.* A lake made from the ingredient used in dyeing purple, being absorbed in tripoli.
- Syricum.* A mixture of sinopis and sandyx

BLUES.

- Armenium,* or } Verd'azur, or blue vitriol. Pliny calls it a
Azure, also } sand; and says there were three kinds,
called *Ceruleum.* } viz. the Egyptian, the Scythian, and the
Indicum. } Cyprian.
Indigo.

GREENS.

- Chrysocholla.* Malachite, or mountain green.
- Appianum.* Another of the same nature.

BLACKS.

- Atramentum.* A common name for all black colours. Pliny speaks of one kind, as oozing from the earth; and it may possibly have been some kind of bitumen. Of another, as being made from smoke of rosin and pitch. Burnt lees of wine, or husks of grapes, produced another, used under the name of Truginon, by Polygnotus and Micon; and another was invented and used by Apelles, by burning ivory. That being made thin by some vehicle, was probably the atramentum or varnish, which he is said to have laid over the surface of his pictures. What the vehicle was is unknown; perhaps, as the mode of painting with wax by heat was practised, it might have been some modification of that material.

According to Pliny, "Apelles and other ancient artists used only four of the colouring substances mentioned above. But if we are to give him credit for the propriety of the praises he bestows upon their productions, we are under the necessity of denying it to him in this matter. Had he not specified the substances themselves, and we had been left to imagine that they possessed others more perfect in quality, the assertion might have been admitted; because, philosophically speaking, four perfect colours, with all their combinations, are certainly adequate to every purpose the art of colouring could require. Unfortunately for him, the substances he has mentioned are not in their nature equal to the power of those we now possess: and the practice of art, even with our present advantages, denies the knowledge of any four pigments, equal to the production of a work worthy of being denominated a fine piece of colouring. He says, lib. xxxv. c. 7. that "they used only MELOS for white; SIL, attic ochre, for yellow; SINOPIS, red; and ATRAMENTUM, black." He has before observed, that "Polygnotus and Micon used a black made of grape husks," which is a *blue-black*; and probably the greyest they had; but this is no substitute for blue, worth mentioning. The mere enumeration of them must suggest to every artist, the utter impossibility of producing any work of fine colouring from them, unless in a very confined scale.

The pigments in present use are very numerous. Those employed in fresco, have been mentioned under that head. The principal ones fitted for the general purposes of oil painting, are, *Cremnitz white, white lead* of different kinds, a fine yellow lately discovered from chromate of iron, *King's yellow* or *orpiment*, *Naples yellow*, *patent yellow*, *ochres*, *Dutch pink*, *terra di Sienna*, *yellow lake*, *red lead*, *vermilion*, *red ochre*, *Indian red*, *Venetian red*, *lakes* of various kinds, *brown pink*, *Van Dyke's brown*, *umber*, *burnt and unburnt*, *terra di Sienna*, *burnt*, *Prussian* and *Antwerp blue*, *ultramarine*, *ivory-black*, *blue-black*, *asphaltum*. These

PAINTING.

are the principal colours for the palette, but there are a variety of others, which are employed for particular purposes, such as verdigris, &c. &c. The natures of these colours may be known by reference to their particular specifications.

The oils best adapted to the purpose of painting, are *poppy*, *nut*, and *linseed oils*; and in this climate a preparation of the latter, by boiling it with some siccativæ, is in very common use. See OILS.

The varnishes most employed are made from *gum mastic* and *gum copal*, the former dissolved in spirit of turpentine, the latter in oil, &c. (See VARNISH.) To those who desire more minute information on the subject of colours and vehicles, we recommend the perusal of P. F. Tingry's Painter's and Varnisher's Guide.

The preparations of grounds for painting upon, is matter worthy of particular attention. The mode now most in use is of absorbent ones; by which the oil being taken up, is of course prevented from coming to the surface of the painting, and giving its own yellow hue to the work. Absorbent grounds are made of different materials. Some employ plaister of Paris, others pipe-clay, whiting, and size, &c. The former are apt to take up the oil too quick, and render the colour too stiff to work agreeably; and the latter are always liable to be affected by damp. A better one than either is produced, by grinding the colour in water, and then mixing a little oil with it. This does not cause the disagreeable effect above-mentioned, and is always firm. One great object in laying on the ground, is not to give too much of it; but just sufficient to cover the threads and interstices of the canvas, or the grain of the wood: if too much be laid on, it is in danger of chipping off, or of cracking.

For the practice of the art of painting, it is very difficult to give many efficient rules. The principal objects which require attention, are to let the preparatory colours be lighter and cleaner, (that is rather more grey,) than those with which

it is intended to finish, and to take care that the full form be made out with the under colour, before any proceeding is made with the finishing ones; which ought not to be disturbed in their hues; and to be employed only to strengthen those prepared, and give lightness and delicacy of execution. It is also desirable in painting, that the colours be disturbed as little as possible with the brush; and not be too much blended, or softened; but rather laid on with touches, beside each other; as that tends to keep them pure; whilst too much fretting causes them to become muddy, and to change in drying. The first part of the process of a picture, after the artist has fixed in his own mind a full idea of his composition in all its material parts, is, for him to draw correctly the general forms, and then begin to paint in his chiaro-scuro, with as simple a scale of colour as possible; and fully to satisfy himself on that head before he proceeds with his positive colours. This is the readiest mode of avoiding confusion and the necessity of frequent repetition; but there are almost as many modes of process as there are painters; each varying in some respect from the other, and every man's practice, either by accident or principle, furnishing him with varieties. Too great an adherence to system, is certainly not favourable to advancement; yet without a system, much time is necessarily lost; and it seems most reasonable, that every artist should commence with one, however he may find it necessary to vary from it in his progress. Rubens, and most of the Flemish school, evidently exhibit theirs, by leaving so much of the coloured ground of the picture to act among the shadows, and under the half tint; as is always seen in their productions. In order to do this effectually, a finished sketch ought to be prepared; and indeed, in any mode of art, such an one is very useful; particularly where the work is of any great extent.

For the great principles which guide and govern the practice of the art, see the respective articles COMPOSITION, COLOURING, DESIGN, &c. &c.

PAINTING.

A Chronological List of ancient Painters ; from the earliest Period, to the Decay of the Art under the Romans.

Names.	Country.	Time.	Excell'd in
Bularchus - -	Greece - -	700 B. C. - -	History.
Panæus - -	Athens - -	about 430 B. C. - -	History and Portraits.
Polygnotus - -	Athens - -	the same time - -	The same, and first gave character.
Timagoras - -	Athens - -	} nearly the same.	History.
Micon - -	- - - -		
Aglaophon - -	- - - -		
Cephalodorus - -	- - - -		
Phytus - -	- - - -		
Evenor - -	- - - -		
Apollodorus - -	Athens - -		soon after - -
Zeuxis - -	Heraclea - -	about 404 B. C. - -	Colour and taste.
Parrhasius - -	Ephesus - -	same time - -	Same qualities.
Timanthes - -	Samos - -	near the same time - -	Great invention and fullness of expression.
Euxenidas - -	- - - -	ditto.	
Aristides - -	- - - -	ditto.	
Pamphilus - -	Athens - -	about 340 B. C. - -	Taught Apelles ; united science to art ; and obtained great privileges of the Sicyonians ; and afterwards of all Greece, for the professors.
Eipion - -	- - - -	same time.	
Therimachus - -	- - - -	ditto.	
Apelles - -	Native of Cos - -	328 B. C. - -	In all the various parts of painting.
Pausias - -	Sicyon - -	- - - -	Encaustic.
Aristelaus - -	Son of Pausias - -	- - - -	History.
Protogenes - -	Rhodes - -	the same time - -	Taste and finish.
Aclepiodorus - -	- - - -	ditto - -	Proportion.
Amphion - -	- - - -	ditto - -	Arrangement.
Aristides - -	Thebes - -	somewhat later - -	Expression.
Nicomachus - -	- - - -	- - - -	History and poetical subjects.
Philoxenus - -	Eretria - -	- - - -	History.
Perfeus.	- - - -	- - - -	
Fabius - -	Rome - -	about 300 B. C.	
Aristippus and } Niceros }	Sons of Aristides - -	- - - -	Poetic subjects.
Antonides and } Euphranor }	Pupils of Aristippus.	- - - -	
Pyreicus - -	- - - -	later - -	Called Rhyparographus, because he painted low or vulgar subjects.
Serapion - -	- - - -	- - - -	Vulgar subjects on a large scale.
Lyfippus - -	Egina - -	- - - -	Encaustic.
Antidotus - -	Pupil of Euphranor.	- - - -	
Nicias - -	Athens, pupil to Antidotus	one of the same name, lived at the time of Apelles	Portraits, History, and Poetry.
Pacuvius - -	Rome - -	150 B. C. - -	History.
Metrodorus - -	Athens - -	170 B. C.	
Timomachus - -	Byzantium - -	30 B. C.	

Pliny mentions many other names of painters, and what kind of pictures they made in the decline of art ; but does not specify at what time they lived. See lib. xxxv. cap. 11. ver. 1.

PAINTING.

A Chronological List of Painters, from the Revival of the Art, to the Beginning of the last Century.

Names.	Studied under	Excelled in	Painted	Country, Place, and Year of their Death.	Age.	Principal Works are at
Giovanni Cimabue	certain Greeks	first revived painting	History	Florence, Flor. 1300	60	almost all perished.
Andrea Taffi	Apollonius, a Greek	revived Mosaic	History	Florence 1294	81	unknown.
Giotto	Cimabue	quitted the stiff manner of the Greeks	History	Florence 1336	60	Rome, St. Peter's, Arezzo—Mosaics. Assisi.
Buonamico Buffalmacco	Andrea Taffi	-	History	Florence 1340	78	Pisa, Campo-Santo.
Ambrogio Lorenzetti	Giotto	-	History	Sienna 1350	83	
Pietro Cavallini	Giotto	-	History	Rome 1364	85	Rome, St. Paolo furor della Citta.
Simon Memmi	Giotto	-	Portraits	Sienna, Florence 1345	60	
Andrea Orgagna	imitated Giotto	-	History	Florence 1389	60	Florence, the Dome.
Tomaso Giottino	imitated Giotto	-	History	Florence 1356	32	
Paolo Uccello	Antonio Venetiano	first who studied perspective	Birds, some Hist.	Florence 1432	83	
Maffolino	Lorenzo Ghiberti and Gher. Starnina	gave more grace to his figures and drapery	History	Florence 1418	37	
Mafaccio	Maffolino	-	History	Florence 1443	24	Florence.
Fra. Giov. Angelico da Fiefole	Giottino	-	Hist. Miniatures	Florence, Rome 1455	68	Florence, the Palace, in the apartments of, the old pictures.

PAINTING, *Economical*, is that application of artificial colours, compounded either with oils, or water, which is employed in preserving or embellishing houses, ships, furniture, &c. &c. The term, *economical*, applies more immediately to the power which oil and varnishes possess, of preventing the action of the atmosphere upon wood, iron, and stucco, by interposing an artificial surface; but it is here intended to use the term more generally, in allusion to the decorative part, as applied to buildings; as well as to its more essential ones; and as it is employed by the architect, throughout every part of his work, both externally and internally.

In every branch of painting in oil, as applicable either to churches, theatres, houses, or any other public or private buildings, or edifices, the general process will be found very similar; or with such variations, as will easily be suggested by the judicious artist, or workman.

The first coatings, or layers, if on wood or iron, ought always to be of ceruse or white lead; the very best that can be obtained; which should have been previously ground very fine in nut or linseed oil, either over a stone with a muller, or, as that mode is too tedious for large quantities, it may be passed through a mill. If used on wood, as shutters, doors, or wainscoting made of fir or deal, it is highly requisite to destroy the effects of the knots; which

are generally so completely saturated with turpentine, as to render it, perhaps, one of the most difficult processes in the business to conquer. The best mode in common cases, is to pass over the knots with ceruse ground in water; bound by a size made of parchment, or some other animal substance. When that is dry, paint the knots with white lead ground in oil, to which add some powerful siccativ, or dryer; as red lead, or litharge of lead, about one-fourth part of the latter. These preparations should be done carefully, and laid very smoothly with the grain of the wood. When the last coat is dry, which will be in twelve or twenty-four hours, then smooth it with pumice-stone, or give the work the first coat of paint, prepared, or diluted with nut or linseed oil. When that is dry, all the nail holes or other irregularities on the surface should be carefully stopped, with a composition of oil and Spanish white, a whitening commonly known by the name of putty; but which is frequently made and sold at the shops of very inferior articles. When that is done, let the work be painted over again, with the same mixture of white lead and oil, somewhat diluted with the essence of oil of turpentine, which process should be repeated not less than three or four times, if the work is intended to be left, when finished, of a plain white or stone colour; if of the latter, the last coat should have a small quantity of ivory or lamp black added, to reduce its whiteness a little; and

PAINING.

this is also of service in preserving the colour from changing : a circumstance which the oil is apt to produce. But if the work is to be finished of any other colour, either grey, green, &c. it will be requisite to provide for such colour, after the third operation, particularly if it is to be finished flat, or, as the painters style it, dead-white, grey, fawn, &c. &c. In order to finish the work flatted, or dead, (which is a mode much to be preferred for all superior works ; not only for its appearance, but also for preserving the colour, and purity of the tint,) after the work, supposing it to be wood, has been painted four times in oil colour, as directed in general cases, one coat of the flatted colour, or colour mixed up with a considerable quantity of turpentine, will be found sufficient ; although in large surfaces it will frequently be requisite to give two coats of the flatted colour to make it quite complete. Indeed, on stucco it will be almost a general rule ; but as that will be hereafter treated, we shall at present say no more concerning it.

It must be observed, that in all the foregoing operations, it will be requisite to add some sort of sicative. A very general and useful one is made by grinding in linseed, or, perhaps, prepared oils, boiled, are better, about two parts of the best white copperas, which must be well dried, with one part of litharge of lead : the quantity to be added, will much depend on the dryness, or humidity, of the atmosphere at the time of painting, as well as the local situation of the building.

It is highly proper here to observe, that there is a kind of copperas made in England, and said to be used for some purposes in medicine, that not only does not assist the operation of drying in the colours, but absolutely prevents those colours drying, which would otherwise have done so by themselves. The best dryer for all fine whites, and other delicate tints, is saccharum saturni, or sugar of lead, ground in nut oil ; but which being very active, a small quantity, about the size of a walnut, will be sufficient for twenty pounds of colours, where the basis is ceruse. It will be always worthy to be observed, that the greatest care should be taken to keep all the utensils, brushes, &c. particularly clean ; or the colours will soon become very foul, so as to destroy the surface of the work. If this should so happen, the colour should be passed through a fine sieve, or canvas ; and the surface of the work be carefully rubbed down with sand-paper, or pumice-stone ; and the latter should be prepared by being ground in water, if the paint be tender, or recently laid on.

The above may suffice as to painting on wood, either on outside or inside works ; the former being seldom finished otherways than in oil, four or five coats are generally quite sufficient.

We shall now proceed to note what is requisite for the painting of new walls or stucco, not painted before, and prepared for oil colours.

It does not appear that any painting in oil can be done to any good or serviceable effect in stucco, unless not merely the surface appear dry, but that the walls have been erected a sufficient time to permit the mass of brick-work to have acquired a sufficient degree of dryness : when stucco is on battened work, it may be painted over much sooner than when prepared as brick. Indeed, the greatest part of the mystery of painting stucco, so as to stand or wear well, certainly consists in attending to these observations ; for whoever has observed the expansive power of water, not only in congelation, but also in evaporation, must be well aware that when it meets with any foreign body obstructing its escape, as oil painting for instance, it immediately resists it ; forming a number of vesicles, or particles containing an acrid lime water, which forces off the layers of plaster, and

frequently causes large defective patches, extremely difficult to get the better of.

Perhaps in general cases, where persons are building on their own estate, or for themselves, two or three years are not too long to suffer the stucco to remain unpainted ; though frequently, in speculative works, as many weeks are scarcely allowed. Indeed there are some nostrums set forth, in favour of which it is stated, in spite of all the natural properties of bodies, that stucco may, after having been washed over with these liquids, be painted immediately with oil colours. It is true there may be instances, and in many experiments some will be found, that appear to counteract the general laws of nature ; but on following them up to their causes, it will be found otherwise.

Supposing the foregoing precautions to have been attended to, there can be no better mode adopted for priming or laying on the first coat on stucco, than by linseed or nut oil, boiled with dryers, as before mentioned, with a proper brush ; taking care, in all cases, not to lay on too much, so as to render the surface rough and irregular, and not more than the stucco will absorb. It should then be covered with three or four coats of ceruse, or white lead, prepared as described for painting on wainscoting ; letting each coat have sufficient time to dry hard. If time will permit, two or three days betwixt each layer will not be too long.

If the stucco be intended to be finished of any given tint, as grey, light green, apricot, &c. it will then be proper, about the third coat of painting, to prepare the ground for such tint, by a slight advance towards it.

Grey is made with ceruse ; Prussian blue, ivory black, and lake, sage green, pea, and sea-greens, with white ; Prussian blue and fine yellows, apricot and peach, with lake ; white, Chinese vermilion, and fine yellow, fawn colour, with burnt terra Sienna, or umber and white ; olive greens, with fine Prussian blue and Oxfordshire ochre.

Painting in distemper, or water colours mixed with size, stucco, or plaster, which is intended to be painted in oil when finished ; but not being sufficiently dry to receive the oil, may have a coating in water colours, of any given tint required, in order to give a more finished appearance to that part of the building.

Straw colours may be made with French white, a ceruse, and mallicot or Dutch pink. Greys, fine, with some whites, and refiners' verditer. An inferior grey may be made with blue-black, or bone-black, and indigo. Pea greens, with French green, Olympian green, &c. Fawn colour, with burnt terra de Sienna, or burnt umber and white : and so of any intermediate tint. The colours all should be ground very fine, and incorporated with white, and a size made of parchment, or some similar substance ; isinglass being too expensive for common works.

It will not require less than two coats of any of the foregoing colours in order to cover the plaster, and bear out with an uniform appearance. It must be recollected, that when the stucco is sufficiently dry, and it is desirous to have it painted in oil, the whole of the water colour ought to be removed ; which may be easily done by washing ; and when quite dry, proceed with it after the directions given in oil painting of stucco.

When old plastering has become discoloured by stains, and it be desired to have it painted in distemper ; it is then advisable to give the old plaster, when properly cleaned off and prepared, one coat at least of white lead ground in oil, and used with spirits of turpentine, which will generally fix all old stains ; and when quite dry, will take the water colours very kindly.

The above processes will also apply to old wainscoting,

in cases where temporary painting is only required; but cannot be recommended for durability.

PAINTLICK, in *Geography*, a town of America, in the state of Kentucky; 14 miles E.N.E. of Stamford.

PAINTLICK Creek, a river of Kentucky, which runs into the river Kentucky, N. lat. $37^{\circ}37'$. W. long. $84^{\circ}43'$.

PAINVILLE, a town of America, in Amelia county, Virginia, with a post office; 197 miles W. of Washington.

PAJOT, LEWIS LEO, *Count d'Ansembray*, in *Biography*, a French nobleman, was born at Paris in the year 1678. He received the advantages of a liberal education, and having discovered an inclination for mathematical pursuits while he was very young, he was instructed in the philosophy of Des Cartes. After this he took a tour to Holland, where he formed an acquaintance with Huygens, Ruysh, Boerhaave, and other persons distinguished by their profound knowledge in literature and the sciences. He was appointed director-general of the posts in France, and conducted the business of that department in such a manner as entitled him to the esteem of the public, and the confidence and favour of his sovereign. Upon the death of his father, the count came into possession of a country-seat at Bercy, where he determined to establish a scientific museum; and he spared neither trouble nor expence to furnish it with rarities of nature and art, and with philosophical and mechanical instruments, and machines of every description. In a short time his cabinet was enriched with a great number of curiosities, particularly in mechanics and natural history, on which account it was visited by Peter the Great, the emperor of Germany, and by other princes. It was thought to be the most valuable museum in Europe, and was unrivalled in articles connected with the science of mechanics. In the Transactions of the Academy of Sciences, of which he was a member, there are several of his papers; among which is a description of an "Instrument for the Measurement of Liquids:"—of "An Areometer, or Wind Gage:"—of a "Machine for beating regular Time in Music." He died in 1753, bequeathing his museum to the academy.

PAIR, PAR, a collective term, used for two equal or similar things ordinarily joined together; though more frequently for artificial things than for natural ones. As, a pair of gloves, of stockings, of shoes, &c.

PAIR is also used in compound things, for two parts alike to each other, though they only make one whole. As, a pair of scissors, &c.

PAIR is also used for a set or system of several things joined to make another complete: as a pair of bagpipes, &c.

PAIR, again, is used, by extension, for a thing that is single, as a pair of tables, &c.

PAIR of Nerves, in *Anatomy*, the right and left corresponding nerves, which are almost every where alike in the body. See *NERVOUS System*.

PAIRA, in *Geography*, a river of Persia, which loses itself in a lake near Tadvan, in the province of Farsistan.

PAIRAN, a town of Sibiu, one of the Philippine islands; inhabited chiefly by Chinese merchants and artificers.

PAIRUMBAUCUM, a town of Hindoostan, in the Carnatic; 30 miles W. of Madras.

PAISHAWUR, or **PEISHORE**, a city of Candahar, and capital of a district, in Cabulistan, seated on the Kameh. In 1738 this town was taken by Nadir Shah; 125 miles S.E. of Cabul. N. lat. $33^{\circ}18'$. E. long. $70^{\circ}36'$.

PAISLEY, a large town and borough of barony, in the county of Renfrew, Scotland, is situated at the distance of six miles and a half westward from the city of Glasgow, on the banks of the White-Cart river. It probably owes

its origin to an abbey, which was founded here in the year 1160. It did not, however, rise to be a place of much importance till after the union in 1707. From this period, the inhabitants began to direct their attention to manufactures, which have ever since been gradually on the increase, and have rendered Paisley at present, second only to Edinburgh and Glasgow, among the towns of North Britain. According to the parliamentary returns of 1811, it contains 2951 houses, and a population of 36,785 persons, including the two suburb parishes of Abbey, East and West.

James IV. king of Scotland, granted to Paisley the first charter, constituting it a borough, in 1488, at the intercession of George Shaw, then abbot of the monastery. Under this grant it enjoys all the privileges of a royal borough, except the right of being represented in parliament, and of sending delegates to the general convention at Edinburgh. The corporation or magistracy consists of three bailies, and seventeen counsellors, who are elected annually, besides a treasurer, town clerk, and other inferior magistrates. The bailies are invested with the full powers of justices of the peace, and take cognizance, in the first instance, of all offences committed within their jurisdiction.

At the commencement of the last century, Paisley is described as consisting only of one principal street, about half a mile in length, with a few narrow lanes branching out on either side. Now, however, it is an extensive and well built town, and contains many excellent public and private edifices, especially in that part called the New Town, which stands on the eastern bank of the Cart, and is laid out with great regularity. Over the river are three bridges, placed at convenient distances, and connecting with each other the buildings on its opposite sides, that is, the New and Old Town, with their respective suburbs. The streets are in general well paved and lighted, and exhibit all the marks of opulence and industry, some of them being crowded with warehouses and manufactories, occupied by the merchants and tradesmen. The whole town is built of stone, and in all the modern streets the houses have squared and smooth free-stone fronts, in the same manner as those of Edinburgh and Glasgow.

Paisley contains three parish churches, and several chapels of ease and dissenting meeting houses, but none of them are peculiarly remarkable as buildings, except the abbey church, which will be described in the sequel of this article. The edifices appropriated to public business, charity, or amusement, are all of modern erection. The hospital or poor-house was built in 1752, and is under the management of fifteen directors. It is a large structure, with an extensive garden attached, and is supported by a small assessment on the inhabitants at large. The town-hall is a handsome building of cut stone. The butcher market is probably the neatest and most commodious range of shambles in Great Britain. The front is of hewn stone. No public theatre has yet been erected here, but there are rooms appropriated to concerts and assemblies. A large subscription room, on the plan of the Glasgow tontine, has been erected within the last five years.

Paisley has attained its present rank and importance from its manufactures; and hence it seems proper to give a slight sketch of the rise, and of the progressive changes which these have undergone at different periods since their first establishment. At the time of the union, and for some years after, scarcely any other goods were produced here, but coarse linen checks, and a kind of striped cloth, called Bengals; and even these were manufactured only on a very limited scale. When a free trade, however, was opened with England, the spirit of manufacture began to display

itself in Paisley, with a vigour seldom paralleled. This effect resulted in a great measure from the exertions of pedlars, or, as they are called in Scotland, packmen, many of whom, having accumulated a small capital, settled in this town and its vicinity, and became resident manufacturers. The experience of what would suit the taste of the people, and the connections they had established in the course of their travelling career, presented many advantages in their new occupation, of which they did not fail to avail themselves. They first improved the quality of the linen cloths above-mentioned; but these in a few years gave way entirely to articles of a lighter and more fanciful description; such as linen gauze and lawns; both plain and ornamented. The manufacture of thread was introduced about the year 1750, and still continues to afford employment to a large portion of the inhabitants. In 1760 the manufacture of silk gauze was begun by Mr. McKerral of Hillhouse, and soon displaced the linen cloths as the staple produce of Paisley. Before that period, the patterns and designs of all fancy goods were made at Paris; but the Paisley manufacturers disdain the servility of imitation, established draughtsmen of their own, whose productions were thought not only to rival, but to excel those of the French artists. Hence such a variety of elegant and richly ornamented gauzes was issued from this town, as surpassed every thing that had hitherto appeared. Spitalfields was compelled almost to abandon the manufacture; and several companies came down from London to carry it on, on the banks of the Cart, where it flourished beyond any manufacture which any town in Scotland could boast of till the invention of Arkwright's machinery for spinning cotton, by rendering fabrics of that material both cheap and elegant, almost excluded silks from any share in female dress, when it of course declined, and is now almost abandoned. Following the tide of fashion, the manufacturers of Paisley turned their exertions into the new channel, and soon brought their cottons into competition with those of Manchester itself. The whole neighbouring waters were speedily occupied with spinning mills and bleach-fields, and many thousand persons took up the employment of weaving cottons here and in the surrounding vilages.

Besides these principal manufactures, Paisley has some others of a more local description, likewise conducted on an extensive scale; tan works, and soap and candle works are numerous, and there is also a calico printing work, a coppers work, and several manufactories for tape and ribbons.

The most important remain of antiquity in Paisley, or indeed in the county of Renfrew, is the monastery already mentioned, as having probably been the nucleus which determined the origin of the town. It was first bounded as a priory by Walter lord high steward of Scotland, and filled by him with monks of the order of Clugni; but afterwards attained the rank of an abbacy. The lands belonging to it were further erected by Robert II. into a regality under the jurisdiction of the abbot. At the reformation this abbey was secularized; and towards the close of the sixteenth century, it was constituted a temporal lordship in favour of lord Claude Hamilton, who was created lord Paisley in 1591. His son James, earl of Abercorn, afterwards sold it to the earl of Angus, by whom it was alienated, in 1653, to William, earl of Dundonald, and continued in his posterity till the year 1764, when it was repurchased by the late earl of Abercorn. The monks here are supposed to have been the authors of the "Chronicon Clugniense," or "The Black Book of Paisley," as it is usually called, from the colour of its boards. This curious monument of antiquity is a chronicle of the public affairs of Scotland during several

centuries, and is frequently quoted by Buchanan. It was long in the possession of the president Spottiswood; after his death it was carried into England by general Lambert, and was subsequently deposited in the king's library at St. James. Many additions have been made to the buildings of this abbey at different eras since its original erection. Abbot Shaw, in particular, enlarged and beautified the whole monastery, and indeed may properly be regarded as a second founder. He built the refectory and other offices necessary for the monks, the church and the precinct of the convent; and inclosed the gardens and orchards by a wall of hewn stone, which measured about a mile in circuit. This wall, observes Mr. Pennant, (*Tour in Scotland*) "is a very noble and extensive one, and indicates the ancient grandeur of the place." On a stone at the north-west corner is this very singular inscription.

"Thy call it the Abbot George of Shaw
About my Abbey gart mak this waw;
An hundred four hundredth zeir
Eighty-four the date, but weir
Pray for his salvtie
That laid this noble foundation."

All the buildings of this abbey are much dilapidated, excepting the chancel of the church, which is still entire, and has of late years been fitted up for parochial service. Judging from this member, and some additional ruins, the church appears to have been, when complete, a very grand and magnificent structure. It was in the form of a cross, but the only part of the transept standing is the great north window, the arch of which is uncommonly lofty and elegant. The chancel is separated into a middle and two side aisles, by two ranges of columns, supporting pointed arches, and having their capitals ornamented with grotesque figures. The exterior of this building displays much sculptural embellishment, especially the north and south doors.

Near the abbey church is an old chapel, which is appropriated as the burying place of the Abercorn family. It is remarkable for its echo, which is probably the finest in Europe, as its effects are said to surpass those of the whispering gallery at St. Paul's. "When the end door (the only one it has) is shut, the noise is equal to a loud and not very distant clap of thunder; if you strike a single note of music, you hear the sound gradually ascending till it dies away, as if at an immense distance, and all the while diffusing itself through the circumambient air; if a good voice sings, or a musical instrument is well played upon, the effect is inexpressibly agreeable." In this chapel is the monument of Marjory Bruce, daughter of Robert I. king of Scotland, and mother of Robert II. Here were likewise interred Elizabeth Muir, and Euphemia Ross, both consorts to the monarch last mentioned. The former died previous to his accession to the Scottish throne.

Of the Roman camp mentioned by Camden, as situated close to Paisley, very few vestiges remain; the walls are nearly levelled, and the ditches filled up. Of the outworks no distinct marks are now visible, excepting of one which was constructed at a spot still bearing the name of Castle Head. A military road led to this entrenchment, which is supposed to have been the Vanduara of Ptolemy.

Elderslie, in the vicinity of this town, is noted, in the annals of Scotland, as the birth place of the illustrious sir William Wallace. (See WALLACE.) Pennant's *Tour in Scotland*. Beauties of Scotland, vo. iii.

PAIT, a provincial term applied to a badger.

PAITA, GIOVANNI, of Genoa, in *Biography*, flourished early in the last century, and was called by all the great masters,

masters, king of *tenors*; they speak still in Italy of the merit of this admirable singer, who was likewise an excellent actor, and a fine performer on the harpsichord.

PAITA, in *Geography*. See PAYTA.

PAITAN, a town on the N. coast of the island of Borneo. N. lat. 6° 32'. E. long. 117° 28'.

PAITLEY, or PATELEY-BRIDGE, a small market town in the parish and liberty of Rippon, lower division of the wapentake of Claro, and west riding of Yorkshire, England, is situated on the river Nidd, at the distance of twelve miles W.S.W. from Rippon. The market is held on Saturday, and here are four fairs annually. Neither the town nor its vicinity present any thing remarkable. It is somewhat singular that it should not be mentioned in the late population reports, though several townships in the same parish are there noticed. Beauties of England and Wales, vol. xvi. by J. Bigland.

PAITSEPOO, a town of Little Bucharia; 50 miles E.N.E. of Cashgar.

PAKA, a town of Bohemia, in the circle of Konigin-gratz; 18 miles N.W. of Konigingratz. N. lat. 50° 25'. E. long. 15° 22'.

PAKANG-YAY, a town of the Birman empire, situated on the Irawaddy, containing several neat temples, and surrounded by lofty palmyra, tamarind, and banyan trees; 25 miles S. of Pagahm.

PAKASHASANA, a name of the Hindoo deity Indra, regent of the visible heavens.

PAKIR, or PACHIR, in *Geography*, a sea-port town of Arabia, in the province of Oman, the inhabitants of which carry on a considerable trade to India. Its environs abound in cattle, grain, dates, raisins, and other fruits; 25 miles E. of Döfar.

PAKOLTSZ, a town of the duchy of Warsaw; 34 miles N. of Gnesna.

PAKRATZ, a town of Sclavonia; 20 miles N.W. of Potzega.

PAKUPZKI, a town of Croatia, on the Kulpa; 20 miles E. of Carlstadt.

PALA, in *Botany*, a name by which some authors have called the nutmeg-tree.

PALA, in *Geography*, a town on the W. coast of the island of Celebes. S. lat. 2° 32'. E. long. 119° 9'.

PALA, in *Ichthyology*, a name used by some authors for a fish of the truttaceous kind, more usually known by the name of *ferra*. See GUINIAD.

PALACE, PALATIUM, a name generally given to the dwelling houses of kings and princes.

Procopius derives the word from a Grecian called Pallas, who gave his own name to a magnificent house he had built; adding that Augustus, after him, gave the name *palatium* to the house of the Roman emperors on the hill which for that reason was called the *Palatine* mount. Others take it the contrary way; and say that Romulus's house, in which Augustus lived, was properly called *palatium*, because situate on the *Palatine* mount. Be this as it will, it is certain, *palatium*, from a proper name, in time became common to all houses of kings.

And as the kings usually heard and determined causes in their houses, in what part of the realm soever they were situate; hence also *palatium* became a name for a court of justice, which usage is still retained, especially in France.

In course of time the name *palace* has also been applied to the houses of other persons: taking different epithets, according to the quality of the inhabitants; as imperial palace, royal palace, pontifical, cardinal, episcopal, ducal palace, &c.

PALACIOS, I.os, in *Geography*, a town of Spain, in the province of Seville; 10 miles S.E. of Seville.

PALACIOS, a town of Spain, in the province of Leon; eight miles S. of Astorga.

PALADA, a town of Hindoostan, in the circle of Aurungabad; 48 miles S.E. of Aurungabad.

PALÆMON, QUINTUS REMMIUS, in *Biography*, a celebrated Roman grammarian in the reigns of Tiberius and Claudius, was a native of Vicenza, and domestic slave to a woman of that place, but by attending her son to the academy he acquired so much knowledge, that she gave him his freedom, and he opened a grammar school at Rome. He gained great reputation as a rhetorician and poet, but his morals were so loose, as to be considered a very improper preceptor for young people. His income, however, as teacher was very considerable, but quite inadequate to his luxurious mode of living. The remains of this writer, who was so arrogant as to say that letters were born, and would die with him, are "Ars grammatica," printed among the "Grammatici Antiqui," of which the best edition is that of 1605; and a treatise "De Ponderibus et Mensuris," printed at Leyden in 1587, which has been ascribed to another writer of the same name.

PALÆPHATUS, a Greek philosopher of whom a treatise *περι των Απισθων* remains; its subject is the explication of ancient fables. It has been several times reprinted in the Greek and Latin; the best edition is that of Fischer, Lips. 1761. It must be observed that there are several ancient writers of this name; one an Athenian, placed by the poets before the time of Homer; one a native of Paros, who lived under Artaxerxes Mnemon; and one, a grammarian and philosopher, born at Athens or in Egypt, posterior to Aristotle. Which of these is author of the work already noticed, is not at all certain.

PALÆSTE, the name of a Greek measure of length, being the same with the *dochme* and *doron*, and containing four finger-breadths, or digits.

PALÆSTRA, *παλαιστρα*, among the ancient Greeks, a public building, where the youth exercised themselves in wrestling, running, playing at quoits, &c.

Some say, the *palæstra* consisted both of a college, and an academy; the one for exercises of the mind, the other for those of the body. But most authors rather take *palæstra* to be a *gymnasium*, or mere academy for bodily exercises, according to the etymology of the word, which comes from *παλν*, *wrestling*, one of the chief exercises among the ancients. See PALE'.

The length of the *palæstra* was marked out by *stadia*, each equal to one hundred and twenty-five geometrical paces; and hence the name *stadium* was given to the arena whereon they ran.

PALÆSTROPHYLAX, formed from *παλαιστρον*, and *φυλαξ*, *guardian*, or *keeper*, among the *Ancients*, was the director of a *palæstra*; and of the exercises performed therein.

This officer was also called *gymnarcha* and *gymnastarcha*.

PALAFIX Y MENDOZA, D. JUAN DE, in *Biography*, a Spanish prelate, was born of a noble family at Arragon, in the year 1600. He studied at Salamanca, after which he was appointed a member of the council of war, and next of that of the Indies; but he renounced civil distinctions for the ecclesiastical state, and was made a bishop in Spanish America, with the title of judge of the administration of the three viceroys of the Indies. Zeal for the interests of the church involved him in some difficulties, and he was compelled to secrete himself to save his life. His conduct was, however, in every respect approved by the king, and he was appointed to the bishopric of Osma in 1653, in which he

continued

continued till his death, in 1659. He was a voluminous writer, but the works by which he is chiefly known, are the "History of the Siege of Fontarabia," and "The History of the Conquest of China by the Tartars."

PALAFUGELL, in *Geography*, a town of Spain, in Catalonia; 20 miles S.E. of Gerona.

PALAIS, LE, a sea-port town of France, and capital of the island of Belle Isle, situated on the E. coast, and defended by a citadel, with good anchorage in the road; containing two churches, and about 500 houses; 2½ miles S.E. of L'Orient. N. lat. 47° 21'. W. long. 3° 4'.

PALAIS, St., a town of France, in the department of the Lower Pyrenées, and chief place of a canton, in the district of Mauléon, seated on the Bidouze; 21 miles S.E. of Bayonne. The town contains 1000, and the canton 14,673 inhabitants, on a territory of 330 kilometres, in 42 communes. N. lat. 43° 19'. W. long. 0° 50'.

PALAIZEAU, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles; seven miles S.E. of Versailles. The place contains 1750, and the canton 9560 inhabitants, on a territory of 130 kilometres, in 17 communes.

PALAKA, a town of Turkish Armenia, in the government of Kars; 60 miles N.N.E. of Kars.

PALALACA, in *Natural History*, the name given by the people of the Philippine islands to a bird common among them, and somewhat resembling the *upupa*, or hoopoe. From the description which father Camelli gives of this bird, it seems very plainly to be a species of woodpecker, of a very large and beautiful kind. See *Picus Bengalensis*.

PALAMADA, in *Geography*, a town of Bengal; 28 miles S.E. of Doefa.

PALAMBANG, or **PALEMBANG**, a river of Sumatra, which takes its rise in the country of Moofee, near the W. coast, and within a day or two's journey from that of Bencoolen, and is the most advantageous for navigation of any in the island. High up, on its banks, the pepper is cultivated, and purchased of the natives at a very cheap rate — Also, a town and kingdom of Sumatra. The town is situated on the above mentioned river, and is the capital of the kingdom, which is very extensive, and comprehends the island of Banca. Palambang is peopled mostly by Javans, in consequence of that part of the island being formerly under the jurisdiction of the Bantam empire, whence its sovereigns derived their appointment. It has been since under the immediate protection of the Dutch government at Batavia, who have had a chief and factory there, and procure from it pepper and tin. It has likewise been an useful mart to them, for vending opium and other commodities from the west of India. The inhabitants of Passumah are mostly supplied with opium, salt, and piece goods from Palambang. The king's agent comes up the river in large boats, which are towed against the stream. Thus the goods are conveyed to a place called "Mooarro Moolang," from whence they are transported on men's backs to that country. The voyage by the river is said to take up 14 days; but the journey from Mooarro Moolang, where they disembark, to Passumah, is performed in one. Their returns are mostly in a species of twine called poolay, silk in its roughest state, and elephants' teeth. The tin, though exported from Palambang, is dug up in the island of Banca, which covers the mouth of the river, and constitutes a trade of considerable importance. The king of Palambang, whose dominions are very extensive, reaching as far as the hills of Lampoon to the southward, and comprehending the island of Banca, accumulates immense riches. It is said that the quantity of pepper brought annually from Palambang is about 2,000,000 lbs.

which is purchased at the rate of two stivers *per lb.* The Dutch company likewise take about 1000 carats of rough diamonds, and a considerable quantity of canes and rattans. For these commodities a large sum in specie is yearly required to balance with the king. In 1771 the Dutch company rebuilt there an old ruined fort in a pentagonal form, at the charge of about 7322½ sterling. S. lat. 2° 50'. E. long. 104° 59'. Marsden's Sumatra. Stavonius's Voyage, vol. 1.

PALAMBUAN. See **BALAMBUAN**.

PALAMCOTTA. See **TINEVELLY**.

PALAMEDEA, the Screamer, in *Ornithology*, a genus of birds of the order Grallæ, of which the generic character is; bill conic, the upper mandible hooked; nostrils oval; feet four-toed, cleft, a very small membrane connecting the toes at the root. There are only two species of this genus.

Species.

CORNUTA; Horned Screamer. Wings with two spines at the bend; the front is horned; hence its specific name. The birds of this species are about as large as a turkey; they have on the crown of their head a slight horn rising perpendicularly, about three inches in length. They feed on herbs and seeds, and perhaps on reptiles. They are found in Guiana and other neighbouring territories of South America, chiefly in the low and marshy grounds. These birds are never observed but in pairs, and so faithful, tender, and constant is their attachment, that the death of one is generally attended with a degree of distress and grief which destroys the other. While young they are eaten, but their flesh is of very dark colour, though not ill tasted. The legs are black, and so is the bill; the irides golden; body above blackish, beneath white; wings reddish beneath; spines strong, sharp, horny, triangular, yellow; horn on the front recurved, round, whitish, three inches long; the hind-toe is straight. They lay two eggs, which are about the size of those of a goose.

CRISTATA; Crested Screamer. Wings unarmed; front crested. It inhabits Brasil, and is about the size of a heron. The bill and legs are yellowish; the irides golden; crest black varied with cinereous, erect; the body is mixed with rufous and brown; the hind toe is placed so high as not to touch the ground in walking. The birds of both species, on hearing the least noise, or seeing any person, though at a distance, rise from the ground, and make a loud screaming noise.

PALAMEDES, in *Biography*, a distinguished Greek, was the son of Nauplius, king of the isle of Eubœa. At the time of the Grecian confederation for the expedition against Troy, Palamedes is said by a stratagem to have detected the counterfeited insanity of Ulysses, who had acted the madman, in order that he might be excused from accompanying the other princes. In resentment for this exposure, Ulysses contrived to bury a sum of money in the tent of Palamedes, and then to charge him with having received a bribe from Priam. The discovery of the treasure was deemed evidence of the fact, and Palamedes was stoned to death for the crime of treason. To him are attributed the invention of weights and measures; the art of drawing up a battalion; the regulation of the year by the course of the sun, and of the month by that of the moon; likewise the games of dice and even chess are ascribed to him. Pliny affirms that during the siege of Troy he invented the four letters in the Greek alphabet θ , ξ , ϕ , χ ; but Philostratus ascribes to him only the ν , ζ , and χ . He has been mentioned as a poet, and Suidas says his poems were suppressed by Agamemnon, or by Homer.

PALAMOS, in *Geography*, a sea-port town of Spain, in

in Catalonia, on the coast of the Medierranean, fortified and defended with a castle; 22 miles S.E. of Gerona. N. lat. $41^{\circ} 50'$. E. long. $2^{\circ} 58'$.

PALAMOW, a town of Bengal, and capital of a circar to which it gives name. The circar is bounded on the N. by Bahar, on the E. by Koondah, Torea, and Nagpour, on the S.E. by Burwah, on the S.W. by Sirgooja, and on the W. by Bittounja, about 80 miles long and 40 in its greatest breadth. The capital is 120 miles S.S.W. of Patna. N. lat. $23^{\circ} 48'$. E. long. $84^{\circ} 20'$.

PALAMPONG, a town on the W. coast of the island of Leyta. N. lat. $10^{\circ} 58'$. E. long. $124^{\circ} 14'$.

PALANA, a town of Peru, in the audience of Quito; 50 miles S. of Loxa.—Also, a town on the W. coast of the island of Luçon, at the entrance of Caigaran bay. N. lat. $16^{\circ} 45'$. E. long. $122^{\circ} 14'$.

PALANDO, a town of South America, in the province of Quito; 45 miles S. of Loxa.

PALANE, a river of Africa, which runs into the Indian sea, near Mozambique.

PALANKA, a town of European Turkey, in Bulgaria; 40 miles S. of Sophia.—Also, a town of European Turkey, in Bessarabia, on the Dniester; 32 miles N.W. of Akerman.

PALANQUIN, or PALANKEEN, a kind of chaise, chair, or litter, borne by men on their shoulders; much used by the people of China, and the East, as a vehicle for their easy conveyance from place to place.

PALANTONE, in *Geography*, a town of Italy, in the department of the Lower Po; 12 miles N.W. of Ferrara.

PALANY, a town of Hindoostan, in Bahar; 7 miles S.E. of Bahar.

PALANZA, a town of Italy, on the W. side of lake Maggiore; 15 miles S.E. of domo d'Oscello.

PALAO. See *New PHILIPPINES*.

PALAPARIJA, in *Zoology*, the name of a species of East India serpent, found in the island of Ceylon. It is a large kind, and beautifully variegated in colour, with a great deal of red about it. It is one of those species which naturally live underground.

PALAPETTY, in *Geography*, a town of Hindoostan, in the province of Dindigul; 18 miles N. of Dindigul.

PALAPOUR, a town of Bengal; 22 miles E. of Boglipour.

PALAPRAT, JOHN, in *Biography*, a poet and dramatic writer, was born at Toulouse in the year 1650. He distinguished himself from his youth by a talent for poetry, and obtained several prizes at the Floral games of that city. He was brought up to the legal profession, and obtained some offices of consideration, in which he conducted himself with great credit. At length an attachment to literature, and a natural simplicity of character, gave him a distaste for business; and after a visit to the wits of Paris, he went to Rome in 1686 for the purpose of being introduced to the celebrated queen Christina, then resident in that metropolis. Thence he returned to Paris, which afterwards became his principal abode. In 1691 the duke of Vendome attached him to his person in quality of secretary. He employed himself, at Paris, chiefly in theatrical compositions, and he contracted an intimacy with the abbé Brueys, in concert with whom he wrote several pieces for the stage. Of their conjunct performances, three have kept their place on the stage, with one of his sole composition. He also wrote eight discourses on different subjects, and published a volume of poems. He died at Paris in 1721, in the seventy-second year of his age. The character of his works is gaiety and vivacity, with an air of simplicity, but with little regard to

correctness. His dramatic pieces are contained in the collection of those of Brueys.

PALARIA, among the Romans, a kind of exercise performed at a stake by the soldiers.

The stake being fixed immovable in the ground, and six feet high above it, the young undisciplined soldiers advanced against it armed with a burdie and cudgel, instead of a shield and sword, and went through all the rules of attack and defence, as if actually engaged with an adversary. Sometimes they stood at a distance, and attacked it with missile weapons, at the same time using all the requisite motions for defending themselves, and warding off what might be thrown against them.

PALASBARY, in *Geography*, a town of Bengal; 6 miles N.N.E. of Goragot.

PALASBONA, a town of Bengal; 16 miles S. of Rajemul.

PALASCO, a town of Corsica; 14 miles N. of Corte.

PALASZ, a town of European Turkey, in Servia; 15 miles S.W. of Belgrade.

PALATCHA, or PALATSA, a town of Asiatic Turkey, in Natolia, near the coast of the Archipelago; 8 miles N. of Milets. N. lat. $37^{\circ} 31'$. E. long. $27^{\circ} 12'$.

PALATCHY, a town of Hindoostan; 15 miles S. of Coimbatore.

PALATE, the upper part or roof of the mouth in animals of different kinds.

In a horse it should be lean, for if it be full and high, so as to be nearly level with the extremities of the upper teeth, the least height in the liberty of the bit will be troublesome, and make him either check in the bridle, and be always throwing up his head, or otherwise carry it too low, which, besides the unfitness, much annoys the rider's hand.

PALATE, in *Anatomy*, the roof of the mouth. It is the arched superior boundary of that cavity, and, at the same time, the inferior surface or floor of the nose. The anterior two-thirds of it are made up of the palatine plates of the superior maxillary and palatine bones, surrounded by the teeth and covered by a firm membrane: the posterior third is a moveable membranous and muscular organ, called the soft palate, velum palati or palatum molle. These parts are more minutely described in the article *DEGLUTITION*.

PALATE, *Diseases of*. See *TONSILS* and *UVULA*. A description of the defective state of the palate, frequently accompanying the hare-lip, is noticed in the article *HARE-LIP*.

PALATI OSSA, in *Anatomy*, two small bones of the upper jaw. See *CRANIUM*.

PALATINATE, PALATINATUS, a province or fignory, possessed by a palatine, and from which he takes his title and dignity.

The palatinates now subsisting, are either those of Germany or Poland. Those of Germany are the principalities of the Upper and Lower Rhine, *i. e.* of Bavaria, and the Rhine.

The palatinates in Poland are the provinces and districts of the Polish grandees or senators, who are the governors thereof.

PALATINATE of the Rhine, or Lower Palatinate, in *Geography*, a country of Germany, in the circle of the Lower Rhine; bounded on the N. by the electorate of Mentz and Catzenelnbogen, on the E. by Catzenelnbogen, the electorate of Mentz, the bishopric of Worms, and a part of Franconia, on the S. by Wurtemberg and the bishopric of Spire, and on the W. by France, the duchies of Deux Ponts and Simmern, and the county of Sponheim. Its greatest extent is about 80 miles. Although the country

is mountainous, it is uncommonly fertile, and produces plenty of corn, pulse, fruit, chestnuts and walnuts, and its pasturage seems to yield a good breed of cattle. It has plantations of tobacco, particularly between Heidelberg and Mannheim, and also good Nectar and Rhenish wines (See BERGSTRASS.) The Rhine traverses this electorate palatine; and out of the lands near Germerheim and Veltz is washed the best Rhenish gold, to which the Rhenish gold florins owe their origin. The electorate palatine contains 41 towns and several boroughs. The ecclesiastical state has undergone many changes, as the doctrines of Calvin and Luther have alternately prevailed ever since the reformation was first introduced in the year 1518. The name and origin of the "Palatines" are deduced from the palatia, or palaces, which the old Frankish and German kings and emperors possessed in various places, and over which they appointed stewards and judges, who were styled "Pfallenzgraves" or "Pfalzgraves." The addition of *by* or *on the Rhine* first occurs in the year 1093. The electoral palatinate, ever since the resignation of the Upper Palatinate to the elector of Bavaria, paid only one-half of the electoral evaluation. All that part of the palatinate which lay on the left side of the Rhine was by the peace of Lunéville ceded to France, and forms the department of Mont Tonnerre.

PALATINATE, *Upper*, a part of Bavaria, bounded on the W. and N.W. by Franconia, on the E. and N.E. by Bohemia, and on the S. by the duchy of Neuburg and Lower Bavaria. In the 12th century this country belonged to the dukes of Swabia: it was afterwards annexed to the palatinate of the Rhine. By the peace of Baden, in 1714, it was ceded, after some previous changes of masters, to the elector of Bavaria. The capital is Amberg.

PALATINE, PALATINUS, in *Anatomy*, an epithet applied to many parts about the roof of the mouth: as the palatine artery, a branch of the internal maxillary, see ARTERY; the palatine glands, see DEGLUTITION; the palatine ducts, which were supposed communications between the nose and mouth through the anterior palatine holes or foramina incisiva; the palatine nerves, branches of the superior maxillary, see NERVE; the palatine processes, of the superior maxillary and palate bones. See CRANIUM.

PALATINE, *Count Palatine, Comes Palatinus*, in *Ancient Customs*, was a title given to all persons who had any office or employment in the prince's palace.

The appellation is derived hence, that anciently the emperors sent the judges of their palace, whom they called *comites palatini*, or *pals-graves*, to correct the abuses of the other judges in the provinces of Saxony, Bavaria, Franconia, and the Rhine.

Matthæus says, that the palatines were originally those who had the superintendance of the palace, the same with what the Greeks called *europalate*, and the French *maîtres du palais*: though in time the name became more general.

The title of count palatine is now appropriated to the princes of Sultzbach, Deuxponts, and Berkenfeld, who are three branches of the same family. The elector palatine is a prince of the first of these branches, *i. e.* the prince palatine of the Rhine.

PALATINE was afterwards a title conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, *i. e.* a court of justice in their own houses.

The French writers make the palatines of Champagne to be the first who bore that title; which, they will have it, the Germans and other people borrowed from them, not they from the Germans.

At present the word palatine is restrained to a prince of

Germany, or a lord of Poland, possessed of a palatinate. In the code we find a title "De palatinis sacrarum largitionum." These were a kind of treasurers of the empire.

PALATINE, in *Geography*, a post-town of America, in Montgomery county, New York, on the N. side of Mohawk river and W. of Caghawaga; containing 3517 inhabitants. The compact part contains a reformed Dutch church, and 20 or 30 houses; 36 miles above Schenectady.

PALATINE *Bridge*, a bridge of ancient Rome, now called *St. Mary's* bridge, which crosses over from the present church of St. Mary the Egyptian, at the lower end of the forum boarium to the via Trans-tiberina. This bridge is supposed to be that which Livy speaks of (Decad. 4. l. 10.), built by M. Fulvius, washed down by the Tiber, and afterwards rebuilt by the censors Scipio Africanus and L. Mummius. Another inundation having damaged it, pope Gregory XIII. repaired it, partly upon the old piles, in the year 1575. But another inundation sweeping away some of it in 1598, it has never since been repaired, so as to be serviceable.

PALATINE, *County*. See COUNTY.

PALATINE *Mount*, one of the seven principal hills inclosed within the walls of ancient Rome. Whether the Palatine hill received its name, from a people called Palantes or Palatini, or from the bleating or strolling of cattle, in Latin balare and palare; or from Pales, the pastoral goddess; or from the burying place of Pallas, is disputed among the learned, and undetermined. Here, however, Romulus laid the foundation of his city, in a quadrangular form; and here the same king and Tullus Hostilius kept their courts; as did afterwards Augustus and all the succeeding emperors; on which account the word "palatium" came to signify a royal seat. To the E. of this hill is Mons Cælius, to the S. Mons Aventinus, to the W. Mons Capitolinus, and to the N. the forum. Its compass is 1200 paces. Romulus's house, preserved for several ages by the care of the senate, was on this hill, near the spot where the church of St. Anastasia now stands; as was also that of his foster-father Faullulus, near the place now occupied by the church of Sancta Maria Liberatrice.

PALATINE *Games, ludi Palatini*, among the Romans, were games instituted in honour of Julius Cæsar, as some will have it, or, as others say, of Augustus, and celebrated in his palace during eight days, from the sixth calends of January. Suetonius informs us, that Caligula attended these games when he was assassinated. "Cum placuisset palatinis ludis spectaculo egressum meridie aggredi."

It is pretended, that Dion calls them *Augustalia*; which should seem to confirm the second opinion. Indeed, it is certain, that he says Livia instituted particular games in the Palatine Mount, in honour of that prince, but he apparently distinguishes them from those called Augustalia. The Romans had also their Apollo Palatinus, a surname of that deity, given him in respect to the temple erected to him by Augustus on the Palatine Mount, in consequence of a report of the aruspices, which required it to be done: Augustus enriched it also with a noble library; as is intimated by Horace, lib. i. epist. iii. ver. 17.

PALATINE *Tribe*, was one of the four tribes into which Rome was anciently divided by Servius Tullus.

Servius Tullus added a fourth tribe to the three tribes into which Rome was divided by Romulus; and having inclosed the seven hills within the city, and divided it into four quarters, which he named from the principal hills they contained, he assigned to each tribe its appropriate district. Thus, the inhabitants of the Capitoline mount, the Palatine mount, and the space between these two hills, composed the

the first tribe, called "Tribus Palatina." They who dwell in the quarter called Suburra, containing mount Cælius, formed the second tribe, which retained the name of "Tribus Suburrana." The inhabitants of the Esquiline mount were called "Tribus Esquilina." And they who lived on the mounts Viminalis and Quirinalis, bore the name of the hills on which they were placed, and were called "Tribus Collina" or "Collatina."

PALATINI. See ACOLYTHI.

PALATO-PHARYNGEUS, in *Anatomy*, a muscle of the palate. See DEGLUTITION.

PALATO-STAPHYLINUS, a synonym of the *azygus uvulæ*.

PALATULUNGA, in *Geography*, a town of Hindoostan, in Coimbatore; 15 miles S.W. of Erroad.

PALATUM MOLLE, in *Anatomy*. See PALATE.

PALAVAI, in *Geography*, a town of the island of Ceylon; 48 miles W.N.W. of Candy.

PALAVASOURY, a town of Hindoostan, in the circar of Joodpour; 15 miles E. of Joodpour.

PALAVIA, in *Botany*, so named in honour of Don Antonio Palau y Verdera, professor of Botany in the royal garden at Madrid, who translated the *Philosophia Botanica* of Linnæus into Spanish, and who, according to Cavanilles (see his *Diff. fasc. 1. 5.*), has given much attention to the genera and species of plants. This gentleman is the author of several botanical or economical treatises in his native tongue. His name appears, with that of *Ortega*, (see ORTEGIA,) in the title-page of a *Curso elemental de botanica*, published at Madrid, in Svo. anno 1785, which perhaps is the translation of Linnæus above-mentioned; but it contains, moreover, a Spanish version of the essential generic characters of that author. Cavanilles wrote the name of this genus *Palava*, which Schreber has properly corrected. Schreb. 464. Willd. Sp. Pl. v. 3. 767. Mart. Mill. Dict. v. 3. (Palava; Cavan. *Diff. 1. 40. Juss. 271. Lamarck Illustr. t. 577.*)—Class and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juss.

Gen. Ch. Cal. Perianth simple, inferior, of one leaf, cloven half way down into five segments, permanent. Cor. Petals five, roundish, inserted into the base of the tube of the stamens. Stam. Filaments numerous, united below into a tube, separate above; anthers roundish. Pist. Germen superior, globose; style short, divided in the upper part into many segments; stigmas capitate. Peric. Capsule roundish, of many cells, which do not burst, and are clustered about an elevated central receptacle. Seeds solitary, roundish, angular.

Eff. Ch. Calyx simple, five-cleft. Capsule of numerous single-seeded cells, clustered irregularly together.

Obs. This genus differs from *Malope*, merely in having a simple calyx. We have already (see MALOPE) mentioned professor Martyn's remark concerning it, and we now adopt it on the authority of the above authors.

1. *P. malvifolia*. Willd. n. 1. Cavan. *Diff. 1. 40. t. 11. f. 4.* (*Malope parviflora*; L'Herit. *Stirp. Nov. fasc. 5. 105. t. 50.*)—Leaves smooth. Flower-stalks the length of the footstalks. Stem prostrate.—Native of Peru and Lima, in sandy ground. See MALOPE, sp. 2.

2. *P. moschata*. Willd. n. 2. Cavan. *Diff. 1. 41. t. 11. f. 5.*—Leaves downy. Flower-stalks longer than the footstalks. Stem erect.—Native of sandy ground about the town of Lima, where it was gathered by the celebrated and unfortunate Dombey, flowering in September. The root is annual, long and fibrous. Whole plant clothed with soft short down, and smelling of musk. Stem erect, branched,

leafy, two feet high. Leaves on shortish stalks, alternate roundish-heart-shaped, obtuse, waved and crenate, about two inches long. Stipulas small, lanceolate, dark-coloured, Flowers solitary, on simple axillary stalks, longer than the leaves. Calyx bell-shaped. Petals yellowish-purple, about an inch long.

PALAWAN, in *Geography*. See PARAGUAY.

PALAZOL, a small island in the Adriatic. N. lat. 44° 46'. E. long. 14° 47'.

PALAZZUOLO, a town of Italy, in Friuli; 14 miles S.W. of Palma la Nuova.—Alfo, a town of Italy, in the department of the Mela; 15 miles W. of Brescia.—Alfo, a town of the island of Sicily, in the valley of Noto; 20 miles W. of Syracuse.

PALCATI NOR, a lake of Tartary, in the country of the Eluthis, called also "Tchoi;" 30 miles W. of Harcas.

PALCIPAS, a town of South America, in the province of Tucuman; 50 miles W.N.W. of St. Fernando.

PALCOOR, a town of Hindoostan; 30 miles S. of Tinevelly.

PALCOTE, a town of Bengal; 16 miles S.S.W. of Doefa. N. lat. 22° 48'. E. long. 84° 53'.

PALDAMO, a town of Sweden, in the province of Cajana; 5 miles N. of Cajanaborg.

PALDIANO, a town of Italy, in the Campagna di Roma; 5 miles E.S.E. of Palestrina.

PALE, PALUS, a little pointed stake, or piece of wood, used in making inclosures, separations, &c.

The pale was an instrument of punishment and execution among the ancient Romans; and still continues so among the Turks. Hence *empalement*; the passing a sharp pale through the fundament up the body.

PALE, in *Heraldry*, is one of the honourable ordinaries of an escutcheon; being the representation of a pale or stake, placed upright; consisting of two perpendicular lines, drawn from the top of the base to the escutcheon, and containing the third middle part of the field.

When there are several, more properly called *pallets*, they are proportioned so as that two take up two-fifths of the field; and three take up three-sevenths: and, in those cases, the number of species are specified, as well as that of those they are charged with, &c.

Pales are borne various ways, as *wavy, crenellé, faillis, indented, ingrailed*, &c. There are also the *cometed*, and *flaming pale*, which are pointed, sometimes waved, &c.

PALE, *Paled*. A coat is said to be *paled*, when it is equally charged with pales of metal, and colour. It is *counter-paled* when it is cut, and the two *demi-pales* of the chief, though of colours the same with those of the point, yet differ in the place where they meet; so that if the first of the chief be metal, that corresponding to it, underneath, is of colour.

The coat is said to be *palisse*, when the pales are pointed like those used in the defence of places.

PALE, *in*, is applied to things borne one above another, in manner of a *pale*.

PALE, *Party per*, is where the shield is divided by a single line through the middle, from top to bottom. See PALY.

PALÉ, *Wrestling*, in *Antiquity*, one of the exercises of the Olympic stadium, first introduced into it in the 18th Olympiad; and Eurybalus, a Spartan, was the first who received the wrestler's crown. Theseus, according to Plutarch, is reported to have been the first who reduced wrestling into a science; and in process of time, though the rules which he laid down are unknown, it was much cultivated by the ancients.

cients. The most remarkable difference between the ancient and modern practice of this art is, that the ancient wrestlers contended naked, and that their bodies were rubbed all over with oil, or with a certain ointment, composed of a due proportion of oil, wax, and dust, mixed up together, which they called "ceroma." These unctions, as some say, were peculiar to the wrestlers, or pancratiasts, whose combats were thus rendered more toilsome and various; while each combatant endeavoured to seize upon the other, whose efforts to escape or break the hold of his antagonist were assisted by the slipperiness, as well as the force and agility of his body. In order, however, to qualify this extreme lubricity of the skin, occasioned by this unction, the athletes were accustomed, before they came to an engagement, either to roll themselves in the mud of the palæstra, (from which some persons derive the words pale and palæstra, πᾶλος signifying mud), or in the sand kept for that purpose, in a place called κομιστήριον, or that with which the place of combat seems to have been covered. It is certain, whatever was the mode of doing it, that the athletes, who were anointed, were always, before they engaged, sprinkled with dust or sand; so that to say an athlete gained a victory, ἀκροῖς, and without being so sprinkled, was the same thing as to say he gained a victory without engaging; which, indeed, sometimes happened, when, either from the great reputation of the champion, or other reasons, none appeared to encounter him. This office of anointing and sprinkling the combatants was sometimes performed by themselves to one another, and sometimes by the officers of the palæstra, called from thence *alipste*, or anointers.

After the wrestlers were thus prepared for the engagement, they were matched by the judges or presidents of the games in the following manner. Into a silver urn, consecrated to Jupiter, and brought forth upon this occasion, were cast so many lots or dice, about the bigness of a bean, as answered to the number of the competitors. These lots were all marked with letters; as for example, upon two of them was written the letter A, B upon two others, and so on in an alphabetical order; if the number of combatants required more, there were always two lots marked with the same letter. This being done, the athletes approached in order, and invoking Jupiter, put their hands into the urn, and drew out each his lot: to prevent all fraud, an officer appointed for that purpose attended upon every one as he came to draw, and held up his hand before him, to hinder his seeing the letters written upon the lot. When every one had drawn, the Alytarches, or one of the presidents of the games, going round to every athlete in order as they stood, inspected the lots. And thus the two, whose lots were both marked with the same letter, as with A or B, were by him matched and appointed to engage with each other. This was the case when the number of the combatants was even, as four, eight, twelve; but when the number was odd, as five, seven, nine, &c. there was put into the urn, together with the duplicate lots, an odd one, marked with a letter to which there was none that corresponded. The athlete who was fortunate enough to obtain this lot, was named *ephedrus*, was to wait till the others had contended, and was then to take up one of the conquerors. This, as Lucian observes, was a very considerable advantage; as the champion, who by virtue of his lot was to wait till the others had contended, and then engage with one of the conquerors, came fresh and vigorous to the encounter, against an adversary, animated indeed and flushed with conquest, but flattered and exhausted in obtaining it.

The wrestlers, being thus matched, proceeded to the combat, in which the victory was adjudged to him who gave his adversary *three falls*; as seems to be evident, from the famous

epigram upon Milo, which will be produced in the sequel of this article.

If one of the combatants in falling drew his antagonist with him, the contest began afresh, or was rather continued upon the ground, until one getting uppermost, constrained his adversary to yield the victory. This combat was called *anacelinopalé*, and seems not so much to be a distinct species from, as a modification of the palé; or an accidental, or perhaps artificial variation of the battle: for he who found himself in danger of being thrown, had sometimes recourse to this stratagem of dragging his adversary with him, and trying upon the ground a combat in which he thought himself better qualified to succeed. However, those authors who have written upon the palé, have made this a distinct exercise; and it is not unlikely but it may have been treated as such in the gymnasia, or schools of exercise; where there were masters whose business it was to give their scholars distinct lessons in every branch of the science they professed to teach: from which custom one may very well account for the many divisions and subdivisions of the palé, and other gymnastic exercises, of which modern writers have made so many distinct species. Of this kind in all likelihood was the *acrocheirismus*; so named, because the combatants, during this part of their engagement, held one another only by the fingers, without seizing on any part of the body. This has been reckoned a distinct exercise, and another division of the palé; though, as Mons. Burette very well observes, it seems rather to have been the prelude of the combat, in which the antagonists made trial of each other's strength, or endeavoured, perhaps, by seizing each other's hands, mutually to prevent one another from taking a firmer and more advantageous hold.

The champion who distinguished himself the most in this exercise, was Milo of Crotona, who gained no less than six Olympic, and as many Pythian crowns. There are so many instances of the prodigious strength of this famous wrestler, and most of them so well known, that it would be endless and impertinent to cite them all: but we cannot forbear producing one, as remarkable for the singularity, as the issue of the experiment.

This Milo, to give a proof of his astonishing force, was wont to take a pomegranate, which, without squeezing or breaking it, he held so fast by the mere strength of his fingers, that nobody was able to take it from him; nobody but his mistress, says Ælian. But however weak he may have been with regard to the fair sex, his superior force was universally acknowledged by the men, as will appear by the following epigram:

When none adventur'd, in th' Olympic sand
The might of boist'rous Milo to withstand;
Th' unrivall'd chief advanc'd to seize the crown,
But 'mid his triumph slip'd unwary down.
The people shouted, and forbade bestow
The wreath on him, who fell without a foe.
But rising, in the midst he stood, and cry'd,
Do not *three falls* the victory decide?
Fortune indeed hath giv'n me one, but who
Will undertake to throw me th' *other two*?

West's Pindar.

PALEARIUS, AONIUS, in *Biography*, an elegant and liberal scholar, and martyr to the cause of the reformation, was born about the beginning of the sixteenth century, at Veruli, in the Campagna of Rome. The name of his family was Della Paglia, and his baptismal name was Antonio, both which he changed to the classical form under which he

is known. Having studied six years at Rome, he quitted it on the approach of the imperial army in 1527, and took up his abode at Perugia, Sienna, Padua, and other places, improving himself by attendance on the most celebrated professors. He fixed at length at Sienna, where he married in 1536, and opened a private school for some young men of rank. Here he passed some years tranquilly in the bosom of his family, till the freedom of his opinions began to excite against him many enemies. The suspicion into which he fell, as being a favourer of the new opinions, gave the monks a handle, and they publicly accused him of heresy. He was brought before the archbishop and governor. On this occasion he wrote an oration, in which, though he did not avow the opinions imputed to him, he spoke of them in a way that shewed what he thought upon those points. He was acquitted, but was successfully opposed in his attempts to obtain a professorship in the university. In 1544 he published a work "On the Merits of Christ," which was written on the principles of the reformers. He received an invitation, in 1546, to take the professorship of eloquence at Lucca, with which he complied, and exercised that office for several years. In 1555 he was invited to Milan, to succeed Majoragio in the chair of eloquence. He resided quietly in that city till the accession of pope Pius V., who having been a Dominican and Inquisitor, began his reign with the severe persecution of heresy. Palearius was one of the first victims to his cruelty; the charges exhibited against him were very serious, and of these he was found guilty, and condemned to the flames. The sentence was executed in July 1570. Such was the lamentable fate of one who was universally admitted to be moral, pious, and learned. Of the writings of Palearius, the best known is his poem "De Immortalitate Animorum," in three books, first printed at Lyons in 1536. Its versification is formed upon that of Lucretius, rather than that of Virgil. It has been reprinted in several collections of select Latin poetry by Italians. His other works are fourteen orations on different subjects, letters, and poems, all written in a pure Latin style. After his death was printed a work entitled "Actio in Pontifices Romanos et eorum Affectus," which he had composed a short time before the meeting of the council of Trent, with an intention of getting it presented by the ambassadors of the emperor. It is said to be an eloquent plea in favour of the reformed religion.

PALECKE, in *Geography*, a town of Prussia, in the province of Oberland; 14 miles S.E. of Mohrungen.

PALED FLOWERS, in *Botany*, are those which have thin leaves set about, or surrounding a head, or thrum; as in marigolds, &c.

PALEE, in *Geography*, a town of Hindoostan, in Oude; 45 miles W. of Kairabad.

PALEMON, in *Mythology*, a deity so called by the Greeks, the same with the Melicartus of the Phœnicians, and Portumnus among the Romans. See PORTUMNUS.

PALENCIA, in *Geography*, a city of Spain, in the province of Leon, which has a very ancient bishopric, suffragan to Burgos: the bishop enjoys a revenue of 2500*l.* to 2900*l.* and bears the title of count. This town is situated in a fertile territory, watered by the little river Carrion, on the banks of which it stands. Most of the edifices of this town are in the Gothic style; and the most remarkable is San-Antolin, a church built and dedicated to that saint by king Sancho, after having escaped great danger in hunting wild boars. At the beginning of the 13th century, this town had an university, established by Rodrigo the bishop, and the first founded in Spain after the invasion of the Moors. In 1239, this university was removed to Salamanca. Its district, called the Tierra de Campos, is remarkable for its

fertility. It contains 5 churches, 11 convents, and 2 hospitals; 57 miles S.E. of Leon. N. lat. 41° 59'. E. long. 4° 34'.

PALENO, a town of Naples, in Abruzzo Citra; 9 miles E. of Sulmona. N. lat. 43° 3'. E. long. 14° 2'.

PALENQUE, a town of Mexico, in the province of Chiapa; 60 miles S.E. of Chiapa dos Espagnoles.—Also, a small island in the Spanish main. N. lat. 9° 30'. W. long. 79° 5'.

PALENSSEN, a town of Westphalia, in the principality of Calenberg; 6 miles S. of Hanover.

PALENZUELA, a town of Spain, in Old Castile; 25 miles S.W. of Burgos.

PALEO-CASTRO. See POLICASTRO.

PALEOCASTRO, a town on the N. coast of the island of Lemno. N. lat. 40°. E. long. 42° 55'.

PALEOTTI, GABRIEL, in *Biography*, a learned Italian cardinal, descended from an illustrious family, was born at Bologna in the year 1524. He was intended for the profession of the civil and canon law, and made a rapid and very successful proficiency in the study of literature and jurisprudence, at the university in his native city. He was in early life appointed to the canonry of Bologna; after which he was appointed professor at the university. Here he acquired high fame by his lectures and publications, and was distinguished by the accuracy of his judgment and the goodness of his taste. Being led to visit Rome, he was appointed by cardinal Alexander Farnese, who had been his fellow-student at Bologna, and who was just appointed perpetual legate of Avignon, governor of Vaïsson, in the county of Venaisin, which he was led to decline, on account of some family concerns which he was obliged to attend to at Bologna, where he resumed the professor's chair. The Farnese family were, however, resolved to make his fortune, and obtained for him the post of auditor of the rota, when he was only thirty-three years of age. When pope Pius IV. opened the council of Trent, he sent Paleotti thither in the capacity of proctor and counsellor to his legates, who took no step of importance without his advice. Of this council Paleotti wrote a history, which still remains in MS. In 1565 he was raised to the dignity of the purple by Pius IV. and by Pius V. he was created bishop of Bologna, and that see was erected into an archbishopric by the same pope, to do honour both to Paleotti and his native country. So exemplary was Paleotti in his diocese, that it was with the greatest reluctance that the popes summoned him to attend the consistories and other business at Rome. He died at Rome in the year 1597, when about the age of seventy-three. He was author of several works of considerable merit, on subjects in antiquities, jurisprudence, and morals. Of these the most considerable are the following, "Archiepiscopale Bonnoniense;" "De imaginibus Sacris, et Profanis;" "De Sacri Consistorii Consultationibus;" "De Nothis, Spuriisque Filiis;" "De Bono Senectutis;" Pastoral Letters, &c. Moreri.

PALEPARTO, in *Geography*, a town of Naples, in Calabria Citra; 10 miles S. of Rosano.

PALEPOLI, a sea-port of Asiatic Turkey, in Carmania, on the S. coast; 220 miles S. of Cogni.

PALERMO, an ancient city of Sicily, in the valley of Mazara, the seat of the viceroy, and the see of an archbishop, was built on the site of the ancient *Panormus*, (which see,) and situated on a bay to which it gives name, on the north coast, well fortified, with a harbour, the entrance of which is defended by two strong citadels. This bay, as well as Palermo, is at the bottom of a great gulf, formed to the eastward by cape Zofarano, and the mountain

of Catalano, and to the westward by mount Pellegrino, the ancient Ereta. Under this hill, which is both high and steep, and the top of which affords a very beautiful and extensive prospect, and commands the most advantageous view of the situation of Palermo, a mote has been formed, where vessels of all sizes obtain a secure shelter. This city, according to Brydone's account, is greatly superior to Naples in beauty and elegance. Although it is not so large, yet the regularity, the uniformity, and the neatness of its streets and buildings render it much more pleasing; it is full of people, who have mostly an air of affluence and gaiety. It stands near the extremity of a kind of natural amphitheatre, formed by very high and rocky mountains; and the country that lies between the city and these mountains is one of the richest and most beautiful spots in the world. The whole appears a magnificent garden, filled with fruit-trees of every species, and watered by clear fountains and rivulets, that form a variety of windings through this delightful plain. From the singularity of this situation, as well as from the richness of the soil, Palermo has had many flattering epithets bestowed upon it, particularly by the poets; who have denominated it "Conca d'Oro," the golden shell, expressing both its situation and richness. It has likewise been styled "Aurea balli," "Hortus Siciliz," &c. and to include all these together, the lasting term of "Felix" has been added to its name, by which it is even distinguished in the maps. Palermo is built upon a very regular plan; its two great streets intersect each other in the centre of the city, where they form a beautiful and regular square called the Ottangolo, adorned with very handsome and uniform buildings. The centre of this square commands the whole of these noble streets and the four great gates of the city which terminate them, and which are at the distance of about half a mile; the diameter of the city being no more than a mile. These are elegant pieces of architecture richly adorned; particularly the Porta Nova and Porta Felice, that terminate the street called the Corso, which runs S.W. and N.E. The lesser streets in general run parallel to these great ones. The Porta Felice (which is by much the handsomest of the gates) opens to the Marino, a delightful and much frequented walk; bounded on one side by the wall of the city, and on the other by the sea, from which there is, in the hottest weather, an agreeable breeze. In the centre of the Marino there is an elegant kind of temple, which serves as an orchestra for music in the summer months. This city contains, besides an university, many churches, abbeys, seminaries, convents, and hospitals. Many of the churches are extremely rich and magnificent. The cathedral (Madre Chiesa) is a very venerable Gothic building, of a large size, supported within by 80 columns of oriental granite, and divided into many chapels, some of which are extremely rich, particularly that of St. Rosalia, the patroness of Palermo, who is held here in greater veneration than even the Virgin Mary herself. Her relics are preserved in a large silver box, curiously wrought and enriched with precious stones. These perform many miracles, and are looked upon as the greatest treasure of the city. The Sacristie too is very rich. The Jesuits church is singularly magnificent; and the Chiesa del Palazzo is entirely covered over with ancient Mosaic. The church of Monreale, about five miles distant from this city, is the next in dignity in the island, after the cathedral of Palermo. About a mile without the city is the famous convent of Capuchins, remarkable for its burial place. This is a vast subterraneous apartment, divided into large commodious galleries, in the walls of which are numerous niches filled with dead bodies, amounting to about 300, standing upright, and dressed in the clothes which they usually wore. The skin and muscles are rendered, by a cer-

tain preparation, as dry and hard as a piece of shell-fish; and although many of them have been here upwards of 250 years, none of them are reduced to skeletons. The bodies of the princes and first nobility are lodged in handsome chests or trunks, the keys of which are kept by the nearest relations of the family. There are two small districts, one to the E. called La Bagaria, and the other to the W. of the city, called Il Colle, where the principal nobility have their country houses. The population of this city is much greater, in proportion to its size, than that of Naples, and the number of carriages is astonishing. One of the grandest exhibitions is that of the feast of St. Rosalia. Palermo had anciently two ports, mentioned by Polybius and Diodorus; which were destroyed by an earthquake in 1327. At present it has two, one for barks, and another for vessels of war, with a light-house at its entrance. This city is commercial, and exports, in favourable years, 40,000 bales of silk. It has some manufactures of stuff and silk. It has occasionally suffered much from earthquakes. Its population is estimated at 130,000 persons. N. lat. 38° 10'. E. long. 13° 25'.

PALERNO, a town of Naples, in Principato Ultra; 12 miles W.N.W. of Conza.—Also, a town of Naples, in Calabria Citra; six miles S.S.W. of Cofenza.

PALES, or PILES, in *Carpentry*, denote rows of stakes driven deep in the ground to make wooden bridges over rivers, and to erect other edifices on.

Du-Cange derives the word from the Latin name *palla*, a hanging, or piece of tapestry: the ancients gave the name pales to the hangings or linings of walls; thus a chamber was said to be *paled* with cloth of gold, with silk, &c. when covered with bands or stuffs of two colours. Hence also the original of the word pale, a stake, &c. The arms of Arragon are *paled*, or *and gules*.

Tertullian observes, that the Romans planted pales to serve as boundaries of inheritances; and that they consecrated them to the god Terminus, under the name of *pali Terminales*.

Ovid tells us, they were crowned and adorned with flowers, festoons, &c. and that the god was worshipped before these pales. See TERMINALIA.

Pales for building, serve to support the beams which are laid across them, from one row to another; and are strongly bound together with cross-pieces.

PALES, in *Mythology*, the divinity of shepherds, or the tutelary deity and protectress of flocks. Her festival was called *Polilia*, which see.

PALESCIANO, in *Geography*, a town of Naples, in the province of Otranto; three miles S.E. of Motola.

PALESTINE, in *Ancient Geography*, a province of Asia, first called the land of Canaan from Noah's grandson, by whom it was peopled; but since distinguished by other appellations, such as the Land of Promise, the Land of Israel, the Holy Land, and by way of pre-eminence, the Land. It derived its name of Palestine from the Palestinæ, or Philistines, who possessed great part of it; and that of Judea, or Judea-Palestina, from Judah, whose tribe was the most considerable of the twelve, and possessed the finest and most fertile part of the whole. Christians, as well as Jews, have dignified it with the title of "Holy Land;" partly on account of its metropolis, supposed to have been the centre of God's worship, and his peculiar habitation, but chiefly because it was the native country of Jesus Christ, and the scene on which he accomplished the great work of our redemption. See JUDEA and JUDAH.

Palestine was enclosed on the W. by the Mediterranean, and on the E. by the lake Asphaltites, the Jordan, the sea of Tiberias or of Galilee, and the Samachonite lake;

to the N. it had the mountains of Libanus, or rather of Antilibanus, or the province of Phœnicia, and to the S. Edom, or Idumæa, from which it was likewise parted by another ridge of high mountains. This was, strictly speaking, the "Land of Promise." Its extent has been variously assigned; some allowing it no more than 170 or 180 miles in length from N. to S., and 140 in breadth from E. to W. where widest, as it is towards the S., and about 70, where it is narrowest, as it is towards the N. But of late it has been made to extend to nearly 200 miles in length, and about 80 in breadth, about the middle, and 10 or 15, more or less, where it widens or shrinks. In the sacred writings it is represented to have been exceedingly fertile, rich, populous, and powerful. Before the Israelites took possession of it, Moses has described its fertility and productiveness in Deut. viii. 7, &c. And it is said to have exceeded even the celebrated land of Egypt, in the number of cattle which it bred, and in the quantity and excellence of the oil, wine, corn, and various fruits which it yielded. To this wonderful fecundity several circumstances are supposed to have contributed; such as the temperature of its climate, the regularity of its seasons, and the richness of its soil. In order to justify the scripture accounts of this country, it ought to be considered that, in the times to which they refer, it was inhabited by an industrious people, who spared no pains to improve its natural fertility, and to render even its rocks, naturally barren, productive. The fecundity of Palestine has been extolled even by Julian the apostate, the avowed enemy both of Jews and Christians, who frequently mentions the perpetuity, as well as excellence, and great abundance, of its fruits and products. The visible effects of divine displeasure, which this country has experienced, not only under Titus Vespasian, but much more since that emperor's time, in the inundations of the northern barbarians, of the Saracens, and of the more cruel and destructive Christians, during the holy war, and in the oppression it now feels under the Turkish yoke, are causes more than sufficient to have reduced the far greater part of the country into a mere desert. If, indeed, we were to judge by its present appearance, nature itself seems to have rendered it incapable of cultivation. The principal river of Palestine was Jordan. Under the Romans, Palestine began to be divided into tetrarchies and toparchies; the larger were those of Judæa, Samaria, and Galilee, Upper and Lower; the lesser those of Geraritica, Saron, and others of less note, which lay on this side of the Jordan. The rest, on the other side, were those of Gilead, Peræa, Gaulonitis, Auranitis, Batanea, and Decapolis. In the reigns of the Christian emperors, it was divided into Palæstina prima, secunda, tertia, or Salutaris, which last included the far greater part, if not the whole country.

Palestine, in its present state (says Volney), comprehends the whole country included between the Mediterranean to the west, the chain of mountains to the east, and two lines, one drawn to the south, by Kan Younes, and the other to the north, between Kaifaria and the rivulet of Yafa. This whole tract is almost entirely a level plain, without either river or rivulet in summer, but watered by several torrents in winter. Notwithstanding this dryness the soil is good, and may even be termed fertile, for when the winter rains do not fail, every thing springs up in abundance; and the earth, which is black and fat, retains moisture sufficient for the growth of grain and vegetables during the summer. More dourra sesamum, water-melons, and beans, are sown here than in any other part of the country. They also raise cotton, barley, and wheat; but though the latter be most esteemed, it is less cultivated, for fear of too much inviting the avarice of the Turkish governors, and the rapacity of

the Arabs. This country is indeed more frequently plundered than any other in Syria, for being very proper for cavalry, and adjacent to the desert, it lies open to the Arabs, who are far from satisfied with the mountains: they have long disputed it with every power established in it, and have succeeded so far as to obtain the concession of certain places, on paying a tribute, from whence they infest the roads, so as to render it unsafe to travel from Gaza to Acre. They might even have obtained the entire possession of it, had they known how to avail themselves of their strength; but, divided among themselves by jarring interests, and family quarrels, they turn those weapons on each other which they should employ against the common enemy, and are at once enfeebled by their disregard of all good order and government, and impoverished by their spirit of rapacity.

Palestine, says Volney, is a district independent of every Pacha. Sometimes it has governors of its own, who reside at Gaza under the title of Pachas; but it is usually, as at present, divided into three appanages, or *Melkana*, viz. Yafa, Loudd, and Gaza. The former belongs to the *Wald*, or sultana mother. The captain Pacha has received the two others as a recompence for his services, and a reward for the head of Daher. He farms them to an aga, who resides at Ramla, and pays him two hundred and fifteen purses for them, viz. one hundred and eighty for Gaza and Ramla, and thirty-five for Loudd.

PALESTRINA, GIOVANNI PIERLUIGI DA, in *Biography*. It has been frequently observed, that the life of a studious man, whose mind is more active than his body, affords few materials for biography, even if every transaction of his life were known; but at a remote period, when every lineament and trace of character is obliterated, it is with difficulty that the time and place, even of his existence, can be established, or the works enumerated which his genius and diligence have produced. Palestrina, whose works have been so long justly admired, is of this class; for little more has been recorded of his life, than if it had been wholly spent in a hermitage. His birth, however, has been fixed, with some degree of certainty, in the year 1529, at Palestrina, the Præneste of the ancients. Italy being divided into many independent states, each of which has a distinct and separate honour to maintain, the natives are not only very careful in settling the spot where a man of genius was born, but of recording the place where he was educated, with the name of his master; and as the painters of Italy are appropriated to different schools, so are the musicians; and a composer or performer of great abilities is seldom mentioned without his country, by which it is known, that he is of the Roman, Venetian, Neapolitan, Lombard, or Bolognese school, each of which has some peculiar characteristic, that enables one intelligent musician of Italy immediately to discover the school of another, by his works, or performance. To these distinctions the natives of other countries so little attend, that when it is known that a musician comes from Italy, no further enquiry is made.

From this ancient custom of naming the master with the scholar and his country, all the writers of Italy, who have given any account of Palestrina, have thought it necessary to say, that he was a scholar of Gaudio Mell, Flemingo, a Fleming; by whom they have been generally understood to mean Claude Goudimel, a native of Franche-Comté, and a Huguenot, who was one of the first that set the translation of the Psalms, by Clement Marot and Theodore Beza, to music; and who was murdered at Lyons in 1572, on the fatal day of the massacre of Paris.

Who Mell was, if different from Goudimel, we know not; of his works or name we have met with no memorial.

Indeed,

PALESTRINA.

Indeed, as the fact is not of sufficient importance to merit a long discussion, we shall leave it as we found it; for who can be very solicitous to know of what master Palestrina learned the mechanical rules of his art, which were established and very well known, at least a century before his superior genius turned them to so good an account.

However, the few circumstances and outlines of Palestrina's life that have been preserved from oblivion, and seem the most indisputable, are, that he was born in the year 1529; that having distinguished himself as a composer, about 1555, he was admitted into the Pope's chapel, at Rome; in 1562, at the age of thirty-three, he was elected maestro di capella of Santa Maria Maggiore, in the same city; as upon the death of Giovanni Animuccia, in 1571, he was honoured with a similar appointment at St. Peter's; and lastly, having brought choral harmony to a degree of perfection, that has never since been exceeded, he died in the year 1594, at the age of sixty-five.

The following account of his death and burial was entered in the register of the Pontifical chapel by Ippolito Gamboce, Puntatore, who at that time had the care of the records.

"February the 2d, 1594. This morning died the most excellent musician, signor Giovanni Pierloisci, our dear companion, and maestro di capella of St. Peter's church, whither his funeral was attended not only by all the musicians of Rome, but by an infinite concourse of people, when *Libera me Domine* was sung by the whole college." To this account Adami adds that of Torrigio, who says: "In St. Peter's church, near the altar of St. Simon and St. Jude, was interred, in consequence of his extraordinary abilities, Pierluigi da Palestrina, the great musical composer, and maestro di capella of this church. His funeral was attended by all the musicians of Rome, and *Libera me Domine*, as composed by himself, in five parts, was sung by three choirs. Upon his coffin was this inscription: *Joannes Petrus Aloysius Præcellentissimus Musicæ Princeps.*"

It would be useless to transcribe all the eulogia that have been bestowed on Palestrina by musical writers, though he has seldom been mentioned by others; but it is left to artists to take care of their own fame: none but painters have written the lives of painters, or musicians those of musicians. Heroes indeed are consigned to historians; and the learned are seldom negligent of themselves.

Indeed very honourable mention was made of our great contrapuntist during his life-time by Giovanni Guidetto, chaplain to pope Gregory XIII. who being appointed to collate, correct, and regulate the choir service of St. Peter's church, 1582, says that he was unwilling to depend solely on his own judgment in this undertaking, and therefore had applied to that prince of musicians, Giovanni Pierluigi da Palestrina, to superintend and correct the whole work, an office which he was so obliging as to undertake; "and if," says he, "the compilation be found to have any merit, it must be chiefly ascribed to his kind assistance."

Some judgment may be formed, says the learned author of the "Essay on Counterpoint," so often mentioned, of the great veneration in which he was held by the professors of his own time, from a collection of psalms, in five parts, that was published in 1592, and dedicated to Palestrina, by fourteen of the greatest masters of Italy at that time; among these were Pietro Pontio, already mentioned, and Costanzo Porta, who will be distinguished hereafter as a composer, whose abilities, in point of learning and contrivance, are truly wonderful.

By the assistance of signor Santarelli, we procured at Rome a complete catalogue of all the genuine productions

of Palestrina, with the several dates and forms of their publication, title of each work, the name and residence of the printer, which the Italians never fail to record. These are classed in the following manner: Masses in four, five, and six parts, twelve books; of which lib. i. appeared at Rome in folio, 1554, when the author was in the twenty-fifth year of his age; and in that city only went through three several editions during his life. Lib. ii. of his masses, which includes the celebrated composition entitled "*Missa Papæ Marcelli*," was published likewise at Rome, in 1567. Of this production it has been related by Antimo Liberati, in the letter above cited, and after him by Adami, Berardi, and other musical writers, that the pope and conclave having been offended and scandalized at the light and injudicious manner in which the mass had been long set and performed, determined to banish music in parts entirely from the church; but that Palestrina, at the age of twenty-six, during the short pontificate of Marcellus Cervinus, intreated his holiness to suspend the execution of his design, till he had heard a mass, composed in what, according to his ideas, was the true ecclesiastical style. His request being granted, the composition, in six parts, was performed at Saller, 1555, before the pope and college of cardinals; who found it so grave, noble, elegant, learned, and pleasing, that music was restored to favour, and again established in the celebration of sacred rites. This mass was afterwards printed, and dedicated to the successor of Marcellus, pope Paul iv. by whom Palestrina was appointed maestro di capella to the pontifical chapel.

The rest of his masses appeared in the following order: Lib. iii. *Romæ per Valerium Doricum*, 1570, in folio. Ven. 1599. Lib. iv. *Venet. per Ang. Gardanum*, 1582, quarto. Lib. v. *Romæ*, 1590. Lib. vi. Ven. 1596. Lib. vii. 1594. Lib. viii. and ix. Ven. 1599. Lib. x. and xi. Ven. 1600. And lib. xii. without date, or name of the printer. Besides this regular order of publication, these masses were reprinted in different forms and collections, during the sixteenth and seventeenth centuries, in most of the principal cities of Italy; of which editions we were furnished with memoranda.

The next division of Palestrina's works consists of Motets for five, six, seven, and eight voices, five books, at Rome and Venice, 1569, 1588, 1589, 1596, and 1601. Motets for four voices, lib. i. *Romæ*, 1590. Lib. ii. Venet. 1604. Two books of Offertories, a 5 and a 6 voc. *Romæ*, 1593. Lamentations, a 4 voc. *Romæ*, 1588. Hymns for five voices, Ven. 1598. Litanies, a 4, Ven. 1600. Magnificat, 8 tomum. *Romæ*, 1591. Madrigals Spirituali, two books, Rome and Venice, 1594.

To the above ample list of the works of this great and fertile composer, are to be added, *La Cantica di Salomone*, a 5; two other books of Magnificats, a 4, 5, & 6 voc. One of Lamentations, a 5; and another of secular Madrigals. These have been printed in miscellaneous publications after the author's death; and there still remain in the Papal chapel, inedited, another mass, a 4, upon the hexachord, *ut, re, mi, fa, sol, la*; with his *Missa Defunctorum*, a 5, and upwards of twenty motets, chiefly for eight voices, *à due cori*.

Nothing more interesting remains to be related of Palestrina, than that most of his admirable productions still subsist. Few of his admirers are indeed possessed of the first editions, or of all his works complete, in print or manuscript; yet curious and diligent collectors in Italy can still, with little difficulty, furnish themselves with a considerable number of these models of counterpoint and ecclesiastical gravity.

If we consider the operose and flow manner in which works of this kind are conducted, from the many real parts they contain, and of which some are generally moving in canon, and the rest always in fugue, we shall be as much astonished at the number of his productions, as pleased with their effects. Indeed the works of Aristotle, Cicero, or the elder Pliny, among the ancients, or of Fabricius, among the moderns, were hardly more numerous. With the union, indeed, of great erudition and great industry we are not surpris'd; but genius is not often so voluminous.

Palestrina having brought his style to such perfection, that the best compositions, which have been produced for the church since his time, are proverbially said to be *alla Palestrina*, it seems as if this were the place to discuss its merit.

Though good taste has banished fugue, canon, and elaborate compositions from dramatic music, yet sound judgment has still retained them in the church; to which, from the little use that is made of them elsewhere, they are now in a manner appropriated. Indeed there seems no more impropriety in their being occasionally used in the chamber, than private prayer or family devotion. It is the church and stage which we wish to be wholly separated; for it has long appeared to us, that whoever lightly brings the rites of the church to a theatre, or theatrical levity to the church, is guilty of want of taste, judgment, and due reverence for the religion of his country.

In the compositions of Palestrina there is, indeed, no unity of melody; but as all the parts have an equal share of importance, and as hardly a note appears in them without some peculiar intention and effect, they cannot, like the *remplissage* of a modern concerto or opera song, be composed with as much rapidity as they could be transcribed; little invention and few flights of fancy are required; yet there is a degree of happiness and genius in finding a few uncommon notes that are favourable to fugue and canon, as well as in creating new and graceful passages in melody. Indeed both the choral and secular style have their peculiar difficulties, beauties, and defects.

Whoever is accustomed to the vocal fugues of Palestrina, Carissimi, or Handel, will be fastidious with respect to those of other composers of equal learning. Preaching upon a text has been called a Gothic contrivance; and yet what admirable lessons of piety and virtue have been produced under the denomination of sermons! Fire, genius, and harmonical resources are discoverable in fugues, as well as in modern songs, solos, or concertos: a musical student, therefore, unacquainted with the laws of fugue, is advanced but a little way in composition; as the hearer, who receives no pleasure from ingenious contrivance and complicated harmony, is but a superficial judge. Our wish is to resolve the discords of contention, to augment the pleasure of both parties, and extend the compass of their views; that, like the music composed *à deux cori*, the friends of harmony and melody may *agree*, though performing different parts, at a distance of each other, and to terminate this long article concerning the most venerable patriarch of choral music, of whose style it has always appeared to us, that notwithstanding its general gravity and elaboration, that genius glows in all his productions, in spite of the trammels of *canto firmo*, canon, fugue, inversions, diminutions, augmentations, double counterpoint, or whatever would chill or petrify any other than himself.

It is hoped, therefore, that no apology will be necessary for the length of this article, which "the reader can make as short as he pleases." In a general history of ancient poetry, Homer would doubtless occupy the most ample and honourable place; and Palestrina, the Homer of the

most ancient music that has been preserved, merits all the reverence and attention, which it is in a musical writer's power to give.

PALESTRINA, in *Geography*, one of the islands near the city of Venice, 12 miles long, but narrow. Its market-town is of the same name and large, containing above 7000 inhabitants; six miles S. of Venice.—Also, a town of Italy, in the province of Campagna, anciently "Præneste," (which see,) the see of a bishop; 18 miles E.S.E. of Rome. N. lat. 41° 51'. E. long. 12° 49'.

PALESTRIUM, a town of European Turkey, in Livadia; 34 miles N. of Lepanto.

PALETTE, CAPE, a cape on the S. coast of the island of Celebes, in Bony bay. S. lat. 3° 20'. E. long. 120° 48'.

PALEY, WILLIAM, in *Biography*, a justly celebrated divine and philosopher, was born at Peterborough, in July 1743, of the cathedral church of which place his father was a minor canon. Soon after the birth of his son he was appointed head-master of Giggleswick school, in Yorkshire, to which place he removed. Young Paley was now educated under his father's eye; at school he soon surpassed his contemporaries, and at length obtained a pre-eminence over them all. He was even at this period more attentive to things than to words, and was ardent in the pursuit of knowledge of every kind. He was very curious in his enquiries about mechanism, whenever he had an opportunity of conversing with any workmen, or others capable of affording him information. In his *mind* he was uncommonly active; in his *body* quite the reverse.

Soon after he had completed his fifteenth year he accompanied his father to Cambridge, and was admitted a sizar of Christ's college, November 16th, 1758. Soon after his return, as the classics alone were taught at his father's school, he went for mathematical instruction to Mr. William Howarth, a teacher of some eminence at Dishforth, near Topcliffe, three miles from Rippon, under whose care he laid an excellent foundation of knowledge in algebra and geometry. In October 1759, he became a resident member of Christ's college, and on the 5th of December he was appointed to one of the scholarships founded by Mr. Carr; was elected a scholar on the foundation of his college, and appointed to the exhibition founded by sir Walter Mildmay. At college he distinguished himself by his diligence and great proficiency, and attracted considerable notice in the university, at the first opportunities which he enjoyed of displaying his talents in the public schools. In 1763 he was admitted to the degree of B. A. having had the honour of appearing the first man of his year in the previous examinations.

After he had become a graduate, Mr. Paley was engaged as second assistant in an academy at Greenwich, kept by Mr. Bracken, and chiefly resorted to by young men intended for the army and navy, where his department of teaching was in the Latin language. He retained this situation about three years. In 1765 he became a candidate for one of the prizes given annually by the representatives of the university of Cambridge to senior bachelors, to the authors of the two best dissertations in Latin prose. The subject proposed was "A comparison between the Stoic and Epicurean philosophy, with respect to the influence of each on the morals of a people." Mr. Paley took the Epicurean side, and obtained the first prize.

Being ordained a deacon, at a proper age, he engaged himself as curate to Dr. Hinchliffe, then vicar of Greenwich, and afterwards bishop of Peterborough. Soon after this he left the academy, but continued to officiate in the church.

church. In June 1766, he was elected a fellow on the foundation of Christ's college, which was worth about 100*l. per annum*, in consequence of which he returned to a residence in the university, took his degree of master of arts, and engaged in the business of private tuition, which was soon followed by his appointment to the office of one of the college tutors. On the 21st of December 1767, he was ordained a priest by bishop Terrick.

The duties of college tutor Mr. Paley discharged with uncommon assiduity and zeal. Not contented with following the usual method of college-lectures, by which the progress of a student is left to depend chiefly on his own industry, or private assistance, he endeavoured to introduce his pupils to an acquaintance with the most important truths, by arguments and illustrations, which were equally pleasing and forcible. His lectures on moral philosophy, and on the Greek Testament, contained the outlines of the works, by which he afterwards so much benefitted the world, and extended his own reputation; and those works may be said to have owed their origin to the situation, which imposed upon him the duty of delivering the lectures. Mr. Paley at this time acted in conjunction with Dr. John Law, the late bishop of Elphin, and son of the celebrated bishop of Carlisle. The exertions and talents of these kindred souls rendered Christ's college extremely popular; and while they retained their offices, that society rose to a flourishing state, unequalled, perhaps, in the history of the university. Mr. Paley maintained an intimate acquaintance with almost every person of celebrity in the university. Among his most particular friends were Dr. Waring, and Dr. John Jebb, well known by his talents, his integrity, and his zeal in religious and political controversy. Through his friendship with Dr. Law, he became intimately acquainted with his father, Dr. Edmund Law, who was master of Peter-house, and who continued chiefly to reside in the university, after he was created bishop of Carlisle. The learned prelate's theological opinions fell greatly below the established standard of orthodoxy, and Dr. Jebb's sentiments were equally obnoxious to the zealous friends of the church; on the same account, of course the intimate friendship that subsisted between these learned men and Mr. Paley was viewed with a jealous eye by many, who were closely attached to the established systems. Because he was liberal, he was suspected to be a latitudinarian, and they were prepared to discover dangerous tendencies in his moral and political speculations, should they ever be given to the public. After Mr. Paley had spent about ten years as college tutor, he quitted the university in 1776, and married. His first benefice in the church was the rectory of Musgrove, in Westmoreland, worth only about eighty pounds a-year: this was in the month of May 1775, and in December 1776, he was inducted into the vicarage of Dalton, in Cumberland, after which he was presented to the living of Appleby, in Westmoreland, worth about 300*l. per annum*. and in a short time he was promoted to a prebendal stall in the cathedral church of Carlisle.

While vicar of Appleby, he gave the world a small volume selected from the Book of Common Prayer, and the writings of some eminent divines, entitled "The Clergyman's Companion in visiting the Sick." This was first published without his name, but it has passed through many editions, and is now printed among his works. The professional usefulness of this book to the clergy, is no small recommendation of its merits, but when considered as originating in Mr. Paley's personal attention to the spiritual wants of his own flock, it affords an additional proof of his value as a parochial minister.

In the year 1782, upon the resignation of Dr. John Law, who was created an Irish bishop, Mr. Paley was made archdeacon of the diocese, and not long after he succeeded Dr. John Burn, author of "The Justice of Peace," in the chancellorship. For these different preferments he was indebted either to the venerable bishop of Carlisle, or to the dean and chapter of the cathedral church. While his residence was divided between Carlisle and Dalton, Mr. Paley engaged in the composition of his celebrated work, "The Elements of Moral and Political Philosophy." This production would probably have never seen the light, had not the instigations of Dr. John Law urged him to the undertaking. Mr. Paley for a considerable time objected to the risk of publishing, imagining there would be but few readers for a work on that subject, and he was the more determined on this point after he had entered on the married state, thinking it a duty that he owed his family, not to print a book that would probably not find purchasers. To remove the objection, a living having become vacant, of which Dr. Law had the disposal, he presented it to Mr. Paley, on the promise that he would consider it as a compensation for the hazard of printing, and he immediately set about preparing his work for the press. When the MS. was completed, he offered it to Mr. Faulder for 300*l.*, which he refused, proposing 250*l.* as the full value; in the mean time the author was offered by another person in the trade 1000*l.* for the copy-right; he felt it his duty to give Mr. Faulder the refusal, rising however in his demands from 300*l.* to 1000*l.* which the publisher agreed to pay. In 1785 the work was brought out in 4to. with an excellent dedication to the bishop of Carlisle, bearing honourable testimony to the purity of the motives by which that prelate was actuated in his religious researches, and avowing sentiments which reflect the highest credit on the author's ingenuity and liberality. "Virtue," says Mr. Paley, "is the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness." The good of mankind, therefore, is the subject, the will of God the rule, and everlasting happiness the motive of human virtue. All obligation consists in being urged by a violent motive resulting from the command of another. As the will of God, then, is the rule, to enquire what is his duty, or what man is obliged to do in any instance, is, in effect, to enquire what is the will of God in that instance, which consequently becomes the whole business of morality. There are two methods of coming at the will of God, *viz.* by having recourse to the *scriptures*, or to the *light of nature*. The tendency of any action to promote or diminish the general happiness, is the criterion for ascertaining the will of God by the light of nature; since the many proofs of benevolence apparent in the works of creation warrant the conclusion, that *He* wills the happiness of his creatures, and that those actions are agreeable to him, or the contrary, which promote or frustrate that effect. Actions in the abstract, then, are right or wrong according to their tendency. Whatever is expedient is right. It is the utility of any moral rule alone that constitutes the obligation of it. The expediency of any action, however, must be eliminated by general rules, and in reference to all its remote consequences, as well as those that are immediate and direct. Right and obligation are reciprocal, for wherever there is right in one person, there must be a corresponding obligation upon others: and since *moral obligation* depends upon the will of God, *right*, which is correlative to it, must depend upon the same. *Right*, therefore, signifies *consistency with the will of God*. Such is the outline of our author's theory, which, from its great popularity, we have thought it right to state under the article

of the author, who has given to it so much celebrity. Concerning the merits of this work, we may say in the words of an able critic, "those who are fond of novelty, of ingenious theories, curious speculations, abstract and metaphysical notions, will find indeed little in it to amuse or entertain them; but those who are solicitous to have their consciences properly directed in the general conduct of human life, to see their duties and obligations delineated with perspicuity and accuracy, will be fully gratified." His reasoning on subscription to articles of religion; and on the British constitution, in which he disputes the expediency of reform in the house of commons, and vindicates the undue influence of the crown in that branch of parliament, is liable to great objection, and has been attacked, deservedly and severely, by persons of considerable reputation in the literary world. "It may, however," says Mr. Meadley, "he esteemed the last effort of an ingenious mind to soften by interpretation the rigour of practice, which he could not seriously approve; and so to enlarge the pale of conformity to liberal and conscientious men." Mr. Paley's casuistry, in this instance, on the nature and extent of obligation incurred, may be most effectually answered by his own better reasoning on the propriety of subscription, in his "Defence of Bishop Law's Considerations," and in this chapter, "of religious establishments and of toleration, in the present work." "In the one case," says Dr. Diney in the works of Jebb, "he seems to betray the yoke of bondage, in the display of a very feeble apology; in the other he resumes somewhat more of his Christian liberty, and recollects the principles of his Protestant faith."

On the death of the venerable bishop of Carlisle in 1787, Mr. Paley drew up a short memoir of him, which has been inserted in Hutchinson's History of Cumberland, and in the Encyclopædia Britannica, and which, in 1803, was prefixed, with notes supposed to have been written by the Rev. Dr. Diney, to an edition of the bishop's Reflections on the Life and Character of Christ, intended for popular circulation.

The next work which Mr. Paley presented to the public, places him in a high rank among the advocates for the truth and authenticity of the Christian scriptures. It is entitled "Horæ Paulinæ; or, the Truth of the Scripture History of St. Paul evinced, by a comparison of the Epistles which bear his name, with the Acts of the Apostles, and with one another," which he dedicated to his friend Dr. Law, at that time bishop of Killala. The grand object of this work is to shew, that by a comparison of several indirect allusions and references in the Acts and Epistles, independently of all collateral testimony, their undesigned coincidence affords the strongest proof of their genuineness, and of the reality of the transactions to which they relate. Instead of requiring the truth of any part of the apostolic history to be taken for granted, he leaves the reader at liberty to suppose the writings to have been lately discovered, and to have come to our hands destitute of any extrinsic or collateral evidence whatever. The design was original, and the execution admirable. Notwithstanding the title, the utility of the work was not confined to the learned: the "Horæ Paulinæ" will furnish the common reader, as well as the biblical student, with ingenious criticisms and remarks, which will afford valuable assistance in the right understanding of St. Paul's epistles. See *ACTS of the Apostles*.

Soon after the appearance of this work, Dr. Yorke, bishop of Ely, made an offer to Mr. Paley of the mastership of Jesus college, Cambridge, in which the worthy prelate was solely influenced by the reputation of Mr. Paley's extraordinary talents, and by a wish to render them serviceable

in a high academical situation. After deliberate consideration he declined the honour intended him, but his sense of gratitude for his lordship's kindness he publicly expressed in a dedication prefixed to his work, which he published in 1794, and which is entitled "A View of the Evidences of Christianity, in three Parts; I. Of the direct historical Evidence of Christianity, and wherein it is distinguished from the Evidence alleged for other Miracles. II. Of the Auxiliary Evidences of Christianity; and, III. A brief Consideration of some popular Objections. This work was first published in three volumes, 12mo. but in a few months it was republished in two volumes, 8vo. and has been continued in this form through many successive editions. It is perhaps the most complete summary of the evidences of our holy religion that has ever appeared. It also possesses a merit of offering a defence of Christianity, which every Christian may read without seeing the tenets, peculiar to the sect to which he is attached, in the least decried.

After the publication of the "Evidences of Christianity," the bishop of London, Dr. Porteus, instituted him to the prebend of St. Pancras, in the cathedral of St. Paul's. This was in August 1794, and in a very short time he was promoted to the subdeanery of Lincoln, a preferment of 700*l. per ann.*, by Dr. Prettyman, bishop of that diocese. In January 1795 he proceeded to Cambridge to take his degree of D.D. and before he left that place, he was surprized by a letter from the bishop of Durham, Dr. Barrington, with whom he had not the smallest acquaintance, offering him the valuable rectory of Bishop-Wearmouth, estimated at twelve hundred pounds a-year. When he waited on his new patron to express his gratitude, his lordship instantly interrupted his acknowledgments; "Not a word," said he, "you cannot have greater pleasure in accepting the living of Bishop-Wearmouth, than I have in offering it to you." After reading himself in, as a prebend, at St. Paul's cathedral, March 8th, Dr. Paley, for he now assumed that title, immediately proceeded to Bishop-Wearmouth, took possession of his valuable cure, and then returned to Cambridge against the Commencement, to complete the Doctor's degree, and on Sunday July 5th, preached before the university his sermon "On the Dangers incidental to the clerical Character." From this time he divided his residence principally between Lincoln and Bishop-Wearmouth, spending his summers at the latter, and his winters at the former of those places. At Bishop-Wearmouth the principal landowners, wishing to remove even the probability of future dispute, offered him an annual compensation for the tythes. He readily acquiesced, and granted them leases for his life, and thus, by sacrificing any eventual interest of his own in the agricultural improvement of the parish, avoided one great source of inquietude and vexation. In his writings he had already reprobated tythes as noxious to cultivation and improvement, and recommended their conversion into corn-rents, as a practicable and beneficial alteration, in which the interest of all parties might be equitably adjusted; and he now acted in strict conformity to these principles, leaving to the industry of his parishioners its full operation and entire reward. He next undertook the composition of his last work, entitled "Natural Theology; or Evidences of the Existence and Attributes of the Deity, collected from the Appearances of Nature." In this he proceeded very slowly, and was much interrupted by ill-health.

This work was published in the summer of 1802; it was dedicated to the bishop of Durham, for the purpose of making the most acceptable return he was able for a great and important benefit conferred upon him. "A weak, and of late, a painful state of health," he says, in his dedication,

“deprived me of the power of discharging the duties of my station, in a manner at all suitable either to my sense of those duties, or to my most anxious wishes concerning them. My inability for the public functions of my profession, among other consequences, left me much at leisure. That leisure was not to be lost. It was only in my study that I could repair my deficiencies in the church. It was only through the press that I could speak. These circumstances, in particular, entitled your lordship to call upon me for the only species of exertion of which I was capable, and disposed me, without hesitation, to obey the call in the best manner that I could. In the choice of a subject I had no place left for doubt:—the following discussion alone was wanted to make up my works into a system; in which works, such as they are, the public have now before them, the evidences of natural religion; the evidences of revealed religion, and an account of the duties that result from both.”

In this admirable work the author has traced and shewn the marks of wisdom and design in various parts of the creation; but he has dwelt principally on those which may be discovered in the constitution of the human body. From nature and man he has advanced to Nature's God, and by a train of argument and illustration, equally forcible and beautiful, he has established the most satisfactory evidence of the personality, natural attributes, unity and goodness of the Deity.

Mr. Meadley, to whose work we are greatly indebted for the facts in this article, says, he saw him for the last time in December 1804. His valuable life was then drawing fast towards a close; and the powers of nature, gradually exhausted by repeated sufferings, were becoming daily less able to resist the force of his disease. At length, on his return from his annual residence at Lincoln early in the month of May 1805, he experienced a very violent attack, in which the usual remedies were found ineffectual. He soon sunk under the accumulated influence of debility and disease. He met the approach of death with firmness, comforted his afflicted family with the consolation of that religion which he had so successfully taught, and on Saturday May 25th 1805, he breathed his last. His remains were conveyed to Carlisle, and were interred in one of the aisles of the cathedral by the side of his first wife, by whom he had eight children, viz. four sons and four daughters. His second wife survived him.

In private life Dr. Paley had nothing of the philosopher about him. He entered into little amusements with a degree of ardour, which, when contrasted with the superiority of his mind, had a pleasing effect, and constituted a very amiable trait of his character. He was fond of company, which he had extraordinary powers of entertaining; nor was he, at any time, more happy than when communicating the pleasure he could give, by exerting his unrivalled talents of wit and humour. No man was ever more beloved by his particular friends, or returned their affection with greater sincerity and ardour. As a divine, the great aim of Dr. Paley's labours was to maintain the authority of the gospel, as an authentic revelation, and to enforce the practice of virtue by the sanctions of a future life. His views of the Christian system were at once cheerful and enlightened, and in strict unison with the benevolent spirit of the founder. It is generally understood that Mr. Pitt did once recommend him to his majesty for a vacant bishopric, and that an opposition was made from a very high quarter of the church, which rendered the recommendation ineffectual. Mr. Meadley has endeavoured to account for this obstruction to royal patronage, and he presumes that the promotion of Mr. Paley was impeded by “the freedom of his manner in the story of

the pigeons:—by his liberal construction of the oath of allegiance:—by his assertion that the government may be too secure:—by his limitation of the duty of civil obedience:—by his argument that the obligation of subjects and sovereigns is reciprocal:—by his just and striking remark that the divine right of kings is like the divine right of constables; and still more by his enlightened views of religious establishments and toleration.” But whatever was the cause, it was not creditable to the age, that such a man, who had laboured so hard in the cause of religion, natural and revealed, and of pure morality, should not have been raised to the highest rank in the church.

As a writer, Dr. Paley is not remarkable for what is called fine writing, though in this he could excel, as is evident from certain parts of his “Moral Philosophy,” and the conclusion of the “Natural Theology,” which contains some passages scarcely to be excelled in the English language. He had higher objects in view; he wished to inform the understanding, and impress the heart with important truth, and for these purposes his style and method are admirably adapted. The general characteristics of his writings are plainness and simplicity; but there is, at the same time, both in his language and his ideas, a peculiarity of manner stamped by the vigour and independence of his mind, which cannot be borrowed, and which will therefore perpetuate his reputation. Dr. Paley was author of several other works besides those referred to: of these Mr. Meadley has given a complete catalogue. Since his death a collection of thirty-five sermons has been published. In compliance with a codicil to his *Will*, they were at first printed and given away among the inhabitants of Bishop-Wearmouth. His family have since acquiesced in the general wish, and presented them to the world, as it would not have been possible to have prevented a surreptitious sale of them. Monthly Magazine; New Annual Register; and Meadley's *Memoirs of William Paley, D.D.* particularly the latter, we refer to as our authorities.

PALFA, in *Geography*, a town of the duchy of Stiria; 18 miles N. of Leoben.

PALFREYS, PALFREDI, *Palafredi, Palefridi*, were an elegant and easy sort of horses, which, for their gentleness and agreeable paces, were used upon common occasions by military persons and others: their pleasing qualities soon recommended them to the fair sex, who, having no coaches, used these palfreys, and always travelled on horseback. Camden says, that W. de Fauconberge held the manor of Cukeny, in the county of Nottingham, in serjeantry, by the service of shooing the king's palfrey, when he came to Mansfield. Co. Lit. 149.

PALFYN, JOHN, in *Biography*, a surgeon and anatomist of reputation, was born at Courtray, in Flanders, in 1649, or the following year. He settled in the practice of his profession, at Ghent, where he obtained considerable reputation, and gave lectures to a number of pupils. Being extremely zealous for improvement, he visited Paris annually, and occasionally went to Leyden, and even to London, to learn the novelties which were acquired in the practice of his art, in these great schools of medicine. He was the contriver of several improvements in the form of chirurgical and obstetrical instruments, and the author of several useful treatises on anatomy and surgery, which obtained considerable popularity. He died at Ghent in the year 1730, at the advanced age of eighty years.

His first work, published at Ghent in 1701, was a treatise on “*Osteology*,” in Flemish, which was afterwards much enlarged by himself, and translated into German and French. It is particularly full relative to the bones of the head, and

was cited with approbation by some of the most eminent professors of the time. In 1708, he published his "Description Anatomique des Parties de la Femme qui servent à la Generation," together with Licetus' treatise on monstres, and a description of one born at Ghent in 1703. This work is chiefly a compilation; but he has given some original observations on the course of the blood in the fœtus, and on monstres. In 1710, he printed his "Anatomic Chirurgicale, ou Description exacte des Parties du Corps humain, avec des Remarques utiles aux Chirurgiens dans la Pratique de leur Art," in French; and in 1718, reprinted it in Flemish. It was regarded as a valuable work, and was republished after his death, in France, Italy, and Germany, Palfyn also translated the treatise of Anthony Petit on "Diseases of the Eyes," into Flemish, adding several other tracts on the same subject. Eloy Dict. Hist. Gen. Biog.

PALGUNGE, in *Geography*, a town of Bengal; 22 miles S. of Currackdeagh. N. lat. 24° 3'. E. long. 86° 20'.

PALIACUR, a town of the island of Ceylon, situated in a bay on the W. coast; 80 miles N.N.W. of Trincomaly. N. lat. 9° 33'. E. long. 80° 14'.

PALIAPADA, a town of Hindoollan, in the Carnatic; 15 miles S.S.W. of Polore.

PALIAR, a river of Hindoostan, which runs into the bay of Bengal; four miles S. of Sadras.

PALIBOTHTHA, in *Ancient Geography*, a very considerable town of India, both with regard to extent and wealth, situated on the right bank of the Ganges (intra Gangem), and at the confluence of a large river with it, which river Arrian calls "Erranobos," inferior to none but the Ganges and Indus, and which Pliny denominates Jomanes (Jumnah). This ancient author says, in one place, that the Jomanes entered the Ganges by Palibothra, between Methora and Clisobara or Caryobara: but in another place he mentions the conflux of the Ganges and Jomanes, and in the next article says, that Palibothra is situated 425 miles below that point of conflux. Pliny's Palibothra, says major Rennell, is clearly Patna; and it is probable that Strabo meant the same place, by the distance from the mouth of the Ganges. Palibothra was the capital of the Prasii, and in dimensions 80 stadia in length and 50 broad, or about ten miles long and nearly two wide.

PALICAUDCHERY, in *Geography*, a town of Hindoostan, in the country of Calicut, taken from Hyder Ali, in 1783, by the British, afterwards evacuated, and at the peace ceded to the English; 26 miles S.W. of Coimbatore. N. lat. 10° 58'. E. long. 76° 45'.

PALICE GREEN, incorrectly written *Palice* or *Pallas Green*, a small post-town of the county of Limerick, Ireland. It is situated at the foot of *Knock-Green*, the hill of the sun, which is remarkable for its basaltic pillars, about a mile from the village, towards Limerick, near the house of Mr. Apjohn. These pillars, though much inferior to those in the county of Antrim, are calculated to arrest the attention of the traveller, and have led to an examination of the hill, and of other parts of the county, which will probably be laid before the public. Palice Green is 12½ miles E. of Limerick, and about 96 miles S.W. from Dublin.

PALICI DII, in *Mythology*, were the sons of Jupiter by the nymph Thalia. The inhabitants of Sicily adopted these for their deities, and in honour of them erected a magnificent temple at Palica. Their altar became the asylum of the unhappy, and particularly of fugitive slaves. In this temple, according to Diodorus, the most important affairs were transacted, and the most severe punishment was inflicted on perjury.

The worship of the gods Palici is said to have been derived from Phœnicia, and their name, according to Bochart, comes from the Hebrew word "Palichin," of *palach*, colere or venerari, and signifies Venerable; which the poet Æschylus, from whom Macrobius has borrowed the fable of their origin, seems to insinuate, when he said Jupiter ordered the gods Palici to have the title of venerable given to them. However this be, the Palici were very much honoured in Italy; and Diodorus assures us, that they had a temple near the city Erice, revered both for its antiquity, and for the wonderful things that happened in it. Accordingly we are told by Macrobius, after Æschylus and Diodorus, that near this temple were two small lakes of boiling and sulphurous water, always full without overflowing, which were called "Delli," and held in the highest veneration by the credulous people, who imagined that they were the brothers of the Palici, or rather that this was the place whence they themselves had sprung, when their mother delivered them. Ovid likewise describes them. (Met. l. 5. 405.) It was near these two pools that solemn oaths used to be made, and controversies determined, which could not otherwise be easily decided. Those who were called to take this oath purified themselves; and after having given security to pay, if the gods condemned them, they approached the pools, and swore by the divinity who presided over them. If this oath was sincere, they went off unhurt; but perjurers were punished upon the spot, as all authors, who have mentioned it, are agreed.

"Perque lacus altos et olentia sulphure fertur
Stagna Palicorum, ruptâ ferventia Terrâ."

Ovid. Met.

"Et qui præfenti domitant perjura Palici
Pectora supplicio."

Sil. Ital.

But they are not quite agreed as to the nature of the punishment. Macrobius asserts that they fell into one of the lakes, and were drowned; Polemon says, that they died suddenly; Aristotle and Stephanus say they were consumed by a secret fire; and according to Diodorus, some of them lost their lives. As the custom of these oaths came from the east, as well as the worship of the gods Palici, it is not improbable that it was an imitation of what is recorded in the book of Numbers, concerning the trials of the water that was given adulterous women to drink; and the punishments above mentioned were merely a tradition of what befel those who were guilty of the crime of which they were accused. The temple of the Palici was also venerable on account of the prophecies that were delivered there from time to time. Macrobius, after Xenagoras, tells us that Sicily being distressed with famine, they consulted the oracle of the Palici, and were answered, that if they sacrificed a certain hero, whom authors have not named, the famine would cease; which accordingly happened. The Sicilians, in acknowledgment of this blessing, heaped fruits and presents upon the altars of these propitious deities; and this, according to Macrobius, has induced Virgil to say,

"Pinguis ara Palici."

The superstition was afterwards carried to such an extreme, that human victims were offered to these gods; but this barbarous custom was afterwards abolished, and the Palici contented themselves with common offerings. To this the above-mentioned poet alludes, when he says,

"Placabilis ara Palici."

PALICONDA, in *Geography*, a town of Hindoostan,
M 2 in

in the Carnatic; 24 miles W. of Arcot.—Also, a town of Hindoostan, in Travancore; 55 miles N. of Anjenga.—Also, a town of Hindoostan, in the circar of Gooty; 20 miles W. of Gooty.

PALICOURÉA, in *Botany*, Aublet. Guian. v. 1. 172. t. 66, a *shrub* seven or eight feet high, whose wood is white, hard, and brittle, the *branches* opposite, forming a pyramidal head. The *leaves* are opposite, on short stalks, oval, entire, pointed, about a foot long and five inches wide, smooth, with a principal longitudinal rib, and numerous parallel transverse ones. *Stipulas* ovate, in pairs, combined with the base of each *leafstalk*, at its inner side, so as all together to embrace the branch. *Panicles* large, terminal, solitary, repeatedly branched, of numerous fragrant scarlet *flowers*, with orange tubes. *Calyx* superior, small, with five sharp teeth. *Corolla* of one petal, funnel-shaped, curved; its limb in five acute segments, the two lower ones smallest. *Stamens* five, their filaments capillary, inserted about the middle of the tube, and extending as far as its orifice; anthers incumbent, oblong, with a longitudinal furrow. *Germs* inferior, roundish, crowned with a glandular disk; style slender, as long as the corolla; stigmas two, spreading, linear, flat, acute. The young *fruit* appeared to consist of two cells, with one seed in each.

Such is Aublet's account of his *P. guianensis*, the only species, which he found in the woods of Guiana, in the district named *Caux*, flowering in February. No explanation is given of the name. Justieu suspects this plant to be of the same genus as the *Simira* of Aublet, t. 65, and his *Mappouria*, t. 67. Willdenow has, very properly in our opinion, referred them all to **PSYCHOTRIA**. (See that article hereafter.) Schreber however has made a genus of the *Palicourea*, by the name of *Stephanium*, from στεφανος, a garland or ornamental crown, on account, as it should seem, of the beauty and brilliancy of the flowers; Schreb. Gen. 124. He records, in his appendix §22, that Dr. Solander had reduced this shrub to *Muffenda*; but the description of the fruit by no means countenances such a decision.

PALIFISCO, in *Geography*, a town of Naples, in Lavora; 5 miles N. of Sezza.

PALIPHERY, a town of Hindoostan, in the circar of Cuddapa; 24 miles W. of Cuddapa.

PALILIA, a feast among the ancient Romans in honour of the goddesses Pales.

The Palilia, by some called *Parilia*, were celebrated by the shepherds on the day of the foundation of Rome, which, according to Cato, was the 11th of the calends of May, that is, the 21st of April; to beseech that goddesses to take care of their flocks, and preserve them from wolves and diseases. On that day the people purified themselves, and also their folds and flocks with water and brimstone, and burned the shrub, called Savine, whose smoke diffused itself all over the fold. After this, they offered in sacrifice to the goddesses milk, boiled wine, and millet: then followed the feast.

Part of the ceremony consisted in lighting heaps of straw, and jumping over them. Ovid (de Fest. l. iv. 721, &c.) describes this whole solemnity at full length. These ceremonies were accompanied with musical instruments, such as flutes, cymbals, and tabours, which played all the day long.

PALILICIUM, in *Astronomy*, a fixed star of the first magnitude in the Bull's eye; called also *Aldebaran*.

Pliny gives the name Pallicium to the Hyades, of which the Pallicum is properly only one. See **TAURUS**.

PALIMERDI, in *Geography*, a town of Hindoostan, in Madura; 35 miles N.N.E. of Coilpetta.

PALINCOTOS, a term used by Hippocrates to express such diseases as are wont to return with all their violence upon

the patient, after their seeming to have left him, whether for a longer or shorter period of time.

PALINDI, in *Geography*, a town of Hindoostan; 45 miles N. of Travancore.

PALINDROMIA, a term used by Hippocrates, and many other writers, to express a preternatural running of the peccant matter of diseases to the more noble parts.

PALINDROMUS, παλινδρομος, *retro currens*, running backward, formed of παλιν, again, and δρομος, course, a verse, or sentence, which reads the same, when read either backwards or forwards.

Such is the verse,

“Roma tibi subitō motibus ibit amor.”

Some people of leisure have refined upon the palindromus, and composed verses, each word whereof is the same backwards as forwards. As that instance in Camden:

“Odo tenet mulum, madidam mappam tenet Anna.”

“Anna tenet mappam madidam, mulum tenet Odo.”

PALING, or **PALEING**, in *Agriculture*, &c. a kind of fence-work for fruit-trees, &c. planted in fields, &c.

It consists of three small posts driven into the ground, at a foot and a half distance; with cross bars nailed to each other, near the top.

In fixing the pales, in form of a triangle, room is to be left for the tree to play and bow by the high winds without galling. The trees are to be bound to a stake for a year or two; after which fern or straw may be stuffed in betwixt the tree and uppermost rails, to keep it upright.

If the pale be open to deer, rabbits, or the like, a post is to be nailed to the bar between every two pales.

PALING-Fence, that sort of fence which is constructed with pales. See **FENCE**.

PALINGENESIA, Παλιγγενεσία, formed of παλιν, anew, and γενεσις, generation, a new birth, or regeneration.

PALINGENESIA is also used by some for the migration or passage of the soul of a deceased person into another body.

The palingenesia is almost the same thing with the metempsychosis taught by Pythagoras, and still believed by the Brachmans, Banjans, and other philosophers of the East.

PALINGENESIA is used among chemists for the reproducing a mixed body from its ashes.

This has been pretended to by many, as well as the philosopher's stone, and other wonderful powers; but as to the palingenesia, or resuscitation of plants, the instances produced are no more than some of those artificial vegetations which the learned Monf. Homberg has observed and described many times. See Homberg in Mem. Acad. Sciences, 1710; and Boyle's Works Abridg. vol. i. p. 69.

PALINGENIUS, MARCELLUS, in *Biography*, a modern Latin poet of considerable note, who flourished about the commencement of the 16th century, was probably a native of Stellata in the Ferrarese; whence he assumed the addition of Stellatus to his name. Some persons have imagined that he was physician to Hercules II. duke of Ferrara, to whom he inscribed his poem, entitled “Zodiacus Vitæ,” i. e. “De Hominis Vita, Studio, ac Moribus optime Instituentis,” lib. xii. It is denominated the Zodiac of Life, from its division into twelve parts, each inscribed with one of the signs of the zodiac. Its professed object is to guide men in the road to present and future happiness. From his invectives against the church of Rome, he is supposed to have been a convert to the reformation. The poem was placed

in the first class of prohibited books in the Index Expurgatorius; and it has been asserted, that his body was dug up, and burned; but very little seems to be known with certainty about the circumstances of his life. The poem has been highly applauded by some, and treated with a good deal of disrespect by others; but it has gone through a great number of editions, of which the best is said to be that of Rotterdam, 1722. It has been translated into the French language.

PALINGMAN, in our *Old Statutes*, seems to be a merchant-denizen, one born within the English pale. Stat. 22 Edw. IV. cap. 23. and 11 Hen. VII. cap. 22.

PALINGUIR, in *Geography*, one of the Philippine islands, about 15 miles in circumference, situated on the north of cape Engano, on the island of Luçon.

PALINIDRŪSIS, a word used by Hippocrates to express the subsiding of a tumour by the dispersion of the matter that occasioned it, without its breaking.

PALINODY, Πάλινωδία, a discourse contrary to a preceding one.

Hence the phrase *Palinodiam canere, to sing palinody*, q. d. to make a recantation.

The word in the original Greek signifies *singing again, or anew*. Hence it has passed as a general name for any poem, or the like, which contains a retraction in favour of a person whom the poet before had offended.

The poet Stesichorus is said to be the first author of the palinody. The sixth ode of the first book of Horace, beginning, "O matre pulchra," is a true palinody.

PALINTOCIA, Παλιντοκία, formed from *παλω, anew*, and *τοκος*, of *τεκεω, I bring forth*, in *Antiquity*, the birth of a child a second time.

Thus the second birth of Bacchus, proceeding out of Jupiter's thigh, was a palintocia.

PALINTOCIA is also used for the restitution of usury, or the refunding of interests.

The Megareans, having expelled their tyrant, ordained the palintocia; that is, they made a law, that all the creditors should return to their debtors the interests they had received for money lent.

PALINUM, CAPE, in *Geography*, a cape on the coast of Naples. N. lat. 40° 2'. E. long. 15° 10'.

PALIRRHŒA, a word used by the old Greek authors to express the reflux or retrograde course of the humours, as in case of the cholera morbus, where people vomit up their stools.

PALISADE, or PALISADO, in *Fortification*, an inclosure of stakes or piles driven into the ground, each six or seven inches square, and nine or ten feet long; three of which are hid underground. They are fixed about six inches asunder, and braced together by pieces nailed across them near the tops, and secured by thick posts at the distance of every four or five yards.

Palisades are placed in the covert-way, at three feet from, and parallel to the parapet or ridge of the glacis, to secure it from being surpris'd. They are also used to fortify the avenues of open forts, gorges, half-moons, the bottoms of ditches, the parapets of covert-ways; and, in general, all posts liable to surpris'e, and to which the access is easy.

Palisades are usually planted perpendicularly; though some make an angle inclining towards the ground next the enemy, that the ropes cast over them, to tear them up, may slip.

PALISADES, *Turning*, are an invention of M. Coehorn, in order to preserve the palisades of the parapet of the covert-way from the besieger's shot.

He orders them so, that as many of them as stand in the length of a rod, or in about ten feet, turn up and down like traps; so as not to be in sight of the enemy till they just bring on their attack; and yet are always ready to do the proper service of palisades.

PALISADE, in *Gardening*, denotes a sort of ornament; being a row of trees which bear branches and leaves from the bottom, cut and spread in manner of a wall, along the side of an alley, or the like; so as to appear like a wall covered with leaves.

These palisades are made of jessamine, phillyrea, &c.

PALISSE', in *Heraldry*, a range of palisades before a fortification represented on a fesse, rising up a considerable height: and pointed at top, with the field appearing through them.

PALISSY, BERNARD DE, in *Biography*, an ingenious artist and proficient in natural philosophy, was born at Agen, a city of France, situated on the Garonne, about the year 1524. He was brought up to the trade of a potter, which he carried on at Saintes, and he was also employed as a surveyor and draughtsman of plans. A thirst for instruction led him to travel, and having by accident got possession of a cup of enamelled pottery, his whole attention was turned upon endeavouring to imitate it. For this purpose he commenced a series of experiments that absolutely impoverished him; he even broke up his furniture to supply his furnaces with fuel, and sold his clothes to furnish his assistant operator with wages. At length his labours were crowned with success, and he so perfected himself in the manufacture, that he was immediately raised to the head of his profession. He now pursued the science of chemistry, and applied his knowledge to the improvement of agriculture. He was the first person who formed a collection of natural history at Paris, upon which he gave lectures at the rate of half a crown each person, a large sum for that period, but he entered into an obligation to return the money four-fold, provided it were found that he taught any thing that proved false. In 1563 he printed at Rochelle "Recepte veritable par laquelle tous les Hommes de la France pourront apprendre à augmenter leur Tresors, &c." which, after his death, was reprinted under the title of "Moyen de devenir riche," in two vols. 8vo. In 1580, he published "Discours admirable de la Nature des Eaux, et Fontaines, de Metaux, des Sols, des Saline, des Pierres, des Terres, &c." This work was exceedingly valuable in the then existing state of knowledge, and in it he first taught the true theory of springs, and asserted that fossil-shells were real sea-shells deposited by the waters of the ocean. He also pointed out the use of marle, and of lime in agriculture. This excellent philosopher was sincerely and ardently attached, with regard to religion, to the principles of Calvinism, on account of which he was, in the reign of Henry III. in 1584, apprehended and committed to the Bastille. The monarch, who, it appears, had a true regard for him, plainly said, that if he did not comply with the prevailing religion, he should be constrained to leave him in the hands of his enemies, to which Palissy replied, with energy, "Your Majesty has often said that you pity me; for my part I pity you for pronouncing the words *I shall be constrained*. This is not speaking like a king; but let me inform you in royal language, that neither the Guisarts, your whole people, nor yourself, shall constrain a potter to bend his knee before images." He used commonly to say, in allusion to his religion and his trade as a potter, "I have no other property than heaven and earth." Such are the only facts known of this estimable citizen; the time of his death is not ascertained.

A new

A new and complete edition of his works was published at Paris in 1777, with notes, by Faujas de Saint-Fonds. Gen. Biog.

PALIURI, CAPE, a cape on the coast of European Turkey, in the gulf of Saloniki. N. lat. $39^{\circ} 50'$. E. long. $23^{\circ} 46'$.

PALIURUS, in *Botany*, a name adopted from Dioscorides, but certainly misapplied here. He speaks of his *παλιυρος*, as a well-known prickly shrub, whose seed is fat, or oily, resembling that of flax, and good for coughs, calculous disorders, &c. Dr. Sibthorp judged that plant to be possibly the *Ziziphus vulgaris*; or *Rhamnus Ziziphus* of Linnæus. The description of the third species of *Rhamnus* in Dioscorides, so exactly accords with our *Paliurus*, that no doubt can exist of its being what he there described, and consequently not his *παλιυρος*. "The fruit," says he, "is broad, white, thin, shaped like a pouch or box, and resembling a socket or vertebra (*σφουδυλος*)." He had previously described the very long prickly shoots, and dark leaves. Tourn. t. 387. Juss. 380. Lamarck Illustr. t. 210. Gærtner. t. 43. Class and order, *Pentandria Trigynia*. Nat. Ord. *Dumofæ*, Linn. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five equal, acute, spreading, deciduous segments, internally coloured; its base permanent. *Cor.* Petals five, minute, with narrow claws, inserted under the glandular disk of the flower, between the segments of the calyx. *Stam.* Filaments five, short, opposite to the petals; anthers small, roundish. *Pist.* Germen superior, roundish, bordered; styles three, very short; stigmas spreading, flat, obtuse, deciduous. *Peric.* Capsule coriaceous, of three cells, not bursting, globular, furrowed at the bottom with the permanent base of the calyx, and crowned at the top with a very broad, orbicular, membranous, striated, notched, horizontally spreading border. *Seeds* solitary, hard, ovate, compressed, rather polished.

Ess. Ch. Calyx tubular, five-cleft; its base permanent. Petals five, opposite to each stamen. Capsule coriaceous, of three cells, not bursting, crowned with a flat dilated border. Seeds solitary.

Obs. We are at length induced to separate this genus from *Rhamnus*, as well as *Ziziphus*, the fruit affording full as good a distinctive character in one case as in the other. (See *RHAMNUS* and *ZIZIPHUS*.) The seed-vessel of *Paliurus* is very peculiar. It has nothing that designates a berry, nor is it a dry drupa, because it consists of more than one cell, and the seeds can scarcely be termed nuts. Its texture and structure are most like what is observable in *Franxinus* and *Ulmus*. The cells, naturally three, are occasionally but two.

1. *P. australis*. Christ's Thorn. Gærtner. v. 1. 203. (*Paliurus*; Dod. Pempt. 756. Ger. em. 1336. Duham. Arb. v. 2. 96. (*Rhamnus Paliurus*; Linn. Sp. Pl. 281. Pallas. Ross. v. 2. 27. t. 64. Rh. tertius; Matth. Valgr. v. 1. 142. *Ziziphus Paliurus*; Willd. Sp. Pl. v. 1. 1103. Ait. Hort. Kew. ed. 2. v. 2. 18. Sm Fl. Græc. Sibth. v. 1. 159.)—Common in hedges and bushy places throughout the south of Europe, as well as in the Levant. Gerarde cultivated it in his garden, and it is sometimes preserved in old or curious collections, for the sake of singularity, or rather perhaps for the reputation attached to it of having been the thorn with which our Saviour was crowned. This its pliant and prickly nature seems to render probable. It is commonly delineated by Italian painters, and we verily believe that, if the sacred deposits of superstition were ransacked, this thorn would be found treasured up in them; at least in Italy. Yet Hasselquist sent Linnæus from the Holy Land a different shrub, which the latter named *Rham-*

nus Spina Christi. Its habit is much like our *Paliurus*, and the one is as likely to have been used for the execrable purpose on record, as the other. Nevertheless, we are most inclined to think neither of these was employed; but rather the prickly *Acanthus*, a common oriental plant, whose leaves would perhaps better serve the intention of mockery, as well as cruelty, than either, having some resemblance to the foliage of a victor's crown, and being most abundantly beset with fine sharp prickles.

The *Paliurus* flowers in June and July, and is perfectly hardy with us. When old, it forms a small upright tree, but in a wild state has long trailing branches, which are alternate, roundish, smooth and grey, somewhat zigzag; armed at the insertion of every leaf with two sharp prickles, one of them straight, the other curved. *Leaves* alternate, spreading, on short stalks, broad-ovate, an inch and a half long, bluntly pointed, crenate, smooth, three-ribbed, with many fine transverse veins. *Stipulas* small, pointed, permanent, changing to the above-described prickles, which are finally deciduous. *Flowers* several together, in little, short, tufted, axillary clusters, of a pale greenish-yellow. *Fruit* about an inch in diameter, pale brown or sometimes reddish, its texture rather spongy, except the middle, which is very hard. Pallas describes only one seed as perfected in Georgia, and about Mount Caucasus; other authors say two or three, as they, for the most part, described from specimens the produce of more favourable climes.

PALIZEUL, in *Geography*, a town of France, in the department of the Forests, and chief place of a canton, in the district of Neufchateau; 18 miles N.N.E. of Sedan. The place contains 800, and the canton 6203 inhabitants, on a territory of 300 kilometres, in 10 communes.

PALIZZI, a town of Naples, in Calabria Ultra; three miles E. of Reggio.

PALKANE, a town of Sweden, in the province of Tavastland; 23 miles N. of Tavasthus.

PALL, a circar of Hindoostan, in Guzerat, S. of Oudipour.

PALL, in *Heraldry*, denotes a kind of cross, representing the *pallium*, or archiepiscopal ornament, sent from Rome to the metropolitans; which is blazoned thus: he beareth gules, a cross pall, argent.

PALL, *Pallium Episcopale*, is a hood of white lamb's wool, to be worn as doctors' hoods upon the shoulders, with four crosses woven into it. And this pallium episcopale is the arms belonging to the see of Canterbury.

PALL. See **PALLIUM**.

PALLA, among the old Romans, a mantle which women wore over the gown called stola.

It was borne on the left shoulder, whence passing to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare. It made abundance of plaits or wrinkles: whence, according to Varro, it had its name: viz. from *παλλω*, *vibro*, I shake, or tremble.

Among the Gauls there was also a kind of palla worn by the men, called *Gallica palla*.

PALLA, in *Geography*, a small island in the East Indian sea; N. lat. $3^{\circ} 4'$. E. long. $125^{\circ} 28'$.

PALLADIA, in *Botany*, a name chosen, either by Lamarck or his continuator Savigny, for a genus of the southern hemisphere, which Gærtner had previously called *Blackwellia*; see **BLACKWELL**, **ELIZABETH**; but the latter appellation being given by Lamarck and Jussieu, as well as Willdenow, to a genus of the class *Dodecandria*, nearly related to **HOMALIUM**, see that article, it could not be retained for

for the plant before us. What *Palladia* means, is no where explained, nor can we form any conjecture worth offering. Lamarck Dict. v. 4. 698. Illustr. t. 285. (Blackwellia; Gært. t. 117.) Class and order, *Obandria Monogynia*. Nat. Ord. *Gentianæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, funnel-shaped, coloured; tube short; limb in four obovate segments. Cor. of one petal, funnel-shaped; tube long, with eight plaits; limb in eight oblong segments. Stam. Filaments eight, rigid, permanent, united to the tube of the corolla for more than half its length; anthers . . . Pist. Germens two, superior; style simple, compressed, situated between the germens and parallel to them, connected with their base, its edges finely toothed; stigmas two, spreading. Peric. Capsules two, club-shaped, prismatic, erect, parallel, close together, membranous, rigid, obscurely angular at one side, marked with a deep furrow at the other, each of one cell and two finally spiral valves. Seeds very numerous, minute, roundish, somewhat angular. Receptacle spongy, as long as the capsule, to the edges of whose valves, at the furrowed side, it is attached, being marked there by a similar furrow, while its other side is convex, and its whole surface rough with extremely minute tubercles.

Ess. Ch. Calyx in four segments. Corolla of one petal, in eight segments. Capsules two, superior, parallel, each of one cell, with two valves, and many seeds.

1. *P. antarctica*. The only species was given to Gærtner, as far as he could recollect, by Dr. J. Reinhold Forster, for a specimen of his own *Skinnera*, Forst. Gen. t. 29. From that it proved, on the slightest examination, totally distinct, for *Skinnera* is the very same genus with *Fuchsia*. But it may be questioned whether Forster, who studied the new plants of the Southern hemisphere, chiefly by the rules of the Linnæan artificial system, without regard to natural orders, might not, in the hurry of collecting, confound these two plants of the *Obandria Monogynia*, so as to lodge them together in his herbarium, and afterwards forget to distinguish them. Still no two plants can be more distinct, what little we know of the *Palladia* being too unlike every thing else, to leave a doubt in the mind of any botanist. Of its habit, herbage, or inflorescence nothing is recorded. The capsules are nearly two inches long. The figures above cited seem to represent the remains of the corolla, in four abrupt toothed segments only, which do not answer to the description of Gærtner, the only person who appears to have seen the plant. As Forster's specimens have been pretty generally distributed, it is much to be wished that some relics of this great botanical curiosity might be detected by one or other of their possessors.

PALLADIO, ANDREA, in *Biography*, a famous Italian architect, was born at Vicenza in 1518. He obtained instructions from the poet Trissino, who discovering in him a genius for sculpture and the arts connected with it, taught him the elements of the mathematics, and explained to him the works of Vitruvius. He soon obtained distinction as an architect, and having an opportunity of accompanying his patron to Rome, he employed all his faculties in examining the remains of ancient edifices in that capital, and formed his taste upon them. On his return, the conduct of many works of importance was committed to him, which he managed with great skill, and obtained for himself a high reputation. He was now sent for to Venice, where he built the palace Foscarini in the style of pure antiquity. Several other Italian cities were afterwards decorated with magnificent edifices, public and private, of his construction, and he was invited to the court of Emanuel Philibert, duke of Savoy, who received him with distinguished honours. To

Palladio is chiefly attributed the classic taste which reigns in so many of the buildings of Italy. His master-piece is reckoned the Olympic theatre at Vicenza, in imitation of that of Marcellus at Rome. He died in that city in 1580, having greatly improved his art, not only by his edifices, but by his writings, which are standard performances. Of these the following account is given; "His Treatise on Architecture, in four books, was first published at Venice in 1570, folio, and has several times been reprinted. A magnificent edition, in three volumes folio, was published at London in 1715, in Italian, French, and English. Another, equally splendid, has since been published at Venice, in four volumes folio, with the addition of his incited buildings. Lord Burlington published in London, in 1730, a volume, entitled "Idisegni delle Terme Antiche di Andrea Palladio." He composed a small work, entitled "Le Antichità di Roma," not printed till after his death. He illustrated Cæsar's "Commentaries," by annexing to Badelli's translation of that work, a preface on the military system of the Romans, with copper plates, designed, for the most part, by his two sons, Leonida and Orazio, who both died soon after." Palladio was modest in regard to his own merit, but he was the friend to all men of talents; his memory is highly honoured by the votaries of the fine arts; and the simplicity and purity of his taste have given him the appellation of the Raphael of architects.

PALLADIUM, in *Antiquity*, a statue of the goddess Pallas, three cubits high, holding a pike in the right hand, and a distaff and spindle in the left, preserved in Troy, in the temple of Minerva, on which the fate of that city is said to have depended.

The tradition is, that in building a citadel, in honour of Pallas, and a temple in the most elevated part of it, the palladium dropped from heaven, and marked out the place which the goddess was pleased to possess. After this Apollo gave an oracle, importing, that Troy should never be taken while the palladium was found within its walls: which occasioned Diomedes and Ulysses, in the time of the Trojan war, to undertake the stealing of it. For this purpose, having entered the citadel by night, or by means of secret intelligence, they stole away this valuable pledge of the security of the Trojans, and conveyed it into their camp; but they were scarcely arrived, when the goddess gave testimonies of her wrath. To which purpose Virgil makes Sinon say:

"Scarce to the camp the sacred image came,
When from her eyes she flash'd a living flame;
A briny sweat bedew'd her limbs around,
And thrice she sprung indignant from the ground;
Thrice was she seen with martial rage to wield
Her ponderous spear, and shake her blazing shield."

Pall's Æn. 2. 228.

It is said, there was, anciently, a statue of Pallas preserved at Rome, in the temple of Vesta; which some pretended to be the true palladium of Troy, brought into Italy by Æneas: it was kept among the sacred things of the temple, and only known to the priests and vestals. This statue was esteemed the destiny of Rome; and there were several others made perfectly like it, to secure it from being stolen. See ANCYLE.

There was also a palladium in the citadel of Athens, placed there by Nicias.

These palladiums, in all probability, were no other than a kind of talismans.

PALLADIUM, in *Chemistry*, a simple substance and a metal. This metallic substance was discovered by Dr. Wollaston in 1803, who gives the following process for preparing it.

It. The grains of platina, as they come from South America, are first to be roasted, to dissipate the mercury, and then digested in weak nitromuriatic acid, to separate the gold, and other metals of easy solubility. The remainder is now to be digested in a sand-bath, with strong nitromuriatic acid. The whole will be dissolved, with the exception of a black scaly powder, from which the metals *iridium* and *osmium* are obtained, and of which we have given an account under those articles. The solution contains platina, rhodium, and palladium, with perhaps other metals. The platina is first to be precipitated by a solution of muriat of ammonia. Into the remaining solution immerse a clean piece of zinc, which precipitates the palladium and rhodium in their metallic forms, with the other metals that may be present. This residuum is next to be digested, with weak nitric acid, in the cold, in order to dissolve any easily oxydable metal that may be present. The remainder, being washed with distilled water, is now to be dissolved in nitromuriatic acid. To this solution some muriat of soda is added, for the purpose of forming a triple salt with palladium, which is soluble in alcohol. The solution, with the common salt added, is now to be evaporated to dryness with moderate heat. This residuum is next to be washed with repeated additions of alcohol, till the liquor becomes colourless. The triple muriat of soda and palladium, and the same of platina, if that metal be present, are dissolved in the alcohol. The substance which the alcohol leaves undissolved is of a deep red colour, and contains the rhodium in the state of triple muriat of soda, and the latter metal. If the alcoholic solution still contains platina, it may be separated by muriat of ammonia. To the remaining solution now add prussiat of potash, which causes an orange precipitate. This, being washed and exposed to a tolerable heat, loses its water, and the acid assumes a grey metallic appearance. This substance is lastly to be heated with sulphur and borat in a crucible, when it will afford a metallic button which is pure palladium.

This metal is of a white colour, more of the appearance of platina than any other metal. It is something harder than the above metal, being about the stiffness of jewellers' gold. It is less malleable than silver or platina, owing probably to its greater hardness. Its specific gravity, according to Dr. Wollaston, varies from 11.3 to 11.8. When heated to about 30° of Wedgewood, it assumes a blue colour, owing to its combination with oxygen, in which property it has some resemblance to iron. If, however, the heat be increased, the oxygen flies off, and it re-assumes its original lustre. It does not fuse at the ordinary temperature of furnaces. Although its oxyd seems to be formed at a certain temperature in the open air, it has not been procured by these means. An orange oxyd is procured by precipitation from the acids, but not sufficiently pure to get the proportion of oxygen; hence we are at present unacquainted with the oxyds of palladium. It does not combine with carbon, nor is it known to combine with hydrogen, nitrogen, or phosphorus.

It combines with sulphur, forming a compound, fusible at a low red heat. The sulphur gradually escapes, leaving the metal in a state of purity.

According to the experiments of Chenevix, it forms an alloy with gold of a grey colour; less ductile than either of the metals. Its fracture was crystallized. Its specific gravity 11.079.

It forms an alloy with platina in equal parts. The alloy is as fusible as palladium. It is less malleable than that with gold. Its specific gravity was 15.141.

It forms an alloy with an equal part of silver, much harder than the latter metal, and whiter than platina. Its specific

gravity was 11.2. Its alloy with lead is very fusible, hard, and extremely brittle. Its specific gravity was 12. Equal parts of copper and this metal form an alloy of a yellow colour, harder than wrought iron. Its specific gravity was 10.392. Its alloys with tin, iron, bismuth, and arsenic, were tried by the same chemist, but had no striking characters.

The oxyd of palladium combines with the acids forming saline compounds, which have not been much attended to.

The sulphuric, nitric, and muriatic acids, when boiled upon palladium, oxydate and dissolve it; but the nitromuriatic acid acts upon it with the greatest energy. All the solutions are of a red colour. The oxyd is not precipitated from these solutions in a state of purity by the earths and alkalis, owing to its forming insoluble triple salts with most of those saline bases. The weight of the atom of palladium is not yet known with precision. Sir Humprey Davy has stated it to be about 17 times the weight of the atom of oxygen.

PALLADIUS, in *Biography*, an eastern prelate and ecclesiastical writer, was a native of Galatia, and born about the year 368. While a very young man he began to travel in foreign countries, and coming to Alexandria, in Egypt, he determined to embrace the monastic life. He spent three years under the discipline of Dorotheus, a celebrated ascetic of Thebes, and in 391 he visited the monasteries, and most celebrated solitaries in the desert of Nitria. At length, having wandered over almost the whole of Egypt, he was obliged, by the infirm state of his health, to quit that country, and retire to Palestine. In the year 400, or 401, he went into Bithynia, where he was ordained bishop of Helenopolis. It is by no means certain whether Palladius, author of the "Lausiac History;" and Palladius, author of a dialogue of the life of St. Chrysostom, written in 408, were different persons, or one and the same. Dupin reckons these works to have been written by the same hand; Tillemont and Fabricius think them the productions of different persons. The facts already cited are taken from the "Lausiac History," so called from Lausus, a man of eminence in the imperial court at Constantinople, to whom it is inscribed. Upon the supposition that it was the same Palladius, the author of the history, who wrote the "Dialogue," the following particulars may be added. He was ordained by St. John Chrysostom, to whose party he attached himself; and upon the banishment of Chrysostom, in 404, Palladius fell under persecution, and being obliged to withdraw from his see, retired into Italy, and took refuge at Rome. Some time after, venturing to return into the East, he was banished to Syene, at the southern extremity of Egypt. Having regained his liberty, he resigned the see of Helenopolis, and was appointed to the bishopric of Aspona in Galatia. It is not certain when he died, but it was probably some time before the year 431, since Eusebius, his successor at Aspona, presided at the council of Ephesus, which was held in that year. He wrote the "Lausiac History" about the year 421, which contains the lives of persons, who, at that time, were eminent for their extraordinary austerities in Egypt and Palestine. The style in which it is written is plain and simple; the first edition of it, in Greek, was published by Meursius at Leyden in 1616. In several manuscripts, there is subjoined to the "History" a book concerning the nations of India and the Brahmins, which has been attributed to Palladius, but without any proof of the fact. Cave says nothing can be affirmed of this work, only that it is the production of a Christian writer, who lived before the destruction of the Roman empire. Dupin. Moreri. Lardner, Cave.

PALLANDROS, in *Geography*, a town of the island

of Cyprus, situated at the foot of the mountain of St. Croix, anciently called "Palea;" 24 miles N. of Limasol.

PALLANTIA, in *Ancient Geography*, a town of Hither Spain, in the country of the Vaccæi; distinguished, according to Appian, by the valour of its inhabitants. See PALENCIA.

PALLANTIUM, a town of Arcadia, N.E. of Megalopolis, and at the extremity of a plain, which, being enfeebled by a colony detached to Megalopolis, became a village in the time of the emperor Antonine, who embellished it with some fine edifices, in honour of Pallas, Ceres, and Proserpine, freed it from every kind of imposition, and gave it entire liberty.

PALLAS, ♀, in *Astronomy*, a small planet, called asteroid by Dr. Herschel, discovered 28th March 1802, by Dr. Olbers, at Bremen, in Lower Saxony, and situated between Mars and Jupiter. It is so small that it does not subtend an angle large enough to be measured by our best instruments. Its orbit is very eccentric, and it is much inclined to the ecliptic; ascending above its plane at an angle of about 35°. The light reflected by it is of a less ruddy hue than that of Ceres, and it is attended by more or less of a nebulosity, proceeding, perhaps, from a copious atmosphere; and extending 468 miles from the body of the planet, whilst that of Ceres is 675 English miles high; and in this respect, as well as in the great inclination of its orbit, it appears to have some affinity to comets.

From Dr. Herschel's observations (Phil. Transf. for 1802. vol. 92.) we may conclude that the apparent diameter of Pallas is either 0."17 or 0."13: its mean distance from the sun 2.8; its distance from the earth, at the time of observation, 1.8333; and its apparent diameter, at the mean distance of the earth from the sun, subtends an angle of 0."3199, so that its real diameter, if the largest measure be taken, will be 147 miles; and if the smallest, resulting from a more distinct observation, be taken, the angle under which it would be seen from the sun will be only 0."2399, and its diameter no more than 110½ miles. (See ASTEROID.) The elements of the orbit of Pallas, as others have stated them, are as follow:

Tropical revolution	- - - - -	4 ^r 7 ^m 11 ^d
Sidereal revolution, from Maskelyne's Table	1703 ^d	16 ^h 48 ⁱ
Annual motion	- - - - -	2° 18' 11"
Mean longitude, Jan. 1, 1804	- - - - -	9° 29' 52" 58
Place of ascending node in 1802, from Maskelyne's Table	- - - - -	5 22 28 57
Place of ascending node in 1804, according to La Lande	- - - - -	5 22 28 0
Place of perihelion	- - - - -	4 1 7 0
Eccentricity, the mean distance being 1	- - - - -	0.24630
Inclination of orbit in 1801, according to Maskelyne's Table	- - - - -	34° 50' 40"
Ditto in 1804, according to La Lande	- - - - -	34 39 0
Greatest equation of centre	- - - - -	28 25 0
Mean distance from the Sun, that of the Earth being 1	- - - - -	2.7910
Mean distance in English miles	- - - - -	266,000,000
Diameter in English miles, according to Herschel	- - - - -	80
Ditto ditto, according to Schroeter	- - - - -	2099
Apparent mean diameter, as seen from the Earth	- - - - -	0."5

See PLANET and SOLAR System.

PALLAS is also a name given by some to the first satellite of Jupiter. Lowthorp's Abr. Phil. Transf. vol. i. p. 407.

PALLAS, in *Mythology*. See MINERVA.
VOL. XXVI.

PALLAS, Dr. PETER SIMON, in *Biography*, son of Simon Pallas, a native of Johannesburg, in Prussia, who was surgeon-major in the regiment of Dœnhof at Berlin, and was appointed, in 1741, professor of surgery at Berlin, and chief surgeon of the hospital in that city. Simon Pallas, the father, signalized himself by a treatise on chyrurgical operations, published in 1763, to which, in 1770, he added a supplement on the diseases of the bowels, and in that year he died, at the age of 76.

Peter Simon Pallas, the celebrated naturalist who forms the subject of this article, was born at Berlin on the 22d of September 1741. He received the early part of his education at home from private tutors, under whom the progress he made in his studies was truly amazing. Of those preceptors, Martin Schœling was one of whom his pupil ever after retained a grateful remembrance. To him he was indebted for a very early attachment to the science of entomology. Being destined to physic, so early as the 15th year of his age he entered upon a course of lectures on anatomy, physiology, botany, medicine, and surgery, under the professors Meckel, Sprœgel, Gleditsch, Rolof, and his father; and applied himself with great assiduity to anatomical dissections. He was so apt a scholar in these several branches of science, that in the beginning of 1758, we find him, according to the account he gave of himself to Mr. Coxe, enabled to read a course of public lectures on anatomy. Yet, although he was thus occupied in his professional labours, he still found leisure to prosecute the study of insects and other classes of zoology, for which he seems very early to have conceived a predilection, and in which he particularly and eminently excelled.

In the autumn of the same year, young Pallas repaired to the university of Halle; where he attended the lectures of the celebrated Segner on mathematics and physics, and improved his acquaintance with mineralogy in the environs of that city.

In the spring of 1759 he removed to Gottingen, and though prevented by a long and dangerous illness from prosecuting his studies with his usual ardour, yet he reaped great benefit from the instructions of the physicians Rœderer and Vœgel, and improved his general knowledge by diligently availing himself of the means of consulting the books in the public library.

During his residence at Gottingen, he made numerous experiments on poisons and the efficacy of other violent remedies, applied himself to the dissection of animals, and made repeated observations on the worms which breed in the intestines. On this subject he composed a very ingenious treatise, under the title of "De Infestis Viventibus intra Vienta;" in which tract he appears to have taken great pains to discriminate these noxious animals; and has with singular accuracy described particularly those worms which are found in the human body.

In July 1760 he was attracted to the university of Leyden by the fame of the celebrated physicians and naturalists Albinus, Gaubius, and Muschenbroeck; and by them he was noticed as a young man of a promising genius and indefatigable application. His talents particularly recommended him to the favour of Gaubius, principal professor and doctor of physic in that university.

In December he took his doctor's degree, and distinguished himself by an inaugural dissertation, in which he defended by new experiments the above-mentioned dissertation composed at Gottingen.

During his stay at Leyden, his taste for natural history became his predominant passion; he employed all the time he could steal from his professional studies in visiting the public and private cabinets of natural history, with which Leyden

abounded, and was particularly charmed with the collection of Gronovius, which he repeatedly examined.

Having visited the principal cities of Holland, he directed his course to London, where he arrived in July 1761. The principal intention of his journey to England was to improve his knowledge in medicine and surgery, and to inspect the hospitals. He was now, however, so much absorbed in his passion for natural history, that he neglected every other pursuit, and gave himself totally up to this favourite branch of science. At this juncture, his zeal was so ardent, that after having passed the day in curiously examining the various collections in natural history, and perusing the principal books he could procure on that subject, he would frequently employ the greater part of the night, and occasionally even whole nights together, whenever he met with new publications that either awakened his curiosity or interested his researches. With a view of extending his information in this department, he took several journeys to the sea-coasts, and particularly in Suffex.

Being at length summoned by his father to return to Berlin, he quitted London with regret in the latter end of April 1762, and repaired to Harwich in order to embark for Holland. Being there fortunately detained some days by contrary winds, he embraced that opportunity of examining the sea-coast, and collecting a variety of marine productions. On the 13th of May he landed in Holland, and passing through the Hague, Leyden, and Amsterdam, he continued his route through the circle of Westphalia, and arrived at Berlin on the 12th of June.

Previously to his commencing the practice of his profession, his father sent him to Hanover for the purpose of procuring the post of surgeon in the allied army; but as, upon his arrival in that city, in the month of July, peace was on the point of being concluded, he returned by Wolfenbuttle, Brunswick, and Helmsdtadt, to Berlin, there he passed a year, which he chiefly employed in preparing materials for a "Fauna Insectorum Marchica," or a description of the insects in the march of Brandenburg.

Animated by his predilection for natural history, and encouraged by the favour and patronage of Gaubius, he at length prevailed upon his father to let him go and settle in Holland. Thither accordingly he went, and resided at the Hague.

His reputation as a man of science was, by this time, so well established, that he was, the same year, elected fellow of the royal society of London; and in the following year member of the Academie des Curieux de la Nature; to both of which societies he had previously sent very interesting and ingenious papers.

The intimacy he now contracted with the most celebrated naturalists in Holland, and particularly with those of the Hague, who had just begun to form a literary society; the free access which he had to the museum of the prince of Orange, and other curious cabinets; the systematic catalogues of those collections that he drew up, and several of which he gave to the public; contributed to advance his knowledge of the productions of nature in the various parts of the globe, and to collect such materials as gave birth to those accurate compositions on zoology, which have deservedly distinguished him as the first zoologist of Europe. One of his earliest works in this branch of science, which rendered him eminently conspicuous, was his "Elenchus Zoophytorum."

The attention which Dr. Pallas had bestowed on the zoophytes, or animal plants, in the investigation of the worms which infest the human body, and particularly the uncommon nature of the *tania*, or tape-worm, as he acknowledges, seems to have led him into this line of natural science,

and in which he has shewn a great degree of accuracy, and surprising industry. In this work, after having treated on the nature of these ambiguous kinds of animals in a general method, and stated the various opinions of authors relating to the place they ought to hold in the system of nature, he describes from his own inspection more than 270 species of those worms and animalcules, known under the several general appellations of polypes, corals, madrepores, corallines, sea-pens, *tania* or tape-worms, sponges, sea-fans, &c.

The free access which he had to the museum of the prince of Orange, and other curious collections in Holland, enabled him to enrich his work with the description of a great variety of these productions, brought from both the Indies. He has described each species at large, and given it a new name, characteristic of its real discrepances; and, what especially increases the merit of his work, he has, with wonderful industry, extricated, as far as possible, the synonyms of former authors, both ancient and modern; thus rendering his book highly useful to such as are inquisitive in this branch of natural history.

In a dedication prefixed to his "Miscellanea Zoologica," published in the same year, the author lays before the prince of Orange a plan for a voyage to the Cape of Good Hope, and to the other Dutch settlements in the East Indies, and which, impelled by his wonted ardour for scientific knowledge, he offered to undertake and superintend. This project was strongly recommended by Gaubius, and approved by the prince; but was prevented from being carried into execution by the author's father; who not only refused his consent to his taking such a distant expedition, but even recalled him to Berlin: in obedience to his father's wishes, but with great reluctance, he quitted Holland in November 1766.

On his return to Berlin (continues Mr. Coxe, from whose ingenious travels these particulars are extracted), his only consolation in being separated from his friends in Holland, and in having lost so many opportunities of improving himself in natural history, consisted in putting into order the numerous materials he had collected, and the observations he was incessantly making, and in giving them to the public. He had, however, scarcely begun to publish his "Spicilegia Zoologica," before he was invited by the empress Catharine II. to accept of the professorship of natural history in the Imperial Academy of Sciences at St. Petersburg. Although in this instance his father and relations again refused their assent; yet the author's ardent zeal for his favourite science, joined to an irresistible desire to visit regions so little explored, induced him, without a moment's hesitation, to accede to the invitation, and to hasten his departure for a country, where his curiosity was so likely to be amply gratified. He accordingly quitted Berlin in June 1767, and arrived at Petersburg on the 10th of August.

He made his appearance among the Russians at a critical period. The empress had already ordered the Academy of Sciences to send astronomers into various parts of the Russian empire, to observe the transit of Venus over the sun's disk in 1769. Being just returned from a voyage down the Volga, and from visiting the interior provinces of European Russia, the enlightened sovereign had received the deficiencies of the topographical and geographical accounts, and anticipated the advantage of deputed learned and skilful men to visit the distant provinces of her extensive dominions; with a view to enlarge the bounds of science, and extend the knowledge of useful arts among the natives. For this purpose Catharine had directed the academy to send, in company with the astronomers, the most able naturalists and philosophers. Pallas instantly offered to accompany this expedition; and was as eagerly accepted. He was immediately charged

charged with drawing out general instructions for the naturalists, and was gratified with the choice of his associates. To him was submitted, at his own request, the conduct of the expedition to the east of the Volga, and towards the extreme parts of Siberia; and he was the most calculated for that expedition, as the elder Gmelin, who had been his precursor in those regions, had almost entirely neglected the zoology of those remote districts. Pallas employed the winter previous to his departure in forming a systematic catalogue of the animals in the cabinet of the Academy of Sciences; in putting into order the celebrated collection of professor Bryn of Dantzic, lately purchased by prince Orlof, in preparing for the press six numbers of his "*Spicilegia Zoologica*," which were printed during his absence, under the direction of Dr. Martin; and in forming the necessary arrangements and notices for his intended expedition.

At length, in June 1768, he quitted Petersburg, in company with Messrs. Falk, Lepekin, and Guldenstadt, as his associates; passed through Moscow, Vlodimir, Kafimof, Murom, Arsamias, to Casan; and having examined great part of that province, wintered at Simbirsk. From thence he departed, in March of the following year; and penetrated through Samara and Orenburg, as far as Gurief, a small Russian fortress, situated at the mouth of the river Yaik or Ural. There he examined the confines of Kalmuc Tartary, and the neighbouring shores of the Caspian, and returning through the province of Orenburg, passed the second winter at Ufa. After several expeditions in the adjacent parts of that province, he left Ufa on the 16th of May 1770; prosecuted his route through the Uralian mountains to Catharinenburgh; visited the mines of that district; proceeded to Tcheliabinsk, a small fortress in the government of Orenburg; and in December made an excursion as far as Tobolsk. The next year he was employed in traversing the Altai mountains, and in tracing the course of the Irtish up to Omak and Kolyvan; where, having inspected the celebrated silver mines, he made for Tomsk, and finished that year's expedition at Krasnoyarsk, a town upon the Yenisei. In that place, situated only in 56° north latitude, the cold was so intense, that the learned professor was witness to the natural freezing of quicksilver; which curious phenomenon he has minutely described. From Krasnoyarsk he issued on the 7th of March 1772; and proceeded by Irkutsk, and across the lake Baikal, to Udinsk, Selenginsk, and Kiakta, where the trade between Russia and China is principally carried on. Having penetrated into that part of Dauria which is situated in the south-easternmost part of Siberia, he journeyed between the rivers Ingoda and Argoon, at no great distance from the Amoor; thence tracing the lines which separate the Russian empire from the Mongul hordes dependent upon China, he returned to Selenginsk, and again wintered at Krasnoyarsk. In the summer of 1773 he visited Tara, Yaitk, and Astracan, and concluded his route for that year at Tzaritzin, a town upon the Volga; from whence he continued his journey in the ensuing spring; and arrived at Petersburg on the 30th of July 1774, after an absence of six years.

The account of this extensive and interesting tour was published by Dr. Pallas in five volumes 4to. which greatly extended his fame, and established his character. The author, in this valuable work, has entered into a geographical and topographical description of the provinces, towns, and villages, which he visited in his tour, accompanied with an accurate detail of their antiquities, history, productions and commerce. He has discriminated many of the tribes who wander over the various districts, and near the confines of Siberia; and specified with peculiar precision their customs, manners, and languages; he has also rendered his travels in-

valuable to the naturalist, by the many important discoveries in the animal, vegetable, and mineral kingdoms, with which he has enriched the science of natural history.

Two years afterwards, in 1776, the professor published his collections relative to the political, physical, and civil history of the Mongul tribes; in which he throws new light on the annals of a people, whose ancestors conquered Russia, China, Persia, and Hindoostan; and, at more than one period, established perhaps a larger empire than ever was possessed by any single nation. Mr. Pallas here proves unquestionably that the Mongul tribes are a distinct race from the Tartars; that they differ from them in their features, language, and government; and resemble them in nothing except in a similar propensity to a roving life. He intended a second volume describing their religious establishment, consisting in the worship of the Dalai Lama. It is the religion of Thibet and of the Mandshur sovereigns who now sit upon the throne of China. "A work," as Mr. Tooke, in his *Russia Illustrata*, Introd. p. cxi. justly observes, "that will enrich the stock of human knowledge with discoveries, the greatest part entirely new, and which no person but Mr. Pallas is able to communicate." Whether, however, this second volume ever made its appearance, we have our doubts.

In the same year in which Dr. Pallas printed his "*Elenchus Zoophytorum*," he also published a treatise under the title of "*Miscellanea Zoologica quibus novæ imprimis atque obscuræ animalium species describuntur, et observationibus iconibusque illustrantur*." This work is in a great measure incorporated into a subsequent publication made the next year on his return to Berlin, intitled "*Spicilegia Zoologica*," and was continued in numbers, or *fasciculi*, till 1780. The works of count Buffon, the illustrious French zoologist, amply attest the labours of Pallas, and our countryman Mr. Pennant makes frequent acknowledgments of his obligations to the same source, particularly for his history of quadrupeds and arctic zoology.

In June 1777, the learned professor read before the academy of Petersburg, in a meeting at which the king of Sweden was present, a dissertation on the formation of mountains, and the changes which this globe has undergone, more particularly as it appears in the Russian empire. This treatise appeared so curious to Mr. Tooke, who was also, as a member of the academy, present at that sitting, that he has given a translation of it in his "*Russia Illustrata*." In 1778 the doctor published "*Novæ species quadrupedum e Glirium ordine*," describing numbers of the rat genus and their anatomy. In 1781 he brought out "*Enumeratio plantarum quæ in horto Procopii à Demidof Moscuâ vigent*," or catalogue of the plants in M. Demidof's gardens at Moscow. His new northern collections on various subjects in geography, natural history, and agriculture, came forth the same year, to which were afterwards added two more volumes.

In 1782 he put forth two fasciculi or numbers of "*Icones infectarum præsertim Russiæ Siberiæque peculiarium*." In 1784 he published the first number of his "*Flora Russica*;" a splendid work, executed at the empress Catharine's expense. About this period her majesty conceived the idea of collecting from all quarters of the globe a universal vocabulary, the superintendance whereof she committed to our author, which necessarily for a time retarded his zoological researches. Exclusive of these separate publications, he printed in the acts of the imperial academy of sciences, various zoological and botanical dissertations.

Not long after this he was distinguished by a peculiar mark of imperial favour, in being appointed member of the board of mines, with an additional salary of 200*l. per annum*, and honoured with the order of St. Vlodimir. The empress also purchased

purchased his ample collection of natural history, in a manner highly flattering to the author, and honourable to herself. Being informed that professor Pallas was desirous to dispose of that collection, her majesty sent to let him know that her country should not be deprived of so exquisite a cabinet; that she would be the purchaser, and ordered him to make out the catalogue and fix the price. He accordingly named 15,000 rubles. Having examined the catalogue, she subjoined with her own hand: "Mr. Pallas understands natural history much better than figures: he ought to have charged 20,000 instead of 15,000 rubles for so many valuable articles. The empress, however, takes upon herself to correct the mistake; and hereby orders her treasurer to pay 20,000 rubles. At the same time Mr. Pallas shall not be deprived of his collection, which shall still continue to be in his own possession during his life, as he so well understands how to render it most useful to mankind."

In 1784 the care of putting in order and publishing the papers of Gmelin and professor Guldenstädt was assigned to Dr. Pallas, which he executed with great diligence and accuracy, though from some incidental cause to us unknown, only the first volume of Guldenstädt's remains, containing his journal and the description of the districts of mount Caucasus, ever came to the public eye.

In 1794 Dr. Pallas travelled to the Crimea, and on his return published an account of that delightful peninsula under the title of "Physical and Topographical Picture of Taurida." On his return, finding his health, by long and incessant labours, upon the decline, so as to render it necessary for him to remove to a warm climate, on preferring his request to the empress, he obtained not only immediate permission to chuse for himself a settlement in her dominions, but also on his pitching upon Taurida for that purpose, the grant of an estate in that province, and to the forming of his establishment a present of 10,000 rubles. Here it was that he was visited by Dr. Clarke on his travels in the year 1800; with whose account of his then situation we shall conclude these memoirs. "Akmetchet," says that spirited and ingenious traveller, "will long be celebrated as the residence of professor Pallas, so well known to the literary world. His fame would have been sufficiently established if he had published no other work than that begun by him under such favourable auspices, the "Flora Russica;" yet the barbarity of the people with whom he is compelled to live is such, that they will not allow him to complete the undertaking. The drawings were all finished, and almost all the text. To the hospitable and humane attentions of this excellent man we were indebted for comforts, equal, if not superior, to those of our own country, and for every literary communication it was in his power to supply. When we delivered our letters of recommendation to him, he received us rather as a parent, than a stranger to whose protection we had been assigned. We refused to intrude by occupying apartments in his house; this had more the appearance of a palace, than the residence of a private gentleman; but one day when we were absent upon an excursion, he caused all our things to be moved, and upon our return we found a suite of rooms prepared for our reception, with every convenience for study and repose. I consider myself indebted to him even for my life. The fatigue of travelling, added to the effect of bad air and unwholesome food, rendered a quartan fever so habitual to me, that had it not been for his care and skill, I should not have lived to make this grateful acknowledgment. He prescribed for me; administered every medicine with his own hands; carefully guarded my diet; and, after nursing me as his own son, at last restored me to health. When I recovered, he ransacked his museum for drawings, charts, maps, books, antiquities, minerals, and whatever

else might gratify our curiosity or promote the object of our travels; he accompanied us upon the most wearisome excursions, in search not only of the insects and plants of the country, but also of every document likely to illustrate either its ancient or its modern history. His decline of life has been embittered by a variety of unmerited afflictions; this he has borne even with stoical philosophy. Splendid as his residence appeared, the air of the place was so bad, that the most rigid abstinence from all sorts of animal food was insufficient to preserve his family from fevers. We left him determined to pass the remnant of his days in cultivating vineyards among the rocks upon the south coast of the peninsula. There was reason to hope, that by the death of Paul he would have been called to honours and emoluments; but subsequent travellers in Russia do not furnish intelligence so creditable to the administration of the new sovereign. When the late empress Catharine sent him to reside in the Crimea, with a grant of lands in the peninsula, it was intended for the re-establishment of his health, and as a reward for his long services; neither of these purposes has, however, been accomplished. A magnificent establishment in the midst of unwholesome air, has been all the recompence he has obtained. Thus it is that we find him, in the sixtieth year of a life devoted to science, opening his last publication with an allusion to "the inquietude and hardships which oppress him in his present residence, and embitter his declining days."—"We used," says Dr. Clarke, "every endeavour to prevail upon him to quit the country, and accompany us to England; but the advanced period of his life, added to the certainty of losing all his property in Russia, prevented his acquiescence. Our intreaties were to no effect; and perhaps before this meets the public eye, our friend and benefactor will be no more." Happily, however, Dr. Pallas survived the departure of our traveller upwards of ten years; when determining once more to see his brother and his native city, he took a journey to Berlin, where he died Sept. 8th, 1811, in the 71st year of his age. See Coxe's Travels; Tooke's View of the Russian Empire; and Dr. Clarke's Travels.

PALLASIA, in *Botany*, is destined to commemorate the very eminent scientific merits of the celebrated Peter Simon Pallas, knight of the Russian order of Wladimir, or Vlodimir, the chosen naturalist of the late empress Catharine of Russia. See PALLAS.

His *Flora Rossica*, his splendid monograph on the *Astragali*, as well as his botanical travels, and other writings, richly entitle him to such commemoration. His liberal communication of finely preserved specimens to Linnæus, assisted greatly to enrich the herbarium, as well as the later publications, of that distinguished man and his son; and the whole collection of dried plants, made by Pallas for his own use, having been purchased of him by Mr. Cripps, the companion of Dr. Clarke, now form a part of the valuable museum of A. B. Lambert, esq.

The original *Pallasia*, published by the younger Linnæus, in his *Supplementum*, p. 37, was what Pallas himself, in the 2d vol. of his travels, had named *Pterococcus*. He subsequently referred it to *Calligonum*, to which it unquestionably belongs; and L'Heritier, having adopted the same measure, chose a new *Pallasia*, in the *Encelia* of Adanson. (See *CALLIGONUM* and *ENCELIA*.) Nobody has given any explanation of the name last-mentioned, nor can we trace its meaning. Hence, probably, L'Heritier thought himself justified in superseding it, notwithstanding its claim to sufferance on account of sound, if not of sense. The latter was, upon principle, disregarded by its author in most of the names he preferred. L'Herit. in Ait. Hort. Kew. ed. 1. v. 3. 498. Mart. Mill. Dict. v. 3. Willd. Sp. Pl. v. 3. 2260. (Encelia; Adans. Fam. v. 2. 128. Juss. 186. Lamarek Dict.

Diét. v. 2. 356. Illustr. t. 709. Cavan. Ic. v. 1. 44. Ximenefia; Cavan. Ic. v. 2. 60. Willd. Sp. Pl. v. 3. 2116.) Class and order, *Syngenesia Polygamia-frustranca*. Nat. Ord. *Compositæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* of numerous, oblong, imbricated, nearly equal scales. *Cor.* compound, radiated; florets of the disk numerous, tubular, five-cleft, all perfect; those of the radius ligulate, spreading, oblong, somewhat wedge-shaped, with three or four obtuse terminal teeth. *Stam.* in the florets of the disk only, filaments five, capillary, very short; anthers united into a cylindrical tube with five teeth. *Pistl.* in the florets of the disk, germen obovate, compressed, fringed; style thread-shaped, the length of the stamens; stigmas two, spreading; in those of the radius, germen obsolete or abortive, smooth; style and stigmas imperfect or wanting. *Peric.* none, except the permanent calyx. *Seeds* in the florets of the disk solitary, obovate, compressed, notched at the top, bordered and fringed at the margin; those of the radius obsolete and smooth. Down none. *Recept.* slightly convex, chaffy; its scales lanceolate, keeled, acute, nearly as long as the florets of the disk.

Ess. Ch. Receptacle chaffy. Down none. Seeds compressed, bordered and fringed. Calyx of numerous, imbricated, nearly equal scales.

Obf. We cannot scruple to reduce the *Ximenefia* of Cavanilles to our *Pallasia*, their habits being so similar, and the structure and appearance of the parts of the flower so much the same, as to overbalance the artificial distinction founded on the florets of the radius in *Ximenefia* being rather less imperfect; though by no means so perfect as to justify its being referred to the order *Polygamia-superflua*. This genus is sufficiently different from *Coreopsis*, with which Jacquin confounds it.

1. *P. halimifolia*. Downy Pallasia. L'Herit. Stirp. Nov. v. 2. t. 19, unpublished. Willd. n. 1. (*Encelia canescens*; Cavan. Ic. v. 1. 45. t. 61. *Coreopsis limesis*; Jacq. Ic. Rar. t. 594. Collect. v. 2. 299.)—Leaves blunt, nearly entire, downy on both sides. Radiant florets deeply and unequally four-toothed, scarcely twice as long as those of the disk. Native of Mexico. It is with us in Europe a stove plant, flowering from July to September, but not much cultivated. The stem is shrubby, branched and downy, about two feet high; branches alternate, leafy. Leaves alternate, on downy stalks about an inch long, broadly ovate, obtuse, one and a half or two inches long, entire, occasionally rather wavy or obscurely toothed here and there, three-ribbed, of a pale glaucous green, densely clothed on both sides with dense, soft, fine, short down. *Stipulas* none, but a dense snow-white tuft of accumulated down is more or less remarkable, at the insertion of each footstalk. *Panicles* terminal, corymbose, downy, rather leafy, of about four or five flowers, scarcely so large as a French Marigold (*Tagetes patula*), with a yellow radius whose florets are broad, short, unequally lobed, and a convex greenish disk.

2. *P. grandiflora*. Smooth Pallasia. Willd. n. 2. (*Encelia halimifolia*; Cavan. Ic. v. 3. t. 210.)—Leaves bluish, nearly entire, glaucous, smooth. Radiant florets slightly three-toothed, thrice as long as those of the disk.—Native of New Spain. It flowered at Madrid in September. *Cavanilles*. This has the habit of the foregoing, but the leaves are smooth, and the flowers larger, in consequence of the florets of the radius being much longer. Their colour is pale yellow; their apex obtuse, with only three very shallow teeth, instead of being deeply and irregularly lobed. The florets of the disk are of a reddish-white below, their limb dark brown. Such is the description in Cavanilles. We have seen no specimen, nor even heard of this species in England.

3. *P. ferratifolia*. Scerrated Pallasia. (*Ximenefia encelioides*; Cavan. Ic. v. 2. 60. t. 178. Willd. Sp. Pl. v. 3. 2116.)—Leaves pointed, ferrated, hoary beneath; with winged ferrated footstalks. Radiant florets three-toothed.—Native of Mexico, from whence the seeds were sent to the royal garden at Madrid. The plant flowered there in November. We have not heard of it in England, but are indebted to our late friend Cavanilles for a specimen. *Root* perennial. *Stem* three feet high, branched, leafy, downy, ribbed, pale, apparently somewhat shrubby, corymbose and many-flowered. *Leaves* mostly alternate, not opposite, except perhaps some of the lowermost, ovate, pointed, three-ribbed, with many lateral veins, strongly and sharply ferrated; their upper side bright green, besprinkled with small depressed bristles; under densely downy, pale, or glaucous. *Footstalks* about a quarter the length of the leaves, bordered with a narrow wing, which is greatly dilated and toothed at the base, where it clasps the stem or branch. *Flowers* terminating each branch, solitary, larger than the last, their radiant florets spreading, bright yellow, each near an inch long; disk brownish. Scales of the calyx lanceolate, acute, roughish, in several rows, hardly imbricated. Border of the seeds pale, ribbed, hairy; their disk beset with numerous, minute, sharp tubercles. Scales of the receptacle pale, finely fringed at the edges and keel.

Cavanilles named this supposed genus after Joseph Ximenes, an apothecary, who undertook a *Flora* of Castulo, in four volumes, in which he delineated more than 700 plants, besides native butterflies and birds of the same neighbourhood. Whatever his merits might be, the generic appellation given by Cavanilles could scarcely be retained, as the Linnæan system already contains a *Ximenesia*, long ago consecrated to one of his countrymen of the same name, by Plumier. See XIMENIA.

PALLAVICINO, FERRANTE, in *Biography*, a man of letters, was born at Placentia about the year 1615. He devoted himself to the church, and became a canon-regular of Augustines; but the turn which he had to satire, and which he could not restrain, was at length the cause of his ruin. During the contest between pope Urban VIII. of the Barberini family, and Edward Farnese, duke of Parma and Placentia, he supported the cause of his sovereign with his pen, and wrote some severe and galling satires against the pontiff, and all his house. The papal court set a price upon his head, which obliged him to withdraw to Venice, where he lived in obscurity. A young Frenchman, by affecting to pity his situation, obtained his confidence, and betrayed him to his enemies, who first imprisoned, and then beheaded him. The wretch who betrayed him was stabbed at Paris, some years afterwards, by a friend of Pallavicino. He was author of many works, which are distinguished by their severity and indecency. He also wrote a history of the public events in Italy in 1636. A selection of his works was published in two volumes 12mo. 1644, at Geneva, under the title of "Villa-franca." Moreri.

PALLAVICINO, SFORZA, a cardinal, born at Rome in 1607, was the eldest son of a marquis of that name, in Lombardy. He adopted the ecclesiastical profession in opposition to the inclination of his parents. He attained, at a very early age, to high preferment in the church, and he was admitted to the prelacy in the pontificate of Urban VIII. The prospects that opened before him did not, however, prevent his putting into execution a design of retiring from the world, and in his thirtieth year he commenced a novitiate in the society of Jesuits at Rome. When this was completed, he was employed several years in giving lectures in philosophy and theology, and in presiding over the studies of the Roman college. He composed a history of the council of Trent in
opposition

opposition to that of father Paul Sarpi, which labour was rewarded by pope Alexander VII. with a nomination to the cardinalate in 1657. After this elevation he continued to live in the cloister occupied in his studies, and in the concerns of the church, and affording an example of Christian virtue and piety till his death in 1667.

The cardinal was author of other works besides the "History of the Council of Trent;" these were partly ascetical, partly moral, and partly theological. He also published a tragedy, entitled "Ermenigildo," which he afterwards republished with a preliminary discourse, said to be more valuable than the tragedy itself. To this ecclesiastic also belongs a grammatical work, entitled "Avvertimenti Grammaticale," published under the name of Fr. Raimondo. His "Letters," in Italian, were published two years after his death. The "History of the Council of Trent" was also written in Italian, and was at first printed at Rome in two volumes folio, 1656, 1657. It was, in 1664, republished in three volumes, 4to. with various corrections and additions by the author. A translation of it in the Latin language was published at Antwerp, in 1672, by father Giattini. Moreri.

PALLEIROS, in *Geography*, a mountain of Arabia, in the province of Oman; 80 miles W.S.W. of Mascat.

PALLENE', in *Ancient Geography*, one of the three peninsulas, which formed at its extremity a more considerable peninsula, between the Thermaic gulf and the Strymon. This peninsula lay to the S.W., and according to Steph. Byz. upon it was also a mountain under the same appellation, of a triangular form, and had upon it, says Scylax, five towns; one of which was called by the same name. It belonged to Macedonia.

PALLET, among *Painters*, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil.

The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but, in lieu thereof, a hole at one end, to put the thumb through to hold it.

PALLET, among *Potters*, *Crucible-makers*, &c. is a wooden instrument, almost the only one they use, for forming, beating, and rounding their works.

They have several kinds; the largest are oval, with a handle; others are round or hollowed triangularly; others, in fine, are in manner of large knives, serving to cut off what is superfluous on the moulds of their work.

PALLET, in *Gilding*, is an instrument made of a squirrel's tail; used to take up the gold leaves from the pillow, to apply and extend them on the matter to be gilt. See GILDING.

PALLET, in *Hera'dry*, is the moiety or half of the pale; or a small pale, half the breadth of the usual one.

The pallet must never be charged with any thing either quick or dead; neither can it be divided into two equal parts; but it may be into four; for one-fourth part of the pallet, or two-eighth parts of the pale, is called an endorse.

If the pale be upon any beast, they say, the beast is *debruised* with the pale; but if the beast be upon the pale, they say he is *supported* by it.

PALLETS, in *Clock and Watch-work*, are those pieces or levers, which are connected with the pendulum or balance, and receive the immediate impulse of the swing-wheel, or balance-wheel, so as to maintain the vibrations of the pendulum in clocks, and of the balance in watches. The pallets in all the ordinary constructions of clocks and watches, are formed on the verge or axis of the pendulum or balance, and

are of various lengths and shapes, according to the construction of the piece, or the fancy of the artist. For the modern improvements, comparative advantages, and the manner of constructing pallets, see ESCAPEMENT.

PALLET, in *Ship Building*, is a room within the hold, closely parted from it, in which, by laying some pigs of lead, &c. a ship may be sufficiently ballasted, without losing room in the hold; which, therefore, will serve for stowing more goods.

PALLETING, a slight platform made over the bottom of the magazine, to preserve the powder from damp.

PALLI, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 85 miles N.E. of Diarbekir.

PALLIANO, or PALLIANO, a town of Campagna di Roma; 28 miles E. of Rome.

PALLIATION, in *Medicine*, signifies the act of alleviating the more violent symptoms of a disease, by those means which have no power of removing the disease radically. Whence also the terms

PALLIATIVE MEDICINES, palliative indications, palliative treatment, &c. are applied to those remedies which the physician adopts, and to the rules of practice to which he is directed by the symptoms, under such circumstances.

The palliative treatment is never resorted to by a skilful practitioner, except under one of two conditions of his patient; namely, when the disease, under which he labours, is clearly of an incurable nature, or advanced to an incurable stage; or, on the other hand, when some of the symptoms of a disease, which is in itself curable, are so violent as to become themselves the source of extreme distress, or even of danger, to the patient. Both these conditions are of frequent occurrence. Every organic disease, in its advanced stage, affords an example of the first, especially when it is accompanied by severe pain: for in that case, it becomes necessary to diminish the sufferings of the patient, by a constant use of narcotic medicines, although these will not contribute, in the smallest degree, to arrest the progress of the disease. Of the second condition just mentioned, many examples might be adduced: but it may be sufficient to observe, that, in *fevers*, many symptoms occasionally occur, which materially aggravate the original disease, if not palliated; and the palliation, therefore, becomes an object of the first importance, although the means to be adopted for that purpose do not strike at the root of the fever. Thus an intense heat of the surface will, by the painful irritation which it produces, occasion extreme restlessness, thirst, loss of sleep, and increased quickness of pulse; whereas if the heat be palliated by external coolness, and by cold drinks, all these secondary circumstances will be removed, and the ultimate chance of recovery greatly increased. In like manner, a severe diarrhoea, great constipation, or a violent local pain, often require palliation, by means which have no direct influence upon the primary fever. There are but too many practitioners, however, who from an imperfect knowledge of the principles of physiology and pathology, cannot see beyond the most prominent symptoms of a disease, and whose whole practice is comprised in a succession of palliative measures: such men are often called *experienced*, because they have seen much disease, but being destitute of first principles, they never acquire a true experience.

PALLICODE, in *Geography*, a town of Hindoostan, in Mytore, at the extremity of a pass leading to the Barmaul country, called either the "Pass of Pallicode," or the "Pass of Oodeadurgum." Through this pass the Mytore armies were generally sent to invade the Carnatic; 11 miles N.W. of Dorempoury.

PALLIER, or PALLIER, in *Building*, a landing-place

in a staircase : or a step, which, being broader than the rest, serves to rest upon. See STAIRCASE.

The term is pure French, and is not much used in English. In perrons, on large staircases, where there are sometimes several palliers in the same range, or line, they ought to have each at least the width of two steps. Those in the turns of staircases ought to be as broad as long. Vitruvius calls the palliers on landing-places of the theatres, *diazomata*.

PALLIFICATION, or **PILING**, in *Architecture*, denotes the piling of the ground-work, or strengthening it with piles, or timber driven into the ground; which is practised when people build upon a moist or marshy soil.

PALLIGORAM, in *Geography*, a town of Hindoostan, in Golconda; 25 miles S.E. of Hydrabad.

PALLIJOW, a town of Hindoostan, in Bahar; 45 miles S.W. of Patna.

PALLIO COOPERIRE. It was an ancient custom, where children were born out of lawful wedlock, and their parents afterwards intermarried, that those children, together with the father and mother, should stand *pallio cooperti*, under a cloth spread over them, while the marriage was solemnizing; which was a kind of adoption, and had the effect of a legitimation.

Thus Robert Grosthead, the famous bishop of Lincoln, in one of his letters, says; "In signum legitimationis, nati ante matrimonium consueverunt poni sub pallio super parentes eorum extento, in matrimonii solemnizatione."

Selden, in his notes on Fleta, adds, that the children of John of Gaunt, duke of Lancaster, by Catharine Swinford, though legitimated by act of parliament, yet were covered with the pall at the time of the marriage of their parents.

PALLIOT, PETER, in *Biography*, was born at Paris in 1608. He settled at Dijon, where he married the daughter of a painter, and followed the same profession. From an early age he had attached himself to the studies of genealogy and heraldry, which he contrived to pursue with great assiduity, publishing several works upon those subjects. He died at a very advanced age in the year 1698. His principal works are, "Le Parlement de Bourgogne," 1649: to which another volume was added by Fr. Petitot in 1733. "Science des Armoiries de Gelliot, augmentée de plus de 6000 Ecuiffons." Besides these he published genealogical histories of particular families, and he left in MS. thirteen volumes folio, of memoirs concerning the families of Burgundy. He not only printed his own works, but engraved with his own hand all the very numerous heraldic plates by which they were illustrated. Moreri.

PALLISADES. See PALISADE.

PALLISADOED CROWN. See CROWN.

PALLISER, CAPE, in *Geography*, a cape on the E. coast of New Britain. S. lat. $4^{\circ} 22'$. E. long. $191^{\circ} 25'$.

PALLISER, CAPE, a cape on the S. coast of Eabeinomaue, the northern island of New Zealand, and N.E. point of Cook's Strait. S. lat. $41^{\circ} 38'$. E. long. $175^{\circ} 23' 12''$.

PALLISER'S ISLANDS, a cluster of islands in the South Pacific ocean; the largest being about fifteen miles long and nine broad, connected together by a reef of coral rocks, and difficult of access. S. lat. 15° to 16° . W. long. 146° to 147° .

PALLIUM, or **PALL**, a pontifical ornament worn by popes, patriarchs, primates, and metropolitans of the Romish church, over their other garments, as a sign of their jurisdiction.

It is in form of a band, or fillet, three fingers broad, and encompasses the shoulder; whence, by some authors, it is called *superhumeralis*. It has pendants, or strings, about a palm long, both before and behind; with little laminæ of

lead rounded at the extremes, and covered with black silk, with four red crosses.

Some, with Eusebius, will have the pallium to have been introduced by pope Linus; adding that as the ephod was the mark of the pontifical authority in the Jewish Synagogue, so is the pallium in the Romish church.

Others have observed, that there is no mention made of it before the year 336.

Lastly, others will have it to have been first granted by Constantine the Great, to pope Sylvester; from whence it passed to the other patriarchs and archbishops.

The pall, it is certain, was originally part of the imperial habit, being a rich robe of state, very magnificent, and reaching quite to the ground; and it has been said, that the bishops of Rome were allowed to wear it by Constantine the Great, and that in process of time the same honour was granted by the emperors to the other patriarchs. Hence, when they were either driven from their sees, or voluntarily quitted them, they returned their palls to the emperors. When the popes first took upon them to grant that honorary badge, which they did before the pontificate of Gregory the Great, chosen in 590, they did not presume to do it till they had obtained leave of the emperor. But the successors of Gregory, upon the decline of the empire, took upon them to bestow that mark of distinction independently of them, and as a gift of their own. However, that it might no longer be deemed part of the imperial habit, which it was treasonable to wear without leave from the emperors, they changed its ancient form to the present. At what time the popes assumed the disposing of the pall, independently of the emperors, is not well known; but it is certain, that no bishop was obliged to apply to Rome for it till the year 742, when Boniface, bishop of Mentz, persuaded the bishops of France and Germany to pass a decree, obliging their metropolitans to apply to the pope for that ornament, and to promise, upon their receiving it, a canonical obedience to the commands of St. Peter. This practice proving very favourable to the ambitious designs of the bishops of Rome, they spared no pains to impose it upon all metropolitans; issuing, with this view, various decrees concerning the nature, virtue, and necessity of the pall; till, at length, they proceeded to declare it unlawful for a metropolitan, archbishop, or primate, to exercise any branch of his power, till he had received his pall from Rome; nay, in several decrees, the metropolitanical jurisdiction and power were said to be conferred by the pall; and thus they made the pope the fountain of all ecclesiastical power and authority. This doctrine seems to have been first broached in the ninth century, though vigorously opposed by Hincmar, archbishop of Rheims, and several others. However, the doctrine prevailed; and the pall was declared by Innocent III. in the thirteenth century, to be an ensign or token of the plenitude of the apostolic power, and said to communicate a competent share of that power to those who received it from the hands of the popes. Till the time of Gregory VII. the new metropolitans were only required to send for their palls within the space of three months after their ordination; but this pope obliged all, unless prevented by some lawful impediment, to come for them in person to Rome; and the promise of canonical obedience, upon receiving their palls, was changed into an oath of allegiance, such as vassals by the feudal laws were obliged to take to their princes. Gregory the Great conferred the pall without fee or reward; and in a council held at Rome in 595, decreed, that it should be given gratis; but it is well known, that in succeeding times the grant of the pall became one of the chief funds of the popish see. Exorbitant sums were exacted not only for the palls that were sent to presbyters, or private bishops, when raised to the archiepiscopal dignity, but likewise for those that were sent

to archbishops on their translation from one see to another. For by the canons, an archbishop is not to carry away his pall with him, but to demand a new one; and his successor is not to make use of the pall, which his predecessor had left, but to apply to Rome for another. Bower's Hist. of the Popes, vol. iii. p. 6. note (c).

The pope pretends to the sole right of conferring the pallium; though some patriarchs have granted it to their suffragans, having first received it themselves from the Roman see.

Anciently, the pope used to send the pallium to certain of his diocesan bishops, on whom he laid a good part of his authority, and who were a kind of collaterals to him, as the patricii were to the emperors.

The first who received it in France was Vigilius, archbishop of Arles: this was done, in order, as Pasquier observes, to give him the precedence over the other bishops.

Anciently they went to Rome to seek the pallium in person; afterwards it was sent by the pope's legates. At last the custom was introduced of sending persons express to demand it, with this form, *Instante, Instantius, Instantissime*.

By the popish canon laws, a metropolitan, till he have received the pallium, cannot consecrate bishops, or churches, and he may not be called archbishop, &c. Upon a translation, he must have the pallium afresh; and till then he cannot hold a synod, nor perform any of his archiepiscopal functions.

The pallium was anciently interred with the person.

The use of the pallium is restrained to certain seasons and occasions; none but the pope having a right of wearing it always, and in all places.

The pope sometimes sends it to bishops of his own accord; and has sometimes given the right hereof to particular churches.

Among the Greeks all the bishops wear the pallium.

In ancient records, we find mention made of another pallium, which was a long garment spread over with crosses, Tertullian says it was a distinguishing garment of the Christians; that of the heathens being called *toga*.

PALLIUM *Episcopale*. See PALL.

PALLIUM *Ducale*, in *Natural History*, a name given by writers on shells to a kind of pecten, or scallop, of a large size and beautiful appearance, though simple colour. There are two species of this, a red and a yellow one.

PALLIUM-*purpureum*, a name given by Basil Valentine, and other of the affected writers in chemistry, to a powder of a purple colour, prepared from gold. It is made by preparing an amalgam of gold and mercury; and after the mercury is driven off by the retort, the remaining matter is mixed with sulphur, and calcined by a well regulated fire till reduced to a purple powder. This is called also the *solar powder*, and has, like the other preparations of this metal, many imaginary virtues ascribed to it.

PALLS, in *Ship Building*, strong short pieces of iron or wood, so placed near the capstan or windlafs as to prevent its recoil or giving way, which may very much endanger the men at the bars, in the act of heaving up the anchor, or otherwise, when charged with any great effort.

PALLUAU, in *Geography*, a town of France, in the department of the Vendée, and chief place of a canton, in the district of Les Sables-d'Olonne; 16 miles E.S.E. of Challans. The place contains 328, and the canton 8794 inhabitants, on a territory of 230 kilometres, in 10 communes.

PALM, PALMUS, an ancient long measure, taken from the extent of the hand.

The Roman palmus was of two kinds: the *great palm*, taken from the length of the hand, answered to our span, and contained 12 fingers, digits, or fingers' breadths, or 9 Roman inches, equal to about 8½ English inches. See DIGIT, and SPAN.

The *small palm*, taken from the breadth of the hand, contained 4 digits or fingers, equal to about 2 English inches, 9 tenths.

The Greek palm or *doron* was of two kinds. The small contained 4 fingers, equal to little more than 3 inches. The great contained 5 fingers. The double Greek palm, called *dichas*, contained also in proportion. See MEASURE.

The modern palm is different in different places where it obtains. At Rome, the canna for woollens and silken stuffs = 78½ English inches = 8 palms; but the builders' canna = 87½ English inches = 10 palms; at Naples, the palm, is the 8th part of the canna = 10½ English inches; at Genoa, the palm is 9½ inches; at Oporto, it is 8 inches: the English palm is 3 inches.

At Leghorn there are two kinds of palms, the one for woollens, the other for silks; the first one-third shorter than the latter. See the Tables under MEASURE.

PALM, *Palma*, in *Anatomy*, denotes the inside of the hand; called also *vola* and *metacarpion*.

PALM, in *Naval Language*, is an implement used instead of a thimble, in making and mending sails. It is formed of a piece of leather, seal's skin, or canvas, on the middle of which is fixed a round plate of iron, of an inch in diameter, whose surface is pierced with a number of small holes, to catch the head of the sail-needle. The leather is formed so as to encircle the hand, and button on the back of it, while the iron remains in the palm; so that the whole strength of the hand may be exerted to thrust the needle through the canvas, when it is stiff, and difficult to be penetrated. Falconer.

PALM, *Dwarf*, or PALMETTO, in *Botany*. See CHAMÆROPS.

PALM-Oil. See OIL.

PALM-Tree. See PALMÆ.

PALM-Wine, called in the East *toddi*, is obtained by incision of the trunk of a species of palm-tree, whence issues a liquor very grateful to the palate, but liable, especially on account of the heat of the climate, soon to turn sour.

PALM Islands, in *Geography*, a chain of islands near the N.E. coast of New Holland; extending about 30 miles in length, at the entrance of Halifax bay. S. lat. 18° 53'. W. long 213° 25'.

PALMA, FILIPPO, in *Biography*, a Neapolitan finging-master, totally without voice that could be called tuneful, yet he sung, or seemed to sing, with such exquisite taste, as to revive the miraculous powers of music equal to those ascribed to Orpheus, Amphion, and Linus. Besides his want of voice, he was so ignorant of counterpoint, that he could not make a base to the most simple melody. And though the airs which he composed for his own singing were universally applauded, he was so humble as to condescend to ask a young apprentice to Dr. Arne to furnish a base; and yet he touched the harpsichord in so original and seemingly masterly a manner, that this apprentice would have given the world to exchange all his knowledge in counterpoint for signior Palma's "Toccatini." Gluck's celebrated air in Artamene, "Rasserena il mesto ciglio," admirably sung by Monticelli at the opera, and encored every night, when sung by Palma without voice in private, the fine voice, figure, action, and knowledge of Monticelli were annihilated and forgotten. A singer in a room may hazard embellishments, which, on a stage, accompanied by a powerful orchestra, would have no effect. Palma's manner of singing and vary-

ing "The Lads of Paties Mill," had more effect, even upon the most enthusiastic admirers of grand airs, than the performance of the greatest singers.

The author of "Traité sur la Melodrame," (le chevalier de Chastellux) relates an anecdote of Palma, which is perhaps as strong an instance of the power of song in a modern, as can be found in the legends of ancient music. Palma was always in "love and in debt, though (being an Italian) seldom in drink." Having been caught at home by surprise by one of his deepest and most enraged creditors, from whom he had been long skulking, in order to escape his gripe; and on the inexorable creditor informing him of his business, and of the care that would be taken of his person by the gentleman whom he had brought with him; Palma made no other reply to his abuse and his threats, than by sitting down to the harpsichord and singing two or three of his most pleasing and touching airs to his own accompaniment: when the fury of the creditor was so softened by degrees, that at length he was entirely appeased, and not only forgave him his debt, but lent him ten guineas to stop the mouth of other creditors, who threatened him with a gaol.

But this security was of short duration, for he was soon after thrown into the king's bench, where we visited him, and found him writing to his brother, then a prisoner likewise in York gaol; when finding that the male Siren was putting his letter into a cover, we informed him of the expence in which it would involve his brother, by a double letter, when he said—"Che fare? é capo di casa, ci vaol rispetto. What can I do? He is my elder brother, and head of our house, we must shew him respect."

PALMA, GIACÓPO, was born at Serinalto, in the territory of Bergamo, and was a disciple of Titian. He had genius and judgment, and his manner much resembled that of his master. His colouring had extraordinary strength and brightness, and his pictures are wrought to great perfection, though the execution of them is free and not over laboured.

Vafari describes, with great fervour, a composition of the elder Palma, at Venice; representing the ship in which the body of St. Mark was brought from Alexandria to Venice. "In that grand design," he says, "the vessel was struggling against the fury of an impetuous tempest, and is expressed with the utmost judgment: the distress of the mariners, the violent curling of the waves against the sides of the ship, the horrid gloom only enlivened with flashes of lightning, and every part of the scene filled with images of terror, are so strong, so lively, and naturally represented, that it seems impossible for the power of colour or pencil to rise to a higher pitch of truth and perfection; and that performance very deservedly gained him the highest applause."

Notwithstanding this deserved praise, his pictures in general are not correct in design, and his latter works did not maintain his early reputation. He died, according to Vafari, at the age of 48; but in what year is not absolutely known.

PALMA, in *Geography*, one of the Canary islands, about 60 miles in circumference, anciently called "Capraria," said by some to have derived this name from a volcano so called; though others ascribe it to the great number of goats that are fed here. The soil is fertile in corn, wine, and sugarcanes, as well as in fruits, quadrupeds, and birds of all kinds. This island has a handsome town and a safe harbour, much frequented for its wines, which are reckoned equal to Malmsey, and thought by some to be the best of any produced in the Canaries. (See CANARY *Islands*.) N. lat. 28° 36'. W. long. 18°.

PALMA, the capital of Grand Canary. (See CANARY.)—
VOL. XXVI.

Alfo, a town of South America, in the province of New Granada; 36 miles N.W. of Santa Fé de Bogota.—Alfo, a town of Naples, in the province of Lavora; 14 miles E. of Capua.—Alfo, a town of Naples, in the province of Calabria Ultra, near the sea, which was a great mart for oil; destroyed by an earthquake; 11 miles W.N.W. of Oppido.—Alfo, a town of Sicily, in the valley of Mazara, in the vicinity of which is a rich sulphur mine; and on a lake near the sea, not far from it, are white partridges; 6 miles S. of Naro.—Alfo, a town of Spain, in the province of Cordova, on the Guadalquivir; 27 miles S.W. of Cordova.—Alfo, a town of Portugal, in Estramadura, on the right side of the river Cadaon; 18 miles E. of Setuval.—Alfo, a river of Brasil, which runs into the Tocantin, S. lat. 14° 16'.—Alfo, the capital of the isle of Majorca, the see of a bishop, and the residence of the captain-general of the Balearic and Pityuse isles. The city is situated on the banks of a large bay formed by the sea, between the capes Blanco and Cala Figuera, which is said to be 3½ leagues wide; the port, though small, is good and safe. The city is built on a declivity on the sea-shore, in the part where the port makes a bend. It is surrounded with walls, flanked by twelve bastions; here are a half-moon, horn-work, and several redoubts; on the land side there is a dry ditch; but all these fortifications could not sustain a well-conducted siege. It has eight gates, three of which are on the side of the sea. The streets in some parts of the city are narrow, and badly paved; those in the lower parts, as well as of the squares, are large and regular. The population of the city is reckoned at 33,000 inhabitants. The bishopric is a suffragan of Valencia; the diocese comprehends 40 parishes, and the revenue amounts to 45,000 piastras a-year. The chapter consists of six dignitaries, whose stipend amounts to 10,000 piastras among them, and the prebends are estimated all together at 42,500 piastras. Here are five rich parish churches, twelve monasteries, eleven convents, besides one in the suburbs, a number of chapels or oratories, four hospitals, two religious houses, nine penitentiaries, two colleges, and several remarkable public edifices. The administration is composed of a captain-general and royal audience, who have the entire government of the kingdom, and decide as a supreme court on civil, criminal, and military affairs. The cathedral church, which stands in the highest part of Palma, is handsome and large, of Gothic architecture, with three aisles and lofty vaulted roofs. The parish of St. Michael is one of the most ancient; it was a mosque in the time of the Moors. The other churches have been built since, and are all large, and ornamented with turrets or spires of different forms. The episcopal palace is large, adjoins the cathedral, and is built of beautiful stone. The palace royal of government, where the captain-general and intendant-general reside, is the most considerable, and commands the sea-shore. The house of Contractation, built in the 14th century, is of Gothic architecture, and is the place where the merchants assemble, and where the public fetes and masked balls are held; near it is the consulate, where the board of commerce holds its sittings, and which gives its audience gratuitously. The mansion-house has a quantity of sculpture on its entablature, and a number of Gothic ornaments. The clock of this building marks and strikes the different hours of the day and night, according to the progress of the sun, and the different solstices, and is generally allowed to be the only one of the kind in the world. The houses in the town of Palma are pleasant; some are even built of marble.

PALMA *la Nuova*, a town of Italy, in the country of Friuli, on the borders of Goritz, situated on a canal, which
O commu-

communicates with the Lizonzo. It is fortified and surrounded with nine bastions, which bear the names of nine Venetian noblemen; 55 miles N.E. of Venice. N. lat. 46° 2'. E. long. 13° 16'.

PALMA *di Solo*, a sea-port town of the island of Sardinia, on the S. coast. N. lat. 30° 20'. E. long. 6° 24'.

PALMA, *Cape*, a cape on the coast of Ancona. N. lat. 43° 3'. E. long. 13° 50'. — Also, a cape on the W. coast of Africa, in the country of Angoy. S. lat. 5° 50'.

PALMA *Christi*, in *Botany*, &c. See RICINUS and CASTOR *Oil*.

PALMÆ, the Palm tribe, a most distinct and important, as well as lately and beautiful, natural order of plants, so named from *Palma*, the ancient appellation of the most valuable among them, the Date tree; whose foliage was consecrated, first by the Greeks and then by the Romans, as an emblem of victory, and whose fruit has been a principal article of food in the East, from the remotest antiquity to the present day. The word *Palma* is supposed to have been applied to this tree, from the divisions of its leaves having some resemblance to the fingers and palm of the hand, whence perhaps, by an association of ideas, the fruit came to be called *dactyli*, from *δακτυλος*, a finger, to which its likeness is, at first, not apparent. The Greeks named this kind of Palm *φαινίξ*; which Linnæus has retained. (See PHOENIX.) That great botanist terms the natural order in question "Princes of the Vegetable kingdom, of Indian origin, distinguished by their sheathed and many-spiked flowers, their flowing habit, their lofty stature, the simple elegance of their unbranched long-enduring stem, the leafy evergreen garlands with which they are crowned, and their princely treasures of rich fruit. They are tributary to the first order, or *Primates*, amongst animals; more especially to the lord of the animal creation, who is destined, in a state of nature, to dwell among them."

Palmæ constitute the eleventh order in the system of Jussieu, the first of his third class. The character of that class is a simple *cotyledon*, with *stamens* inserted into the *calyx* or *corolla*. The class is thus defined at length by Jussieu.

Calyx of one leaf, tubular or deeply divided, superior or inferior, sometimes naked, but mostly accompanied by a sheath, containing one or many flowers, rarely by an involucre, resembling an outward calyx. *Corolla* none, for what is so termed by Tournefort, Linnæus and others, Jussieu reckons a true calyx, as above. *Stamens* definite in number, rarely indefinite, inserted into the lower or the upper part of the calyx, opposite to its segments; their filaments usually distinct, rarely combined, with distinct two-celled anthers. In a few cases the *germens* are more than one, superior, with the same number of *styles* and of *stigmas*, each *germen* becoming a *capsule* of one cell, either with a single *seed* or with several, in which latter case the capsule consists internally of two valves, to whose margins the *seeds* are annexed. More frequently, however, the *germen* is solitary, either superior or inferior; the *style* solitary, rarely three, or wanting; *stigma* simple, or divided; *fruit* pulpy, or capsular, of three cells, containing three or many *seeds*; sometimes two of the cells prove abortive, and one *seed* only of the whole is perfected. The *seeds* of the pulpy kinds are attached to the internal angle of their cells; in those furnished with *capsules*, usually of three valves, they are inserted here and there, upon the margin of an elevated receptacle, constituting the partition, in the middle of each valve, and separating along with it. The *corculum* is small, in a large horny *albumen*.

The orders of this class are eight, *Palmæ*, *Asparagi*, *Junci*, *Lilia*, *Bromelia*, *Asphodeli*, *Narcissi* and *Irides*.

The same author thus characterizes the *Palma*. *Calyx* in six deep segments, often permanent, the three outer segments often smallest. *Stamens* six, rarely more or fewer, inserted into the base of the segments of the calyx, or rather perhaps into a glandular body situated beneath the germen, their filaments often combined at the bottom. *Germen* superior, simple, rarely three-fold (in *Chamerops*); *style* one or three; *stigma* simple or three-cleft. *Fruit* a berry, or a drupa, in the latter case internally reticulated, each of one or three cells, and with one or three bony *seeds*. *Corculum* very small, in a cavity at the base or side, rarely at the base, of a large *albumen*, which is at first soft and eatable, but subsequently hardened and horny.

The *stem* is simple, cylindrical, like the trunk of a tree, shrubby or arborescent, either scaly with the permanent bases of the leaves, or rough with the circular scars where the bases of old leaves have been. *Leaves* terminal, crowded, alternate, sheathing at their base; the young ones folded, and either covered or surrounded with the reticulated sheaths of last year's leaves, remaining between their bases. *Spadix* central among the leaves, terminal, many-flowered, either simple, or more frequently branched, each branch accompanied by a pair of *sheaths*, and the whole enclosed in one very large common *sheath*, mostly simple, rarely of several leaves. *Flowers* either diœcious or monœcious, but perhaps from the abortion of one or other of the organs of impregnation in each; the sexes situated on the same spadix or on a separate one; rarely hermaphrodite, each flower accompanied by two short sheaths.

Mr. Brown, *Prodr. Nov. Holl.* v. 1. 266, remarks that the *flowers* are hermaphrodite (or united), though often polygamous, and that the *stamens* in some of the polygamous palms are indefinite in number. The *stem*, when shrubby, is sometimes branched. The same author adds that *Palmæ* are certainly widely removed from *Gramina*, having apparently more affinity to the *Junci*, through the medium of *Xerotes* and *Flagellaria*.

This order is divided into two sections, according to the structure of the foliage.

1. Leaves pinnate, contains *Calamus*, *Phœnix*, *Arcaea*, *Flatz*, *Cocos*, *Elais*, *Caryota*, *Nipa*; to which Willdenow has added *GEONOMA*, and Brown *SEAFORTHIA*; see those articles.

2. Leaves palmate, or fan-shaped, comprehends *Corypha*, *Licuala*, *Latania* of Commerçon, *Borassus*, which Jussieu is pleased to call *Lontarus* after the example of Rumphius, and *Chamerops*; to which are to be added *Thrinax* of Swartz, and *Rhapis* of the younger Linnæus, see Ait. Hort. Kew. ed. 1. v. 3. 473; as well as *LIVISTONA*, Brown Prodr. 267; see that article.

Of the internal structure of the *Palmæ* we have already given some idea, in speaking of the great natural class to which they belong. (See *MONOCOTYLEDONES*.) The following account of their vegetation, extracted from Desfontaines, is published in Lamarck's Dict. v. 4. 701.

"When the seed of a Palm-tree is committed to the earth, the leaves unfold in succession, and increase in number, during four or five years. The crown of the root dilates in the same proportion. The bulb, formed by the re-union of the footstalks of the leaves, swells insensibly, its solidity gradually augments, and at length the stem rises above the surface of the ground, of the full diameter that it ever will acquire. The leaves, produced every spring, originate always from the summit. The older ones, standing below the others, gradually dry up, and, on separating from the stem, leave behind them circular impressions, which furrow its surface, and mark the years of its age, as long as it continues

tinues to grow. The stem is exactly cylindrical from top to bottom, and if its measure be taken at different periods, no increase of diameter will ever be discovered. This fact did not escape Kæmpfer." The same able writer remarks nevertheless, that Palm-trees are liable to accidental irregularities in their growth, either from a deficiency of nourishment, whence they become slender in that portion of their stems elongated under such circumstances; or from a superabundance of food, whence the new part proves of a greater diameter than the old; for the latter retains, in both cases, its original dimensions. Such being the mode of increase in the plants of this natural order, and their duration very long, amounting sometimes to 800 years or more, no wonder that they attain an extraordinary degree of elevation, much exceeding the generality of trees, though scarcely equal to the Norfolk Island Pine. (See DOMBEYA.) Yet, notwithstanding this great loftiness of growth, botanists have doubted whether they strictly ought to be denominated trees or herbs. They certainly have not the proper trunk, gradually augmented by successive annual concentric layers, which is characteristic of a tree or shrub. Their annual circles of leaves all spring in reality from the root, or at least from its singularly protruded crown; but so little of any such protrusion is discernible in herbaceous plants, which die down to the surface of the earth every winter, that the difference between them and the Palm tribe is abundantly marked. Linnæus, not knowing whether to call their foliage leaves, adopted the term *frons*, a frond or bough; but, as it seems to us, without any necessity. That they were, by the ancients, very improperly termed branches, we readily allow, but the objections that "they have no bud for the following year, neither have they the substance of leaves, nor do they, like leaves, all wither and fall off together," see *Linn. Præleç. in Ord. Nat.* 23, appear to us very unsatisfactory. They have, in fact, a central bud, like trees of tropical countries, though not the scaly *hybernacula* appropriated to those of cold climates; their substance is much like that of a variety of other leaves; and they fall off in succession, like the foliage of other evergreen plants. When their whole summit is cut off, the plant perishes, they having no power of producing lateral buds.

The botanical arrangement of *Palme* was, in the early days of Linnæus, a work of considerable difficulty. Tournefort had distinguished no proper genera in this order, nor Plumier more than one. So imperfect were the accounts of their flowers in early botanical works, and so impossible was it for the author of the sexual system to procure access, in most instances, to the reality, that he could not ascertain enough of their structure to refer more than a very few to his classes and orders; hence he assembled as many as he knew of the family, in an appendix to his system, except *Calamus*, of whose relationship to the rest he was not aware. Linnæus, on the other hand, confounded with the *Palme Cycas* and *Zamia*, which are more nearly allied to the *Filices*, though properly distinct from both. These genera are now referred by Pearson and Brown to a separate order, under the name of *Cycadæ*. See *Br. Prodr. Nov. Holl.* v. 1. 346.

Mutis paid great attention to the *Palme* of South America, but his remarks and descriptions have only in part reached us. Dr. Roxburgh's work, on the plants of Coromandel, has thrown much light on the East Indian Palms. Thunberg has, long ago, ascertained so much of their fructification, as to refer most of the established genera to their places in the Linnæan artificial system, where they chiefly belong to the class *Hexandria*, like their near relations the *Liliaceæ*. The native country of the greater part of the

Palme is within the tropics. The requisite degree of heat, and the space, which they occupy in a hot-house, as well as their tardy growth, and backwardness in flowering, render them difficult of cultivation, and prevent their being general in collections. The stoves of the late marchioness of Rockingham at Hillingdon were splendidly furnished with some of these Princes of the vegetable kingdom, as are those at Kew, and the long established ones of J. Blackburn, esq. at Orford, Lancashire.

PALMAJOLA, in *Geography*, a small island in the Mediterranean, near the coast of Italy. N. lat. $42^{\circ} 53'$. E. long. $9^{\circ} 35'$.

PALMAR, a river of Africa, in Benin, which runs into the Atlantic, N. lat. $6^{\circ} 25'$. E. long. 3° .

PALMAR Point, a cape on the west coast of Africa. S. lat. $5^{\circ} 30'$.

PALMAR, a town of South America, in the audience of Quito; 40 miles S.W. of Riabamba.

PALMARIA, a small island in the Mediterranean, about 45 miles from the coast of Naples; 3 miles W. from the island of Ponza. N. lat. $40^{\circ} 58'$. E. long. $12^{\circ} 53'$.—

Also, a small island in the Mediterranean, near the coast of Genoa, at the entrance of the gulf of Spezza; 8 miles S. of Spezza. N. lat. $44^{\circ} 4'$. E. long. $9^{\circ} 40'$.

PALMARIGI, a town of Naples, in the province of Otranto; 3 miles W.S.W. of Otranto.

PALMARIS *Longus et Brevis*, in *Anatomy*, two muscles of the fore-arm. See FASCIA.

PALMARIS *Fascia*. See FASCIA.

PALMAROLA, in *Geography*, a small island in the Mediterranean, near the coast of Naples, about three miles long from north to south, and very narrow; 4 miles W. of Ponza. N. lat. $41^{\circ} 3'$. E. long. $12^{\circ} 55'$.

PALMAS, a small island in the Pacific ocean, near the coast of Peru. N. lat. $4^{\circ} 35'$.—Also, a town of South America, in the province of Tucuman; 30 miles S. of St. Miguel de Tucuman.—Also, one of the Philippine islands, near the south-east coast of Mindanao.—Also, a river of Mexico, which runs into the bay of Campechy, N. lat. $18^{\circ} 20'$. W. long. $94^{\circ} 20'$.—Also, a town of North America, formed by the union of the rivers Nicas and Saucedo, in New Biscay, and which, thus united, traverses the province of New Leon, and then falls into the gulf of Mexico, N. lat. 25° . W. long. $98^{\circ} 56'$.

PALMAS, or *Palmez*, the chief town of Gomera, one of the Canary islands.

PALMAS, *Cape*, a cape of Africa, on the Grain coast. N. lat. $4^{\circ} 30'$. W. long. $7^{\circ} 41'$.

PALMATED-ROOTS, in *Botany*, are tuberose roots of a flattish shape, and divided into several oblong and slender branches, resembling so many fingers. Of this sort are the roots of some of the orchid kind, called hence palmated.

PALMATED-Stones, *Pa'mati Lapidés*, in *Natural History*, a name given by the ancients to a sort of stones, which were always found of the shape of a hand with its fingers. They were frequent in Spain; and some, which were found of a fine black, were reputed to be a kind of marble. The greater number were white, and were composed of the matter of one of the softer and less beautiful quarry-stones.

PALMATIAN HORSES, in the *Manege*, Cappadocian horses, which, together with the *Hermagenian*, were reckoned the noblest and first in merit. They were so prized, that they were devoted to the sole use and pleasure of the emperors, and they were not allowed to be sold without express licence or permission. With the Palmatian and Her-

magenian horses it was usual to couple Phrygian mares; and the produce of this mixture, especially if derived from the horses of Argæus, a mountain in Cappadocia, were thought the finest and best for the labours of the circus, to which they were always pre-eminently devoted, both at Constantinople and at Rome. The Palmatian horses owe their name to a person called Palmatus or Palmatus, who was rich in a most valuable breed of horses, whose possessions being seized and confiscated, his horses were appropriated to the emperor, and formed the most valuable part of the *græd dominicus*, or imperial stables. Palmatus is said to have resided at Andibilis, a town of Cappadocia, not far from mount Taurus; and living in a country productive of fine horses, by his knowledge and care he raised so generous a breed, that they have at the same time perpetuated his fame and their own. The Hermagenian horses were reckoned next, if not equal in repute, to the Palmatian race. These were so denominated from Hermagenes Ponticus, who was a general of horse under the emperor Constantius, and is supposed to have been the founder of this distinguished kind of horses, whose praises have descended to these times. *Beutinger's History, &c. of Horsemanship, vol. i.*

PALMATUM FOLIUM, in *Botany*, a Palmate Leaf, is, like those of the Common Fig, and the *Alcea ficifolia*, with several of the Mallow tribe, deeply divided into oblong finger-like segments; but still so as to leave an entire portion, like the palm of the hand, of greater or less extent, at the base. See **LEAF**.

PALMAW, in *Geography*, a town of Bengal; 24 miles S.S.W. of Rogonapour. N. lat. 23° 13'. E. long. 86° 54'.

PALMEIRA, a small island in the Persian gulf, near cape Bardistan.

PALMELA, a town of Portugal, in Estramadura, with a castle on a rock; 6 miles N. of Setuval.

PALMER, in our *Ancient Writers*, is used for a pilgrim, and sometimes for a croise, on account of a staff made of the palm-tree, which they ever afterwards bore as a badge of their devotion. See **PILGRIM** and **CROISES**.

PALMER, in *Geography*, a township of America, in Hampshire county, Massachusetts, on the south side of Chickapee river, and bounded eastward by Western or Worcester county; incorporated in 1752, and containing 1039 inhabitants.

PALMERA, CAPE, a cape on the east coast of the island of Formentera. N. lat. 38° 42'. E. long. 1° 30'.

PALMERIN, a town of Africa, in Beol, where is a mart for hides and teeth. N. lat. 13° 50'. W. long. 16° 21'.

PALMERO, CAPE, a cape on the east coast of the island of Sardinia. N. lat. 39° 40'. E. long. 9° 56'.

PALMERSTON, CAPE, a cape on the north-east coast of New Holland. S. lat. 21° 30'. W. long. 210° 54'.

PALMERSTON'S Island, an island in the South Pacific ocean, discovered by captain Cook in June 1774. In the "Missionary Voyage," it is described as a group of small islets, eight or nine in number, connected together by a reef of coral rocks, and lying in a direction nearly circular. Captain Wilson and some of his companions landed upon one of these isles, which is not a mile in circuit, and which, at high water, is not more than four or five feet above the level of the sea. The soil is coral sand, with an upper stratum of blackish mould, produced from rotten vegetables. The inner area of the islet is covered with cocoa-nut trees, which, decaying and falling, form a thick underwood. They saw a number of men of war birds, tropic birds, and boobies. Among the trees there was plenty of red crabs,

dragging after them a shell in form of a periwinkle, but larger, being in diameter about two or three inches. When they ran along the ground, they only put their claws out; but being touched, they withdrew themselves wholly into their shell. Here they saw the submarine grotto, described in Cook's Third Voyage. At one part of the reef which bounds the lakes within, almost even with the surface, there is a large bed of coral, which affords a most enchanting prospect. Its base, which is fixed to the shore, extends so far that it cannot be seen, so that it appears to be suspended in the water. The resplendence of the sun, when the sea is unruffled, exposed to view the various sorts of coral in the most beautiful order; some parts luxuriantly branching into the water, others appearing in a vast variety of figures, and the whole heightened by spangles of the richest colours, glowing from a number of large clams interspersed in every part. This scene was much improved by the multitude of fishes that gently glided along, seemingly with the most perfect security: their colours were the most beautiful that can be imagined, blue, yellow, black, red, &c. far excelling any thing that can be produced by art. Our navigators observe, that no traces appear of this island's ever having been inhabited. S. lat. 18° 4'. W. long. 163° 10'.

PALMETTO, in *Botany*. See **CHAMÆROPS**.

PALMETTO-Royal, a name given by Ligon to a tree of the palm kind. Its trunk is very tall and straight, and hollowed regularly in the centre; yet so tough, that it is never blown down, nor destroyed by storms. It is recommended for making long telescopes for celestial observations.

PALMETTO, in *Geography*, a town of the island of St. Christopher, situated on a bay to which it gives name; 3 miles W. of Basse-Terre.

PALMETTO Point, a cape on the north coast of Jamaica. N. lat. 18° 18'. W. long. 76° 20'.—Also, a cape on the south coast of Jamaica. N. lat. 18° 7'. W. long. 77° 57'.

PALMIERI, MATTEO, in *Biography*, an Italian man of letters, born at Florence about 1405, was descended from an ancient and illustrious family, and educated in the sciences and learned languages under the ablest masters. In 1437 he was present, in some public capacity, at the general council of Florence. He was several times entrusted by his fellow-citizens with offices of magistracy, and rose to the supreme dignity of gonfalonier of justice. He was likewise appointed several times to important embassies to the popes, the emperor Frederic III., Alphonso king of Naples, the republic of Sienna, and other states. He died in 1475, at the age of 70. As a literary man, his most considerable work was a Chronicle from the creation down to his own times. He also wrote "The Life of Niccolò Acciajuoli," which has been published by Muratori; as likewise has his book, "De Captivitate Pisorum;" and a work in form of a dialogue, "Della Vita Civile," several times printed and translated into French. The Chronicle, already mentioned, was continued to the year 1482, by a native of Pisa, very nearly his namesake, *viz.* Mattea Palmieri, who was apostolic secretary, and died in 1483.

PALMINOPOS, in *Geography*, a town of Spain, in New Castile; 25 miles N.N.W. of Cuenca.

PALMIPÉDES, WEB-FOOTED, in *Ornithology*, the name of an order of birds living about waters, and furnished by nature with feet for swimming.

This order corresponds to the Anseres of Linnæus, and comprehends two divisions, *viz.* those with long legs, and those with short legs. The characters of the former are, that the body is conical and somewhat flattened; the thighs are naked on their lower halves; the legs are very long; the feet

feet are fitted for wading; and the toes are only connected together at their posterior parts by a membrane, so that they are "semipalmati." These birds mostly pair in breeding time, and build their nests on the ground. They feed in the water, on small fishes and various insects; and, especially when young, are good food. The second division comprehends those called "palmati," the characters of which are, that the bill is smooth, covered with a membranous skin, and increasing in size towards the point. The feet are fitted for swimming, having short legs, which are thin, or compressed laterally; and the toes are all connected, to their ends, by an interposed membrane. These birds are mostly polygamous, one male associating with many females. They build their nests chiefly on the ground, and the mother seldom takes any trouble in feeding the young, which are very soon able to provide for themselves. They live very much in the water, feeding on aquatic plants, fishes, and other substances; and their flesh has generally a rancid fishy flavour. To the former division belong the avocet, courier, and flamingo; and to the latter, the duck, merganser duck, penguin, petrel, albatross, pelican, darter, tropicker, guillemot, diver, gull, tern, and skimmer.

PALMIPES, among the Romans, a long measure, containing a foot and a palm, or five palms; and was less than the cubit by one palm.

PALMIRAS, POINT, in *Geography*, a cape of Hindoostan, on the coast of Cattaek, in the bay of Bengal, anciently called "Promontorium Calington." N. lat. $20^{\circ} 44'$. E. long. $87^{\circ} 5'$.

PALMISTRY, a kind of divination, performed by inspecting the lines and marks of the hands and fingers; called also *chiromancy*; which see.

PALMO, in *Commerce*, a long measure in Italy, Spain, and Portugal. At Genoa, the palmo corresponds to $109\frac{1}{2}$ French lines, or $9\frac{3}{8}$ English inches. The canna is of three sorts; the canna piccola, used by tradesmen and manufacturers, = 9 palmi, or $87\frac{1}{2}$ English inches; the canna grossa, used by merchants, = 12 palmi, or $116\frac{1}{8}$ English inches; and the canna, used at the custom-house, = 10 palmi, or $97\frac{1}{2}$ English inches.

In Portugal, the palmo is equal 8 pollegadas = 8.64 English inches; each pollegada or inch is divided into 12 linhas or lines, and each linha into 10 pontos or points. This is called the "palmo de cravada," or standard span, being the legal measure of the kingdom; and all other measures, derived from it, are likewise distinguished by the same term. See VARA and PORTUGAL. For the palmo of Spain, see SPAIN. See also *Tables of WEIGHTS and MEASURES*.

PALMS, among *Botanists*, white buds shooting out of willows, or fallows, before the leaf; of the expansions of which the flowers of that tree are formed.

PALMS, *Isle of*, in *Geography*, a narrow island on the coast of Africa, at the entrance of the river Senegal, about six miles in length.

PALM-SUNDAY, DOMINICA PALMARUM, the Sunday next before East Sunday; or the last Sunday in Lent.

It has been thus called from the primitive days, on account of a pious ceremony then in use, of bearing palms, in memory of the triumphant entry of Jesus Christ into Jerusalem, eight days before the feast of the passover, described by St. Matthew, chap. xxi. St. Mark, chap. xi. and St. Luke, chap. xix.

The ancients had other names for this day. For, 1. They called it *Dominica Competentium*, i. e. *Sunday of the Competentes*; because, on that day, the catechumens came to ask

the bishop leave to be admitted to baptism, which was conferred the Sunday following.

They had also then given them the symbol, or credo, to get off by heart, to be repeated to the bishop in the ceremony of baptism.

2. They called it *Capitulivium*, the Sunday of washing the head; because those who were to be baptized the following Sunday, were prepared by washing their heads on this day.

Some time afterwards they called it *Indulgence Sunday*, because the emperors and patriarchs used to distribute gifts on that day.

PALMULARII, more properly called PARMULARII, in *Antiquity*, a sort of gladiators, who fought armed with a sort of little buckler, called *parma*; which see.

PALMYRA, RUINS OF, or *Palmyrene Ruins*, in *Ancient and Modern Geography*, are the ruins of a famous city of this name, situate in a desert of Syria, in the pachalic of Damascus, about 48 leagues from Alepp, and as far from Damascus, 85 miles west from the Euphrates, and about 117 miles from the Mediterranean, and in N. lat. $34^{\circ} 20'$. E. long. $38^{\circ} 48'$. This city appears to have been originally built by Solomon, and called Tadmor. (1 Kings, ix. 18. 2 Chron. viii. 4.) Josephus assures us, that this was the same city which the Greeks and Romans afterwards called Palmyra; and it is still called Tadmor by the Arabs of the country. But many circumstances, besides the style of the buildings, render it probable that the present ruins are not those of the city built by Solomon, though neither history nor tradition mention the building of any other.

The site of Palmyra is one of those few cultivated spots, which rise in the deserts of Arabia and of Egypt, like islands out of the sandy ocean. (See OASIS.) The name of Tadmor, or Palmyra, by its signification in the Syrian, as well as in the Latin language, denoted the multitude of palm-trees which afforded shade and verdure to that temperate region. It is needless, therefore, to recur to the etymologies, suggested by Hesychius and Dr. Halley (*ubi infra*). The air on this spot was pure, and the soil, watered by some invaluable springs, was capable of producing fruits, as well as corn. A place possessed of such singular advantages, and situated at a convenient distance between the gulf of Persia and the Mediterranean, was soon frequented by the caravans, which conveyed to the nations of Europe a considerable part of the rich commodities of India. Palmyra insensibly increased into an opulent and independent city, and, connecting the Roman and the Parthian monarchies by the mutual benefits of commerce, was suffered to observe an humble neutrality, till at length, after the victories of Trajan, the little republic sunk into the bosom of Rome, and flourished more than 150 years in the subordinate though honourable rank of a colony. It was during that peaceful period, if we may judge from a few remaining inscriptions, that the wealthy Palmyrenians constructed those temples, palaces, and porticoes of Grecian architecture, whose ruins, scattered over an extent of several miles, have attracted the curiosity of our travellers.

History is silent as to the fate and circumstances of this city during the great revolutions in the several empires of the East; but it may well be supposed, that so advanced a garrison as this was, being above 300 miles from Jerusalem, continued not long in the possession of the Jews, who immediately after Solomon fell into civil dissention, and divided their force; so that, without doubt, it submitted to the Babylonian and Persian monarchies, and afterwards to the Macedonians, under Alexander and the Seleucidæ. But when the Romans advanced to these parts, and the Parthians

seemed

PALMYRA.

seemed to put a stop to their farther conquests in the East, then was this city of Palmyra, by reason of its situation, being a frontier, and in the midst of a vast sandy desert, where armies could not well subsist to reduce it by force, courted and caressed by the contending princes, and permitted to continue a free state, a mart or staple for trade, for the convenience of both empires, as we learn from the information both of Appian and Pliny. Palmyra is first mentioned by the Roman historians as a place which Mark Antony, after his victory at Philippi, about 40 years B. C. attempted to plunder, pretending that it had not observed a just neutrality between the Romans and Parthians. When the Romans, under Trajan, had made it appear by his victories, as we have already said, that there was no comparison between their power and that of the Parthians (Trajan having taken Babylon and Ctesiphon, the seat, at that time, of the Parthian empire), the Palmyrenes were induced to declare for the Romans; which they did, by submitting themselves to the emperor Adrian, about the year of Christ 130, when Adrian made his progress through Syria into Egypt. This magnificent emperor, being highly delighted with the situation and native strength of the place, situated on an extensive plain, and surrounded on three sides by a long chain of mountains, determined to furnish it with various splendid edifices and ornaments; and at this time he probably conferred upon it the privileges of a "Colony Juris Italici," which, as we learn from Ulpian, it actually enjoyed, and the inhabitants of the city were induced by gratitude to call themselves "Hadrianopolitæ." Many of its marble pillars, particularly those of the long porticos, were probably the gift of this emperor. In the time of Caracalla it was a Roman colony; and from Adrian to Aurelian, for about 140 years, it continued to flourish and increase in wealth and power to a very considerable degree; and the Palmyrenes, who assisted Alexander Severus against the Parthians, were again conspicuous in the reign of Gallienus, under Odenathus, who, when the emperor Valerian was taken prisoner by Sapor, king of Persia, brought a powerful army into the field, recovered Mesopotamia from the Persians, and penetrated as far as their capital city Ctesiphon, and who, for this service to the Roman state, was made the associate of Gallienus in the empire. He was succeeded by Zenobia his queen, who broke the alliance with Gallienus, and made herself sole mistress of Syria and Mesopotamia. (See the biographical article ZENOBIÆ.) At length Aurelian, having taken Palmyra, A. D. 273, after a long siege, by means of his light horse pursued Zenobia, who had mounted the fleetest of her dromedaries, and had reached the banks of the Euphrates, about sixty miles from Palmyra, and having seized the princess, carried her to Rome, to grace his triumphs, and with her, her secretary Longinus, known for his admirable work on the Sublime, who was put to death. Her capital was treated with unexpected lenity. The arms, herds, and camels, with an immense treasure of gold, silver, silk, and precious stones, were all delivered to the conqueror. The city revolting in her absence, Aurelian returned and destroyed it, putting to death most of the inhabitants, without regard either to age or sex. Little is known concerning the state of Palmyra since the time of Mahomet, except that it was considered as a place of strength, and that in the 12th century there were two thousand Jews in it. Aurelian himself had lamented the destruction to which he had devoted it: and he not only manifested a concern for the re-establishment of the temple of the Sun, but he granted to the few Palmyrenians, who had survived the slaughter which he had ordered, the permission of rebuilding and in-

habiting their city. But it is easier to destroy than to restore. The seat of commerce, of arts, and of Zenobia, gradually sunk into an obscure town, a trifling fortress, and at length a miserable village. The present citizens of Palmyra, consisting of thirty or forty families, have erected their mud-cottages within the spacious court of a magnificent temple.

With respect to the ruins, they appear to be of two different and distinct periods; the oldest are so far decayed as not to admit of mensuration, and seem to have been reduced to that state by the hand of time; the other appear to have been broken into fragments by violence. Of the inscriptions, none are earlier than the birth of Christ, and none are later than the destruction of the city by Aurelian, except one, which mentions Dioclesian. It is scarcely less difficult to account for the situation of this city than for its magnificence; the most probable conjecture is, that as soon as the springs of Palmyra were discovered by those who first traversed the desert in which it is situated, a settlement was made there for the purpose of carrying on the trade of India, and preserving an intercourse between the Mediterranean and Red sea. This trade, which flourished long before the Christian era, accounts not only for its situation, but also for its wealth. As it lay between Egypt, Persia, and Greece, it was natural to expect, that traces of the manners and sciences of those nations should be discovered among the Palmyrenes; who accordingly appear to have imitated the Egyptians in their funeral rites, the Persians in their luxury, and the Greeks in their buildings; and therefore the buildings, which now lie in ruins, were probably neither the works of Solomon, nor of the Seleucids, nor, few excepted, of the Roman emperors, but of the Palmyrenes themselves.

Palmyra was formerly encompassed by palms and fig-trees, and covered an extent of ground, according to the Arabs, near ten miles in circumference; and might probably have been reduced to its present confined and ruined state by quantities of sand, driven over it by whirlwinds. The walls of the city are flanked square towers; and it is probably by their general direction, that they included the great temple, and are three miles in circumference. But of all the monuments of art and magnificence in this city, the most considerable is the temple of the Sun. The whole space containing its ruins, is a square of two hundred and twenty yards, encompassed with a stately wall, and adorned with pilasters within and without, to the number of sixty-two on a side. Within the court are the remains of two rows of very noble marble pillars, thirty-seven feet high; the temple was encompassed with another row of pillars fifty feet high; but the temple itself was only thirty-three yards in length, and thirteen or fourteen in breadth. This is now converted into a mosque, and ornamented after the Turkish manner. North of this place is an obelisk, consisting of seven large stones, besides its capital, and the wreathed work about it, about fifty feet high, and just above the pedestal, twelve in circumference. Upon this there was probably a statue which the Turks have destroyed. At a small distance there are two others, and a fragment of a third, which gives reason for concluding that they were once a continued row. There is also a piazza forty feet broad, and more than half a mile in length, inclosed with two rows of marble pillars, twenty-six feet high, and eight or nine feet in compass; and the number of these, it is computed, could not have been less than five hundred and sixty. Near this piazza appear the ruins of a stately building, supposed to have been a banqueting house, elegantly finished with the best sort of marble. In the west side of the piazza there are several apertures for gates into the court of the palace, each adorned with four porphyry

porphyry pillars, thirty feet long, and nine in circumference. There are several other marble pillars differently arranged, on the pedestals of which there appear to have been inscriptions, both in the Greek and Palmyrene languages, which are now altogether illegible. Among these ruins there are also many sepulchres, which are square towers, four or five stories high, and varying in size and splendour. We are indebted for an account of these very magnificent remains of antiquity, partly to some English merchants who visited them in 1678 and 1691, (Phil. Transf. N^o 217, 218, or Lowthorp's Abr. vol. iii.), but chiefly to M. Bouverie and Mr. Dawkins, accompanied by Mr. R. Wood, who travelled thither in 1751. The result of their observations was published in 1753, in the form of an Atlas, containing fifty-seven copper plates, admirably executed. Since this publication, it is universally acknowledged that antiquity has left nothing, either in Greece or Italy, to be compared with the magnificence of the ruins of Palmyra.

PALMYRA, in *Geography*, a post-town of America, and the only port of entry and delivery in the state of Tennessee; so constituted by a law of the United States in 1797; situated on the south bank of Cumberland river.

PALNAUD, a country of Hindoostan, which is a district belonging to the Carnatic, but situated towards the Kistnah river, on the W. of Guntoor. The principal place in it is Timerycotta.

PALO, a town on the E. coast of the island of Leyta. N. lat. 11° 15'. E. long. 124° 55'.—Also, a cape on the coast of Albania; 6 miles N.W. of Durazzo.—Also, a town of Naples, in the province of Bari; 3 miles W. of Bittetto.—Also, a town in Patrimonio, on the sea-coast, defended by a strong castle; 13 miles W.N.W. of Rome.

PALO, Cape, a cape on the coast of Albania, in the Adriatic. N. lat. 41° 44'. E. long. 19° 10'.

PALOCZA, a town of Hungary; 11 miles E. of Szeben.

PALOMAR, a town of Spain, in Aragon; 22 miles N. of Teruel.

PALOMBARA, a town of Naples, in Lavora; 5 miles N.E. of Capua.

PALOMERA, or **PALUMARIA**, a sea-port town on the N.E. coast of the island of Majorca. The port is covered by a rocky island, called by the ancients "Columbria." Some coral has been found on this coast, and in the rocks.

PALOMINOS, small islands on the coast of Peru, three miles W. of St. Lawrence island.

PALONGOLA, a town of Congo, on the Lelanda; 2 miles S. of St. Salvador.

PALONGONG, a town of Matamba; 70 miles S.E. of St. Maria de Matamba.

PALOS, a gulf in the straits of Macassar, near the W. coast of Celebes. S. lat. 0° 24'. E. long. 119° 15'.—Also, a town on the W. coast of Celebes, in a bay to which it gives name. S. lat. 0° 56'. E. long. 119° 39'.—Also, a sea-port town of Spain, in the province of Seville, at the mouth of the Tinto, in which is a tolerable harbour formed by the tide. In the year 1492 Columbus failed from this port, on his first voyage for the discovery of the new world; 2 miles S. of Moguer. N. lat. 37° 10'. W. long. 6° 58'.

PALOS, Cape, a cape of Spain, on the coast of Murcia. N. lat. 37° 37'. W. long. 0° 48'.

PALOTTA, a town of Hungary, with a castle, and fortified with a high wall and a moat; 8 miles W.S.W. of Stuhl-Weisenburg.

PALOTZA, a town of Hungary, on the river Poprat; 54 miles N. of Caschau.

PALOU, a town of Asiatic Turkey, in the government

of Diarbekir; 60 miles N. of Diarbekir. N. lat. 38° 52'. E. long. 39° 40'.

PALOUÉ, and **PALOVEA**, in *Botany*. See **GINANNIA**.

PALPABLE, something that may be perceived by the senses, especially by the sense of feeling. Hence impalpable powder.

PALPEBRÆ, in *Anatomy*, the eyelids. See **EYE**.

PALPEBRÆ Superioris Levator, a muscle belonging to the upper eyelid. See **EYE**.

PALPEBRALIS CONJUNCTIVA, that portion of the membrane which lines the eyelids. See **EYE**.

PALPEBRARUM ORBICULARIS, a circular muscle, surrounding the opening of the eyelids. See **EYE**.

PALPETER, in *Geography*, a town of Candahar, in the Cabulistan; 50 miles E. of Ghizni.

PALPITATION, in *Medicine*, a vehement and inordinate action of the heart. This affection is very various in respect to the degree of its violence, and of the distress which accompanies it, as well as in regard to the actual morbid changes of which it is symptomatic, and therefore to the degree of impunity or danger with which it may occur. For it appears under all the gradations of severity, from the slight beating occasioned by active exercise, or a sudden emotion of the mind, to the most tremendous convulsions of the heart and arteries, which are not only perceptible to the touch of others, but are obvious to the sight, and even sometimes to the hearing of by-standers. It is, indeed, only to the more severe instances of the disease to which the term is applied in a medical view, and such only which it is the object of this article to describe.

This morbid pulsation of the heart is seldom constant in its vehement degree, for that would be inconsistent with the continuance of the functions of life; it sometimes continues in a minor degree, *i. e.* the ordinary action of the heart is carried on with more force than is natural, and with a constant sense of oppression about the region of the præcordia. But, in general, the palpitation occurs in paroxysms, at uncertain intervals, and, after continuing with extreme violence for a short space of time, then ceases, the heart resuming its ordinary moderate and measured action.

The *fit of palpitation* is extremely distressing. It is usually sudden in its attack, beginning instantaneously in all its violence, from the operation of very slight causes, or frequently without any obvious excitement. The slightest jar of the body occasioned by a false step, or slip of the foot, in walking,—any emotion of the mind,—certain impressions upon the stomach, arising from flatulence, acidity, or particular food or drink,—or even the mere distention of the stomach by a meal, will give rise to the paroxysm in those who are subject to the disease. Sometimes it comes on in the night; and certain positions of the body, such as lying on the left side, and compressing the heart, will occasionally produce it; and, in other cases, it recurs at regular periods, like the paroxysm of an intermittent.

The distress which accompanies the paroxysm, is not occasioned by the mere violence of the contractions of the heart, and by its blows against the ribs; but arises also from the complicated sensations of oppression and disturbance, which are produced in the different organs of the body, especially in the brain and lungs, by the torrents of blood, rapidly and vehemently injected into them from the labouring heart. The spasmodic motions of this viscus are commonly visible at a considerable distance from the sufferer, by the motion of his garments, by which his pulse may be counted; and if he is stripped, the successive projection and collapse, not only of the ribs, but even of the pit of the stomach and abdomen, are very visible. At the same time, the violent palpitations

PALPITATION.

pulsations of the carotid arteries, and even of the jugular veins in the neck, which successively elevate the coverings of that part, evince the impetus with which the blood is projected through them. The extreme sufferings of the patient under these circumstances are depicted in his countenance, which is at once expressive of anguish, oppression, helpless imbecility, and terror. In the chest, the sense of suffocation, of load, and anxiety, often with acute pain in the præcordia, increases the oppression which the vehement pulsation occasions: while in the head, the pain is commonly most severe, and every stroke of the arteries is felt, and even heard, like the blows of a hammer; and in a short time, confusion of the senses, ringing of the ears, and giddiness, ensue; while the whole frame suffers with this disturbance of the sensorium, and tinglings, tremors, and spasmodic twitches of the limbs, alarm the patient with the expectation of immediate paralysis. At length, sometimes gradually, but sometimes instantaneously, and not unfrequently with one most violent stroke, the heart resumes its calm and ordinary pulsations, and all these distressing sensations are immediately relieved. As in all cases of violent excitement, however, the patient is left in a state of considerable languor and lassitude, which sometimes goes to the extent of syncope, and the respiration is for a little while laborious, and accompanied with sighing. If, indeed, there is considerable organic derangement, this oppressed state of respiration continues more or less, together with anxiety in the præcordia.

During the continuance of the paroxysm, the vehemence of the palpitation often varies, being at times diminished, and again increasing; the pulse is very various in different instances, sometimes being extremely full and strong, according with the action of the heart, and sometimes remarkably small and feeble; sometimes intermitting and unequal, sometimes perfectly regular, and sometimes not corresponding in its beats with the pulsation in the chest. Before the termination of the paroxysm, the extremities often become cold, and the surface of the body, especially of the face and extremities, becomes livid, from the imperfect transmission of blood through the extreme vessels; sometimes there are alternate chills and heats.

The duration of the paroxysm, as well as of the interval of remission, is various and uncertain, even in the same individual. We have seen the paroxysm continue, in different instances, from a few seconds to a quarter of an hour; and, as to the interval, which depends much upon the accidental absence or occurrence of exciting causes, it may vary from a few minutes to many weeks or even months.

The occurrence of palpitation, whether it be constant or in paroxysms, as above described, is always the consequence of some morbid condition of the heart itself or its great vessels, or of the neighbouring organs, or of the general habit; and as the degree of danger, as well as the proper methods of treatment, can only be determined from a clear view of the actual state of disease, in each particular case, it is necessary to inquire into the nature of these morbid conditions, and into the symptoms by which they may be distinguished from each other.

1. The most alarming and dangerous cases of palpitation, are those which are connected with organic derangement of the heart, or of the great vessels arising from it. These derangements occasion palpitation in three ways; *viz.* by increasing the irritability of the heart, by exciting irritation in that organ, or by obstructing the exit of the blood from its ventricles.

The irritability of the heart is increased by *inflammation*, occurring in its substance, or in its investing membrane; the

symptoms, indeed, which belong to inflammation of the heart or of the pericardium, are not easily distinguished; but as we have already described them at length, we need not repeat them here. (See *CARDITIS*.) It will be sufficient to observe, that the degree of fever which accompanies the palpitation, together with a fixed pain in the region of the heart, will afford the principal means of diagnosis of this variety of the disease.

Supposing the irritability of the heart to remain unaltered, an inordinate irritation may be excited by whatever impels the blood into it with unusual force; hence in some individuals palpitation has been produced by violent muscular exertion. It seems to be merely by the irritation, which is excited during the alternate contraction and dilatation of the heart; that partial ossifications in the membranes, or in the substance of the organ, sometimes give rise to palpitations; for such ossifications have been, in other cases, found upon dissection after death, when palpitation had not occurred.

But the most frequent instances of palpitation, arising from disease of the heart, are those which originate from obstruction to the free exit of the blood from the ventricles. The older writers have described the presence of *polypi* in the heart, as a common obstruction of this sort; but the moderns at present are inclined to reject such a notion altogether. It appears to be ascertained, indeed, that these polypi (which are large masses of coagulable lymph, nearly filling up the cavities of the heart, and extending into the neighbouring large vessels) have been invariably formed *after death*, by the slow coagulation of the blood. (See Baillie's *Morbid Anat.* chap. ii.) The valves of the heart are sometimes thickened and opaque, or nearly cartilaginous in their texture, and sometimes partially or entirely converted into bone; so that they are no longer adequate to act as valves, *i. e.* to close the passages. The impediment to the circulation becomes, in such a case, extremely great; for, after the ventricle of the heart has propelled the blood into the artery by its contraction, and again relaxes itself to receive the returning blood from the auricle, it is again partially filled by the reflux of the former, on the contraction of the great artery, through the aperture left by the unclosing valves. Whence a great struggle is occasioned in the heart, to rid itself of the load of accumulating blood. The absence of acute pain, and of fever, a sense of oppression about the heart, and a difficulty of breathing, from the accumulation of blood in the chest, will distinguish the palpitations, arising from diseases of the valves, from those which accompany carditis. The symptoms, however, are not always sufficiently clear to be accurately distinguished in practice.

Every cause of impediment to the complete contraction and evacuation of the heart, is liable to produce palpitation. Hence tumours, pressing upon, and diminishing the calibre of the great arteries, disease in the coats of the arteries themselves, adhesion of the pericardium round the heart, dropsy of the pericardium, aneurism of the heart itself (though this is a very rare disease), or a general enlargement of one or both ventricles. This enlargement of the substance of the heart, indeed, is one of the most common organic causes of palpitation. (See the disease discussed at length, under the article *CARDIOMEGUS*.) The principal means of diagnosis in regard to this variety of palpitation, are to be found in the broad and extended beat under the hand applied to the side of the chest, in the pulsation being felt lower, as between the ninth and tenth ribs, and in a sort of jarring sensation given to the hand by each systole. See Ferriar's *Med. Hist. and Reflect.* vol. i. p. 148.

2. Palpitations of a severe nature are sometimes occasioned by the condition of organs in the vicinity of the heart, in
some

PALPITATION.

some cases irritating it, in others obstructing its action. When the circulation of the blood in the lungs is impeded, it necessarily follows, that the right ventricle of the heart will be oppressed and overcharged; whence palpitations sometimes occur in asthma, in peripneumony, in hydrothorax, and other obstructions in the chest. Disorder, or even mere distention of the stomach, will occasionally give rise to palpitations, especially where there is much irritability of the heart, or any actual disease of that organ or its valves. Thus after a full meal, or from the distention of the stomach by flatulence, this viscus presses the diaphragm upwards, diminishing the cavity of the chest, and therefore obstructing the circulation, as well as compressing the heart; it likewise somewhat compresses the descending aorta in the abdomen, and thus also tends to impede the emptying of the left ventricle of the heart. Such an obstruction, though unperceived in health, is sufficient to produce palpitation, in those in whom the heart is predisposed to it, as above stated. Senac, who has collected several cases illustrative of this fact, remarks also, that distention of the intestines by flatulence, or the accumulation of feces, enlargement of the liver, the presence of worms, and some other abdominal irritations, occasionally give rise to palpitation in a similar manner.

3. The most frequent source of palpitations, next to the actual organic diseases of the heart, is that general condition of the constitution, which gives rise to the various affections, that are called *nervous*. Whence women, who are subject to hysteria, and men labouring under hypochondriasis, are often distressed by most severe paroxysms of palpitation of the heart, inasmuch that the utmost alarm is excited, lest there should be organic disease of that important organ. Indeed, under almost all circumstances of general debility, palpitation is liable to occur, as well as other spasmodic affections; as in the state of chlorosis in young women, during the convalescence from acute diseases, after great hemorrhages, or after long watching, severe study, long continued fatigue, and other causes of exhaustion to the animal frame. It is one of the common torments of extremely sedentary and studious men, and especially of students of medicine, who reduce themselves to a hypochondriacal state, and are then ready to find a whole system of nosology in their own persons.

It is often extremely difficult to pronounce with decision, that palpitations arise from organic diseases of the heart and great vessels, or that they are merely sympathetic of some local irritation, or dependent on a general debilitated nervous condition. In order to form a satisfactory *diagnosis*, it is necessary to examine carefully, not only the seat, nature, and violence of the palpitation, but also the various concomitant symptoms, and to inquire into the previous state of health and diseases of the patient, and to attend to the influence of medicine on the complaint.

In the instances of palpitation, originating from organic derangement, the paroxysms are commonly more violent, and of longer duration,—they occur more frequently, and often without any obvious or adequate cause,—and they are often accompanied with acute pain across the chest, from the sternum to the spine. In the intervals, too, between the paroxysms, the patient is not so entirely free from all beating in the breast, or from some other distressful sensations, such as pain, a sense of stuffing, weight, and oppression; difficulty of breathing, &c. as in the mere sympathetic cases of palpitation. The labouring action of the heart, even in the intervals, is often perceptible to the hand applied over the ribs; and the apex of the organ, instead of being felt between the fifth and sixth ribs, just under the mamma of the left side, is perceived considerably lower, as between the

ninth and tenth ribs. The pertinacity and long duration of this state of disease, with repeated paroxysms, will often afford a strong argument, in conjunction with the other circumstances, for deeming the cause organic. And the previous occurrence of some severe acute disease, especially the rheumatic fever, or acute rheumatism, which is known to leave a frequent disposition to disease of the heart, particularly to enlargement of it, will also tend to modify the judgment in these cases.

It is still more difficult, of course, to distinguish by any symptoms the particular kinds of organic lesion of the heart, than to discriminate these from the other forms of palpitation; and, with a view to practical purposes, it is obviously of little importance; for one organic change is equally inaccessible to the influence of medicine as another. Nevertheless this has been attempted; and an attention to the minute differences of the symptoms, will doubtless, in many cases, enable the experienced practitioner to form shrewd approximations to the truth. For instance, the palpitation will probably be more palpable and obvious to the bystander, when the ventricles, and especially the left ventricle, are enlarged, than when the auricles are dilated or aneurysmatic, in which case, the beating is more obscure and distant under the hand pressing the ribs; and the motions of the pulse and of the heart will be more distinctly synchronous. When the valves are ossified, a hissing or chirruping sound is in some cases distinctly heard, during the violent spasmodic pulsations of the heart. When the heart is much enlarged, the pulsation is less circumscribed and pointed under the hand, applied to the breast, than is natural: in fact, it is broad and diffused; and Dr. Ferriar has remarked, that a certain jarring sensation, which he conceives to be peculiar to this disease of the heart, is felt by the hand under these circumstances. (See *CARDIOG MUS*.) If there is a considerable adhesion of the heart and pericardium with the contiguous parts, Senac is of opinion, that there is rather a tremor than an actual palpitation of the organ. It is not to be overlooked, however, that none of these symptoms are sufficient to establish a certain diagnosis; for it is admitted by the ablest practitioners, that palpitations of the most severe degree, and of different modifications, which had been pronounced the symptoms of organic disease, have, nevertheless, yielded to remedies. See Senac, *Traité de la Structure du Cœur*, liv. iv. chap. xi. § 11; and Ferriar, *loc. cit.* vol. ii.

Although, however, considerable caution is required in deciding that palpitation is the result of organic disease; yet, on the contrary, it may, with more confidence, be pronounced to be independent of such disease, if the paroxysms are slight, and speedily terminate, while the intervals are more completely free from any affection of the chest, and of longer duration. And this conclusion will be farther confirmed, if at the same time other symptoms are present, which indicate a morbid irritability of the habit; such as those of chlorosis, hypochondriasis, hysteria, &c.; or if it be known that the patient has been recently exposed to the operation of the debilitating causes above enumerated. See Headlam, *Diff. Mang. de Palpitatione*, Edin. 1800, p. 23.

According to the decision which is made, as to the source of the disorder, the *prognosis* will be favourable or otherwise. If it be pretty obvious that it is of the latter class, and unconnected with any organic lesion of the heart, it may be expected to be relieved or removed by medicine, according to the age, constitution, and manner of living of the patient, and to the mildness of the disorder of which it is a symptom. But if it appear to be clearly the result of organic disease, a cure cannot be expected, and palliation must be the sole object of the practitioner, and the sole hope of the patient.

PALPITATION.

patient. In this case, the disease will continue, gradually augmenting, for an indefinite period; and as the obstruction to the circulation is increased, other distressing symptoms are apt to supervene, such as asthma, spitting of blood, constant oppression of the respiration, dropsy of the pericardium and of the thorax, and ultimately anasarca; and during the occurrence of any of these affections, or sometimes before any of them have supervened, the patient is not unfrequently cut off by a sudden death, when it was not expected.

In considering the proper *methods of treating* palpitation, two indications are to be kept in view, the one regards the measures to be adopted during the paroxysm; the other, those which are to be pursued during the intervals of remission.

1. *The paroxysm* is to be viewed in the same light as other convulsive actions, from whatever source it may originate; and, like others, it may be relieved by *blood-letting*, and by what are called *antispasmodics*, the choice of which is a matter of some importance. Whether the palpitation be connected with organic lesion or not, if the patient be robust or plethoric,—if he suffer severe pain and a great sense of suffocation,—if the respiration be exceedingly laborious and difficult,—if the pulse beat with a full and hard stroke,—and if there are no obvious marks of great debility or of a dropical tendency,—a free blood-letting from the arm will be safe, and afford speedy relief; nay, it may probably ward off an apoplectic attack, or prevent a rupture of the heart or some great vessel, and thus preserve life. If the palpitation be not of long standing or habitual, and if it be accompanied with the symptoms that belong to carditis, or inflammation of the heart, then copious blood-letting is the principal remedy upon which any dependance can be placed; and it must be repeated, either in the paroxysm, or during the intermission, as those symptoms may require. In the majority of cases, however, the paroxysm will not be of this kind, and the detraction of blood will not only be unnecessary, because useless during the paroxysms, but it will be prejudicial to the subsequent state of the patient.

For whether the disease be organic, and of considerable standing, or sympathetic of the hypochondriacal, hysterical, or nervous temperament, considerable debility is usually present, and the tendency of the disorder is to increase that debility. Whenever, therefore, the patient is obviously not plethoric or robust,—when there is much disposition to syncope, or fainting,—when the pulse is small and weak,—and when the palpitation appears to be the result of strong mental emotions, or to have followed the debilitating circumstances, before enumerated,—then it will be proper to resort to antispasmodics, for the purpose of alleviating and shortening the paroxysm. Of these it will be necessary, in many cases, to take any that may be at hand; as camphor, ammonia, asa fœtida, opium, æther, valerian, castor, &c.; but where the choice can be made, a mixture of æther and the tincture of opium is preferable, as productive of the most speedy and powerful sedative effects.

The patient should not be constrained to assume any particular posture, but should be retained as quietly as possible in that which he instinctively chooses, and which experience satisfies him is the easiest. This is commonly a sitting posture, in which he reclines a little forwards; and sometimes gentle but steady pressure on the ribs of the left side, affords considerable relief.

2. *The treatment required in the interval* will be different, in those cases in which the palpitation results from organic disease, and in those in which it is merely a nervous symptom.

In the organic cases, as we have before observed, palliation is all that medicine and regimen can accomplish; and it

is certain that much alleviation of the sufferings of the patient, and probably that a considerable prolongation of life, is often thus effected. For this purpose two indications are to be kept in view: namely, the one, to avoid every thing that may hurry the circulation of the blood; and the other, to avoid every source of plethora, or turgescence of the vessels.

Both the frequency of the returns of the paroxysms, and the violence of them, may be materially diminished by avoiding all hurry of the circulation. This is effected by a series of minute attentions, in respect to which, although the physician may point them out, the patient "must minister to himself." Constant quietness both of body and mind must be studied; the patient should move carefully and slowly, whenever motion is necessary, and especially should cautiously avoid false steps in walking on uneven ground. He should ascend declivities, as stairs, as little as possible, and therefore sleep on the ground floor of his house. He should shun heated rooms, the influence of strong fires, and of close unventilated apartments. He should avoid entering into the discussion of subjects that are liable to excite any strong emotion, or to ruffle his temper. The regulation of his diet becomes of extreme importance in this point of view; for nothing tends more directly to hurry the circulation, and to produce partial turgescences, than a heating and stimulant regimen. He should, therefore, totally proscribe all spirituous, vinous, and fermented liquors from his table, and should use the lightest and most digestible food, and that in great moderation, avoiding condiments, and a variety of dishes. This regulation of regimen affords, in fact, one of the most effectual means of fulfilling also the second indication, that of avoiding a plethoric condition of the system.

Medicine, however, though inadequate to accomplish these purposes alone, may be made to contribute materially to the same ends, when united with a proper conduct of regimen. The constant and regular evacuation of the bowels, especially by means of saline and other cooling laxatives, conduces both to moderate the activity of the circulation, and to prevent plethora, and cannot be neglected with impunity, where there is organic disease producing palpitation of the heart. If there is actual plethora to any extent, even actual depletion by the lancet may be necessary.

There is another class of medicines which appear to be indicated under these circumstances; namely, such as have the power of directly diminishing the action of the heart and arteries: of these the digitalis is the most effective. This medicine, when combined with the repeated use of saline laxatives, and with the cooling regimen, and system of quietude, above recommended, has, in several cases under the inspection of the writer of this article, appeared to procure a very valuable degree of ease, and freedom from palpitation, when there were obvious signs of organic disease, and to retard the progress of that disease itself.

A very different practice is requisite in the interval of remission, in those cases of palpitation that are merely connected with a morbid irritability of the habit, or with some local irritation. If the palpitation is excited by over-dilatation of the stomach, the meals should be moderate, and the causes of flatulence particularly avoided, while, at the same time, the proper remedies for indigestion should be employed. If the irritation arise from the presence of worms in the intestines, the remedy will be equally obvious. And the use of laxatives, which we have recommended above with another view, will also obviate one source of irritation, which not unfrequently accompanies both indigestion and the hysterical and hypochondriacal habit, namely, an accumulation of feces in the bowels, or habitual constipation.

It is scarcely necessary to dwell upon the treatment required in the intermissions of palpitation, connected with chlorosis, hysteria, hypochondriasis, and other states of debility and irritability of habit; since these diseases have been amply discussed under their respective heads. The general indication is to employ medicines possessed of a tonic power, and to avoid every cause of debility, moral and physical. Preparations of cinchona, gentian, calumba, serpentaria, and other vegetable bitters, the mineral tonics, especially the preparations of iron, the chalybeate waters, &c. and the use of the cold bath, are among the most efficacious means of removing that morbid irritability which gives rise to the spasmodic actions of the heart. Moderate exercise, in the open air, taken in such a way as to avoid any extraordinary hurry of the circulation, which might bring on the paroxysm of palpitation, will be advisable. And every source of anxiety, or other severe emotion of mind, should be avoided as much as possible; by fixing the attention upon interesting and agreeable pursuits, or by travelling.

PALREDYGUR, in *Geography*, a town of Hindoostan, in Palnaud; 16 miles W.S.W. of Timerycotta.

PALSCHAU, in *Biography*, born in Germany, who, before he was thirteen years old, travelled with his father to several parts of Europe, and astonished every auditor by his performance of Sebastian Bach's most difficult harpsichord lessons; and by running most rapid divisions in thirds and sixths, with both hands: eighths he could not reach; and indeed he astonished spectators with his dextrous use of pedals, particularly in our country, where, though there have been pedals in our very large old organs, particularly at St. Paul's, Exeter, and St. Michael's, Cornhill; yet they seem never, or but rarely, to have been used by our organists after Handel's first arrival here, who, we are told, used to go with young Green, then an apprentice, to exercise himself on these *feet* keys in private; intending always, during the reign of his patron the elector (afterwards George I.), to return to Hanover; but young Palschau must have been here very early in our musical life, before we had ever seen or heard of pedals; as, when Mr. Boyce desired us to officiate for him at St. Michael's, Cornhill, we knew not of their existence. (See **PEDALS**.) But soon after we had heard the young German, and seen him use pedals, we heard Miss Robinson, the singer, daughter of Mr. Robinson, the organist of Westminster Abbey, perform wonders on a harpsichord with pedals; which instrument it is probable Palschau's father borrowed of Robinson: for wherever he stopped on the continent, he was sure to find pedals. But after this period, we had been many years surpris'd at hearing nothing further concerning Palschau; and supposed he was either dead, or that some accident had befallen him to stop the progress of his premature talent. And when we went to Germany, one of our first enquiries was after Palschau, when we were told that he was at Riga; but was still regarded as a great player of the Bach school: yet finding on his return home, that his performance became less miraculous every day, as he grew up he acquired great reputation in instructing youths intended for the profession of music, in which he had acquitted himself with an intelligence and integrity so superior to common organists, and masters who take apprentices, in thoroughly grounding his pupils in every branch of the art which they were pursuing, that he was invited to Riga, where he continued to qualify young organists, not only in that city, but from all parts of Germany. He had himself been instructed by Mützel, who was an élève and imitator of C. P. Emanuel Bach. He compos'd but little, except two harpsichord concertos, and some songs. But

we have heard since that his fame became so extensive as to produce an invitation to Petersburg, where his good taste in playing, and manner of teaching, pleas'd so much, that he was appointed court-master by the empress Catharine, and his salary in that office, and the many scholars he had in great families, made him so easy in his circumstances, that he would undertake no more boys on the chance of their becoming great musicians, unless, on examining their hands, he found them well formed by nature; and that every finger on both hands were equally strong. He likewise examined their heads, by putting questions to them, which, to answer, required intellect. He then assign'd, for practice to them, as a first lesson, one of the most complicated and difficult compositions for keyed instruments that he could find. We are to suppose, before these students apply'd to him, they were well acquainted with the first elements of music; as the gamut, time-table, clefs, flats, sharps, and the usual characters for graces, &c. He inform'd these young candidates for his institutes, that he would set no limits to the time they should take in accomplishing this task: as, if they only learn'd a bar in a week, they must come to the end of their labour at last.

We were furnish'd with the character and singularities of this musician, by the Rev. Mr. Smernove, of the Greek church (the chaplain of count Worantow) and his brother, John Smernove, a fine performer on the violin, and private secretary to the count, when ambassador from Russia.

PALSCHOV, in *Geography*, a town of Prussia, in the province of Pomerelia; 11 miles N.W. of Marienburg.

PALSGRAVE, a term used among the Germans, of the same import with *palatine*.

It is compounded of the Latin *palatium*, and the Dutch *grave*, *governor*, *g. d.* governor, or superintendent of a prince's palace.

PALSY, in *Medicine*, a corruption of *paralyfy*, from *παρλυσις*, *paralysis*, *laxatio*, *resolutio* or, as the Latins wrote, *nerovorum resolutio*, (relaxation of the muscles,) signifies a loss of the power of voluntary motion.

The appellation of *palsy* is, therefore, not applicable to those cases of impaired mobility of muscular parts, which arise from mechanical stiffness, or from inflammation; but only to those which are occasioned by an inherent imbecility in the muscles themselves, or rather in the nerves with which they are furnish'd, and through the medium of which the moving power is communicated from the brain.

It will not be necessary, in this place, to enter into any detail respecting the nature and functions of the nervous system in the animal body, as the structure and properties of that system have been amply delineated under its proper head. (See **NERVOUS System**.) It is sufficient for our purpose to know, that a multitude of accidents and experiments have demonstrat'd the dependence of *sensation* and *voluntary motion*, in every part of the body, upon the uninterrupted communication of nerves between that part and the brain respectively; and that the interruption of this communication, either by the division of the trunks of the nerves, or of the great nervous mass in the canal of the spine, (incorrectly call'd the *spinal marrow*,) or by pressure on the same; or, lastly, by pressure or other mechanical injury to the brain itself,—is invariably followed by a loss of one or both these faculties in the parts beyond such injury.

Hence the term *paralysis* comprehends a great variety of sensitive and muscular incapacity, to which various appellations have been given, according to the general or partial loss of power, or to the nature of the sensation so impaired. Where the whole power of motion and faculty of sensation

PALSY.

are abolished, the term *palsy* is, indeed, seldom employed, but the disorder is called *apoplexy*. When one-half of the body, longitudinally, is paralyzed, *i. e.* when the leg, arm, &c. of one side only lose their powers, while those of the other remain unimpaired, (which is the most common form of palsy,) the disease is termed *hemiplegia*, or *hemiplexia*: and when one-half of the body is palsied *transversely*, for example, when both the lower extremities are palsied, while the arms and upper parts retain their power, the malady is called *paraplegia*, or *paraplexia*. Some writers have appropriated the term *parefis* to the palsy of individual parts or muscles, as of the arms or legs, of the tongue, eye-lids, bladder, &c. Originally, however, these appellations appear to have been employed as general terms, without much discrimination. Again, a paralytic condition of the different organs of sense has been designated by corresponding appellations. Thus the loss of feeling, or of the sense of touch, has been called *anæsthesia*, that of vision, *amaurosis*, that of smell, *anosmia*, that of taste, *agheusia*, that of hearing, *dyscæa*, &c. These affections will be found described under their proper heads; and, in this place, our attention will be directed to the more general forms of palsy, especially to the *hemiplegia* and *paraplegia*, and to those partial kinds, which are the result of particular agents, such as of the poison of lead, mercury, &c.

I. *Of the Hemiplegia.*—The palsy, which is most frequently seen, and which consists in the loss or diminution of the power of motion of one side of the body, is sometimes the consequence of an attack of apoplexy, where that has not proved fatal; but it more commonly occurs instantaneously, and without any actual apoplectic attack. In the latter case, however, the disease differs from the former only in the degree of injury which has taken place in the brain, the pressure upon that organ being more partial than in apoplexy.

The *symptoms of hemiplegia* are distinct and obvious, and scarcely liable to be confounded with those of any other disease. The most manifest symptom is the want of command over the limbs of the side affected, which either remain totally immovable by the will of the patient, or are possessed of so little power, that the arm hangs dangling by the side, and the leg is dragged along the ground, rather than elevated in attempting to walk, and vibrates from want of firmness, whenever the foot is planted on the ground. At the same time, the limbs are perfectly flexible by any external impulse, to which they offer no resistance. As the muscles of one side of the head are also paralyzed, the features, especially the mouth, are commonly drawn away, giving a distorted appearance to the countenance; for, as the paralyzed muscles offer no resistance, so the constant tendency to contraction in the healthy muscles of the opposite side necessarily operates in drawing the whole towards themselves. The face is contracted, therefore, not on the palsied, but on the sound side. The same palsied condition exists also in one-half of the tongue, which, if it be attempted to be protruded, is shewn in a curved state, the point always turning towards the angle of the mouth on the paralytic side. This palsied state of the tongue and lips, and other organs subservient to the voice, is necessarily the cause of indistinct articulation; so that various degrees of defect of speech accompany *hemiplegia*. From the morbid state of the brain, which gives rise to palsy, the functions of the mind are frequently more or less injured; the memory especially is liable to be impaired, and, in many cases, every faculty is so debilitated, that a considerable degree of fatuity or childish imbecility is the consequence. Indeed, there are perhaps few instances, in which the intellectual functions escape entirely unimpaired from an attack of hemiplegia: so that, where the stroke of

palsy has been severe, few persons are left in a condition fitted for the active and important duties of life subsequently.

Some other phenomena accompany the paralytic state, which vary in different cases, and of which our knowledge of the nature of the nervous system and its functions is insufficient to afford an explanation. Although the nerves are unquestionably the medium, both of *motion* and *sensation*; yet these two faculties are seldom injured in the same proportion. In the majority of cases of hemiplegia, the sensation of the palsied limbs is unimpaired; in a few instances, it is considerably diminished, *i. e.* a degree of numbness and torpor exists throughout; whilst in others, the sensation of the affected parts is entirely abolished, *anæsthesia* being combined with the *paralysis*. But, on the other hand, many cases of a total abolition of the power of sensation, in parts which retained the full power of motion, are recorded. Dr. Gregory used to mention an instance in his lectures at Edinburgh, in which there was a perfect *anæsthesia* on one side of the body, and a *hemiplegia* on the other; *i. e.* the nerves, on one side, ceased to be the instruments of sensation, while, on the other, they ceased to be the instruments of motion. Afterwards the hemiplegia attacked the other side; so that there was palsy without feeling on one side, and palsy with the feeling perfect on the other: the patient recovered; and the side, in which both faculties were lost, was the first to regain its powers.

In some cases of palsy, too, the circulation is materially affected, and in others not. Thus, sometimes the pulse in the affected side is slower than in the other; sometimes it is not to be felt, and the temperature of the limb is much diminished. In some cases the substance of the muscles is partly absorbed, and the palsied limbs waste; and occasionally anasarca effusions take place in them; but in others no such changes occur. Sometimes the sensations of the palsied parts are depraved, such as feelings of prickling and tingling, or actual pain; and sometimes there is numbness, with a sense of weight and load, as if from an extraneous body. A patient under this state of feeling exclaimed, "will nobody own that arm?" an exclamation sufficiently characteristic of the helpless condition of the limb.

Although the attack of palsy is sudden, yet, in the majority of cases, various pre-monitory symptoms occur, sometimes for a long period before the attack, which indicate the approaches of the disease. These symptoms are the result of an increasing determination of blood to the head, and consist of head-ache, giddiness, a sense of weight, and distention in the head; dimness of sight, or the appearance of motes floating before the eyes (called *muscæ volitantes*); sometimes a degree of squinting, and even of double vision; noise in the ears; occasional stammering in the speech; transitory numbness or loss of motion in the extremities; failure of the memory; drowsiness, especially after eating, but disturbed sleep; flushing of the face and neck; throbbing of the temporal arteries; and bleeding from the nose. Some one or more of these signs frequently precede the actual change in the state of the brain, which gives rise to paralysis, and an attention to them is therefore of great practical importance. They will, however, more certainly lead to an apprehension of an impending apoplexy or palsy, when they occur in persons who are constitutionally predisposed to these diseases.

The *predisposition* to paralytic affections is connected with a particular habit of body, which is frequently hereditary, and is characterized by a large head, and a short neck, especially in persons with dark eyes and hair, and by a corpulent habit. The large head implies a considerable proportion of blood circulating in the brain, and the short neck,

that

PALSY.

that it is carried thither with greater impetus. The corpulent state both gives and indicates the predisposition; for an over-proportion of fat generally implies an over-proportion of blood, as both arise from the same causes. A great quantity of fat, too, presses upon the organs and vessels of the body, and necessarily tends to produce an accumulation in the parts where no fat is secreted, as in the brain. A certain advanced age also contributes to the predisposition to palsy, as a degree of venous plethora is then often produced; so that palsy seldom takes place before the age of forty. The same effect is produced by an indolent and sedentary mode of life, by a full diet, and especially by a habit of intoxication, which produces a great determination of blood to the head. But any habitual excess in the use of wine and malt liquors, although inconsiderable, and not occasioning intoxication, will have a similar effect. A plethora, and therefore a predisposition to palsy, is also induced by the stoppage of customary discharges, such as bleeding at the nose, a copious hæmorrhoidal or catamenial flux, the drying of habitual ulcers, &c.

Where this predisposition exists, various circumstances may operate as the *exciting causes*, and bring on the paralytic seizure; and these causes produce that effect, either by determining an extraordinary quantity of blood into the brain, or by preventing a free return of it from thence; whence a *morbid degree of pressure* is occasioned in that important organ, either from simple congestion and over-distention of the vessels, or from congestion, followed by an effusion of serum, or by a rupture of vessels and an extravasation of blood. Now, an unusual flow of blood to the head is occasioned by every stimulus to the general circulation; whence *violent exercise*, by which the pulsations of the heart are quickened and increased in force; great external *beat*, which produces a similar effect; paroxysms of *anger, intoxication*, or even a more moderate excitement by strong liquors, have, in different instances, produced the paralytic attack. On the other hand, the blood is impeded in its exit from the head in various ways: thus *slooping*, or any other situation in which the head is kept in a depending position, and in which therefore the gravity of the blood increases the afflux of it by the arteries, and opposes the return of it by the veins; *tight ligatures* round the neck, which compress the veins more strongly than the arteries; *impeded respiration*, or a full and long continued *inspiration*, as in violent straining, or a *long expiration*, as in coughing, laughing, &c., which impede the circulation through the lungs for a time, and therefore interrupt the free return of the venous blood from the head; *over-distention of the stomach* by a full meal, which compresses the great descending artery, and also prevents the descent of the diaphragm, and therefore impedes the pulmonary circulation; all these circumstances have occasionally given rise to apoplectic and paralytic seizures. Indeed the manifest redness and flushing of the face and eyes, and the general turgescence of the countenance, occasioned by slooping, by tight neckcloths, by long fits of coughing and laughing, by intoxication, by violent muscular exertions, and by a full hearty meal, sufficiently demonstrate the determination of blood to the head, which they excite. With respect to the influence of a full meal, the common reports of the newspapers afford abundant evidence; since nothing is more frequent than the accounts of sudden death, just after persons had eaten a hearty dinner or supper, and enjoyed the company of their friends.

This view of the nature of the causes of palsy, is completely confirmed by the examination of the state of the brain, by dissection, where the disease has terminated fatally; appearances of congestion and accumulation of blood in the

vessels of the brain, or of effusion of serum, or of actual rupture of the vessels and extravasation of blood, have always been observed, where the attack was sudden; and in cases of the gradual supervention of palsy, some morbid growth, producing a slowly increasing pressure, which gradually disturbed the functions of the sensorium, has been commonly found. So that, in all these cases, the obvious cause of the palsy has been the interrupted communication of the nervous influence, whatever that may be, from the brain to the parts which had become paralytic.

The palsy and the apoplexy, which are thus produced, in connection with an over-distended condition of the vessels of the brain, and with a plethoric habit, a short neck and large head, have had the epithet of *sanguineous* given to them; because it has occasionally been observed, that the same diseases have occurred in habits of a very different character. For example, persons of tall and slender form, of spare habit, with small heads and long necks, and pallid complexion, in whom no external marks of plethora, or of determination of blood to the head, were visible, have nevertheless been now and then seized with palsy, or died from a sudden apoplectic stroke. It has been supposed, that these diseases in such persons, originated from pressure produced in the brain by an effusion of serum, which is occasioned, not by an over-distention of the blood-vessels, but by a state of relaxation in the exhalant artery, the same as in other cases of a *dropical diathesis*, or by an over-proportion of the watery part of the blood, which is therefore ready to run off by the exhalants. Whence, in contra-distinction from the ordinary forms of these diseases, the epithet, *serous*, has been applied to this variety. (See Cullen, First Lines, par. 1112.) Dissection, however, does not seem to have confirmed this theoretical division of the forms of the disease; for, in several cases of fatal apoplexy, which occurred in thin and spare habits, the same congestions and ruptures have been found to have taken place, as in those patients, whose large heads and plethoric condition implied a fullness of the blood-vessels. In fact, medical observation teaches us, in numerous other instances, that local determinations and partial congestions of blood are liable to occur in persons very far removed from a plethoric condition; and that a paucity of the circulating fluids is no infallible security against local fullness. In our practical considerations, therefore, the notion of *serous apoplexy* or palsy should perhaps be altogether discarded.

It is a curious fact, which has been ascertained by anatomical investigation, that in most of the instances of hemiplegia, the cause of derangement in the brain is found on the side *opposite* to the paralytic affection. A few cases have occurred, in which the morbid cause is said to have been on the same side as the palsy; but this is certainly an exception to the general fact, and therefore the matter may still be considered as liable to doubt. Nevertheless anatomy has not taught us a satisfactory explanation of the phenomenon, that the injury of the brain and the palsy of the body occur on opposite sides. Anatomists have supposed a certain decussation or crossing of fibres from one hemisphere of the brain to the other; but there has been no very satisfactory demonstration as to this point. M. M. Gall and Spurzheim, the most accurate investigators of the structure of the brain, maintain that there is no decussation, except for the space of four or five lines at the lower extremity of the medulla oblongata, and they therefore deny that injury to one side of the brain (with exception of injury to the anterior *corpora pyramidalia*) ever affects the opposite side of the body. The facts, however, are perhaps too numerous to be set aside by the mere hypothesis, suggested by a difficult examination of a very obscure structure. See NERVOUS System.

Neither

PALSY.

Neither has any anatomical investigation afforded the means of explaining the different phenomena above alluded to, respecting the various and disproportionate affections of the *sensation* and power of *motion*, in parts supplied by the same nerves. For a clear and copious detail of the researches and opinions of anatomists and pathologists on these topics, we shall refer the reader to a paper of Dr. Yelloly's, in the *Medico-Chirurg. Transactions*, vol. i. p. 181.

Independently of mechanical pressure produced in the manner above described, some other causes occasionally injure the functions of the brain, and render it incapable of diffusing the nervous power to the limbs, and thus produce a species of palsy. Certain poisonous substances have that effect, such as lead, and perhaps mercury, and some of the narcotic vegetables, such as the belladonna. A severe and continued impression of cold, long continued grief, great terror, and other depressing passions, occasionally also give rise to paralytic affections, by their direct influence upon the state of the brain.

The *prognosis* is generally unfavourable in *hemiplegia*, more especially when the patient is in advanced life, or debilitated in constitution, or has been in habits of intemperance. For under such circumstances, the system seldom recovers its powers, and the patient remains enervated both in mind and body, and generally incapable of the ordinary business of life. If, as the disease continues, the paralysed limbs gradually lose their sense of feeling, or if they are affected with coldness, and the flesh wastes, the prospect is most unfavourable. But, if there is a frequent prickling sensation, or even some degree of pain, in the parts; if they are occasionally affected with flushings of heat, or with spasmodic twitchings; or if rheumatic or inflammatory swelling take place in them, these appearances are to be deemed favourable, inasmuch as they imply a less complete interruption of the nervous power, or its returning influence.

The *treatment of hemiplegia* will necessarily be somewhat different in different instances, according to the age and constitution of the patient, and to the obvious exciting cause of the disease. Before we state the general indications of cure, however, and the methods of fulfilling them, it will be proper to observe that the *prophylactic* treatment is often the most essentially useful. It too often happens, that, when the attack has taken place, some irremediable injury has been inflicted on the delicate texture of the brain, which, had the warning symptoms, which we have enumerated above, been attended to and removed, might have been altogether averted.

As a plethora of the vessels, either general or topical, is indicated by those premonitory symptoms; so the means of obviating that plethora are equally obvious, and within our power. Whenever, therefore, we observe these symptoms in persons, whose form and habit evince a predisposition to the disease, and more especially in those who have suffered a previous attack, every means should be resorted to, which diet, regimen, and an evacuant plan of medicine, can afford, to reduce the plethoric condition. The diet should now be low, consisting of whey, butter-milk, fruits, and farinaceous food, animal matters being discarded, or a little plain meat taken once every other day, and all fermented liquors totally abstained from. Even filling and distending the stomach frequently with mere vegetable matters ought to be avoided, for the reasons above explained. If the symptoms of oppression about the head are very considerable and menacing, it may be advisable to take some blood from the vessels of the head or neck, either by the lancet, by leeches, or by cupping; and at the same time the bowels should be well evacuated by cathartic medicines.

If, however, the previous symptoms have been neglected, and the attack of hemiplegia have actually come on, the *first* indication that presents itself, will be to remove or diminish the cause of compression, which may exist in the brain, whether it may be mere vascular turgescence, the extravasation of blood, effusion of serum, &c.; and the *second* indication will be gradually to excite the torpid portion of the brain and nerves to a sensible and active state. How very little power we possess, however, to accomplish either of these purposes, except in the case of mere vascular congestion, medical experience too clearly demonstrates.

Whatever may be the nature of the compression in the brain, it cannot be doubted, that a diminution of the turgescence of the vessels will tend to diminish it, by removing some portion of the bulk of the fluids in the general mass of the viscus. If the compression arise from mere congestion, it may be entirely removed by such a measure; and if it arise from actual rupture and extravasation, or from a serous effusion the result of plethora, the abstraction of some portion of the circulating fluids will tend to arrest the progress of the extravasation or effusion, and therefore at least prevent an increase of the evil. Under all circumstances, therefore, the local detraction of blood seems to be advisable at the onset of *hemiplegia*. The quantity of blood to be taken away, as well as the mode of taking it, will be determined by the severity of the attack, and by the strength and plethoric condition of the patient. If the patient be extremely full and florid, and has not passed the middle age, a free *bleeding* from the *temporal artery*, or the *jugular vein*, may be preferable: but, even in the pale and thin habit of body, *cupping* the neck or temples, or the application of *leeches* to those parts, should be resorted to. In the full and florid habits, general blood-letting from the arm is often employed; but the same general depletion may be accomplished by the section of the temporal or jugular vessels, while at the same time a more effectual depletion of the vessels of the brain will be produced. And in order that the local effect may be still more complete, it is desirable to make the evacuation from the side of the head opposite to the hemiplegic affection.

At the same time, other means of diminishing the impetus of the circulation in the head must be resorted to, as auxiliaries. The bowels should be emptied by active *cathartics*, by which a considerable depletion of the vessels, and a determination of the fluids downwards, are produced. Some practitioners also recommend emetics; but the objection of Dr. Cullen against these medicines, that the action of vomiting might impel the blood with too much violence into the vessels of the head, seems to be well founded, and they are seldom now employed. *Blisters* applied to the shaven scalp, or to the nape of the neck, by the counter-irritation which they occasion externally, tend to diminish the internal action of the vessels.

It is a practice, but too generally adopted by routine-practitioners, to begin immediately with the exhibition of strong stimulants, upon the superficial inference, it should seem, of a torpor of the nervous power. But if they were to penetrate a little below the surface of things, it would be evident that this torpor of the nerves depends entirely upon an oppressed state of their origin, the brain, in consequence of an over-action and turgescence of its vessels; and, therefore, that every measure, which tends to augment vascular action, must necessarily be a source of aggravation to the disease. Upon the plainest principles, the very opposite object is to be pursued; and until the symptoms of plethora, and the active state of the disease be subdued, the measures, which we have recommended as proper with a preventive view, should still be adhered to.

The

PALSY.

The second indication, therefore, which is "gradually to restore the torpid portion of the brain and nerves to a sensible and active state," can only be followed, after the hemiplegia has subsisted for some time, and when the symptoms, indicating a considerable compression of the origin of the nerves, are removed. But even under these circumstances, the use of stimulants would appear to be of very ambiguous advantage. For it may be doubted, whether any paralytic affection, originally produced by compression of the brain, would continue after the compression was removed, *i. e.* whether the very existence of the hemiplegia does not imply the continuance of a compressing cause, or at least of some organic injury, which it had inflicted and left behind. And at all events, the multitude of patients, who have in vain swallowed, for a long period of time, all manner of volatile, fetid, and spirituous stimulants, who have submitted to electricity and friction, and stimulant liniments, and warm bathing, and who have nevertheless neither obtained a recovery of the power of their limbs, nor even prevented subsequent attacks, do not bear any very favourable testimony to the efficacy of these expedients; while, on the contrary, the small proportion of persons, who do recover the full use of their hemiplegic limbs, may justly ascribe their recovery to the slightness of the original attack, to the absence of effusion, extravasation, or any other organic mischief, and to the self-adjusting powers of the constitution, as soon as the cause of disease is removed. In some cases, indeed, it may be supposed that, even where actual effusion or extravasation had taken place, without materially injuring the texture of the brain, the fluids may be ultimately removed by absorption, and the brain therefore be restored to health; but, even in such cases, the beneficial aid of stimulants is more than problematical. In a word, it appears, that stimulants are perhaps never advisable in true hemiplegia; and that the benefit of these remedies is limited to those species of general palsy which arise from the influence of cold or narcotic poisons on the brain and nerves, or to those *local* varieties of palsy which seem to depend upon disease affecting the branches and extremities of the nerves, while the brain remains uninjured; of which we shall have occasion to speak presently.

For the purpose, therefore, of aiding recovery from an attack of hemiplegia, the principal indication will be, to avoid every species of intemperance; to restrict the diet to light and cooling articles, and to take these with great moderation; to employ regular but always gentle exercise, avoiding every extraordinary hurry of the circulation; to preserve a regular, and rather free, state of the bowels; and to manage the clothing, so as to preserve a regular state of the cutaneous exhalation, and to avoid the impressions of vicissitudes of heat and cold. In a word, the object will be to free the constitution from all embarrassment, in which condition it will be the best enabled to resume its healthy actions. We may liberate and assist, but we cannot command the powers of the *vis medicatrix nature*.

It may be observed, however, that where the attack has been slight, and the tendency to recovery obvious, the return of power in the paralyzed muscles seems to be considerably accelerated by a constant exertion of them, or at least by constant attempts at exertion by directing the volition to them. The advantages of this voluntary exertion are commonly obvious in the more speedy and complete recovery of the motion of the leg, when compared to that of the arm, in persons who have suffered hemiplegia: a circumstance to be ascribed solely to the necessity of *using* the leg in moving from place to place, while the arm is too commonly hung in a sling, and no attempt is made to employ it.

II. *Of the Paraplegia, or Palsy of the lower Extremities.*— Without referring to the original acceptance of the term *paraplegia*, respecting which there has been some difference of opinion, and no very determinate definition (see Van Swieten, Comment. Aph. 1018.); we take it in its modern sense. A palsy of the lower extremities may perhaps sometimes arise from injury or disease in some part of the brain itself; but of this the evidence appears to be imperfect; and at all events the occurrence is rare. The ordinary instances of this palsy obviously originate from pressure on some part of the *vertebral nerve*, or spinal marrow, below which the palsy shews itself, while the parts supplied with nerves, that branch off above the seat of the pressure, continue to possess their power of motion unimpaired.

The *paraplegia* may occur at all ages, and in either sex, and is always productive of much distress: for if the patient is a child, it becomes an object of constant and unavailing anxiety to its parents; and if an adult, he is rendered perfectly helpless to himself, and useless to all others, which of all possible states is surely the worst.

When this palsy attacks an infant of only a year or two old, the true cause of it is seldom discovered, until some time after the effect has taken place, at least by parents and nurses, who know not where to look for it. The child is said to be uncommonly backward in the use of his legs, or it is thought to have received some hurt in its birth. When it affects a child, who is old enough to have already walked, and who has been able to walk, the loss of the use of the legs is gradual, though not very slow. He at first complains of being very soon tired, is languid, listless, and unwilling to move much: or at all briskly: in a short time after this he may be observed frequently to trip, and stumble, although there be no impediment in his way; and whenever he attempts to move briskly, he finds that his legs involuntarily cross each other, by which he is frequently thrown down, and that without stumbling; upon endeavouring to stand still and erect, without support, even for a few minutes, his knees give way and bend forward. When the distemper is a little farther advanced, it will be found that he cannot, without much difficulty and deliberation, direct either of his feet precisely to any exact point; and very soon after this, both legs and thighs lose a good deal of their natural sensibility, and become perfectly useless for all the purposes of locomotion.

When the disease occurs in an adult person, its progress is much the same but rather quicker. He complains also, in the early part of its course, of a sense of numbness in the affected limbs, with transitory tremblings and twitchings, and sometimes of rigors: and he finds, as the bladder and lower portion of the bowels are included in the disease, that the stools pass off unconsciously, and the urine flows without his consent, at the same time that he has a difficulty of emptying the bladder. Ultimately the legs become rigid, and the knees and ankles stiff, and the feet extended, so that they cannot be placed flat on the ground. This last circumstance is likewise observed in children.

When the back is examined, some prominence or curvature of the spine is always found. This curvature varies in situation, extent, and degree, being in the neck or back, and sometimes, though very rarely, in the upper part of the loins; sometimes comprehending two vertebræ only, sometimes three or more, by which the extent of the cure becomes necessarily more or less; but whatever may be the number of the vertebræ concerned, or whatever the degree or extent of the curvature, the lower limbs only feel the effect, the arms never being affected.

The effect is also different in different subjects: some are rendered

PALSY.

rendered totally and absolutely incapable of walking in any manner, or with any help, and that very early in the course of the distemper; others can make a shift to move about with the help of crutches, or by grasping their own thighs with their hands; some can sit in an erect posture, in a chair, without much trouble or fatigue, which others are incapable of, at least for any length of time: some have such a degree of motion in their legs and thighs, as to enable them to turn and move for their own convenience in bed; others have not that benefit, and are obliged to lie till moved by another.

The general health of the patient does not seem at first to be materially, if at all, affected; but when the disease has continued some time, and the curvature is much increased, many inconveniences and complaints come on; such as difficulty in breathing, indigestion, pain, and what they call a tightness at the stomach, obstinate constipations, purgings, the involuntary flux of urine and feces before mentioned, together with what are called nervous complaints. Some of these are occasioned by the alterations made in the cavity of the thorax, and others seem to arise from impressions on the abdominal viscera, by the intrusions of the ribs, as the spine is distorted. The confinement and inability for taking exercise, will account for the other symptoms, that are not the direct result of the paralysis.

The disease is commonly ascribed to some injury, such as a blow, fall, or violent strain, which had affected the spine; and probably this is actually the origin of it in many instances. But there is no doubt, that the spine and its ligaments often become diseased, so as to produce paraplegia, independently of such violence. For it is not the mere distortion or curvature of the spine which gives rise to the palsy; since the most extensive crookedness often occurs where no paralysis exists; but actual pressure upon the vertebral nerve, by the concomitant disease of the spine.

This morbid change in the structure of the spine has been described by Mr. Pott as follows. By many dissections he ascertained, that in infants, in young children, and in those who had been afflicted with the disorder but a short space of time, the ligaments connecting the vertebræ of the curved part were altered from their natural state, being somewhat thickened and relaxed, and the bodies of these bones were palpably enlarged in their texture, just as in the joints of rickety children. In those who had laboured for a long time under the malady, and in whom the symptoms were consequently aggravated, whatever might be their age, the ligaments were still more thickened, relaxed, and altered, the bodies of the bones more enlarged and spread, and more inclining to become carious, and the cartilages between the bodies of the vertebræ much compressed and lessened in size: and in all those who had so long laboured under the disease as to be destroyed by it, or by its consequences, the corpora vertebrarum were completely carious, the intervening cartilages totally destroyed, and a quantity of sanies lodged between the rotten bones and the membrane investing the spinal marrow.

The cure of paraplegia was seldom effected till the proper treatment was devised by Mr. Pott. While the curvature of the spine remained undiscovered or unattended to, the disease was generally considered as nervous, and medicines so called were most frequently prescribed, together with warm liniments, embrocations, and blisters, to the parts affected; and when the true cause was known, recourse was always had to steel stays, the swing, the screw-chair, and other pieces of machinery, in order to restore the spine to its true and natural figure. But these expedients did not serve any real or permanent good purpose: the patients usu-

ally became unhealthy, and, after languishing for some time under a variety of complaints, died in an exhausted and emaciated state; or, which was still worse, dragged on a miserable existence, confined to a great chair, or bed, totally deprived of the power of moving.

The sagacious mind of that eminent surgeon, Mr. Pott, partly from a consideration of the diseased state of the ligaments and bones, which precedes and occasions the curvature, and partly on the suggestion of a learned physician, Dr. Cameron, of Worcester, who, in consequence of an observation of Hippocrates, that a paraplegia had been cured by an abscess in the back, had imitated that process with advantage; devised the plan of instituting a free discharge, by means of a large issue, from both sides of the spine. Experience confirmed the utility of this practice, and many examples of the complete restoration of strength and motion, in these deplorable cases, have been subsequently recorded. (See "Select Cases of the Disorder, commonly termed, the Paralysis of the Lower Extremities," by John Jebb, M.D. &c. 1782.) Mr. Pott's method of practice is related, in his own tract on the subject, in these words.

"The remedy for this most dreadful disease, consists merely in procuring a large discharge of matter, by suppuration, from underneath the membrana adiposa on each side of the curvature, and in maintaining such discharge, until the patient shall have perfectly recovered the use of his legs. To accomplish this purpose, I have made use of different means, such as setons, issues made by incision, and issues made by caustic; and although there be no very material difference, I do upon the whole prefer the last. A seton is a painful and a nasty thing; beside which it frequently wears through the skin, before the end for which it was made can be accomplished. Issues made by incision, if they be large enough for the intended purpose, are apt to become inflamed, and to be very troublesome before they come to suppuration. But openings made by caustic are not in general liable to any of these inconveniences, at least not so frequently, nor in the same degree; they are neither so troublesome to make nor to maintain. I make the eschars about this size and shape," [here he inserts an ellipsis, of an area equal to that of a shilling,] on each side the curve, taking care to leave a sufficient portion of skin between them. In a few days, when the eschar begins to loosen and separate, I cut out all the middle, and put into each a large kidney-bean. When the bottoms of the sores are become clean by suppuration, I sprinkle, every third or fourth day, a small quantity of finely powdered cantharides on them, by which the sores are prevented from contracting, the discharge is increased, and possibly other benefit obtained. The issues I keep open till the cure is complete, that is, until the patient recovers perfectly the use of his legs, or even for some time longer; and I should think that it would be more prudent to heal only one of them first, keeping the other open for some time, that is, not only until the patient can walk, but until he can walk firmly, briskly, and without the assistance of a stick; until he can stand quite upright, and has recovered all the weight, which the habit, or rather the necessity of stooping, occasioned by the distemper, had made him lose."

Although this remedy is sufficient for the cure of the disease, Mr. Pott admits, that there is no reason why every assitant means should not be applied at the same time, in order to expedite it; such as cinchona, cold bathing, frictions, &c. See "Remarks on that kind of Palsy of the Lower Limbs, which is frequently found to accompany a Curvature of the Spine, &c." By Percivall Pott, surgeon to St. Barthol. Hosp. 1779.

III. Of Paralysis, or local Palsy.—Under this head we shall in-

PALSY.

include all the forms of paralysis which are partial, and seem rather to depend upon a disordered condition of the nervous cords, near their extremities, than upon any injury done to the common sensorium, or to the great trunk of the spinal nerve. The partial palsies of this kind are chiefly those which are connected with long-continued rheumatic inflammation, or with the long application of cold, or lastly, with the operation of certain mineral poisons, especially lead and mercury.

After a limb has been for some time the seat of inveterate rheumatism, especially in debilitated habits, it sometimes becomes torpid, and benumbed as it were, losing its power of motion, and commonly some degree of its sensibility. A similar condition is more speedily produced by the direct application of cold to the parts; as, for example, in the legs and feet of persons who work with these parts in water. The extremities of the nerves appear to be no longer capable of receiving and conveying the nervous power from the brain, while the latter shews no symptom of any disease. The *poison of lead*, by whatever means it is introduced into the system, produces a species of palsy peculiar to itself: its first effect is the production of a severe colic, which from its being most frequently seen in painters, has been called the *painter's colic*; and it has received also several other appellations, from certain districts in which it has been prevalent, as the *Devonshire colic*, *colic of Poitou*, &c. (See COLICA PICTORUM.) After one or more attacks of this colic, the patient perceives that one of his hands grows weak, and at length he finds himself altogether unable to extend either the hand or the fingers, which hang down (nearly at a right angle to the arm, when it is held out horizontally,) torpid and moveless, except from external force. As this commonly succeeds the attacks of colic, it may be probably connected with irritation in the intestinal canal, which appears at times to produce other forms of partial palsy. The palsy from the influence of *mercury* is also of a peculiar nature; it seems indeed to be rather an extreme debility of the muscles of the limbs, combined with tremors, than an absolute paralysis. See the accounts given of this disease by Ramazzini de Morbis Artificum; and by De Haen, in his Ratio Medend. See also some observations of Dr. Bateman, in the Edinburgh Med. and Surg. Journal for 1812.

It is to these varieties of palsy, in which there is no plethora, congestion, or pressure upon the brain, that the employment of *stimulant* remedies alone is properly applicable, and that in fact any benefit is to be expected from them. For if a slight attack of hemiplegia is gradually removed during their exhibition, all that can be said is, that the stimulants did not prevent recovery; for assuredly the recovery would take place, the pressure of the brain having ceased to exist, if no stimulants were employed; and where, as happens in the majority of cases, some pressure still remains, no benefit can possibly be derived from stimulants; but the risk of injury is manifest. But in the local palsies just described, the local torpor of the nerves may be often effectually removed by the use of stimulant remedies.

In the palsy that is occasioned by protracted rheumatism, or by cold, recovery has frequently followed a perseverance in the use of the warm bath, of repeated and continued friction with the flesh-brush, or with various stimulating oils and liniments, of which camphor, turpentine, and the acrid gums, together with alcohol, constitute the principal ingredients. Internally, also, stimulant medicines of a similar nature have been at the same time administered, with a view to aid these effects; especially the ammoniacal salts, or tinctures of the stimulant gums in alcohol, and medicines which

have been supposed to possess peculiar powers of exciting the nervous system, such as the arnica, the rhus toxicodendron, &c. Electricity has also been extensively applied to paralytic limbs under these circumstances, and it is probable, both from its obvious influence in exciting spasmodic twitches in the muscles, and from the number of successful instances of its application which have been recorded, that it has been of material benefit. There is, however, great room for self-deception in these cases, as we have shewn at length under the article IMAGINATION, and the metallic tractors and animal magnetizers can adduce ample testimony of their powers in the same sort of disease. For our own part, we have seen so little obvious advantage derived from electricity in *any disease*, as to have nearly relinquished the employment of it; and the use of galvanism, for the same purposes, seems to be sinking also into discredit.

We have mentioned, among other stimulants that are really successful in the cure of these species of local palsy, the *warm-bath*, an expedient which is hazardous, in the early stages at least, of *hemiplegia*. Hence the Bath waters, and more especially the use of the *hot pump*, commonly succeed in removing the palsy from lead, as well as from cold and rheumatism, although dangerous in cases of *hemiplegia*. There is, indeed, no remedy that appears to possess an equal efficacy: in the palsy from lead, after the disease has resisted all ordinary expedients, the hot-pumping seems to be almost a specific. We have in vain tried the pouring of hot water upon the palsied hand, from the spout of a tea-kettle, held at some height, in those patients, who have afterwards speedily recovered under the pump at Bath. There appears no reason, however, to suppose that any water of the same temperature, poured upon the limb in the same quantity, and with the same impetus, could not equally affect the cure, as the water of Bath; since it is the *quantity* of the stimulation, and not any peculiar quality of the water, that produces that effect.

For the palsy, arising from the poison of lead, and affecting principally the extensor muscles of the hand and fingers, Dr. Pemberton recommended a simple contrivance, which appears to have contributed to accelerate the cure of this disease; namely, a sort of battle-dore of wood, of the length of the fore-arm and hand, which is tied to the former, and supports the latter extended at length. Under this support, he conceives the muscles sooner recover their tone, than when they are constantly stretched by the pendulous hand. See his Treatise on the Diseases of the Abdom. Viscera.

Under all the forms of palsy, a constant exercise of the palsied limb contributes materially to expedite its recovery. This principle is equally applicable to the hemiplegia, as to these partial forms of palsy. To the palsy, or tremors originating from the poison of mercury, neither this nor any of the preceding precepts very clearly apply. The brain, in this case, seems to be affected by the poison, and the whole system suffers from its deleterious influence. Many remedies have been recommended, but especially sulphur, which was suggested perhaps upon chemical notions, rather than from a proper estimate of its operation upon the living body. On the whole, the disease is very unmanageable, and we know not how it is to be cured. The manufacturers, (among whom it almost exclusively occurs,) viz. watch and button-gilders, silversmiths, &c. have contrived means of preventing the mercury, especially when used in its most pernicious form, vapour, from entering into the body so fully as formerly; and, therefore, the disease is become less frequent. But even now, as we are informed, the persons employed in what is called water-gilding, that is, in laying an amalgam of gold and mercury upon the articles to

be gilded, and driving off the mercury by evaporation, are generally short-lived from this cause.

PALSY, *Eleuary for the*, is made of powdered mustard-seed and conserve of roses, of each an ounce, with as much syrup of ginger as is sufficient to make an electuary. A tea-spoonful of this may be taken three or four times a day.

PALSY, *Infusion for the*. See **INFUSION**.

PALSY Drops, in *Botany*. See **LAVANDULA**.

PALTE', in *Geography*. See **JAMRO**.

PALTERCAMP, a town of Westphalia, in the bishopric of Osnabruck; 14 miles S.S.E. of Osnabruck.

PALTZ, New, a township of America, on the west side of Hudson's river, in Ulster county, New York, about 20 miles N.W. of Newburgh; containing 3255 inhabitants, including 308 slaves.

PALVARYA, a town of Hindoostan, in Oude; 32 miles E. of Kairabad.

PALUDAMENTUM, in *Antiquity*, a garment worn by the Romans in time of war; being the coat of arms of their principal men, especially the generals; who, for that reason, were distinguished by the appellation *paludati*.

The soldiers only having short coats, were therefore named *pagati*.

This garment was open on the sides with short sleeves, by some resembled to angels' wings; and came down no lower than the navel. It was either white or red. Valerius Maximus remarks, it was an ill omen to Crassus, that they gave him a black paludamentum: "Pullum ei traditum est paludamentum, cum in prælium euntibus album, aut purpureum, dari solet."

Cornutus says, the Romans wore the toga in peace, and the paludamentum in war. And hence the phrase, "Togam paludamento mutavit." See **CHLAMYIS**.

PALUDE, in *Geography*, a town of Turkish Armenia, in the government of Erzerum, the residence of a prince, partly independent of the grand signior. N. lat. 38° 35'. E. long. 39° 14'.

PALVERETO, a town of Naples, in Calabria Citra; 10 miles E.N.E. of Cofanza.

PALUM SANCTUM, in *Botany*, a name by which some authors have called a species of the guaiacum-tree, called the *lignum sanctum*, or holy wood.

PALUMBARIUS ACCIPITER, in *Ornithology*. See **FALCO Palumbarius**.

PALUMBUS, or **RING-DOVE**. See **COLUMBA**.

PALUS, in *Antiquity*, a military exercise among the Romans, by which the young men prepared, and qualified themselves for real combat. The palus was a pillar, about six feet high, fastened into the ground: against this the soldiers made an attack, assailing it in several different modes and attitudes; always taking care so to manage their weapons, that, supposing it was a real enemy, they might not expose any part of their body to be hurt, while they were striking their adversary. Instead of a sword, they used a rod or stick. They likewise ran at the palus with lances, and threw javelins and darts at it, endeavouring to hit particular parts; and their success was a proof of their dexterity. See **PALE**.

PALUS Maotis, in *Ancient Geography*. See *Sea of AZOF*.

PALWAL, in *Geography*, a town of Hindoostan; 35 miles S of De'hi.

PALY, or **PALÉ**, in *Heraldry*. When an escutcheon is divided into six, eight, or ten divisions, pale-wise, *i. e.* by perpendicular lines drawn from the top to the bottom, it is blazoned paly of six, eight, or ten, &c. pieces.

If the number be odd, then the field is first named, and the number of the pales specified. See **PALE**.

The like is to be understood also of *barry* and *bendy*.

PALY-BENDY is, when a coat is divided, both pale and bend-wise: in paly-bendy, the field is divided by perpendicular lines, which is called *paly*; and then, again, by diagonals crossing the former, from the dexter side to the sinister, which is the *bendy*. The field is paly-bendy, topaz and diamond.

PALYANGHA, in *Hindoo Mythology*, a name of the Hindoo goddesses Bhavani, or Parvati, consort of Siva.

PAMADA, in *Geography*, a town of Birmah, on the Ava; 24 miles N. of Prome.

PAMAKASSAN, a town on the north coast of the island of Madura.

PAMALANG, a town on the north coast of the island of Java. S. lat. 6° 45'. E. long. 109° 28'.

PAMANAKAN POINT, a cape on the north coast of Java. S. lat. 6° 12'. E. long. 107° 54'.

PAMANDOOOR, a town of Hindoostan, on the coast of Tinevelly; 10 miles N. of Tutacurin.

PAMBAMACA, a lofty mountain in the province of Quito, being one of the peaks of the eastern Cordilleras.

PAMBŒOTIA, *παμβοιωτια*, in *Antiquity*, a festival celebrated by all the Bœotians, who assembled near Coronea, at the temple of Minerva, surnamed Itonia.

PAMBU, in *Geography*, a town of Thibet; 20 miles E. of Tankia.

PAMEA, in *Botany*, a name which seems to have no meaning, Aubl. Guian. 946. t. 359. Juss. 76, is applied by the former author to a tree of Guiana, of which he knew nothing but the *calyx* and the *fruit*. From these however he rightly deduced its affinity to the Linnean *Terminalia*, of which it appears to be, as Jussieu suspects, undoubtedly a species. Its *trunk* is thirty feet high, and two or more in diameter; the *branches* widely spreading, knotty. *Leaves* oblong, entire, stalked, many together at each joint, in a spreading, whorl-like cluster. *Fruit* racemose, each consisting of a triangular, oblong, brittle *drupa*, with an ovate-oblong, angular, furrowed *nut*, about an inch and a half long, whose kernel is very good eating; on which account the tree is cultivated in Guiana, and the isle of Bourbon. See **TERMINALIA**.

PAMENE, in *Geography*, a town of the island of Ceylon, on the east coast; 55 miles S. of Trincoli.

PAMER, a lake of Prussia; 12 miles W. of Lick.

PAMIERS, a town of France, in the department of the Arriège, and chief place of a canton, in the district of Mirepoix, near which is a medicinal spring; 12 miles W. of Mirepoix. The place contains 5300, and the canton 10,600 inhabitants, on a territory of 235 kilometres, in 22 communes. N. lat. 43° 6'. E. long. 1° 42'.

PAMISUS, in *Ancient Geography*, a river of Messenia, which had its source in the mountains that lay towards the north between Messenia and Arcadia, ran north-east, and discharged itself into the sea, at the extremity of the Messenian gulf.—Also, a river of Greece, in Thessaly.—Also, a river of Lower Mæsia, in the environs of Odesius, called by Ptolemy *Panyfus*, and placed between Odesius and Mæsambrina.

PAMLICO SOUND, in *Geography*, a large bay on the east coast of North Carolina, which is a kind of lake or inland sea, from 10 to 20 miles broad, and nearly 100 miles in length. It is separated from the Atlantic ocean, in its whole length, by a beach of coral hardly a mile wide, generally covered with small trees or bushes. Through it are several small inlets, by which boats may pass; but Ocre-cock

cock inlet is the only one that can admit vessels of burden into the districts of Edenton and Newburn. Pamlico sound communicates with Albemarle and Core sounds; and it receives Pamlico or Tar river, the river Neus, and other small streams. The mouth of Pamlico river is in N. lat. $35^{\circ} 25'$. W. long. $76^{\circ} 42'$.

PAMMACHION, *παμμαχιον*, a name by which the exercise *pancratium* is sometimes called, whence the combatants were likewise called *panmachi*, *παμμαχιον*.

PAMMELIA was a title given to the first collection of canons, rounds, and catches, that was printed in England. The full title of these ingenious and exhilarating effusions for social purposes is curious, and runs thus: "Pammelia (a word formed, perhaps, from *παιον* and *μελο;*) Musick's Miscellanie; or, mixed varietie of pleasant Roundelays and delightful Catches of 3, 4, 5, 6, 7, 8, 9, 10 parts in one. None so ordinarie as musical, none so musical as not to all very pleasing and acceptable. London, printed by William Barley, for R. B. and H. W., and are to be sold at the Spread Eagle at the north doore of Paules," quarto, 1609. The names of none of the composers of these epigrammatic and pointed effusions have been preserved; but many of them seem of great antiquity, which is discoverable both by the words and style of composition. Great musical science is manifested in the canons, and the harmony and contrivance of the rest are excellent. The words, indeed, except those of the canons, which consist of small portions of the psalms, and other parts of scripture, in Latin, (which seems to imply that they were set before the Reformation,) are, in general, devoid of wit, humour, poetry, and common sense. Our lyric poetry, during the 16th and part of the 17th century, was in a barbarous state, and far inferior to the music of the times. But the composers seemed so little solicitous about the words they had to set, as frequently to prefer the syllables of solmisation *Ut re mi fa sol la*; *Hey down down, derry down*; or merely *Fa la*, to songs of Spenser and Shakspeare. In the same year was published another collection, entitled "Deuteromelia, or the second Part of Musick's Melodie, or melodious Musicke of pleasant Roundelays, &c. London, printed for Thomas Adams, dwelling in Paules Church-yard, at the sign of the White Lyon, 1609." This publication is much inferior to the preceding, and chiefly consists of songs for three voices, in which different stanzas are sung to the same music, after the manner of what are now called *glees*.

PAMMENOCKE POINT, in *Geography*, a cape on the north coast of New Guinea. S. lat. $0^{\circ} 24'$. E. long. $133^{\circ} 21'$.

PAMNAGUR, a town of Hindoostan, in the circar of Kitchwara; 13 miles N.W. of Burdwar.

PAMOACAN, a town of Borneo, on the east coast, near the fourth part of the island; 150 miles N.E. of Banjer-Massing.

PAMODURIE, a town of Hindoostan, in Myfore; 20 miles S. of Tademeri.

PAMPA-HERMOSA, a town of Peru, in the diocesse of Truxillo, and province of Pataz, on the west bank of the Gualaga, inhabited by Indians.

PAMPANGAN, a town of the island of Luçon, capital of a province, which is both extensive and populous. The inhabitants have, in general, adopted the religion and manners of the Spaniards. The town is situated on the east coast. N. lat. $15^{\circ} 5'$.

PAMPARA, a town of Africa, in Bambarra; 156 miles W. of Sego.

PAMPAS, a province of South America, in the viceroyalty of Buenos-Ayres, consists of vast plains, which ex-

tend from the sea-coast on the east to that great chain, which forms the beginning of the Cordilleras of Chili, about 140 leagues west from the city of Buenos-Ayres. Towards the south, they stretch about 100 leagues to a chain proceeding W.N.W. from the Atlantic. The northern boundaries are not distinctly known, but the name of Pampas is chiefly applied to the territory on the south of Buenos-Ayres, Cordova, and Mendoza. These vast plains, like the Steppes of Russia, having scarcely any elevations: the view, as at sea, is terminated by the horizon. They are only diversified with paths and ditches, which collect the rain-waters, and which commonly end in lakes, as there is no declivity; yet there are wide tracts in which no water is found, nor is that element pure; and trees are extremely rare, except a few shrubs round the lakes. Hence this region is only inhabited by a few wandering savages. The soil is generally a black earth, of little depth, and is followed by a kind of coarse white chalk, so that it is difficult to form wells, as the water can scarcely pass so tenacious a substance. The chief pasturage is clover, and, in the best parts, sometimes so strong as to resist the step of a horse: it is much liked by the cattle, which, when there is water, multiply prodigiously in the Pampas. The savages who roam through these deserts sometimes surprize Spanish caravans, and small settlements. Pinkerton.

PAMPAS del Sacramento, immense plains in Peru, lying between the Gualaga and the Maranon west and east, bounded by the Tunguragua on the north. The names "Montana Real" and Pampas del Sacramento have been confounded; whereas the former, in its strict original acceptation, implied a mountainous region of no great extent, to the east of the provinces of Tarma and Guanuco; whilst the latter has been carried to an immense extent, so as to include the vast territories on the north and south of the Maranon, as far as the line of demarcation with the Portuguese settlements. In this acceptation the medial length from the country of the Majos, S. lat. 15° , to the river Guaviari, N. lat. 3° , is 18° , or 1080 geographical miles. The breadth depends upon the Portuguese frontier, but the medium may be 10° , or 600 geographical miles.

The name of Pampas del Sacramento, plains or steppes of the holy sacrament, was imposed by the pious fathers on an enormous territory, watered by the Ucayal or genuine Maranon, and which they fondly represent as being as large as Europe; but they deserve greater credit when they inform us, that it is about 8000 leagues square, and capable of maintaining five millions of inhabitants. The recent discovery of the Pampas is chiefly owing to father Girval, who has navigated about 400 leagues south to north, and 70 west to east, on the grand and genuine Maranon, and has inspected and described the country with considerable care. He has discovered 25 nations, or rather tribes of Indians, of whom he pretends to have converted four, *viz.* the Panos, Cambos, Chipeos, and the Piros. The common deity of all the tribes he found to be the Moon; and they dread a demon, called the "Nugi," whom they regard as the author of all their calamities. In war, for the conduct of which they elect a chief of the greatest courage and cunning; and in the prosecution of their contests, the men are slain, and women and children only become captives. Some tribes are more courteous and humane; while others, as the Casivos and Carapachos, are anthropophagi. The Carapachos are about 8° S. lat., on the bank of the river Pachitea; and the Chipeos, at $7^{\circ} 35'$. Among all the nations on this part of the genuine Maranon, circumcision is practised among the men, and excision among the women. The Capanaguas, a tribe on the river Mague, dress and eat

their dead, and think this action meritorious; and yet they are one of the most humane tribes.

The Pampas del Sacramento are divided from the Sierra, or the hills of Peru, by a lofty chain, from which this vast country appears so level that it resembles the ocean. The perpetual verdure of its fields forms a delicious perspective; and for some hours in the day, there is so thick a fog on the tall trees, that the clouds seem to be under your feet. Rain and thunder are frequent. Insects and reptiles are abundant. Many of the vegetable products are rare and singular. Balsams, oils, gums, resins, incense, cinnamon, though inferior to that of Ceylon, cacao, cascarilla, and an excellent spice, called the pucheri, are very plentiful. But the warmth and humidity render a country, equal in size to an Asiatic empire, almost uninhabitable; and even the few traders on the banks of the rivers rarely see a man of the age of 50. Yet the missionaries have founded several villages. New entrances have been found to the Montana reale, Pampas, or rather great territory of Colonna, since the late missions were established. For further particulars, we refer to Pinkerton's account of recent discoveries, 1790—1800, in the 3d volume of his Geography.

PAMPËL, a town of the duchy of Courland; 24 miles S. of Goldingen.

PAMPÉLONNE, a town of France, in the department of the Tarn, and chief place of a canton, in the district of Alby; 12 miles N. of Alby. The place contains 1839, and the canton 5896 inhabitants, on a territory of 105 kilometres, in 10 communes.

PAMPHELIS, in *Ancient Geography*, a town of Asia Minor, on the confines of Pamphylia, near a mountain called "Climon." Strabo says, that it was a considerable town; and that it had three ports and a lake.

PAMPHILUS, in *Biography*, a presbyter of Cæsarea, in Palestine, is supposed to have been a native of Berytus in Phœnicia, and a descendant from a good family. Having received the rudiments of an excellent education at his native place, he went to Alexandria in Egypt, where he completed his studies, and then settled at Cæsarea. Here he became intimately acquainted with Eusebius, who has given many testimonies of his sincere respect for the memory of his friend, and added his name to his own. Pamphilus is supposed to have flourished about the close of the third century. He was possessed of such zeal for the interests of religion and sacred literature, that he founded, at a great expence, a library at Cæsarea, which contained all the most celebrated writers of the church, collected from all quarters. He was concerned with Eusebius in publishing a correct edition of the Greek version of the Seventy, from Origen's Hexapla. He was jointly concerned with Eusebius, in writing five books of "An Apology for Origen;" to which Eusebius added a sixth. He is thought, by some learned men, not only to have founded a library, but also a school or academy, at Cæsarea. Lardner, however, seems to doubt the fact; though he says, he is not prepared to contest it.

In the year 307, when the persecution raged against the Christians, Pamphilus was apprehended, and carried before Urbanus, the Roman president at Cæsarea, who, after trying his knowledge in various ways, required him to offer sacrifice. Pamphilus steadily refused to obey him, despised his threatenings, and bid defiance to his malice. In the year 309, after he had endured, with the greatest constancy, a variety of tortures inflicted upon him, he was put to death by the orders of Firmilianus, who had succeeded Urbanus in the presidency of the city. Eusebius, in speaking of Pamphilus, says, that "he was the great glory of the church of Cæsarea, and, on account of his eminent virtue,

the most renowned martyr of the age: a man, who, throughout his whole life, excelled in every virtue; in contempt and renunciation of this world, in liberality to the indigent, in disregard of all earthly honours and preferments, to which he might have aspired, and in an ablemistic philosophical course of life. But he was especially eminent, and remarkable above all men of our time, for an unfeigned zeal for the holy scriptures, and for unwearied application in whatever he undertook, whether it were kind offices to his friends, or to others who sought his aid." Dupin. Lardner. Gen. Biog.

PAMPHYLIA, in *Ancient Geography*, a considerable province of Asia Minor, and which included Pisidia, that occupied the northern part. Pamphylia was bounded on the south by the Mediterranean, and extended along the coast from mount Climax, which separated it on the west from Caria, as far as the chain of mountains which separated it on the east from Cilicia; to the north it had Phrygia. The principal towns of Pamphylia, commencing westward, were Olbia, at the mouth of the Cataractes; Perga (Karakhisar) towards the east, at a small distance from thence, on the Cestrus; Aspendus to the south-east, on the Eurymedon; Sede (Cordeloro) directly south, on the sea-coast; Cibyra (Ibuzar) situated to the north-east; Lyrbæ to the north-east; and Corybrassus on the Melas. Towards Phrygia were Tormessus (Elsenaz), a principal town of the people called Solymi, and of the small country called Cabalia; Cormosa; Cremna (Kabriacz) to the north-east; Sandalium, a fortress north-west of Cremna; Baris, south-east of Cremna, in which the Romans established a colony; Lyfinoe (Ag-Jafon), east of Cormosa; Trogitis (Egridi), south of a lake, and south-east of Cremna; Oroanda (Haviran), north of the lake; Seleucia Ferrea (Eushar), at some distance east of the lake; and Petnelissus, south-east of Selga and Catenna, upon the Eurymedon, towards the north-east. Isauria is found within the limits assigned by M. d'Anville to Pamphylia. See ISAURIA.

PAMPILHOSA, in *Geography*, a town of Portugal, in Estramadura; 34 miles N.N.E. of Thomar.

PAMPINIFORME CORPUS, or *Plexus Pampiniformis*, in *Anatomy*, the veins of the testis, which communicate and divide very frequently. See GENERATION.

PAMPLIEGA, in *Geography*, a town of Spain, in Old Castile; 12 miles S.W. of Burgos.

PAMPLONA, or PAMPÉLUNA, a city of Spain, and capital of the province of Navarre, partly situated on a little eminence, and partly in a fertile plain, on the banks of the Arga, near the Pyrenées. It is surrounded on all sides by lofty mountains, at the distance of two or three leagues. This city is said to have been built by Pompey, after the defeat of Sertorius, whence it derived the name of Pompeiopolis. It is a fortified town, and defended by two castles, one in the town and the other contiguous, though without the walls. This last place, which is the citadel, was built by Philip II.; it is strong from its situation on a rock; it has five bastions covered with stone, and good fosses; a deep marsh, of considerable extent, renders the approaches to it difficult towards the side on which it could be attacked. This citadel has a handsome tower, several magazines, a square ornamented with trees, and an armory in the centre of the fortrefs; which is round, and opens by five grand and open streets, which lead to the five bastions. Here is a hand-mill of ingenious construction, that would be useful in case of a siege; it is a large machine, composed of several wheels, which turn five grinding-stones, with as many hoppers; 120 loads, or 360 quintals of wheat, may be ground with it daily: it is turned with the hand, or

may be worked by horses. This town boasts of having been the first in Spain which received the light of the gospel; its bishopric, one of the most ancient in Spain, was re-established after the expulsion of the Moors; it is suffragan to Burgos. The chapter of the cathedral comprehends twelve dignitaries, as many canonries, and forty-four prebends and chaplaincies. There is another chapter in the same cathedral. This town is the residence of the viceroy of Navarre. Its population consists of about 2800 families, composed of nearly 14,000 persons, occupying 1632 houses. In this capital of Navarre the flutes held their fittings. The college for the instruction of youth is an university, founded in 1608. Pampeluna contains a cathedral, three parishes, nine convents of monks, and two of nuns.

The city itself is confined and ill-built, but its streets are kept remarkably clean. There are some squares, two of which have tolerably handsome houses, particularly that which is appropriated to bull-fighting. The town is destitute of agreeable society, which some have ascribed to the severity of the police. The commerce consists merely of imports, and its manufactures are few and inconsiderable. Those of parchment and of leather, and another of coarse cloth, are of little importance; here also they make common earthenware, and blanch wax, which they import; 78 miles N.N.W. of Saragossa, and 172 N.N.E. of Madrid. N. lat. 42° 50'. W. long. 1° 46'.

PAMPLONA, or *Pampeluna*, a town of South America, in the new kingdom of Granada; having in its vicinity gold mines; 170 miles N.N.E. of Santa Fé de Bogota. S. lat. 6° 30'. W. long. 71° 36'.

PAMPUS, a channel between the Zuyder see and Amsterdam.

PAMPUS, in *Ichthyology*. See *STROMATEUS Paru*, and *CHÆTODON Glaucus*.

PAMUCHLEN, a name by which some call the species of cod-fish, commonly named by authors *afellus striatus*. See *GADUS Callarias*.

PAMUNKY, in *Geography*, the ancient name of York river, in Virginia; but now restricted to the southern branch formed by the confluence of the N. and S. Anna. This and the northern branch, Mattaponi, unite and form York river, just below the town of De la War.

PAN, in *Mythology*, the son of Mercury and Penelope, and the deity who presided over huntsmen, shepherds, and those whose occupations led them to frequent the fields. The fable says, that Mercury transformed himself into a he-goat to please Penelope; and to this circumstance is attributed the origin of his horns and cloven feet, as well as the whole tribe of fauns and satyrs. He is called *Pan*, Πᾶν, it is said, because Penelope, in the absence of Ulysses, granted favours to all her lovers, and Pan himself was the fruit of this intercourse. However, Epimenides says, that he was the son of Jupiter and Calista; others say, that he was the son of the Air and a Nereid, or of the Heaven and Earth. He is commonly represented with a shepherd's crook, and a kind of flute, with many pipes. He was particularly revered among the Arcadians, to whom he issued oracles, and who celebrated, in honour of him, the Lupercalia. Evander carried the worship and feasts of Pan to Rome.

The Egyptians give a different account of this deity. According to them, he was one of the generals of Osiris, who engaged with Typhon; and whose army being situated in a valley, all the avenues of which were guarded by the enemy, he ordered the soldiers in the night to march with loud exclamations, which being returned in echoes, terrified the enemy, and put them to flight; whence they say comes the expression of *panic* terror. But Bochart pretends that there

is no other reason for making Pan the author of those terrors, except that the Hebrew word Pan or Phan, denotes a man under consternation. Diodorus Siculus says, that Pan was so much honoured by the Egyptians, that his statues were to be seen in all the temples, and that to his honour they had built in Thebais the city of Chemmis, that is, the city of Pan. This author, who takes no notice of Mendes in Lower Egypt, where that god was in high veneration, adds, that he had accompanied Osiris in his expedition to the Indies, together with Anubis and Macedo. We do not learn from Herodotus why the Egyptians represented the god Pan under the figure of a goat; but ancient mythologists assure us, that they were induced to do this, because Pan, having found the gods in Egypt, whither they had fled from the giants, advised them, as the means of preventing their discovery, to clothe themselves with the figures of different animals; and as a pattern to them, he himself assumed that of a goat. Upon the whole, all the Greek fables relating to Pan are said to amount to these particulars: that he was one of the greatest gods of Egypt; that he was honoured especially at Mendes; that his worship was brought into Greece by the Egyptian colonies; that he became more remarkably famous in Arcadia; that Evander made him known in Italy, where he came and settled with his colony some years before the Trojan war; and that at last the worship of this god was received at Rome with the festivals which were celebrated to his honour. Polyænus attributes to Pan the invention of the order of battle of the phalanx, and of the distribution of an army into the right and left wings, or horns, whence, it is said, he derived his horns. The name Pan, which signifies *all*, has led some to make him the symbol of nature.

Diodorus makes Pan one of the attendants upon Osiris in his Indian expedition. The same author, however, tells us, that he was the leader of a troop of fauns and satyrs, or wild and rustic men, much addicted to singing, dancing, and feats of activity, who were presented to Osiris in Ethiopia; and with whom that prince was so much pleased, that he retained them in his service.

Pan was the inventor of the instrument called the syrinx, or fistula; which invention has given birth to a fable in Ovid's *Metamorphoses*.

A nymph of late appear'd, as Dian chaste,
Whose beauteous form all other nymphs surpass'd;
The pride and joy of fair Arcadia's plains,
Belov'd by deities, ador'd by swains,
Syrinx her name; by Sylvans oft pursu'd,
As oft would she the wanton gods delude.

Descending from Lycæus, Pan admires
The matchless nymph, and burns with new desires.
A crown of pine upon his head he wore,
And vainly strove her pity to implore:
For ere he could begin, she took her flight,
And, wing'd by fear, she soon was out of sight,
Nor stay'd to hear the courtship of the god,
But bent her course to Ladon's gentle flood;
There by the river stopt, and tir'd before,
Relief from water-nymphs her pray'rs implore.
Now while the am'rous god, with speedy pace
Just thought to strain her in a fond embrace,
He fills his arms with reeds, new rising on the place. }
And while he fights, his ill-succes to find,
The tender canes were shaken by the wind;
And breath'd a mournful air, unheard before,
Which greatly Pan surpris'd, yet pleased him more.

Admiring

Admiring this new music, Thou, he said,
Who can't it not be the partner of my bed,
At least shalt be the comfort of my mind,
And often, often, to my lips be join'd!
The tuneful reeds he form'd, and wax'd with care,
Which still retain the name of his ungrateful fair.

Dryden.

Pan was regarded by the Egyptians, after his apotheosis, as the god who presided over the whole universe, as Παν, *omne*, implies. He represented nature and fertility, and was god of the woods and fields, wholly taken up with the pleasures of a country life; dancing constantly with the fauns and satyrs, and running after the nymphs, to whom he was such a terror, that it is supposed by some the word *panic* is derived from *panici terrores*, with which those who were said to have seen him were seized. Apuleius, however, gives an agreeable description of him. "By chance the god, Pan, happened to be seated on a little eminence near a river, and, always constant in his love to the nymph Syrinx, transformed into a reed, he taught her to produce all kinds of agreeable sounds, while his goats were skipping round him, and feeding on the banks."

Lucian describes him as the companion, minister, and counsellor of Bacchus, a servant of *all work*: having been occasionally employed in the capacity of shepherd, musician, dancer, huntsman, and soldier. In short, he served not only as maestro di cappella, to direct the Bacchanals, but was so expert in playing upon flutes, and was such an excellent piper on the fistula, that Bacchus was never happy without him. We have the authority of the grave Virgil, and of the sentimental and pious Plato, for his attributes. Pausanias Corinth. cap. 22.

PAN, in *Agriculture*, a term applied to the bed or flooring upon which the cultivated soil lies or is placed. Mr. Marshall, in speaking of the Norfolk soils, remarks, that "immediately under the cultivated soil, a hard crust, provincially 'the pan,' occurs universally. And under this substratum of various qualities an unfathomable ocean of sand may be considered as the prevailing substratum. In some places a hungry gravel, but more frequently an absorbent brick-earth is the immediate subsoil."

And that "marle sometimes rises to near the surface, but seldom so high as the pan. This seems to be universally considered as a distinct something, poisonous in its nature, and partaking neither of the soil nor the subsoil. It is not his intention to ridicule this received opinion; it may be well founded; but to him the pan appears to be a production, not of nature, but of art, or, to speak more accurately, a consequence of the Norfolk culture carried on time immemorial with the Norfolk plough, whose broad flat share, being held invariably in a horizontal position, and (unless in following) invariably at the same depth, the surface of the subsoil becomes formed by the action of the share, the pressure and sliding of the heel of the plough, and the trampling of the horse, into a firm even floor, upon which the soil is turned and returned in the same manner, it would be, if spread on a floor of stone, or other material. But, be this as it may, and whether the pan is a natural or a fictitious production; it is a fact well established, that breaking it up for ploughing below the accustomed depth is very injurious to succeeding crops." And further, that "two reasons may be offered in explanation of this effect; the pan, year after year, and perhaps century after century, has been a receptacle of the seeds of weeds, which, by being trodden, or otherwise pressed into it, have remained there, locked up from the sun and air, and thereby deprived of the power of vegetation. But no sooner are these seeds re-

leased from their confinement, by being brought to the surface with the plough, than they vegetate in myriads to the annoyance of the crop. The other reason is this,—the firm close texture of the pan renders it in a degree watertight, it is at least a check to the rain-water which sinks through the soil, prolonging its stay in the sphere of vegetation. But the pan being broken, the filter is no more: and the rain, which is not immediately retained by the soil, escapes irretrievably into an insatiable bed of sand, or some other absorbent subsoil."

It must, therefore, in many cases of tillage, be highly injurious to break or destroy this crusty layer, which preserves the manures, and contributes much to the production of good crops of different kinds.

PANA, in *Geography*. See PUNA.

PANACA, a burning mountain on the W. coast of New Mexico.

PANACEA, in *Medicine*, from παν, *all*, and ακιουσι, *I cure*, signifies an universal remedy, or one that is capable of curing all diseases.

Among the old practitioners, with whom the discovery of new drugs was often a pursuit of greater interest, than the investigation of pathology, several medicines were esteemed worthy of this appellation. But it is sufficient to take a very superficial view of the various organs subject to disease, of the various kinds of disease that affect the same organ, and of the various ages and constitutions of different individuals, as well as of the different agency of the causes of disease, *e. g.* high living and starvation, sloth and hard labour, cold and heat, the various species of contagion, marsh effluvia, and other morbid exhalations, and the various poisons, animal, vegetable, and mineral, which are deleterious to the animal frame,—it is sufficient to glance at these ever-varying circumstances which necessarily modify the nature of diseases, in order to be satisfied of the absurdity of the attempt to cure them all by one remedy. The pretenders to *panaceas* are, therefore, only found at present among empirical impostors.

PANACEA, *Panaces*, or *Panax*, *all-heal*, is also applied to several plants, by reason of the extraordinary virtues ascribed to them.

There are three of the panaceas peculiarly famed among the ancients: the *Heraclean*, *Asclepien*, and *Chironian*: these were so called from their inventors Hercules, Asclepias, and Chiron.

The first is the *panax Heraclea vera ficulnea folio*, in English, *true all-heal of Hercules*. From the root and stem of this is drawn, by incision, the gum opopanax.

The *Asclepien*, according to some botanists, is a kind of ferula, which Cas. Bauhinus call *Libanotis ferrule folio & semine*.

The *Chironian*, according to some, is a kind of helianthemum: according to Bradley, it is Doria's woundwort.

PANACEA, in *Mythology*, one of the divinities of medicine, the pretended daughter of Æsculapius, to whom were rendered divine honour, as well as to his other children, Hygeia, Thelephorus, and Jaso.

PANACMUS, in *Biography*, a musician, quoted by Aristides Quintilianus, whose definition of music agrees entirely with that of the Chinese. "Music (he said) was not only the order and arrangement of sounds proper to regulate the voice, but was likewise the regulator of all the harmony of nature." See *CHINESE Music*.

PANADA, PANATA, or *Panarella*, a diet consisting of bread boiled in water to the consistence of a pulp; given to sick persons whose digestion is weak, or to whom stronger food would be improper.

The

The word is formed from the name of the principal ingredient *panis, bread*.

It is sometimes made thin, to serve as drink; and sometimes, likewise, is sweetened, &c. to render it more palatable.

PANADOU, or MANADOU, in *Geography*, a bay on the coast of cape Breton island, near the S. part of the gulf of St. Laurence.

PANÆI, in *Ancient Geography*, a people of Thrace, in the environs of Amphipolis. They formed a part of the Hedoni, according to Steph. Byz. and Thucydides.

PANÆTIUS, in *Biography*, a celebrated philosopher among the Stoics, who flourished in the second century before Christ, was a native of Rhodes, and descended from ancestors who had distinguished themselves in the military transactions of the republic. His inclination leading him to the study of philosophy, he became a disciple of Antipater of Tarsus, but did not at this time approve the doctrines of the Stoics. He was a great admirer of Plato, whom he called divine, most wise, and most holy, and he freely borrowed opinions and sentiments from philosophers of every sect. From Rhodes he went to Athens, where he maintained the reputation of the school of Zeno, and had many disciples. His fame having reached Rome, he went thither; his lectures were crowded by the young nobility; and he enjoyed an intimate acquaintance with several eminent Romans, particularly Scipio and Lælius. According to some writers he accompanied Scipio in some of his expeditions, and is said to have rendered him essential services; he at the same time employed his interest with this great man in conferring various benefits on his fellow citizens at Rhodes. Panætius appears to have spent the latter part of his life partly at Athens, and he died at the last-named city, but it is not at all certain in what year. None of his works have come down to us; but his moral doctrines were, doubtless, very excellent, since they are greatly extolled by Cicero, in his treatise "De Officiis." Cicero. Enfield's Hist. Phil.

PANAGE, or PANNAGE, in our *Ancient Customs*. See PANNAGE.

PANAGIA, in *Geography*, a small island in the Grecian Archipelago, scarcely a league in circumference; 16 miles N.W. of Santorin. N. lat. 36° 39'. E. long. 25° 5'.—Also, a town of European Turkey, in Romania; 14 miles N. of Gallipoli.

PANAGRA, in *Ancient Geography*, a town of Africa, in Libya Interior, upon the northern bank of the Niger. Ptolemy.

PANAGUR, in *Geography*, a town of Hindoostan, in Gurry Mundella; 10 miles N. of Gurrâh.

PANAIA, a town of Naples, in Calabria Ultra; 4 miles N. of Nicotera.

PANAMA, or *Tierra Firmé Proper*, a province of South America, in the viceroyalty of New Granada, bounded on the N. by the Spanish main, on the E. by the province of Darien, on the S. by the Pacific ocean, and on the W. by Ve-agua. The towns and villages of this province are mostly situated in small plains along the shore, the other parts of the country being covered with enormous and craggy mountains, which are sterile, and of course uninhabited. In this province are three cities, twelve villages, and a great number of rancheiras or assemblages of Indian huts. Its gold mines are neglected by the Spaniards, who derive greater profit from the pearl fishery, which has engrossed their attention, though this species of traffic is almost abandoned.

PANAMA, the capital of the fore-mentioned province, is a city and sea-port, built on the isthmus of Darien, at the

bottom of a large bay of the Pacific ocean. The first discovery of Panama is ascribed to Tello de Guzman, who landed here in the year 1515, when he found only fishermen's huts, and from its peculiar appropriation to this business, it was called "Panama," denoting a place abounding with fish. In 1518, a colony was established here under Pedrarias Davila, governor of Terra Firma, and in 1521 this place was constituted a city. In 1670 it was taken and burned by the English adventurer, John Morgan; and afterwards rebuilt in its present situation, which is much more convenient, about 1½ league from the former. Being at first generally constructed of wood, it was almost wholly destroyed by fire in 1737, and again rebuilt chiefly of stone. Panama was the seat of a royal audience, abandoned in 1752; and by the fire in 1756, and a decline of commerce, it was reduced to a miserable situation. Nevertheless it is still a strong city, the see of a bishop, and contains several churches and convents. The harbour of Panama is formed in its road under the shelter of several islands, where ships lie safe, at the distance of about 2½ or 3 leagues from the city. After its fall by the loss of the galleons, it was almost completely ruined by a dreadful conflagration in 1784. Its only remaining trade is with the villages in its jurisdiction, and with the province of Veragua, the goods being received by Portobello, mostly from Carthagena: the vessels from Peru commonly return empty. The neighbouring mountains produce excellent wood, especially the most esteemed mahogany (caoba), and cedar, with many precious balsams. The spirit of trade ridiculously maintains itself, as the chief inhabitants of both sexes sell baubles and trifles by means of their slaves. The royal chest is so poor, that it cannot even pay the garrison, which is now defrayed from Carthagena. The trade with Guayaquil is maintained by an easy and short voyage; the passage of the line being rather accompanied with calms, while in the Atlantic it is esteemed dangerous. This circumstance, as Pinkerton suggests, may have led to the name of the Pacific ocean, given by the Spanish conquerors of Mexico and Peru, before Magalhaens had felt its tempests. N. lat. 8° 58' 12". W. long. 80° 15' 15".

PANAMA Shell, in *Ichthyology*, a species of dolium.

PANAMA, in *Geography*, one of the Philippine islands, about 15 miles in circumference, of a triangular form. N. lat. 11° 27'. E. long. 124° 15'.

PANAMARIBA, a river of Guiana, which runs into the Atlantic, N. lat. 6°.

PANAMGOODY, a town of Hindoostan; 25 miles S. of Tinevelly.

PANAMOS, a mountain of Peru, in the diocese of Truxillo; being part of the Andes.

PANAMGOODY, a town of Hindoostan; 18 miles S.E. of Madura.

PANAON, one of the Philippine islands, about 45 miles in circumference, mountainous, but watered with many streams; thinly inhabited. N. lat. 10° 7'. E. long. 125° 12'.

PANAOUÏTICK, a river of Canada, which runs into the Saguenay, N. lat. 48° 24'. W. long. 70° 55'.

PANARA, in *Ancient Geography*, a town of Arabia Felix, in the isle of Panchæa. Diod. Sic.

PANARAGA, in *Geography*, a town of the island of Java, and capital of a kingdom, situated on the southern side of the island; 60 miles E. of Mataran.

PANARCOUCHI, a town of Hindoostan, in the Carnatic; 16 miles from Cuddalore.

PANARD, CHARLES FRANÇOIS, in *Biography*, an ingenious French poet, was born about the year 1690, at Courville, near Chartres. He became distinguished as a

writer

writer for the stage, and produced a number of dramatic pieces of the light and humorous kind, which were in general well received, and some of them are still represented in the French theatre. His satire was never personal, but was directed against vice and folly in general, without making the application to individuals. His works are stamped with facility, nature, sentiment, wit, and good sense; but they are often negligent, prolix, and incorrect. He was uneducated, and drew all from his own sources. He died at an advanced age, in 1765. His works were printed at Paris, in 4 vols. 12mo. in 1763, under the title of "Theatre et Œuvres diverses de M. Panard."

PANARIA, in *Geography*, a town of Prussia, in Oberland; 5 miles S. of Liblitz.—Also, one of the Lipari islands, between Lipari and Stromboli. N. lat. 38° 40'. E. long. 15° 21'.

PANARIS, or PANARITUM, formed probably of *παρονοια*, *q. d.* an abscess at the root of the nails, derived from *παρη*, *juxta*, and *ονυξ*, *unguis*, a word used by some authors to express a whitlow, or *paronychia*.

PANARO, in *Geography*, a river of Italy, which rises in the S. part of the duchy of Modena, and runs into the Po near Bondeno, in the Ferrarese. It gives name to a department of Italy, composed of the duchy of Modena, with Mirandola, containing about 211,448 inhabitants, who elect 15 deputies. Its capital is Modena.

PANARUCAN, or PANAROCAN, a town of the island of Java, on the N. coast, and capital of a kingdom of the same name, near the eastern part of the island. The principal commerce consists of slaves and long pepper. Many of its inhabitants are Portuguese. S. lat. 7° 30'.

PANASA, or PANASSA, in *Ancient Geography*, a town of India, on this side of the Ganges, and on its bank. This is the *Pannab*, or *Parna*, which see. Ptolemy.

PANASNESTI, in *Geography*, a town of Turkish Armenia; 28 miles N.W. of Cars.

PANAT, a town of France, in the department of Aveyron; 17 miles S. of Rhodéz.

PANATELLAH, a town of Hindoostan, in the circuit of Ruttunpour; 40 miles N.W. of Ruttunpour.

PANATHENÆA, *παναθηναια*, in *Antiquity*, a feast celebrated at Athens in honour of Minerva, whom the Greeks called *Athena*.

Harpocration and Suidas refer its institution to Erichthonius IV. king of Athens, who lived before Theseus. Theodoret, alone, says the feast was established by Orpheus.

Be this as it will, till Theseus, this was a particular feast of the city of Athens, and was called simply *Athenæa*: but that prince uniting all the people of Attica into one republic, they afterwards all assisted at the feast; whence the name panathenæa, *i. e.* the feast of all Attica.

In effect all Attica was present; and each people sent a bullock for the sacrifices, and for the entertainment of the vast multitude of people assembled. At first it lasted only one day, but to add to its solemnity, it was continued afterwards for several days.

There were two kinds of Panathenæa; the *great*, celebrated every five years; and the *little*, every year, or every three years; if we may credit the author of the argument of Demosthenes's oration against Midias.

The ceremonies were the same in the great and the little Panathenæa; excepting for a *peplus* or banner, on which the actions of the goddess were represented in embroidery performed by maids, with the names of those who had distinguished themselves in the service of the republic; which was only borne at the greater. See PEPLUS.

PANATHENÆAN GAMES. See GAMES.

PANAUR, or PONEAUR, in *Geography*, a river of Hindoostan, which rises near Ouscotta, in Mysore, and runs into the bay of Bengal, near Cuddalore.

PANAX, in *Botany*, a name borrowed from the old Greek botanists, whose *παναξ*, or *πανακνι*, was so denominated from *παν*, *all*, and *ακος*, *a medicine*, because of its abundant virtues, and appears by the account in Dioscorides, to have been a broad-leaved umbelliferous plant, though modern writers are not agreed respecting the species. The name therefore being unoccupied, Linnæus very happily adopted it for the Chinese Ginseng, that famous restorative and panacea, whose reputed virtues certainly yield in no respect to the ancient *παναξ*, and which is moreover of the umbelliferous order. Linn. Gen. 554. Schreb. 740. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 448. Juss. 218. Lamarck Dict. v. 2. 713. Illustr. t. 860. Michaux Boreal. Amer. v. 2. 256. Class and order, *Polygamia Dioecia*, or rather perhaps *Pentandria Digynia*. Nat. Ord. *Umbellata*, Linn. *Umbellifera*, Juss.

Gen. Ch. *Cal.* Umbel equal, close. Involucrum of several, small, awl-shaped, permanent leaves. Perianth very small, superior, five-toothed, permanent. *Cor.* universal, uniform; proper of five oblong, equal, recurved petals. *Stam.* Filaments five, very short, deciduous; anthers simple. *Pist.* Germen roundish, compressed, inferior; styles two, erect, small; stigmas simple. *Peric.* Berry heart-shaped, umbilicated, of two cells. *Seeds* solitary, heart-shaped, acute, slightly convex.

Male flowers only are found on a separate plant, in more globose umbels, with larger leaves to the involucrum, a turbinate, coloured, entire perianth to each flower, and longer filaments, which, as well as the petals, are inserted into the perianth.

Eff. Ch. Umbel of many rays. Berry compressed, with two seeds. Petals five, equal, recurved. Calyx five-toothed. Male flowers on a separate plant; their calyx entire.

Obs. This is the only known genus of the true digynous umbelliferous tribe, whose fruit is pulpy. That very natural order is so liable to occasional variations in the organs of impregnation, or, in other words, so many of its genera or species are, more or less constantly, polygamous, that it is desirable they should all be kept together in the *Pentandria Digynia*, to which they properly belong, notwithstanding that difference of structure, which is said to exist between the calyx of the male and that of the perfect flowers. Bernard de Jussieu remarked that there are sometimes three styles and three seeds; and his nephew refers *Panax* to his order of *Aralia*, as does Linnæus to his own, nearly equivalent, order of *Hederacea*. A. de Jussieu moreover suspected that *Cussonia*, of which he knew nothing but from description, was not generically distinct from *Panax*, but we find no authority for believing the fruit of the former to be pulpy, though described in Linnæan language as *dicoccus*, or two-lobed. The smooth, very juicy, and usually beautifully coloured berries of *Panax*, are peculiar and characteristic.

1. *P. quinquefolium*. Gin-seng. Linn. Sp. Pl. 512. Woodv. Med. Bot. t. 99. (*Araliastrum foliis ternis quinquepartitis*; Trew. Ehret. t. 6. f. 1. *Aureliana canadensis*; Lafitau Gin-seng, t. 1.)—Leaves three together, quinate; leaflets stalked. Stem herbaceous.—Native of Chinese Tartary, and of various parts of North America, in mountainous woods. The celebrated Peter Collinson procured it alive from the last mentioned country, in 1740. The plant is perennial, flowering with us in June, but not readily increased, nor preserved without care, in our gardens. The root is spindle-shaped, but mostly divided or branched, pale and yellowish,

PANAX.

of a mucilaginous, sweetish, slightly aromatic, and rather bitterish, flavour. *Stem* herbaceous, erect, round, simple. *Leaves* terminal, three together, on longish stalks; each of five, stalked, very unequal, obovate, pointed, serrated, smooth, veiny leaflets. *Flower-stalk* terminal, between the leaves, solitary, erect, simple, shorter than the footstalks, bearing a simple umbel of several small white flowers, each flower succeeded by a kidney-shaped, or heart-shaped, scarlet berry. For the medical history of this celebrated root, and the mode of procuring it, see GINSENG; where for *Panax* read *Panax*. See also NIXSI and SIUM.

2. *P. trifolium*. Lesser American Gin-seng. Linn. Sp. Pl. 512. (*Aralia* *foliis ternis tripartitis et quadripartitis*; Trew Ehret. t. 6. f. 2. *Nasturtium marianum*, *anemones sylvaticæ foliis enneaphyllon*, *foribus exiguis*; Pluk. Mant. 135. t. 435. f. 6.)—Leaves three together, ternate or quinate; leaflets nearly sessile. *Stem* herbaceous.—Native of North America. Michaux found it at New York, and in Pennsylvania. Miller is said to have had it alive, but never saw the flowers. We received a living specimen from the curious garden of J. Vere, esq. Knightbridge, in May 1811. This plant differs from the former chiefly in being much smaller, the leaflets nearly sessile, and usually only three to each leaf; but the last character is variable, there being very often two small lobes, occasionally becoming distinct leaflets, at the base of the others. Linnæus suspected this to be a variety, or perhaps a male plant, of the true Gin-seng, nor is it improbable that weak plants of that species, perhaps the first season of their flowering, may produce male blossoms only, not having strength to perfect both organs of fructification. There is reason to think the American Gin-seng, when in its full vigour, is of an inferior quality to the Chinese, if indeed it be the same plant, which the observations of father Loureiro, *Cochinch.* 656, render doubtful. He had received the seeds from Tartary, but they did not vegetate. He describes the "fruit as containing seven or eight roundish, umbilicated seeds, rather larger than a peppercorn, brown and of a liony substance." This is totally foreign to the characters of our *Panax*.

3. *P. spinosum*. Spinous Tree Gin-seng. Linn. Suppl. 441. (*Aralia pentaphylla*; Thunb. Japon. 128. Kiôh, vulgo Dara; Kämpf. Amoen. 895?)—Leaves clustered, quinate, crenate. *Stem* arboreous, with solitary spines. *Umbels* lateral, simple. Gathered by Thunberg between Miaco and Quana, and near Jedo, in Japan. A specimen given by him to the younger Linnæus is what the latter described as *P. spinosa*, though Thunberg, who describes neither the pistils nor the fruit, refers the plant to *Aralia*, perhaps on the authority of Kämpfer, who speaks of the seed-vessel as the size of Coriander, with five cells, each of which contains one seed, not unlike that of Flax. We presume this author's synonymy is misapplied, for it must belong to a real *Aralia*. Our specimen has every where but two styles, so that, though the fruit is in no state of forwardness, we must conclude it to have but two seeds. The stem is said by Thunberg to be arboreous and prickly. The branches are round, leafy, with a smooth greyish bark, and furnished with scattered, sharp, horizontal prickles, or rather as they appear to us spines proceeding from the wood, half an inch long. Leaves three, four, or more, from each bud, on smooth footstalks, from two to five inches long, each composed of five slightly stalked, obovate, acute, smooth leaflets, from one to nearly two inches long; unequally crenate upwards; tapering much, and entire, at their base. *Umbels* solitary, stalked, simple, from the same bud with the leaves, much shorter than their footstalks, each of numerous

flowers, on slender partial stalks, with but small traces of an involucre. *Calyx* with five reflexed teeth. *Petals* ovate, reflexed. *Stamens* longer than the petals. *Germen* ovate-oblong. *Styles* two; in some flowers but half the length of the petals, first slightly divaricated, then incurved, with capitate stigmas; in others longer than the petals, erect, parallel, straight, with acute, slightly spreading stigmas. One flower in our specimen has a style of each description. The former are probably abortive, as far as we can judge from other umbelliferous plants. Thunberg says this species flowers in May and June. The corolla appears to be white. Nothing could have determined this plant to be that of Linnæus, except the authority of an original specimen; for the difference between these writers, as to the genus and order, implies that they had counted the styles.

4. *P. arboreum*. Serrated Tree Gin-seng. Forst. Prodr. 75. Linn. Suppl. 441.—Leaves fingered; leaflets stalked, strongly serrated. *Stem* arboreous. *Umbels* compound.—Gathered by Forster in New Zealand. The stem is arboreous. *Leaves* alternate? on stout footstalks four inches or more in length, composed of five, six, or seven, spreading, unequal, elliptical or obovate, acute, smooth, coriaceous leaflets, each from two to four inches long, and supported by a partial stalk an inch in length. *Umbels* large, compound and proliferous, of numerous, spreading, smooth rays. *Calyx* wavy, very slightly toothed. We find scarcely any traces of general or partial involucre, nor have we seen the fruit.

5. *P. undulatum*. Wavy Tree Gin-seng. Aubl. Guian. 949. t. 360.—Leaves fingered; leaflets stalked, undulated; downy and rusty beneath. *Stem* arboreous. *Umbels* panicled.—Gathered by Aublet in Cayenne, Hispaniola, and the spacious forests of Guiana, bearing half-ripe fruit in the month of May. The French call it *Arbre de Mai*, or *de St. Jean*; the Indians *Morototoni*, which last word is retained as the specific name in Aublet's letter-press, though not in his plate. The trunk rises to the height of 100 feet, though only two feet thick, with a whitish bark, and a white light spongy wood. The branches are all at the summit, spreading in a round head, leafy at their extremities. *Leaves* alternate, stalked, of about eight stalked leaflets, much resembling the last, except that they are strongly undulated, not serrated, and their under side is clothed with soft dense tawny down. The largest are eight inches long. *Umbels* alternate, collected into large panicles about the ends of the branches, with an ovate rigid bractea at the base of each partial stalk. *Styles* two. *Fruit* sometimes of three lobes. Aublet saw it but half ripe. Every part of the plant is aromatic.

6. *P. attenuatum*. Taper-pointed Tree Gin-seng. Swartz Ind. Occ. 562.—Leaves fringed; leaflets stalked, ovate, crenate, with taper points. *Stem* arboreous. *Umbels* panicled.—Native of mountainous woods in the islands of Guadeloupe and St. Christopher. A tree 40 feet high, with round, smooth, unarmed branches. *Leaves* alternate, on stalks a foot long, whose base is dilated into an ovate, pointed, sheathing intrafoliaceous stipula, such as may be observed in other arboreous species of this genus, as well as of *Aralia*; the leaflets are five, rarely only three, on partial stalks from one to two inches long, broad-ovate, smooth, wavy and crenate, about three inches long, with a taper point more than half that length; their under side pale, with one central rib, and numerous straight transverse ones, connected by reticulated veins. *Umbels* very numerous, on long, racemose, imperfectly whorled stalks, which stalks are themselves collected, about five together, into one large but

imperfect umbel, at the top of each branch. Partial involucre of several minute, awl-shaped, deciduous leaves, like the bracteas. Calyx with five small teeth. Petals ovate, acute. Stamens five. Styles two, rarely three, combined. Stigmas spreading, obtuse. We have not seen the ripe fruit. Swartz thought it a berry; but we rather suspect that he, like ourselves, had only seen dried specimens, and that it is by mistake he terms this plant a shrub.

7. *P. fruticosum*. Shrubby Compound-leaved Gin-feng. Linn. Sp. Pl. 1513. (Scutellaria tertia; Rumph. Amboin. v. 4. 78. t. 33.)—Leaves triply pinnate; leaflets stalked, lanceolate, fringed with slender teeth. Stem shrubby. Umbels paniced.—Native of the island of Ternate, from whence, according to Rumphius, it was brought to Amboyna. This is a shrub, about six feet high, used in its native climate for hedges. The leaves somewhat resemble parsley, whence the Dutch call it Tree Parsley. They are repeatedly compound, their leaflets lanceolate, acute, fringed with slender, almost spinous, teeth. Umbels irregularly collected into panicles. Styles two, rather spreading. Berries purple, resembling those of Juniper. The whole plant has a strong aromatic parsley-like flavour.

8. *P. aculeatum*. Prickly Shrubby Gin-feng. Ait. Hort. Kew. ed. 1. v. 3. 448. L'Herit. Stirp. Nov. v. 2. t. 99, unpublished. (Zanthoxylum trifoliatum; Linn. Sp. Pl. 1455.)—Leaves ternate; leaflets stalked, crenate. Footstalks and branches prickly. Stem shrubby.—Native of China. Dr. Fothergill is said to have cultivated this shrub in 1773, and it existed in the English or French stoves about 1788, when L'Heritier had a figure taken; but we have never met with a living specimen. The stem is shrubby. Branches round, smooth, with a solitary hooked prickle under the insertion of each footstalk. Leaves alternate, their common stalks an inch and half long, with a small recurved prickle at the top; leaflets three, broadly obovate or elliptical, an inch long, on short partial stalks, smooth, crenate or somewhat ferrated. Umbels on simple stalks, longer than the footstalks, usually several together at the extremity of each branch, simple, of numerous rays. Involuerum of many minute downy leaves. Calyx with five short broad teeth. Stamens twice the length of the petals, with large white anthers. Styles two, short, at length recurved, with downy stigmas.

9. *P. simplex*. Simple Lanceolate-leaved Gin-feng. Forst. Prodr. 75. Mart. Mill. Dict. n. 9.—Leaves simple, alternate, lanceolate, ferrated. Umbels compound.—Gathered by Forster in New Zealand. We know nothing of this species but what is given in his *Prodromus*.

10. *P. horridum*. Palmate Prickly-leaved Gin-feng.—Leaves simple, alternate, palmate, ferrated, with prickly ribs. Stem shrubby, very prickly.—Gathered by Mr. Archibald Menzies, at Nootka Sound, on the west coast of North America. The branches are round, leafy, hispid, beset with innumerable yellow prickles, most crowded about the insertion of each leaf. Leaves on long, furrowed, prickly, somewhat downy footstalks, heart-shaped, a span wide, deeply lobed, sharply cut and ferrated, of a fine green; smooth and veiny above; paler beneath, their veins hairy and beset with numerous, yellow, prominent prickles. Flowers numerous, in a terminal hispid cluster or spike, shorter than the leaves, whose lower branches are much elongated, imperfectly umbellate, bearing many crowded yellowish flowers, chiefly male, their stamens being large and conspicuous, their styles small or deficient. The upper part of the cluster consists of crowded, imperfectly umbellate, female flowers, each with two rather spreading styles, and blunt simple stigmas,

but few or no stamens, unless the latter have fallen off early, which seems to have been the case with the petals. Fruit nearly orbicular, pulpy, crowned with the permanent styles. Seeds angular.

We have seen sketches from New South Wales of what appears to be another species of *Panax*, different from all the foregoing, with compound, elder-like leaves, and beautiful blueish berries, of which no doubt we may expect an account in the sequel of Mr. Brown's *Prodromus*.

PANAX, in *Gardening*, contains plants of the herbaceous and shrubby perennial kinds, of which the species cultivated are; the gin-feng (*P. quinquefolia*); the three-leaved panax (*P. trifolium*); and the prickly panax (*P. aculeata*).

Method of Culture.—The first and second sorts are increased by sowing the seeds procured from abroad upon a moderate hot-bed, or in pots plunged into it, in the early spring season; and when the plants have acquired a few inches in growth, removing them into beds or borders where the mould is good, and the situations sheltered.

The third sort is increased by layers or cuttings, laid down or planted out in the summer months in pots, and plunged into the bark-bed of the stove. When they have stricken root, they may be removed into separate pots, and be constantly kept in the stove.

The two first sorts afford variety in the borders, and the last among stove collections.

PANAY, in *Geography*, one of the Philippine islands, of a triangular form, about 180 miles in circumference, populous and fertile, and abounding in rivers. The chief article of exportation is rice. The Indians tributary to the Spaniards amount to about 17,000. N. lat. 11° 15'. E. long. 122° 33'.

PANAYAS, a town of Portugal, in Alentejo; six miles N.W. of Ourique.

PANCALA AUREA, a name of a famous antidote composed of many ingredients, described by Myrepsus.

PANCALE, or PANCALIER, in *Geography*, a town of France, in the department of the Po, on the Po; 12 miles S. of Turin.

PANCARPIA, the name of a sort of cake much used at Alexandria, and usually covered with paper for the sake of its keeping the longer.

PANCARPUS, in *Antiquity*, a sort of spectacle or show, which the Roman emperors frequently exhibited to the people.

The word is formed from the Greek παν, all, and καρπος, fruit. Whence the name was also given by the Athenians to a sacrifice, in which all kinds of fruits were offered.

The pancarpus of the Romans was a kind of chase, or hunt: for the performance hereof, a number of beasts, as hares, deer, bullocks, &c. were shut up in the circus, or amphitheatre; into which trees were frequently transplanted, so as to form a kind of forest, wherein the beasts were let loose; whence the pancarpus was also called *sylva*.

The beasts were thus abandoned to the people, *i. e.* to all who were disposed to share in the pleasure of the chase, who pursued, shot, killed, and cut in pieces, all they could lay hold of. Helioabalus, the Gordians, and Probus, gave this diversion very frequently, and it continued till the time of the emperor Justinian, in the sixth century.

Casaubon, Cujas, Pithou, &c. make the pancarpus and *sylva* the same thing; Salmasius will have them different. The *sylva*, according to him, was such a diversion as that

above described: but the pancarpus a combat, wherein robust people, hired for that purpose, fought with wild beasts; which opinion he confirms from Cassian, Justinian, Claudian, Firmicus, Manilius, and Cassiodorus.

PANCAWIR, in *Geography*, a town of Hindoostan, in the country of Malwa; 60 miles N. of Ougein. N. lat. 24° 14'. E. long. 76 6'.

PANCH, in *Mast-making*, a plank of oak upwards, and fir below, about eleven inches wide, fayed over the hoops to the convexity of the mall on the fore-side, to make a fair surface for the yard to slide up or down, and prevent its chafing or rubbing against the hoops: hence often called rubbing-panch.

PANCH, a thick texture made of plaited rope-yarn, wove very close. It is fastened round the yards or rigging, to prevent their surfaces being rubbed by the friction of some other contiguous object.

PANCHÆA, in *Ancient Geography*, an island of the ocean, upon the coast of Arabia. According to Diodorus Siculus, it was inhabited by natives of the country, Indians, Cretans, and Scythians. In this island was a town called "Panara," whose inhabitants, according to Diodorus, were singularly happy. They had a temple of Jupiter Triphylia, of which this author details all sorts of marvellous circumstances. The other three towns were Hiraia, Dabi, and Oceanis. But the existence of such an island is doubtful.

PANCHAGNI, an expiatory self-inflicted penance resorted to by Hindoo ascetics. The word means five fires; and the mode of the penance is for the devotee to look constantly on the sun, with four other fires close to him. Such devotees are called Tapaswi, and are described in Hindoo books very circumstantially, but not, we may conclude, very faithfully, as "standing, with uplifted arm, without aid or support, day and night, feeding on air, immovable, on the right toe, on the afflicted earth," &c. &c. See TAPAS.

PANCHA-MUKI, a name of the Hindoo deity Siva, meaning five-faced, he being so represented and described in pictures and books. When five-headed he has usually ten hands.

PANCHAW, in *Geography*, a town of Bengal; 43 miles N.E. of Doega. N. lat. 23° 30'. E. long. 85° 38'.

PANCHBEYA, a town of Bengal; 27 miles E.S.E. of Purneah.

PANCHCOWRYE, a town of Hindoostan, in Oude; 20 miles S.S.E. of Bahraitch.

PANCHDOWNA, a town of Bengal; 20 miles N.E. of Dacca.

PANCHGURRY, a town of Bengal; 15 miles N.N.E. of Calcutta.

PANCHGUTCHY, a town of Bengal; ten miles S. of Oliapour.

PANCHMOOL, a town of Bengal; 10 miles E. of Rogonapour.

PANCHPARA, a town of Bengal; 15 miles N.N.E. of Bassin-pour.

PANCHPEER, a town of Bengal; eight miles S. of Oliapour.

PANCHREST, PANCHRESTOS, *παναχρηστος*, formed of *παν*, all, and *χρηστος*, useful, in *Medicine*, a panacea, or remedy for all distempers. See PANACEA.

PANCHRESTARII, among the Romans, are those who prepared the *panchrest*, or *universal remedy*.

PANCHRUS, the name given by some of the ancient writers on natural history to a gem which they say has all colours: probably the opal.

PANCHYMAGOGUE, PANCHYMAGOGUM, formed

from *παν*, all, *χυμος*, juice, and *αγειν*, to draw off, in *Pharmacy*, a purging extract made from aloes, rhubarb, senna, scammony, jalap, agaric, coloquintida, and black hellebore. Its name arises hence, that being a composition of all the kinds of purgatives, it was supposed to have the virtue of purging all the sorts of humours from the body at once.

PANCIATICA, in *Botany*, so named by Piccioli, author of the *Hortus Panciaticus*, published at Florence in 1783, in compliment to his patron the marquis Niccolò Panchiaticchi, president of the Academy of the *Georgofili*, and owner of the garden. See CADIA.

PANCIROLI, GUIDO, in *Biography*, an eminent jurist and antiquarian, son of Alberto Panciroli, who was also a person learned in the law, was born at Reggio in 1523. After he had made a proficiency in classical literature in his native place, he went to Ferrara to study jurisprudence. He pursued the same study successfully at Pavia, Bologna, and at Padua. In the latter university his reputation stood so high, that in 1547, while only a scholar, he was chosen to an extraordinary professorship of the Institutes. When he had taken his degrees, he was, in 1554, promoted to the principal chair, and in two years afterwards he was appointed to the second professorship, in ordinary, of civil law. This honourable situation he held till 1570, when he accepted an invitation from Emanuel Philibert, duke of Savoy, to occupy the law professorship at Turin, with a handsome salary. He continued in that university till he found the situation unfavourable to his health. He found some difficulty in obtaining his dismissal, but at length returned to Padua in 1582. He was now promoted to the first chair of civil law, with a large salary; and notwithstanding the wishes of the popes Gregory XIV. and Clement VII. to obtain his services at Rome, he preferred the tranquillity of his situation at Padua, where he died in 1599. He was author of a number of learned works, of which the principal are as follow: "Commentarii in Notitiam utriusque Imperii et de Magistratibus;" this was not only printed separately, but also in the Roman Antiquities of Grævius: "De Numismatibus antiquis:" "De quatuordecim Regionibus Urbis Romæ:" "Rerum Memorabilium jam olim deperditarum, et contra recens atque ingeniose inventarum, lib. ii.:" also of a valuable treatise which was not published till the year 1637, entitled "De Claris Legum Interpretibus."

PANCIROLLUS, a writer on music, among other arts; but as he belongs as much to all the other arts as to music, we shall leave him to general literature.

PANCLA, in *Geography*, a mountain of Thibet. N. lat. 29° 22'. E. long. 87° 14'.

PANCLADIA, *Πανκλαδία*, in *Antiquity*, a festival celebrated by the Rhodians when they pruned their vines.

PANCO POINT, in *Geography*, a cape on the N. coast of Java. S. lat. 6° 48'. E. long. 112° 44'.

PANCOCA, a town of Peru, in the diocese of La Plata; 30 miles S. of Potofi.

PANCORVO, a town of Spain, in Old Castile, near mountains called "Pennas de Pancorvo;" near midway between Burgos and Vittoria, and four miles W. of Mirardo de Ebro: overhung by an ancient castle.

PANCOVIA, in *Botany*, so named by Willdenow, in memory of Thomas Pancovius, a Berlin botanist, who died in 1665 at the age of 43, having published, in 1654, a quarto volume entitled *Herbarium portatile*, with 1363 wooden cuts, which has since been republished. Willd. Sp. Pl. v. 2. 285. Class and order, *Heptandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, inferior, in four deep, ovate, rather unequal segments. *Cor.* Petals

four, rather smaller than the calyx, hooded, toothed, plaited and crisped, their claws inserted into the receptacle, at the base of each segment of the calyx. *Stam.* Filament seven, awl-shaped, ascending, hairy half way up, inserted into the receptacle between the two longer segments of the calyx, and twice their length; anthers oblong, incumbent. *Pist.* not observed by Willdenow, who found in place of it a glandular depressed body. Mert, who discovered the plant, noted a solitary pistil. *Peric. and seeds* unknown.

Ess. Ch. Calyx bell-shaped, in four deep segments. Petals four, hooded, plaited, crisped and toothed; with claws. Stamens ascending, longer than the calyx.

1. *P. bijuga.*—Native of Guinea. A tree, with round branches; the young ones clothed with rusty down. *Leaves* alternate, abruptly pinnate, of two pair of stalked, coriaceous, elliptical, entire, smooth, veiny leaflets, each terminating in an elongated blunt point. *Footstalks* of the younger ones downy, of the full-grown ones transversely wrinkled. *Clusters* intrafoliaceous, short, simple, many-flowered, on the last year's branches. *Flowers* downy, on downy stalks. *Braëtes* ovate, obtuse, densely downy, shorter than the flower-stalks.—We have some suspicion that this may possibly be the same genus with *Afzelia*, whose characters are given in Tr. of the Linn. Soc. v. 4. 221, to which the name of *Pancovia* must, in that case, give place, as being of a later date, and by no means preferable in any respect. See AFZELIA.

PANCRAS, in *Geography*, a large parish in the Holborn division of the hundred of Offulton and county of Middlesex, England, is situated on the north side of London, and comprises about 2700 acres of land, including the site of buildings. It is bounded by the parishes of Islington, Hornsey, and Finchley on the north; by Hampstead and Maryle-Bone on the west; by St. Giles in the Fields, St. George the Martyr, St. George-Bloomsbury, and St. Andrew's, Holborn, on the south; and St. James, Clerkenwell, on the east. The increase of houses in this parish within the last forty years has excited the astonishment of all persons, who can recollect its condition previous to that period. The proportion is calculated as upwards of twenty to one. The first augmentation of much consequence happened in the neighbourhood of Tottenham-court-road, about the year 1765, when all the streets near Percy chapel were built. Somers-town was begun in 1786, Camden-town in 1791, Fitzroy-square in 1793, Brunswick-square in 1797, and Tavistock-square about 1800. Kentish-town has been enlarged more than two-thirds within these twenty-five years, and a considerable number of streets have been built between Brunswick and Russel-squares, and the New Road. Many houses have likewise been added at Battle-bridge, and hence this parish is now by far the most populous of any in the vicinity of London. According to the late parliamentary returns (1811), it contains 6743 houses, and 46,333 inhabitants.

Pancras is said to have been a parish before the Conquest; and is mentioned in Domesday book. It derived its name from the saint to whom the church is dedicated. That edifice is of ancient date, and is certainly the smallest parochial church in London, or its vicinity. It consists only of a nave and chancel. In this church and in the surrounding cemetery, are buried most of the Roman Catholics who die in the metropolis, among whom are several eminent French refugees. Here also rest the ashes of the illustrious Paoli, of Mary Wollstonecroft Godwin, of the chevalier d'Eon, and many other persons distinguished in their career of life by their actions or their writings. Besides the parish-church there are, as may be supposed, several chapels appropriated to public worship within this parish. Of these the principal

are, Kentish-town chapel; Percy chapel, near Tottenham-court-road; Fitzroy chapel; Woburn chapel; Bethel chapel, at Somers-town; St. James's chapel; Whitfield's chapel, belonging to the Methodists of Mr. Whitfield's persuasion; and St. Giles's chapel, attached to the parish of St. Giles's in the Fields. Several burying-grounds annexed to other parishes are likewise locally situated in Pancras, as the cemeteries of St. Andrew, Holborn, St. George the Martyr, and St. George-Bloomsbury.

Many public institutions for charitable and other purposes are placed within this parish. At the head of Lamb's Conduit street stands the Foundling hospital, which was first established in 1739, for the maintenance and education of foundlings, and of other poor children who are admitted in their infancy. The hospital for inoculation, and the natural small-pox hospital, are situated in a field close to Battle-bridge turnpike. Both these excellent charities were founded in 1746, but the present buildings were only erected, the former in 1765, and the latter in 1793. In Gray's-Inn-lane is the Welsh charity school, built in 1771; and at Camden-town is the Veterinary college, established in 1791. (See VETERINARY.) In this college is a theatre for lectures and for dissections, and a room for a museum. The present professor is Mr. Colman, who reads lectures on the anatomy, physiology, and pathology of the horse, from November till June. The pupils pay twenty guineas on admission, which includes every expence, and they have besides the great privilege of attending the principal anatomical lectures in the metropolis. Near the college has lately been erected a large workhouse; and in different parts of the parish are several alms-houses and charity schools, which our limits preclude us from enumerating.

At a place called the Brill, on which part of Somers-town is built, was an entrenchment, supposed by Dr. Stukeley to have been the camp of Cæsar. Caen-wood, or Kenwood, at the northern extremity of the parish, is noted for having been the country seat of the celebrated earl of Mansfield, who purchased it in 1755 from the earl of Bute. The pleasure grounds, including the wood, whence the mansion derive its name, comprehend about forty acres, and display, both in their natural and artificial features, much beauty and picturesque effect. Adjoining are the reservoirs belonging to the Hampstead water-works.

A noted place of public entertainment, called Bagnigge-wells, is situated in this parish, in the valley between Pentonville and the Foundling hospital. It was first opened in 1767 as a tea-garden, soon after the discovery of the two mineral springs here, one of which is chalybeate and the other cathartic. Another mineral spring near the church was formerly in great repute, but is now abandoned. The water of this spring was similar in its properties and effects to that of St. Chad's-well near Battle-bridge, which is still held in considerable estimation for its diuretic and aperient qualities. Lysons's Environs of London, vol. iii. edit. 1795. Supplement by the same author, edit. 1811.

PANCRASIUM, in the *Materia Medica*, a name used by some authors for the squill, of the root of which the oxymel of squills is made.

PANCRATIAN VERSE, the name of a sort of Greek verse, consisting of two trochees and a supernumerary syllable: Πενυγε λαιδοργων.

It is so called from its supposed inventor Panocrates, who is said to have lived before the time of Meleager, another poet who flourished under the first successors of Alexander.

PANCRATIASTES, in *Antiquity*, a combatant in the exercise called pancratium.

PANCRATIASTES was also applied to one, who had gained the

the victory in all the kinds of exercise used in the pancratium.

PANCRATIUM, Πανκρατιον, compounded of παν, *all*, and κρατειν, *I overcome*, among the *Ancients*, a kind of intermixed exercise, consisting of the *lucta*, (*palé*), or wrestling, and the boxing, pugilate, or *cæstus*.

The pancratium was the third gymnastic exercise, and was not introduced till long after the others.

The people, who were engaged in these exercises, were called Pancratiastæ; which name was also given to such as did not confine themselves to one exercise, but succeeded in several different ones.

As this exercise partook both of the *cæstus* and the *palé*, as we learn from both Aristotle and Quintilian, the *athleta* borrowed many things from each of these sciences to render himself eminent in the pancratium. It was necessary for him to learn how to trip, and strike, and box, and grapple with his antagonist; to stand with firmness, fall with advantage, and rise with vigour and celerity, or maintain the combat upon the ground; to attack and to defend, to annoy and resist his enemy in every attitude; and to employ in one or other of those purposes every limb, and nerve, and sinew, all the faculties and all the strength of his whole body, which is implied in the word pancratium; and this term gives the best account of an exercise, in which the combatants were allowed (under certain restrictions) to make what use they thought proper of all the arms which nature had given them, both offensive and defensive, and of only those: for neither (as in the *cæstus*) were their hands and fingers bound up or armed, nor their legs and feet prohibited from joining in the battle, nor were they constrained from striking, as in the *palé*. With no further arms than those, however, they were able to mangle and injure one another, that it was thought proper to subject them to some restraints; lest a contest, in which they engaged for victory and honour, should be disgraced by murder or malice, and the combatants be provoked to encounter one another in a manner more becoming beasts than men. An *athleta* was therefore forbidden to kill his adversary designedly, to dig or pluck out his eyes, to tear him with his teeth, or strike him under the ribs with the ends of his fingers; but notwithstanding these restrictions, scope enough was left for the combatants to exercise their skill and strength, their courage and resolution; because it was a common practice for a pancratiast to choke the strength and skill of his antagonist by twisting and entangling himself about his legs and arms; and to endeavour by fatigue, and pain, and suffocation, to worry him into a surrender of the victory. The pancratium was forbidden by the Spartan legislator, whilst he allowed and encouraged many contests no less rude and bloody; for the law of these two exercises requiring that one of the two combatants should yield either in words, or by stretching out his hand or finger, or by giving some other testimony of his so doing, Lycurgus forbade his Spartans to engage in either of them, because, as he said, he would not have them accustom themselves to yield the victory not even in sport. The combatants in these exercises were naked; and as it was necessary to pair them, this, we may suppose, was done by lot. Pausanias speaks of a pancratiast named Soltratus, who had an easy method of obtaining the victory in these contests: his custom was to seize fast hold of his adversary's fingers, which he broke, and never quitted his hold, till they renounced the contest. This method gained him twelve Isthmian and Nemean, two Pythian, and three Olympic crowns, together with a statue at Olympia, and the surname of Acro-Cherites. *West's Pindar*, vol. iii.

PANCRATIUM, in *Botany*, probably Πανκρασιον of Dioscorides, as Dr. Sibthorp found it called ἀγρια σκίλλα, or Wild Squill, by the modern Greeks; and that old writer speaks of it immediately after the true Squill, as a root of similar virtues, denominated by some the Little Squill. Πανκρασιον has been sometimes applied as a name to the *Moly*, and in that case is supposed to be derived from παν, *all*, and κρατις, *power*; an etymology which the reputed virtues of that herb might justify, more than the qualities of the present. These Dioscorides mentions, as like those of the Squill, but milder. *Linn. Gen.* 161. *Schreb.* 216. *Willd. Sp. Pl.* v. 2. 41. *Mart. Mill. Dict.* v. 3. *Ait. Hort. Kew. ed.* 2. v. 2. 218. *Sm. Prodr. Fl. Græc. Sibth.* v. 1. 220. *Juss.* 55. *Lamarck Illustr.* t. 228. *Class and order, Hexandria Monogynia. Nat. Ord. Spatheaceæ, Linn. Narcissi, Juss.*

Gen. Ch. *Cal.* an oblong, obtuse, compressed, membranous sheath, splitting along its flat side, containing one or many flowers, permanent. *Cor.* Petals six, lanceolate, flat, inserted into the tube of the nectary externally, at some distance above its base. Nectary of one leaf, funnel-shaped, regular, cylindrical below, coloured above, having a spreading border with twelve variously shaped segments. *Stam.* Filaments six, awl-shaped, inserted into the rim of the nectary, and usually exceeding its segments in length; anthers oblong, incumbent. *Pist.* Germen inferior, with three obtuse angles; style thread-shaped, longer than the stamens; stigma obtuse. *Perc.* Capsule roundish, with three blunt angles, membranous, of three cells and three valves. *Seeds* several, globose.

Ess. Ch. Petals six. Nectary with twelve segments, bearing the stamens.

Obf. The structure of the nectary, and the insertion of the stamens, afford an excellent instance of an essential generic character, with which no other can be confounded.

1. *P. zeylanicum.* One-flowered Pancratium. *Linn. Sp. Pl.* 417. *Willd. n.* 1. *Ait. n.* 1. *Salisb. Parad.* t. 86. (*Narcissus zeylanicus*, flore albo hexagono odorato; *Herm. Lugdbat.* 691. t. 693. *Commel. Hort.* v. 1. 75. t. 38. *Lilionarcissus zeylanicus*, flore albo hexagono odorato; *Rudb. Elyf.* v. 2. 179. f. 7. *Lilium indicum*; *Rumph. Amboin.* v. 6. 161. t. 70. f. 2)—Sheath single-flowered. Petals recurved. Stamens incurved.—Native of Ceylon, Java, and other parts of the East Indies. It was cultivated by Miller, but is now very rare in the English collections, flowering in the stove about July. The *bulb* is ovate, as big as a hen's egg. *Leaves* several, radical, spreading, linear, three-ribbed, an inch wide, bright green, slightly keeled. *Flower-stalks* one or more, about a foot high, erect, simple, bearing one large white fragrant flower, with yellow anthers, and a cloven greenish sheath. The nectary expands nearly an inch and a half, with twelve equal, acute, triangular, marginal segments, between every pair of which, and opposite to each petal, the stamens are inserted. Their strong inflexion is noted by Rumphius. The petals spread horizontally about four inches, and are linear, recurved at the points.

2. *P. mexicanum.* Mexican Pancratium. *Linn. Sp. Pl.* 418. *Willd. n.* 2. *Ait. n.* 2. (*P. mexicanum*, flore gemello candido; *Dill. Elth.* 299. t. 222.)—Sheath two-flowered. Leaves lanceolate. Six of the segments of the nectary bearing the stamens; the intermediate ones simple.—Native of Mexico. Sherard had it in his garden at Eltham, and Dillenius says the bulbs brought from Mexico flowered in May.—The leaves are broader and more lanceolate than in the former. *Stalk* hardly a foot high, shorter than the leaves, bearing, from one divided sheath, two white scentless

PANCRATIUM.

scentless flowers, with linear narrow petals, about two inches long, and a much smaller nectary than the foregoing, six of whose segments bear the slender spreading stamens from their points, with saffron-coloured anthers.

3. *P. rotatum*. Large-crowned Pancratium. Ker in Curt. Mag. t. 827. Ait. n. 3. (*P. disciforme*; Redout. Liliac. t. 155.)—Sheath with few flowers. Leaves linear. Stamens between the jagged segments of the horizontal nectary. Native of Carolina, in ground that is occasionally overflowed, from whence it was brought by the younger Michaux to Paris, and sent to Mr. Loddige before the year 1803. It flowers in the stove, during most part of the summer, and increases greatly by offsets from the root. Leaves many-ribbed, linear, from half an inch to an inch wide. Flowers two, three, or more, with a segment of the sheath under each, white, nearly a span in diameter, from the great length of the linear channelled petals. The great flatness, and wide expansion, of the cup of the nectary, with its variously-jagged segments, between which the wide-spreading stamens, about twice its length, are attached, form the striking character of the present species, which Michaux in his Flora mistook for the *mexicanum*.

4. *P. calathinum*. White Brazilian Pancratium. Ker in Curt. Mag. t. 1561. (*P. calathiforme*; Redout. Liliac. t. 353.)—Sheath with few flowers. Leaves linear. Stamens between the jagged segments of the cup-shaped nectary, and scarcely exceeding them in length. Tube nearly cylindrical.—Native of the Brazils, from whence it was received by the late lady Amelia Hume, who favoured us with a specimen in May 1794. The leaves are linear, obtuse, an inch wide and two feet long. Flowers two or three from a sheath of as many or more divisions, white, very fragrant, somewhat drooping. Nectary large and cup-shaped, its segments nearly upright, variously and sharply jagged and toothed. Stamens about the length of the segments, and inserted between them, bent inwards, each bearing a yellow anther longer than itself. Redoutè's figure represents the nectary as large as a flower of the common White Lily, with longer and less jagged segments than are exhibited in the Bot. Magazine; but Mr. Ker considers it as merely taken from a stronger plant.

5. *P. Amancaes*. Golden Pancratium. Curt. Mag. t. 1224. Ait. n. 4. (*Narcissus Amancaes*; Ruiz and Pavon. Peruv. v. 3. 53. t. 283. f. a.)—Sheath with few flowers. Leaves lanceolate. Stamens between the abrupt toothed segments of the cup-shaped nectary, and about the same length. Tube with six furrows.—Native of Lima and Peru. Imported from the Brazils, in 1808, by Messrs. Middlemist and Wood at Shepherd's bush, in whose stove it flowered in July 1809. This species is distinguished from all the preceding, by the golden yellow of its flowers, which are described as exceedingly fragrant, and used by the Peruvian women to ornament their hair. The shape and size of the flowers most agree with the last-described, particularly the inflexed posture of the very short stamens; but the segments of the nectary seem more abrupt, and more regularly toothed. The tube of the flower moreover has six strong furrows, and as many rounded angles. The leaves are more lanceolate, and broader, tapering to a point.

6. *P. humile*. Small Pancratium. Cavan. Ic. v. 3. 4. t. 207. f. 2. Willd. n. 3.—Sheath two flowered. Leaves thread-shaped. Nectary cup-shaped, very short, in six obtuse cloven segments. Stamens spreading, as long as the petals.—Gathered by Cavanilles in Andalusia, flowering in October, before the leaves come out. There are two only, scarcely six inches long, very slender. Stalk not quite so tall, slender, thread-shaped, bearing two yellow flowers

from one sheath, on unequal capillary stalks. Petals elliptic-oblong, obtuse, each rather above half an inch in length. Nectary short, and rather fleshy, cup-shaped, in six cloven segments, more resembling that of a *Narcissus*, but Cavanilles expressly says it bears the stamens. The tube is short. Stamens capillary, almost equal to the petals. This appears to us a very doubtful *Pancratium*, and if the lobes themselves of the nectary do not bear the stamens, it ought to be removed to *NARCISsus*; see that article.

7. *P. caribæum*. Caribæan Pancratium. Linn. Sp. Pl. ed. 1. 291. ed. 2. 418. Willd. n. 4. (*P. n. 1*; Brown. Jam. 194. *Narcissus totus albus latifolius polyanthos major odoratus, staminibus sex e tubi amplè margine exstantibus*; Sloane Jam. v. 1. 244. Mart. Cent. t. 27.)—"Sheath many-flowered. Leaves lanceolate."—Native of Jamaica, in lowland woods, very common, as well as in other sugar islands, according to Sloane and Bröwne. The bulb is said to be as large as a man's fist. Leaves two feet long, and about three inches broad, channelled or concave. Flower-stalk flat, two-edged, four feet high, solid. Flowers six, seven, or more, large, white, fragrant; their tube, mistaken by Sloane for a partial footstalk, six inches long; petals five inches long; nectary with six ribs, bearing the very long stamens. This is all we can gather from Sloane. Bröwne says "the root is pretty acrid, and has been sometimes used in poultices by antiquated and pale-faced ladies, to raise a forced bloom in their fading cheeks."—*P. caribæum* is a much-disputed species. Linnæus adopted it from the above authors, adding a reference to Commelin, which certainly belongs to what is now called *amoenum*, see n. 12. He had however an original specimen in his herbarium, sent by Gronovius, with the synonym of Sloane and Martyn; but this specimen consists merely of a few separate flowers, which appear to belong to *amoenum*, but can scarcely be ascertained. In this difficulty we leave the present species as we find it, the above synonyms of Sloane and Martyn not being with certainty referrible to any of the following, whatever may become of the specimen, which neither accords with them, nor could possibly have suggested the specific definition.

8. *P. maritimum*. Sea Pancratium. Linn. Sp. Pl. 418. Willd. n. 5. Ait. n. 5. Cavan. Ic. v. 1. 41. t. 56. Redout. Liliac. t. 8. Salf. Tr. of Linn. Soc. v. 2. 70. t. 9. (*P. carolinianum*; Linn. Sp. Pl. 418. *P. marinum, et floribus rubris*; Ger. em. 172, 173. f. 3, 4.)—Sheath many-flowered. Leaves linear, obtuse, glaucous. Stamens between the twelve entire equal segments of the large cup-shaped nectary, and about the same length, incurved.—Native of the sandy sea-coasts of the south of Europe, frequent in Greece and the neighbouring islands. Gerarde cultivated it in his garden, and it is still occasionally to be seen in collections, flowering in May and June, in the open ground, though much less frequent than the *illyricum*, which Miller mistook for this. Our *maritimum* is, if any of the genus, the true *πανκράτιον* of Dioscorides. It is known by its narrow glaucous leaves, and the large bell-shaped nectary, with twelve short, equal, entire segments, between every two pair of which stands an incurved stamen, not exceeding them in length. Redoutè's plate is excellent. The flowers are fragrant, usually white, but occasionally tinged with a faint red, whence the species was termed *verecundum* in Ait. Hort. Kew. ed. 1, where it occurs twice.

9. *P. littorale*. Tall Pancratium. Jacq. Amer. 99. t. 179. f. 94. Hort. Vind. v. 3. 41. t. 75. Salf. Tr. of Linn. Soc. v. 2. 74. t. 13. Willd. n. 7. Ait. n. 6. Redout. Liliac. t. 154. Curt. Mag. t. 825. (*P. foliis ensiformibus, spatha multiflora, floribus magnis candidis fragrantibus*; Trew Ehret. 6. t. 27.)—Sheath many-flowered. Leaves linear-lanceolate.

Nectary

PANCRATIUM.

Nectary with six teeth bearing the stamens; the intermediate space wavy, obscurely toothed.—Native of the West Indies, said to have been cultivated by Miller in 1758. It flowers in the stove throughout the summer. Linnæus having misquoted the synonym of Trew's Ehret under his *illyricum*, has, as Mr. Salisbury remarks, caused the present species to be sometimes called by that name, though the two are as unlike as possible. The present bears a great number of powerfully-scented, large, white flowers, whose tubes are seven inches long, and their common stalk three or four feet high. *Petals* long, narrow, recurved and pendulous. Cup of the *nectary* wide and shallow, its six principal teeth bearing the very long *stamens*, while the intermediate space is merely wavy, with scarcely the appearance of teeth.

10. *P. fragrans*. Fragrant Pancratium. Salif. Tr. of Linn. Soc. v. 2. 72. t. 11. Willd. n. 6. Ait. n. 7. (*P. foliis amplis ovatis acutis petiolatis, spatha multiflora, floribus minoribus candidis fragrantibus*; Trew Ehret. 6. t. 28.)—Sheath many-flowered. Leaves elliptical. Nectary with six teeth bearing the stamens; the intermediate space wavy and cloven.—Native of Barbadoes, flowering in our stoves in the summer. Mr. Salisbury first well distinguished this species, and suspected that the synonyms above quoted under *P. caribæum* might belong to it, which we can scarcely believe. Willdenow seems to have rightly referred to Trew's Ehret. The scent of the flowers is very sweet. The want of intermediate teeth to the *nectary*, in the place of which there is a notch, and the broad elliptical foliage, well mark this *Pancratium*. The tube of the flower is not half the length of the last.

11. *P. speciosum*. Great West Indian Pancratium. Salif. Tr. of Linn. Soc. v. 2. 73. t. 12. Willd. n. 8. Ait. n. 8. Redout. Liliac. t. 156. (*P. caribæum*; Curt. Mag. t. 826.)—Sheath many-flowered. Leaves elliptical. Nectary with six teeth bearing the stamens; the intermediate ones simple, acute.—Native of the West Indies, flowering in a stove most part of the summer. The leaves are numerous and broad, with contracted stalks. Flowers numerous, large, white, very fragrant, distinguished by the intermediate teeth of their *nectary* from the last. Martyn's t. 27, on which the Linnæan *caribæum* is supposed to depend, is noted in Hort. Kew. as belonging to this species, which may be the case, though the *nectary* is there incorrectly drawn. The present is the finest of the whole genus, and most generally cultivated, by those who have the means to make it bloom in perfection, which sometimes takes place twice in one summer.

12. *P. amocnum*. Broad-leaved Cayenne Pancratium. Salif. Tr. of Linn. Soc. v. 2. 71. t. 10. Willd. n. 9. Ait. n. 9. Andr. Repof. t. 556. (*P. declinatum*; Jacq. Hort. Vind. v. 3. 10. t. 11. *Narcissus americanus, flore multiplici albo hexagono odorato*; Commel. Hort. v. 2. 173. t. 87.)—Sheath many-flowered. Leaves elliptic-lanceolate. Nectary with six teeth bearing the stamens; the intermediate ones acute, deeply cloven.—Native of Guiana. Mr. Salisbury cultivated it before 1790, and Jacquin long before that period. This has narrower leaves, and much smaller flowers, than the *speciosum*, with small cloven intermediate teeth to the *nectary*, which part seems to us well chosen by Mr. Salisbury for the specific differences, notwithstanding the doubts of other authors. The lying down of the stalk, when the seed-vessels are forming, is, as he remarks, by no means peculiar to this kind of *Pancratium*, and therefore he could not retain Jacquin's specific name. Yet it may be doubted whether what he has adopted be equally discriminative.

13. *P. illyricum*. Starry Pancratium. Linn. Sp. Pl. 418. Willd. n. 10. Ait. n. 10. Curt. Mag. t. 718. Redout.

Liliac. t. 153. (*P. stellare*; Salif. Tr. of Linn. Soc. v. 2. 74. t. 14. *P. spatha multiflora, petalis planis, foliis linguatis*; Mill. Ic. t. 197. *Narcissus tertius Matthioli*; Ger. em. 173. *N. constantino-politanus*; Matth. Valgr. v. 2. 580, excellent.)—Sheath many-flowered. Leaves lanceolate, obtuse, glaucous. Stamens between the deep, acute, cloven, widely-spreading segments of the *nectary*, and twice their length.—Native of the south of Europe. Lord Zouch is recorded as having cultivated this species in 1605. It is now not uncommon in our open borders, requiring no particular care, and flowering in May or June. Miller and others have mistaken this for the Linnæan *maritimum*, from which it is totally different. The leaves spread in two ranks, and are very glaucous, rigid, a foot long, concave, one inch and a half wide. Flower-stalk a little inclining, not so long as the leaves, bearing numerous white flowers, of an agreeable scent, and well characterised by their starry appearance, caused by their widely-spreading petals and *nectary*, whose segments are cloven half way down, and much more deeply separated from each other, with the stamens between them.

14. *P. amboinense*. Amboina Pancratium. Linn. Sp. Pl. 419. Willd. n. 11. Ait. n. 11. (*P. nervifolium*; Salif. Parad. t. 84. *Narcissus amboinensis, folio latissimo rotundo, floribus niveis inodoris*; Commel. Hort. v. 1. 77. t. 39. Rudb. Elyf. v. 2. 238. f. 17. *Cepa sylvestris*; Rumph. Amboin. v. 6. 160. t. 70. f. 1.)—Sheath many-flowered. Leaves elliptic-heart-shaped, many-ribbed. Nectary in six deep segments, with two distant teeth, bearing the stamens between their teeth.—Native of Amboyna and Java. We received it from the late Mr. Christopher Smith. Miller cultivated this species in 1759, but it has been lost till within a few years. It flowers in the stove early in spring. The remarkably broad heart-shaped leaves, of a pale green, with many strong ribs, abundantly distinguish this *Pancratium* from all the rest. The flowers are extremely numerous, white, without smell, their shape and proportion most like *illyricum*, the petals being about the length of the tube, but the *nectary* is essentially different, being divided above half way down into six broad wedge-shaped segments, each having two divaricated teeth, and between these teeth the stamens are inserted, extending far beyond them, and about half the length of the petals.

PANCRATIUM, in Gardening, contains plants of the bulbous-rooted, showery, perennial kind, of which the species cultivated are; the sea pancratium (*P. maritimum*); the Illyrian pancratium (*P. illyricum*); the Ceylonese pancratium (*P. zeylanicum*); the Mexican pancratium (*P. mexicanum*); the Caribbean pancratium (*P. caribæum*); the Carolina pancratium (*P. carolinianum*); the broad-leaved pancratium (*P. amboinense*); the narcissus-leaved pancratium, and the *P. speciosum*.

Of the seventh fort there are several varieties; as the *American*, which grows naturally in the islands of the West Indies, where it is called *white lily*; and the *latifolium* and *ovatum* also grow naturally in the same place.

Method of Culture.—All these plants are capable of being increased by planting off-sets from the roots in the latter end of summer, when their stems and leaves decay. The roots may be divided every second or third year.

In the two first sorts, the off-sets may be planted out in nursery-beds for a year or two, to become sufficiently strong, when they may be removed into warm sheltered dry borders; the first being sheltered from frost in severe winters, and the latter in very severe weather, by being covered with tanners' bark, straw, or peas-haulm. The second fort may also be increased by seeds sown in pots, and plunged in a hot-bed.

The other sorts must be planted out in small pots filled with

with light earth, separately plunging them in the bark-bed of the stove. They should be kept constantly in the tan-bed, and have the management of other tender bulbs. In this way they generally succeed well.

The two first sorts afford variety in the dry warm borders of the pleasure-ground, and the other kinds produce variety as well as fragrance in the stove collections.

PANCREAS, in *Anatomy*, a glandular body, situated in the abdomen, and connected to the beginning of the small intestine, in the cavity of which its excretory duct terminates. The structure of this gland so nearly resembles that of the salivary glands, that we refer on this part of the subject to our account of them in the article DEGLUTITION, and to the general remarks in the article GLAND.

The shape of the pancreas is elongated: the right extremity, which is the largest part, is sometimes called the head of the pancreas (*caput pancreatis*): the left, which is smaller, its tail (*cauda*). The length is from eight to ten inches, and corresponds nearly to that of the stomach: the breadth about two inches, and the thickness about one inch. It is much the largest gland in the body of this particular kind of structure. It is said to weigh from two to six ounces; the specific gravity to that of water as 2029 to 1000.

This gland is deeply hidden in the upper and back part of the abdominal cavity—in the epigastric region, where it lies nearly transversely. The right or larger end lies in the concavity of the second curvature of the duodenum, and adheres closely to this intestine for a considerable breadth by a short and dense cellular tissue. The substance of the organ, advancing over the anterior and posterior surfaces of the gut, seems to inclose it. The portion, which lies along the intestine, is much broader than the rest of the gland, and was called by Winslow the pancreas minus, although it is not distinct from the rest. From the duodenum the pancreas stretches across the vertebral column into the left hypochondrium, directed a little upwards as well as to the right. Its left end, which is the smallest part, touches the interior end of the spleen, or is connected to it by the intervention of a portion of peritoneum.

The anterior and posterior surface of the pancreas are nearly flat: but the whole is rather curved in accommodation to the projection of the vertebral column. The anterior surface, inclined forwards and slightly convex, is covered by the upper layer of the transverse mesocolon, through which it can be easily discerned behind the stomach and little omentum. The latter parts lie in front of it, and are in contact with the gland, when the stomach is empty: but when that bag is filled, it rises from the gland, which is then behind its lesser arch. The posterior surface corresponds to the transverse part of the duodenum, from which the superior mesenteric vessels and nerves separate it. The superior edge, thicker than the inferior, and inclined backwards, is connected by copious cellular substance to the aorta and vena cava, the superior mesenteric vessels, and the left kidney and renal capsule. It possesses a groove, in which the splenic artery is lodged. The inferior edge is thin and inclined forwards, and placed between the upper layer of the transverse mesocolon and the duodenum.

The external surface is granulated, and the consistence of the organ, in its recent state, very firm. It becomes softer soon after death, and is very much softened, when putrefaction commences. The colour is a greyish-white, inclining to red.

The excretory duct (sometimes called ductus Wirsungi, from Wirsung, who discovered it in 1642) runs from one end of the gland to the other, nearly in its centre. It is

remarkable for its whiteness, and is less dense and thick than those of the salivary glands. Very fine tubes arise from the glandular acini, and unite together like veins: they end in a single tube, which gradually increases in size, as it proceeds from the left to the right end of the gland, does not follow quite a straight course, and is rather nearer to the anterior than to the posterior surface of the organ. When it arrives near the duodenum it has attained the size of a small writing quill, and it receives a branch rather larger than the others from the part called pancreas minus. It turns a little downwards to join the ductus communis choledochus at an acute angle, and the common tube immediately penetrates the coats of the duodenum, at the lower and posterior part of the second curvature of the intestine. (See LIVER.) The opening is smaller than the diameter of the duct before its end: and Soemmerring states that the entrance of the bile into it is prevented by a valve, “*valvula fimbriata et valde subtilis.*” Sometimes a small canal opens separately at a short distance from the common duct; or the great duct itself may terminate separately from the ductus communis choledochus; or there may be three pancreatic ducts opening into the duodenum.

The texture of the duct is tolerably firm: its internal surface is perfectly smooth.

It has no proper external covering: one surface has the anterior layer of the mesocolon lying on it pretty closely: but the rest of the gland is connected by a loose cellular tissue to the surrounding parts.

The arteries of the pancreas are numerous and small, and produced from the gastro-duodenalis, the splenic and the superior mesenteric: the veins join the superior mesenteric, the splenic and the gastro-duodenal, all of which end in the vena portarum. It has absorbents, in which nothing peculiar has been observed. The nerves, which are very small, and distributed on the arteries only, come from the cæliac ganglia.

The points in which this and the salivary gland agree are; 1, the organisation, including the excretory ducts; 2, the possessing numerous small blood-vessels; 3, the being placed in a situation where they are subject to motion from the surrounding organs. These, in the pancreas, are the trunks of the aorta, superior mesenteric and splenic arteries, the stomach, and duodenum.

In the mammalia and birds, the pancreatic and biliary ducts are sometimes united, sometimes separate: and sometimes there are two pancreatic ducts, one opening into the ductus choledochus, and the other separately.

The pancreas secretes a fluid, called the pancreatic juice or liquor, which is poured by its excretory duct into the duodenum. The difficulty of procuring this in a pure state has prevented any very accurate investigation of its chemical properties: but it appears, from whatever inquiries have been made, very closely to resemble the saliva. (See DEGLUTITION.) The duct is always found empty after death.

In the controversies about the nature of the pancreatic fluid in the seventeenth century, numerous dogs were slaughtered without any very interesting results being obtained. De Graaf placed tubes in the pancreatic ducts of living dogs: phials were connected to the opposite end of them. In this way he collected two drachms, half an ounce, and even an ounce, in eight hours. Schuyl procured two and three drachms in two hours. (See De Graaf de succi pancreatici natura et usu; and Schuyl de veteri medicina.) Brunner attempted to cut out the gland, or to tie the duct in dogs. (*Experimenta nova circa pancreas.*) These tortures were inflicted in the attack and defence of a doctrine promulgated by Sylvius de le Boe, and very generally adopted,

that

that the pancreatic liquor was acid, and the bile alkaline, and that their mixture occasioned a fermentation in the stomach, by which chylification was effected! These notions were employed in explaining disease: the cold stage of fever was ascribed to the acid pancreatic juice, and alkaline remedies were ordered to correct it.

We know that the salivary glands secrete their fluid very largely during mastication (see DEGLUTITION): this analogy leads us to infer that the pancreas must furnish a large quantity of fluid, which is mixed with the chyme from the stomach. As we are ignorant of the quantity and exact nature of this secretion, we cannot be expected to explain what share it has in the changes which our food undergoes in the alimentary canal. Haller's *Elementa Physiologiæ*, lib. 22. Siebold, *Historia Systematis Salivalis*, 4to. Jenæ 1797.

PANCREAS *Afelli*, in *Comparative Anatomy*, the large single mesenteric gland of some animals, which holds the place of the numerous smaller ones. See MAMMALIA.

It has its name from the author who first took notice of it, Afellius. M. Perrault observes, that the fish called plaice, has four hundred and forty pancreases; though it has but five ducts opening into the intestine, three of which correspond to eighty pancreases, and two of them to one hundred a piece. See FISH.

PANCREATIC, in *Anatomy*, an epithet given to various parts situated about the pancreas; as the duct of the gland, its arteries, veins and nerves. See PANCREAS.

PANCREATIC Juice, an insipid, limpid juice or humour separated from the blood, and prepared in the pancreas.

This juice is not acid as most authors have supposed; nor alkaline, as some authors have thought; but a little saline, and much resembling the saliva in its origin, vessels, and properties.

It is carried by the pancreatic duct into the duodenum, where it serves to dilute the chyle, to render it more fluid, and fit to enter the mouths of the lacteals: and perhaps to temper and dilute the bile, to change its viscosity, bitterness, colour, &c. and make it mix with the chyle, in order to reduce the several tastes, odours, and properties of the several foods into one homogeneous one.

Jansson ab Almeloveen will have the pancreatic juice to have been known to Hippocrates and Galen. De Graaf, a Dutch physician, has found means of collecting a quantity of it for experiments; and has published a treatise expressive, "De Succo Pancreatico."

Brunner relates, that the pancreatic duct, in several dogs, having been tied and cut, they still continued to eat and drink, and perform all the other functions of life as usual. One of them seemed only to have the better stomach for it.

PANCSOVA, in *Geography*, a town and fortrefs of Hungary, on the N. side of the Danube, in the bannat of Temesvar; 8 miles N. of Belgrade. N. lat. 45° 15'. E. long. 12° 16'.

PANCTOU, a town of Thibet; 70 miles N.N.E. of Lassa.

PANDA, a town on the N. coast of the island of Cumbava. S. lat 8° 27'. E. long 118° 48'.

PANDA, in *Mythology*, a goddess who was invoked and honoured as the protectress of travellers and navigators. The goddess of peace was also called Panda, because she opened the gates of cities which were shut in time of war. According to Varro, Panda is a surname of Ceres, derived à pane dando, because she gave bread to mankind. According to Arnobius, this goddess was so called because she opened the way to the capitol to T. Tatius.

PANDAIA, or PANTAIA, in *Geography*, a town on

the N. coast of the island of Cyprus, in a bay to which it gives name; 28 miles W. of Nicofia.

PANDALEON, in *Medicine*, a remedy appropriated to disorders of the breast and lungs, invented by the Arabians and later physicians; consisting of grateful ingredients answering the same end with the linctus, but different from it in form, in which it agrees with troches: it differs however in this, that troches are made in a certain figure, whereas the pandaleon, after the fugar is duly boiled, and the ingredients sufficiently mixed, is poured into a box, and becomes indurated, and a sufficient quantity is to be taken out either in a spoon, or on the point of a knife.

The pandaleon, therefore, is a solid medicine like a cake, receiving its form from the box into which it is poured: and it consists of powders, pectoral conserves, and lozenges of fugar.

PANDANEÆ, in *Botany*, a natural order of plants, recently established by Mr. R. Brown, Prodr. Nov. Holl. v. 1. 340, and so denominated from *Pandanus*; which see. The characters are thus given.

Flowers either diœcious or polygamous; destitute of a perianth.

Male, *Spadix* entirely covered with filaments, each bearing a single anther of two cells.

Female, *Spadix* entirely covered with gemens: mostly combined in parcels, each gemen of one cell, with a sessile clofely attached stigma. *Drupas* fibrous, mostly combined in parcels, each drupa with one seed; or else berries of several cells, with many seeds in each cell.

Albumen fleshy. *Embryo* central, erect. *Plumula* inconspicuous.

Trunk arboreous, but often sending down shoots to take root, and sometimes weak and decumbent. *Leaves* imbricated in three ranks, elongated, linear-lanceolate; clasping the stem, their edges most frequently spinous. *Floral leaves* smaller, often coloured.

This is a tropical family of plants, placed by its author near the *Aroidæ*, chiefly on account of the similarity of their inflorescence, the want of a perianth, the texture of the albumen, and the situation of the embryo; in all which characters it differs widely from the PALMÆ, see that article, resembling the latter only in having an arborefcent trunk.

A second genus, first observed by sir Joseph Banks, and lately most beautifully delineated by Mr. Ferdinand Bauer, during his stay at Norfolk island, differs from *Pandanus* in having a soft pulpy fruit, with several minute striated seeds in each cell, furnished at one side with a longitudinal appendage.

PANDANG, in *Geography*, a town on the W. coast of the island of Celebes. S. lat. 3° 33'. E. long. 120°.

PANDANG *Coëbin*, a town on the W. coast of the island of Sumatra. S. lat. 4° 36'. E. long. 102° 57'.

PANDANUS, in *Botany*, a name adopted by Linnæus from Rumphius, who fabricated it from the Malay *Pandang*, which signifies to behold, and which is supposed to allude either to the beauty of the tree in question, or to its conspicuous appearance at a distance. Whatever the meaning may be, the structure of the word is uncouth, and we cannot but regret that Forster's *Athrodactylis* was not retained; or if the genus must have a barbarous appellation, sanctioned by antiquity. *Kaida* of Rheede would surely have been preferable to the above. By the manuscript of the *Supplementum Plantarum*, it appears that the younger Linnæus, and not his father, is responsible for the name we presume to disapprove. Linn. Suppl. 64. Schreb. 670. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 387. Brown Prodr.

Nov. Holl. v. 1. 341. Juss. 444. Lamarck Illustr. t. 798. (Athrodactylis; Forst. Gen. t. 75.)—Class and order, *Diccia Monandria*. Nat. Ord. uncertain, Juss. *Pandaneæ*, Brown.

Gen. Ch. Male, *Cal.* Spadix compound, naked. Perianth none. *Cor.* none. *Stam.* Filaments scattered over the whole spadix, cylindrical; anther vertical, linear, acute, cloven at the base, of two cells, bursting longitudinally at one side.

Female, on a separate plant, *Cal.* none. *Cor.* none. *Pist.* Germens numerous, aggregate, sessile, tapering inwards, with five angles, convex at the summit, smooth; Style none; stigma two-lobed, bordered. *Peric.* Drupas aggregate, angular, fibrous, farinaceous. *Seed.* Nut bony, oval, smooth, its kernel inserted by the base into the centre of a *receptacle*, attached to the inner side of the shell.

Eff. Ch. Male, Calyx none. Corolla none. Spadix compound.

Female, Calyx none. Corolla none. Drupas aggregate.

1. *P. odoratissimus*. Linn. Suppl. 424. (Male, *P. verus*; Rumph. Amboin. v. 4. 139. t. 74; female, *P. spurius*; *ibid.* 142. t. 75. Kaida; Rheed. Hort. Malab. v. 2. 1. t. 1-6?)—Trunk throwing out runners. Drupas obovate at the summit—Native of the East Indies; cultivated there, as well as in many of the South Sea islands, and, according to Forskall, in Arabia, for the sake of its male flowers only, whose fragrance is said to be very delightful, and powerfully diffusive. The young plant is without any stem, and its long narrow pointed leaves, whose margins are serrated with spines, and whose under side is whitish and mealy, much resemble a *Bromelia*, to which genus Linnæus, in his Fl. Zeylanica, referred it. The floral-leaves are white, as well as the male flowers, which latter compose long, branched, dense spikes, in which nothing is discernible but innumerable filaments and anthers. The fruit, on a separate tree, resembles a Pine-apple, but is hard, dry, not eatable, nor of any use whatever. The cultivation of the female plant therefore is neglected. In an adult state the trunk is eight or nine feet high, much branched, sending down numerous long shoots from its lower part, which take root in the earth.

We are by no means competent to unravel all the varieties, or rather species, of this plant, described by Rumphius and Rheede, but which succeeding botanical travellers have left unexplained. Mr. R. Brown only has given definitions of the following two species, without any synonyms, and therefore we presume they are not supposed to be included among the above.

2. *P. pedunculatus*. Br. n. 1.—Trunk throwing out runners. Drupas conical and lobed at the summit; somewhat contracted at the base. Native of the tropical part of New Holland.

3. *P. spiralis*. Br. n. 2.—Trunk without runners. Drupas depressed and tessellated at the summit; very obtuse at the base.—Gathered likewise by Mr. Brown, in the same part of the world.

We have a specimen of a small, apparently distinct, species, gathered by Commerçon in the isle of Bourbon, and which he says grows also in Madagascar, and on the coast of Coromandel. In this the summit of each drupa is conical and acute, but we cannot judge how far the fruit is advanced towards maturity. The whole compound female spike is scarcely more than two inches long.

PANDANUS, in *Gardening*, contains a plant of the herbaceous, perennial, exotic kind for the stove, of which, the species is sweet-scented pandanus, or screw pine (*P. odoratissimus*).

Method of Culture.—This plant may be increased by sowing the seeds, brought from the places where it grows naturally, in pots of light earth, and plunging them in the bark-bed of the stove, where they must be constantly retained, having the management usually practised for other tender exotic plants.

They have a fine ornamental effect among other stove plants, in their large spreading foliage.

PANDECTS, PANDECTÆ, in *Jurisprudence*, the Digest, or collection made by Justinian's order, of five hundred and thirty-four decisions, or judgments of the ancient lawyers. on so many questions occurring in the civil law; to which that emperor gave the force and authority of law by an epistle prefixed to them. The jurisprudence of the Pandects is circumscribed within a period of one hundred years, from the perpetual edict to the death of Severus Alexander.

The word is Greek, Πανδεκταί, compounded of παν, all, and δεχομαι, capio, I take; q. d. a compilation, or a book containing all things. Though others, as Bartoli, will have it formed from παν, and δεχομαι; as if these books contained the whole doctrine of the law.

The Pandects consist of fifty books, and make the first part of the body of the CIVIL law; which see.

They were originally denoted by two π π; but the copyists taking those π π for ff, the custom arose of quoting them by ff. When the monuments of ancient Rome were neglected or destroyed by the envy or ignorance of the Greeks, the Pandects themselves escaped with difficulty and danger from the common shipwreck, and criticism has pronounced that all the editions and manuscripts of the west are derived from one original. It was transcribed at Constantinople in the beginning of the seventh century, and was successively transported by the accidents of war and commerce, to Amalphi, Pisa, and Florence, and is now deposited as a sacred relic in the ancient palace of the republic. The original at Constantinople was revered by Politian as the authentic standard of Justinian himself; but this paradox is refuted by the abbreviations of the Florentine MS. It is composed of two quarto volumes, with large margins, on a thin parchment, and the Latin characters betray the hand of a Greek scribe. The discovery of the Pandects at Amalphi (A.D. 1137) is first noticed (in 1501) by Ludovicus Bologninus, on the faith of a Pisan chronicle, without a name or a date. The whole story, though unknown to the 12th century, embellished by ignorant ages, and suspected by rigid criticism, is not, however, destitute of much internal probability. The Liber Pandectarum of Pisa, was undoubtedly consulted in the 14th century by the great Bartolus. Pisa was taken by the Florentines in the year 1406; and in 1411 the Pandects were transported to the capital. Gibbon's Hist. vol. viii. p. 44. 8vo.

Papias extends the denomination of Pandects to the Old and New Testament.

There are also *pandecta medicina*, *pandects of medicine*: these are a kind of dictionary of things relating to medicine, compiled by Mat. Sylvaticus, of Mantua, who lived about the year 1297. Leunclavius has published pandects of Turkey; and bishop Beveridge pandects of the canons, "Pandecta Canonum."

PANDEMON, Πανδημος, in *Antiquity*, the same with the festival Chalceia and Athenæa.

It was so called from the great concourse of people that used to meet at this solemnity.

PANDEMOS, in *Mythology*, a name given to *Venus*; which see.

PANDERLA, in *Geography*, a town of Hindooستان, in Madura; 30 miles N.N.E. of Coilpetta.

PANDIA,

PANDIA, Πανδία, in *Antiquity*, an Athenian festival in honour of Jupiter. For the origin of this solemnity, see Potter, *Archæol. Græc. lib. ii. cap. 20. tom. i. p. 422.*

PANDICULATION, PANDICULATIO, in a general sense, is a violent and tensive motion of the solids, which usually accompanies the act of yawning; and is otherwise called *stretching*.

PANDIPOUR, in *Geography*, a town of Hindoostan, in Oude; 22 miles S. of Fyzabad.

PANDOLY, a town of Hindoostan, in Baglana; 25 miles N.W. of Junera.

PANDONSER, a town of Hindoostan, in Dowlatabad; 20 miles E. of Poorundar.

PANDOO, a town of Hindoostan, in Visiapour; 20 miles N. of Sattarah.

PANDOOKAN, a small island in the Sooloo Archipelago. N. lat. $6^{\circ} 15'$. E. long. $120^{\circ} 34'$.

PANDORA, in *Mythology*, the name of the first woman, according to Hesiod; so called from παν, *all*, and δωρον, *gift*: because the gods united to confer upon her every quality and endowment that could conduce, as the fable says, to the misery of mankind. Pandora, it is farther said, kept these gifts in a vessel, the cover of which she opened, and they were dispersed over the face of the earth.

According to the fable, Jupiter, incensed at the conduct of Prometheus (see his article), ordered Vulcan to form a woman endued with all perfections, whence her name of Pandora originated. The gods loaded her with presents, and sent her to Prometheus with a box full of all kinds of misery. This prince, suspecting the trick, would have nothing to do with her; but Epimetheus, to whom she offered herself, was so captivated with her charms, that he took her to wife, and had by her Pyrrha, the wife of Deucalion. His curiosity, too, led him to look into the fatal box, which he no sooner had opened, than there issued out of it that deluge of miseries which have since overrun this earth. He shut it up again in haste, but all was gone but hope, which had not time to escape, and this, of consequence, is the only blessing that remains with wretched mortals.

PANDOSIA, in *Ancient Geography*, a town of Italy, in Brutium, upon the W. coast, near the sea, and the boundaries of Lucania. It was founded by the Ænetrians, who made it the capital of their territory. It was situated on a small mountain, at the foot of which ran a stream called "Acheron."—Also, a town of Epirus, in the interior of the country.

PANDROSOS, Πανδρόσος, in *Antiquity*, an Athenian festival in honour of Pandrosia, the third daughter of king Cecrops, who, not disobeying Minerva, was rewarded by the Greeks for her piety with a temple, built after her death, near that of the goddess, as Pausanias relates the story.

PANDSA TALA, in *Geography*, a group of several small lakes in Thibet. N. lat. $30^{\circ} 42'$. E. long. $79^{\circ} 26'$.

PANDU, in *Mythology*, the name of a personage of some importance in the heroic history of the Hindoos. He was the father of the five brothers or Pandavas, whose contests with the sons of Kuru form the subject of that splendid poem, the MAHABARAT, under which article the names and parentage of the Pandus, or Pandavas, and some other particulars of them, will be found. To these five heroes, it is usual in India to attribute the construction of any great work whose origin is lost in its antiquity. Such as the excavations on Elephanta, at Elora, &c.

PANDURA, or PANDORON, a musical instrument, used among the ancients, much resembling the lute.

The word, according to some, is formed from the Greek παν, and δωρον, *i. e.* all gifts, all sorts of gifts. Isidore de-

rives the name from its inventor Pandorus; others from Pan, to whom they attribute this invention, as well as that of the flute.

It has the same number of strings with the lute; but they are of brass, and of consequence give a more agreeable sound than those of the lute. Its frets are of copper, like those of the cistre; its back is flat, like that of the guitar; and the rims of its table, as well as its ribs, are cut in semi-circles.

Du-Cange observes, that Varro, Isidore, and others of the ancients, mention it as having only three strings; whence it is sometimes also spoken of under the denomination τριχορδον, *trichordum*.

The instrument called the Pandura or Bandoræ, of the lute kind, was very much in favour in our own country during the 17th century: but now, not only its scale, but even its form is forgotten. Julius Pollux relates that the Assyrians made use of an instrument with three strings, called the *Pandore*, or Pandarum, invented by the Arabians, and by them called the *trichord*. Pythagoras attributes this invention to the Troglodites, and pretends that this instrument was made of the water laurel.

PANDURIFORME, FOLIUM, in *Botany*, a leaf so named from its resemblance to the form of an ancient lyre, or πανδύρα, being rounded and dilated at each end with a contraction in the middle. The form of the modern violin seems to have been borrowed from that instrument, though it does not clearly appear for what reason. The leaf so denominated is scarcely to be found but in the species of *Rumex*, called from this resemblance, which is very correct and striking, Fiddle Dock. See LEAF.

PANDYSIA, Πανδυσία, in *Antiquity*, public rejoicings when the season, through its coldness and intemperance, forced the sailors to stay at home.

PANE', in *Geography*, a town on the N. coast of the island of Sumatra. N. lat. $2^{\circ} 40'$. E. long. $99^{\circ} 35'$.

PANEAS, a town of Syria, called also Casarea-Philippi (see CÆSAREA); 24 miles E. of Seir.

PANEGYRIC, PANEGYRIS, or *Panegyricus*, an oration in praise of some extraordinary thing, person, or virtue.

The name is Greek, πανηγυρις, formed of παν, *all*, and αγειν, *I assemble*; because anciently held in public and solemn assemblies of the Greeks, either at their games, their feasts, or their religious meetings.

The panegyric is ranked among the demonstrative kind of orations. See ORATION.

To make their panegyrics the more solemn, they used to begin with the praises of the deity in whose honour the games, &c. were celebrated; then they descended to the praise of the people or country where they were celebrated: then to the princes or magistrates who presided at them; and at length to the champions, especially the conquerors, who had gained the prizes in them.

F. De Colonia lays down two methods, or series, observed in panegyrics. The *artificial*, where, without any regard to the order of time, every thing is reduced to certain heads. Thus Tully refers the whole praise of Pompey to his skill in war, his virtue, authority, and felicity.

The other *natural*; in which the order and time of history are observed. This series he divides into three periods: the space before the person's birth; that wherein he lived; and, if he be dead, that which followeth his death. This natural series requires much less art, genius, &c. than the other.

The topics or sources of panegyric are, chiefly, the family and country of the hero, auguries at his birth, his vir-

tues, the talents of his body and mind, honours, riches, manner of his death, and the consequences thereof.

PANEGYRIC, πανηγυρικος, is also the name of a church-book in use among the Greeks: so called, as consisting of panegyrics, or discourses in praise of Jesus Christ, and the saints; it is found in MS. in most churches, but is not the same in all, each church having its particular saints; and the compilers of this kind of books usually suited their collections to the taste of their own devotion. They are disposed according to the order of months, and frequently consist of twelve volumes, answering to the twelve months of the year.

PANEGYRIS, Πανηγυρις, among the Greeks, a fair, or festival day, on which the people used to meet together. It exactly corresponded to the Nundinæ of the Romans.

PANEL, PANELLA, or *Panellum*, in *Law*, is derived, by Spelman, from *pagella*, a *schedule*, or *page*; in which sense we say, a *panel* of parchment, a *counterpanel* of an indenture, &c.

PANEL, or *Pannel*, is more commonly used for a schedule, or roll, containing the names of such jurors as the sheriff returns to pass upon any trial.

Hence the impanelling of a jury, is the entering of their names, by the sheriff, into a panel, or little schedule of parchment; called also the *panel of assize*, *panellum assise*. Coke on Littleton will have panel to be an English word, signifying a little part; as being a diminutive of the word *pane*, *part*; but Spelman takes this for an oversight.

PANEL, in *Joinery*, &c. See PANNEL.

PANEL, in *Ship-Building*. The captain's cabin and ward-room bulkheads consist of rails, stiles, and panels, framed together. The other cabins, of panels grooved and tongued together only.

PANELLENIA, Πανελληνισια, in *Antiquity*, a public festival, celebrated by an assembly of people from all parts of Greece.

PANEMUS, in *Chronology*, the Bœotian name of the Athenian month Metagitnion, which was the second of their year, and answered to the latter part of our July and beginning of August.

PANEMUS, among the Corinthians, answered to the Attic month Boedromion, or, according to Petavius, to our November. In the ancient Macedonian calendar, it was the ninth month of the year: but after the conquest of Arabia, they gave this name to the sixth month.

PANEPHYSIS, in *Ancient Geography*, a town of Egypt, and capital of a nome, called by Ptolemy "Neut."

PANERE, in *Geography*, a town of the island of Ceylon; 24 miles N.N.E. of Colombo.

PANEROS, the name of a beautiful stone dedicated to Venus; it was called also by some *pansebastos*, and was probably one of the beautiful azates.

PANES, in the *Ancient Theology*. See FAUNS.

PANETURE, in *Geography*, a town of the island of Ceylon; 18 miles S. of Colombo.

PANGA, a town on the E. coast of Celebes. S. lat. 1° 54'. E. long. 121° 16'.

PANGA, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Metz. The place contains 232, and the canton 12,847 inhabitants, on a territory of 247½ kilometres, in 48 communes.

PANGÆUS MOUNTAINS, in *Ancient Geography*, a mountain of Thrace, on the confines of Macedonia, the foot of which was watered by the Nestus.

PANGASINAN, in *Geography*, a town on the W. coast of the island of Luzon, and capital of a province or kingdom. N. lat. 15° 40'.

PANGASMAN, a small island in the Sooloo Archipelago. N. lat. 6° 8'. E. long. 120° 58'.

PANGESANA, an island in the East Indian sea, about 45 miles long, and 9 broad, situated between the islands of Celebes and Boutan. S. lat. 5° 5'. E. long. 122° 50'.

PANGIMODOO, a small island in the South Pacific ocean, at the entrance of the harbour of Tongataboo.

PANGKER, a town of the duchy of Holstein; 3 miles N.N.W. of Lutkenborg.

PANGLO, or PANGLAO, one of the smaller Philippine islands; 60 miles N. of Mindanao.

PANGO, a town of Africa, capital of a province in the kingdom of Congo, on the Barbela; 40 miles N. of Congo Batta.

PANGOLIN, of Buffon, in *Zoology*, is the short-tailed manis, or MANIS *pentadactyla* of Linnæus; which see.

PANGONIA, in *Natural History*, the name of a genus of crystal.

The word is derived from the Greek πᾶς, *numerus*, and γωνία, *an angle*, or *bending*, and expresses a crystal composed of many angles.

The bodies of this genus are single-pointed, or imperfect crystals, composed of dodecangular, or twelve-plated columns, terminated by twelve-plated pyramids, and the whole body, therefore, made up of twenty-four planes. Of this genus there are only three known species.

PANGOOTARAN, in *Geography*, an island in the Sooloo Archipelago, about 10 miles long and 4 broad. N. lat. 6° 15'. E. long. 120° 28'.

PANGUCI, a small island in the East Indian sea, near the coast of Queda. N. lat. 5° 50'. E. long. 100° 5'.

PANGY, a town on the E. coast of the island of Celebes, in Gunong Tally bay. S. lat. 1° 6'. E. long. 120° 15'.

PANJAB, a province of Hindoostan, watered by the five branches of the Indus, frequently called *Lahore*, which see; though Panjab, being applied to a natural division of country, is applicable also to part of *Moulton*, which see. The five rivers from which Panjab derives its name, are Behut or Jhylum (the *Hydaspes* of Alexander), the Chunaub or Junaub (Alexander's *Acetines*), the Rauvee (Alexander's *Hydraotes*), the Beyah (Alexander's *Hyphasis*), and the Setlege, Suttuluz, or Sutluj. The sources of all these rivers are situated in the great chain of snowy mountains, that extend from Sirinagur to the north of Cashmere, and which are in fact the true *Imaus*, which see. The eastern boundary of the Panjab is properly, this ridge of mountains; but in a more limited sense, and particularly according to the ideas of the present times, the Panjab means the country situated *without*, or to the west of the hilly tract; and which is of considerable width, being possibly from 50 to 60 miles from the edge of the plains to the summits of the highest mountains. From the Setlege to the Jhylum, and to the hills that bound the Panjab, on the N. and E., it appears to be chiefly a tract of flat and very fertile land; and, indeed, the courses of the four eastern rivers very plainly indicate a regularity of surface and fertility of soil. But between the Jhylum or Behut and the Indus, there is a large proportion of hilly country, which may be supposed to influence the course of the Jhylum, and give it so different a form from the others; the river conforming to the border of the hilly tract. The Panjab country being the frontier province towards Tartary, and the northern parts of Persia, from whence have sprung the conquerors of Hindoostan in every age, Alexander excepted, their route to the interior parts of the country must have led through it. Nadir Shah's route was the ordinary one, by Attock and Lahore. For the other routes of Timur and Alexander, we refer to Rennell's memoir.

memoir. From these we learn that the lower part of the Panjab towards Moulton is flat and marshy, and inundated, like Bengal, by the periodical rains, which fall between the months of May and October. The revenues of this province, under Aurungzebe, amounted annually to 206½ lacks of rupees.

PANJANY, an island in the East Indian sea, near the coast of Siam, about 14 miles long, and 6 broad. N. lat. 8°. E. long. 98° 42'.—Also, a small island in the East Indian sea, near the east coast of the island of Borneo. N. lat. 2° 15'. E. long. 117° 59'.—Also, an island near the west coast of Siam, about 40 miles in circumference. N. lat. 8°. E. long. 98° 42'.—Also, a small island in the Pacific ocean, near the north coast of New Guinea. S. lat. 3° 18'. E. long. 135° 25'.

PANIANY, a town of Hindoostan, in Calicut; opposite to which is a passage through the Gaunts, about 16 miles wide, and 14 or 15 miles long, occupied by forest trees, and defended by the fort of Annamally on the E., and Paicaudcherry on the W., and opening finally into the low country on the Malabar coast; 42 miles S.S.E. from Calicut. N. lat. 10° 41' 45". W. long. 75° 55'. The river of Paniany takes its course from the Combettore country, through the above-mentioned opening; and is said to be navigable in the rainy season, for small boats, to the foot of the Gaunts. This circumstance, together with the inundated state of the country at that season, may serve to shew, that the country W. of the Gaunts has no great declivity, in a course of nearly 60 miles. This river, as well as that of Daraporum, has its source from an elevated plain, about 60 miles in extent, stretching itself across the eastern mouth of the gap or valley already mentioned. This plain rises suddenly from the level of the surrounding country, like a vast terrace; and the forest bounds it on the west.

PANJAPILLY, a town of Hindoostan, in Myfore; 13 miles W.S.W. of Caveripatam.

PANJASSAS, a town of Louisiana, on the Akanfas. N. lat. 36° 25'. W. long. 94° 21'.

PANIC, or PANIC Fear, a term used for a needless or ill-grounded fright.

Polyænus fetches the origin of the phrase from Pan, one of the captains of Bacchus, who, with a few men, put a numerous enemy to rout, by a noise which his soldiers raised in a rocky valley, favoured with a great number of echoes. This stratagem making their number appear much greater than it really was, the enemy quitted a very commodious encampment, and fled. Hence all ill-grounded fears have been called *panics*, or *panic fears*; and it was this that gave occasion to the fable of the nymph Echo's being beloved by the god Pan.

Others derive the origin of the expression hence; that, in the wars of the Titans against the gods, Pan was the first who struck terror into the hearts of the giants. Theon on Aratus says, he did it by the means of a sea-shell, which served him for a trumpet, of which he was the inventor. See PAN.

PANIC, in *Botany*. See PANICUM.

PANICASTRELLA, a sort of Italianized name, formed by Micheli from *Panicum*, for what is now the *Cenchrus* of Linnæus and other botanists, which Micheli perceived to be akin to that genus. There is certainly a resemblance in character, as well as in habit, to some of the numerous species which have been arranged under it. See PANICUM, and PENNISETUM.

PANICLE, in *Gardening*, is the part which shews the particular mode of flowering in some plants, and which is of

two sorts or descriptions, the one loose or diffuse, the other close or bound up. See PANICULA.

PANICOLO, in *Geography*, a town of Naples, in Lavora; 22 miles N.W. of Naples.

PANICULA, in *Botany*, is used by Pliny for the flowery tuft which crowns the summit of the reed, as well as for the male catkins of the fir tribe, whose dense scaly structure he very clearly mentions. Linnæus uses the word technically, according to the first meaning, for a particular kind of inflorescence, called in English a panicle. In this the flowers are disposed in a sort of loose subdivided bunch or cluster, without any order, as in the Common Reed, *Arundo Phragmites*, and the Oat. If the stalks are distant, as in the latter example, it constitutes a diffuse or lax panicle; if otherwise, a close or dense one. *Panicula sparsa*, implies a panicle whose branches spread every way; *secunda* is used when they are all turned to one side, usually in a drooping manner. The panicles of grasses are, for the most part, *semi-verticillata*, or half-whorled, their principal branches being disposed in a close ring, half round the main stalk. Very dense panicles are found in some of this family, as *Agrostis stolonifera*, the Fiorin grass, now so much talked of; *Panicum italicum*, the Millet; and especially the *Phleum paniculatum*, (see Engl. Bot. t. 1077.) whose inflorescence cannot be distinguished from a spike, till it is bent to one side, by which means it separates into lobes. Some plants have a forked panicle, so termed because a solitary flower is placed between each of its ramifications, as in various species of *Silene*, *Spergula*, &c. A remarkably divaricated, or rigidly spreading, panicle is seen in the Wall Lettuce, *Prenanthes muralis*. The sugar-cane, when it blossoms, which most West Indians will tell us never happens, but which the writer of this has seen with admiration, bears one of the largest and most elegant panicles in nature. The distinction between a panicle and a spike is in all cases very great, but particularly important in the natural family of grasses, where it separates most of the genera into two grand sections—A very compact panicle is, in some instances, termed a THYRSUS; see that article.

PANICUM, an old Latin name for the most celebrated species of the genus, *P. italicum*, and which Faber and Ambrosinus, after Pliny, declare to allude to its panicle of seed. Certainly the inflorescence of that grass, or corn, though now termed a spike, answers peculiarly well to the classical idea of a panicle. (See PANICULA.) Other etymologists deduce the word *Panicum* from *panis*, *bread*; for which, however, it seems to have served less than many other sorts of grain. Linn. Gen. 32. Schreb. 46. Willd. Sp. Pl. v. 1. 333. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 64. Prodr. Fl. Græc. Sibth. v. 1. 39. Ait. Hort. Kew. ed. 2. v. 1. 139. Brown Prodr. Nov. Holl. v. 1. 189. Swartz. Ind. Occ. 139—178. Juss. 29. Lamarek Illustr. t. 43. Michaux Boreal-Amer. v. 1. 46. Gært. t. 1. (Digitaria; Juss. 29.)—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. reformed. *Cal.* Glume of two flowers, and two, nearly ovate, ribbed valves; the outermost minute and somewhat inferior; one floret perfect, the other either neuter or male. *Cor.* of the perfect floret a glume of two nearly ovate cartilaginous valves; the outermost convex, embracing with its margins the inner one, which is smaller and flatter; that of the neuter or male, often very small, a glume of two valves; the outermost, in the bosom of the smaller valve of the calyx, flattish and ribbed; the innermost membranous, flat, with inflexed margins. Nectary, in the perfect as well as male florets, minute, gibbous, of two leaves; in the neuter wanting. *Stam.* in the perfect and male florets

PANICUM.

florets only; filaments three, capillary; anthers oblong. *Pist.* in the perfect florets only, germen roundish; styles two, capillary; stigmas feathery. *Peric.* none, except the corolla closely combined with the seed. *Seed* solitary, clothed with the corolla, roundish, flattened at one side.

Ess. Ch. Calyx of two very unequal valves, containing two flowers, the outer one male or neuter. Corolla of two unequal valves, finally cartilaginous, and investing the seed.

Obf. Schreber remarks, that botanists, having overlooked the inner glume of the imperfect floret, conceived its outer glume to belong to the calyx; hence the latter was thought to consist of three valves, of which the third was much the least. We plead guilty to this charge, but have never been satisfied with the opinion we adopted. The inner valve of the imperfect floret, discovered by Dr. Stokes and Mr. Sowerby in *P. Crus-galli*, is figured in *Engl. Bot.* t. 876; and though we agreed to refer it, as a fourth valve, to the calyx, this was, in reality, because we could dispose no otherwise of the troublesome intruder. Mr. Brown has adopted the ideas of Mieg, Adanson, Forskall, and Schreber, on this subject, and we have profited by their corrections of the Linnæan characters. It is necessary to observe, however, that the neutral floret very generally consists of but one valve, so that the above error might easily be committed.—Our learned friend, in his *Prodr. Nov. Holl.* v. 1. 193—195, has established three new genera as distinct from *Panicum*, which we scruple to adopt. These are, 1st, *Chamaraphis*, distinguished only by having three styles instead of two, and consisting of but one species; 2d, *Orthopogon*, which has nearly equal calyx-valves, as well as smooth awns, and consists of *P. compositum* and *birtellum*, with a few new species; 3d, *Pennisetum* of Richard, comprising *P. viride*, *verticillatum*, *glaucum*, *helvolum*, *italicum*, with a new species called by Mr. Brown *compressum*, all which have a partial involucre, composed of separate bristles, including one or three flowers. The genus of *Panicum* is indeed overburdened with species, but above all things we hesitate to admit *Pennisetum*, as its character is taken rather from a part of the inflorescence than of the flower, and as it embraces the original *Panicum* of the ancients, from whence, and its allies, all botanists have taken their ideas, in general, of the genus in question. We perceive, moreover, in *P. Crus corvi*, *Crus galli*, &c. something of an approach to a similar bristly involucre.

Panicum consists of thirty-four species only, in Linn. *Syst. Veg.* ed. 14. Willdenow has eighty, having profited much by the labours of Retzius and Swartz, the former of whom has described many new species from the East, and the latter a considerable number from the West Indies. The new edition of *Art. Hort. Kew.* contains twenty-five species, all among those of Willdenow. Five of them are natives of England. One new species only is defined in the *Prodr. Fl. Græc. Sibth.*

The whole are distributed by Linnæus, and consequently by Willdenow, into two sections, *flowers spiked*, and *flowers panicled*. The author last named has forty species in each section. Mr. Brown, however, who has defined thirty-two new species of *Panicum*, even as he limits the genus, from New Holland alone; besides five other new ones referred to his genera of which we have spoken above; has divided *Panicum*, upon new principles, into seven sections.

Of these, for want of knowing his new species, we can form no conclusive judgment; and we shall therefore content ourselves with the old arrangement, selecting a few examples, that may indicate certain subdivisions of the sections, or

assemblages of species, so as to give a comprehensive idea of the whole, with the characters of the most remarkable.

SECT. 1. Flowers spiked.

Here at first nine species present themselves, which belong to Mr. Brown's *Pennisetum*, and of which two are British.

P. verticillatum. Rough Panick-grass. Linn. *Sp. Pl.* 82. Willd. n. 3. Curt. *Lond. fasc.* 4. t. 6. *Engl. Bot.* t. 874. (*Gramen geniculatum*; Ger. em. 15. f. 1.)—Spike whorled; spikelets in fours. Involucre of two bristles, rough, with reversed teeth to each flower.—Native of the warmer parts of Europe, in cultivated ground, especially where the situation is rather moist, but rare in England, chiefly occurring in Battersea fields and that neighbourhood. We have found it on the west side of Norwich, in gravelly fallow fields, flowering in July or August. The root is annual, fibrous. Stems straight, but widely spreading, leafy, rough above. Leaves harsh, straight, pointed, dark green, very rough at the edges; their *stipula* fringed. Spikes solitary, terminal, erect, green, with a purplish tinge, composed of many dense whorled spikelets. The bristles which compose the involucre, being rough with teeth that point backwards, afford the most certain mark of distinction, first pointed out by the ingenious Mr. Curtis, between this and *P. viride*. Both these are harsh useless grasses, not abundant enough to be known to the farmer as noxious weeds.

P. viride. Green Panick-grass. Linn. *Sp. Pl.* 83. Curt. *Lond. fasc.* 4. t. 5. *Engl. Bot.* t. 875. Knapp, t. 10. *Leerf.* 13. t. 2. f. 2. (*G. panicis effigie spicâ simplici*; Ger. em. 17.)—Spike cylindrical; spikelets crowded. Involucre of several bristles, rough, with erect teeth, and embracing two flowers.—Native of the warmer parts of Europe, rather less rare in England than the former, and usually found in more dry sandy ground. It is annual, flowering at the same time with the *verticillatum*, and, as far as we know, equally unprofitable to the agriculturist. Small birds however are fond of the seeds of both species. The spikelets in the present are irregularly crowded, not whorled. Flowers generally in pairs, with about six bristles, which are rough with teeth that point forwards or upwards, a clear and decisive character. The same difference is observable in the direction of the minute bristly teeth which form the roughness of the upper part of the stem in each species. These marks were, nevertheless, unknown to Linnæus, nor were his ideas clear concerning the two grasses in question.

P. glaucum. Glaucous Panick-grass. Linn. *Sp. Pl.* 83. Willd. n. 5. Schreb. *Gram.* 21. t. 25. *Leerf.* 12. t. 2. f. 2. †. (*Pennisetum glaucum*; Brown *Prodr. Nov. Holl.* v. 1. 195.)—Spike cylindrical; spikelets crowded. Involucre of many bristles, rough, with erect teeth, and usually embracing two flowers. Case of the seed transversely wrinkled.—Native of the south of Europe, as well as of America, the East Indies, and New Holland, being one of the most general of grasses, though not found wild in England. Its habit is like the two former, but the stems are taller and more erect; the herbage rather glaucous; the numerous bristles of the involucre with a tawny or golden tinge, not purple; and the outer glume of the perfect floret curiously marked, in its upper part, with transverse wavy wrinkles. The upper part of the stem is strongly furrowed, but not rough to the touch.

P. italicum. Italian, or True, Panick-grass. Linn. *Sp. Pl.* 83. Willd. n. 8. Bauh. *Theatr.* 519. (*Panicum*; Matth. *Valgr.* v. 1. 368. Rumph. *Amboin.* v. 5. 202. t. 75. f. 2.)—Spike compound, drooping; interrupted at the

PANICUM.

the base; spikelets clustered. Involucrum of many, very long, rough bristles. Common stalk woolly.—Native of both Indies. Cultivated in Italy and other parts of Europe. This is believed to be the true *Panicum* of the ancients, and its drooping panicle is described by Pliny, who speaks of it as not so much used as the Millet, *P. miliaceum*, in making bread, but weighing more than any other grain, as well as increasing more in bulk when cooked. It is annual, with the habit of the foregoing, but much larger, the root producing several stems, four or five feet high, with broad harsh leaves, and a solitary, very heavy, dense spike, or rather condensed panicle, bent downwards, beset with innumerable very long bristles, and producing abundance of small oval smooth seeds, not bigger than those of *P. glaucum*.

P. germanicum, Willd. n. 7, seems to us but a starved variety, or perhaps the true wild state, of the *italicum*.

After this tribe follows a train of species, with rather distantly branched compound spikes, which Mr. Brown considers as properly belonging to *Panicum*. We cannot but concur with him in the union of three supposed species, under the following.

P. Crus galli. Loose Panick-grafs. Linn. Sp. Pl. 83. Curt. Lond. fasc. 4. t. 8. Engl. Bot. t. 876. Knapp. t. 11. Leers. 13. t. 2. f. 3. (*P. Crus corvi*; Linn. Sp. Pl. 84. *P. flagginum*; Retz. Obs. fasc. 5. 17.)—Spike twice compound; its branches angular, rough and bristly, alternate or in pairs. Calyx angular, hispid, awned.—Native of Europe, North America, the East Indies, and New Holland, in cultivated or waste land, that is either moist or inundated. With us it is rare, flowering in July. This is a coarse annual grass, two feet or more in height. Leaves broad, harsh, with long tumid sheaths, and either no stipula, or only a few hairs in the place of one. The common spike is four or five inches long, with a five-angled, rough and furrowed, common stalk, and from six to ten alternate branches, distant below, crowded into the top of the spike above. The branches are also slightly compound. Flowers crowded, all turned to one side, hispid or prickly, accompanied by scattered tufts of rather distant, fine, smooth, pellucid bristles, about as long as the flowers. The outer valve of the neuter *floret* is hispid, and awned or pointed, like the valves of the calyx, of the nature of which it participates throughout the genus; the rest are smooth, that which invests the seed even and polished.

P. brizoides. Briza-like Panick-grafs. Linn. Mant. 184. Willd. n. 17. Ait. n. 10. (*Gramen panicum, multiplici spicâ maderaspatanum*; Pluk. Phyt. t. 191. f. 1.)—Spike compound; its branches alternate, erect, oblong. Flowers crowded, turned to one side, without awns. Stem simple, smooth.—Native of the East Indies. A smooth pale grass, whose stem is simple, or rarely branched; the leaves long, loosely spreading, smooth and naked. Spike terminal, straight, composed of several alternate, oblong, obtuse branches, of crowded whitish-green flowers, all turned to one side. The outer *glumes* are ovate, tumid, with hairy ribs, the inner one which invests the seed very smooth and shining.

P. eruciforme. Caterpillar Panick-grafs. Sm. Fl. Græc. Sibth. v. 1. 44. t. 59.—Spike compound; its branches alternate, erect, close-pressed, linear, hairy. Flowers crowded, turned to one side, without awns. Stem branched from the bottom.—Discovered by Dr. Sibthorp in fields about the temple of Juno, in the island of Samos. Differs from the last in having a slender hairy stem, branched from the bottom, with numerous bent joints; leaves short and spreading; branches of the spike more slender, linear, and hairy; *glumes*

less tumid, and the outermost valve of the calyx much more minute.

This tribe, including several more species, is followed by such as constitute the genus *ORTHOPOGON* of Mr. Brown, (see that article,) who indicates six species, *P. Burmanni*, Willd. n. 20; *hirtellum* and *compositum*, Linn. with three new ones named by him *Orthopogon æmulus, flaccidus* and *imbricellus*, the four last being found in New Holland. One example is sufficient.

P. hirtellum. Rough-haired Panick-grafs, called in the West Indies Scotch-grafs. Linn. Sp. Pl. 83. Willd. n. 21. Ait. n. 1. Hofst. Gram. Austr. v. 3. 36. t. 52.—Spike compound; its branches alternate, close-pressed. Flowers smooth, in pairs, turned to one side. Calyx with long, smooth, channelled awns. Leaves ovate, pointed.—Native of the West Indies, as well as of the south of Europe. Root biennial. Stems branched, decumbent, taking root at the joints, two or three feet long. Leaves spreading, ovate, pointed, varying in breadth, ribbed, rough, besprinkled with soft hairs; their sheaths extremely hairy, particularly at the top and bottom. Spikes terminal, conspicuous for the prominent purplish awns of the calyx, which are linear, obtuse, quite smooth, flattened or channelled above, three quarters of an inch long. The corolla has similar, but much shorter, awns. The common stalk is winged and hairy.

A tribe with fingered spikes, the *Digitaria* of Haller and Jusseu, succeeds. The differences in the number of the calyx-valves in different species, or their variableness in the same, have caused a diversity of sentiments among botanists. The genus *Cynodon*, Brown Prodr. Nov. Holl. v. 1. 187, is formed out of this tribe. Their habit, especially their long, linear, clustered, but divaricated, spikes, give them an aspect very distinct from all the species we have hitherto mentioned.

P. sanguinale. Cocks-foot Panick-grafs. Linn. Sp. Pl. 84. Willd. n. 28. Ait. n. 12. Curt. Lond. fasc. 4. t. 7. Engl. Bot. t. 849. Knapp. t. 12. Schreb. Gram. v. 1. 119. t. 16. Hofst. Gram. Austr. v. 2. 14. t. 17. Mart. Rust. t. 78. (*Ischæmon vulgare*; Ger. em. 27)—Spikes fingered; knotty on the inside at the base. Flowers in pairs, awnless. Sheaths of the leaves dotted.—Native of various parts of Europe, as well as of America; rare in England. It is annual, flowering in July, and prefers a rich moist soil. The stems are numerous, bent and decumbent at their base, spreading widely upwards, twelve or eighteen inches long, smooth, rigid, leafy. Leaves linear-lanceolate, broad, nearly smooth, generally shorter than their sheaths, which are striated, and besprinkled with small cartilaginous dots or tubercles, frequently producing fine hairs. Spikes about four or five, spreading, two inches or more in length, nearly umbellate, or at least approximated, linear, the common stalk of each zigzag, winged, tumid at the bottom. Flowers dull violet, in alternate pairs leaning one way, on unequal short partial stalks. Outer valve of the calyx very minute, and often abortive. This is a hard coarse grass, of no agricultural use.

P. dactylon. Creeping Panick-grafs. Linn. Sp. Pl. 85. With. 116. t. 21. Engl. Bot. t. 850. Knapp. t. 13. Sm. Fl. Græc. Sibth. v. 1. 45. t. 60. (*Cynodon Dactylon*; Brown Prodr. Nov. Holl. v. 1. 187.)—Spikes fingered; hairy on the inside at the base. Flowers solitary. Calyx equal to the corolla. Shoots creeping. Leaves pungent.—Native of the sandy shores of Cornwall, as well as of the south of Europe, the Levant, the East Indies, and New South Wales. In the north of Italy it is common in the

PANICUM.

the streets of many towns, and flowers at various seasons. The strong perennial *roots*, with smooth fibres, are formed of hard polished runners, shooting horizontally to a great extent in the sand, and clothed with the permanent sheathing bases of the rigid, pungent, glaucous, hairy *leaves*. Flowering *stems* a span high, more or less, leafy. *Spikes* from three to five, shorter than in the last, their common stalks zigzag and angular, but not winged. *Flowers* solitary, alternate, close-pressed, at one side only. *Calyx* of two nearly equal lanceolate valves, almost as long as the *corolla*, which is compressed, polished and beardless. Mr. Brown notices the rudiment of a second *floret*, in the form of a naked bristle, at the base of the inner valve of the *corolla*. This grass was perceived by Mr. Lambert, Tr. of Linn. Soc. v. 7. 309, to be no other than the *Agrostis linearis* of Koenig, Retzius, and Willdenow, Sp. Pl. v. 1. 375, the *Durva* of the Hindoos, which the late Sir William Jones, in the 4th volume of the Asiatic Researches, has celebrated for the extraordinary beauty of its flowers, and its sweetness and nutritious quality as pasture for cattle. We cannot but remark what extraordinary celebrity is attached, every now and then, to one grass or other, and how their fame passes away "like the morning cloud," while the best graziers scarcely know perhaps, better than their fat cattle, any thing of the nature of the common never-failing herbage, to which they are both so much indebted. It is but justice however to the memory of the great Sir William Jones, to mention, that the very *Panicum* in question appears to be, as Dr. Sibthorp judged, the real *αγρωστής* of Dioscorides, which that ancient botanist describes as having "jointed creeping shoots, throwing out sweet roots from their joints; and pointed, hard, broad leaves, like a small kind of reed, which are the food of cattle." This description is very characteristic; and the grass is called by the modern Greeks, on all whose coasts it abounds, either *αγρωστόν* or *αγρωστάδα*.

Section 2. *Flowers paniced.*

P. repens. Paniced Creeping Panick-grass. Linn. Sp. Pl. 87. Willd. n. 45. Ait. n. 18. Sm. Fl. Græc. Sibth. v. 1. 45. t. 61. Cavan. Ic. v. 2. 6. t. 110.—Panicle with stiff upright branches. Leaves divaricated. Root creeping.—Native of the banks of rivers in the Levant; gathered by Dr. Sibthorp near Platania in Crete, flowering in June; by Mr. Schlanbusch about 30 miles south of Naples; and by Broussonet and Desfontaines at Algiers. It is said in Hort. Kew. to be cultivated in the East Indies. The *root* is perennial, creeping to a very great extent, and by no means annual. It throws out copious fibres from its joints, and many ascending *stems*, twelve or eighteen inches high, simple, smooth, clothed with numerous, spreading, rather stiff *leaves*, whose margins and long sheaths are fringed with hairs, but their under side is very smooth to the touch. *Panicles* terminal, rather close, of numerous, upright, zigzag, rough-edged, repeatedly subdivided, slender branches; bearing a number of solitary, upright, smooth *flowers*. The *glumes* are ovate, tumid, ribbed. *Anthers* yellow. *Stigmas* purple, beautifully feathered, cylindrical. We are not informed whether the grain or the herbage be the object of culture in this plant.

P. miliaceum. Millet Panick-grass, or true Millet seed. Linn. Sp. Pl. 86. Willd. n. 49. Ait. n. 19. Hoff Gram. Austr. v. 2. 16. t. 20. (Miliun; Matth. Valgr. v. 1. 367. M. femine luteo vel albo; Bauh. Theatr. 502.)—Panicle loose and flaccid. Sheaths of the leaves hairy. Glumes pointed, ribbed.—Native of the East Indies. Cultivated from time immemorial in the south of Europe for the

fake of its seeds, which are among the more delicate, though not the most nutritious, kinds of grain. Small birds are very fond of these seeds, and the crop therefore requires strict vigilance while ripening. It is sown in the spring. The *root* is annual. *Stem* four or five feet high. *Leaves* pale, broadish; their sheaths ribbed, dotted, clothed with long, spreading or deflexed, hairs. *Panicle* terminal, lax and spreading, of innumerable, slender, compound, angular, rough-edged branches. *Flowers* larger than in the last, tumid, smooth, ribbed, awnless, a little drooping. Covering of the *seed* exquisitely polished.

P. latifolium. Broad-leaved American Panick-grass. Linn. Sp. Pl. 86. Willd. n. 62. Ait. n. 21. (Miliun virginianum lato brevique folio; Morif. sect. 8. t. 5. f. 4.)—Lateral branches of the panicle simply racemose. Leaves ovato-lanceolate, finely fringed at the base. Outer glumes obtuse, strongly furrowed, hairy.—Native of North America, from whence Kalm sent it to Linnæus. This is perennial and hardy in our climate, flowering late in autumn. The very broad *leaves*, almost heart-shaped at their base, where they are finely and densely fringed, mark this species; their sheaths are tight and smooth. *Panicle* wavy, loosely spreading, its branches angular, but scarcely rough; the lateral ones, for the most part, simply racemose, with distant *flowers*, on slender stalks of various lengths. The *glumes* are turgid, ovate, obtuse; the outer ones very strongly ribbed and furrowed, clothed with short hairs; the inner highly polished, and perfectly even.

P. oryzoides. Rice-like Panick-grass. Swartz Ind. Oec. 162. Willd. n. 65. (Miliun indicum arundinaceo caule; Sloane Jam. v. 1. 104.)—Panicle nearly simple, erect. Leaves ovato-lanceolate; their sheaths finely fringed at the summit. Glumes acute, all smooth and even; the outer ones obscurely ribbed.—Native of mountainous shady places, in the south of Jamaica, according to Dr. Swartz, whose obscure reference to Sloane leads us to suppose this is the plant the latter intended under the above name, which he says is "planted every where in Jamaica, yielding very great increase. It is thought to nourish little, and to be astringent as rice." Linnæus, who had a specimen from Browne's herbarium, confounded it, at the suggestion of Solander, with *latifolium*, from which the present species widely differs, in having *flowers* three times as large, with perfectly smooth, even, pointed glumes.

P. clandestinum. Sheath-flowered Panick-grass. Linn. Sp. Pl. 86, excluding the synonym. Willd. n. 66.—Panicles simple, concealed in the hairy sheaths of the heart-shaped leaves.—Native of Pennsylvania, from whence Kalm communicated it to Linnæus. The latter greatly errs in quoting a synonym of Sloane, which evidently belongs to his own *Cenchrus granularis*. We can indeed find no figure of the present species, nor have we seen it but in the Linnæan herbarium. The *stem* is very much branched, round, purplish, smooth and polished. *Leaves* about three inches long and one broad, alternate, spreading, heart-shaped and minutely crenate at the base, flat, tapering gradually into a sharp point; smooth on both sides, finely striated, paler beneath; *sheaths* nearly as long as the leaves, rather inflated, ribbed, besprinkled with cartilaginous umbilicated tubercles, as in *P. sanguinale*, many of which bear horizontally prominent brittle hairs. Within the sheaths of several of the uppermost *leaves* are completely concealed solitary, simple *panicles*, or rather clusters, of but few *flowers*, whose outer glumes are ribbed, ovate, obtuse and awnless, scarcely hairy or downy. The *glumes* do indeed greatly resemble those of *P. latifolium*, to which Linnæus considers this plant nearly allied.

allied. The sheaths of the *leaves* however, as well as the *inflorescence*, are very unlike that species.

P. arborefcens. Tree Panick-grafs. Linn. Sp. Pl. 87. Willd. n. 67. Ait. n. 22.—Stem arborefcent, very much branched, fmoth. Leaves heart-shaped-oblong, crenate, fomewhat fringed, with fmoth fheaths. Panicles capillary, level-topped, many-flowered. Glumes elliptical; the outer ones ribbed.—Native of the East Indies. Said to have been fent to Kew garden in 1776, by M. Thouin; flowering in the ftove in March and April. We know neither figure nor defcription of this, except that Linnæus fays it vies in height with the moft lofty trees, though the *flem* is fcarcely thicker than a goofe-quill. That part, in his fpecimens, is very much branched and divaricated, round, fmoth, highly polished, fender, but hard and rigid, with many knotty joints, and hard fealy buds, from whence the copious lateral fhots are produced. The *leaves* are lanceolate, pointed, three or four inches long, fcarcely one broad; ovate at the bafe, but much contracted, almoft into a fhort footftalk, before they join the fheaths, as well as very hairy there at the back, though otherwife naked, or merely roughift to the touch. The *fheaths* are tight, hard, fmoth and polished, crowned with a tuft of briftles. In the younger or flowering branches, the *leaves* are larger, with lefs elongation of the contracted part at their bafe. *Panicles* terminal, on long ftalks, with repeatedly fubdivided, long, capillary, fmoth-ift, level-topped branches, bearing numerous, fmall, upright, folitary *flowers*, whose glumes are elliptical and naked; the outer ones ribbed; that which enclofes the feed highly polished. We are not certain of our two Linnæan fpecimens belonging to the fame fpecies, as only one of them has *flowers*, and the *leaves* differ as above mentioned, as well as in being more harfh, with larger ftipulaceous briftles, in the barren fpecimen. The younger *branches* moreover are ftriated, and not fo finely polished. Both however are marked, and confidered as the fame, by Linnæus.

P. divaricatum. Straddling Panick-grafs. Linn. Sp. Pl. 86. Willd. n. 80. Ait. n. 25. Jacq. Hort. Schoenbr. v. 1. 10. t. 25.—Stem arborefcent, very much branched, divaricated, fmoth. Leaves linear-lanceolate, entire, with fmoth fheaths. Panicles rigid, compound, divaricated. Glumes obovate, tumid; the outer ones ribbed.—Native of Jamaica; flowering in our ftoves in fummer. The *flem* agrees in habit with the laft, and is perennial, climbing apparently to a great height if it meets with fupport; the branches copious, fpreading, leafy, round, fmoth and polished. *Leaves* about three inches long, and half an inch wide, lanceolate, acute, ftriated, fmoth, except at the edges, dark green; their *fheaths* much fhorter than the leaves, ribbed, naked, a little fwelling; each crowned with a fhort, membranous, fringed *ftipula*. *Panicles* terminal, erect, twice compound, with alternate, divaricated, rigid, angular, zigzag branches, roughift at the edges. *Flowers* five times as big as the laft and much fewer, being the fize of a grain of wheat, bent to one fide, obovate, polished; their outer glumes ribbed. Sometimes the glumes all affume a black or dark purple colour.

We have received from M. Delile, a celebrated French botanift and traveller, many fpecimens of this genus which appear to be nondefcript. Of thefe fome are the produce of North America, others of Egypt, and feveral of them very curious. They may probably have been published at Paris, fince the fpecimens reached us, and therefore we fhall not venture on their particular determination here. Michaux has alfo many fpecies unknown to us. All thefe, added to the New Holland ones of Mr. Brown above-men-

tioned, will perhaps extend the fpecies of *Panicum* to about 130 in all.

PANICUM, in *Agriculture*, a genus of grafes of which there are feveral fpecies, but none of which can be cultivated, except for bird-feed.

PANIEFOULE, in *Geography*, a lake of Africa, in Hoval, which communicates with the Senegal. N. lat. 16° 40'.

PANIGAROLA, JEROME, in *Biography*, an Italian prelate, and one of the moft celebrated preachers in the fixteenth century, was born at Milan, of a noble family, in 1548. At a very early age he difcovered great genius and abilities, and befides an uncommon facility in acquiring knowledge, he poffeffed furprifing powers of memory, which enabled him to retain whatever he learned. Being fent to the univerfity at Pavia he diftinguifhed himfelf in a few months by the rapidity of his progreffs in learning, though it was, at the fame time, a matter of great regret, that he rendered himfelf notorious for his irregularities and turbulent fpirit. No difturbance ever occurred in the univerfity, but Panigarola would be found deeply concerned in it; and fcarcely a night paffed, in which, at the head of pupils from Milan, he was not engaged in quarrels and battles with the ftudents from Placentia, Pavia, or fome other place. At length his exceffes became fo great, that the fenate of Milan ordered his father to withdraw him from Pavia. He was now fent to Bologna, where, for fome time, he rendered himfelf equally notorious for his ill conduct, and for the licentious example which he gave to his contemporaries. Suddenly an entire change took place in his mind, and he expreffed a ftrong inclination for embracing the monaftic life. He accordingly took the habit of St. Francis at Florence in 1567, when he was only nineteen years of age. His whole delight now confifted in the moft regular and punctual obfervance of the duties of the cloifter, and in affiduous ftudy. In the year 1570, the perfon appointed to preach the Lent fermons was fuddenly taken ill, and Panigarola was appointed his fubftitute. The difplay of his eloquence on this occafion obtained for him the higheft reputation. From this moment, wherever he appeared in the pulpit admiring crowds of all ranks attended. Pope Pius V. heard him, and was aftonifhed; but thinking that fo young a man flood in need of a more perfect acquaintance with the facred fcriptures, and the fathers, than it was poffible he could have acquired fo foon, recommended it to him to devote fome time to clofe ftudy. He accordingly went to France for this purpofe, and attended the profefors at the univerfity of Paris. Upon his return to Italy his celebrity was fo great, that there was no church fufficiently large to accommodate the crowds who were attracted by his preaching, and when he was upon a journey, he could fcarcely pafs through any city or town, without being, in a manner, compelled to preach. In 1586 he was confecrated at Rome titular bifhop of Chryfopolis, and appointed coadjutor to the bifhop of Ferrara; but in lefs than three months he received an order to quit Ferrara, and the duchy, a difgrace which he attributed to the intrigues of a minifter jealous of his renown, who perfuaded the duke that he betrayed the fecrets of the ftate to cardinal Ferdinand de Medici. Under thefe circumftances he was received with great kindnefs by pope Sixtus V. who appointed him to preach at St. Peter's in the year 1587. In 1589 he was fent by the fame pontiff into France to encourage the party of the league againft Henry IV. He was prefent at the fiege of Paris, and employed all his eloquence in animating the citizens to fubmit cheerfully to the priva-

tions and miseries which they suffered during the memorable blockade of that place. He died in 1594, at the early age of forty-six. As an author, his most celebrated productions consist of several volumes of sermons, in Latin and Italian: besides these he published many other theological pieces, theses, orations, and poems; also "Paraphrasi sopra Demetrio Falerio, &c." consisting of a learned commentary upon the treatise of Demetrius Phalereus on eloquence. Moreri.

PANIGENA, in *Ancient Geography*, a town on this side of the Ganges, and on a gulf of this river, between Paluga and Conagera. Ptolemy.

PANIONIA, Πανωνία, in *Antiquity*, a festival in honour of Neptune, celebrated by a concourse of people from all the cities of Ionia.

One thing is remarkable in this festival, that if the bull offered in sacrifice happened to bellow, it was accounted an omen of divine favour; because that sound was thought to be acceptable to Neptune.

PANIS, in *Geography*, an island in the Atlantic, at the mouth of the river Bandi, near the coast of Africa. N. lat. 5°.

PANIS, a tribe of Indians, 120 miles from the mouth of the river Platta, or Shallow river, a western branch of the Missouri. This tribe numbers 700 warriors, in four neighbouring villages. They hunt but little, and have few firearms. They are often at war with the Spaniards in the vicinity of St. Fé, near which is the place of their abode.

PANIS & *cerevisia affisa*, in *Law*. See ASSISA.

PANIS & *cerevisia emendatio*. See EMENDATIO.

PANIS Demonum, in *Natural History*, a name given by authors to a sort of coarse stone, common in Sweden, and some other places, and usually found in roundish, but somewhat flattened masses, resembling a loaf in form.

PANIUM, in *Ancient Geography*, a promontory of Europe, on the coast of the Thracian Bosphorus.

PANIUS, or PANEUS, a mountain of Syria, which formed part of mount Libanus, and at the foot of which was situated the town of Paneus.

PANKE, in *Botany*, a name, as we presume, of American origin, published by Feuillée, and adopted by Molina, though the latter has transferred it from the original plant of Feuillée, which is a *Gunnera*, to a totally distinct genus, termed by that author *Llaupanke*. Willdenow has retained this name, and thus it has found a place in a popular work, which we greatly lament, the word being, according to every sound principle, inadmissible.—Molin. Chil. (the German edition according to Willd.) 119. Willd. Sp. Pl. v. 2. 486.—Class and order, *Enneandria Monogynia*. Nat. Ord. near *Bocconia*?

Ess. Ch. Calyx four-cleft. Corolla bell-shaped, four-cleft. Capsule of two valves, with one seed.

1. *P. tinctoria*.—"Leaves stalked, five-lobed."—Native of moist situations on the mountains of Chili.—*Root* perennial. *Leaves* five-lobed, serrated, five-ribbed, papillary, downy, pulpy, permanent. *Footstalks* round, prickly, half a foot long. *Cluster* terminal. *Flowers* very numerous, on partial stalks. *Willd after Molina*.

Jussieu says, Gen. 452, that the *stem* is five feet high, with three or four *leaves* at the top.

2. *P. foveifolia*. Willd. n. 2. (*Llaupanke* amplissimo Sonchi folio; Feuill. Pernu. v. 2. 742. t. 31.)—*Leaves* lyrate, clasping the stem. — Found by Feuillée on the mountains of Chili. The *root* is said to be perennial, tapering. *Stem* herbaceous, three feet high, simple, round, leafy. *Leaves* a foot long, lyrate, obtuse, slightly wavy, and finely toothed or crenate; their lobes rounded, close, lying over

each other, finely downy, reticulated with veins; their base oblong, clasping the stem; midrib strong and convex; the under side palest. *Cluster* terminal, erect, bracteated, many-flowered. *Flowers* crimson, the lowermost a little remote, and of six petals or rather segments, the rest of but four; each segment is oval, about half an inch long, with a violet spot in the middle. *Stamens*, according to Feuillée, only equal in number to the petals, or rather segments of the flower. There is a disagreement between his account and the class, as well as character, indicated by Molina. This species is used in dyeing black. It also serves to stop the bleeding of the piles, when immoderate, as well as to relieve the pain of that complaint; the qualities of the herb being, as it seems, astringent.

For the *Panke* of Feuillée, a very different genus, see GUNNERA, sp. 2.

PANKINA, in *Geography*, a town of Russia, in the government of Kolivan; 68 miles N.W. of Biisk.

PANKIRA, a town of Hindoostan, in Baglana; 12 miles N. of Saler Moular.

PANKLIER, a town of Curdistan, in the government of Van, on the lake Van; 25 miles E. of Aklat.

PANKOVA, a town of Russia, in the government of Irkutsk, on the Ilim; 56 miles W. of Orlenga.

PANLANG, a town of the Birman empire, on the Rangoon branch of the Irrawaddy, from which the Rangoon is frequently called the Panlang-mioup. This was once a place of considerable magnitude, and is now of some importance; 16 miles N.W. of Rangoon.

PANNAGE, PANAGE, or *Pawnage*, are used in our law-books, &c. for the maff of woods; as of beech, acorns, &c.

As also for the running and feeding of swine, or other cattle, in forests.

And for the money taken by the agistors for the same.

PANNAGIUM LIBERUM, or *Free Pannage*, was a liberty of free running of swine in certain forests or woods, granted by privilege to certain private persons, and several religious houses.

Linwood defines pannagium, by "pastus pecorum in nemoribus, & in silvis, utpote de glandibus, & aliis fructibus arborum sylvestrium, quarum fructus aliter non solent colligi." It is also mentioned, 20 Car II. "Quisque villanus habens decem porcos dat unum porcum de pannagio;" by which it appears that one hog in ten was given for the pannage.

PANNAH, in *Geography*, a town of Hindoostan, in the country of Allahabad; 30 miles E.S.E. of Chatterpour. N. lat. 24° 48'. E. long. 80° 28'.

PANNEL, in *Law*. See PANEL.

PANNEL, in the *Scotch Law*, denotes the prisoner at the bar or person who takes his trial before the court of judiciary for some crime.

PANNEL, or *Panel*, in *Joinery*, &c. a tympan, or square piece of wainscot, sometimes carved, framed, or grooved in a large piece, between two mounters or upright pieces, and two traverses or cross pieces.

Hence also pannels or panes of glass, are compartments or pieces of glass of various forms; square, hexagonal, &c.

PANNEL, in *Masonry*, denotes one of the faces of a hewn stone.

PANNEL, in *Rural Economy*, a low stuffed saddle.

PANNELS of a *Saddle*, the two cushions or bolsters, filled with cow, deer, or horse hair, and placed under the saddle on each side, so as to touch the horse's body, and prevent the bows from galling or hurting the back.

PANNELA,

PANNELA, *Old*, in *Geography*, a town of Hindoostan, in Visiapour; 12 miles E. of Merritch.

PANNELA, *New*, a town of Hindoostan, in Visiapour; 22 miles W. of Merritch. N. lat. $7^{\circ} 3'$. E. long. $74^{\circ} 58'$.

PANNERBARY, a town of Bengal; 8 miles N.E. of Goragot.

PANNI, a town of Naples, in Capitanata; 9 miles S. of Troja.

PANNICULUS ADIPOSUS, in *Anatomy*, the stratum of fat placed under the skin. See *CELLULAR Substance*, and *MEMBRANE, Cellular*.

PANNICULUS Carnosus, in *Comparative Anatomy*, a thin subcutaneous stratum of muscular fibres in animals, to which there is no corresponding structure in the human subject. See *MAMMALIA*.

PANNIER, in *Architecture*. See *CORBEL*.

PANNIPUT, in *Geography*, a town of Hindoostan, in the country of Delhi; 50 miles N.W. of Delhi. N. lat. $29^{\circ} 25'$. E. long. $77^{\circ} 10'$.

PANNOA, in *Ancient Geography*, a town situated in the interior of the isle of Crete, between Gortyna and Gnoffus. Ptolemy.

PANNONIA, a large province of Europe, which was known to the Romans in the time of Augustus. It was bounded on the N. by the Danube, on the W. by Noricum, on the E. by the Danube as far as its junction with the Savus, near Mœsia, and on the S. it extended as far as Illyricum. The principal rivers of Pannonia were the Danube, the Dravus, and the Savus, which discharged themselves into the Danube, the Dravus E. of Murfa, and the Savus a little to the S. of Sirmium. It was during the war of Augustus with the Japydes and the Dalmatians that the Roman arms penetrated into the country of the Pannonians. But it became a Roman province under Tiberius. In the time of Antonine, Pannonia was divided into superior and inferior, the separation being made by the river Arrabo (Raab): one of these divisions was called Pannonia prima, and the other Pannonia secunda. The more ancient inhabitants of Pannonia were the Scordisci and Taurisci, who were in their origin Gauls. Ptolemy assigns to this country a great number of places; but none of them appear to be very considerable. This country was occupied by a semi-barbarous people, when Philip, king of Macedon, conquered it: but they soon afterwards revolted, and Alexander reconquered them. The Gauls, under the conduct of Brennus and Belgius, forcibly transferred it to Ptolemy, brother of the king of Macedon. Cæsar gained a settlement in part of it, and passed to it across the mountains, hence called "Alpes Juliæ." Tiberius, as we have said, added Pannonia to the Roman empire, and it continued tributary to the Romans till the fall of their empire. It afterwards became subject to the Goths, and then to the Huns, from whom Hungary is said to have derived its name.

PANNONICA BOLUS, in the *Materia Medica*, a name by which Kentman, and some others, have called the earth more usually known by the name of *bolus Toccaviensis*.

PANNONIUS, JANUS, in *Biography*, a modern Latin poet, born in 1434, was a native of Hungary. He travelled into Italy for instruction in polite literature, in which he excelled, and for the spread of which he felt so much ardour, that he used every effort to promote the study of it in his own country. He was raised to the see of Fünfkirchen, in Lower Hungary, where he died in 1472. He was distinguished for his proficiency in the Greek and Latin languages, in the latter of which he composed a variety of poems, which were printed separately, and also in the

"*Delicæ Poetarum Hungarorum*." An edition of them was published at Utrecht so lately as 1784, in two volumes 8vo.

PANNUNAH, in *Geography*, a town of Hindoostan, in the circar of Kariéh; 20 miles S.E. of Maltoy.

PANNUS, derived from *πᾶννός*, a web, a Latin word signifying cloth, web, &c.

PANNUS, in *Medicine*, a disease of the eye, popularly called the *web*.

The pannus is an excrescence arising on the adnata or conjunctiva, less hard and membranous than the unguis; and representing a web, or plexus of little veins swelled with blood.

Its cause is, an obstruction of the blood in the minute vessels of that tunic.

Its cure is much the same with that of the ophthalmia.

A chief difference is, that, in the unguis, the membranous excrescence only covers part of the eye, after the manner of a nail; whereas in the pannus it covers the whole.

PANNYA, in *Geography*, a town of Bengal; 45 miles W. of Nagore.

PANNYALLUM-CRUTCH, a town of Hindoostan, in Tinevelly; 15 miles S.E. of Coilpetta.

PANOCHIÆ, a name by which some chiralurgical authors call *buboes* in the groin.

PANOMI, in *Geography*, a town of European Turkey, in Macedonia; 16 miles S. of Saloniki.

PANOMPHÆUS, Παννομφαῖος, in *Mythology*, a designation given to Jupiter, because he was looked upon as the original author of all sorts of divination, having the books of fate, and out of them revealing either more or less, as he pleased, to inferior dæmons.

PANOPOLIS, in *Ancient Geography*, a town of Egypt, in the Thebaid, and the capital of the Panopolite nome.

PANOPSIA, Πανόψια, in *Antiquity*. See *PYANEPSIA*.

PANORAMA is a picture exhibiting a succession of objects, such as may be by the rays of light intercepted by the surface of a hollow sphere or cylinder, from all points of external objects to the eye in the centre of the sphere, or at a fixed point in the axis of the cylinder.

Panoramic Projection is the method of forming a panorama from the geometrical consideration of the properties of vision.

In the following principles of the panorama, the surface on which objects are supposed to be represented is that of a cylinder; though a sphere may be considered still more perfect, as its surface is every where equally distant from the eye, but a cylindric surface is more convenient for the purpose of delineation; and if the objects are not very distant from the intersection of a plane passing through the eye perpendicular to the axis, the distortion will not be perceptible. We premise the following definitions.

1. The cylindric surface on which objects are to be represented, is called also the panoramic surface; and the picture formed is called a panoramic view, or panoramic picture.

2. The point of sight is the place where the organ of vision is placed, in order to receive the impression of the images of the objects on the panoramic picture.

3. An original object is any object in nature, or an object which may be supposed to exist in a given position and distance, as a point, line, or solid.

4. An original plane is the plane on which original objects are supposed to be placed.

5. The point where an indefinite original line cuts the picture, is called the intersection of that original line.

6. The line on the picture where an original plane meets

PANORAMA.

or intersects it, is called the intersection of that original plane.

7. A line drawn through the point of sight parallel to an original line, is called the parallel of that original line.

8. A plane passing through the point of sight parallel to any original plane, is called the parallel of that original plane.

9. A surface of rays is that which proceeds from an original line, or from any line of the original object, by rays from all points of that line terminating in the eye. If the line in the original object be straight, the surface of rays is called a plane of rays, optic plane, or visual plane.

10. When the rays proceed from one or more surfaces of an original plane, the whole is called a pyramid of rays, or optic pyramid; and if the base is circular, it is called a cone of rays, visual cone, or optic cone.

In every kind of projection from a given point, the projection of a straight line upon any surface is the intersection of a plane of rays with the surface from all points of the straight line to the given point. Therefore the panoramic projection of a straight line is the intersection of the cylindrical surface and a plane. If a right cylinder is cut by a plane perpendicular to its axis, the section is a circle; if cut parallel to the axis, the section is a rectangle; and if cut obliquely to the axis, the section is an ellipsis. If the surface of the cylinder be extended upon a plane with the sections of the cylindrical surface and a plane cut in each of the positions here stated, the section made by the plane perpendicular to the axis will be a straight line; and the section made by cutting it parallel to the axis will also be a straight line; but the section made by cutting it obliquely will be a curve of similar properties as that known to mathematicians by the name of the sinical curve, or figure of the lines; therefore the projection of every straight line in a plane passing through the eye perpendicular to the axis of the cylinder, will also be a straight line on the extended surface; and every straight line in a plane passing through the axis will also be a straight line on the extended surface, perpendicular to that formed by the plane passing through the eye perpendicular to the axis.

The panoramic projection of any straight line not in a plane passing through the eye perpendicular to the axis, nor in a plane passing through the axis, is in the curve of an ellipsis; for in this case the optic rays which cut the cylinder will neither be in a plane parallel to the axis, nor in a plane perpendicular to it.

The panoramic representation of any straight line in a plane perpendicular to the axis, but not passing through the eye, is in the curve of an ellipsis, and the optic plane will be at right angles to another plane passing through the axis at right angles to the original line.

In the panoramic representation of any series of parallel lines, the optic planes have a common intersection in a straight line passing through the eye, and the common intersection will be parallel to each of the original straight lines; therefore the indefinite representations will pass through the extremities of the common intersection.

In the panoramic representation of any series of parallel lines in a plane perpendicular to the axis, but not passing through the eye, the common intersection of the optic planes is parallel to the plane on which the original lines are situated.

In the indefinite representations of any number of straight lines parallel to the axis, the visual planes will have a common intersection in the axis, and will divide the circumference of the cylinder into portions which have the same ratio to each other as the inclination of the visual planes.

If an original straight line parallel to the axis be divided into portions, the representations of the portions will have the same ratio to each other as the originals.

If in any original plane there be a series of straight lines parallel to each other, and also another series of straight lines parallel to each other, and at any given angle with the former series, the common intersections of the visual planes will make the same angle with each other, which any line of the one series makes with any one of the other series, and the common intersections will be in a plane parallel to the original plane; and, therefore, if the original plane be perpendicular to the axis, the common intersections of the visual planes will also be in a plane perpendicular to the axis. Hence the common intersections of visual planes from any two systems of straight lines, parallel to any two straight lines at a given angle with each other in a plane perpendicular to the axis, are also in a plane perpendicular to the axis, and make the same angle with each other which the two lines in the original plane make with each other.

11. The two points where the parallel of an original line inclined to the axis of the cylinder meet the panoramic surface, are called the vanishing points of that original line.

12. The intersection of the parallel of an original plane is called the vanishing line of that plane.

13. A straight line drawn from any point in the axis of the cylinder at right angles to the same to meet the panoramic surface, is called the distance of the picture.

14. The centre of a plane parallel to the axis, is the point where a straight line from the eye perpendicular to the plane meets it.

15. The panoramic centre of a plane parallel to the axis, is the point where a straight line drawn from the eye perpendicular to the plane cuts the picture.

16. The station point, is the point where the axis intersects the original plane.

17. The centre of an original line, is the point where a straight line, drawn from the station point perpendicular to the original line, cuts the original line.

18. The panoramic centre of an original line, is the point where a straight line, drawn from the station point perpendicular to the original line, cuts the picture.

19. The distance of an original plane parallel to the axis from the picture, is the straight line drawn from the panoramic centre to the centre of the original plane.

20. The distance of an original line from the picture, is the straight line drawn from the panoramic centre to the centre of the original line.

21. The distance of an original plane, is the straight line drawn from the eye to the centre of the original plane.

22. The distance of an original line, is the straight line drawn from the station point to the centre of the line.

An original line parallel to the axis of the panorama has no vanishing points.

An original plane parallel to the axis of the panorama has two vanishing lines.

The vanishing line of a plane perpendicular to the axis of the panorama, is a circle on the panoramic picture; but if the panoramic surface be extended upon a plane, it becomes a straight line.

The vanishing lines of all planes inclined to the axis are ellipses, and when extended upon a plane become sinical curves, which are also termed panoramic curves, as being the only curve which the cylindrical picture produces when developed.

PROBLEM I.

To describe the panoramic curve to given dimensions. Let
A B

PANORAMA.

AB (*Plate 1. fig. 1.*) be the length of the curve; bisect AB in C, draw CD perpendicular to AB; make CD equal to the deflection of the arc from the chord AB; from the point C, with the distance CD, describe the quadrant DE; divide the arc DE into any number of equal parts (say four,) also divide either half, CB, into the same number (four) of equal parts; let *l, i, g,* be the points of division in the quadrantal arc; draw *lk, ib, gf,* perpendicular to AB, cutting it at *k, b, f;* and let *K, H, F,* be the points of division in CB; draw *KL, HI, FG,* perpendicular to AB; make *KL, HI, FG,* respectively equal to *kl, bi, fg;* construct perpendiculars upon CA in the same manner; through all the points *G, I, L, D,* describe a curve, which will be that of the panorama.

The curve ADB is that which would be found by cutting a semi-cylinder, whose circumference is AB, at an altitude CD distant from the surface from a plane perpendicular to the axis, at a quadrant's distance from the point A or B in the extremity of the diameter of the plane, perpendicular to the axis. Therefore the whole panoramic curve will be double the length of AB; the other part being a similar and equal curve above the line AB produced, and consequently a curve of contrary flexure.

The panoramic curve takes place when the cylinder is cut by a plane at oblique angles to the axis.

PROB. II.

To find the indefinite representation of lines parallel to the original plane, in a plane parallel to the axis of the picture; given the height of the eye, the intersection of the original plane, and the distance of the original plane from the picture.

Let *P,* *fig. 2. N° 1,* be the station point; *GKH I* the intersection of the picture; and *AB* a line in the original plane on which the plane parallel to the axis stands.

In *fig. 2, N° 5,* draw *PK,* which make equal to *PK, N° 1.* In *N° 5,* draw *PO* and *Kw* perpendicular to *PK;* make *PO* equal to the height of the eye; draw *ow* parallel to *PK;* produce *PK* to *r;* in *N° 1,* draw *Pr* perpendicular to *AB,* cutting *AB* at *r,* and the intersection of the original plane with the panoramic surface at *K;* make *Pr, N° 5,* equal to *Pr, N° 1;* draw *rs* perpendicular to *PK;* in *N° 5,* make *ri, tu, uv,* equal to the height of the several lines, whose indefinite representations are required above the original plane; produce *ow,* meeting *rs* at *s;* produce *Kz* to meet *Os* at *w;* draw *Or, Ot, Ou,* and *Ov,* cutting *Kw* respectively at *v, x, y,* and *z.* In *N° 2,* make *GH* equal to the semi-circumference *GKH, N° 1;* bisect *GH* at *w;* draw *wv* perpendicular to *GH;* make *wv, wx, wy,* and *wz,* respectively equal to *wv, wx, wy,* and *wz, N° 5;* then with the common length *GH,* and the deflections *wv, wx, wy,* and *wz,* describe the curves *GvH, GxH, GyH, GzH,* which will be the envelope of the representation of the lines required, and *G* and *H* will be their vanishing points. For *OPrs, N° 5,* may be considered as a plane passing along the axis of the cylinder; *OP* the axis, *O* the eye, *P* the station point, *Kw* a section of the cylindrical surface, and *Or, Ot, Ou,* and *Ov,* visual rays; and, consequently, the points *v, x, y, z,* will be the representations of *r, t, u, v;* and since *r, t, u, v,* may be considered as the centres of the original lines, whose representations are required, and since the optic planes of these lines cut the cylinder obliquely, the sections will be elliptical, and, consequently, their envelope will be the figure of the lines as here described.

PROB. III.

To describe the representation of a line in a plane perpendicular to the axis of the cylinder, giving the seat of the line on the original plane.

In *N° 2,* draw *Gd* perpendicular to *GH;* make *Gd* equal to the descent or deflection of the curve, and describe the quadrantal sinical curve *d w,* and *d w* will be the representation of a line perpendicular to the plane, in which the originals of *G v H, G x H, G y H,* and *G z H,* are situated.

PROB. IV.

Given the indefinite representation *GzH, N° 2,* of a straight line, to determine the finite portion, whose seat is *AB, N° 1.*

Draw *PA* and *PB, N° 1,* cutting the intersection at *a* and *b;* make *wa, N° 2,* equal to the extension of *Ka, N° 1;* and *wb, N° 2,* equal to the extension of *Kb, N° 1;* draw *aa' and bb', N° 2,* perpendicular to *GH,* cutting the curve *GzH* at *a' and b',* and *a'z b'* will be the finite portion required; *a''y b'', a'''x b''',* and *a''''v b'''',* will be the same portions of the indefinite representations *GyH, GxH,* and *GvH.*

The following examples shew the application of the principles in the representation of solid objects.

Example 1.—Let *CDEF, fig. 2, N° 1,* be the plan of a house, in contact with the picture at *C.* Through the station point *P* draw *GH* parallel to *DC,* cutting the intersection of the panoramic picture in the points *G* and *H;* also through *P* draw *KI* parallel to *ED,* or *FC.* cutting the picture in *I* and *K;* then *G* and *H* are the vanishing points of all lines parallel to *EF* or *DC,* and *I* and *K* the vanishing points of all lines parallel to *CF* or *DE;* draw *FP* and *DP* cutting the picture at *f* and *d.* Let *WV* be the ridge of the building, bisecting *ED* at *W,* and *EC* at *V;* produce *WV* to *Y,* cutting *IK* at *U;* make *UY* equal to the height of the house, *N° 3* and *4;* and make the angle *UYZ* equal to half the vertical angle of the roof, and let *YZ* cut *IK* at *Z;* draw *XQ* parallel to *YZ,* cutting *KI* or *KI* produced at *Q;* draw *Zx* parallel to *VW;* produce *ED* to *x,* and *FC* to meet *xZ* at *T;* join *Qx* and *QT,* which are the intersections of the optic planes, formed by the inclined side of the roof, and the vertical planes standing upon *DE* and *CF;* draw *IN* parallel to *PO* and *ON* parallel to *IP.* To find the inclination of the optic planes; draw *PM* perpendicular to *xQ,* cutting *xQ* at *u,* and the panoramic intersection at *M;* from *P,* with the distance *Pu,* describe the arc *uJ,* cutting *PI* at *J;* join *OJ;* produce *NI* and *OJ* to meet each other in *S.* In like manner, draw *Pt* perpendicular to *TQ,* cutting *TQ* at *v,* and the panoramic intersection at *t;* from *P* as a centre, with the radius *Pv,* describe the arc *vw,* cutting *IP* at *w;* join *ow;* produce *NI* and *ow* to meet each other in *R;* then *NOS* is the inclination of the optic plane whose intersection is *Qx,* and *NOR* is the inclination of the optic plane whose intersection is *QT.*

Upon any convenient line *IH, fig. 2, N° 6,* extend the panoramic intersection; according to the corresponding places of *N° 1,* are shewn by similar letters; that is, *I t, t G, G d', d C', C' f', f' K,* and *K H, N° 6,* would cover *I t, t G, G d', d C', C' f', f' K,* and *K H, N° 1.* In *N° 6,* draw *t R, G o, d' d, C' c, f f', K k* perpendicular to *I H.*

In *N° 5,* produce *K P* to *a;* make *Pa* equal to the radius of the cylinder; through *a* draw *io* parallel to *OP;* on *Pa* make *Pj* equal to *Pj, N° 1,* and *Pq, N° 5,* equal to *Pq, N° 1;* draw *jq* and *qb, N° 5,* perpendicular to *Pa;*

PANORAMA.

make $q b$ and $j g$ each equal to the height of the walls, $N^{\circ} 3$ and 4 ; join $O g$ and $O h$; produce $O g$ to l , and $O h$ to i , meeting $o i$; produce $O j$ and $O q$ to meet $G o$ at o and k .

In $N^{\circ} 6$, make $t R$ equal to $N R$, $N^{\circ} 1$; $G o$ equal to $G o$, $N^{\circ} 5$; $G l$ equal to $G l$; $K k$ equal to $G k$; $K i$ equal to $G i$; describe the panoramical curves $I l K$, $I o K$; $G k H$, $G i H$; then the curves $I o K$ and $G k H$ will cut each other at c , and the curves $I l K$, $G i H$, will cut each other at C , so that the points C , C , c , will be in the same perpendicular; $C c$ will thus represent the angular line of the building; let the perpendicular $d' d$ cut the curve $G i H$ at D , and the curve $G k H$ at d ; and the intercepted portion $D d$ is the angular line at one end; in like manner, let the perpendicular $f f$ cut the curve $I l k$ at F , and the curve $I o K$ at f ; and the intercepted portion $F f$ of the perpendicular $f f$, is the representation of the angular line at the other end; therefore $c C D d$ represents the front, and $c C F f$ the end, exclusive of the triangular part adjoining the roof, which will be formed in the following manner; make $t x$ and $x u$ equal to $G K$ each; describe the same panoramical curve $R C x$; and if the other semi-panoramical curve $x v w$ is described, and if $k K$ be produced to v , v will be the vanishing point for the gable top; and if $K n$ be made equal to $K v$, n will be the vanishing point of the other inclined plane of the roof; and thus the representation of lines and planes will have vanishing points and vanishing lines, as in the methods of describing the perspective representation of objects upon a plane surface; and if the points d , D , c , C , f , F , are found, and the lines $c d$, $C D$, and $c f$, $C F$, are made straight instead of being curved and produced, they will find their own vanishing points in the line $I H$; but more remote from each other than the points G and K . What is here observed, is exemplified in $N^{\circ} 7$, as will appear sufficiently clear by a little reflection.

The example here shewn is very distorted, on account of the smallness of the panoramical cylinder, and the size of the object, which was obliged to be very large, in order to give a clear elucidation of the principles.

Example 2. *fig. 3*, shews the panoramical representation of a row of houses, upon the surface of a cylinder of greater radius than that of *fig. 2*. $N^{\circ} 1$, where the pictorial objects appear much more agreeable to the eye than that of *fig. 2*; the lines which form the roofs are in this example represented straight, though in reality they are curves, as a great deal of trouble is saved, and as the error occasioned by their introduction is so trifling as not worth regarding.

It now remains to shew the truth of the operations used in the construction of *fig. 2*; let it now be proved, that $x Q$ and $T Q$ are the intersections of the optic planes, formed by the inclined lines of the gables. From the definition given, an optic plane is that passing along an original line, and through the eye; therefore, if a straight line be drawn through the eye parallel to the original line, the line thus passing through the eye, and the original line, will be in the same plane, that is, both in the optic plane; and if two planes be drawn along two parallel lines, their intersections with a third plane will be parallel; now the parallels $F T$ and $K I$ are the intersections of two parallel planes; $F T$ that of the vertical plane in which the inclined original line is situated, and $K I$ that in which the eye is situated, or in which the line parallel to the inclined line is situated; the point T is the intersection of the inclined line of the roof, and the point Q the intersection of the line drawn through the eye parallel to the inclined line of the roof; therefore the optic plane will pass through the points T and Q , and consequently $T Q$ is the intersection of the optic plane, and

the original plane. In the same manner it may be shewn that $x Q$ is the intersection of the optic plane, formed by the other inclined line of the farther gable in the same plane with the former line.

Next let it be shewn that the angles $N O S$ and $N O R$, $N^{\circ} 1$, are the inclinations of the optic planes, whose intersections are $x Q$ and $T Q$. The inclination of any two planes is measured by a third plane, perpendicular to their common intersection; now $T Q$ is the intersection of the optic plane, and $P v$ is perpendicular to $T Q$; and because $P w$ is equal to $P v$, and $P o$ perpendicular to $P w$, and equal to the height of the eye; conceive the plane of the triangle $w P O$ to be raised perpendicular to the original plane, so that the base $P w$ may coincide with $P v$; then O will represent the eye in its true place, and the point w will be upon v ; and since the intersection $T Q$ would be perpendicular to the plane of the triangle, every line drawn in the plane of the triangle from v , would be perpendicular to the intersection $T Q$, and consequently, the line drawn in this plane from v to O , would also be perpendicular to the intersection; therefore the angle $P w O$ is the inclination of the plane, and, consequently, the alternate angle $N O R$. In the same manner it may be shewn, that $N O S$ is the inclination of the plane whose intersection is $x Q$.

Now to shew that $N R$ is the deflexion of the curve made by the optic plane, it only requires to be considered that the transverse axis of the ellipsis made by the optic plane, is in the plane which measures the inclination of the optic plane to the original plane: for this purpose, $P O N R$ may be considered as a semi-section of the cylinder along the axis, and $N R$ a section upon the surface; therefore $O R$ will represent half the greater axis, and $N R$ the deflexion of the curve, or its descent below the vanishing line of the horizon. *Fig. 2*. $N^{\circ} 5$, is also to be considered as a section of the cylinder, of which $O P$ represents the axis, $G o$ and $w K$ the sides; and because the appearance of all points in the same plane perpendicular to the axis, at equal distances from the station point, will be at the same height on the surface from the original plane, or from the plane passing through the eye parallel to the original plane, their heights will be found by setting their distances upon $P a$, then erecting lines perpendicular to $P a$, from each point of the section; then setting the heights of the points upon these lines, and drawing lines from O through the top of each perpendicular till they cut $G o$; then the distance from G to each point of section, gives the distance of each point from the plane passing through the eye upon the panoramical surface.

Now let the cylinder be conceived to be enveloped by $N^{\circ} 6$, so that $I H$ may fall upon the circumference of a circle in a plane perpendicular to the axis, then every line will fall in its true position, and the representative object will produce the same pyramid of rays as the original object, the eye being supposed to be fixed at its true distance above the line $I H$; and, consequently, nothing more will be required to excite the existence of the object, than to give the representative surfaces their proper colours, light, and shade, according to the distance of the original.

Hitherto straight lines have been represented by portions of the sinical curve when extended, or by portions of an ellipsis, when the sheet on which the objects are represented is brought in contact with the surface of the cylinder, as they ought properly to be; but if the radius of the cylinder is of sufficient extension, and the objects to be represented of proper magnitude, any attempt to represent straight lines by curves from the hands of an artist would be absurd, except when the object to be represented is very near to the pano-

PANORAMA.

ramic surface, in which case a curvature in the line may be sensible, also at a moderate distance: the curve can only be observed in a series of objects in a straight line; it will therefore be sufficient to represent the straight lines of each individual object by straight lines also, but to preserve the curve, or rather the polygonal figure inscribed in the finical curve in the series, as the inflexions or angles will hardly be visible.

A straight line will therefore be represented by finding the representation of its extremities, and joining the representative points; but if it is of great extent, it may be found by finding a number of points, and joining every two adjoining points in succession by a straight line, and the whole will assume the form of a curve, which will be the representative of the straight line.

Plate II. shews a series of figures, such as may be supposed to constitute the whole of the practice of representing panoramic objects. S is the station point; the objects are referred to in alphabetical order from A, B, C, &c. to H; each extreme point of the lineal parts of the same object has the same letter affixed, with a numerical index, which increases, by unity, in tracing round the circumference in progressive order. The points where the optic lines cut the panoramic surface are numbered with the same figure from the same object, each number having an index corresponding to that of the point of the object to be represented. The numbers are placed in successive order, agreeing with the order of the alphabet.

N^o 1. The intersection of the panorama and the original plane, with the figures of the objects to be represented.

N^{os} 2, 3, 4, Vertical sections of the panorama passing along its axis, in order to ascertain the heights of the several places of each object; E the point of sight or place of the eye, S the station point, P Q a section of the cylinder, shewing the heights of the objects.

The objects to be represented are, A, a point, the optic ray from which cutting the intersection at 1; B a straight line, the optic rays from which cutting the intersection at 2¹, 2²; C a line standing upon C, the optic ray from which cutting the intersection at 3; D an inclined line, whose feet is represented by D¹, D², the optic rays from which cutting the intersection at 4¹, 4²; E an angle, the optic rays from which cutting the intersection at 5¹, 5², 5³; F a triangle, the optic rays from which cutting the intersection at 6¹, 6², 6³; H a rectangle, the optic rays from which cutting the intersection at 7¹, 7², 7³, 7⁴; and, lastly, G a circle, the optic rays from which cutting the intersection at 8¹, 8², 8³.

The distances of the objects are placed upon the panoramic sections N^{os} 2, 3, 4, from S, upon the lines S, P, or upon S P produced; then drawing lines from the points to E, give the heights upon P Q.

The perpendicular standing upon C, N^o 1, is thus found: In N^o 3, draw C C from C, perpendicular to S P, equal to the height of the perpendicular upon C, N^o 1, and draw the straight lines C E, C E, N^o 3, cutting P Q at 3 3, then 3 3 is the panoramic length of C C. The upper extremity of the inclined line D will be found by ascertaining the panoramic height of the perpendicular, from the elevated end to the original plane.

N^o 5 shews the panoramic representation of the several objects; V L the vanishing line of the horizon; the intersections of the optic rays are extended upon V L from N^o 1, the references upon the intersection N^o 1, and upon V L N^o 5, being the same. The heights of the several points are taken from the sections N^{os} 2, 3, and 4, from Q downwards towards P, and placed from the corresponding points in V L, N^o 5; also downwards upon the perpendiculars, gives

the several points of the objects; thus *a* is the representation of the point A, N^o 1; *b*, *b*, of B¹, B², &c. In the circle, the points for half the curve are found, the other half being repeated in the same order from the middle line, each line serving for two points, so that the three lines give eight points; the extreme lines are tangents which are equivalent to two points.

The points around the circumference of the intersection N^o 1, are extended upon V W and X Y, according to the principle of Renaldinus, by setting three-fourths of the radius, without the circle, upon the opposite side of the tangents V W and X Y; and transferring the divisions of V W and X Y upon V L, N^o 5, gives the points corresponding to the intersection.

The panoramic surface being enveloped by N^o 5, the representations of the objects will be placed in their true position, and will form the same picture at the point of sight, if correctly, painted as the objects themselves.

A practical method of forming all straight lines on the panoramic surface in its place, without development, is to ascertain the position of the objects, also the heights of the centres of the line to be represented; then fixing the eye in its position, and holding a straight edge parallel to the line to be drawn in a plane with the point of sight and the point representing the centre of the line, mark several points in the same plane, on the panoramic surface; these points being joined, will give the representation of the line required.

In preparing for panoramic projections, whatever objects are intended to be represented, a proper point of view should be chosen from this situation; a sketch of all the surrounding objects should be made according to the development of the panorama; for though the painting itself may be performed upon the cylindric surface, it is more eligible to sketch upon a plane. The next thing to be done is to take a survey of the objects, observing their positions to each other; then with a plane table fixed on the point of view quite level, take the successive angles of the surrounding objects by means of a moveable limb which may carry two pieces, one at each extremity, perpendicular to the surface of the plane table; one piece being fixed in the supposed axis of the panorama, containing a sight hole for the point of view, so that the moveable part will consist of three bars, the bottom one serving as a straight edge for drawing the angles of position: the heights of the objects may be marked upon the other limb parallel to that fixed in the axis; and let it be observed, that the point of view in the axis, the edge of the limb which gives the heights of the objects, and the edge of the bottom bar by which the angles are drawn, must be in a plane passing along the axis: mark the vertical lines on the sketch, and the lines on the plane table, which shew their position, with corresponding characters, otherwise it would be difficult to distinguish what the numerous lines apply to. The moveable edge of the index, which describes the circumference of the cylinder, should be of ivory, as the various heights may be marked with pencil, and rubbed out at pleasure, as these heights may be transferred to a piece of paper marking them with the same character as that of the sketch, and with the addition of top of chimney, shaft, ridge of roof, top of wall, as the heights may be the terminations of such parts of the said objects, or instead of writing any mark, in drawing by representing a slight form of the parts of the object.

Instead of the ivory edge of the bar, which describes the panoramic surface, a slit, or very narrow aperture, formed by a double bar, may be used.

The tendency of every line, horizontal or inclined, may be found by a fifth bar, moveable round a centre, which centre must be also moveable upon the edge of the limb which gives

gives the panoramic heights of the objects; the plane in which this fourth bar moves must be a tangent to the panoramic surface, at the line which is intersected by the plane passing along the axis, along the straight edge of the bottom bar, and along the edge where the heights of the objects are marked; then if the edge of this fourth moveable bar be brought in a plane with the eye and the original line, the angle which it forms with the edge of the vertical limb is the inclination of the line on the picture.

PANORMA, or **PANORAMA**, in *Geography*, a harbour on the N. coast of the island of Myconi. N. lat. $37^{\circ} 29'$. E. long. $25^{\circ} 23'$.

PANORMO, a town of Asiatic Turkey, in Natolia, on the S. coast of the sea of Marmora; 16 miles S.E. of Artaki.—Also, a town of European Turkey, in Albania, situated on a gulf of the Adriatic, opposite the island of Corfu; 45 miles S.S.E. of Valona. N. lat. 40° . E. long. $20^{\circ} 1'$.

PANORMUS, in *Ancient Geography*, (*Palermo*), a town of Sicily, situated towards the N.W., founded, as it has been said, by the Phœnicians. It held a distinguished rank among the towns of Sicily. In the year of Rome 499 it was taken by the Romans, and in 503 they gained a battle there under the orders of the proconsul Metellus. It afterwards became a Roman colony.—Also, a small gulf of Achaia, towards the N.W., into which the three rivers Charadus, Lelemus, and Bolineus discharged themselves.—Also, a port of Greece, and the first on the E. coast of Attica, near the promontory of Sanium. Ptolemy.—Also, a town on the N. coast of the isle of Crete, between Citzæum and Heraclæum. Ptol.—Also, a port of the isle of Cephalonia.—Also, a port of Epirus, near that of Onchestus. Ptol.—Also, a town of the Thracian Chersonesus, between Elœa and Cardia. Pliny.—Also, a town of Macedonia, in Chalcidia. Ptol.—Also, a port of Africa, in Marmorica, upon the coast of the nome of Lybia. Ptol.—Also, a port of the town of Oricum, on the Ionian sea. Strabo.—Also, a small port of Asia Minor, in Ionia, N.E. of the promontory of Posidium, S.E. of the promontory of Trogilium, and S. of Miletus. South of this port was the famous temple of Apollo Branchidæ, and to this place strangers repaired to consult the oracle. The ancients pretended that the stream which discharged itself into the sea at this port, sprang from mount Mycale, and passed under the sea till it re-appeared in the vicinity of this temple.

PANORPA, in *Entomology*, a genus of insects of the order Neuroptera: the generic character is, mouth lengthened into a cylindrical horny proboscis; feelers four, nearly equal; stemmata three; antennæ filiform, longer than the thorax; tail of the male armed with a chelate appendage; but in the female it is unarmed. There are nine

Species.

* **COMMUNIS**. This, as its name imports, is the most familiar of all the species. It is frequently seen in our meadows during the early part of the summer. It is a longish-bodied fly of a moderate size, with four transparent wings, elegantly variegated with deep brown spots; the tail of the male insect, which is generally carried in an upright position, is furnished with a forceps, somewhat in the shape of a lobster's claw.

GERMANICA. Wings equal, hyaline, tipped with brown. It inhabits Germany, and resembles the communis.

SCORPIO. Wings equal, black spotted with white; body dusky. It is found in different parts of North America.

FASCIATA. The wings of this likewise are equal, yel-

lowish with black dots and bands. It is found in North America.

HYEMALIS. Wings subulate, slightly incurved, ciliate: the female is apterous. It is a small insect, and is found in Saxony.

TIPULARIA. Wings immaculate; abdomen falcate; the legs are very long. It inhabits Italy; the body is yellow, the wings equal.

CAPENSIS. The wings are equal and immaculate; body ferruginous. It inhabits the Cape.

JAPONICA. Wings equal, hyaline, with two black wings. It is found in Japan.

COS. Wings erect, lower ones nearly linear and very long. This is a native of Greece and the islands of the Archipelago, and is an insect of a very peculiar appearance. It is distinguished by having the lower wings so extremely narrow or slender as to resemble a pair of linear processes with an oval dilatation at the tip, while the upper wings are very large, oval, transparent, and beautifully variegated with yellowish-brown bars and spots.

PANORPA. See *CICADA Tibicen*.

PANOV, in *Geography*, a river of Russia, which runs into the Niznei Tungusku, N. lat. $64^{\circ} 40'$. E. long. $102^{\circ} 54'$.

PANREEDY, a town of Bengal; 30 miles S.S.E. of Currackdeagh.

PANSACCHI, DON, in *Biography*, an Italian serious opera singer with a tenor voice, who having resided nine years in Spain, was allowed to qualify himself with the title of Don. He was in the service of the elector of Bavaria in 1772, when we often heard him. His voice was not bright, or very mellifluous; but his knowledge of music, intelligence in the drama, taste, and expression, were of a superior kind. He had acquired, by his long residence in Spain, the true national style of singing *seguillos, tonadillas*, and other music of that country.

PANSAGUTCHY, in *Geography*, a town of Bengal; 8 miles N. of Rajemal.

PANSANG, or **PULO-PANSANG**, a small island in the gulf of Siam. N. lat. $9^{\circ} 15'$. E. long. $103^{\circ} 30'$.

PANSAR, a town of Hindoostan, in Guzerat; 16 miles N. of Amedabad.

PANSHAH, a town of Meckley; 55 miles S.S.E. of Munnypour.

PANSHALA, a town of Guriel; 30 miles E. of Pati.

PAN-SIEN-ING, a town on the W. coast of the island of Formosa. N. lat. $23^{\circ} 56'$. E. long. $119^{\circ} 52'$.

PANSRUCKY, a town of Hindoostan, in Bahar; 27 miles S. of Bahar. N. lat. $24^{\circ} 46'$. E. long. $85^{\circ} 44'$.

PANTÆNUS, in *Biography*, a learned Christian philosopher of the Stoic sect in the second century, flourished, according to Cave, about the year 182. His descent, his country, and the time of his birth, are all uncertain. He is thought to have been one of the masters of Clement of Alexandria; and is mentioned with high respect by Alexander, bishop of Jerusalem, in a fragment of a letter to Origen, preserved by Eusebius, in which he expressly says that Pantænus was the person who introduced him to the acquaintance of that father. He was held in very high estimation, and is referred to by Origen with great respect, and Photius speaks of him as a hearer of some of those who had seen the apostles, and even of the apostles themselves. He presided over the catechetical school at Alexandria with great reputation and success. He was extremely zealous in the cause of Christianity, and undertook a mission into Ethiopia, to instruct the inhabitants in the principles of that

that religion. After his return to Alexandria Pantæus resumed the presidency of the catechetical school, in which he continued to explain the scriptures publicly under the reigns of the emperors Severus and Caracalla. According to Jerome, there were, in his time, extant "Commentaries" of Pantæus upon the Scriptures, but there is nothing now remaining of his writings, excepting a short passage in the "Eclogæ," ascribed to Clement of Alexandria, containing the following rule respecting the language used in the prophecies of the Old Testament; "that the prophets often express themselves in indefinite terms, and that the present tense is frequently used by them both for the preterite and future." Pantæus is supposed to have died about the year 213. Dupin. Lardner.

PANTAIA, in *Geography*. See PANDAIA.

PANTALARIA, a small island in the Mediterranean, between the island of Sicily and Cape Bon, on the coast of Tunis; about 25 miles in circumference, and containing about 4000 inhabitants. Its chief productions are olives, figs, raisins, capers, and cotton; the cattle are numerous; but bread corn is imported from Sicily. The language is a mixture of Italian and African. N. lat. $36^{\circ} 55'$. E. long. $12^{\circ} 15'$.

PANTALEO, ST., a town of the island of Sardinia, the site of which was anciently that of the episcopal city of Dolio; 16 miles N. of Cagliari.

PANTALEONE, a small island in the Mediterranean, near the W. coast of Sicily, formerly united to the continent by a neck of land, which was destroyed by the inhabitants in order to secure themselves against the enemy. The ancient Motya stood in this island. N. lat. $37^{\circ} 56'$. E. long. $12^{\circ} 28'$.

PANTALEONE, in *Music*, a stringed instrument in Germany at the latter end of the seventeenth century. The inventor's name was Hebenstrich; but from the success of his instrument, he assumed that of *Pantaleone*. It was more than nine feet long, and had, when in order, 186 strings. The tone was produced by two *bagettes*, or sticks, like the dulcimer; it must have been extremely difficult to the performer, but seems to have been capable of great effects. Mr. Binder, organist of the Duom Kirk, at Dresden, was the last person who played upon it. It was this instrument, and the performance upon it at Paris in 1705, which gave birth to a very ingenious little work, under the title of "Dialogue sur la Musique des Anciens," by the abbé Chateaufeu. When we saw the ruins of this instrument at Dresden, soon after the seven years' war, the strings were almost all broken, and the court was so impoverished as not to like to be at the charge of new mounting it. It used to be one of the musical curiosities of that city, during the time that the elector of Saxony was king of Poland.

PANTALOON, or PANTALON, the name of an ancient garment frequent among our forefathers, consisting of breeches and stockings all of a piece. A dress somewhat similar has been lately revived and much used.

The denomination comes from the Venetians, who first introduced this habit, and who are called *Pantalonis*, from St. Pantalon, who was formerly their patron.

PANTALON, on the *Theatre*, is a buffoon or masked person who performs high and grotesque dances, and shews violent and extravagant postures and airs.

The word is also used for the habit and dress these buffoons usually wear; which is made precisely to the form of their body, and all of a piece from head to foot.

And hence those who wear a habit of this kind, for convenience under their other clothes, are called pantaloons of Venice.

PANTANO, in *Geography*, a town of Sicily, in the valley of Noto; 10 miles S. of Modica.—Also, a town of Italy, in the department of the Panaro; 15 miles S.W. of Modena.—Also, a town of Naples, in Calabria Ultra; 9 miles E. of Bova.—Also, a river of Naples, which runs into the sea; 10 miles E. of Bova.

PANTAR, an island in the East Indian sea, of a square form, about 48 miles in circumference, separated from the E. coast of the island of Lomablen by the strait of Alvo; and from the W. coast of Ombay by a narrow channel, called the "Strait of Pantar." S. lat. $8^{\circ} 10'$. E. long. $124^{\circ} 30'$.

PANTARBE, in *Natural History*, a name given by authors to an imaginary stone, the virtues of which were similar to those of the magnet; but exerted upon gold as those of the load-stone upon iron. The ancients, as well as later writers, seem to have all had an opinion, that there was such a stone as this, and the amphitane of Pliny is described as possessing this remarkable quality; but neither they nor we ever found reason from any experiment to believe that there was any such stone.

PANTHEA, Πανθεα, among the *Ancients*, were single statues, composed of the figures, or symbols, of several different divinities combined.

Father Joubert, who calls them Panthea, and who has observed them on several medals, says their heads are most commonly adorned with the symbols or attributes belonging to several gods.

An instance of this kind we have in a medal of Antoninus Pius; which at the same time represents Serapis, by the bushel it bears; the Sun, by the crown of rays; Jupiter Ammon, by the ram's horns; Pluto by the large beard; and Æsculapius, by the serpent twisted in his hand.

M. Baudelot, in a dissertation on the Lares, will have the Panthea to have had their rise from the superstition of those, who, taking several gods for the protectors of their houses, united them all in the same statue, by adorning it with the several symbols proper to each of these deities.

PANTHEISTS, is a denomination by which the followers of Spinoza are distinguished, and derived from the nature of their doctrine, which confounds God with the universe; representing them as one and the same being, and admitting only one substance whence all things proceed, and into which they all return. See SPINOZISM.

PANTHEON, Πανθεον, thus named from παν, *all*, and θεος, *God*, in *Architecture*, a temple, or church, of a circular form; dedicated to all the gods, or to all the saints.

The Pantheon of ancient Rome is of all these edifices the most celebrated, and that from which all the rest take their names. It was built by Agrippa, son-in-law of Augustus, in his third consulate, twenty-five years before Christ: though several antiquarians and artists have supposed that the Pantheon existed as long ago as the commonwealth, and that Agrippa only embellished it and added the portico. To this purpose they allege the authority of Dion Cassius, who speaking of Agrippa, says, he also finished or perfected the Pantheon.

It was dedicated by him to Jupiter Ultor, Jupiter the Revenger, according to Pliny's account; according to Dion Cassius, to Mars, Venus, and Julius Cæsar; but according to the most probable opinion, to all the gods; and had the name Pantheon, on account of the great number of statues of the gods ranged in seven niches all round it; and because it was built of a circular form, to represent heaven, the residence of the gods; or because it was dedicated to all the gods, (quali παντων θεων.) It has but one door.

PANTHEON.

It was one hundred and forty-four, or, as Fabricius says, one hundred and forty feet diameter within, and just as much in height, and of the Corinthian order. The roof was curiously vaulted, void spaces being left here and there for greater strength. The rafters, forty feet long, were plated with brass. There were no windows in the whole edifice; but sufficient light was let in through a round hole in the top of the roof. Before each niche were two columns of antique yellow marble fluted, and of one entire block. The whole wall of the temple, as high as the grand cornice inclusive, was cased with divers sorts of precious marble in compartments: and the frieze was entirely of porphyry. The outside of the front was anciently covered with plates of brass gilt, and the top with plates of silver, in lieu of which lead was afterwards substituted. The gates were of brass, and of extraordinary size and workmanship.

The eruption of Vesuvius, in the reign of Tiberius, and a great fire in the reign of Titus, damaged the Pantheon very considerably: but it was successively repaired by Domitian, Adrian, and Septimius Severus: and it subsisted in all its grandeur till the incursion of Alaric, in the time of Honorius: on this occasion it was stripped of several of its statues and ornaments of gold and silver. About thirty-nine years after this, Genseric, king of the Vandals, took away part of its marbles and statues: at length pope Boniface IV. obtaining this Pantheon of the emperor Phocas, converted it into a church, without any alteration in the building; and dedicated it to the Virgin, and all the martyrs. And it still subsists at Rome under the title of Notre Dame de la Rotonda. However, in 655, Constantius II. stripped it of its inside and outside brazen coverings, which he transported to Syracuse.

There was also at Rome another Pantheon, dedicated to Minerva, as the goddess of medicine. It was in the form of a decagon, and the distance from one angle to another measured $22\frac{1}{2}$ feet. Between the angles there were nine chapels of a round figure, designed for so many deities: and over the gate there was a statue of Minerva. The Pantheon of Athens was in many respects little inferior to that of Rome, built by Agrippa. The Greek Christians converted it into a church, dedicated to the Virgin, under the name of *Panagia*. The Turks changed it into a mosque.

The Pantheon of Nismes, was a temple in that city, in which were twelve niches, for statues, supposed to have been destined for the twelve great gods.

In the Escorial is a magnificent chapel, called Pantheon, thirty-five feet in diameter, and thirty-eight high, from the pavement, which is of marble and jasper inlaid. The whole inside of the chapel is of black marble, except the luthern, and some ornaments of jasper, and red marble.

In this chapel are deposited the bodies of the kings and queens: there are only places made for twenty-six; eight of which are already filled.

The square of the Pantheon, or "Piazza della Rotonda" is adorned with a fountain and an obelisk, and terminated by the portico of Agrippa. This noble colonnade consists of a double range of Corinthian pillars of red granite. Between the middle columns, a passage opens to the brazen portals, which, as they unfold, expose to view a circular hall of immense extent, crowned with a lofty dome, and lighted solely from above. It is paved and lined with marble. Its cornice of white marble is supported by sixteen columns, and as many pilasters of Giotto antico: in the circumference there are eight niches, and between these niches are eight altars, adorned each with two pillars of less size, but the same materials. The niches were anciently occupied by statues of the great deities; the intermediate altars served as pedestals

for the inferior powers. The proportions of this temple are admirable for the effect intended to be produced, its height being equal to its diameter, and its dome not an oval, but an exact hemisphere. The Pantheon is the most noble and perfect specimen of Roman art and magnificence which time has spared, or the ancients could have wished to transmit to posterity. It has served in fact as a lesson and a model to succeeding generations, and to it Constantinople is indebted for Santa Sophia, and to it Rome, or rather the universe, owes the unrivalled dome of the Vatican. Upon the whole this is the most ancient edifice that now remains in a state of full and almost perfect preservation. It has nevertheless undergone many alterations from pillage and reparations, chiefly restricted to its decorations. It was first altered by Domitian, and afterwards repaired by Severus. The pillars, pilasters, and marble lining remain nearly as they were placed by the latter. It was plundered of part of its bronze ornaments, by Genseric, the Vandal monarch of Africa, and afterwards more completely stripped of all its metal decorations by Constantine, the grandson of Heraclius, in the 7th century. It was converted into a church by pope Boniface IV., about the year 609, and since that period has attracted the attention and enjoyed the patronage of various pontiffs. Although the Pantheon probably owes its preservation to its having been converted into a church; yet, leaving to it its principal character as a temple, it seems better adapted to the purposes of a mausoleum; and it has actually been in some degree appropriated to this use; for it contains at present the tombs or rather the bulks of several distinguished characters, among which are the celebrated antiquary Winckelman, Metastasio, Mengs, Poussin, Hannibal Carracci, and Raffaello himself. Two musicians also, Corelli and Sacchini, have been admitted to the honours of the Pantheon.

The dedication of this church on the 1st of November, in the year 830, gave occasion to the institution of the festival of All Saints.

PANTHEON, in England, a modern building erected in Oxford-street, London, begun in 1763, and finished in 1771, for concertos and other musical performances. It was built by Mr. James Wyatt, and regarded, both by natives and foreigners, as the most elegant structure in Europe, if not on the globe. This splendid and elegant edifice was opened as a place of public entertainment, on Monday, January 27, 1772. During the first winter there were assemblies only, without dancing or music, three times a-week. On other days, each person paid five shillings for seeing the building only. But the great room, though spacious, was so crowded on all these occasions, that in July, a general meeting of the proprietors was advertised, in order to take into consideration the enlarging of the building.

After the opera-house in the Haymarket was burnt down in 1790, this master-piece of architecture was transformed into a theatre for the performance of operas; when, though many of its internal beauties were hidden and annihilated, it still was a perfect model of a complete theatre in its new form. But unhappily, before it had been used as a lyric theatre two seasons, it was burnt down by some fatal accident or design, which has never yet been divulged to the satisfaction of the public.

During its pre-existent state, it was here that the Agujari and Pacchierotti exercised their talents; it was here that the king, queen, and royal family, with all the first nobility in the kingdom, assembled, at the commemoration of Handel in 1784; and it was here that one of the first bands in Europe graced the orchestra, alternately headed by Giardini, La Motte, Cramer, or Giornovich, who, with Fifeher, Crofdil,

Crofdil, Cervetto, &c. produced effects in symphonies, concertos, solos, and vocal accompaniments, which had never before been heard in this country. No persons of taste in architecture, or music, who remembers the Pantheon. its exhibitions, its numerous, splendid, and elegant assemblies, can hear it mentioned without a sigh!

PANTHER, in *Zoology*. See *FELIS Pardus*, *Leopardus*, and *Uncia*.

PANTHER CREEK, in *Geography*, a river of Kentucky, which runs into the Green river, N. lat. 37° 29'. W. long. 84° 48'.

PANTHERA LAPIS, in *Natural History*, the name of a species of stone found in Egypt, and the East Indies, and described to be of a yellowish colour, variegated with dusky spots of the colour of those on the skin of the panther. The writers of the middle ages have attributed many absurd properties to it: it seems to have been a species of agate.

PANTHERINE TABLES, *Pantherine Mensæ*, among the Romans, tables made of citron wood, which were held in such high esteem, as to equal the value not only of silver and gold, but likewise of pearls. They had this name from their being spotted after the manner of panthers.

PANTICAPÆA, in *Ancient Geography*, a town of the Tauric Chersonesus, according to Ptolemy and Strabo. This town became the capital of the kingdom of Cimmerian Bosphorus. Under the successors of Spartacus, according to Diodorus Siculus, Panticapæa was the place where the waters of the Palus Mæotis discharged themselves into the Euxine sea.

PANTICAPES, a river of European Scythia. According to Pliny it separated between the Nomades and the Georgians. Herodotus says that it took its rise from a lake situated towards the north, that it pursued a S.W. course and passed by Ilæa, which was the first country which those enter who have traversed the Borysthenes, near the sea. He adds that Panticapes ran into the Borysthenes, a little above the mouth of this large river. Strabo, however, does not mention a river of this name; he might indeed have omitted it, and it might be the river now known under the name of Samara.

PANTICOSA, in *Geography*, a town of Spain, in Aragon; 13 miles N.N.E. of Jaca.

PANTICUM, or PANTICHUM, in *Ancient Geography*, a town of Asia, in Bithynia, between Chalcedon and Libyssa, according to the Itinerary of Antonine.

PANTIKA, in *Geography*, a town of Asiatic Turkey, in Natolia, on the N.E. coast of the sea of Marmora; 12 miles S.E. of Constantinople.

PANTIN, a town of France, in the department of the Seine, and chief place of a canton, in the district of St. Denis. The place contains 1172, and the canton 10,932 inhabitants, on a territory of 57 $\frac{2}{17}$ kilometres, in 12 communes.

PANTIPIOLIS, in *Ancient Geography*, a town of India, on this side the Ganges, between Berderis and Adirama. Ptolemy.

PANTOMATRIUM, a promontory on the N. coast of the isle of Crete, between the promontory Dion and the town Rithymac. Ptolemy.

PANTOMIME, Παντομιμοί, among the *Ancients*, a person who could imitate all kinds of actions and characters by signs and gestures, without speaking.

The pantomimes made a part in the theatrical entertainments of the ancients; their chief employment was to express, in gestures and action, whatever the chorus sung,

changing their countenance and behaviour as the subject of the song varied.

They were very ancient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato's time. In Rome it was so late as the time of Augustus before they made their appearance. Under his reign and that of Tiberius, the pantomime, carried on by much gesticulation, was the favourite entertainment of the public. The people were moved, and wept at it, as much as at tragedies; and the passion for it was so strong, that laws were obliged to be made for restraining the senators from studying the pantomimic art.

As to the dress, it was various, being always suited, as near as possible, to that of the person they were to imitate. The crocota was much used among the Roman pantomimes, in which, and other female dresses, they personated women. See *MIME*, *BALLET*, and *BATHYLLUS*.

PANTON, in *Geography*, a township of America, in Addison county, Vermont, on the E. side of lake Champlain, about 87 miles N. of Bennington.

PANTON-SHOE, in the management of farm and other horses, an old sort of invention contrived for the purpose of receiving the narrow and hoof-bound heels of them, in particular cases. The sponges of it are much thicker on the inside than on the outside, so that the part which rests upon the horn or hoof, runs sloping to the end, that the thickness of the inside of the shoe may bear up the heel, and throw or push it to the outside. Shoes of this kind were recommended by Guillet as proper for horses which had false quarters.

PANUCO, in *Geography*, a river of North America, which runs into the gulf of Mexico; 21 miles E.S.E. of Panuco. N. lat. 22° 40'. W. long. 98° 36'.

PANUCO, or *St. Stilvara del Puerto*, a town of Mexico, and capital of the province of Guasteca or Panuco, on a river of the same name, navigable for barks up to the town. It is the see of a bishop, and contains about 500 families; 190 miles N.N.E. of Mexico. N. lat. 23° 23'. W. long. 99° 6'. See *GUASTECA*.

PANUCO, a town of South America, in the province of Tucuman; 15 miles W. of St. Fernando.

PANVILAO, a town on the S. coast of the island of Luçon. N. lat. 14 2'. E. long. 121° 36'.

PANVINIO, ONOFRIO, in *Biography*, a very learned historian and antiquary, was born at Verona in the year 1529. From a very early period of his life he manifested an insatiable thirst for study, and to indulge it he entered into the order of the Augustines. He was sent to Rome to complete his studies, and in 1553 he was appointed to instruct novices in the sciences. After a few months' residence in Rome, he was sent to Florence to teach scholastic theology, but that science not being adapted to his taste, he quitted his charge, and obtained permission to live at large out of the cloister. He passed some time at Venice, where he printed one of his works, but his ordinary abode was at Rome, being patronized by cardinal Marcello Cervini, whose pontificate, under the name of Marcellus II., was of too short duration to contribute to his advancement. From thence he passed into the court of cardinal Alexander Farnese, with whom he travelled into Sicily in 1568, where he died. "Very few instances," says his biographer, "are to be met with of such extensive erudition, and indefatigable industry, left by one whose career was restricted to such narrow limits. Besides his published works, which form a numerous catalogue, he left a still greater number in MS. either completed

er begun." One of the first objects of his labours was Roman history and antiquities. The "Fasti Consulares," though first brought to light by Sigonius, were published and illustrated with notes by him at Venice in 1557. He published treatises also, "De Antiquis Romanorum Nominibus;" "De Principibus Romanis;" "De Republica;" "De Triumphis et Ludis Circensibus;" and "Topographia Romæ." These valuable works are founded in a great measure upon ancient inscriptions, of which he had collected and copied nearly three thousand. He was a profound investigator of sacred or Christian antiquities. Of his published works in this class are treatises "De Ritu sepeliendi mortuos apud veteres Christianos;" "De Antiquo Ritu baptizandi Catechumenos;" "De Primatu Petri;" "Chronicon Ecclesiasticum;" "De Episcopatus Titulis, et Diaconis Cardinalium;" "Annotationes et Supplementa ad Platinam de Vitis Pontificum;" "De Septem præcipuis Urbis Romæ Basilicis;" "De Bibliotheca Vaticana." He had undertaken a general ecclesiastical history, for which he collected matter sufficient to fill six large manuscript volumes, which are preserved in the Vatican. He wrote a Chronicle of his own order, and a history of his native city, Verona, including an account of its antiquities, printed many years after his death.

PANWELL, in *Geography*, a town of Hindoostan, in Visiapour; 60 miles W.N.W. of Poonah.

PANYASUS, in *Ancient Geography*, a river of Macedonia, the mouth of which is placed by Ptolemy between Dyrhachium and the mouth of the river Apfus.

PAZA, or PENGGA, in *Geography*, a town of Africa, in Congo, in the province of Bamba.

PANZANO, a town of Etruria; 14 miles S. of Florence.

PANZEN, a town of Bohemia, in the circle of Leitmeritz; 15 miles N.N.E. of Leitmeritz. N. lat. 50° 44'. E. long. 14° 25'.

PANZERA, in *Botany*, named by Willdenow in honour of Dr. G. W. F. Panzer, a physician at Nuremberg, author of some well known tracts on Botany and Entomology. This genus was originally called *Eperua* by Aublet, and is considered by Schreber as not distinct from *Dimorpha*, though Willdenow says it is perfectly different in its stamens and legume, as well as in other particulars.—Willd. Sp. Pl. v. 2. 540. (*Eperua*; Aubl. Guian. v. 1. 369. Juss. 349. Lamarck Illustr. t. 338.)—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, cloven into four, broad, oblong, obtuse, concave segments. Cor. Petal one, broad, spreading, roundish, convolute at the sides of its base, inserted at the mouth of the calyx. Stam. Filaments ten, very long, variously inflexed, inserted into the calyx, thicker at the base, villose, nine of them united at the bottom, one single; anthers oblong, obtuse, two-celled, nodding, five of them barren. Pist. Germen superior, stalked, nearly ovate; style very long, incurved; stigma obtuse. Peric. Legume coriaceous, compressed, rather downy, rusty, long, hooked, with an acute, incurved point, of one cell and two valves, bursting elastically. Seeds three or four, large, compressed, coriaceous, sometimes emarginate on one side.

Ess. Ch. Calyx of one leaf, four-cleft. Petal one, lateral, convolute at the base. Filaments thickened at the base, bearded, five of them abortive. Legume.

1. *P. falcata*. Willd. (*Eperua falcata*; Aubl. Guian. t. 142.)—Native of woods, and banks of rivers, in Guiana. It flowered and bore fruit towards winter.—The trunk of this large tree is sixty feet in height, much branched at the

upper part. Branches widely scattered. Leaves alternate, pinnate; leaflets in three pairs, opposite, nearly sessile, ovate-oblong, acute, smooth, entire, springing from the furrow of the leaf-stalk. *Stipulas* two, small, deciduous. *Flowers* numerous, red. See *DIMORPHA Falcata*.

As there is so much diversity of opinion about this plant, we have thought it best to exhibit Willdenow's view of it, though it had been already mentioned under *DIMORPHA*.

PANZY. See *VIOLA*.

PAO, in *Geography*, a river of South America, which rises near Valencia, in the province of Caraccas, and after a course of about 100 miles, joins the Bariquicemeto, in N. lat. 8° 20'; and the united streams form the Portuguesea.—Also, a town of Corea; 30 miles S.E. of Ou-tchuen.

PAO-DE-NAO, a town on the coast of Africa, near the river Camarones, belonging to the Portuguese.

PAO-KING, a city of China, of the first rank; in Hou-quang. N. lat. 27° 4'. E. long. 111°.

PAOLI, PASCAL DE, in *Biography*, a very distinguished character in modern times, born at Rostino, in the island of Corfica, in 1726, was the son of Giacinto Paoli, who had been always attached to the popular cause, and who, when all his attempts against the Genoese had proved unavailing, had retired with his family to Naples. Pascal was educated among the Jesuits, and at their college he made a rapid progress in his studies, and displayed an understanding equally solid and capacious. He appears to have been formed by nature with powers capable of attaching to himself the hearts and suffrages of his countrymen; for his deportment was grave and prudent, and his judgment was matured by reflection rather than by age, while his patriotism was unquestioned, and his eloquence superior to that of any of his rivals. He was accordingly unanimously chosen generalissimo, in a full assembly of the people, when he had attained but to the 29th year of his age. He was not long in deciding how he should act: he complied with his country's call, and devoted himself to its service. Having taken leave of his father, now advanced in years, he embarked for the island, and was formally invested with the chief command. The situation of the island, in respect to its internal government, being exceedingly unpromising, this chief new-modelled the laws, and established the appearance, if not the reality, of subordination: he instituted schools, and laid the foundation of a maritime power. In 1761 the government of Genoa, perceiving the change lately effected among the natives, sent a deputation to a general council, convoked at Vecovato, for the express purpose of proposing terms of accommodation; but it was unanimously resolved never to make peace with the oppressor, unless upon the express condition of Corfica being guaranteed in the full enjoyment of its independence. A memorial to the same effect was also addressed, at the same time, to all the sovereigns of Europe. But appeals to the principles of freedom were not likely to obtain favour in royal cabinets, and nothing was gained by the memorial of the Corficans: indeed the court of France entered into a treaty with the Genoese, for supplying them with a force to garrison the towns yet remaining in their hands. The presence of the French soldiers effectually prevented any progress towards freeing the island, and the only military transaction of any note that took place during the four years in which this treaty subsisted, was the conquest, by the Corficans, of the isle of Capraia.

At length, in 1768, the Genoese despairing of rendering the stubborn islanders subservient to their will, transferred the sovereignty of Corfica to France, on condition of receiving in lieu of it 40,000,000 of livres. This was a thunderstroke to the wretched Corficans, but the noble leader remained

firm

firm to his cause: he roused and prepared the spirit of his followers for a fresh contention, and animated them to persevere, with additional zeal, in defence of their rights and liberties as an independent people, promising never to abandon them, but either to triumph or fall at the head of his countrymen. This heroic resolution was circulated with rapidity, and, when coupled with the justice of the cause in which he had embarked, obtained for him the esteem and regard of every lover of freedom and humanity throughout Europe.

He was at first tempted with the offer of being confirmed in his supreme authority, provided he would consent to hold it under the French government, but he rejected the proposal with indignation: he was a lover of liberty, and not attached to the mere exercise of power; and he nobly declared, in answer to the disgraceful application, as he thought it, that "the rocks which surrounded him should melt away, ere he would betray a cause which he held in common with the meanest Corsican." A rigorous war commenced, in which, for some time, the French were beaten, and in one instance their general was obliged to capitulate, with all his infantry, artillery, and ammunition. An immense force was now sent from France which overwhelmed the Corsican patriots; they were defeated with great slaughter, and Paoli, left with only about 500 men, was surrounded by the French, who were anxious to get possession of his person; he, however, cut his way through the enemy, and escaped to England with his friends, where they were received with all the sympathy and respect due from freemen to patriots who had so nobly supported the cause of liberty. Dumourier, who afterwards made a figure in the revolution of his own country, and was at length deservedly disgraced, served at this period against the Corsicans, with the rank of adjutant-general; and in his own memoirs, published a few years since, he pays very high compliments both to the people of the island and their chief: "it is astonishing," he says, "that this handful of islanders, destitute of artillery, fortifications, magazines, and money, should have kept France at bay during two campaigns, although she had no other enemy to cope with. But liberty doubles the valour and strength of man."

The case of the oppressed Corsicans had excited much interest in this country, and it was but a few days before his final retreat, that he received a liberal subscription from a number of private individuals, of which number were aldermen Beckford and Trecothick, and Samuel Vaughan, esq. who were also trustees for the sums raised, for the express purpose of enabling him to carry on the war against France. On his arrival Paoli was introduced at court, and the duke of Grafton, then prime minister, obtained for him a pension of 1200*l.* a-year, which he liberally shared with his companions in exile.

From this time the ex-general lived a retired life, devoting himself chiefly to the cultivation of literature. During his retirement, which lasted more than twenty years, he was introduced to Dr. Johnson by Mr. Boswell, who had visited the general while he was in Corsica; and who speaks of the interview with pleasure, saying, "the general spoke Italian, and Dr. Johnson English, and understood one another very well, with a little aid of interpretation from me, in which I compared myself to an isthmus, that joins two great continents."

At length the revolution that promised to raise France to the rank of a free state, extended its influence to Corsica, and the national convention passed a decree by which that island was numbered among the departments of France, and entitled to all the privileges of the new constitution. The return of Paoli to the dignified station of its chief, was the

first wish of his liberated countrymen, and Paoli could not resist their entreaties, which were enforced by the solicitations of the French assembly. He resigned his pension from the English court, took a grateful leave of the country in which he had been so hospitably entertained, and in the month of April 1790, presented himself at the bar of the national assembly at Paris, together with the Corsican deputies. Soon after this he embarked for Corsica, where he was received with an extraordinary degree of attachment and respect. He was elected mayor of Bastia, commander-in-chief of the national guard, and president of the department; and, in short, he at once acquired more authority in the island, than before its subjugation by the French. He was, however, not quite contented; he was ambitious of seeing Corsica wholly independent, which, upon the execution of Lewis XVI., was the prevailing wish of the Corsicans. The convention was soon apprized of their views, and summoned Paoli to their bar to justify himself against the charges exhibited against him: to gain time, he pleaded his age and infirmities as excuses why he could not comply with their demand. To a second order, more peremptory than the first, he replied in a different manner, and with more frankness. After this he repaired to Corte, the ancient capital, in the centre of the island, where, surrounded by his friends and adherents, he laughed at the proclamation which had been issued, declaring him a traitor, and setting a price upon his head. Sensible, however, that it would be impossible for a small island permanently to withstand the power of France, without foreign support, he resolved upon an expedient, which, though it was a renunciation of independence, promised to secure all the advantages of real liberty. This was an union of Corsica with the crown of Great Britain; the particulars of this business will be found in the article *CORSICA*. Paoli, as will be seen in that article, returned to England, having unfortunately lost all his property, by the failure of a mercantile house at Leghorn, and passed the remainder of his life in great privacy. He died in London, February 5, 1807, in the eighty-first year of his age. Few foreigners, however distinguished, have been so much caressed in England as general Paoli. By living in habits of familiarity with men of letters, his name and exploits acquired high celebrity: and Boswell, Goldsmith, Johnson, and many others, equally eminent in the literary world, although differing in almost every thing else, cordially united in his praise. On the continent his reputation was greatly respected: it was usual to compare Paoli to Timoleon and Epaminondas. He was unquestionably a great man; but it is the opinion of those who have enjoyed the opportunity of studying his character, that he was a politician rather than a soldier: that he shone more in council than in arms; and that the leading feature of his public conduct was a certain degree of Italian policy, which taught him to refine and speculate on every event. Boswell's Account of Corsica. Athenæum, vol. i. Monthly Mag. vol. xxiii.

PAOLO, AGOSTINO, a learned ecclesiastical composer of music, scholar of Bernardo Nanini, and successor in the pontifical chapel to Soriano. Antimo Liberati speaks of him as one of the most scientific and ingenious composers of his time, in every species of music then cultivated: and tells us, that while he was maestro di capella of St. Peter's church at Rome, he astonished the musical world with his productions for four, six, and eight choirs or chorusses; some of which might be sung in four or six parts only, without diminishing or enervating the harmony. Padre Martini, who bears testimony to the truth of this eulogium, has inserted an *Agnus Dei*, in eight parts, of this composer, which is truly a curious production: three different canons

being carried on at the same time, in so clear and natural a manner, both as to melody and harmony, that this learned father, who had been long exercised in such arduous enterprises, speaks of it as one of the greatest efforts of genius and learning in this most difficult kind of composition.

PAOLO, in *Commerce*, a small silver coin at Florence, Rome, and other places in Italy. As a money of account at Florence, the feudo d'oro is worth $7\frac{1}{2}$ lire, $11\frac{1}{2}$ paoli, or 90 crazie. The ducato, or feudo corrente, called also the piastra, is an imaginary coin, valued at 7 lire, $10\frac{1}{2}$ paoli, or 84 crazie; the lira = $1\frac{1}{2}$ paoli; the paolo or giulio = 8 crazie = 40 quatrini = 160 denari di lira; a tellone = 2 lire = 3 paoli.

The coins in silver are pieces of 10 paoli, or $6\frac{1}{2}$ lire, called francefconi and leopoldoni; half ditto, called francefchini, of 5 paoli; tallari, of 6 lire, or 9 paoli; tefconi of 2 lire, or 3 paoli; single, half, and quarter lire, of 20, 10, and 5 foldi; double, single, half, and quarter paoli; double, single, and half crazie.

The piece called francefcone weighs 23 denari 10 grani, Florence weight, or 426 English grains; and the silver is 10 denari 22 grani, or 10 oz. $18\frac{1}{2}$ dwts. fine; and therefore contains $387\frac{1}{2}$ English grains of fine silver, or 419 grains of standard silver, and is worth 4s. 6d. sterling. According to this valuation, the feudo d'oro, of $7\frac{1}{2}$ lire, = 5s. $0\frac{3}{4}$ d. sterling; the ducato, or feudo corrente, of 7 lire, = 4s. $8\frac{3}{4}$ d. sterling; the pezza, of $5\frac{1}{2}$ lire, = 3s. $10\frac{3}{4}$ d. sterling; the lira is worth about 8d.; or 1l. sterling = 29 lire, 12 foldi, 7 denari, or 4 ducati, 4 foldi, 7 denari di ducato; or 5 pezze, 2 foldi, 8 denari di pezza, all in silver. For the paoli of Rome, see ROME.

PAOLO, *St.*, in *Geography*, a river of Sicily, which runs into the sea, on the E. coast, N. lat. $37^{\circ} 16'$. E. long. $15^{\circ} 13'$.—Also, a small island, near the coast of Naples, in the gulf of Taren'to. N. lat. $40^{\circ} 42'$. E. long. $17^{\circ} 6'$.—Also, a town of Naples, in the Capitanata; 3 miles S.E. of Dragonera.

PAOLOS, in *Geography*, a town of Asiatic Turkey, in the province of Sivas; 25 miles W. of Sivas.

PAON, in *Ornithology*. See TRINGA *Pugnax*, and PAVO *Cristatus*.

PAO-NGHAN, in *Geography*, a city of China, of the second rank, in Pe-tche-li, on the river San-cam; 62 miles N.W. of Pekin. N. lat. $40^{\circ} 20'$. E. long. $114^{\circ} 41'$.

PAO-NING, a city of China, of the first rank, in the province of Se-tchuen, comprehending within its jurisdiction ten cities.

PAOOM, one of the smaller *New Hebrides*; which see.

PAOS, a town of Portugal, in the province of Beira; 16 miles N.W. of Viseu.

PAO-TCHING, a town of Corea; 30 miles S. of Koang-cheou.

PAO-TCHUEN, a town of Corea; 28 miles S.S.W. of Hoang-tcheou.—Also, a town of Corea; 23 miles E. of King-ki-tao.

PAO-TING, a city of China, in the province of Pe-tche-li, in which the viceroy resides, and the most considerable in the province, next to Pekin. It has 20 others under its jurisdiction; the country round it is pleasant, and inferior in fertility to no part of China. In going from Pe-kin to the province of Chan-fi, it is necessary to pass through this city. N. lat. $38^{\circ} 54'$. E. long. $115^{\circ} 14'$.

PAOULA, a town of Naples, in Principato Ultra; 4 miles N.E. of Benevento.

PAOWAH, a town of Hindoostan, in Bahar; 5 miles S. of Bahar

PAP, in *Rural Economy*, a provincial term applied to the teats of cows, or other animals that give milk. The paps distend after the young is produced, and as the bodies of them contain the terminations of the tubuli lactiferi, where they are tortuous, and act as valves; they are distensible, as they are squeezed becoming straight, and thus the milk has a free passage, whether the pressure be caused by the mouth of the young animal in sucking, or the hand in the act of milking. See TEAT.

PAPA. See POPE.

PAPA, in *Ornithology*. See VULTUR.

PAPA, in *Geography*, a town of Hungary; 25 miles S. of Raab.

PAPA *Stour*, one of the Zetland or Shetland islands of Scotland, is situated about a mile westward from the Mainland. This island extends about two miles in length, and one in breadth. Its soil is a rich sand, producing excellent pasturage grafs, and even good crops of oats, with beans and potatoes. Along the coast are numerous small *voes*, or harbours, which afford a safe retreat to the boats employed in the Zetland islands. Here is a remarkable cave, by which the sea flows for a considerable distance into the interior of the island, under the rocks. The beach, being admirably adapted for drying fish, is occupied by a number of houses appropriated to that purpose. History of the Zetland Islands, by Dr. A. Edmonston. Sinclair's Statistical Account, vol. xx.

PAPA, or PAPAY-*Stronfay*, one of the Orkney islands, off the coast of Scotland, is situated on the north-east quarter of the isle of Stronfay. Though little more than three miles in circumference, its surface is remarkably level, and equally beautiful as fertile. Here are the ruins of two ancient chapels, one dedicated to St. Bride, and the other to St. Nicholas. On an eminence called Earl's knoll, are several graves, and some vestiges of buildings which formerly belonged to one of the ancient earls of Orkney. History of the Orkney Islands, by the Rev. Dr. Barry, 2d edit. 1808, by the Rev. James Headrick.

PAPA, or PAPAY-*Westray*, one of the Orkney islands of Scotland, lies about one mile to the north of Westray. It is nearly four miles long, and one broad; and scarcely yields in fertility of soil to any district in Scotland. At its south-eastern extremity is a beautiful lake of fresh water, the centre of which is adorned with an islet, where are the ruins of the once noble chapel of St. Tredwall, to whom superstition, till lately, attributed many wonderful and miraculous works. History of the Orkney Islands, by Dr. Barry, 3d edit. 1808.

PAPACY. See POPEDOM.

PAPAGAY, or PAPEGAY, in *Ornithology*. See PSITTACUS.

PAPAGAYO, in *Geography*, a river of Mexico, which runs into the Pacific ocean, 25 miles N. of Acapulco, N. lat. $17^{\circ} 40'$. W. long. $101^{\circ} 46'$.

PAPAGAYO *Bay*, or *Parrot Bay*, a bay on the North Pacific ocean, and on the W. side of the isthmus of Nicaragua, at a small distance from the western part of the lake of Nicaragua. N. lat. $11^{\circ} 10'$. W. long. $87^{\circ} 36'$.

PAPAKUNK, a town of New York, on the Papaciton. N. lat. $42^{\circ} 5'$. W. long. $74^{\circ} 58'$.

PAPAL CROWN is a deep cap, or mitre of cloth of gold, encompassed with three coronets, or circles of gold, adorned with flowers; and the whole enriched with precious stones; having a globe at top, finished with a cross. See CROWN.

PAPALLACLA, in *Geography*, a town of South America, in the province of Quito; 50 miles N.W. of Archidona.

PAPALOAPAIN, a river of Mexico, called Alvarade, or Alvarodo; which see.

PAPALQUIAN, a town of Mexico, in New Biscay; 130 miles N.W. of Durango.

PAPAMOW, a town of Hindoostan; 8 miles N. of Allahabad.

PAPAN, in *Ornithology*, the name given by the inhabitants of the Philippine islands, to a species of duck common in their lakes and marshes. This is very large and beautiful, and is called by father Camelli *anas regia*, or the *royal duck*: it is not so common, however, as the little kind which they call *salayafir*.

PAPANAUD, in *Geography*, a town of Hindoostan, in the Carnatic; 25 miles S.S.E. of Tanjore.

PAPAS, a lake of South America; 40 miles S. of Popayan.

PAPAS *Adassi*, or *Papadonissa*, or *Prince's Islands*, a cluster of small islands in the N.E. part of the island of Marmora, at the entrance of the Straits of Constantinople; 8 miles S. of Constantinople. The islands known under the name of Prince's islands, are nine in number, four large, and five small. The first is called "Prota;" the second, "Antigona;" the third, "Chalkis;" and the fourth, "Prinkipos:" to the south of the latter lies the little island, called "Rabbit" island; to the west are two small islands, one of which is known by the name of "Oxya," and the other by that of "Plata;" the two others are nameless rocks. The principal of these islands is *Prinkipos*; which see.

PAPAS-ILI, a town of European Turkey, in Romania; 32 miles N. of Adrianople.

PAPAYER, in *Botany*, the Poppy, so called, according to the most learned etymologists, because it was commonly mixed with the pap, *papa*, given to children, in order to procure sleep. This plant and its name have ever been associated with the idea of sleep in most languages, in poetry and philosophy, in history and fable. Its juice is still the best opiate known, and in the most general use.—Linn. Gen. 263. Schreb. 350. Willd. Sp. Pl. v. 2. 1144. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 565. Prodr. Fl. Græc. Sibth. v. 1. 358. Ait. Hort. Kew. ed. 2. v. 3. 288. Juss. 236. Tourn. t. 119, 120. Lamarck Illustr. t. 451. Gærtner. t. 60.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Rhæadææ*, Linn. *Papaveraceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, ovate, emarginate, of two nearly ovate, concave, obtuse, immediately deciduous leaves. *Cor.* Petals four, roundish, flattish, spreading, large, contracted at the base, alternately smaller. *Stam.* Filaments numerous, capillary, inserted into the receptacle, much shorter than the corolla; anthers oblong, compressed, erect, obtuse. *Pist.* Germen superior, sessile, large, roundish; style none; stigma depressed, peltate, flat, radiated. *Peric.* Capsule oval, or somewhat oblong, crowned with the large, flat, permanent stigma, of one cell, though imperfectly divided into many, bursting at the top by numerous orifices under the stigma. *Seeds* numerous, minute. *Receptacles* longitudinal folds, attached to the inside of the capsule, equal in number to the rays of the stigma.

Eff. Ch. Calyx of two leaves. Petals four. Stigma radiated. Capsule superior, of one cell, opening by pores under the permanent stigma.

Obs. The seed-vessel differs in shape in different species, from globose to oblong, and the rays of the stigma differ greatly in number, according as the shape of the capsule appropriated to each species, is more or less oblong and narrow. The species are commodiously divided into two sections, distinguished by the roughness or smoothness of the capsule.

SECT. 1. Capsules bristly.

1. *P. hybridum*. Mongrel Poppy. Linn. Sp. Pl. 725. Engl. Bot. t. 43. (*Argemone capitulo torulo*; Ger. em. 373.)—Capsule nearly globular, furrowed, bristly. Stem leafy, many-flowered.—Native of fields, on a light soil, in the more temperate or southern parts of Europe; rare in England, though we have several times gathered it sparingly about Norwich. The root is annual. Stem branched, about a foot high, leafy, covered with close-pressed bristles. Leaves dark green, alternate, doubly pinnatifid, in many narrow segments, bristly like the stem. Flowers terminal, solitary, erect, smaller than usual in the genus. Calyx rough with tawny hairs. Petals deep red, with more or less of a violet spot at the base. Stamens violet. Pollen bright blue. Capsule the size of a filbert, deeply channelled, obovate, belet with ascending prickles. The whole herb partakes of the fetid and disagreeable flavour common to its genus, but is scarcely milky.

2. *P. Argemone*. Long rough-headed Poppy. Linn. Sp. Pl. 725. Curt. Lond. fasc. 5. t. 38. Engl. Bot. t. 643. Fl. Dan. t. 867. (*Argemone capitulo longiore*; Ger. em. 373.)—Capsules club-shaped, bristly. Stem leafy, many-flowered.—Native of sandy fields, in various parts of Europe, flowering in June or July. Much like the last, but the segments of the leaves are generally broader, and the colour of the whole herb, as well as of the flowers, is lighter. The bristles of the stem are not so closely pressed. Stamens very broad at their summit, each anther being supported by a little partial stalk. Stigma with only four or five rays, the capsule being slender, obscurely five-sided, by no means channelled like the former, nor is it so bristly, except in the upper part. The flowers have been found double in England, but such a circumstance is rare. Both these species occur but sparingly, in a scattered manner, and never in the abundance of the common *P. rhæas* hereafter described, let the soil and situation be ever so favourable.

3. *P. alpinum*. Alpine Poppy. Linn. Sp. Pl. 725. Jacq. Austr. t. 83. Seguier. Veron. 416. t. 4. f. 4.—Capsule bristly. Stalk radical, single-flowered, bristly, leafless. Leaves doubly pinnate.—Native of the mountains of Switzerland, Austria, the rocks of mount Baldus, Dauphiny, and the Pyrenees. Miller appears to have cultivated this species in 1759, but it is now rarely to be seen with us. Though tolerably hardy, it thrives best in a frame, flowering in May or June. Root perennial, tasted. Leaves numerous, all radical, stalked, doubly pinnatifid, the segments linear or obovate, decurrent, entire, rather glaucous, smooth, or slightly hairy. Flower-stalks few, ascending, simple, five or six inches high, bristly, with close hairs, leafless, each bearing one flower, about an inch and half broad, usually pale yellow, sometimes, according to Villars, reddish or whitish; Jacquin says it is constantly pure white in Austria. The anthers are always yellow. Capsule ovate, bristly, with four, five, or six angles in the upper part, and as many rays to the stigma.

4. *P. nudicaule*. Naked-stalked Poppy. Linn. Sp. Pl. 725. Fl. Dan. t. 41. (*P. erraticum nudicaule, flore flavo odorato*; Dill. Elth. 302. t. 224.)—Stalk radical, single-flowered, bristly, leafless. Leaves simple, pinnatifid.—Native of Norway and Siberia. More frequently seen in our gardens than the last, being a hardy biennial, flowering in June and July. The leaves differ from the last in being simply pinnatifid, and their segments much broader. The stalk is a foot high. Flower of a most decaute sulphur colour, but with a disagreeable smell, at least in our opinion, Dillenius nevertheless compares it to the scent of a Jonquil.

and

PAPAYER.

and says it is chiefly perceptible in a morning and evening. Linnæus considered the two species last described as too nearly related to each other, but they seem distinct, notwithstanding the agreement in their habit, the hairy calyx, and ovate bristly seed-vessel. The present is said to have occasionally a white flower.

SECT. 2. Capsules smooth.

5. *P. Rhæas*. Common Red Poppy, or Corn Rose. Linn. Sp. Pl. 726. Curt. Lond. fasc. 3. t. 32. Engl. Bot. t. 645. Woodv. Med. Bot. t. 186. Ger. em. 371. (*P. erraticum*; Matth. Valgr. v. 2. 404.)—Capsules smooth, nearly globular. Stem many-flowered; rough with horizontal hairs. Leaves pinnatifid, cut.—Native of cultivated and waste ground, throughout Europe, and a very troublesome, though splendid weed in ill managed corn-fields. It flowers in Greece in the early spring, with us not till June or July. The root is annual. Stem about two feet high, branched, clothed all over with bristly hairs, that all spread horizontally. Leaves pinnatifid; often in some degree bipinnatifid; their segments oblong, serrated, and cut, more or less hairy. Flowers larger than in any of the foregoing, of a deep and most brilliant scarlet red, slightly fœtid. Capsule quite smooth and even, short and abrupt, with a many-rayed stigma.

Varieties with more or less double flowers, white, red or parti-coloured, are common in gardens, but if suffered to scatter their seed without a careful renewal of soil, their beauties and distinctions are transient in their offspring. The heads or capsules of this species are recommended as an opiate by Dioscorides, and its use is still retained; especially a red syrup is made of the flowers, which serves as a mild soporific for children.

6. *P. dubium*. Long smooth-headed Poppy. Linn. Sp. Pl. 726. Curt. Lond. fasc. 5. t. 37. Engl. Bot. t. 644. Fl. Dan. t. 902.—Capsules smooth, oblong. Stem many-flowered, hairy; the hairs on the flower-stalks close-pressed. Leaves doubly pinnatifid.—Native of fields in various parts of Europe, chiefly on a sandy soil, and not very abundantly, flowering in June and July. This approaches the last very nearly in habit, but the flowers are of a paler hue, the capsule slender, furrowed, with a stigma of only six or eight rays, and the bristles on the flower-stalks are closely pressed to the stalk, not spreading as in *P. Rhæas*. Crantz thought this species a variety of *P. Argemone*, but there seems little reason for such an opinion. *P. dubium*, Jacq. Austr. t. 25, if correctly drawn, is very puzzling. The bristles on the flower-stalks are represented deflexed, which is quite the reverse of our Linnæan specimen, as well as of the English ones; the petals are white, with a violet spot.

7. *P. somniferum*. White, or Garden, Poppy. Linn. Sp. Pl. 726. Woodv. Med. Bot. 185. Engl. Bot. t. 2145. Bulliard. t. 57. (*P. sylvestre*; Ger. em. 370.)—Calyx and capsules smooth. Leaves embracing the stem, glaucous, cut. Stem smooth in the lower part; rough with spreading hairs above.—Native of fields and waste ground in the south of Europe; rare in England. The Rev. Mr. White observed it to be truly wild on the sandy banks of the fen ditches in Marshland. In gardens it is well known, as a hardy annual, sporting in the forms and colours of its rich beautiful double petals, but easily returning, if neglected, to its single state, and pale purple or white hue, having a violet stain on each petal. The largest heads, for medical use, are obtained from the single-flowered kind, cultivated in warm countries on a fertile soil. These being wounded as they grow, yield a milky juice, which by drying becomes opium. The herb is erect, four feet or more in

height, branched, very glaucous, with broad, obtuse, simple, lobed and crenate, wavy leaves, clasping the stem, which in its upper part only is naturally clothed with coarse spreading hairs. The buds droop, but the flowers are erect, with a faint unpleasent scent, a smooth calyx, large petals, and a nearly globose capsule, crowned with a stigma of many rays. The seeds are either dark brown or white, of a pleasant sweet flavour.

8. *P. pilosum*. Hairy Red Poppy. Sm. Prodr. Fl. Græc. Sibth. v. 1. 360. Fl. Græc. t. 492, unpublished.—Capsules smooth. Stem many-flowered, clothed with spreading hairs. Leaves clasping the stem, cut, hairy all over.—Gathered by Dr. J. Sibthorp, about the Bithynian Olympus. The root of this new and handsome species appears to be perennial. Herb about the size of the last, but of a bright green, not glaucous, and clothed with bristly hoary hairs, which spread horizontally on the stem, where they are very abundant, as well as on the flower-stalks, where they are sparingly scattered. The leaves are simple, broad, heart-shaped, and clasping the stem, bluntly lobed and cut, hairy, with strong ribs and veins; the radical ones narrower, oblong, and stalked. Flowers about the size of the last, and indeed larger than the wild *P. somniferum* of Greece, drooping in the bud, then erect. Calyx bristly. Petals of a pale tawny scarlet, or full orange, with white claws. Anthers yellow. Germen obovate, smooth, glaucous, with six ribs, and the same number of broad rays in the stigma.

9. *P. virgatum*. Wand-like Poppy. (*P. orientale*, tenuiter incisum, ad caulem floridum; Tourn. Cor. 17.)—Capsules smooth. Stem straight, panicled, many-flowered, rough with spreading bristles. Leaves pinnate, cut, bristly.—Native of Armenia. We described it formerly from Tournefort's herbarium at Paris. The stem is straight and stiff, panicled, bearing a great number of flowers, and clothed with spreading rigid bristles. Radical leaves numerous, pinnate, cut, hispid, especially their ribs, all the points callous, and tipped with a bristle, as in those of *P. orientale*, which they in all respects much resemble. Flower-stalks scattered, each bearing one, two, or three flowers. Calyx bristly. Petals red. Germen roundish, smooth. This species differs from the following one, in having a straight, panicled, many-flowered stem, the bristles covering which are horizontal, not close-pressed.

10. *P. orientale*. Great Oriental Poppy. Linn. Sp. Pl. 727. Curt. Mag. t. 57. (*P. orientale hirsutissimum*, flore magno; Tourn. Cor. 17. Voy. v. 2. 118. t. 118. Comm. Rar. t. 34.)—Capsules smooth. Stem single-flowered, leafy, rough, with close-pressed bristles. Leaves pinnate, serrated, bristly.—Native of the Levant. Tournefort found it near Erzerum, in Armenia, flowering in June. He introduced it into the gardens of Holland and France, and it has been, for about a century, a hardy perennial in our parterres, flowering early in summer, and very conspicuous for the great size, and peculiarly brilliant scarlet colour of its flowers, which are too dazzling to be looked on in the sunshine. They are nearly a span wide, with dark stamens, and sometimes a black spot on each petal. Germen globose, quite smooth and even, without ribs. Rays of the stigma sixteen, peculiarly dilated. The root creeps moderately, by which the plant is increased, for it scarcely ever ripens seed with us. Stems about two feet high, simple, leafy, round, densely clothed with erect, rigid, pungent, close-pressed bristles. Leaves most numerous from the root, a foot long, dark green, harsh and bristly, pinnate, with serrated decurrent segments. The juice of the plant is hot and acrid, yet Tournefort says the Turks and Armenians eat the unripe heads by way of luxury. They extract no opium from this species;

species; but perhaps the similarity of its flavour and effects, to that great foolher of their cares, may cause it to be thus employed.

11. *P. fugax*. Small Fugacious Poppy. Lamarek Dict. v. 5. 118.—Capsules smooth, orbicular. Stem panicled, many-flowered, smooth. Petals minute. Leaves pinnatifid, ferrated, hispid. Brought by Michaux from Persia. It flowered in May 1789, in the royal garden at Paris. Poiret described it from Lamarek's herbarium, and we know this species merely from his description, having seen neither specimen nor figure. He says it is distinguished by the *stem*, forming at the summit an ample panicle of many very small flowers, which last but a few hours. Each *stem* is slender, straight, striated, smooth, about eighteen inches high, simple, except at the top. *Leaves* scattered, stalked, not unlike those of *P. orientale*, but less deeply pinnatifid, not pinnate, furnished with a few long scattered hairs, the segments or teeth, more or less distant, each terminated by a long bristle. *Petals* pale red, very small in comparison with the rest of the genus, and extremely fugacious. *Capsule* small, globular, smooth, crowned with a conical, obtuse *stigma*, of four or five rays.

12. *P. cambricum*. Yellow Welch Poppy. Linn. Sp. Pl. 727. Engl. Bot. t. 66. (*P. cambricum* perenne, flore sulphureo; Dill. Elth. 300. t. 223. *Argemone lutea cambro-britannica*; Morif. sect. 3. t. 14. f. 12.)—Capsules smooth, oblong, beaked. Stem nearly smooth, bearing several flowers. Leaves pinnate, cut.—This species, one of the most elegant of our native plants, seems peculiar to rocky shady situations in Wales and Westmoreland; for the reference to Bauhin's Prodomus, on which Linnæus grounds his assertion of its being found on the Pyrenæes, appears to belong either to the *alpinum* or *nudicaule*. It is perennial, flowering in June; and may be cultivated in the moist shady parts of a garden, where, though each root does not, in general, last many years, the seeds scattering themselves in the undisturbed soil, will from time to time produce new plants. The *stem* is twelve or eighteen inches high, leafy, somewhat branched, clothed with a few rather upright hairs. *Leaves* tender and delicate, of a pale but pleasant green, pinnate, their common stalk winged; their leaflets ovate, acute, cut or lobed, almost entirely smooth, glaucous underneath, each above an inch long. *Flowers* terminating the few branches, solitary, on long stalks, about the size of *P. dubium*, but of a beautiful lemon colour, with a scent like those of *Craffula coccinea*, or *Mesembryanthemum nodiflorum*, which most people compare to the Bergamot Pear. The *stigma* has about five rays, and is elevated on a sort of beak, resembling a style, above the obovate, smooth, five-ribbed *capsule*. The *calyx* is hairy. The herb when wounded discharges a yellowish fluid, not unlike the juice of the common Celandine, to which indeed this plant is so nearly allied in botanical affinity, that such a coincidence is not surprizing. The same may be said of the American *Sanguinaria*.

PAPAVER, in *Gardening*, contains plants of the hardy, herbaceous, fibrous-rooted, annual, and perennial kinds, of which the species cultivated are, the white poppy (*P. somniferum*); the corn, or red poppy (*P. rhæas*); the Welch poppy (*P. cambricum*); and the Oriental poppy (*P. orientale*).

There are several varieties of the first sort, differing in the colour and multiplicity of their petals, which are preserved in gardens for ornament: the single-flowered sort is chiefly cultivated for use.

The common black variety of poppy has stalks about three feet high, smooth, and dividing into several branches; the leaves are large, smooth, deeply cut or jagged on their

edges, and embracing; the petals purple, with dark bottoms; succeeded by oval, smooth capsules filled with black seeds, which are sold under the name of *maco-seed*.

And of this there are many sub-varieties; as with large double flowers, variegated of several colours; with red and white, purple and white, and some finely spotted like carnations.

There are few plants whose flowers are so handsome; but as they have an offensive scent, and are of a short duration, they are not in general much regarded.

In the second sort there is a variety with an oval, black, shining spot, at the base of each petal, from which many beautiful garden sub-varieties are produced, which have double flowers, white, red bordered with white, and variegated.

The fourth has also a few varieties, differing in the colour of the flowers; and it is said that the flower is sometimes double, but with us it is always single.

Method of Culture.—All the different sorts may be increased by seeds, and the two last sorts also by parting and planting out the roots.

The seeds should be sown in the autumn, or very early in the spring, but the former is the better season, either in the places where the plants are to grow, or in beds, to be afterwards planted out. The first is probably the best method, as these plants do not bear removing well.

When they are cultivated for ornament, seed of the finest double sorts should be carefully provided and made use of, and be sown in patches.

In the practice of Mr. Ball, in cultivating the first sort for the purpose of preparing opium from it, "the seed was sown at the end of February, and again the second week in March, in beds three feet and a half wide, well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine, either in small drills, three in each bed, or broadcast; in both cases, thinning out the plants to the distance of a foot from each other, when about two inches high, keeping them free from weeds." They produced from four to ten heads each, and shewed large flowers of different colours. "With an instrument something like a rake, but with three teeth, the drills may be made at once." He found that the plants did not bear transplanting; as out of 4000 which he transplanted, not one plant came to perfection.

The roots of the two last sorts may be divided in the autumn or spring, but the first period is the better, leaving some root fibres to each parting, planting them out where they are to remain, as soon afterwards as possible.

In all the sorts the plants only require afterwards to be kept free from weeds, and those raised from seed properly thinned out.

They all afford ornament and variety in the clumps, borders, and other parts of pleasure grounds and gardens; and the first sort may sometimes be grown to advantage for the purpose of having the juice which it affords made into opium.

PAPAVERACEÆ, in *Botany*, a natural order of plants, the 62d in Jussieu's system, the 2d of its 13th class. This order owes its name to *Papaver*, the Poppy, the principal, and best known, of the genera that compose it. For the characters of this 13th class, see GERANIA.

The *Papaveraceæ* are thus defined. *Calyx* mostly of two leaves, soon falling off. *Petals* generally four. *Stamens* either definite or indefinite. *Germen* one; style often wanting; stigma divided. *Fruit* either capsular or siliquose, for the most part of a single cell, and generally with many seeds, which are affixed to lateral receptacles, each seed half covered with a membranous integument. *Stem* herbaceous, scarcely

ever shrubby. *Leaves* alternate. *Juice* in some instances coloured. See PAPAVER.

SECT. 1. *Stamens* indefinite; their anthers combined with the filaments. This contains *Sanguinaria*, *Argemone*, *Papaver*, *Glaucium*, *Chelidonium* and *Bocconia*; see PANKE. Surely *Aëæa* and *Podophyllum* more naturally belong to this place, than to the *Ranunculaceæ*, where Jussieu has placed them.

SECT. 2. *Stamens* definite. This section consists of *Hypocoum* and *Fumaria*; to which we would, at the suggestion of Jussieu himself, add his *Balsamina*, (*Impatiens* of Linnæus,) as more allied, at least to this order, than to his GERANIA; see that article.

Jussieu indicates the connection between this order and the *Cruciferae*, of which *Chelidonium* and *Hypocoum* are the slight and obscure links, they having, like the cruciform plants, four petals and a pod, as well as seeds destitute of albumen; but differing in having but two leaves to their calyx, and only four stamens.

PAPAW. See CARICA.

PAPAW-Tree of North America. See ANNONA.

PAPAWS, in *Geography*, a name given in the West Indies to the Negroes of Whidah, or Fida, in Africa. These are unquestionably the most docile and best-disposed slaves that are imported from any part of Africa. Without the fierce and savage manners of the Koromantyn Negroes, they are also happily exempt from the timid and desponding temper of the Eboes. The cheerful acquiescence with which these people apply to the labours of the field, and their constitutional aptitude for such employment, arise, without doubt, from the great attention paid to agriculture in their native country. Bosman speaks with rapture of the improved state of the soil, the number of villages, and the industry, riches, and obliging manners of the natives. He observes, however, that they are much greater thieves than those of the Gold Coast, and very unlike them in another respect, namely, in the dread of pain and the apprehension of death. They are, he says, so very apprehensive of death, that they are unwilling to hear it mentioned, for fear that alone should hasten their end; and no man dares to speak of death in the presence of the king or any great man, under the penalty of suffering it himself, as a punishment for his presumption. He adds, that they are addicted to gaming beyond any people of Africa. These propensities, it is said, are observable in the character of the Papaws in a state of slavery in the West Indies. That punishment which excites the Koromantyn to rebel, and drives the Eboe negroes to suicide, is received by the Papaws as the chastisement of legal authority, to which it is their duty to submit patiently. The case seems to be, that the generality of these people are in a state of absolute slavery in Africa, and having been habituated to a life of labour, they submit to a change of situation with little reluctance. Many of the Whidah negroes are found to be circumcised. Whether it be a religious ceremony common to all the tribes that go under the appellation of Papaws, has not been ascertained. It is practised universally by the "Nagoes;" a people that speak the Whidah language; but some Negroes on this part of the coast disavow the practice.

PAPAYA, in *Botany*, an Indian name, retained by Tournefort, Plumier, and Jussieu, for the *Carica* of Linnæus, or Papaw-tree. See CARICA.

PAPAZLI, in *Geography*, a town of European Turkey, in Rumania; 12 miles E.S.E. of Filippopoli.

PAPEMBERG, an island of Japan, resembling a mountain, surrounded by the sea. The Dutch ships have been accustomed to anchor here for wind, when they wish to re-

turn to Batavia. Its Japanese name is "Takaboko," or "Takajama."

PAPENBERG ISLANDS, five small islands in the East Indian sea. S. lat. 6° 54'. E. long. 131° 58'.

PAPER, a thin flexible leaf, usually white, artificially prepared of some vegetable substance, chiefly to write upon with ink.

The word is formed from the Greek *πᾶπυρος*, *papyrus*, the name of an Egyptian plant, called also *βιβλος*, *biblus*, on which the ancients used to write.

Various are the materials on which mankind, in different ages and countries, have contrived to write their sentiments; as on stones, bricks, the leaves of herbs and trees, and their rinds or barks; also on tables of wood, wax, and ivory; to which may be added plates of lead, linen rolls, &c. At length the Egyptian papyrus was invented; then parchment, then cotton paper; and, lastly, the common, or linen paper. Vide Maffei *Istor. Diplom. lib. ii. § 3. 10. Bibl. Ital. tom. ii. p. 242.* Leo Allat. *Antiq. Hetrusc. p. 127, seq. Hug. de Scrib. Origin. Alex. ab Alexand. lib. ii. cap. 30. Barthol. diss. 4. de Libr. Legend. p. 90, seq.*

In some places and ages they have even written on the skins of fishes; in others on the intestines of serpents; and in others on the backs of tortoises. (Mabill. de Re Diplom. lib. i. cap. 8. Fabric. Biblioth. Nat. cap. 21, &c.) There are few sorts of plants but have at some time been used for paper and books; and hence the several terms, *billos*, *codex*, *liber*, *folium*, *tabula*, *tillura*, *philura*, *scheda*, &c. which express the several parts on which they were written; and though in Europe all these disappeared upon their introduction of the papyrus and parchment, yet in some other countries the use of divers of them obtains to this day. In Ceylon, for instance, they write on the leaves of the talipot. And the Bramin MSS. in the Tulinga language, sent to Oxford from Fort St. George, are written on leaves of the ampana, or palma Malabarica: Hermannus gives an account of a monstrous palm-tree called *coddâ pana*, or *palma montana Malabarica*, which, about the thirty-fifth year of its age, rises to be sixty or seventy feet high, with plicated leaves nearly round, twenty feet broad; with which they commonly cover their houses; and on which they also write; part of one leaf sufficing to make a moderate book. They write between the folds, making the characters through the outer cuticle. Knox. *Hist. Ceyl. lib. iii. Le Clerc. Bibl. Univ. tom. xxiii. p. 242. Phil. Transf. N° 246. p. 422, seq. Vide Hort. Ind. Malab. p. 3. Phil. Transf. N° 145. p. 108.*

In the Maldivé islands, the natives are said to write on the leaves of a tree called *macaraquean*, which are a fathom and a half long, and about a foot broad. And in divers parts of the East Indies, the leaves of the musa arbor, or plantain-tree, dried in the sun, served for the same use, till of late that the French have taught them the use of European paper. Ray, in fine, enumerates divers kinds of Indian and American trees which bear leaves proper to be used as paper; particularly one called *xagua*, which has something in it extraordinary; its leaves are so large, and of so close a texture, that they cover a man from top to toe, and shelter him from the rain, and other inclemencies of the weather, like a cloak: and from the innermost substance of these leaves, a paper is taken; being a white and fine membrane like the skin of an egg, as large as a skin of our vellum or parchment, and nothing inferior for beauty and goodness to the best of our papers. Vide Savar. *D. de Comm. tom. ii. p. 967. Vide Ray Hist. Plantar. tom. ii. lib. 32. Nouv. Rep. Let. tom. xii. p. 361.*

Paper is chiefly made among us of linen, or hempen rags, beaten

beaten to a pulp in water, and moulded into square sheets, of the thickness required. But it may also be made of nettles, hay, turnips, parsnips, colewort-leaves, asbestus, or any thing that is fibrous; nay, it may be made of white woollen rags: though this would not serve for writing, because of the hairiness. The Chinese paper is so fine, that many of the Europeans have thought it was made of silk; not considering, says Du Halde, that silk cannot be beat into such a paste, as is necessary to make paper: but it is to be observed, that the same author afterwards speaks of a paper, or parchment, made of the balls of silk worms; and the like, we are assured by others is done at Cathay. Hought. Collect. N^o 360. tom. ii. p. 418, seq. Description of China, p. 360. seq. Vide Busbeq. Legat. Turc. Epist. iv. p. 329.

PAPER, with regard to the manner of making it, and the materials employed therein, is reducible to divers kinds: as the *Egyptian*, *European*, and *Chinese paper*: we also find mention of *cotton paper*, *bark-paper*, and *asbestine* or *incombustible paper*.

PAPER, *Egyptian*, is that which was principally used among the ancients: it was made of a rush called papyrus, or biblus, growing chiefly in Egypt, about the banks of the Nile: though it was also found in India; and Guilandinus assures us, he saw in Chaldæa, at the confluence of the Tigris and Euphrates, large fens, in which, with his own hands he plucked a papyrus differing in nothing from that of the Nile. Strabo likewise speaks of a sort of papyrus growing in Italy; but we do not find this was ever used for making paper.

The description given by Pliny of the papyrus, or paper-reed, is somewhat obscure. Its root, according to him, is of the thickness of a man's arm, and ten cubits long; from this arise a great number of triangular stalks six or seven cubits high, each thick enough to be easily spanned; its leaves are long like those of the bull-rush; its flowers staminateous, ranged in clusters at the extremities of the stalks; its roots woody and knotty like those of rushes, and its taste and smell near akin to those of the cyperus, under which genus Linnæus has classed the papyrus. (See CYPERUS.) Vide Plin. Hist. Nat. lib. xiii. cap. 11. Vide Theophr. Hist. Plant. lib. iv. cap. 9. and Delecamp, who gives us a figure of it, Hist. lib. xviii. p. 1883. See also Bauhin. lib. xviii. cap. 186, who, with Gesner, makes it a species of Cyperus. Grew Mus. Reg. Societ. p. 2. sect. 2. p. 225, seq. Maffei Ist. Diplomat. Bibl. Ital. tom. ii. p. 246.

Besides paper, they made sails, ropes, and other naval rigging; as also mats, blankets, clothes, and even ships, of the stalk of the papyrus. Moses, we are told, when a child, was exposed on the banks of the Nile, ἐν δίβλῃ πάπυρος, i. e. in a basket of papyrus. The Egyptian priests wore shoes of papyrus.

Guilandinus, a Prussian physician before mentioned, has a celebrated work expressly on the ancient papyrus, by way of commentary on three chapters of Pliny, in which is amply, and with great learning, explained all that relates to this subject; yet Scaliger has written a severe critique on it, in which some inaccuracies of Guilandinus are pointed out; but this has not hindered Kirchmayer from adopting almost Guilandinus's whole book in his dissertation on the papyrus. Add, that the most ingenious and learned count Scipio Maffei has lately vindicated Guilandinus against the exceptions of Scaliger, as well as of Vossius and Hardouin. (Vide Ist. Diplomat. lib. ii. Bibl. Ital. tom. ii. p. 248. Melch. Guilandini Papyrus, h. e. Commentarius in tria C. Plinii Majoris de Papyro capita, fc. lib. xiii. cap. 11, 12, 13, first published at Venice in 1572, and afterwards

at Amberg, in 1613, by Salmuth.) It seems, Guilandinus intended a commentary on the whole of Pliny's Natural History; but this small part, not exceeding a moderate page, taking him up full six months, it is no wonder he was discouraged from proceeding with the rest. In these three chapters he has restored about twenty passages in the text of Pliny, not merely from his own conjecture, or the help of MSS. but from the nature of the things described, and the testimonies of authors of the first rank: besides that, he had been upon the spot, where formerly the papyrus was manufactured, and had carefully examined all the ancient Greek and Latin authors who speak of it.

Jos. Just. Scaligeri Animadversiones in Melchioris Guilandini Commentarium in tria C. Plinii capita, lib. xiii. Historiæ Mundi sive Naturalis, quibus agit de Papyro, first published in the Lectiones Bibliothecariæ Memorabiles, of Rudolphus Capellus, at Hamburg, in 1682, where he follows Guilandinus step by step, finds as many faults in him as his father had done in Cardan, and uses him altogether as coarsely; every where pointing out his literary mistakes, and labouring to shew, that instead of restoring Pliny, he has often mistaken and corrupted him. M. Seb. Kirchmaieri Uffenhaimensis Franci Dissertatio Philologica de Papyro veterum, Wittebergæ 1666, 4to.

He had done better service, if, besides Guilandinus, he had consulted others, and particularly Scaliger. But as he chose to follow one rather than many, and that too as the blind follow their guides, his fate has been much the same.

The origin of the art of making paper of the papyrus is very obscure; no doubt it was first discovered in Egypt. Isidore fixes it more particularly to the city Memphis, Orig. lib. vi. cap. 10. in which he seems to be countenanced by Lucan, where he says,

“ Nondum fluminea Memphis contexere biblos
Noverat———” Pharfal. lib. iii. v. 222.

The era of this invention is warmly disputed: Varro, the most learned of the Romans, fixed it to the time of Alexander the Great, after the building of the city of Alexandria by that conqueror; but several objections, of no small weight, are brought against this decision. Pliny recites a passage out of a very ancient annalist, one Cassius Hemina, wherein mention is made of paper books found in Numa's tomb, five hundred and thirty-five years after his death, which had been buried with him: now Numa was prior to Alexander by above three hundred years. Guilandinus, in effect, maintains, with great erudition, that the name and use of the papyrus were known to the Greeks long before Alexander conquered Egypt; and that the words βιβλος, and βιβλίον occur in their received signification in authors prior to, or at least older than, Alexander: particularly Anacreon, Alcæus, Plato the comedian, Aristomenes, Carinus, Antiphanes, Plato the philosopher, Æschylus, and Aristotle. And whereas some speak of a kind of unknown pseudo-biblos, in use before the discovery of the true sort, he argues, on the contrary, that the biblos mentioned by those authors, prior to the conquest of Alexander, appears from Herodotus, Theophrastus, and others, to be the very same plant with the biblus, or papyrus, of which paper was afterwards made: even Homer and Hesiod, the most ancient Greek poets, and who by Herodotus's testimony lived about four hundred years before himself, appear to have been no strangers to the papyrus, since they both make express mention of it. Vide Plin. lib. xiii. cap. 13. Guiland. Papyr. Membr. 2. Reim. Idea Syft. Antiq. Liter. p. 285, seq. Kirchman Diff. de Papyr. art. 11. sect. 2.

To this it may be answered, that supposing the plant papyrus known in Greece long before Alexander's conquest of Egypt; it no more follows, that they had then the use of paper; than it follows, that men had wine immediately on the discovery of the vine.

In reality, Guilandinus produces testimonies, from Anacreon and Alcæus, in which the papyrus is employed for binding, and not for paper; add, that he ill translates τὸ ἑλεγχνιον, *ellyphnium*; since λυχνιον here is the torch itself. Nor does the poet say it was made of papyrus, but tied up with it. Vide Scalig. lib. cit. Reimm. ubi supra, p. 305. seq.

Some have even doubted whether the art of manufacturing the papyrus was so ancient as Alexander's time; chiefly on this ground, that, for two hundred years after Alexander, men wrote on skins, and on the barks of trees: but this is nowise conclusive. The scarcity of the new manufacture may account for it: for some ages afterwards, even as low as Tiberius, we read of such a scarcity of paper, that its use, even in contracts, was dispensed with by a decree of the senate, and the opinion of the judges. The same consideration may be carried farther: paper might have been known in Egypt, Judæa, Syria, and Asia on this side Taurus, long before the birth of Alexander, though not in common use; but it might be later before the Europeans received it; and probably it was by means of Alexander's conquest that it first became publicly known there.

When the manufacture of the Egyptian paper ceased, is another question; for, at present, the *papyrotechnia Ægyptiaca* may be reckoned among those arts that are lost. Euthatius, the learned commentator on Homer, testifies, that even in his time, viz. in 1170, it was disused: Mabillon, indeed, maintains, that it continued till the eleventh century after Christ; and cites one Fridegod, a monkish poet of the tenth century, as speaking of it as subsisting in the age before his, that is in the ninth; and that it continued longer, the same Mabillon endeavours to evince, from several papal bulls wrote on it as low as the eleventh century. Vide Euthat. ad Homer. Odyss. c. Voss. de Art. Gram. lib. i. c. 37. Vide Mabill. De Re Diplom. lib. i. cap. viii. sect. 6. seq. Reim. Idea Syst. Antiq. Liter. p. 311.

Maffei, on the other hand, maintains, with more probability, that the papyrus was generally disused before the fifth century; for that we find no authentic records, written on it, dated since that time; those bulls of popes, cited by Mabillon, appearing rather to be written on cotton paper. But this, we may observe, relates only to the general and legal use of the papyrus. For that it should have continued to be made by particular persons several hundred years after it first began to give way, is not to be wondered at. Vide Maffei Ist. Diplom. loc. cit. Bibl. Ital. tom. ii. p. 251.

In reality, a more commodious sort of paper, made of cotton, having been invented some ages before in the East, and coming to be introduced into Europe, seems to have brought the papyrus into disuse. To which the continual wars with the Saracens, by which the traffic to Alexandria was rendered precarious, might possibly not a little contribute.

Yet several books, written on leaves of the papyrus, have even continued to our days: Mabillon says, he had one of them; and adds, that there was another in the Petavian library, being a volume in small folio, containing several sermons of St. Augustine; he also mentions a third, containing that father's epistles, formerly belonging to the church of Narbonne, and afterwards in the custody of madame De Phirmacon; besides the homilies of Avitus, bishop of

Vienne, and divers diplomas or charters, all written on the papyrus, which appear not to be less than eleven hundred years old. But the decisions of this learned father concerning MSS., notwithstanding all his diplomatic skill so highly boasted of, are not always infallible; witness his taking the MS. of St. Mark's Gospel, at Venice, to be written on the Egyptian papyrus; and that of Josephus, at Milan, not to be so. Maffei shews, on the contrary, that the former is cotton paper; and that the latter appears, at first sight, to be Egyptian; not but the Venetian MS. is very old; but it has been so much used, that its leaves are, as it were, transformed into the original paste from whence they are made. Vide Mabill. Suppl. ad Libr. de Re Diplom. Journ. des Sçav. tom. xxxii. p. ii. p. 992. Maffei, lib. cit. Bibl. tom. ii. p. 252. And Montfaucon. Paleog. Græc. p. 14.

PAPER, *Manner of making the Egyptian.* They began with lopping off the two extremes of the papyrus, viz. the head and root, as of no use in this manufacture; the remaining stem they slit lengthwise into two equal parts, and from each of these they stripped the thin scaly coats or pellicles, of which it was composed, with the point of a pen-knife. The innermost of those pellicles were looked on as the best, and those nearest the rind or bark the worst; they were kept apart accordingly, and constituted different sorts of paper.

These pellicles are called, in Pliny, by twelve different names; viz. *philura, ramentum, scheda, cutis, plagula, corium, tania, subtegmen, statumen, pagina, tabula, and papyrus.*

The generality of critics, in lieu of a pen-knife, employ a needle to separate the pellicles; in which they are warranted by the common text of Pliny, "Præparantur ex eo chartæ, diviso acu in præstenues, sed quam latissimas philuras." But Guilandinus makes a correction here: he had found, by experiment, that the pellicles of papyrus cannot be separated by a needle; but that a very sharp knife is required; for which reason, instead of *diviso acu*, he reads *diviso scapo*. In which he is followed by Maffei, though Hardouin, Vossius, Pitiscus, and others, retain the ancient reading. Vide Guiland. Papyr. Memb. 10. sect. 3. and 5. Maffei Ist. Diplom. ap. Bibl. Ital. tom. ii. p. 247, seq. Voss. De Art. Grammat. lib. i. cap. 37. Pitisc. L. Ant. tom. i. p. 413. vcc. Charta. Hardou. ad Plin. lib. xiii. cap. 12.

As the pellicles were taken off, they extended them on a table; then two or more of them were laid over each other transversely, so as that their fibres made right angles: in this state they were glued together by the muddy waters of the Nile. These, being afterwards pressed to get out the water, then dried and lastly flattened and smoothed by beating them with a mallet, constituted paper: which they sometimes polished farther by rubbing it with an hemisphere of glass or the like.

In other countries where the waters of the Nile were not to be had, the pellicles were fastened together with a paste made of the finest wheat-flour, mixed with hot water, and a sprinkling of vinegar.

The ingenious and learned count de Caylus, in his account of the papyrus, informs us, that the intermediate part of the stalk was cut and separated into different laminæ, which were set apart, and dried in the sun for the manufacture. These laminæ were joined together horizontally or transversely, in sheets or leaves, upon a smooth board: then moistened with water, which dissolved a kind of viscous glue in the pores of the plant, serving to cement and render the whole uniform. The sheet, being thus formed, was put into a press, and afterwards dried for use. Such,

he says, was the process of making paper in Egypt; but as the sheets were coarse, brown, unequal, and imperfect, the Romans invented methods to bring the fabric to perfection. They contrived a glue or gum, by means of which they could occasionally enlarge the size and volume. They bleached it to a surprising degree of whiteness; they beat it with hammers, so as to render it more thin and less porous; they smoothed and polished it with ivory; and by a sort of calender gave it a shining gloss, like that of the Chinese paper. According to the different degrees of delicacy, whiteness, and size, it acquired different appellations either from the names of particular manufactures, from the great personages who used it, or from the particular uses to which it was applied; such as the Fannian, the Livian, the Claudian, the Imperial, the Hieratic and the Amphitheatric.

There were paper manufactures in divers cities of Egypt; but the greatest and most celebrated was that at Alexandria, where, according to Varro's account, paper was first made. It is certain at least it was from hence that Greece and Italy was furnished, on account of the convenient situation of that port; and it is more than probable it was this that gave the Romans occasion to conclude the art had been invented there. It was not till late, when Egypt was reduced into a Roman province, that they had much intercourse, or even knowledge of the inland cities of Egypt, where paper was also made. The trade and consumption of this commodity were in reality incredible. Vopiscus relates, that the tyrant Firmus, who rebelled in Egypt, publicly declared he would maintain an army only with paper and glue, "papyro & glutine." This, Casaubon understands as spoken of the produce and revenue of paper; though Salmastius takes it to be meant of the papyrus itself, which could supply most of the necessaries of life. Vide Montfauc. Palæogr. Græc. lib. i. cap. 2. p. 14.

We find divers species of Egyptian paper mentioned in ancient writers: some denominated from the places where they were manufactured; as 1. The *Amphitheatrica*, supposed to have been made in some building belonging to an amphitheatre at Alexandria; though Guilandinus, with more probability, reads it *Arthribitica*, from Arthribus, a city in the middle of the Delta, which was the place of its manufacture. What countenances this correction, is, that we find mention of this paper before there was so much as an amphitheatre at Rome, much less at Alexandria. 2. *Saitica*, made in the city Sais. 3. *Taniotica*, or, according to others, *Taitica*, whose place authors are not agreed on. There were also other sorts denominated from the makers; as 1. The *Fanniana*, from the grammarian Rhem. Fannius Palæmon, who kept a paper work. This kind was small, but finer than the Amphitheatric paper; being first wrought at Alexandria, and afterwards finished at Rome. 2. *Claudia*, first made by order of the emperor Claudius. This was reputed the best of all, in that, besides the two pellicles, in common with the rest, it had a third. Others were denominated from the uses they were intended for; as, 1. *Hieratica*, the first or oldest sort, which was appropriated to religious uses; this was afterwards denominated *Augusta* and *Liviana*, in compliment to the emperor of that name, and his wife; who, according to some, improved and made it whiter than before. 2. *Emporetica*, or *Emporica*, a small and coarse sort, serving for shopkeepers uses, to tie up goods, &c. The qualities for which the ancient papers were prized, were their thinness, closeness, whiteness, and smoothness; though their breadth also considerably enhanced their value. That sort called *charta Claudia* was thirteen inches wide; the *Hieratica*, eleven; the *Fanniana*,

ten; and the *Amphitheatrica*, nine; as to the *Saitica*, it exceeded not the diameter of the mallet it was beaten with.

See farther concerning the ancient paper, in Nigrifoli Diff. de Charta, ejusque Ufu apud Antiquos. Ext. in Galer. de Minerv. tom. iii. p. 249, seq. Other authors are enumerated in Fabric. Bibl. Antiq. cap. xxi. sect. 9. p. 609. Pitfc. L. Ant. loc. cit.

PAPER, *Bark*, if it may be so called, was only the *liber*, or inner whitish rind enclosed between the outer bark and the wood of divers trees, as the maple, plane, beech, and elm, but especially the *tilia*, Φιλύρα, or *linden-tree*, which was that mostly used for this purpose. On this, stripped off, flatted, and dried, the ancients wrote books; several of which are said to be still extant. Vide Plin. Hist. Nat. lib. xiii. cap. 11. Hardou. Not. ad eund. Suid. Lex. in voc. Φιλύρα. Ifid. Orig. lib. vi. cap. 13. Alexand. ab. Alexand. lib. ii. cap. 30. Salmuth. ad Pancirol. lib. ii. tit. 13. p. 252, seq.

Mabillon and Montfaucou speak frequently of manuscripts and diplomas on bark, and are very express in distinguishing between the papyrus used by the Egyptians, and the liber or bark in use in other countries. The two are alleged to differ in this, that the bark paper was thicker and more brittle than the papyrus, as well as more apt to cleave or shiver, by which the writing was sometimes lost; as is the case in a bark manuscript in the abbey of St. Germain's, where the bottom of the paper remains, but the outer surface, on which the letters had been drawn, is in many places peeled off. Vide Montfauc. Palæogr. Gr. lib. i. cap. 2. p. 15. Mabill. de Re Diplom. lib. i. cap. 8. Reimm. Idea Syst. Antiq. Liter. p. 311.

But Maffei, it must not be forgot, combats the whole system of bark manuscripts and charters as a popular error; and maintains, that the ancients never wrote diplomas on bark; that the distinction between the papers made of papyrus and of cortex, is without foundation; that the only use of the *tilia*, or *linden*, was for making thin boards or tablets for diptycha or pocket-books, wherein they wrote on both sides, as is done among us: an advantage which they could not have in the Egyptian paper, by reason of its thinness.

A late French writer on the rules of criticism wanders still farther out of the way, when he speaks of a sort of paper, in Egypt, made of the pith of the cyprus: he describes the manner of preparation, which was by reducing this pith to a pulp, and then spreading it out in leaves. Vide Hon. St. Marie Reflex. sur les Regl. de la Crit. tom. ii. diff. 77. This we suspect for a chimera hatched only in the critic's brain.

Not but there occur divers anomalous sorts of paper, which antiquaries are not a little puzzled what species to refer them to; such is that of two bulls in the archives of the church of Gironne, issued by the anti-popes Romanus and Formosus, between the years 891 and 895. They are two ells long and one broad; and consist of two leaves or pellicles glued together transversely, and are still legible in most places. The conjectures of the French literati, in regard to these, are numerous; the abbot Hiraut de Belmont has a discourse express on the occasion. Some will have them made of the leaves of the *alga*, or sea-wreck; others of the leaves of a rush, called *la boga*, growing in the marshes of Rouffillon; others of papyrus; others of cotton; and others of bark. So little certainty does there really appear to be in these things, on which the critics nevertheless often lay a great stress. Vide Mem. de Trev. Sept. 1711. p. 1559, seq.

PAPER, *Cotton*, *charta bombycina*, Βομβυκινη (thus called from

from *βομβυξ*, a word which anciently signified *flax*, though in after-times *βομβυξ* and *βαμβυξ* came to denote *cotton*), is a sort of paper which has been in use upwards of seven hundred years ago, as is shewn by Montfaucon from several authorities; what is more, cotton paper appears to have been very common at the beginning of that time, and consequently must have been invented long before, probably about the clofe of the ninth, or the beginning of the tenth century.

In the French king's library are MSS. on this paper, which, by the character, and other circumstances, appear to be of the tenth century. Be this as it will, from the twelfth century, cotton MSS. were more frequent than parchement ones. Vide Montfaucon. Palægr. Græc. lib. i. cap. 2. p. 17, seq. item, lib. iv. cap. 6. p. 209. Maffei, lib. cit. Bibl. Ital. tom. ii. p. 252.

PAPER, *Incombustible*, is made of the lapis asbestos, or *linum vivum*, which will bear burning without being injured.

Dr. Bruckman, professor at Brunswick, has published a natural history of the asbestine, or incombustible paper; and, what is most remarkable, has printed four copies of his book on this paper: they are deposited in the library of Wolfenbützel. Vide Bibl. Germ. tom. xiv. p. 190.

The manner of making this extraordinary paper is described by Mr. Lloyd, from an essay made by himself. He pounded a quantity of the asbestos in a stone mortar, till it became a downy substance; then sifted it in a fine searce, and by this means purged it indifferently well from its terrene parts; because the earth or stones he could not pick out of it before, or at the pounding, being reduced to a powder, came through the searce, the *linum* remaining. This done, he brought it to the paper-mill; and putting it in water, in a vessel just big enough to make a sheet with such a quantity, he stirred it pretty much, and desired the workmen to proceed with it in the usual method, with their writing-paper mould; only to stir it about always before they put their mould in; considering it as a far more ponderous substance than what they used; and that consequently, if not immediately taken up after it was agitated, it would subside.

The paper made of it proved but coarse, and was very apt to tear; but this being the first trial, there is reason to believe it might be much improved; nor did the workmen doubt, but in case it were pounded in one of their mortars, for twenty hours space, it would make good writing-paper. Vide Phil. Transf. N^o 166. p. 824. See ASBESTOS.

PAPER, *Linen or European*, is chiefly made of linen rags beaten to a pulp with great hammers, and the foil carried off by a continual supply of fresh water, conveyed among the pulp in little troughs, till it be rendered perfectly white.

Besides the chief use of this paper, which is for writing and printing, there is a great consumption of it in packing up goods, and on other occasions.

The manufacture of paper has got footing in most countries; though France, Holland, and Genoa, are the places where it has succeeded best. In the general it depends much on the quality of the linen worn in the country where it is made; where that is coarse and brown, &c. the rags, and consequently the paper made of them, must be so too. Hence the whiteness of the Dutch and Flemish papers, beyond the Italian and French, and much more the German papers. The English manufacture was a long while in no great reputation; but it is every day improving; inasmuch that we now import little of the ordinary sorts, which were formerly all brought from abroad. Yet paper-mills are of some standing among us. We find one erected at Dartford

as early as the year 1588, which we believe was the first, and which is celebrated by a noted poet of that age, Tho. Churchyard, in a work in verse, intitled "A Description and Discourse of Paper, and the Benefits it brings; with the setting forth of a Paper-mill, built near Dartford, by a High-German, called Mr. Spilman, Jeweller to the Queen, Lond. 1588. 4to."

In reality, the deficiency of the English paper manufacture did not seem owing so much to the quality of our rags, as to the want of skill and attention in the makers; but the manufacture of paper has been very considerably encouraged in our country, and has already arrived to a great degree of perfection.

Anderson, in his Hist. of Com. vol. ii. p. 197. says, that till about the year 1690, there was scarcely any other kind of paper made in England, but the coarse brown sort. But the war with France occasioning high duties on foreign paper, the French Protestant refugees settled in England chiefly, and also our own paper-makers now began to make white writing and printing paper, which, he adds, in length of time, has been brought to so great perfection, both for beauty and substance, that in our own time we import only certain kinds of Genoa and Dutch paper, which bears but a very small proportion to all the paper used in the British dominions. This has produced, it is said, a saving to Britain of 100,000*l.* which was paid annually to France for paper only.

Another writer says, that the English manufactures now provide above seven-eighths of the whole quantity of paper consumed in Great Britain.

When and by whom linen paper was invented is a secret, which Polydore Virgil owns he could never trace. Scaliger will have it to have been found out by the Germans. Maffei affirms it certain, that the invention is owing to the Italians. Others ascribe it to some refugee Greeks at Basil, who took the hint from the manner of making cotton paper in their own country. Conringius takes the Arabs to have first brought it among us. Perhaps the Chinese have the best title to the invention; who for many ages have made paper much after the same manner; and even, in some provinces, of the same materials, *viz.* hemp, &c. Vide Polyd. Virg. de Inventor. Rer. lib. ii. cap. 8. Secund. Scaliger. p. 7. Fabric. Bibl. Antiq. cap. 9. lect. 21. Hitor. Diplom. lib. ii. Bibl. Ital. tom. ii. p. 253. Phil. Transf. N^o 288. p. 1515. Conring. Epist. ap. Act. Erud. Lips. an. 1720. p. 94. Savaar. D. Comm. tom. ii. p. 963. Du Hald. Descr. Chin. tom. i. p. 363.

Linen paper appears to have been first introduced among us towards the beginning of the fourteenth century.—The learned Conringius denies, that there are many manuscripts of this paper above four hundred years old; with whom agrees the count Maffei, who finds no marks of its use before the year 1300. Vide Conring. Epist. ap. Act. Erud. Lips. an. 1720. p. 94. Maffei Hitor. Diplom. lib. ii. Bibl. Ital. tom. ii. p. 253.

Some indeed go much farther back; and take the *libri lintei*, mentioned by Livy, and other Roman writers, to have been written on linen paper; but Guilandinus, and after him Allatus, and others, have sufficiently refuted this notion; and shewn, that the *libri lintei* were written on actual pieces of linen cloth, or canvas, prepared for this purpose, such as painters still use; and not on paper made of linen rags. Vide Liv. Dec. 1. lib. iv. Plin. Hist. Nat. lib. xiii. cap. 11. Paus. L. Ant. tom. ii. p. 85. Guiland. Papyr. Memb. 25. Salmuth. ad Pancirol. lib. ii. tit. 13. p. 253.

Others run into the contrary extreme, and make paper the invention of a very late date. The Jesuit Inchofer dates

PAPER.

its origin about three hundred years ago; with whom agrees Milius, in his "Hortus Philoſophicus," who maintains, that the art of making paper was not invented till about the year 1470. Of the ſame opinion ſeems Ray, who tells us the art of making this paper was not known in Guernſey till the year 1470, and when two perſons, named Anthony and Michael, firſt brought it to Baſil, out of Galicia in Spain. In effect, if the invention be owing to the refugees Greeks at Baſil, who fled thither after the ſacking of Conſtantinople, it muſt at leaſt be poſterior to the year 1452, when that city was taken. Some add a farther argument for the novelty of paper, drawn from the novelty of hempen cloth, which Rabelais, who died in 1553, mentions as firſt found out about a hundred years before him; and which was ſo ſcarce in the time of Charles VII. of France, who died in 1461, that the queen, his wife, was the only woman in France that had a couple of ſhifts of it. Vide Mabill. de Re Diplom. lib. i. cap. 8. Reimm. Idea Syll. Antiq. Liter. p. 313, ſeq. Balbin. Miſcell. Hiſt. Bohem. cap. 22. Aët. Erud. Lipſ. 1682. p. 243. Ray Hiſt. Plant. lib. xxii. Phil. Tranſ. N^o 288. p. 1515. Naudæan. p. 82. Nouv. Rep. Let. tom. xxvi. p. 571.

But theſe ſuggeſtions are refuted by Mabillon, from the teſtimonies of writers prior to the time here ſpoken of, and from many manuſcripts of about four hundred years old, which are written on linen-paper. The Jeſuit Balbinus produces divers inſtances of paper manuſcripts, written before the year 1340. An ingenious writer of our own country affures us, he had a piece of paper which agreed well with the charter dated in 1358, in the thirty-ſecond year of Edward III. He adds, that in the archives of the library belonging to the dean and chapter of Canterbury, is an inventory of the goods of Henry, prior of Chriſt-church, who died in 1340, written on paper; and that in the Cotton Library there are ſeveral writings on our paper, in the times of moſt of our kings and queens, as high as the fifteenth of Edw. III. which coincides with the year 1335. And Dr. Prideaux affures us he has ſeen a regiſtration of ſome acts of John Cranden, prior of Ely, made on paper, which bears date in the fourteenth year of king Edward II. that is, anno Domini, 1320. Mabill. loc. cit. Balbin. lib. cit. Phil. Tranſ. N^o 288. p. 1515. Prid. Connect. p. 1. l. 7. p. 710.

Add, that the invention of paper may appear more modern than it is, becauſe records were not uſed to be written on it, but it was a conſiderable time confined to letters, and other fugacious compositions; which is ſo true, that, to this day, few inſtruments of any conſequence are written on it, though it have been ſo long in uſe. It is even alleged, that Peter, the venerable abbot of Cluny, who died in 1157, has a paſſage in his book againſt the Jews, which plainly indicates paper books to have been then known; on the authority of which Valeſius, in his notes on the panegyric of Berengarius Auguſtus, ſcruples not to make paper upwards of 500 years old.

Father Hardouin affures us, he had ſeen records or diplomas on it prior to the 13th century. But this will hardly be credited. Count Maffei affures us, that in all his reſearches he could never meet with one more ancient than the year 1367. It is highly probable the learned Jeſuit miſtook a cotton manuſcript for a linen one: a miſtake eaſily made, as the chief difference between the two conſiſts in the greater thinneſs of the linen paper. But it is known we have linen papers of very different degrees of thickneſs; and the like may be ſaid of thoſe of cotton. Vide Maffei Iſtor. Diplom. lib. ii. Bibl. Ital. tom. ii. p. 253, ſeq.

The invention, according to Prideaux, ſeems to have

been brought from the Eaſt; becauſe moſt of the old manuſcripts, in Arabic, and other Oriental language, are written on this ſort of paper; ſome of which are certainly much older than any of the dates above-mentioned. This author thinks it moſt probable, that the Saracens of Spain firſt brought it out of the Eaſt into that country; from whence it was propagated through the reſt of Europe.

PAPER-Making. Nature preſents us, as we have already obſerved, with a variety of ſubſtances from which paper may be made, as linen or hempen rags, the ſtalks of nettles, ſtraw, hay, and the down of thiftles. It may be alſo made of cotton, or white woollen rags, though ſuch paper would not ſerve for writing, becauſe of its hairineſs. Of all theſe ſubſtances, linen or hempen rags alone are employed by the manufacturers, except a ſmall quantity of cotton rags, which are ſometimes mixed with the linen for inferior purpoſes.

The chief proceſs of making paper conſiſts in ſeparating the fibres of the rags, by grinding, into exceedingly fine and ſhort filaments; which being mixed with water, till they make a fine pulp, may be taken up in a very thin and even layer upon a mould of wire cloth. Now by the draining away of the water through the wire, the filaments are left, interwoven or felted ſo completely among each other, that they will not ſeparate without breaking, and when dry will make a ſheet of paper; the ſtrength and quality of which depend very much upon the materials it is made from, and the equality of length and ſize to which the filaments are reduced by the grinding, which equality alone can cauſe them to float equally in the water of the pulp, and thus diſtribute themſelves fairly and equally over the wire mould when taken up by it. For writing paper, a fine white colour is neceſſary, and this is obtained either by uſing the whiteſt rags by themſelves, or by a chemical proceſs of bleaching.

The incalculable advantages which the moderns have derived from the art of printing, would have been only imperfectly known, but for the invention of linen rag paper. A more plentiful and economical ſubſtance could not be conceived than the tattered remnants of our cloths, linen worn out, and otherwiſe incapable of being applied to the leaſt uſe, and of which the quantity every day increaſes: nor could a more ready operation be imagined, than a few hours tritulation in a mill. It has been obſerved by a French writer, that the diſpatch of the proceſſes of paper making is ſo great, that five workmen in a mill may furniſh ſufficient paper for the continual labour of 3000 tranſcribers.

The art of printing would have been comparatively of little importance, without having the means of procuring a proper material to receive the impreſſions. Whiſt the Egyptian papyrus was the only kind of paper, it would have been impoſſible to have procured it in ſufficient quantities to have made large editions of books. The cotton paper, though in a progreſſive ſtage of improvement, was but a rude and perſhable article, unfit for any of the nice purpoſes to which paper is now applied.

The perfection of the art of paper-making depended upon finding a material which could be procured in ſufficient quantities, and which would be eaſy of preparation. Such is the paper now in uſe, of which we ſhall endeavour to deſcribe the manufacture.

The operation of paper making admits of three diviſions, viz. the preparation of the rags, the forming of the ſheets, and the finiſhing of the paper. The ſucceſſion of the ſeveral proceſſes is as follows: 1. The rags are waſhed, or duſted, if they are dirty; then ſorted into many qualities proper for different purpoſes. 2. The rags are bleached, to render them white; but this operation is ſometimes deferred to the next ſtage of the proceſs. 3. The waſhing engine of the paper mill

PAPER.

mill is employed to grind the rags, in water, till they are reduced to a coarse or imperfect pulp, called *half stuff*, or *first stuff*, in which state the bleaching is sometimes performed; or at other times it is bleached in the washing engine during the grinding. 4. The *half stuff* is again ground in the beating engine, and water added in sufficient quantity to make a fine pulp, which being conveyed to the vat, the preparation of the rags is completed, and the pulp or stuff is ready for making the sheets. 5. This is done by a workman who takes up a quantity of pulp upon a mould of fine wire cloth, through which the water drains away, and the pulp coagulates into a sheet of paper. 6. Another workman takes the sheet of paper off from the wire mould, and receives it upon a felt; he then covers it over with a second felt, evenly spread out; and continues this operation, which is called *couching*, till he has made a pile of sheets called a *post*, containing six quires. 7. The post of paper, with the felts, is placed in the *vat-press*, and the whole is subjected to a strong pressure, to press out the superfluous water, and give the paper a solidity and firmness it would not otherwise have. 8. The pile of paper is removed from the *vat-press*, the felts taken out from between the sheets, and they are pressed again by themselves, for a certain time, in a screw press. 9. The sheets are taken from the press, and hung up, five or six together, on lines in the drying loft, till dry. The paper is now made, and only requires to be finished; but it should be observed, that the greater number of the processes of finishing are only performed upon fine writing paper, common printing paper being ready for packing up when dried. 10. The paper, in five or six sheets together, is dipped into a tub of fine size, and afterwards pressed to force out the superfluity; it is then dried again in the drying loft: but in printing papers this process is rendered unnecessary, by sizing the stuff whilst in the engine, and adding certain ingredients. 11. An examination of each individual sheet of the paper is made, all knots and burrs are removed, and the bad sheets taken out. 12. A very large pile of paper is made, and pressed with a most immense force, to render the sheets flat and smooth. 13. The pile is taken down, sheet by sheet, and another made, without turning the sheets over: by this means new surfaces of the sheets are brought in contact with each other, and the pile being again subjected to the press, the surface of the paper is improved. This operation is called *parting*, and is repeated two or three times for the best papers. The paper is now counted into quires, folded and packed up into reams for market.

The strength and tenacity of paper depend upon the staple or fibre of the materials from which it is made. Rags of new cloth, and cordage, compose a tougher and stronger paper than old rags, which make a soft and pliable paper. The first of these materials presents a great variety, on account of the quality of the hemp or flax of which it is fabricated. Rags of fine new cloth, whether raw or bleached, stand in the first rank, after which old rags, cordage, &c. may be classed.

The sorting of the rags is of no small importance in the art of making paper; for unless the rags, which are ground at the same time in the engine, are all of the same quality, both as to substance and condition, the finest and best parts will be ground away in the mill, and carried off by the water before the coarser are sufficiently reduced to make a fine pulp. For this reason, in the sorting of the rags which are intended to make fine paper, the hems and seams should be kept apart, and the coarseness of the cloth should be considered. That cloth which is made of tow, should be separated from that which is made from the longer fibres; cloth of hemp from cloth of flax; and lastly, the degree of wearing in the

cloth should be attended to. For if rags, almost new, are mixed with those which are much worn, the one will not be completely reduced to a pulp, whilst the other will be so attenuated as to be carried off by the water, and pass through the hair strainers of the engine; hence there must be a considerable waste in the operation, a real loss to the manufacturer, and even to the beauty of the paper; for the particles first carried off by the current of the water, are perhaps those which give it that smooth velvet softness which is so great a recommendation. When the sorting is imperfectly performed, the pulp or stuff is found to have cloudy parts floating in it, owing to some masses being less reduced than others. This produces those cloudy papers wherein are seen by intervals parts more or less clear, and more or less weak, occasioned by flakes assembled on the wire of the mould, which are not sufficiently tempered and diluted to incorporate with more fluid parts.

But as it is necessary, in many cases, to mix the different qualities of rags together, to produce various kinds of paper, this should be done by reducing the different sorts of rags separately in the mill, as also the hems and threads of the stitching, because the sewing thread, being never so much worn as that of the cloth, and not so easy to be reduced, forms filaments in the paper. When the rags, unequally disposed for trituration, have been ground apart, the different pulps may be mixed together without inconvenience, and will be found homogeneous or alike, each having been ground during the time that was necessary for the state of the rag.

Without this precaution the finest particles will be always lost, and of course the beautiful quality of the paper will be altered by the coarsest. Therefore this care in sorting the rags produces a great beauty of the paper, without hurting its goodness. It will, besides, be attended with the advantage of mixing a pulp, which will form the strength of the paper, with another which will give it softness and lustre; and thus two qualities may be united which otherwise existed separately.

There are people in London, who, by dealing very extensively in rags, have it in their power to observe these precautions in sorting, and to sell separately all the different qualities to the paper makers. The same may be said of those great manufacturers who have the perfections of their work at heart. As to small country mills, it is scarcely possible for them to make so great a choice. They are often obliged to lay up for fine many rags which are properly middling, and their middling may with better reason be reserved for making the coarser sort of paper.

The people who go about the streets to buy up rags and old garments, sell them to the great dealers, who for the London market employ women to sort them into five sorts, which are denominated Nos. 1, 2, 3, 4, and 5, according to their respective qualities. No. 1 being superfine, and wholly linen, is used for the finest writing papers. The other sorts have different degrees of fineness down to No. 5, which is completely canvas, but is proper for making inferior printing papers, when it has been bleached to a good colour. There is also rag bagging, which is the materials of the strong canvas sacks the rags are sewed up in for carriage; and coloured rags, which consist of cotton, and are of all colours promiscuously mixed; but the blue are generally sorted out, for the purpose of making blue paper. The rag bagging and cotton rags are only fit for common papers. The rags are first put into a machine, called a *duster*, made in the form of a cylinder, four feet in diameter and five feet in length. It is all through covered with a wire net, and put in motion on pivots at its ends by a connection with some part

PAPER.

part of the machinery. The whole is inclosed in a tight close box to keep in the dust. A convenient quantity of rags, before the sorting, is inclosed in the cylinder of the duster, and the rapidity of its motion separates the dust from them, and it passes through the wires into the box. It is of considerable advantage to use the duster before sorting, as it makes that operation less pernicious to the people.

The sorting is performed by women and children, who are seated on benches, in a large room full of old linen, before a chest or box, which is divided into six cases, to receive as many different sorts of rags. Each woman has a piece of pasteboard, hung from her girdle, and extended on her knees, upon which, with a long sharp knife, she unrips seams and stitches, and scrapes off all filth.

Whatever can be used, after being well examined, is distributed into one of the six cases, according to the degree of fineness, and the women throw the rest at their feet. The six cases are for the six different sorts of rags: the superfine; the fine; and stitches of the fine; the middling; the seams, and stitches of the middling; and the coarse; without including the very coarse parts, which are totally rejected, at least for the making of white paper, but may serve for white-brown paper; but even for this purpose they should be mixed up with a large parcel of coarse linen. Old paper may also serve for the same use, but the waste is considerable; it is therefore reserved for pasteboard, in the manufacture of which, the stuff being worked less time in the engine, and with less force, though with the same water, it will lose much less than if worked sufficiently to make paper. Besides, paper that has been once sized still gives the pulp a viscidty, which ought to be guarded against, as it prevents the fibres floating so completely detached in the water as is necessary to make them distribute themselves sufficiently equal and regular upon the wire mould, to make a true and even sheet of paper.

Paper intended for bills of exchange, or other commercial and legal instruments, ought to be tough, in order that it may not be easily torn, when made as thin as it is necessary to be, for the ease of conveyance by post. For this, paper materials of the best quality must be entirely, or in large proportion, employed; and the price which the consumers are disposed to pay for the article is sufficient to allow the best materials, and still indemnify the manufacturer for his care and industry.

Common papers also require to be more or less tough, according to their thickness, and the use to which they are applied; but a clear white colour is sought in paper of every description, whether for writing or printing. The manufacturers of paper were formerly obliged to attend to the colour of the rags in the sorting, as well as to their qualities; but of this care they are now in a great measure relieved, by the introduction of bleaching, which enables them to produce the finest paper, in point of colour, from any kind of rags. They have only therefore to find such materials as will make paper of a strong texture, and a fine even surface, knowing they can produce colour at pleasure. To bleach the rags by the oxymuriatic acid gas, they are first washed in hot water, by a fulling mill, such as is used for scouring cloth: this removes the dirt, and they are put into a receiver or chamber, made of wood, in a cubical form, and the joints air tight. It is provided with several stone retorts, which being filled with a mixture of manganese, with two-thirds its quantity of sea-salt, and a quantity of sulphuric acid equal to the salt, will, when moderately heated by a small sand-bath furnace, throw into the receiver a gas which quickly discharges any colour the rags may contain. This process, which is very similar to that used for bleaching

cotton thread, was invented by Mr. Campbell, who had a patent for it in 1792. In his specification, he directs that the rags should, before they are put into the receiver to be bleached, contain about their own weight of fair water, the super-abundant water being pressed out. The rags should first be opened by a machine, called by the cotton manufacturers a *devil*. or some machine, of that nature, and they are to be distributed in the receivers, in layers spread on frames, so that they will not come in contact with each other, or they may be placed in the body of the receiver, and have stirrers or agitators, provided to expose every part of them to the action of the bleaching gas.

After the process, which must be concluded as soon as ever the rags are sufficiently bleached, lest the gas should act upon and injure their quality, they are to be washed in water, and will be ready for the mill. Some manufacturers think that this mode of bleaching the rags makes them rotten, and injures the quality of the paper, which it certainly does if carried too far, though there is no doubt of the advantages of the process if well conducted.

The bleaching process has given rise to great complaints from the printers, as many printing papers are now made from cotton rags. The oxygenated muriatic acid being applied for the purpose of obtaining dispatch and delicacy of colour, produces a paper of a good appearance from inferior staple. Nothing can be more perplexing to a printer, nor more detrimental to his labours, than this kind of bleached paper; for although it may be thick, and seem strong in the ream, no sooner does the water penetrate through it, than it loses its adhesive quality, and becomes so loose and soft as scarcely to bear handling, and in working under the press sinks down into the cavities of the letters, leaving a part of its substance behind, after every impression, until it so clogs the type, that the work is rendered scarcely legible. Nor is it less exceptionable in point of durability, as it must moulder away in a little time, with the common use that popular books generally undergo. Notwithstanding this it must be allowed, that if by bleaching the paper makers can produce a bad article from such materials as were otherwise of no use, they are also able to improve their manufacture when they use the same materials as formerly. It is found most advantageous to bleach the rags in the state of half stuff, that is, when they have been once worked by the mill, as the fibres being by that means separated, the gas has greater access to the interior parts, and they are bleached quicker, so as to have less danger of injury to particular parts, by too long an action of the gas. Another method of bleaching is by muriat of lime put into the washing engine, which for printing papers is the best mode of any. We shall describe it in the process of washing.

The engines now used in the paper mills are constructed on such a powerful principle, that they are capable of reducing the strongest and toughest rags to pulp in a moderate time; whereas the old machines were not able to work the rags without *fermenting* them, as a previous process. The following extracts from a French work, on the art of making paper, will shew the manner in which it was conducted 60 years ago.

“ The rags, being sorted, are put into a large stone vat, sixteen feet long, ten broad, and three deep; water is poured upon them to the top during ten days, and eight or ten times every day without stirring them. They are afterwards left to rest the same number of days, and sometimes more or less, without pouring water upon them. Then being turned over, the centre is brought to the surface, to facilitate the fermentation; and after being turned again, they are still left fifteen or twenty days in fermentation,

tation, so that the rotting may last five or six weeks; the term is not fixed, but when the heat becomes so great, that the hand, thrust in, cannot endure it above some seconds, it is judged that it is time to stop it.

"In mills, which have but few rags to work upon, they are left to rot longer, because the heaps being smaller, heat less, and with more difficulty; so that nothing can be justly determined of the time proper for the rotting part. It depends also on the quality of the rags; the finest linen does not rot so soon as the coarse; and linen that has been worn with more difficulty than new, because the internal humidity, that disposes the fibres to fermentation, is more considerable in new or coarse, than in fine or worn linen. Such as are more or less strong, more or less worn, resist the action of rotting in different degrees, some being spoiled, when others have not gone through the first fermentation: so that the rags, which have been sorted with great care, ought to be left to rot together, to avoid the risk of altering the whole parcel, by the mixture of a portion of rags quite different from the rest. When champignons grow on the heaps of rags, it is reckoned to be a sign of their being well rotted.

"Besides this, there is another method for disposing of the rags in the place for rotting and fermenting them. Having been wetted with water, a heap is made of them in a corner of the vaulted room, which is destined for that purpose. They are watered from time to time, and when sufficiently heated, are transported into another angle of the same room, so that what was at the top of the first heap, is now laid under the second, and care is taken to throw water upon them from time to time. When this heap takes heat again, it is transported to the third corner, where, having fermented again, it is carried into the fourth angle; observing always to lay those rags under the heap that were at the top of the foregoing, and to water them often, for a reddish water will come from them, which it is very necessary to clear the rags of. When the heap in the first corner is brought away, another is formed in the same corner, which passes in its turn to the several corners of the room.

"Some, to accelerate the operation of rotting and fermenting, throw lime upon the rags. Perhaps a very small quantity of lime may be used: but if too much is laid on, the corroded rags will be too soon reduced into a pulp, and will pass through the strainer with the water, which ought to carry off only their filth, and will occasion a considerable waste. The use of lime, for the purpose of rotting rags, is absolutely prohibited in France.

"Fermentation, or rotting, makes the paper even, curdled as it were, soft, and gives it weight; if stopped too soon, the paper becomes crude, hard, light, stiff, requires more time to be worked, and the fecula, or pulp, does not so easily form a coagulation on the wire of the mould. It is sometimes observed, in regard to good rags that have not rotted, that the fecula is, as it were, enveloped in a viscid substance, which prevents its uniform precipitation; and this proves that rotting helps to clear off the unctuous matter in rags. If, on the contrary, the rags were left to ferment too long, a considerable waste would be occasioned, and more matter required for the same quantity of paper, because the parts attenuated by fermentation, would be too readily carried off by the washing. And lastly, if they were left to heat too long, they would be reduced to dust, and burn into smoke and ashes."

The action of rotting was, at that period, thought necessary for abridging the labour of making paper, and facilitating the operation of the mill; but several advantages are

procured by dispensing with it, now we are able to destroy the texture of the cloth and reduce it to pulp, without previously corrupting its substance by rotting it; the paper is much stouter, is less liable to break, and is also whiter, for the fermentation gave a yellowish hue to the surface of the rags, which the mill could not take out without difficulties, and never could entirely, if the rags were too rotten.

We now come to describe the structure of paper mills. In England they now work with cylinders, or engines, an invention which was brought from Holland many years ago, and found to be so great an improvement, that it has been universally adopted. The old mills, which are still in use in some parts of the continent, actuate a number of stampers, or pestles, which pound the rags in wooden mortars till they are reduced to a pulp. These mortars are cut out in a block of heart of oak, well seasoned, the cavity being of an oval figure, about eighteen inches broad, thirty inches long, and eighteen or twenty in depth; the bottom concave, and lined with an iron plate an inch thick, eight inches broad, and thirty long, shaped inwards like a mould for a falcon, with the head and tail rounded. In the middle of the mortar is a cavity beneath the plate, and four or five grooves are cut, forming channels which lead to a hole cut from the bottom of the cavity quite through the block: it is covered by a piece of hair sieve fastened on the inside. This plate is grooved to make teeth, on which the teeth of the hammers act, to cut the rags in pieces. The use of the hair sieve is to prevent any thing from going out except the foul water. Two hammers or pestles work side by side in each mortar, and are lifted alternately by the mill: they are sometimes made in the same manner as the stampers of an oil mill, to lift perpendicularly. In other mills they are large hammers moving on a centre like a fulling mill, and lifted by cogs upon the mill shaft in the same manner. The mortars are kept constantly supplied with fair water, by little troughs, leading from a cistern, which is kept full by small buckets affixed to the floats of the water-wheel; these, when they have raised the water to the top, pour it out into the cistern, in the same manner as the Persian wheel.

This rude and imperfect machine operated very slowly, and suffered a great part of the rags to escape being reduced, whilst other parts were beaten too much. It is not now to be met with in England, the Dutch engines having taken their place, to the great improvement of the paper trade; these are turned by water mills, as they require a very great power to actuate them, though their performance is far greater, with the same power, than the mortars.

The construction of the mills is varied in different situations; but to explain the best kind, we have in *Plate I. Paper Mill*, given a drawing of one made with iron wheels, *fig. 1.* being an elevation, and *fig. 2.* a plan: the same letters of reference are used in both. The water-wheel which gives the motion cannot be seen, as it is situated beneath the floor, but its dimensions are marked by four dotted lines AAAA: in the plan it is enclosed between the three walls of the house PPR, and a fourth wall Q, which is built up across the house, to support the floors N and O, on which the engines stand: the wall R has arches in it to admit the water of the stream to the wheel, a proper gate being fixed to regulate its quantity: the axis of the water wheel, which is of cast iron, comes through the wall Q, and has a large cog-wheel E upon it, which is the full size of the water wheel, and by the paper makers is termed the *master-wheel*; the extreme end of the shaft is sustained in a bearing, which lays on a beam G G, supported on a wall of masonry. The pinion C, called the

wallower,

PAPER.

swallower, is turned by the master-wheel B, and on its axis is fixed the large spur-wheel D, called the *fly-wheel*, giving motion to the two pinions E, F, of the engines K and L: the shaft of the wheel D and pinion C are supported at one end in a frame H H I, and the other, in a bearing fixed in the wall Q. The engines K and L are placed on the floors N and O upon different levels, as shewn by *fig. 1*, the bottom of L being higher than the top of K, so that the contents of L may be let down through a plug-hole in the bottom. The upper engine L is called the *washer*, where the rags are first worked coarsely, with a stream of water running through them to wash and open their fibres; after which washing they are called *half stuff*, and are then let down into the beating engine K, to be ground, and reduced to a finished pulp, proper for moulding into sheets of paper.

By the arrangement of the wheels of the mill, the cylinders, *k* and *l*, of the two engines are contrived to make about from 120 to 150 revolutions *per* minute, when the water-wheel moves with its proper velocity; though the beating engine revolves much quicker than the washer, its pinion, F, having only 24 teeth, while the washer, F, has 28. The great wheel, B, has 196 teeth, and the pinion, C, 38 teeth; therefore it makes about $5\frac{1}{2}$ turns, for one of the water-wheel. The wheel D has likewise 196 teeth, and turns the washer, F, of 28 teeth about 36 times, for once of the water-wheel; and the beater, E, about 42 times. M is a cog-wheel, put in motion by the teeth of the great wheel B: on the extremity of its spindle is a crank *a*, which, by a connecting rod, gives a reciprocating motion to a lever *c d*, for the purpose of working two pumps, *e, f*, which raise water into a cistern *b*, drawing it from the water of the mill-dam by a suction-pipe *g*. These pumps raise up a constant stream of fair water, which is necessary to be kept running through the rags in the washing-engine, to carry away the dirt separated from them by the operation.

The engines are shewn at K and L, in the plan: each consists of a wooden vat or cistern, divided by a partition in the middle; and in one of these divisions, their cylinders, *k* and *l*, are seen. These are provided with teeth or cutters, which act against similar teeth fixed in blocks, situated beneath the cylinders, to cut the rags between them, when they revolve. The structure of an engine is more minutely explained by *figs. 1, 2, 3, 4, &c. of Plate II.*; *fig. 1* being a section through the length of the engine, and *fig. 2*, a horizontal plan. The large vat or cistern, A A, is of an oblong figure on the outside, the angles being cut off; but the inside, which is lined with lead, has straight sides and circular ends. It is divided by a partition B B, also covered with lead. The cylinder, C, is fixed fast upon the spindle D, which extends across the engine, and is put in motion, as before described, by the pinion E, placed on the extremity of it. The cylinder is made of wood, and furnished with a number of teeth, or cutters, fixed fast on its circumference, parallel to the axis, and projecting about an inch, as is shewn on a larger scale at *fig. 5*. Immediately beneath the cylinder, a block of wood, H, is placed, and provided with similar cutters to those of the cylinder, which, when they revolve, pass very near the teeth of the block, but do not touch; the distance between them being capable of regulation, by elevating or depressing the bearings on which the necks, D, D, of the spindle are supported. These bearings are made on two levers, F, F, which have tenons at their ends, fitted into upright mortises, made in short beams, G, G, bolted to the sides of the engine. (See also *fig. 3.*) The levers, F, F, are moveable at one end of each,

the other ends being fitted to rise and fall on bolts, in the beams G, as centres. The front one of these levers, or that nearest to the cylinder C, is capable of being elevated or depressed, by turning the handle of the screw *b*, which, as shewn in *fig. 3*, acts in a nut *a*, fixed to the tenon of F, and comes up through the top of the beam G, upon which the head of the screw takes its bearing. Two brasses are let into the middle of the levers, F, F, and form the bearings for the spindle of the engine to turn upon. The screw, *b*, is used to raise or lower the cylinder, and cause it to cut finer or coarser, by enlarging or diminishing the space between the cutters in the block and those of the cylinder.

Near K, *figs. 1* and *2*, is a circular breasting made of boards, and covered with sheet-lead: it is curved to fit the cylinder very truly, and leaves but very little space between the teeth and breasting. An inclined plane, K, leads regularly from the bottom of the engine-vat to the top of this breasting; and at the bottom of it the block, H, is fixed. The engine is supplied with water by a pipe, Q, bringing it from the pump: this pipe delivers it into a small cistern, M, adjoining, and communicating with the engine. The pipe has a cock, P, to stop the entrance of the water, when required, or to regulate the quantity of its discharge. The small cistern has a grating fixed across it, covered with a hair-strainer, to catch any extraneous matter, which may come in with the water; or a flannel bag is sometimes tied over the orifice of the cock P, through which all the water must be filtered. When the engine is filled with water, and a quantity of rags put in, they are, by the revolution of the cylinder, drawn between its cutters and the teeth of the block H. This cuts them in pieces; then, by the rapid motion of the cylinder, the rags and water are thrown over the top of the breasting, upon the inclined plane: in a short time, this raises more rags and water into that part of the engine-vat; and the tendency to restore the equilibrium puts the whole contents of the vat in slow motion, down the inclined plane K, and round the partition B B, by which they come to the cylinder again in about the space of 20 minutes; so that the rags are repeatedly cut and chopt in every direction, till they are reduced to a pulp.

This circulation is of advantage, in turning the rags over in the engine, and causes them to present themselves to the cutters in a different direction every time; for as the cylinder cuts or clips in straight lines, in the same manner as a pair of shears, it is requisite to cut the rags across in different directions, to reduce them to a pulp. The manner of the cutting is this: the teeth of the block are placed rather inclined to the axis of the cylinder, as shewn by *fig. 4*, but the teeth of the cylinder are parallel to its axis; therefore, the cutting edges, when they meet, are at a small angle, and come in contact first at one end, and then successively the contacts proceed along to the other end, so that any rags interspersed between them are cut in the same manner as they would be between the blades of a pair of shears. Sometimes the plates or cutters, *k*, in the block are bent to an angle in the middle, instead of being straight, and inclined to the cylinder: in this case, they are called elbow plates, and of course the two ends are both inclined to the axis of the cylinder in opposite directions. In either case, the edges of the plate of the block cannot be straight lines, but must be curved, to adapt themselves to the curve which a line traced on the cylinder will of course have. The plates or cutters of the block are united, by screwing them altogether, and fitting them into a cavity cut out in the wooden block H; their edges are bevelled away on one side only, as shewn at *k* in the section, *fig. 4*. The block is fixed in its place by being made dovetailed, and truly fitted into the

bottom of the cistern, so that the water will not leak by it. The end of it comes through the wood-work of the chest, and projects a small distance on the outside of it, being kept up to its place by a wedge, so that by withdrawing this wedge, the block becomes loose, and can be removed, to sharpen the cutters, as occasion requires. This is done on a grindstone, the plates being first separated from each other.

The cutters of the cylinder are fixed into grooves, cut in the wood of the cylinder, at equal distances from each other round its circumference, in a direction parallel to its axis: the number of these grooves is twenty; and for the washer, each groove has two cutters or bars put into it; then a fillet of wood is driven fast in between them, to hold them firm; and the fillets are kept fast by spikes driven into the solid wood of the cylinder. The beater is made in the same manner, except that each groove contains three bars, and two fillets, as shewn in *fig. 5*.

In the operation of the cylinder, it is necessary that it should be inclosed in a case, or its great velocity would throw all the water and rags out of the engine. This case is a wooden box *LL*, inclosed on all sides except the bottom: one side of it rests upon the edge of the vat, and the other upon the edge of the partition *BB*. The lines, *c, c*, represent the edges of wooden frames, which are covered with hair or wire-cloth; and immediately behind these, the box is made with a bottom, and a ledge towards the cylinder, which makes a complete trough. The dark spaces, *e, e*, in *fig. 1*, shew the situation of two openings, or spouts, through the side of the case, which lead to flat lead-pipes, *h, h*, *fig. 2*, which are placed by the side of the vat; the beam, *F*, being cut away for them. There are waste pipes, to convey away the foul water from the engine; for the cylinder, as it turns, throws a great quantity of water and rags up against the sieves: the water goes through them, and runs down into the trough at *e, e*, and from thence into the ends of the leaden pipes, *h, h*, *fig. 2*, by which it is conveyed away: *d, d*, *fig. 1*, are grooves for two boards, which, when put down in their places, cover the hair-sieves, and stop the water from going through them, if it is required to retain the water in the engine. This is always the case in the beating-engines, and therefore they are seldom provided with these waste-pipes, or at most on one side only; the other side of the cover being curved, to conform to the cylinder. Except this, the only difference between the washing-engine and the beater is that the teeth of the latter are finer, having 60 instead of 40 bars on its circumference; and it revolves quicker than the washer, so that it will cut and divide those particles which pass through the teeth of the washer.

In small mills, where the supply of water is limited, they frequently have but one engine, and use it both for washing and beating, by setting the screw so as to let the cylinder down and make its teeth cut finer; but the system of all considerable works is to have two engines, or four, if the supply of water is sufficiently great. We have seen a very capital paper mill containing five engines, where three of them are beaters and two workers; because the beating takes so much more time, that when the numbers are equal, the washers will often do too much for them, and they will have to stand still. A mill to drive four engines is generally made double, that is, it has two water-wheels, and all the machinery shewn in the plan; and if either of these give motion to three engines, they are arranged rather differently: thus the two beaters are placed on the same level with each other, and this removes them to a greater distance asunder than shewn in *fig. 1*, *Plate I.*; so that the ends of the two engines,

when placed on the same floor or platform, will just touch each other. The washer is then placed on the opposite side of the wheel *D*, *viz.* where the word *plan*, *fig. 2*, is written, its pinion being upon the summit of the wheel, which raises it to the proper level: the vat of the washer has a valve or cock in each end, to let out its contents into either of the beaters at pleasure.

The mills with spur-wheels, such as is given in our drawing, are not very common, though they work much better than the ordinary arrangement of the wheels for a paper mill: in this the shaft of the water-wheel has a large face, or crown-wheel, fixed upon it, which actuates a wooden trundle fixed upon a vertical shaft, proceeding upwards through the floor of the mill, and there it carries two large horizontal crown or face-wheels, giving motion to the pinions of the engines, which are situated on opposite sides of the upright shafts. It is necessary to have two horizontal wheels, because of the different levels at which the engines must be placed. These mills are generally made in wood, in a very rude and coarse manner, with crown-wheels and large cogs, so that the friction is very great. Their only recommendation to the paper-maker is their cheapness of erection; but this is only on account of their inferior workmanship, for to make a mill in iron with a vertical shaft and bevelled wheels, as they should be to work properly, would be far more expensive than the construction shewn in *fig. 1*, which is therefore adopted by those manufacturers who choose to have their mills made in a complete and durable manner.

The quantity of water which a paper mill can command to turn its engines, generally limits the extent of its trade; and hence the manufacturers should attend to every improvement of the machinery which can increase their effect. Where the supply of water is constant, they work the engines day and night, though the making the paper, as it requires many workmen, is of course carried on in the day time only. This system necessarily requires a large vat to be provided, which is called the *stuff-chest*, and is a general receptacle for the pulp, where it is kept till wanted to be made into paper; at the same time this mixes the pulp of different day's work together, and produces an uniformity in the quality and colour of the paper, which is a great recommendation for printing large editions of books.

A very large and capital paper mill, at Maidstone in Kent, which is the principal seat of the paper trade in England, is worked by steam-engines, and is found to answer very well. The machinery and building of a paper mill should be well made, and firmly put together, otherwise its great velocity, and power, produces a tremor, which in time shakes every thing to pieces. The noise and vibration of a washing-engine is most tremendous; for when it revolves 120 times *per* minute, and has 40 teeth, each of which passes by 12 or 14 teeth in the block at every revolution, it will make near 60,000 cuts *per* minute, and each of them sufficiently loud to produce the most horrible growling sound which can be conceived. The beater revolving quicker, having 60 teeth, and 20 or 24 cutters in the block, will make 180,000 cuts *per* minute, which is so rapid, as to produce a coarse musical note or humming, which may be heard at a great distance from the mill. This great number of cuts will account for an engine being able, in the course of four or five hours' working, to reduce a quantity of rags to those exceedingly minute filaments, of which paper is composed.

The operation of grinding the rags in the engines requires some management to produce the best effect: the operation of the washing-engine is to open the rags, and to separate their fibres from each other, rather than to cut them

PAPER.

them, and at the same time, by the stream of water which runs through, to carry off all dirt. At first putting into the washing-engine, they should be worked gently, not to cut, but only to rub the rags violently, that the water may have the best effect in carrying off the impurities: this is done by raising up the cylinder, so that its teeth do not touch the teeth of the block, for if the washer cut and divided the rags too much in the first instance, the water would carry away a considerable portion of the finest parts. The cock is at this time opened to admit a great stream of water. When this has continued 20 or 30 minutes, the bearing of the cylinder is let down so low, that its weight rests upon the teeth of the cutter, and it now begins to cut the rags in pieces, the supply of water is diminished, and the operation is at first very violent, the rags frequently causing the cylinder to leap up a considerable height. After working about three or four hours, the engine will get to work very steadily, because the rags, though not reduced to a pulp, are cut very small, and make less resistance to its motion: at this period the washing is usually concluded, and the contents of the engine, called *half stuff*, discharged into a large basket, which allows the water to draw away. For some kind of paper it is thought advisable to let the half stuff remain four or five days to *mellow*, or indeed ferment; and if fermentation is at all proper, this must certainly be the best stage for it, when all the mass of rags is brought to an equal state of division of the fibres. The bleaching is, as before-mentioned, sometimes performed upon the half stuff, instead of bleaching the rags previously; but more commonly it is done in the washing-engine, and this is the most convenient method of all, as it requires no apparatus, and takes very little time, puts the manufacturer to no other expence than the bleaching salt (muriate of lime) by which it is performed, and the effect, if well managed, is equal to that of bleaching by the oxymuriatic acid gas, as at first described. After the rags have been washed for four hours, as above-mentioned, if it is required to bleach the stuff in the engine, they stop the water from running in at the cock, and throw into the engine a quantity of bleaching salt, or muriate of lime. For fine rags, one or two pounds, more or less, are used, according to the quantity of rags the engine contains, which is usually one hundred weight: the two sliders, *d, d*, *fig. 1*, *Plate II.*, are put down in the cover of the cylinder, to prevent the water getting away. In this state the engine is worked about an hour for the bleaching to take place, and during this time the rags lose their colour; but this does not colour the water, though it is rendered rather white and milky by the salt. The very best rags, when first put into the engine, are of a very yellow and dirty colour; but they become, by the bleaching, a very perfect snow white: the cylinder is usually raised up a very little during the bleaching, which being concluded, the water-cock is opened again, the boards, *c, c*, are removed, and the washing continued about an hour to wash the salt away, which must be done very perfectly, or it will continue to act upon, and injure the quality of, the materials.

The half stuff is next put into the beating-engine, and worked till it becomes a fine pulp, which will generally take four or five hours, water being let into it at proper times, to dilute the pulp to its proper consistence, but no water is let out of the beating-engine as in the washer. The quantity of water requires great judgment, as it has an influence on the quality of the paper; and the kind of water the manufacturer is obliged to employ must be considered. The fairest water is the best for paper-making, on account of the clean and white quality so desirable in the manufacture. The water that dissolves soap best, is also

the fittest for taking the grease out of rags. Paper-makers say that the water which is most beaten, and that which comes from afar, makes a better curdled paper, stouter, and of stronger consistence, as to matter: if this is the case, it is probably because this water has had more time for depositing the slime, and other heterogeneous parts, and that, being more exposed to the air by motion, it is thereby in a better condition for dissolving grease and soap. Water, subject to be mudded by rain, and that which runs through marshy grounds, ought to be avoided. In like manner, a paper mill ought not to be placed below other manufactories or machinery, which, by using the same water, might communicate to it a bad quality. The water of ponds, and rain water, are very good for dissolving soap, and may therefore be used for paper, if in a pure state. Water, impregnated with lime, by having run off from chalky soils, is generally very pure and clear to the eye, and is, therefore, much used for paper-making, but it is apt to deposit a slight incrustation upon the brass wire of the moulds, which they remove by occasionally washing them with vinegar.

For printing papers, the sizing is done in the beating-engine, towards the end of its operation, as we shall describe: the size is necessary to prevent the ink from sinking into the paper like blotting-paper; but printing-ink not being so fluid as writing-ink, the paper can be sufficiently sized in substance, without subjecting the sheets to a separate operation after they are made. The size for the engine is composed of alum pounded very fine, and mixed up with a quantity of oil: about a pint and a half of this mixture, thrown into the engine at intervals, during the last half hour of the beating, is sufficient. In order to give that bloom, or blue cast to the paper, which some kinds have, a quantity of powder blue is frequently put into the engine at the same time. The pulp is now run off into the *stuff-chest* where the different kinds are mixed, and it is taken out as it is wanted, in the vats where the dippers, &c. work to form the sheets.

The moulding of the paper should be carried on in a lofty room, well ventilated, and with a smooth and even ceiling, that the steam arising from the several vats of pulp may not be condensed upon it, and fall in drops, for a single drop falling upon a sheet of paper, whilst it is moulding, will beat a hole through it, or at least spoil it. The people in this apartment work at the *vats*, with *moulds*, *deckles*, *felts*, *vat press*, and *wet press*. The *vat* used to contain the pulp is a tub, generally about five feet in diameter, and two and a half in depth. It is provided, on the upper part, with planks enclosed inwards, and even railed in with wood, to prevent any of the stuff from running over in the operation: a plank, pierced with holes at one of the extremities, is placed across the vat, and resting on the planks which surround the vat, forms a support to rest the mould upon, when a sheet of paper has been made, and it remains here a short time to drain off the superfluous water. The stuff in the vat is kept at a proper temperature, by means of a grate introduced at a hole in the side, and surrounded on the inside of the vat with a case of copper. For fuel to this grate charcoal or wood is used, and frequently, to prevent smoke, the wall of the building comes in contact with one part of the vat, so that the fire has no communication with the room where they make the paper. The paper is made into sheets upon the *mould* and *deckle*. The *mould* is a square frame, or shallow box, made of well-seasoned mahogany, and covered at the top with wire-cloth; its dimensions are an inch or an inch and a half larger than the sheet of paper intended to be made upon it. The wire-cloth of the mould is varied in proportion to the fineness of the paper and the nature of the stuff.

PAPER.

stuff. It consists of a number of parallel wires stretched across the frame, very near together, and tied fast through holes in the sides; also a few other stronger wires, extending across in a direction at right angles to the former, and a considerable distance asunder, the small wires being bound down to them by fine wire at the intersections. This may be readily understood, from the examination of a sheet of some kind of paper on which the marks of the wires remain, because the paper is thinner in those places where the wire touched it.

By a modern improvement, these marks, called water-marks, are avoided, and the paper has a smooth even surface. For this the wire is wove in a loom, exactly like cloth, and stretched over the frame of the mould. The wire-cloth is in this case made larger than the intended sheet of paper, and turned down over the sides of the frame, being sewed fast to it by fine wire, so that the cloth is strained tight over the frame. The wove paper, as it is called, when made on these moulds, is a very superior article to the old paper, particularly for books, but a prejudice still prevails in favour of the old paper with lines, which obliges manufacturers still to make it, though by no means so fine or good as the wove.

The *deckle* is a square frame of mahogany, bound with brass at the angles; it is made very thin, and its outside corresponds with the sides of the mould, while the inside is the size of the sheet. This frame is necessary to retain the stuff of which the paper is made on the cloth, and it must be exactly flat, that it may fit upon the wire-cloth of the mould, otherwise the edges of the paper will be ragged and badly finished. The deckle, when placed upon the wire of the mould, forms a shallow sieve or mould, in which a quantity of the pulp is taken up, and by the draining through of the water, the pulp is left in a sheet upon the wire. There is no fastening for the deckle, as it is moveable, and only held upon the mould, by the workman grasping the mould and deckle together in both hands at the opposite sides. This admits of the deckle being removed, that the sheet of paper may be taken up from the wire, by applying the mould upon a piece of felt. The *felts* are pieces of woollen cloth, spread over every sheet of paper, and upon which the sheets are *laid*, to detach them from the wire of the mould; they also prevent them from adhering together, and imbibing part of the water with which the paper is charged, transmit the whole of it when placed under the action of the *vat press*. The moulding of the paper is performed by three workmen, the *dipper*, the *coucher*, and the *lifter*. The first of these having filled the vat with pulp, must be attentive to mix it up well; for this purpose, he employs two implements, one of which is a simple pole, and the other a pole armed with a piece of board, rounded and full of holes. This operation is repeated as often as the stuff falls to the bottom. In the principal mills they use for this purpose what is called a *hog*, which is a machine within the vat, that, by means of a small wheel on the outside, is made to turn constantly round, and keep the stuff in perpetual motion.

When the stuff and water are perfectly mixed, it is easy to perceive whether the previous operations have been complete. If the stuff floats close, and in regular flakes, it is a proof that it has been well ground, and the parts of the rags, which have escaped the cylinder of the engine, also appear. The dipper stands in a niche, or hollow part of that kind of ledge or table which goes round the circumference of the vat; he holds a mould in both hands, by the two extremities, with the deckle applied exactly over the mould, as if only one piece; then inclining it a little

towards him, he dips it into the vat, and brings it up again into a horizontal position. The superfluous part of the pulp flows over on all sides, and the quantity thought sufficient is shaken gently, from the right to the left, and up and down horizontally, until it is equally extended over the whole surface of the mould. These two motions are also accompanied by a slight shake, that serves to fix and stop the sheet. As the water drains through the wire, the fibrous parts of the stuff arrange themselves regularly on the wire-cloth of the mould, not only in proportion as the water escapes, but also as the workman favours this effect, by gently shaking the mould. This done, the mould is immediately laid on the edge of the vat, the deckle taken off, and the mould made to slide along the board which is laid across the vat, to the part where the sheet is to be laid or taken off. The board, which is but two inches in breadth where the sheet is laid, is nothing more than a deal board, which runs along the length of the vat, and is pierced with several holes at the extremity, for letting the mould drain into the vat. The dipper taking the deckle off the first mould, places it immediately on a second, which is given him for dipping in its turn; and the second workman, called the *coucher*, taking the mould off the board that runs across the vat with the left hand, raises it gently, and lays it in an inclined position against one or two small pins, which are driven into the board on the edge of the vat. In this condition the mould remains two or three seconds of time for draining into the vat, whilst the *coucher* extends a felt, on which he applies the mould to take off the sheet, which being done he returns the mould to the dipper.

They proceed in this manner, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a *post*, and this they do with such swiftness, that in many sorts of paper two men make upwards of twenty posts in a day.

When the last sheet of the post is covered with the last felt, all the workmen about the vat unite together, and submit the heap to the action of the *vat press*. They begin at first to press it with a middling lever, and afterwards with a lever about fifteen feet in length.

The dipper should be attentive, in distributing the matter on the mould, to reinforce the corner the *coucher* is to take hold of, in raising and extending the sheets; for without this precaution he would break a great many. Also, if he takes up too much matter with his mould, if he does not equally extend it, or if he strikes his mould against the drainer. In all these cases the matter is accumulated in certain parts of the mould, producing something like ridges in the paper, or if he lets the matter rest on the mould, and does not distribute it immediately, there will be parts of unequal thickness. When the vat is too hot, the stretching out of the sheet will be ill performed, because the water evaporates too soon from the mould. Add to this, that in letting the matter run towards one of the edges, by not giving his arm a regular motion, he may form a feather-edged paper, which may likewise happen if he does not extend his stuff sufficiently; or if the vat be too hot, or the scum of the pulp is too crude, and does not run well; if his arms are too stiff, and if he gives a bad shake, or if the mould be ill made.

In order to avoid drops of water, which, if they fall upon the paper, will make disagreeable spots, the mould should be raised readily; and as often as the *coucher* returns his mould to the drainers, he ought to be careful to shake his hands behind him; for without this precaution, his fingers, which are wet, would drop upon the sheet already laid, whilst he is covering it with the felt. If he is also too quick

PAPER.

in laying, the air detained and compressed under the sheet occasions a bloating, and makes some parts more clear than others.

In consequence of the construction of the mould, it is easy to perceive that the sheets of paper will take, and preserve, the impression of all the wires which compose it, and of the empty spaces between them. This is seen in examining a sheet of paper before the light, a greater opacity being found on both sides of each brass wire, than towards the middle of the space. This thickness is occasioned by the pulp, which the motion of the mould could not distribute, being stopped by the small wires, and still more by the large cross wires. This defect is completely remedied by the improvement of weaving the wire of the mould like cloth. The traces of the old wires are most evidently perceived on the side of the sheet which was attached to the mould, and on the other side they form an assemblage of rounded risings. In the paper which is most highly finished, the regularity of these impressions is still visible; therefore it is evident, that all the operations to which it is submitted, have chiefly in view to soften these impressions without destroying them; it is necessary, therefore, to attend to the combination of labour which operates on these impressions. The coucher, in turning the mould on the felt, flattens a little the rounded eminences, which are in relief on one of the surfaces, and occasions, at the same time, the hollow places made by the wire-cloth to be partly filled up; meanwhile the effort which is made in detaching the paper, produces an indefinite number of small hairs on every protuberant part of the sheet. Under the action of the prefs, first with the felts, and then without them, the perfecting of the grain of paper still goes on. The vestiges of the protuberances made by the wires of the mould are altogether flattened, and in consequence the hollows opposite them disappear also, but the traces formed by the interstices of the wire, in consequence of their thickness, appear on both sides, and are rounded by the prefs.

The grain of the paper is often disfigured by the felts when they are too much used, or when the wool does not cover the thread. In this case, when the paper is submitted to the prefs, it takes the additional traces of the warp and the wool, and composes a surface extremely irregular.

The two sides of the felt are differently raised, and that on which the hair is longest, is applied to the sheets which are laid down, and any alteration of this disposition would produce a change in the texture of the paper. The stuff of which the felts are made should be sufficiently strong, in order that it may be stretched exactly on the sheets, without falling into folds, and at the same time sufficiently pliant to yield in any direction, without injury to the wet paper. As the felts have to resist the reiterated efforts of the prefs, it appears necessary that the warp be made strong, of combed wool, and well twisted. On the other hand, as they have to imbibe a certain quantity of water, and to retain it, it is necessary that the wool be of carded wool, and drawn out into a slack thread.

The paper remains in the vat prefs during the time that the next post of paper is preparing, and when it is removed to make room for that, the business of the third workman, called the lifter, begins; it is to take the sheets off the felt, (for they are caused to adhere to them by the action of the prefs,) and then making the sheets up into a second pile; but if the coucher works too fast, and the lifter finds himself hard pressed, he cannot stretch out his sheets exactly upon one another, so as to make a neat and compact pile, which is very necessary to make paper of a regular and equal thickness, when put under a second or wet press, which is done as soon as several of the piles are completed, and can be collected together.

This second pressure being made with all the sheets in contact with each other, expresses a great quantity of water from the paper, and gives the sheet a very considerable strength; it also tends to take out those freckles on the surface of the sheets, which were occasioned by the impression of the felt, though it is necessary to have felts in the first pressure, because the paper is then so soft and pulpy, that it would be pressed into a solid mass if the sheets touched each other. The paper remains in the second press as long as it can, until another pile is made ready by the lifter. When the paper has undergone these operations, it is not only softened in the surface, but better felted, and rendered more pliant in the interior parts of the stuff. In short, a great part of the water which it had imbibed in the operation of the vat is dissipated. By the felting of paper is understood the approximation of the fibres of the stuff, and their interlacing so as to adhere close together. The paper is felted in proportion as the water escapes, and this effect is produced by the management and reiterated action of the prefs: without this action the paper would be porous, and composed only of filaments without adhesion. When the sheets are very thin, and it is found, after the second pressure, that they are formed by a fecula, which is still so saturated with a great deal of water, that they have little consistence, it is probable that the second press will join them to one another, and it is difficult to separate them; indeed they cannot well be taken off singly without tearing a great number. This is a proof that the business of the prefs has been badly conducted. To avoid this inconvenience, it is necessary to bring down the prefs at first gently, and by degrees with greater force, and to raise it as suddenly as possible. By this means the water, which is impelled to the sides of the heaps which has not yet escaped, returns to the centre, the sheets are equally dried, and the operation is executed without difficulty. The separation, sheet by sheet, is not necessary for drying, so that seven or eight may be taken together, which is called forming the pages; sometimes also a less number may do, when the paper is of a large size, but never less than three sheets are hung up together. It is of more importance than we are aware of, that the sheets should thus remain, as it were, pasted several of them together: if they were single, they could not resist the moisture of the size, yet this moisture is sufficient to facilitate their separation; but to prevent their separating when they are hung up to dry, they should be so placed that the pages may receive the wind in the surface, and not in the sides and edges. When the paper is removed from the second press, it is taken to the drying lofts, which are very extensive apartments, usually the upper parts of all the buildings of the mill: the sides are formed by luffer boards, which are a kind of lattice or boarding which can be opened or shut, to admit more or less air, at pleasure. The sheets are taken up upon a piece of wood like a T, and hung upon hair lines, stretched across large horizontal wooden frames, called *tribbles*, and these, as they are filled, are lifted up between upright posts to the top of the room, and retained by pegs put in the posts; then another frame being filled, is put up in its turn, and so on till the loft is filled from top to bottom.

The principal care in drying the paper, consists in gradually admitting the external air, and in preventing the cords from imbibing moisture; for this reason the lattices or luffer boards should be constructed with great exactness, and the cords may be prevented from imbibing the water by covering them with wax. In using such cords, the moisture does not continue in the line of contact between the paper and the cord, which prevents the sheet from stretching in that particular place by its weight, and from
the

PAPER.

the folds which the moisture in the subsequent operations might occasion. The cords are of considerable thickness, by which means they diminish the point of contact, and give a better and more equal circulation to the air. By these precautions, the Dutch paper is dried equally, and is extremely supple before the sizing. The time necessary for drying the paper depends so much upon the state of the atmosphere, and the thickness of the sheets, that it cannot be stated with any degree of accuracy; but being dried, is taken down, and sleeked, dressed, and shaken, to make the dust fall out, and to separate the pages from one another. It is then laid in heaps in the warehouse, and from thence brought out in order to be sized. The size for paper is made of the shreds and parings got from tanners, curriers, and parchment makers. All the putrified parts, and the lime, are carefully separated from them, and they are inclosed in a kind of basket, and let down by a rope and pulley into the cauldron. This is a late invention, and serves two valuable purposes; it makes it easy to draw out the pieces of leather when the size is extracted from them by boiling, and easy to return them into the boiler, if the operation is not complete. When the glutinous substance is sufficiently extracted, it is allowed to settle for some time, and it is twice filtered before it is put into the vessel in which they dip the paper. Immediately before the operation, a certain quantity of alum is added to the size. The workman takes a handful of the sheets, smoothed and rendered as supple as possible, in his left hand, dips them into the vessel, and holds them separate with his right hand, that they may equally imbibe the size. After holding them above the vessel for a space of time, he seizes on the other side with his right hand, and again dips them into the vessel. When he has finished ten or a dozen of these handfuls, they are submitted to the action of the press. The superfluous size is carried back to the vessel by means of a small pipe. The vessel in which the paper is sized is made of copper, and furnished with a grate, to give the size, when necessary, a due temperature, and a piece of thin board or felt is placed between every handful of sheets, as they are laid on the table of the press. The Dutch are very careful in sizing their paper, to have every sheet in the same handful of equal dryness, because it is found that the dry sheets imbibe the size more slowly than those which retain some degree of moisture.

They begin by selecting the pages in the drying house, and after having made them supple, and having destroyed the adherence between the sheets, they separate them into handfuls, in proportion to the dryness, each of them containing that number which they can conveniently dip at one time. Besides this precaution, they take care to apply two sheets of brown paper, of an equal size, to every handful: this brown paper, being firm, solid, and already sized, is of use to support the sheets.

It is the practice at some paper mills, to carry the paper immediately it is sized to the drying house, and hang it up before it cools, sheet by sheet, on the cords; but particular attention must be paid to the lattices of the drying house, or it is apt to dry too fast, whereby a great part of the size goes off in evaporation, or if too slow it falls to the ground. The paper, being sufficiently dried for the last time, is carried to the building where it is examined, finished, and pressed: this is called the *Saul*. Women are here employed to remove all damaged and imperfect sheets: it is then put into the dry press, shewn at *figs. 6, 7, and 8, of Plate II.*, and squeezed with a most immense force, to render the paper flat, and give it a good surface. The lever of this press is fifteen or eighteen feet long, and ten or twenty

people are employed at the last to work it, though they sometimes use *Samson*, that is, a windlass like a crane, with which they purchase the lever of the screw; but this excessive labour is altogether avoided, and a much greater pressure given, by using Mr. Bramah's ingenious hydrostatic press, instead of the screw press, which consume a great portion of the power in friction. For a description of this, see *Press. Hydrostatic*. The dry press is generally large enough to hold two packs of ordinary paper, at once placed one at the other's side. When the compression is judged sufficient, the heaps of paper are carried back to the table, and parted, that is, the whole turned, sheet by sheet, in such a manner, that the surface of every sheet is exposed to a new one, and in this situation they are again brought under the press. It is in extending these two operations, sometimes to four or five times, or as often as the nature of the paper requires, that the perfection of the paper consists. If the stuff is fine, or the paper slender, the parting is less frequently repeated. In this operation it is necessary to alter the situation of the heaps with regard to one another every time they are put under the press; and also, as the heaps are highest towards the middle, to place small pieces of felt at the extremities, in order to bring every part of them under an equal pressure. A single man, with four or five presses, may part all the paper produced by two vats, provided the previous pressing is well performed. The work of the parting generally lasts about two days, on a given quantity of paper. The paper is now sorted into different lots, according to its quality and faults, after which it is made up into quires. The person who does this must possess great skill, and be capable of attention, because he acts as a check on those who separate the paper into different lots. He takes the sheets with the right hand, folds them, examines them, lays them over his left arm till he has the number requisite for a quire, then brings the sides parallel to one another, and places them in heaps under the table. An expert workman, if proper care has been taken in assorting the lots, will finish in this manner 6000 quires in a day. The paper is afterwards collected into reams of 20 quires each, and for the last time put under the press, where it is continued for 10 or 12 hours, or as long as the demand of the paper mill permits.

The operation of moulding the sheets of paper has, for some years past, been performed by a machine which produces it an endless and continued sheet, instead of moulding them separately one by one; and this it does with such accuracy and dispatch, that many paper-makers have procured machines, notwithstanding their great expense of erection, and the premium which they are obliged to pay the patentees for working them. The first idea of this curious machine was brought from France, but it has been wholly perfected here; and we think it one of the most important inventions, as applied to the manufactory of paper, which has been produced since the fourteenth century, when the method of making paper from linen rags was first discovered. In general, the progress of invention is slow and gradual; and with regard to the fabrication of paper, there have been very few striking improvements in relation to machinery for nearly a century, except the present. The processes for improving the general texture and appearance of the paper, by the more skilful use and application of sizing and hot-pressing, have certainly made important advances, even in the course of the last twenty years; while, for a much longer period, the modification in the machinery used for the conversion of rags into pulp, and of pulp into paper, have been very slight, and, for the most part, very unimportant.

Messrs. Henry, and Sealy, Fourdriner and John Gamble, are the proprietors of this invention, for which they have obtained

obtained several patents during its progressive stages of improvement; but an act of parliament was passed in 1807, to extend the usual term of all these patents to fifteen years from that period, and they then enrolled a specification in the records of Chancery, detailing the machine, in its most improved state, and from this we have taken the following description; though it is scarcely possible to describe such a very complicated machine without figures. The pulp having been prepared, in the usual manner, to due consistence, by the admixture of water, kept in motion in the vat by means of what are denominated hogs, is let out through several circular apertures in front of the vat, which can be narrowed or widened at pleasure, by means of a sliding plate. These apertures admit the pulp into a trough, which has a low side, or lip, and over the edge of this it flows, in a continued cascade, or even sheet: this trough of the vat is placed at one end of the machine, so that the stream of pulp falls upon a wire-cloth, or web, of many yards in length, the ends of which being united together, it is extended horizontally, in the manner of a jack towel, over two rollers, one of them placed close under the lip, or mouth of the vat, so that the stream of pulp descends as little as possible. The wire is kept supported by several other parallel rollers, that it may not hang down or bag, but be kept as level as possible, and by a very ingenious contrivance is kept extended in breadth to a proper tension; it therefore represents a table of several yards in length, which, by the revolution of the rollers, is kept in continual motion from the vat towards the end of the machine. The pulp is kept within bounds upon this table, according to the width intended to be given to the paper, by two pieces or rulers of wood, exactly parallel with each other, and also with the line of motion of the wire. Between the wire itself and these rulers are placed two endless straps of leather, as wide as the rulers, and revolving with the same velocity as the wire, but over different rollers. Similar rulers, and endless straps, are also placed in contact with the lower surface of the wire, so that the wire is confined between them on each side, and the liquid pulp thus prevented from running off on the sides, and they act as deckles to the mould. As they move together, they occasion no friction to destroy the wire. Near that part of the wire upon which the pulp falls from the lip in the vat, there is placed a flap of oiled silk, or other material, to prevent the pulp from running back towards the vat over the roller of the wire.

As the wire revolves upon its rollers, and carries the pulp along upon its surface from the vat to the other extremity, it is conducted between two rollers, fitted up in the manner of a rolling mill, which cause a pressure upon the pulp and paper to force out the water, and are therefore called the wet-presses. In order to guard the pulp, which before passing between the rollers is in a soft state, from being dislodged, or otherwise injured by the upper roller coming immediately in contact with it; a revolving endless web of felt is applied. This is made of the same width as the endless wire, but not so long, and it is extended, like that, upon rollers situated above the wires; it is likewise brought between the rollers of the wet-presses, so that its under surface falls upon the surface of the pulp, or paper, and defends it from the action of the upper cylinder: the wire and the felt are thus brought into contact with the paper between them, and the required pressure is given by means of screws, which increase or diminish the distance of the large compressing rollers, and these being covered with flannel cloth, or felting, are prevented from injuring the wire webbing, as well as producing a better effect upon the paper than naked cylinders would do.

To prevent the water thus pressed out of the pulp from running back upon the paper, the wire is not only made to descend before it passes the wet-press, but there is also placed a small roller resting upon the wire, as near the press as possible, and some part of the water is previously got rid of, by both the wire and felt, with the pulp between them, passing through a small pair of rollers, to the axis of the upper one of which rollers are hung weights, in order to give a slight pressure. The water that drains from the pulp is collected into a trough, and returned to the vat by means of a scoop-wheel instead of a pump, which might form the paper stuff into lumps or rolls, by the mutual friction or rubbing of any parts of the apparatus against each other, and the reason for returning the water into the vat is to prevent the loss of a considerable portion of the paper, stuff, blue, size, &c. which would otherwise be sustained by its running to waste.

It is evident then, that if motion is given in the proper direction to the wet-press cylinders, having both the web and wire thus compressed between them, they will be drawn along by them, and caused to revolve upon their respective rollers; and that, as long as these webs continue so to revolve, and the pulp continues supplied and running upon the surface of the under web, so long will the machine continue making a sheet of paper, of continually increasing length. But as the paper, even after having passed between the rollers of the wet-press, is not of that consistency and strength as would allow of its being removed from the machine and cut in sheets, the new-made paper is caused to detach itself from the wire, at the moment it comes to the extreme roller, over which the wire revolves, and is immediately received upon a second web of felt, which is, like the former, stretched by two principal rollers and other subordinate ones. By the revolution of this web, which must have the same velocity as the former, the paper is brought between two rollers of brass or other hard metal, which are turned perfectly smooth, and placed some distance from the wet-press cylinders, but exactly parallel to them, and after passing through them, the paper is received and wound upon a reel, or roller, which is from time to time removed, and others applied in their room as they are filled with paper.

This is the general action of the machine, but there are a number of very ingenious movements, which we have not mentioned. The shaking movement of the mould, which is so necessary to make the pulp coagulate into paper, is, in this machine, given to the wire thus: the frame of the roller on which the wire is extended at the end near the vat, is so placed on the top of upright legs, which are moveable on centres, as to admit the roller and wire with the deckle straps to move sideways a small quantity, and to return, in the manner of vibration, by the action of a crank. The number of these vibrations, or shakes, necessary in a given time, and the space passed through by the wire in each, will vary according to the quality and preparation of the pulp. The number, however, seems, by observation, to be limited to one or two hundred *per* minute, and the space between a quarter of an inch, and an inch. To enable the paper-maker readily to give a proper velocity to the crank according to his judgment, the same is turned by a small independent water-wheel, the velocity of which, and consequent number of vibrations, are regulated, at pleasure, by the quantity of water admitted upon the wheel. The sliding plate in the vat, which admits the pulp to flow out as first mentioned, is regulated by a screw, by which the circular aperture may be opened or shut in any intermediate degree, so that the quantity of pulp required to run from the

PAPER.

vat to the wire, may by this be regulated, and so adjusted to the velocity of the wire, as to produce a sheet of paper of any required thickness. The whole machine is turned by a water-wheel, which is preferable to any other power, as by it is obtained the most regular and uniform motion, and such as is best adapted for this purpose, though other first movers might be used.

As the paper is drawn off the endless wire by the motion of the revolving web of felt, it is necessary to have the riggers, or band-wheels, which communicate the motion from the rollers of the dry-press to those of the wet-press, made upon an adjustable principle, or capable of having their diameters increased or diminished, as occasion requires, whilst the machine is at work. By this adjustment, an exact correspondence is obtained between the velocity of the revolving wire and that of the revolving felting, so should one exceed the other in the smallest possible degree, the paper would either be torn asunder, or carried round upon the under side of the web, and be spoiled. It is effected by a very ingenious application of an expanding rigger; which see. The machine will make paper of any required width, by diminishing the distance between the deckles upon the wire; and for this purpose, the rollers over which the deckle straps are conducted, are adjustable upon their spindles. The long sheet of paper, thus obtained, is unrolled from the reel upon a cutting table, having grooves, with steel edges, placed at a proper distance; and thus the sheets, of the usual sizes, are cut off, by means of steel cutting wheels running into the grooves of the table, and pressed down by a loaded carriage. The reel of paper is placed parallel to these grooves, which are so much longer than the utmost width of the sheet, as is sufficient to let the carriage be retained on either side while a sheet is taken off the table, and fresh paper drawn on; in doing which, care is taken to keep the edges of the sheet at right angles to the grooves, for which purpose, direction lines are drawn upon the table. We have been informed by those who have seen these machines at work, that this method of cutting has been abandoned; and they are now worked with reels made adjustable to the required width of the sheet, and when a sufficient quantity is wound on it, is cut off by a knife, which, by cutting through the folds, divides the paper into separate sheets, which are ready for the operation of the second press. The machines are constructed with a cloth, so wide, that the continual sheet is cut up into two, and sometimes three in width, by which means it produces an immense number of sheets in a short time; but the greatest advantage is in making very large sheets, which it will do to almost any extent in length, and as much as two yards in width.

This machine is only adapted for making wove paper; but a patent has lately been taken out for carrying this invention farther, and making the paper with lines in it; but this is done with separate moulds, similar to those at present used, though worked by machinery, which in some measure resembles the other, the moulds being attached to an endless chain in lieu of the endless wire.

Chinese paper is of various kinds; some is made of the rinds or barks of trees, especially the mulberry tree and elm, but chiefly of the bamboo, and cotton tree. In fact, almost each province has its several papers. The preparation of paper made of the barks of trees, may be instanced in that of the bamboo, which is a tree of the cane or reed kind. The second skin of the bark, which is soft and white, is ordinarily made use of for paper: this is beat in fair water to a pulp, which they take up in large moulds, so that some sheets are above twelve feet in length: they are com-

pleted by dipping them sheet by sheet in alum water, which serves instead of the size among us, and not only hinders the paper from imbibing the ink, but makes it look as if varnished over. This paper is white, soft, and close, without the least roughness, though it cracks more easily than European paper, is very subject to be eaten by the worm, and its thinness makes it liable to be soon worn out.

The celebrated Dr. Franklin has, in the American Philosophical Transactions, given the following account of the method used by the Chinese for making these extremely large sheets of paper; suppose of four and half ells long, and half an ell wide. They have two large vats, each five ells long, and two ells wide, made of brick and lined with plaster, that holds water; in these the stuff is mixed ready to work. Between these vats is built a kiln, or stove, with two inclining sides, each side something larger than the sheet of paper; they are covered with fine stucco, that takes a polish, and are so contrived, as to be well heated by a small fire circulating in the walls. The mould is made with thin, but deep sides, that it may be both light and stiff. It is suspended at each end with cords, that pass over pulleys fastened to the ceiling, their ends connected with a counterpoise, nearly equal to the weight of the mould.

Two workmen, one at each end of the mould, lift it out of the water by the help of the counterpoise, turn it up, and apply it, with the stuff for the sheet, to the smooth surface of the stove, against which they press it, to force out a great part of the water through the wires. The heat of the wall soon evaporates the rest, and a boy takes off the dried sheet by rolling it up. The side next the stove receives the even polish of the studs, and is thereby better fitted to receive the impression of fine colours. If a degree of sizing is required, a decoction of rice is mixed with the stuff in the vat. Thus, the great sheet is obtained smooth and sized, and a number of the European operations, of uniting the edges of several small sheets together, are saved. If the stove has two polished sides, and there are two vats, the same operation is, at the same time, performed by two other men at the other vat, and one fire serves both.

We conclude with just hinting the importance, in the present state of our political relations, and the extreme difficulty of obtaining rags, of directing the attention of manufacturers to other substances, from which paper may be fabricated. Silk, it is well known, has been used in the East as long ago as the seventh century, but the article is too expensive for general adoption. Cotton, when treated in a manner similar to that practised with linen rags, affords an excellent paper, which at present forms a very extensive branch of the Levant trade.

The Japanese paper is, according to Kämpfer, made of the bark of the *morus papyrifera sativa*, or true paper tree. (See *JAPAN PAPER*.) Other substances are the pith of thistles, the bark of the fallow (*Salix caprea*), hemp, shaws of hemp, shaws of flax, hop bines, stalks of cabbage, of mallow, of common broom, of the sun-flower (*Helianthus annuus*), of mugwort, of clematis, &c. the down of the ear's-tail, the catkins of the white poplar, the husks of maize, flraw, &c. Trials of some of these, and especially of flraw, have been made in England as far back as the year 1799; but much remains to be done; and as the occasion is important, especially as it relates to commerce, and to the promulgation of arts and sciences, we should be happy to find, that some public-spirited individual, of enterprize and talent, would turn his attention to an extensive series of experiments; for the purpose of ascertaining the merits of these or other substitutes for linen rags, in the fabrication of paper for writing and printing.

The

The excise duties on paper are subject, like other impositions of the same kind, to successive variation, both in their amount and rate; and so are likewise the bounties and drawbacks. And as, in the course of a few years, the enumeration of them would not only be useless, but erroneous, we shall content ourselves with observing, in general, that the principal act by which duties of excise are now collected, is the 43 Geo. III. c. 69; that by the 43 Geo. III. c. 81. more duties were added to those imposed by the former act, and by other subsequent statutes other duties increase the whole amount; and the particulars may be found in the schedules annexed to the several acts. We shall here subjoin some more permanent regulations.

Paper which hath paid the duty may be exported, and also books; and drawbacks are to be allowed subject to the regulations prescribed in several acts. (26 Geo. III. c. 78. 34 Geo. III. c. 20. 43 Geo. III. c. 69. sched. G.) The officer attending the packing of paper for exportation, shall take off the stamps from each ream or bundle, and any person obstructing him in this service shall incur a forfeiture of 50*l.* (26 Geo. III. c. 77.) By 49 Geo. III. c. 98. certain duties of customs are also payable upon papers; but old rags, old ropes or junks, or old fishing nets, may be imported duty free. (11 Geo. I. c. 7.) By 32 Geo. III. c. 54. Officers of the customs shall cause any printed, painted, or stained paper that is imported to be marked; and counterfeiting or forging the mark or number, subjects to a forfeiture of 100*l.*; and counterfeiting or forging any stamp or seal for making the impression, incurs a forfeiture of 500*l.*; and any person who shall sell paper with such counterfeit stamp, knowing the same, shall forfeit 50*l.* By 34 Geo. III. c. 20. the importation of books for sale, first printed in this kingdom, and reprinted in any other, incurs forfeiture of the same, and also 10*l.*, and double the value of such book; provided this shall not extend to any book that has not been printed or reprinted in this kingdom, within twenty years before the same shall be imported, &c.

Every maker of paper or pasteboard, and every paper-stainer, shall take out a license from the office of excise, annually, for which he shall pay 2*l.*, on pain of forfeiting 20*l.* (24 Geo. III. c. 41. 43 Geo. III. c. 69. sched. A.) All brown paper, made of old ropes, or cordage only, without separating or extracting the pitch or tar from them, and without any mixture of other materials, shall be deemed paper of the second class or denomination, and be chargeable with the duty accordingly; and all other paper whatever (glazed paper for clothiers and hot-pressers excepted) shall be deemed to be of the first class or denomination. (42 Geo. III. c. 94.) No paper shall be painted or stained for hangings, except that for which the duty on paper of the first class hath been charged, duly stamped, &c. (41 Geo. III. c. 8.) Nor is the maker to diminish any paper before it be charged, under the penalty of 50*l.* and also such paper. Pasteboard is to be made of paper charged, and unused for any other purpose, on pain of 100*l.*, together with forfeiture of the same, and utensils, &c. employed in making it. (42 Geo. III. c. 94.) By the same act, the maker of pasteboard shall produce to the officers all such paper as he intends to use for pasteboard, duly wrapped and stamped, after 24 hours' previous notice, on pain of 100*l.*: nor shall any maker of pasteboard be a paper-maker, nor manufacture within a quarter of a mile of a paper manufactory, on pain of 100*l.* Places of making or keeping paper, pasteboard, mill-board, scale-board, or glazed paper, all utensils and materials employed, shall be entered, on pain of forfeiture, and also of 50*l.* (34 Geo. III. c. 20.) All paper shall be made up into quires, each quire consisting of 24 sheets, and

such quires shall be made up into reams of 20 quires each; and all pasteboard, &c. shall be made up in parcels, each parcel containing even dozens of sheets, of one and the same denomination, and of equal dimensions, and not less than 24, nor more than 72 such sheets in every parcel; tied up, &c. in wrappers, and marked with the class of paper to which it belongs, the number of the reams made by the maker during the current quarter, &c. &c. on penalty of 200*l.* and forfeiture. (42 Geo. III. c. 94.) Every maker may make his paper into quires without folding, provided that such quires, when made up into reams, be separated by a slip of coloured paper placed between each quire, and visible on the outside of the ream, and that the outside quires of each ream consist of not less than 20, nor more than 24 sheets, at the option of the maker. Every maker, whose mill or workhouse is situated in any city or market-town, who shall have any paper, paste-board, &c. to be weighed, and charged with the duty, shall give 24 hours (elsewhere 48 hours) previous notice, in writing, to the officer of excise, who shall attend, and such maker, or his servant, shall produce to the officer all such paper, pasteboard, &c. duly tied up, that the duty may be charged previous to removal; stamps shall be provided by the commissioners of excise; and if any person shall counterfeit such stamps, and sell with such counterfeits, knowingly, he shall forfeit 500*l.* (34 Geo. III. c. 20.), but this penalty is repealed, and the person committing the offence is adjudged guilty of felony, and subjected to transportation, as a felon, for seven years. 47 Geo. III. sess. 2. c. 30.

Paper-makers are enjoined to give notice to the proper officers of their names, places of abode, store-houses, &c. and to make regular entries, on oath, every six weeks, of all paper, &c. made by them, on penalty of 50*l.* and the duty shall be paid in six weeks after entry, on pain of double duty. 34 Geo. III. c. 20.

Paper-makers are forbid to remove or to conceal their paper, &c. till the officer has taken account thereof, on penalty of 50*l.*, and forfeiture of the paper, &c. (24 Geo. III. c. 18. 34 Geo. III. c. 20. 42 Geo. III. c. 94.) Nor shall paper, &c. be removed in less than 24 hours, under the same penalty; nevertheless it may be removed from one mill to another, upon giving 48 hours' notice, in writing, to the officer. Paper that has been stamped and charged, is to be kept separate from other paper, and also paper of one class from that of another, on pain of 50*l.*

Persons molesting officers in the execution of this act (34 Geo. III. c. 20.) incur a penalty of 100*l.* and the penalties and forfeitures shall be appropriated, one moiety to the king, and the other moiety to the informer.

There is a drawback of the duties on paper exported; and also for books printed at Oxford or Cambridge, in the Latin, Greek, Oriental or Northern languages, and also for bibles, testaments, psalm-books, or books of common prayer, printed either in those universities, or by the king's printer, under certain conditions. 43 Geo. III. c. 69. sched. C.

Pasteboard, made of paper that hath paid the duty, shall not be charged with farther duty. (34 Geo. III. c. 20. 42 Geo. III. c. 94.) Allowance shall be made on paper damaged, for which the duty hath been paid; upon seven days' notice: and allowance shall be made to clothiers and hot-pressers; on certain conditions. 42 Geo. III. c. 94. 43 Geo. III. c. 69.

Stained paper (besides the duty paid for the paper before staining) is subject, by the former acts, to a duty of 1*¼d.* a yard square. 43 Geo. III. c. 69.

Papers are of various kinds. With regard to colours,

they may be divided into *white, brown, blue, &c.* With regard to quality, into *fine, second, bastard, superfine, &c.* With regard to use, into *writing, printing, pressing, cap, cartridge, copy, chancery, post, &c.* With regard to dimensions, into *demy, medium, fool's-cap, pot, royal, super-royal, imperial, elephant, atlas, &c.* With regard to country, into *German, Lombard, Rochelle, Genoa, Holland, &c.*

French paper is divided into *large, middle, and small.* To the small belong those called *petit Romaine, petit Raisin,* or *Bâton royal, petit nom de Jesus,* and *petit à la main,* all thus denominated from the marks impressed on them in making. Also the *cartier,* for the backs of playing cards; *pot* for the figure side; *couronne,* which has commonly the arms of the comptroller-general of the finances; *telliere,* with the arms of the late chancellor Tellier, and a double T; and *champany,* or *à chajis la serpente,* so called from its mark, the serpent; which being extremely fine and thin, is used by fan-makers.

To the middling sort belong the *grand raisin simple, carré simple, cavalier,* and *lombard,* the three last of which are for printing; *l'ecu,* or *de compte simple, carré double, l'ecu double, grand raisin double,* and *couronne double,* which three last are denominated *double* on account of their strength and thickness. Add to these the *pantalon,* or paper with the Dutch arms; and *grand cornet,* so denominated from the impression on it.

To the larger belong the *grand Jesus, petit et grand fleur-de-lis, chapelet, colombier, grand aigle, dauphin, soleil,* and *l'étoile,* which are thus called from the figures they bear, being all proper for printing either at the letter-press or rolling-press; also for merchants books, and for drawing on. The *grand monde* is the largest of all. Vide Savar. D. de Comm. tom. ii. p. 965, seq.

We have also *printed paper,* for hanging rooms. (See PAPER-hangings.) *Stamped paper,* to write obligations, deeds, and contracts upon. (See STAMP.) *Ruled paper,* for books of accounts, &c. To which may be added *cut paper,* and *gilt paper,* for letters, &c. See GILDING of Paper.

PAPER, *Blue,* is a sort used by tradesmen to wrap up goods; as sugar-loaves, pieces of linen, &c.

PAPER, *Blotting,* is paper not sized, and in which therefore ink readily sinks or spreads. It is used in books of account, &c. in lieu of sand, to prevent blotting and disfiguring the opposite pages. The same kind is likewise used by apothecaries in filtrating juices, and other matters, for which the *manica Hippocratis* is not so proper.

PAPER, *Teint,* or *demi-teint,* for designing on, is either *brown, blue, or bisterd.*

PAPER, *Bisterd,* is white paper washed over with a sponge dipped in foot-water. Its use is to save the labour of the crayon, in places which are to be shadowed the same depth with the teint of this paper. For light places, they are made thereon with white chalk. Vide Corneil. Elem. de la Peint. Prat. cap. 15, p. 35, seq.

PAPER, *Marbled,* is a sort of paper variously stained, or painted as it were with divers colours; made by applying a sheet on the surface of a liquor wherein colours diluted with oil or ox's gall are suspended.

The manner of making it is thus: a trough is provided of the shape and dimensions of a sheet of the paper to be marbled, and about four fingers deep: this is made of lead or wood well joined, and pitched or primed to contain the liquor. For the liquor, a quarter of a pound of gum tragacanth is macerated four or five days in fair water; this they stir from time to time, and add to it daily fresh water, till it be of a consistency somewhat thinner than oil; then they strain it into the trough.

The colours to be applied thereon, for blue, are indigo ground up with white lead, or Prussian blue and verditer may be used: for green, indigo and orpiment, the one ground and the other tempered, mixed and boiled together with common water; or verdigris, a mixture of Dutch pink and Prussian blue, or verditer, in different proportions: for yellow, orpiment bruised and tempered; or Dutch pink and yellow ochre: for red, the finest lake, ground with raspings of Brasil wood, which has been prepared by boiling half a day; or carmine, rose pink, vermillion, and red-lead; the two latter of which should be mixed with rose pink or lake, to bring them to a softer cast: for orange, orange lake, or a mixture of vermillion, or red lead, with Dutch pink: for purple, rose pink and Prussian blue. Into all these colours, properly ground with spirit of wine, they put a little ox or fish gall, which is two or three days old; and if the colours dilate not of themselves sufficiently, they add more gall: on the contrary, if they spread too much, the gall is over-dosed, and must be corrected by adding more of the colour without gall.

For the operation of marbling, when the guin is well settled in the trough, they extend a sheet of paper, and plunge it very shallow into the liquor, suddenly lifting it out again, in order to stir up, and raise the subsiding gum towards the surface, and for the more universal impregnating of the liquor.

This done, and all the colours ranged in gallipots on the table, where also the trough is placed, they begin by dipping a brush of hog's hair into any colour, commonly the blue first, and sprinkle it on the surface of the liquor: if the colour has been rightly prepared, it will dilate itself duly therein. This done, the red is applied in the like manner, but with another pencil: after this the yellow: lastly the green. For white, it is made by only sprinkling fair water, mixed with ox's gall, over the liquor.

When all the colours are thus floating on the liquor, to give them that agreeable cambletting, which we admire in marble paper, they use a pointed stick; which being applied by drawing it from one side of the trough to the other, with address, stirs up the liquor and fluctuating colours; then with a comb, made of wood, about five inches long, with brass teeth, about two inches in length, and a quarter of an inch distant from each other, taken by the head with both hands, they comb the surface of the liquor in the trough, from one extreme to another, permitting only the teeth to enter: this being performed with a gentle and uniform motion, makes those clouds and undulations on which the beauty of the paper depends.

If it be farther desired to have the colours lie in any other fantastical posture, representing serpents, or the like, it is effected with the pointed stick above-mentioned, by drawing it over what has been already combed; but this must be done with a dextrous hand, and with a shallow dip into the liquor, circling, as if you would draw some flourish, or figured letter.

Lastly, the colours being in this posture, the operator displays and applies on them a sheet of white moistened paper; to do which, artful like, requires a sleight only to be obtained by practice; because the surfaces of the liquor and the paper are to meet equally in all parts; which done, before the colours have time to soak through, which, unless the paper be very thick, will be in the space of two or three pulses, he lifts up the paper nimbly, and with an even hand; and then, after spreading it a while on a board, hangs it on a line to dry; which, when sufficiently done, they first rub it with a little soap, and then polish it with a marble

stone, ivory knob, or glass polishers; or with a burnisher of jasper or agate.

It must be observed, that the sprinkling of the colours is to be renewed, and all the other ceremonies performed with the stick and comb, at every application of fresh paper, by reason that every paper takes off all the colour from the liquor. Vide Kirch. de Luce & Umbra, lib. x. par. 2. cap. 4. Merr. Observ. on Neri de Art. Vitr. cap. 42. p. 312. Hought. Collect. tom. ii. p. 419, seq.

Some attempts have been made to enrich the marbling, by mixing gold and silver with the colours; which succeeded well in many attempts in the French king's library, though the expence has hindered the practice from obtaining. Savar. ubi supra.

Mr. Boyle tells us, that paper, besides its common uses, may be made into frames for pictures, fine embossed work, and other parts of furniture. For this purpose, a convenient quantity of the best white sort may be steeped for two or three days in water, till it becomes very soft; then reducing it by the mortar and hot water into a thin pulp, it is laid on a sieve to draw off its superfluous moisture; then putting it into warm water, wherein a considerable quantity of fresh glue, or common size, has been dissolved, it may afterwards be put into moulds to acquire the designed figure; and when taken out may be strengthened, as occasion requires, with plaster, or moistened chalk, and when dry painted or overlaid.

This hint is since improved into a regular manufacture, under the name of *papier machée*.

Another use of paper is to stop up cracks or fissures in wooden vessels to hold water; for, in this case, it will forcibly dilate, and fill the place in which it is to lodge.

PAPER, *Chinese*, is of various sorts; some is made of the rinds or barks of trees, especially those abounding in sap, as the mulberry-tree and elm, but chiefly of the bamboo and cotton-tree; but, in reality, almost each province has its peculiar paper; that of Se-tchuen is made of hemp; that of Fo-kiang, of soft bamboo; that used in the northern provinces, of the bark of the mulberry-tree; that of the province of Che-kiang, of wheat or rice-straw; that of the province of Kiang-nang, of the skin found in the silk-worms balls; in fine, in the province of Hu-quang, the tre-chu, or ko-chu, furnishes the principal material for paper.

As to PAPERS made of the barks of trees; the manner of their preparation may be exemplified in the instance of that of the bamboo, a tree of the cane or reed kind, being hollow, and divided into joints; but much larger, smoother, harder, and stronger, than any other sort of reed.

For this paper, they ordinarily only use the second coat or skin of the bark, which is soft and white; this they beat in fair water to a pulp, which they take up in very large moulds or frames, so that they have sheets ten or twelve feet long, and sometimes more. They are completed by dipping them sheet by sheet in alum-water, which serves instead of the size used among us; and not only hinders the paper from too freely imbibing the ink, but gives it that lustre which at first sight makes it look silvered, or at least varnished over.

The paper thus made is white, soft, and close, without the least roughness to stop the motion of the pen, or occasion the rising of any of its fibres; though being made of the bark of a tree, it cracks more easily than the European paper: add that it is more apt to take moisture, that the dust sticks to it; and that the worms soon get into it; to prevent which last inconveniency, they are obliged often to beat their books and expose them to the sun. Add, that its thinness making it liable to be soon worn out, the Chinese

are under a frequent necessity of renewing their books, by fresh impressions taken from their blocks. Vide Le Compt. Nouv. Mem. sur Chin. lett. 7. Kust. Bibl. Nov. Libr. an. 1697, p. 67, seq. Lett. Edif. & Cur. tom. xix. p. 479.

But the paper of the bamboo, it is to be observed, is neither the best, nor the most used, in China. In the former of these respects, it yields the priority to the paper made of the cotton-shrub, which is the whitest and finest, and at the same time least subject to the inconveniencies above-mentioned; because it keeps as well, and is as durable, as the European paper.

Dr. Grew thinks we may have plants in England, which contain a down that in all probability would make as fine a paper as that made by the Chinese, from their cotton-shrub. By which it appears he mistakenly imagined that the Chinese paper was made not from the rind of the cotton-shrub, but from the down or cotton itself. Vide Grew Mus. Reg. Soc. par. ii. sect. i. cap. 5. p. 215.

But the paper in most common use in China, is that made of the tree called *chu ku*, or *ku chu*, which Du Halde compares, first, to a mulberry-tree, then to a fig-tree, then to a sycamore tree, and lastly, to increase the embarrassment, to a strawberry-tree. By all which, we know no more of it than if he had said nothing about it.

The method of preparing it for paper, is by first scraping off lightly the thin outside of the tree, which is greenish: then they take off the inner rind in long thin slips, which they blanch in water, and in the sun; and afterwards prepare them in the same manner as the bamboo. It must not be forgot, that in the other trees it is only the inward bark that serves for making paper; but the bamboo, as well as the cotton-shrub, have this peculiarity, that not only their bark, but their whole substance, may be employed, by means of the following preparations.

Out of a wood of the largest bamboos, they select shoots of a year's growth, which are about the thickness of the calf of a man's leg: these they strip of their first green rind, and split them into straight pieces of six or seven feet long; the pieces thus cleft, they steep in a pond of muddy water, till they rot and grow soft by the maceration. In a fortnight they take them out, wash them in clean water, spread them in a large dry ditch, and cover them with lime for a few days; then they take them out again, and having washed them a second time, they slip them into small filaments, which they expose in the sun to dry and whiten: they throw them into large coppers, where they are thoroughly boiled: and lastly, reduce them by the strokes of large hammers to a thin palle or pulp.

After this, they take some shoots of a plant called *ko-teng*; they soak them four or five days in water, till there come out an unctuous sily sort of juice; this they mix with the pulp of which the paper is to be made, somewhat in the same manner as painters temper their colours; care being taken not to put in too much, nor too little of it; on which the goodness of the paper much depends.

When they have mixed the juice of ko-teng with the cleft bamboo, and beaten the whole till it resembles a thick clammy water, they pour it into a large deep reservoir, consisting of four walls, raised breast high, and having the sides and bottom so cemented, that the liquor cannot run out, nor soak in.

This being done, and the workmen placed at the sides of the reservoir, they dip in their moulds, and take up the surface of the liquor, which almost instantly becomes paper; the mucilaginous and gluey juice of the ko-teng binding the parts, and rendering the paper compact, soft, and glossy, qualities

PAPER.

qualities which the European paper never has when first made.

To harden the sheets, and make them bear ink, they dip them into alum water: this operation is called *fining*, from the Chinese word *fan*, which signifies *alum*. The manner is this: six ounces of fish glue, cut very small, are put in divers porringers of water, which they afterwards boil up, stirring it all the time to prevent lumps: when the whole is reduced to a liquid substance, they throw into it three quarters of a pound of calcined alum, which they melt and incorporate with it.

This mixture is next poured into a wide basin, across which is laid a small round stick; then they shut the edge of each sheet in another cleft from end to end, and in this manner dip the sheet, gently drawing it out as soon as it is wetted, by sliding it over the round stick. When the whole sheet has been passed nimbly through this liquor, which makes it whiter, and more compact, the long stick that holds the sheet by the edge is stuck into a hole in the wall, and the sheet hung up to dry.

As to the mould, with which they take up the sheet, its frame is so contrived, that it may be raised or lowered at pleasure; and its bottom is not made with wire as ours, but with little slender slips of bamboo, drawn several times through holes made in a steel plate, whereby they are rendered as fine as wire: they are then boiled in oil till thoroughly soaked, that the mould may enter lightly into the water, and not sink deeper than is requisite to take up matter enough for a sheet.

To make sheets of any extraordinary size, care is taken to have a reservoir and mould large in proportion. This mould is sustained by strings which pass over the pulley; and the moment these pull up the frame, the workmen, placed aside the reservoir, assist to take the sheet off; working together in a regular manner. See PAPER *supra*.

For drying the sheets when taken off, they have a hollow wall, whose sides are well whitened: at one end of it is an aperture, through which, by means of a pipe, they convey the heat of a neighbouring furnace: and at the opposite end is a small vent to let out the smoke. By help of this sort of stove, they dry the paper almost as fast as it is made.

Silvering of paper, as it is called, is another secret among the Chinese, practised at a very small charge, and without using any silver. In order to this, they take two scruples of glue, made of neats-leather, one scruple of alum, and half a pint of clean water: these they simmer over a slow fire, till the water is consumed, that is, till no more steam arises; then on a smooth table they spread some sheets of paper, and on this, with a pencil, they apply two or three layers of the glue: then they take a powder made of talc boiled, and mixed with one-third the quantity of alum; the two are ground together, sifted, and the powder boiled again in water, then dried in the sun, and lastly pounded again. This powder they sift through a fine sieve, spreading it uniformly on the sheets prepared as above: after which they hang them in the shade to dry; and this effected, they lay them again on the table, and rub them gently with clean cotton to take off the superfluous talc, which serves a second time for the same purpose. With this powder, diluted in water, mixed with glue and alum, they draw any figures at fancy on the paper. Vide Du Halde, *Descr. Chin.* tom. i. p. 368.

The era of the invention of paper, among the Chinese, was, according to Martini, about 160 years before Christ.

PAPER, *Japan*. Paper is made in Japan of the bark of the *morus papyrifera sativa*, or *true paper-tree*, after the following manner: every year, when the leaves are fallen off,

or in the tenth Japanese month, which commonly answers to our December, the young shoots, which are very succulent, are cut off into sticks about three feet long, or something less, and put together in bundles to be afterwards boiled with water and ashes. If they should grow dry before they can be boiled, they must be first soaked in common water, for about twenty-four hours, and then boiled. These bundles, or faggots, are tied close together, and put upright into a large kettle, which must be very well covered, and then they are boiled till the bark shrinks so far as to let about half an inch of the wood appear naked at the top. When the sticks have all been sufficiently boiled, they are taken out of the water, and exposed to the air till they grow cold, then they are slit open lengthways, for the bark to be taken off, which being done, the wood is thrown away as useless, but the bark dried and carefully preserved, as being the substance out of which they are in time to take their paper, by letting it undergo a farther preparation, consisting in cleansing it a-new, and afterwards picking out the better from the worse. In order to this, it is soaked in water three or four hours, and being grown soft, the blackish skin which covers it is scraped off, together with the green surface, of what remains, which is done with a knife, which they call *kaadsi kusaggi*, that is, a *kaadsi razor*; at the same time also the stronger bark, which is a full year's growth, is separated from the thinner, which covered the younger branches, the former yielding the best and whitest paper, the latter only a dark and indifferent sort. If there is any bark of more than a year's growth, mixed with the rest, it is likewise picked out, and laid aside as yielding a coarser and worse sort of paper; all gross knotty particles, and whatever else looks in the least faulty and discoloured, is picked out at the same time, to be kept with the last coarse matter.

After the bark has been sufficiently cleansed, and prepared and sorted according to its different degrees of goodness, it must be boiled in clear ley. From the time it begins to boil, they keep perpetually stirring it with a strong reed, pouring from time to time so much fresh ley in as is necessary to condense the evaporation, and to supply what hath been already lost by it; this boiling must be continued till the matter is grown so tender, that being but slightly touched with the finger it will dissolve and separate into flocks and fibres. Their ley is made of any sort of ashes, in the following manner: two pieces of wood are laid across over a tub and covered with straw, on which they lay wet ashes, and then pour boiling hot water upon it, which, as it runs through the straw into the tub underneath, is imbued with the saline particles of the ashes, and makes what they call ley.

After boiling the bark as above described, follows the washing of it, which is of no small consequence in paper-making, and must be managed with great judgment and attention; if it hath not been washed long enough, the paper will be strong, indeed, and of a good body, but coarse and of little value; and if, on the contrary, the washing has been too long continued, it will afford a whiter paper, but such as will not bear ink. This part of paper-making, therefore, must be managed with the greatest care and judgment, so as to keep to a middle degree, and avoid either extreme. They wash it in a river, putting the bark into a sort of sieve, which will let the water run through, and stirring it continually with the hands and arms, till it comes to be diluted into a delicate soft pulp, or mucilage. For the finer sort of paper the washing must be repeated; but the bark must be put into a piece of linen, instead of a sieve, because the longer the washing is continued the more the bark

PAPER.

bark is divided, and would come at last to be so thin and minute, that it would run out at the holes of the sieve and be lost, and at the same time also, what hard knots or flocks, and other heterogeneous useless particles remain, must be carefully picked out, and put up with a coarser sort of bark for worse paper. The bark having been sufficiently washed, is put upon a thick, smooth, wooden table, in order to its being beaten with sticks of the hard *kufnoki* wood, which is commonly done by two or three people, until it is wrought fine enough, and becomes withal so thin, as to resemble a pulp of baked paper, which being put into water will dissolve and disperse like meal.

The bark, being thus prepared, is put into a narrow tub, with the fat slimy infusion of rice, and the infusion of the *oreni* root, which likewise is very slimy and mucilaginous. These three things being put together must be stirred with a thin clean reed, till they are thoroughly mixed and wrought into an uniform liquid substance, of a good consistence; this succeeds best in a narrow tub, but afterwards the mixture is put into a larger one, which is not unlike those made use of in our paper-mills; out of this tub the leaves are taken off one by one, on proper patterns made of bulrushes, instead of brass wire, called *mys*. Nothing remains now but a proper management in drying them; in order to this they are laid up in heaps, upon a table covered with a double matt, and a small piece of reed is put between every leaf, which standing out a little way, serves, in time, to lift them up conveniently, and take them off singly. Every heap is covered with a small plank or board, of the same shape and size with the paper, on which are laid weights, first, indeed, small ones, lest the leaves, being then wet and tender, should be pressed together into one lump, but, by degrees, more and heavier, to press and squeeze out all the water. The next day the weights are taken off, the leaves are lifted up one by one, by the help of the small stick above mentioned, and with the palm of the hand, clapped to long rough planks made for this purpose, which they will easily stick to, because of the little humidity still remaining. After this manner they are exposed to the sun, and when quite dry, taken off, laid up in heaps, pared round, and so kept for use or sale.

It has been observed, that the infusion of rice, with a gentle friction, is necessary for this operation, because of its white colour, and a certain clammy fatness, which at once gives the paper a good consistence, and pleasing whiteness. The simple infusion of rice-flour will not do it, because it wants that clamminess, which, however, is a very necessary quality. The infusion spoken of is made in an unglazed earthen pot, wherein the rice grains are soaked in water, and the pot afterwards shaken, gently at first, but stronger by degrees; at last, fresh cold water is poured upon it, and the whole percolated through a piece of linen. The remainder must go under the same operation again, fresh water being put to it, and this is repeated so long as there is any clamminess remaining in the rice. The Japanese rice is by much the best for this purpose, as being the whitest and fattest sort growing in Asia.

The infusion of the *oreni* root is made after the following manner: the root pounded, or cut small, is put into fresh water, which in one night's time turns mucilaginous, and becomes fit for use, after it has been strained through a piece of linen. The different seasons of the year require a different quantity of water to be mixed with the root. They say the whole art depends entirely upon this. In the summer, when the heat of the air dissolves the jelly, and makes it more fluid, a greater quantity is required, and less in proportion in the winter, and in cold weather; too much of this infu-

sion mixed with the other ingredients will make the paper thinner in proportion; too little, on the contrary, will make it too thick, therefore a middle quantity is required to make a good paper, and of an equal thickness; however, upon taking out a few leaves, they can easily see whether they have put too much or too little of it. Instead of the *oreni* root, which sometimes, at the beginning of the summer, grows very scarce, the paper-makers make use of a creeping shrub, called *sane kadfura*, the leaves of which yield a mucilage in great plenty, though not altogether so good for this purpose, as the mucilage of the above mentioned *oreni* root. They also use the *juncus sativus*, which is cultivated in Japan with great care and industry. It grows tall, thin, and strong; the Japanese make sails of it, and very fine matts to cover their floors.

It hath been observed above, that when the leaves are fresh taken off from the patterns, they are laid up in heaps, on a table covered with two matts. These two matts must be of a different fabric, one, which lies lowermost, is coarser, but the other, which lies uppermost, is thinner, made of thin, slender bulrushes, which must not be twisted too close one to another, but so as to let the water run through with ease, and very thin, not to leave any impression upon the paper.

A coarser sort of paper, proper to wrap up goods, and for several other uses, is made of the bark of the *kadse kadfura* shrub, after the method above described. The Japanese paper is very tight and strong, and will bear being twisted into ropes.

A thick strong sort of paper is sold at Siriga (one of the greatest towns in Japan, and the capital of the province of that name), which is very neatly painted and folded up, so much in a piece as is wanted for a suit; it looks so like silken or woollen stuff, that it might be mistaken easily for them. A thin neat sort of paper, which hath a yellowish cast, is made in China and Tonquin, of cotton and bamboos: at Siam, the Siamites make their paper of the bark of the *pliook-kloi* tree, of which they have two sorts, one black and the other white, both very coarse, rude and simple, as they themselves are. They fold it up into books, much after the same manner fans are folded, and write on both sides, not, indeed, with a pencil, in imitation of those more polite nations who live farther east, but with a rude stylus made of clay.

Thus far we have given a description of the way of making paper in the East, which the late learned Bemannus was so desirous to know, and so earnestly intreated travellers to enquire into, being, however, mistaken, in supposing that it was made of cotton, whereas it evidently appears by this account, that all the nations beyond the Ganges make it of the bark of trees and shrubs. The other Asiatic nations on this side the Ganges, the black inhabitants of the most southernmost parts excepted, make their paper of old rags of cotton stuff, and their method differs nothing from ours in Europe, except that it is more simple, and the instruments they make use of are grosser. See *SON*.

PAPER, Flock, is a kind of paper-hanging, lately invented, which is embossed by means of chopt cloth. The paper designed for receiving the flock is generally first prepared with a varnish ground, of a proper colour; and it is not uncommon to print some mosaic, or other small running figure, in colours, on the ground, before the flock is laid on: this may be done with any pigment of the colour desired, tempered in varnish, and laid on by a print cut for the purpose.

The manner of laying on the flock is either by means of a print, or by a stencil. But as the stencil can execute nothing
but

PAPER.

but detached parts, and consequently is unfit for all designs where running work, scrolls, or other more complicated ornaments are introduced; it is extremely confined, with respect to the nature of the designs for which it can be employed; and the print is therefore most generally preferred. The method of laying on the flock by means of a print is this: a wooden print being cut (see *PAPER-hangings*) in such manner, that the part of the design, which is intended for the flock, may project beyond the rest of the surface, the varnish is put on a block covered with leather, or oil-cloth, and the print is then used to lay the varnish on all the parts where the flock is to be fixed. The sheet, thus prepared by the varnished impression, is now to be removed to another block or table; and to be strewn over with flock: which is afterwards to be gently compressed by a board, or some other flat body, to make the varnish take the better hold of it. Then the sheet is to be hung on a frame till the varnish be perfectly dry; at which time the superfluous part of the flock is to be brushed off by a soft camel's-hair brush, and the proper flock will be found to adhere in a very strong manner. When the stencil is used, the same method is to be pursued: the varnish for holding the flock being laid on by that instead of a print; and the flock afterwards strewn upon it, as in the other case.

The usual method of preparing the flock is, by cutting woollen rags, or pieces of cloth, with the hand, by means of a large bill or chopping-knife. But it is much more easily and better done by a machine; which may be worked by a horse-mill, at the same time such mill is employed for cutting diamonds, or any other similar purpose. In such case, the construction of that part of the machine, which is made for the cutting the flock, is this.

A box is made for containing the rags or cloth to be cut; which is open at the top; and of such size, as may best suit the quantity of rags that the force employed can cut. A blade is also to be made, the length of which is to be equal to the breadth of the box; and it should be strong; and must be charged with as great a weight as the force employed can be made to raise with a quick motion. The box being filled with the rags or cloth to be cut, is placed under the blade, and made to move by hitches, after the stroke of the blade is given, just so far as where it is proper the blade should again cut the cloth or rags; while, at the same time, the blade is lifted up, and let fall on the cloth, which it cuts through, till by successive strokes, and the progressive motion of the box under it, the whole quantity of cloth or rags in the box has been cut. The box must then be turned, so that one of the sides may become the front; and the operation must be repeated; by which means the cloth or rags, having been cut both ways, will be reduced to the state in which the matter is called flock; and fit to be employed for the purpose of paper-hangings. The work necessary for conveying from the principal mover in the mill, the motion for thrusting forward the box, and raising the blade, may be easily supplied by any ingenious wheelwright, and need not therefore be particularly described here.

There is a kind of counterfeit flock-paper, which, when well managed, has very much the same effect to the eye as the real: though done with less expence. The manner of making this sort is, by laying a ground of varnish on the paper; and having afterwards printed the design of the flock in varnish, in the same manner as for true; instead of the flock, some pigment, or dry colour, of the same hue with the flock required by the design, but somewhat of a darker shade, being well powdered, is strewed upon the printed varnish, and produces greatly the same appearance. Handmaid to the Arts, vol. ii. p. 458, &c.

PAPER-hangings are of several kinds; some of which are made in the representation of stucco-work, for covering ceilings, or the sides of halls, stair-cases, passages, &c. and others in imitation of velvet, damask, brocades, chintzes, or such silks and stuffs as are employed for hanging rooms.

The principal difference in the manufacture lies in the grounds; some of which are laid in varnish, and others in the common vehicles for water colours.

The kind of paper employed for this use is a sort of cartoon, manufactured for the purpose, which must be stamped before it be painted. 1 Geo. stat. 2. c. 36.

The colours proper to be used for painting paper-hangings are all those that can be used in water and varnish. But for common designs done with water only, the following are most proper.

For red, lake, vermilion, rose-pink, and red-ochre: for blue, Prussian blue, verditer, and indigo: for yellow, the yellow-berry wash, Dutch pink, and yellow ochre: for green, verdigris, or a mixture of the blue colours with the yellow colours, particularly with the yellow-berry wash: for orange, vermilion, or red lead, with Dutch pink: for purple, a wash made of logwood, or a mixture of the lake, or rose-pink, with deep coloured Prussian blue, or with indigo: for black, ivory black, and in some nicer cases lamp-black: for white, whiting: and for the heightnings, white-lead.

Where great brightness is required, the lake should be used for the crimson red, and Prussian blue for the blue; but for many purposes, rose-pink used alone for the crimson red, and indigo mixt with whiting for the blue, will answer the purpose with greatly less expence. The lake, rose-pink, Prussian blue, and Dutch pink, intended for this use, should be procured in a moist state.

The colours used in varnish may be the same as those used in water; but for this purpose, those just mentioned should be obtained dry.

As for the vehicles of the colours; when water is used, it must be inspissated with size and gum Arabic or Senegal. When burnish is used, it must be formed of oil of turpentine, and the resins and gums which will dissolve in that menstruum. With respect to the grounds for paper hanging, those that are laid in water are made by mixing whiting with the size above mentioned, and laying it on the paper, with a proper brush, in the most even manner. Nothing more is necessary, when the ground is to be left white; and the paper being hung on a proper frame, till it be dry, is fit to be painted. When coloured grounds are wanted, the same method must be pursued; and the ground of whiting first laid; except that, in paler colours, a second coating may sometimes be spared, by mixing some strong colour with the whiting. But where a greater force of colour is wanted, the pigment or colouring substance must be tempered with the proper vehicle, and then spread over the white coat. The varnish grounds are made much in the same manner, by mixing the proper colour with the varnish, and spreading it on the paper.

There are three methods by which paper-hangings are painted: the first by printing on the colours; the second by using the stencil; and the third by laying them on with a pencil, as in other kinds of painting.

When the colours are laid on by printing, the impression is made by wooden prints; which are cut in such manner, that the figure to be expressed is made to project from the surface, by cutting away all the other part. This, being charged with the colours tempered with their proper vehicle, by letting the print gently down on a block, on which the colour is previously spread, conveys it from thence to the ground of the paper, on which it is made to fall more forcibly by means of its weight, and the effort of the arm of the

person

PAPER.

person who uses the print. The manner of doing this, when more particularly explained, is thus.

The paper being properly prepared by a ground of whitening, colour, or varnish, is laid on a proper block, on which a piece of leather is strained. The colour, mixed with its proper vehicle, is spread on another piece of leather, or oil cloth, laid on a flat block, somewhat larger than the print; which is done by a boy or man who attends for that purpose; and having the colour by him, in a pot, spreads it with a brush on the block betwixt every stroke and impression the printer makes. The print is previously cut in such manner, correspondently to the design of the painting, that there shall be a projection on the surface answering to every part, where that colour intended to be conveyed by this print is necessary. The printer then takes the print either in his right hand, or, when too heavy to be so managed, in both, and drops it gently on the block, just charged with colour; from whence he again immediately raises it in the most perpendicular direction, and lets it fall in the strongest, though most even manner, he can, on the paper; increasing the force by all the additional velocity he can give the print. When this is done, the sheet printed is immediately taken off the block, and hung up to dry; and another being put in its place, the same operation is repeated, till the whole quantity of paper be printed. It is easy to conclude, that there must be as many separate prints, as there are colours to be printed; and they are to be used successively in the same manner as the first. But where there are more than one, great care must be taken, after the first, to let the print fall exactly in the same part of the paper, as that which went before: otherwise the figure of the design would be brought into irregularity and confusion. In common paper of low price, it is usual, therefore, to print only the outlines, and lay on the rest of the colours by stencilling; which both saves the expence of cutting more prints; and can be practised by common workmen, not requiring the great care and dexterity necessary to the using of prints.

The manner of stencilling the colours is this. The figure, which all the parts of any particular colour make in the design to be painted, is to be cut out, in a piece of thin leather, or oil cloth. These pieces of leather, or oil cloth, are called stencils; and being laid flat on the sheets of paper to be printed, spread on a table or floor, are to be rubbed over with the colour, properly tempered, by means of a large brush. The colour passing over the whole is consequently spread on those parts of the paper where the cloth or leather is cut away, and give the same effect as if laid on by a print. This is nevertheless only practicable, without great care, in parts where there are only detached masses, or spots of colours: for where there are small continued lines, or parts that run one into another, it is difficult to preserve the connection or continuity of the parts of the cloth, or to keep the smaller corners close down to the paper; and therefore, in such cases, prints are preferable. Stencilling is indeed a cheaper method of ridding coarse work than printing; but without such extraordinary attention and trouble, as render it equally difficult with printing, it is far less beautiful and exact in the effect. For the outline of the spots of colour want that sharpness and regularity that are given by prints; besides the frequent extralinations, or deviations from the just figure, which happen by the original misplacing of the stencils, or the shifting the place of them during the operation.

Pencilling is only used in the case of nicer work, such as the better imitations of the India paper. It is performed in the same manner as other paintings in water, or varnish.

VOL. XXVI.

It is sometimes used only to fill the outlines already formed by printing; where the price of the colour, or the exactness of the manner in which it is required to be laid on, render the stencilling or printing it less proper: at other times it is used for forming or delineating some parts of the design, where a spirit of freedom and variety, not to be had in printed outlines, are desired to be had in the work.

The manner of proceeding with these several methods is, in common work, to stencil first all parts of the colour in the design, and to give an outline to the whole at last, by printing with brown or black: but where there is any running part of the designs, such as scrolls, or the stems or stalks of creeping plants, or flowers, which are to be printed in any other colour than brown or black, a print must be used for them; though, if they require only brown or black, they may be done by the same print which makes the outlines.

In the finer paper, where several colours are laid on with the prints, the principal colour is begun with; and the rest taken successively; the print for the outline being laid on last. In cases where the pencil is to be used, the outline is nevertheless to be made before the colours are laid on by the pencil, if such outline is to be made at all; because that is the guide to the person who lays on the colour; and confines them to a correctness.

In paper printed with designs in chiaro-scuro, such as the imitation of stucco work, and bas-relievos, the order of printing must be, to lay on the ground colour first; afterwards the shades; and lastly the lights: and the same rule of succession must be observed where the colours are pencilled. *Handmaid to the Arts*, vol. ii. p. 445, &c.

Paper-hangings may be spangled with that kind of talc called isinglafs, which being reduced to a gross flaky powder, has a great resemblance to thin silver scales or powder. It is laid on by strewing over the varnish, which forms the ground, before it begins to dry. When it is laid on in a figure, for the representation of embroidery, the figure must be printed in varnish, and the talc strewed upon it, and treated like flock. Smalt may also be used in the same manner as flock or spangles. But hangings of this kind are now little used.

PAPER, ruled for the reception of musical characters. Rousseau was the first, we believe, who made this a lexicographical article. Five parallel lines form what musicians call the *staff*; upon which lines in the spaces are disposed all the notes of the time-table and their places in the general scale, regulated by clefs at the beginning of each staff.

All our music for keyed instruments, till the latter end of the seventeenth century, was written on staves of six lines, of which the lowest in the treble clef, and highest in the base, was the middle C of the general scale. See *STAFF*.

Almost all the music paper in Italy is ten-staved, for the convenience of scoring songs with four instrumental parts: as the violino primo, violino secondo, alto viola, voice part, and base. These being linked together by braces, are easily found, not only by the fingers, but by the instrumental performers, by whom they may be accompanied from the score.

The English have paper ruled on all forms and number of staves. In general, for violins, of 12 staves, and for the piano forte, and vocal parts, long quarto, as it is more on a level with the eyes, and conceals the visage of the performers less from the audience.

PAPER, among *Bankers*, and other negociants, is also used for bills of exchange, bank and promissory notes, &c.

Substituting paper for money, and giving the paper an arbitrary

arbitrary value, was the way of paying debts introduced in France by Mr. Law. A royal bank was established, to which people were to carry their money, and receive the value of it in bills, which were to pass current in trade as so much money. (Vide Cheygn. Scienc. des Perf. de la Cour, tom. ii. p. 292.) It was made confiscation of goods, and the gallies, for any man to keep above forty livres by him of any but paper money. When the regent was told what a rage was spirited up against him about the arrears of making paper current, and how openly the people threatened him, he answered coolly, the French were like watch-dogs, they would bark, but not bite: "Les François ressemblent aux chiens a garde, ils aboyent, mais ne mordent pas." Misc. Lett. tom. iv. p. 16.

PAPER-Books, in *Law*, are the issues in law, &c. upon special pleadings, made up by the clerk of the papers who is an officer for that purpose.

Upon an issue in law, it is termed the "Demurrer-book." The clerks of the papers of the court of king's bench, in all copies of pleas and paper-books made up by them, shall subscribe to such paper-books the names of the counsel who have signed such pleas, as well on behalf of the plaintiff as defendant: and in all paper-books delivered to the judges of the court, the names of the council who signed these pleas are to be subscribed to the books, by the clerks or attorneys who deliver the same. R. Pafch. Car. 2. 2 Lill. Abr. 268.

PAPER-Frames, in *Gardening*, are such as are formed with oiled paper, upon a slight frame-work of thin slips of wood. These frames are useful for several purposes in the early spring and summer season; such as in defending late hot-beds, and sometimes in particular natural ground beds of curious tender plants, seeds, cuttings, &c.

When formed as above, they are made, either in a ridge manner, with two sloping sides, longways, or arch-fashion, in dimensions from five to ten feet in length, and three to four in width, and two to three feet in perpendicular height; the wood-work is covered with large sheets of strong white paper, pasted on securely, and, when dry, brushed over regularly with linseed oil, to resist and shoot off the falling wet of rains and dews, and to render them more pellucid, so as to admit the rays of light, and the heat of the sun, in a proper degree. When thus prepared, and perfectly dry, they are ready for placing over the beds for the purposes required; in which the paper continues durable generally only one season; but the frame-work will last several years, by being fresh papered.

These kinds of temporary frames are also useful in some of the hand-glass crops of melons, and occasionally in those of cucumbers, but more generally in the former; which after having advanced in growth, to fill and extend beyond the compass of the hand-glasses, they should be removed, and the paper-frames placed over the bed, covering it wholly in width and length, the runners of the plants being trained out regularly along the surface; continuing them constantly over the plants, which are thereby protected from external injuries, and inclement weather, either cold or excessive rains, winds, &c. likewise from the too powerful heat of the sun. See *CUCUMIS Melo*.

They may also be used for late hot-bed cucumbers, when in want of garden-frames or hand-glasses for the purpose, being placed over the bed, at once finally to remain: and with proper care in giving occasional air, water, and covering over the frames with mats in cold nights, and very hard rains, &c. cucumbers may be raised in a tolerable manner.

They may likewise be employed occasionally, in default of others, in the raising moit of the less hardy or tenderer

annuals, both in sowing them into hot-beds, and warm borders of natural earth.

Paper-frames may likewise be used advantageously in pricking out many sorts of small tender seedling plants in the hot summer months, to defend them from casual unfavourable night air, heavy rains, &c. and afford a fine growing shade from the hot rays of the mid-day sun. The same kind of frames may still further be beneficial in raising many sorts of tender exotics, from small cuttings and slips in summer, both of the woody, herbaceous, and succulent kinds, either planted in hot-beds, or in the natural earth, as the different kinds may require: which being covered close with them, they exclude the outward air, admit the light and influence of the sun in a proper degree, and at the same time afford a peculiar kindly shade.

These frames are chiefly made in the forms mentioned above, in an open manner, having the ribs or spars twelve inches asunder, first forming a bottom frame, rather stronger than the other parts, with a ridge-piece supported at a proper height, extending longways in the middle; then narrow side rafters, arranged from the bottom to the ridge-rail at top, a foot distant, both for the advantage of pasting the paper regularly, and to admit a proper degree of light between them through the paper: but when of great length, it is proper to have one or two pannels on one side, eighteen inches or two feet in width, to open outward with hinges, convenient for admitting air, and performing other occasional culture: the whole being thus formed in the wood-work, it is then proper to extend lines of packthread cross-ways of the ribs, going round each, level or even with the upper surface of the frame, continuing two or three rows a foot asunder, from the lower part upward, drawing other lines, crossing and intersecting these at the same distance, regularly between the ribs of the frame-work; which arrangement of the lines is of essential service for the more effectual support of the paper when pasted on the frame, and strengthening it against the power of winds and heavy rains. The paper for this use should be of the larger strong printing or demy kind; which, previously to pasting on the frame, should be moderately damped with water, that it may not sink in hollows after being fixed; and as soon as thus prepared, it should be pasted on, sheet and sheet, in a regular manner, one large sheet and a half, or two at most, generally ranging from the bottom to top, contriving to have whole ones along the ridge-rails above, extending lengthways and across, placed conveniently to join regularly with the other sheets below; and if, at the intersections of the packthreads, a small square or round bit of the same paper be pasted on the inside to the main sheets over that part of the packthread, it will give it additional strength against rain and wind. And, when the paper is thus pasted on, and perfectly dry, it must be oiled over with linseed oil, either raw or boiled; the latter is, however, rather apt to harden the paper, and more liable to crack or break; it may be applied by means of a painter's soft clean brush, dipping lightly, and brushing the outside of the paper all over, equally in every part; then placing the frame in some dry covered shed, to remain till the whole is thoroughly dry; when it may be used.

But though these sorts of frames may be cheap, and answer many little purposes of the gardener, they are not by any means so useful as those made with glass in the usual manner.

PAPER-Mills, (in the court of king's bench) is where the writings belonging to that court are repositd.

PAPER-Money, *Currency*, or *Credit*, as they are indifferently called, in *Political Economy*, is a subject of great importance - and

PAPER CURRENCY.

and no small difficulty. The different and opposite opinions which have been entertained respecting its nature, operation, and advantages and disadvantages, arise, partly from a want of regular and clear reference, in discussing this subject, to the undisputed and fundamental principles of political economy, and partly from not attending to that particular branch of this science to which this subject more especially and closely belongs.

If we examine what the most celebrated and judicious authors have written respecting paper money, we shall find that scarcely any of them have adverted with sufficient precision, and in a sufficiently decided and distinct manner, to the points of difference which exist between paper money issued by government, and which it is rendered obligatory upon the people to receive, and that species of paper money which consists in the notes of bankers, payable to the bearer on demand, and which pass current for the sums specified in them. Of the former kind were the assignats and mandats issued by the government of France during the first years of the Revolution; the paper money issued in America, before and during the war with this country; that which was issued by the Dutch during their long and arduous struggle for independence; and, generally speaking, the paper money which most of the governments on the continent of Europe have found themselves compelled to issue during the French Revolutionary wars. It will be sufficiently evident, from the slightest consideration of these two species of paper money, that they differ completely and essentially in their nature, and that we shall be led far astray from the truth in our discussions on paper currency, if we infer, from what has taken place respecting the one species, what will probably, or must necessarily take place respecting the other species.

In order that in this article we may not be led into any confusion of these two species, it may be proper, before we proceed, to consider the nature, effects, and advantages and disadvantages of bank paper, properly and strictly so called, briefly to discuss the subject of government paper. In general the paper issued by the governments on the continent of Europe, contains no promise to pay either on demand, or at the termination of a limited and specific period; it is, in reality, nothing more than paper stamped with the amount of the sum for which it is to pass current, and with such marks or signatures, as may serve to distinguish what is genuine from what is forged. Here, then, we at once perceive an essential difference between government paper and bank paper: the former is in fact, strictly speaking, *paper money*; or, in other words, paper issued as money instead of the precious metals; the latter, as we shall shew more clearly and fully afterwards, is not, strictly speaking, paper money, though thus denominated in general and popular language, but a written obligation to pay a certain sum of money on demand. Another striking and essential difference between these two species of currency arises from the distinction just pointed out: it is plain, that if the written obligation to pay on demand is given by persons who are of undisputed and established credit, few will be disposed to refuse such written obligation, and therefore this species of paper currency will be received without compulsion, and where the credit of the issuer or issuers is undoubted, equally as metallic money. But the reverse must be the case with regard to government paper money: it contains no obligation to pay metallic money, and therefore will never be preferred to the latter, or taken, unless in cases where there is no alternative. With respect to bank paper, it is sought after; the taking of it is a matter of choice: with regard to government paper, it is compulsory on the people; the government which issues it, tenders it in payment of the debts which it may have contracted, and it

is taken, only because, if it is refused, no other payment will be made. It may, however, be remarked, that another cause operates, in some degree, towards the acceptance and circulation of compulsory government paper; for though this paper contains no obligation or promise to pay in metallic currency, yet as all governments necessarily receive large sums from their subjects in taxes, the unwillingness of the people to receive this compulsory money, is in some measure removed, by the conviction that part of it will be taken back by government in payment of taxes. It will be no difficult matter to perceive what, in almost every case, must be the consequence of an issue of compulsory government paper: as long as any government confines itself to a metallic currency, there is some check to the extravagance and carelessness of its expenditure; for if it be extravagant or careless, it will experience great difficulty in replacing the money it has thus expended; but, on the other hand, if it substitute compulsory paper money in the room of a metallic currency, there can be no check to its carelessness or extravagance, except what arises from the necessary consequence of an excessive issue of paper money.

This consequence it may be proper to consider somewhat at large, since, though all authors are agreed, that an over-issue, and consequent depreciation of compulsory government paper may take place, and, in fact, has almost uniformly occurred, yet great difference of opinion exists, whether, in the case of bank paper, an over-issue and consequent depreciation can possibly occur. In order to keep quite separate and distinct the question of the depreciation of government paper currency, as it arises from a diminution of confidence in the stability of the government which issues it, it will be proper to consider this point; on the supposition, that the confidence of the people in the stability of their government remains the same, during the whole course of the increasing issues of its paper currency; and to confine ourselves solely to the investigation of the consequence produced by an increased issue, and of the mode in which this consequence is produced.

Money, of whatever it is composed, whether of metal or paper, like every other commodity, depends, for its value, on the proportion between it and the commodities for which it is exchanged: if this proportion is altered or deranged, the value of the money will be altered: if, while the quantity of money remains the same, the quantity of the commodities is diminished, the money must necessarily bear a larger proportion to them than it previously did; and consequently, its power to purchase them will be diminished: strictly speaking, however, this cannot, with propriety and precision of language, be denominated a depreciation of the currency, as the variation in its value or power of purchase, arises entirely from a change in the quantity of commodities, and not, in the smallest degree, from any alteration in the quantity of the currency. But if, while the quantity of commodities continues stationary, the amount of the circulating medium is increased, the consequence already pointed out will equally ensue; that is, the power of the currency to purchase commodities will be diminished; and the currency, therefore, so far as it is considered in relation to commodities, will be depreciated. But in all countries where a compulsory government paper is issued, the metals, even when coined, soon are regarded solely as commodities, and are affected, equally with all other commodities, by the increased issue of the paper currency. As, therefore, there is no check to the issue of government paper, and extravagant or careless expenditure calls for increased issue, a depreciation of such paper necessarily ensues; and each stage in the depreciation occasions a further issue, which in its turn in-

PAPER CURRENCY.

creates the depreciation; for when the government perceives that one thousand pounds in paper money, for instance, will no longer command the same quantity of the commodities which it needs, that it would formerly do, but that one thousand and fifty pounds are requisite for this purpose, it is compelled to increase its issue of paper money in this proportion, and this increased issue, again raising the price of commodities, requires a still larger issue, the next time that the government has occasion to make a purchase.

Hitherto we have considered the question of the depreciation of compulsory government paper as arising solely from the circumstance of an increase in the quantity issued: but other causes are operating, at the same time, and towards the production of the same effect; for no compulsory government paper can possess the confidence of the people, (and *value* or *confidence* are absolutely necessary to the character and uses of money,) if that character is to be preserved inviolate, and those uses are to be obtained and preserved in their full and complete effect. On the first issue of compulsory government paper, it is received with reluctance: metallic money is preferred to it, and where it can be procured, a premium is willingly given for it, or, in other words, the compulsory government paper is at a discount. But, if this is the case at the first issue of it, and when the amount is comparatively small, we may easily conceive what will be the consequence, if a larger and constantly increasing quantity is forced on the people: this increasing quantity must act, not only in the manner which we have already described, towards its own depreciation, by the same process in which all commodities are depreciated by increase, but it will also operate towards its own depreciation in another manner. The very first issue of a compulsory government paper is a sufficient proof of an impoverished and embarrassed government; and every future issue, especially if the amount of the issue be increased, is a proof that the poverty and embarrassment of the government are increasing: but it is utterly impossible, that while the poverty and embarrassment of a government are increasing, the confidence which the people repose in it can remain stationary: it must diminish, and a diminution of public confidence in a government displays itself in no respect so unequivocally and materially, as in the estimate which is formed of the value of the paper currency. Here, then, we perceive the real and full state of the case, whenever a government increases the issue of its compulsory paper: a larger quantity of a currency, on its first circulation received with reluctance, and only because no other mode of payment could be obtained, is issued; the increased issue, of itself, would necessarily diminish the value of the currency, but this consequence is increased by the suspicion which such a measure on the part of government creates, that the finances of government are on the decline; hence, from the operation of both these causes, *viz.* an increased issue, and diminished confidence, a depreciation of the compulsory government paper must necessarily ensue.

There is still another subject incidentally connected with paper currency, on which it may be proper to say a few words, before we proceed to the immediate topic of this article. By many, bills of exchange, or exchequer bills, payable only at a certain time, and bearing interest, are considered as paper currency; and it is contended that an increase in the issue of them has exactly the same effect as an increase in the issue of government or bank paper. This notion, though certainly plausible, and maintained by writers of considerable acuteness and knowledge on the subject of political economy, a little reflection will serve to convince us is erroneous and unfounded. We have only to reflect on the nature and operations of currency, to be convinced

that bills of exchange and exchequer bills do not form a part of it; and, indeed, that notes *bearing interest*, are by that very circumstance excluded from the character and operations of currency; and that the increased issue of these, so far from tending to depreciate the value of money, must rather operate to raise it. Under the article MONEY we endeavoured to shew that the mere increase or diminution of the circulating medium did not necessarily tend to lower or raise the rate of interest: but that the rate of interest must depend on the quantity of money offered to be lent, and on the number of the borrowers, and the terms which they were willing and able to give: so that if the increased quantity of money thrown into the market was entirely employed in the purchase of commodities, and not offered to be lent, the rate of interest would not be affected, in the smallest degree, by this increased quantity: while, on the other hand, if the quantity of money in circulation continued the same, but part of it was withdrawn from the purchase of commodities, and offered to be lent, the rate of interest would fall. The same train of reasoning which serves to establish these facts, will conduct us to a proper consideration of the nature and operation of bills of exchange and exchequer bills. They are brought into the market, not for the purpose of employing them in the purchase of commodities, but for the purpose of sale; and they are generally bought by those who wish to put out their money to interest: hence they may operate on the rate of interest, but they cannot operate on the price of commodities, unless it be, as has been already stated, to lower the price of commodities, or, in other words, to raise the value of money. That they may have this effect will appear from the following considerations: let us suppose that the money and commodities in any market bear a certain proportion to one another, and that this proportion is disturbed, by the introduction, either of a greater quantity of some of the commodities formerly in the market, or by the introduction of some new commodity; it is plain that in either case, if the quantity of money continue the same, that its value or power of purchase will be increased, since it will now exchange, not merely for the commodities formerly in the market, but also, in addition, for the increased quantity of the old commodities, or for the new commodities. If, instead of a new commodity properly so called, we suppose that a person comes into the market, wishing to borrow money, and offering such a rate of interest, as secures to him part of that money which used to be expended in the purchase of commodities; in this case also, the value of the money, or its power to purchase must be increased, since it will now command, not only the commodities it formerly did, but also the interest offered for the sum wished to be borrowed. But in this question, it is a matter of mere indifference in what manner the interest to be paid is promised or secured; whether in the usual way, or by bills of exchange, or by exchequer bills. The general fact and consequence are precisely the same in all cases: if bills of exchange or exchequer bills are brought into the market, they are brought, not to purchase commodities with, but for sale; and if they are sold, for part of that money which used to be expended in the purchase of commodities, it is evident that the price of these commodities must be lowered, not raised, by the introduction of these bills of exchange, or exchequer bills; and consequently, that as their nature and operation is that of commodities, not of circulating medium, their issue cannot lower the value of money, but must, in some degree, tend to raise it.

Having thus cleared the way for the uninterrupted consideration of the more immediate and proper subject of this article, we shall arrange the remarks which we mean to offer

PAPER CURRENCY.

under the following heads: 1. The real nature of bank notes. 2. The effects of this species of currency. 3. Its advantages and disadvantages, as compared with a metallic currency. 4. The nature and process of the checks to the over-issue of bank paper, when it is payable on demand: and, 5. The state of bank paper, when not payable on demand, so far as regards its over-issue, and its supposed depreciation, arising from this or other causes.

1. Bank notes have very generally, but very erroneously and improperly, been denominated the representatives or symbols of coin. This is one, among many other instances of vagueness and confusion of ideas, arising from the injudicious and careless use of metaphorical language, which has so much retarded the advance of the science of political economy. What precise or clear idea can we attach to the terms representative of coin? or how can bank notes be so denominated? It has been justly remarked, "that the most accurate representatives of coin, are well fabricated counterfeits, yet every man, when he knows them, refuses these in payment." Indeed it is not easy to perceive how this language came to be adopted, or where was the necessity or temptation to have recourse to metaphorical language, to express a fact sufficiently obvious, clear, and undoubted. A bank note does not represent coin; nor is it circulated and received on that account; but it is an obligation on the part of the person or persons who issue it to pay, on demand, a certain quantity of gold or silver. "A common cheque upon a banker, which nobody ever dreamed of calling a representative of money, is just as much a representative of it as bank notes; nay, in fact, the order which the manufacturer, on the Saturday night, puts into the hands of one of his workmen, to get from his clerk the wages of the week, is a representative exactly of the same description. The only real difference in practice is, that the one obligation generally passes but through one or a few hands, till it comes upon the obligee: the other passes through many hands, each accepting it as a satisfactory security for the valuable commodity which it is an order to receive."

Having thus, it is presumed, refuted, perhaps at the expence of more words than it deserved, the notion, that bank paper is a representative of coin, the next topic of enquiry under this head, is what, in fact, does the person who issues the note oblige himself by such issue, and by the terms of the note, to pay on demand. This enquiry may, at first sight, appear as little necessary as the previous investigation, since the obligation on the note is clear and distinct: there is no vagueness or ambiguity about it, and, indeed, if there were, the value of the note would be in a great measure, if not entirely, destroyed. It is only of late years, that any question or doubt has been started respecting the nature of the obligation expressed on a bank note; and the strange and almost unintelligible opinion which has been broached on the subject, forming part, as it does, of the doctrine of abstract currency, scarcely deserves notice here, especially as this doctrine has been already canvassed under the article MONEY. A few words, however, may be spent to state this opinion; and it is believed an impartial statement of it, if it can be made intelligible, will render almost unnecessary any formal and direct refutation of it.

The leading principle of those who hold this opinion is, that the pound sterling is an imaginary or abstract portion of the currency, and not any thing tangible or substantial: hence they infer, that as the bank note promises to pay one, five, or any given number of pounds sterling, the obligation laid on the issuer, is not to pay any precise and real sum, nor can the note be said to be depreciated, if it does not pass current for the value of the metal expressed on it. In

support of this opinion no argument is advanced; no reference to general, undisputed principles is made; it is left to struggle, arbitrary and absurd as it is, relying solely on the hardy and reiterated assertions of its defenders: they forget that though there is no coin called a pound sterling, the value of a pound is known and acknowledged both by the laws and by common consent; that their doctrine is totally inapplicable to notes such as those common in Scotland, which promise the payment of a guinea, an existing and known coin; and that while the notes of the bank of England were payable on demand, their opinion was neither acted upon by the bank, nor entertained by themselves.

2. With regard to the effects of paper money, they may be considered under two heads: the effect it produces on the price of commodities, and the effect it produces on the metallic currency along with which it circulates. Mr. Hume entertained the notion that paper money raises prices, whereas Dr. Adam Smith, referring to what he considers as a general fact in the theory of circulation, that every addition of paper to the currency displaces an equivalent quantity of gold, holds an opposite opinion. This notion of Smith, however, must be received with some limitation: if by an addition of paper to the currency in any country, the price of any commodity is raised in that country so high, as will pay for its importation, it will be imported, and part of the metallic currency will probably be employed to pay for the commodity thus imported. But whenever the addition made to the currency by paper money is employed in the production of commodities, and the increase in the quantity of these commodities is in the same proportion as the increase to the currency, by the addition of paper money, there will be no reason for exporting gold, and the whole currency, consisting of the precious metals, and of paper, will be no more than is necessary to circulate the increased quantity of commodities in the market. In considering this branch of the subject in a more extended sense, it will be necessary to look to the effect produced on the value of the precious metals, in the general market of the world, by the addition of paper to the currency of any particular country, in cases where that addition, not producing a corresponding increase in the quantity of commodities, enhances their price, and thus leads to the exportation of gold from the country where the paper currency is issued. In these cases, "the same exportation of gold, which remedies the temporary rise that takes place in the particular country where paper has been issued, has a tendency to increase the supply of precious metal in the general market of the world, and thus to occasion a general rise of prices in which that particular country must participate. The whole quantity of bullion, of which Great Britain has spared the use by adopting a different medium of domestic exchange, is added to the general stock of the mercantile commonwealth, as much as if an equal quantity had been brought additionally from America; and the saving of that annual loss which would have been occasioned by the waste of British coin, is equivalent to an increase in the annual produce of the mines."

The above remarks display considerable command of the subject, and are worthy of that author, who by his analysis of, and observations on, "Thornton on the Paper Credit of Great Britain," contributed so materially to bring the Edinburgh Review into notice; we are, therefore, the more surprised that in the remark immediately following the passage which we have just quoted, he should have so completely misunderstood the subject and contradicted himself: we allude to the following observations. "But, on the other hand, it must be remembered that the use of paper money tends, in some degree, to *lower* the price of commodities. In proportion

PAPER CURRENCY.

tion as the instruments of commerce, or the machinery of manufactures are of a less expensive construction, the articles which they contribute to produce may be afforded at a lower rate. To employ paper money instead of gold, is to substitute a very cheap instrument of commerce in the room of a very expensive one." Now the inference to be drawn from the circumstance here alluded to, appears to us directly the reverse; when any saving of labour or expence takes place in the production or manufacture of any commodity, that commodity, costing less, can be sold at a lower rate, with an equal profit to the seller: in like manner, when paper, a very cheap instrument of commerce, is employed in the stead of gold or silver, very expensive ones, more paper money can be afforded in exchange for the same quantity of any commodity than could have been afforded of metallic money: but in this case certainly the price of the commodity is not *lowered*, but raised, since for it more money is now given than was formerly given.

On the whole, with respect to the effect of a paper currency on the price of commodities, and on the precious metals with which it circulates, it may be remarked, that it must vary according to the circumstances under which the paper currency is emitted, and the quantity which is thrown into the market: and these variations in its effects will more properly be considered under the next head, *viz.* the advantages and disadvantages of a paper currency, as compared with a metallic currency.

The first advantage resulting from the use of a paper currency, which occurs to the observation of a person reflecting ever so superficially on the subject, is, that by the substitution of paper in the room of gold and silver money, a very expensive instrument of commerce is replaced by one much less costly. So far the substitution of paper money must be advantageous to the community; the currency of a country is a part of its capital, which may be considered as unproductive; it is, indeed, necessary to carry on the operations of its commerce, but it does not, strictly speaking, increase that commerce; it is, therefore, of the utmost importance, that this instrument, thus unproductive, should be procured and kept in action, with the least possible expence. But where gold and silver alone are employed as the currency of a country, they must either be obtained directly from the mines at great labour or expence, or purchased by commodities on which the same quantity of labour and expence has been laid out. Again, if in a country, the currency of which consisted entirely or principally of gold and silver, a paper currency is introduced, it is evident that a part of its former metallic currency will be set at liberty, and may be expended in the purchase of foreign commodities. Paper currency, as we have already shewn, is in fact only an obligation to pay on demand a specific sum of gold and silver; it therefore might be inferred that the substitution of paper for gold and silver would not set at liberty any portion of the latter, since it would be necessary to retain the whole, in order to answer the demand of those who brought the paper currency for payment. But the fact is, that a comparatively small proportion of gold and silver is required to answer the demands occasioned by a very extensive paper circulation; those who issue bank notes soon ascertain, with sufficient and perfectly secure precision, the exact amount of gold and silver, which it is necessary or prudent to keep by them, and the rest is employed in the purposes of commerce.

Whatever evils may have resulted from an injudicious and superabundant issue of paper money, there can be little doubt that this species of currency has been of great service in increasing the produce and extending the commerce of the country. Let us suppose an instance of common occur-

rence, and of no intricacy or complication in its detail: a gentleman possesses a large estate, that is in a great measure in an uncultivated and unproductive state: he does not possess the capital adequate to the full improvement of it; and yet there can be no doubt, that if sufficient capital were laid out upon it, in a judicious and skilful manner, not only the owner, but the community, would be greatly benefited. In a country destitute of paper currency, he would experience great, perhaps insurmountable difficulties, in borrowing the requisite capital; whereas, in a country possessed of a paper currency, the means of improvement would be easily obtained, and a great increase of produce, and consequently of wealth, would be added to the public stock. Whoever has watched the progressive improvement of Great Britain, not only in the extended and superior cultivation of her soil, but in the increase of her manufactures and commerce, must be convinced that the rapid and great advances she has made in wealth within these few years, have been in a great measure owing to her paper currency.

The following passage from Smith's *Wealth of Nations* will set the advantages of a paper currency, perhaps, in a still clearer light. "It is not by augmenting the capital of the country, but by rendering a greater part of that capital active and productive than would otherwise be so, that the most judicious operations of banking can increase the industry of the country. That part of his capital which a dealer is obliged to keep by him unemployed, and in ready money for answering occasional demands, is so much dead stock, which, so long as it remains in this situation, produces nothing, either to him or to his country. The judicious operations of banking enable him to convert this dead stock into active and productive stock; into materials to work upon, into tools to work with, and into provisions and subsistence to work for; into stock which produces something, both to himself and his country. The gold and silver money which circulates in any country, and by means of which the produce of its land and labour is annually circulated and distributed to the proper consumers, is, in the same manner as the ready money of the dealer, all dead stock. It is a very valuable part of the capital of the country, which produces nothing to the country. The judicious operations of banking, by substituting paper in the room of a great part of this gold and silver, enable the country to convert a great part of this dead stock into active and productive stock; into stock which produces something to the country. The gold and silver money which circulates in any country may very properly be compared to a highway, which, while it circulates and carries to market all the corn and grain of the country, produces itself not a single pile of either. The judicious operations of banking, by providing, if it may be allowed so violent a metaphor, a sort of waggon-way through the air, enable the country to convert, as it were, a great part of its highways into pastures and corn-fields, and thereby to increase very considerably the annual produce of its land and labour. The commerce and industry of the country, however, it must be acknowledged, though they may be somewhat augmented, cannot be altogether so secure, when they are thus, as it were, suspended upon the Dædalian wings of paper money, as when they travel about upon the solid ground of gold and silver. Over and above the accidents to which they are exposed from the unskilfulness of the conductors of paper money, they are liable to several others, from which no prudence or skill of those conductors can guard them."

The disadvantages and evils of paper money, indeed, arise from the same causes which produce its advantages and benefits: we must never forget, that the foundation of paper money

PAPER CURRENCY.

money is credit; that it is, in fact, an obligation to pay on demand a certain sum of metallic currency. Credit does not create capital, it only sets that portion of capital in operation, which would otherwise be inactive: the person who gives credit, in reality gives part of his capital, which he has not the disposition or the means to employ: and the person who receives credit or capital, by employing his industry and skill along with his borrowed capital, is enabled to repay it, and the stipulated interest. So long as the credit of the lender is good, and the repayment of the borrower punctual or undoubted, so long a paper currency thus established, if not pushed too far, must be beneficial to the lender, the borrower, and the nation at large. But let us suppose that from any cause, confidence in the paper money of a country was destroyed or shaken, and we shall immediately perceive the disadvantages and evils of this species of currency, as compared with a metallic currency. Where the commercial transactions of a country are entirely carried on in a metallic currency, opinion has no room for operation: no confidence is reposed; commodities are sold, not for what may or may not be worth the value which they represent or promise, but for what possesses absolute and intrinsic value. No circumstance will point out and exemplify the difference between a paper and a metallic currency so clearly and strikingly, as the invasion, or dread of invasion, in the countries in which they respectively exist. If a country, the currency of which consisted principally or entirely of paper, were actually invaded, or threatened with invasion; or even, if its internal state were convulsed or disturbed, or its finances considerably disarranged, its paper currency would be immediately affected: its value would fall, in proportion as the confidence reposed in it was diminished: people would prefer metallic currency for this strong and obvious reason, that whoever had possession of the country, whatever change took place in its government, or into whatever circumstances of political or financial embarrassment and confusion it was thrown, the value of the metallic currency would remain unchanged, whereas the value of the paper currency would be subject to constant variation, and might probably be totally destroyed.

It is sometimes objected to a paper currency, that by exchanging commodities for it, we in fact get nothing valuable, whereas when we sell our commodities for gold or silver, we obtain something of real and intrinsic value: but this observation amounts to nothing, provided the credit of the paper currency be good; it is, indeed, founded on the erroneous idea, that when we sell our commodities, we look for any thing else in the money which we receive, but the certainty that it will be taken from us at an undiminished value. When a person sells a quarter of wheat for five pounds, it must be a matter of perfect indifference to him, whether he receives five pounds in silver, or five pounds in paper, provided he is convinced that in the purchase of what he may want, the latter will go as far as the former: in selling his wheat he is never disturbed by the idea, that five pounds in silver have intrinsic value, *i. e.* value as metal, while the five pounds in paper possess no intrinsic value; the power each possesses over commodities is all he regards, and if that power be equal, their value, for all the purposes he needs them for, is equal in his estimation.

It has also been objected to paper currency, that its use is solely confined to transactions of domestic traffic; and consequently that a country, which has no other species of currency, must go to a foreign market to purchase commodities at a great disadvantage; the fact is undoubted, that, generally speaking, a paper currency is without value in a foreign country, but the inference by no means follows, that

on this account foreign commodities must be purchased by a country which possesses only a paper currency, at a great disadvantage. On the first establishment of a paper currency, the very reverse must be the case; or to speak more correctly, the establishment of a paper currency setting loose a portion of the metallic currency, this may be employed in purchasing a larger quantity of foreign commodities, than the country could afford to purchase, while this metallic currency was necessary for the circulation of its internal commerce. But, even after a paper currency is established, foreign commodities may be purchased at an equally cheap rate, as they were while the currency was metallic; for in the first place, foreign commodities are seldom purchased by the coin of the country purchasing, but either by bullion, or the interchange of commodities; and secondly, while a bank note for a guinea will exchange for a guinea, it will always command, indirectly, the same quantity of foreign commodities, as could be purchased, if the currency were entirely metallic.

But the objection to paper currency, urged most frequently, and with the most confidence in its appositeness and solidity, arises from the extreme facility with which it may be increased; the strong temptations to increase it, and the evils to the community, to which an improper increase must give rise. The consideration of this objection naturally leads us to the fourth head of our disquisition, *viz.* the nature and process of the checks to the over-issue of bank paper, when it is payable on demand.

It may be proper first to consider what is meant by an over-issue of paper money: the term is too often used without any clear and definite idea being attached to it. When the quantity of circulating medium, whether metallic, or of paper, is increased in a country, the increase either operates to the production of a great quantity of commodities, that is, is usefully employed, or it merely operates to raise the prices of the commodities already in existence: before, therefore, the addition of any sum to the circulating medium can be said to be an over-issue or not, the effects produced by it must be traced and ascertained: if a correspondent addition to the quantity of commodities has taken place, there cannot be said to be an over-issue of currency; but if no such correspondent addition has taken place, as the sum added to the currency cannot be inactive or unapplied, a rise of price must take place, and then an over-issue may justly be said to have occurred. Those who sell as well as buy, probably will not be much or long injured by this rise, since any addition to the currency is not long in adjusting itself to the various commodities in the market, and consequently, if some commodities are bought dearer, other commodities are also sold dearer: but those persons, whose whole property consists in money, are injured, when there is an over-issue of the currency; *i. e.* when an addition to the currency does not produce a correspondent addition to the commodities in the market. While the currency is entirely metallic, they are in a great measure guarded from a sudden or violent over-issue, and consequently, from a sudden or violent rise of prices, or depreciation of money, their sole property; since before any great addition can be made to the circulating medium, additional labour must have been bestowed on the mines. But where paper currency is established, the case at first sight seems different; the value of their property, *i. e.* money, is at the mercy of all who can issue bank notes: if, however, we investigate what actually takes place, where there is a paper currency payable on demand, we shall find that the property of the monied man is guarded as effectually, though not so directly, as if the currency were metallic. Let us suppose a large addition to be made to the paper currency of any particular district in this country;

country; this addition operates either to the rise of prices solely, or to the increase in the quantity of commodities; in the latter case, the monied man has no cause to complain; there is indeed more money in his neighbourhood, but as there are also more goods, the value of his money is not affected. On the other supposition, that the increase to the paper currency raises the price of commodities, let us see what will occur: those commodities, the price of which is raised, will be purchased in another district, where they have not undergone a similar rise; but before they can be purchased, the local notes must be exchanged for such as are current in the district where the purchase is to be made; or, in other words, some part of the over-issued notes will return to the bank which issued them. This will be a sufficient proof and warning to the bank, that they have issued more notes than the commercial transactions of the district required, and as on notes almost immediately returned, the expence in manufacturing them, and their proportion of the establishment must far exceed the profit made on them while they were in circulation, the bank will be careful in future not to over-issue their notes.

A process similar in all its steps, and in its result, will take place, if the bank of England, while subject to be called upon for cash payments, should over-issue their notes: the over-issued notes will either spread themselves over the country, for the purchase of such commodities as have become cheaper in the country than in London, by the addition to the circulating medium, or they will be returned to the bank of England for gold, wherewith to go to a foreign market.

Thus it would appear that the property of the monied man is rather more secure, and better protected from depreciation, in a country, the currency of which consists of paper payable on demand, than in a country, the currency of which is entirely metallic; since, in the former country, the real and well understood interest of those who issue the paper money must lead them most carefully to avoid any over-issue; whereas in a country, the currency of which is entirely metallic, though no addition to it, sufficient to raise the prices, can long remain in it, yet it may both remain longer, than an over-issue of paper money, and be repeated more frequently.

We now come to the last head, *viz.* the state of bank paper, when not payable on demand, so far as regards its over-issue, and its supposed depreciation arising from this or other causes.

The suspension of cash payments in the bank of England, in the beginning of the year 1797, forms a most memorable era in the history of the science of political economy; and the undiminished confidence which after this measure was, and is reposed in the bank of England notes, has shaken to the foundation many favourite theories in this most intricate and delicate science. By some it is alleged, that the confidence in bank of England paper remained the same, even after the suspension of cash payments, because there was a general and well-founded belief, that the bank was able to pay all its notes in specie; but something more than mere ability would seem necessary to inspire or continue confidence. Of what moment is it to the holder of a bank of England note, to be told that the bank can pay it in specie, if he knows that they will not, and that he cannot compel them? By others it was argued, that the confidence was still continued, because it was expected, that in a short time cash payments would be resumed; this consideration might have operated on some persons, at the time of the imposing the restriction, but now it can have no weight, as the expectation that cash payments will soon be resumed, must be

utterly banished from the mind of every man; and yet no diminution of confidence has taken place. The continued confidence, without diminution, in the bank of England paper, after they were relieved from the obligation to pay in cash, seems to have arisen from the following circumstances; all the principal merchants, and government itself, declared their willingness to receive bank paper as before; the mass of the nation were content with this, for, as has been remarked under the article MONEY, though intrinsic value is indispensibly necessary, at first to give circulation, yet, in process of time, that circumstance is never adverted to, except by those whose business it is to watch the variations in the value of the metals of which the money is formed. The nation at large knew, that the bank would no longer pay in cash, but they also knew, that bank of England paper, though thus deprived of its intrinsic value, would be received the same as before by all those to whom their principal or most common payments were to be made: as, therefore, the bank of England paper still retained the character and uses of money, the alteration in its intrinsic value was not adverted to.

With respect to the danger of over-issue, when cash payments are suspended, it is argued, that it is merely chimerical; since no one will pay interest to the bank for money, from which he does not expect to derive more profit than the interest he pays; and consequently, as all issues are made for commercial purposes, they will not be carried to a greater extent than the state of commerce requires. But it may be very true, that there are no issues, but what the state of commerce requires, and what will produce, or are expected to produce a profit to the borrower; and yet there may be an over-issue of bank paper; or, in other words, an issue, that will raise the price of commodities; since, in many instances, the profit expected by the borrower, may arise from this increase of prices. Let us suppose a merchant wishes to buy largely cotton, corn, or any other commodity, and for this purpose gets his bills discounted at the bank of England: his speculations succeed, and he makes a large profit; in this case, the price of the cotton or corn is necessarily increased by the greater sum brought into the market for the purchase of it, by means of the discount afforded by the bank of England: there is a real commercial transaction; and yet, as there is no increase in the quantity of commodities, but a mere transfer, the bank notes issued for this purpose ought to be considered an over-issue, that is prejudicial to the property of the monied man, though advantageous to the bank and the merchant.

It is evident that paper money, when not payable in cash on demand, must be more liable to depreciation from any doubt respecting the security of the country, than if it could be converted into cash at pleasure; but how far it is liable to depreciation from other causes, is a question on which there is much difference of opinion. If, as we have endeavoured to shew, there may be an over-issue, *i. e.* such an issue as will raise the price of commodities, the price of gold and silver bullion must rise as well as all other commodities; but when the bullion price of the metals rises above the mint price, the coin will soon be regarded only as a commodity, and will in spite of all laws and penalties be bought and sold as such. When a difference in the estimated value of paper currency and metallic currency takes place, from whatever causes it may arise, one of two effects must follow; either the paper currency and the metallic currency will be equally current, each at its respective value; or the metallic currency, being regarded solely as a commodity, will disappear. Where depreciation has occurred from want of confidence, it has generally happened, that the paper and metallic

metallic currency have circulated together, each at its own value; but where depreciation has taken place, from an increase in the quantity of paper, from a diminution in the quantity of the precious metals, or from an increased demand for them, it has generally happened, that the metallic currency, being regarded solely as a commodity, has disappeared. These two different effects may easily be accounted for; a rise in the price of bullion, occasioned by an over-issue of paper, by a diminished supply of bullion, or by an increased demand for it, is only known to, and acted upon by, comparatively a few people; the great mass of the nation, as has been already observed, in receiving or paying money, do not advert in the slightest degree to the character or value of the money as bullion, but solely to its character and value as a means of interchanging commodities; the variations in its bullion value, therefore, are unheeded both in their payments and receipts; they are, however, constantly and carefully watched by all whose business consists in dealing in bullion, and as soon as the bullion value of coin exceeds its mint value, it disappears from circulation by their means. The case is widely different, when there is any alarm respecting the credit of the paper currency; in this all are immediately and deeply concerned; all are eager to exchange it for the precious metals, and under these circumstances, as the precious metals, in their character of coin, can thus be exchanged for as much paper as they could command as bullion, there is no temptation to withdraw them from circulation. It is not just, therefore, to infer, that the paper currency of a country is not depreciated, because two prices do not exist, if the other effect of depreciation, *viz.* the disappearance of the precious metals, has taken place; each circumstance marks depreciation, but of a different kind, and arising from different causes. On the other hand, it is not fair to infer, that where the credit of the paper currency, or in other words, a difference of value between the paper currency and the coin it promises to pay, may arise, like a difference of value between any other two commodities, from the quantity of the one being increased, or the demand for it being diminished, or from the quantity of the other being diminished, or the demand for it being increased.

PAPER-Office, (in the palace of Whitehall,) is an ancient office, where all the public writings, matters of state and council, proclamations, letters, intelligences, negotiations of the king's ministers abroad, and generally all the papers and dispatches that pass through the offices of the secretaries of state, are lodged, and disposed in the way of library. It was chiefly from this noble repository that bishop Burnet had materials for his History of the Reformation.

PAPER Portraits and Pictures. One Elizabeth Pyberg, who lived at the Hague in 1699, cut in paper not only towns, as Loo and Hounslersdyke, but even faces to an extreme likeness. Mr. Ellys assures us, she did king William and queen Mary better than any limner he had ever seen, and refused 1000 guilders for the pieces; which were so curious, that he could not believe the queen's drapery not to be point till he had most accurately examined it. Vide Phil. Trans. N^o 286, p. 1418.

PAPER, Stamped. See STAMP.

PAPERS, a term used for writings, especially those relating to a man's estate, property, dealings, or the like. In which sense, papers include books of accounts, invoices, and orders; also deeds, bonds, charters, and the like.

PAPERS is also sometimes used for manuscript books.

PAPERS is more particularly used of late days for gazettes, journals, and other public news-writings.

We have daily papers, weekly papers, morning papers,
VOL. XXVI.

evening papers, occasional papers, political papers, literary papers, papers of entertainment, &c.

PAPETTO, in *Commerce*, a small silver coin of Rome, valued at two paoli. The papetto of 1775, weighs 3 dwt. 8½ gr., contains in pure silver 72.8 gr., and is valued at 10¼ d. sterling.

PAPHIS, in *Ichthyology*, a name by which some have called the gar-fish. See *Esox Belone*.

PAPHLAGONIA, in *Ancient Geography*, a province of Asia Minor, situated on the Euxine sea, between Bithynia to the W., and the gulf Amifenus towards the E.; to the S. was Galatia. When other divisions were introduced, such as the province of the Hellespont, &c. the name of Paphlagonia disappeared. On the northern coast it had a considerable promontory, that of Carambis (Kerempi.) The river Parthenius served for a considerable time as a boundary between Paphlagonia and Galatia. Towards the E. the mouth of the Halys served as a limit to Paphlagonia on that side. In the interior of the country were the Heneti or Veneti, regarded as the progenitors of those who afterwards passed over into Italy; they occupied the parts towards the N. In the centre of Paphlagonia was a country called Domaniis, which included a considerable town under the name of Germanicopolis (Kastamoni.) This country was bordered on the S. by a chain of mountains called Olgassys (mount Etkas.) In the country called Blacua, S. of these mountains, was Docea (Toussich), and towards the E. Pompeiopolis.

PAPHOS, (*Baso* or *Bafa*), a town of the island of Cyprus towards the W., at the bottom of a small creek, terminated by the promontory Zephyrium. In this town was a very ancient temple of Venus, whence her appellation "Paphian." Of its origin there have been many conjectures. Tacitus pretends, that it was built by Aerias, and that the goddess, having conceived in the midst of the waves, was landed in this place. He adds, that every one offered any victims according to his pleasure, but the most select were males. It was prohibited to spill any blood on her altar. Pausanias relates, that the Arcadians, in returning from the war of Troy, were cast by a tempest on the isle of Cyprus. Agapenor, their chief, founded a colony at Paphos, and there erected a temple in honour of Venus.

In this temple was an oracle, which was consulted by Titus, in his way to compliment Galba upon his elevation to the empire. When Cato was sent to the isle of Cyprus, he was assured by Ptolemy, that if he retired without opposition, he should want neither money nor honour, and that the Roman people would confer upon him the profitable and honourable post of chief priest of Venus. The first town that bore the name of Paphos was in the interior of the country; the second was on the sea-coast.

PAPIA, in *Botany*, a name given by Micheli, to what he supposed a new genus, in honour of Joseph del Papa, physician to several of the Tuscan princes of the Medici family, whom he celebrates for his various learning, eloquence, virtue, and affability, as well as his zeal in promoting the studies of Medicine and Botany. Whatever the merits of this gentleman might be, the plant consecrated to immortalize them, after having been named *Orvala* by Linnæus, is now considered as the very same plant with his *LAMNUM Orvala*; see that article.

PAPIAN-POPÆAN Law, in *Roman Antiquity*, was enacted by the consuls M. Papius Mutilus, and Q. Popæus Secundus. This law obliged all men to marry at a certain age, established great exemptions and privileges in favour of those that had children, and laid heavy fines on all who, after a certain age, continued single. It was also called the

Julian law, because it had been published by the order of Augustus, who was of the Julian family. The severity of this law was mitigated by Tiberius.

PAPIAS, in *Biography*, bishop of Hierapolis, a city of Phrygia, who flourished in the early part of the second century. He is supposed to have died a martyr; and the author of the "Alexandrian Chronicle" affirms, that he suffered at Pergamos, during the severe persecution in the reign of Marcus Aurelius. As these facts are not noticed by Eusebius or Jerome, Lardner does not think them entitled to much credit. Irenæus speaks of him as a hearer of John, and a companion of Polycarp; the John here mentioned is supposed by some to be the apostle of that name, but Eusebius observes, that "Papias does not say that he heard or saw any of the apostles, but only that he received the things concerning the faith from those who were well acquainted with them, that he received the apostles' sayings from those who conversed with them, and that he was a hearer of Aristion, and John the Presbyter." Eusebius and Jerome esteemed him as a good man, but extremely credulous, and of very shallow abilities, who delighted much in hearing and telling stories, and relating miracles, which he learned from tradition. But Dr. Lardner says, "I esteem the testimony very valuable, which he has given to the gospels of St. Matthew and St. John. If Papias had been a wiser man, he had left us a confirmation of many more books of the New Testament." Papias was the first person who propagated the famous notion concerning a *Millennium*, or personal reign of Jesus Christ upon earth for a thousand years after the resurrection, when he believed the elect should be gathered together at Jerusalem, and enjoy all the felicity imaginable during that period. He was author of five books, entitled "An Explication of the Oracles of the Lord," of which only a few fragments are preserved in the works of Irenæus and Eusebius. Lardner, vol. ii. edit. 1788.

PAPIER MACHE' is made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced into a kind of paste, and then boiled with a solution of gum arabic or of size, to give tenacity to the paste, which is afterwards formed into different toys, and by pressing it into oiled moulds either of wood or of plaster of Paris. When dry, it is done over with a mixture of size and lamp-black, and afterwards varnished. See GILDING, JAPANING, and VARNISH.

PAPIGOHAVEN, in *Geography*, a bay on the E. coast of Scotland, and county of Caithness; one mile N. of Wick.

PAPILIO, the Butterfly, in *Entomology*, a genus of insects of the order Lepidoptera. The generic character is, antennæ thickening towards the extremity, commonly terminating in a knob or clavated tip; wings, when sitting, erect and meeting upwards. They fly in the day-time.

The prodigious number of species of this numerous and beautiful tribe has made it necessary to divide the whole into sections, instituted from the habit or general appearance, and, in some degree, from the distribution of the colour of the wings. "This division of the genus is," says the late excellent naturalist, Dr. Shaw, to whose labours we have frequently been indebted, "conducted by Linnæus in a peculiarly elegant and instructive manner; being an attempt to combine, in some degree, natural and civil history, by attaching the memory of some illustrious ancient name to an insect of a particular cast."

The first Linnæan division consists of *Equites*, which are distinguished by the shape of their upper wings: these are longer, if measured from their posterior angle to their anterior extremity, than from the same point to the base.

Some of this division have filiform or sharpened antennæ, in which they resemble moths, but may commonly be distinguished by their habit or general shape. The Equites are denominated *Troes* or *Trojans*, distinguished by having red or blood-coloured spots or patches on each side their breasts; or *Achivi*, *Greeks*, without red marks on the breast, of gayer colours, in general, than the former, and frequently having an eye-shaped spot at the inner corner of the lower wings.

The second division consists of *Heliconii*, which are distinguished by wings that are narrow and entire, frequently naked or semi-transparent; the upper ones are oblong, the lower ones very short.

The third division consists of the *Danai*, so called from the sons and daughters of Danaus. They are divided into *Danai candidi*, which have whitish wings; and *Danai festivi*, in which the ground-colour is never white, and the wings are variegated.

The fourth division consists of the *Nymphales*, distinguished by the edges of the wings being scolloped or indented. It is subdivided into the *Nymphales gemmati*, in which the wings are marked with eye-shaped spots; and *Nymphales phalerati*, in which the wings are without those spots.

The fifth division contains the *Plebeii*. These are commonly smaller than the preceding kinds of butterflies, and are subdivided into *Rurales* and *Urbicole*: the wings of the former are marked with obscure spots; those of the latter have for the most part transparent spots.

The above distribution, says Dr. Shaw, is not entirely accurate; the task of arrangement, though apparently very trifling, is really extremely difficult. The blood-coloured spots, mentioned by Linnæus as characteristics of the Trojans, are not always found; and the anterior angle of the wings in the Achivi is not always marked with an eye-shaped spot. The surest method, therefore, is to consider such of the Equites as are of a dark or mourning colour, as belonging to the Troes, and those of gayer or livelier ones to the Achivi. The under wings in some of the Heliconii are slightly indented, and might perhaps as well have been referred to the *Nymphales phalerati*; the under wings of the *Danai festivi* are also often indented; and the family of the *Plebeii* is also very inaccurate, many of those insects having characters which would more properly entitle them to a place in some of the other divisions.

The larvæ of butterflies are universally and emphatically known by the name of caterpillars, and are extremely various in their forms and colours; some being smooth, others beset with either simple or ramified spines, and some, especially those belonging to the division Equites, are observed to protrude from their front, when disturbed, a pair of short feelers, somewhat analogous to those of a snail. (See ENTOMOLOGY.) In our account of the species, we shall give, in general, little more than the name, specific character, and native place where it is known.

Species.

Equites. Trojans.

PARTS. Wings tailed, that is, furnished with a pair of lengthened processes, black; the lower ones with a large blue spot and purple eye, and seven lunules beneath. It is found in China, and other parts of Asia.

BIANOR. Wings tailed, black, both surfaces nearly of the same colour; the lower ones with five rufous lunules. It inhabits China, and has five red crescents on the lower wings.

HELENUS.

PAPILIO.

- HELENUS.** Wings tailed, black; the lower ones with a white spot and double purple lunule. Found in Asia.
- THESEUS.** Wings tailed, brown, both surfaces of the same colour; the lower pair with nine red lunules, dotted with white. It is found in the island of Sumatra.
- POLYTES.** Wings tailed, black, both surfaces of the same colour; the upper ones with a band composed of five white spots and red lunules. It is an inhabitant of Asia.
- MUTIUS.** Wings tailed, black; the upper ones with a white band; lower ones with a band of five red spots and lunules. It is found in the island Tranquebar. It is thought to be a variety of the last.
- HECTOR.** Wings tailed, black, both surfaces of the same colour; the upper pair with an uninterrupted white band; lower ones with numerous crimson spots. The thorax is red on each side. It is a native of the East Indies, and feeds on the *Aristolochia* or Birthwort.
- ASCANIUS.** Wings tailed, black, with a common white band, both surfaces alike; the lower ones clouded red. It inhabits Brazil.
- ANTENOR.** This is a very large species, measuring six inches and a half in extent of wings. Its colour is black, with numerous cream-coloured spots and patches; and the under wings, which are tailed, are edged with a row of red crescent-shaped spots. It is a native of India.
- TROILUS.** Wings tailed, black; the upper ones with pale marginal spots; lower ones with pale spots above, and fulvous ones beneath. Found in North America.
- ILIONEUS.** Wings tailed, black; the lower ones with a blueish border, fulvous at the angle of the tail, with red spots beneath. It inhabits Georgia.
- GLAUCUS.** Wings tailed, brown; the lower ones blue-black, fulvous at the angle of the tail, with yellow lunules beneath. It inhabits America.
- PALINURUS.** Wings tailed, black, with green-gold specks, and a common blue-green band. It is found at Tranquebar.
- CRINIS.** Wings tailed, black, with green-gold specks, and a common blue-green band; the lower ones beneath with green, blue, and cinereous lunules. It is found in Africa.
- DEIPHOBUS.** Wings tailed, black, the base beneath spotted with red; the lower ones with seven red and almost angular spots. It is found in divers parts of Asia.
- PELEUS.** Wings tailed, black; the upper ones with a white band; the lower pair with white marginal lunules, and two red dots. It is found in India.
- ASTERIAS.** Wings tailed, black, with two macular bands; angle of the tail fulvous, with a deep black dot. Found in America.
- PHORBANTA.** Wings tailed, black, spotted with blue; lower ones with an interrupted white band beneath. Found in the island of Cayenne.
- PHILENOR.** Wings tailed, black; the lower ones with a greenish gloss, and seven eye-like spots beneath. It inhabits America.
- CYRUS.** Wings tailed, black, the margin spotted with white; lower ones with a white macular band, and marked beneath with seven red lunules. A specimen is preserved in the British Museum.
- PAMMON.** Wings tailed, black, both surfaces of the same colour; the margin is spotted with white; lower ones with seven white spots.
- ASIS.** Wings tailed, black, with a common white band; lower ones spotted with red beneath, at the base, and tip. Found in South America.
- ACAMUS.** Wings indented, tailed, brown, both surfaces of the same colour; upper ones with a yellow band; lower ones with red, blue, and yellow lunules. Found in Jamaica.
- LAODOCIUS.** Wings indented, tailed, black; the upper pair with an abbreviated yellow band; lower ones with rufous, blue, and white lunules beneath. It inhabits Brazil.
- ACHATES.** Wings tailed, black, rufous at the base, both surfaces nearly of the same colour; the lower ones with a white spot divided into eight parts. It is found in China. There is a variety of this species named *Papilio Alcenor*, with brown wings, black at the base; the upper ones with a rufous spot; lower ones with white spots.
- LYSANDER.** Wings tailed, black; upper pair with a white streak; lower ones with a white spot in the middle, and red lunules. It is found in India.
- POLYDORUS.** Wings tailed, both surfaces alike, black; lower ones with a fix-cleft spot at the future, and seven red lunules. It inhabits India.
- COON.** Wings tailed, both surfaces alike; upper ones brown; lower ones black, spotted with white at the base, and a double yellow spot at the angle of the tail. It inhabits China.
- ANTIPHUS.** Wings tailed, black, both surfaces of the same colour; the lower ones with seven red lunules. It resembles the Polydorus, and is found in India.
- DARDANUS.** Wings tailed; the upper pair with a green round spot; lower ones with a red palmate spot. It is found in Brazil.
- TROS.** Wings indented, tailed, black, both surfaces alike; upper ones with an abbreviated white band; lower ones with a macular red one. It is found in Brazil.
- ANTIMACHUS.** Wings indented, elongated, black; upper ones with subradiate fulvous spots; lower ones with a radiate rufous disk speckled with black. It is found in Africa.
- PRIAMUS.** Wings indented, silky; upper pair above green, with a black disk and edge; lower ones with from four to six black spots. This, says Dr. Shaw, should take the lead, not only from the corresponding dignity of the name, but from the exquisite appearance of the animal itself, which Linnæus considered as the most beautiful of the whole papilionaceous tribe. It measures more than six inches from wing's end to wing's end; the upper wings are velvet-black, with a broad band of the most beautiful grass-green, and of a satiny lustre, drawn from the shoulder to the tip, and another on the lower part of the wing, following the shape of that part, and of a somewhat undulating appearance as it approaches the tip; the lower wings are of the same green colour, edged with velvet-black, and marked by four spots of that colour, while at the upper part of each, or at the part where the upper wings lap over, is a squarish orange-coloured spot; the thorax is black, with sprinklings of lucid green in the middle; and the abdomen is of a bright yellow or gold colour. On the under side of the animal the distribution of colours is somewhat different, the green being disposed in central patches on the upper wings, and the lower being marked by more numerous black as well as orange spots. It is a very rare insect, and is a native of the island of Amboyna.
- AMPHRSIUS.** Wings indented, black, both surfaces alike; upper ones with yellow spots; lower ones with a yellow disk.
- REMUS.** Wings indented, black, both surfaces nearly alike; lower ones with yellow marginal spots on each side. It inhabits Amboyna.
- LAOMEDON.** Wings indented; upper pair brown, lower ones

PAPILIO.

ones black, with a double rufous spot at the angle of the tail. It inhabits China.

MEMNON. Wings indented; all of them marked beneath with rufous at the base. It inhabits China.

ASTYANAX. Wings indented, black, both surfaces of the same colour; the upper ones with a striate white band, including a smaller one, lower ones spotted with black. It is found in India.

PROTENOR. Wings indented, black; the lower ones beneath with an irregular red spot at the angle of the tail. It is found in Surinam.

AGENOR. Wings indented, black, sanguineous at the base; lower ones white on the disk, with black spots. It is found in China.

ANCHISES. Wings indented, black, both surfaces alike; lower ones with seven ovate scarlet spots.

SARPEDON. This is a highly elegant species; the wings are of a lengthened shape, and the lower pair are stretched downwards into a pointed process; the whole animal is black, with a broad, interrupted, sea-green stripe, or band, passing through all the wings; on the lower part is also a border of crescent-shaped green spots.

POLYDAMAS. Wings indented, black, bronzed with a spotted yellow band; the lower ones with flexuous red lunules beneath. This is found on the *Aristolochia anguicida*.

ANDROGEUS. Wings indented, black, bronzed; the lower pair beneath with red, blue, and yellow lunules. It inhabits Surinam.

PERANTHUS. Wings indented, tailed, black; above green at the base, beneath pale at the tip, lower ones with seven fulvous lunules. It is found in China.

AMPHIMEDON. Wings indented, brown, both surfaces alike; upper ones radiate with white, lower ones with a five-cleft red spot, and red lunules. It inhabits Amboyna.

ZACYNTHUS. Wings indented, black; the upper ones with a green-white spot, lower ones with a palmate red one. It inhabits Brazil.

DIMAS. Wings indented, black, both surfaces alike; the upper wings with a white spot divided by the veins; lower ones with a palmate red spot. This also is a native of Brazil.

IDÆUS. Wings indented, black; upper pair with an abbreviated yellow band; lower ones with a palmate red spot and dots. Found at Madras.

VERTUMNUS. Wings indented, black; upper pair with a round green spot in the middle; lower ones with a palmate sanguineous spot. Inhabits Surinam.

ÆNEAS. Wings indented, black; upper pair with a green spot above; lower ones with a red palmate spot. It is found in India.

ILUS. Wings indented, black; upper pair with a white spot, lower ones beneath with red dots at the base and angle of the tail. This is an American insect.

IPHIDAMUS. Wings indented, black, both surfaces uniform; upper pair with an abbreviated white band; lower ones with a broad red one.

BELUS. Wings indented, greenish; lower pair rather pale at the inner margin, beneath brown, with red lunules. It inhabits Surinam.

POMPEIUS. Wings indented, black, both surfaces uniform; lower pair with red spots. It inhabits Surinam.

POLYMNESTOR. Wings indented, black, both surfaces nearly of the same colour; lower pair blueish towards the tip, and spotted with black and white. Found in divers parts of Asia.

PANTHOS. Wings indented, black, both surfaces uni-

form; upper pair spotted with white, lower ones with white spots, including some black ones. It is found in India. There is a variety in which the upper wings are clouded; lower ones with yellow spots.

PANDARUS. Wings slightly indented, both surfaces nearly alike, blackish, spotted with white; lower pair yellow, with seven black eyes; the pupil blue. It inhabits India.

ASTENOUS. Wings indented, black, both surfaces of the same colour; upper pair with a radiate white spot; lower ones yellow on the disk. It inhabits the Cape of Good Hope.

HELENA. Wings indented, black, both surfaces alike; common disk of the second pair of a brilliant gold-colour. It inhabits Surinam.

HELLACOR. Wings indented, black, both surfaces alike; disk of the lower ones yellow, dotted with black. It inhabits India.

EURYPYLUS. Wings indented, black, both surfaces alike, with an interrupted green band and spots; lower pair beneath spotted with red. It inhabits India.

CRESSIDA. Wings indented; upper pair hyaline, with two black spots; lower ones black, with a white spot. It is found in New Holland.

HARMONIA. Wings scalloped, white; both surfaces alike; upper pair with a black spot; under ones with a brown margin, and five white dots. It inhabits New Holland.

Equites. Greeks.

RIPHEUS. Wings with six tail-like processes, black with green bands; lower ones with a large red patch, enclosing two black dots. It inhabits Coromandel.

LELUS. Wings tailed, both surfaces alike, black with a shining green band, and numerous narrow stripes. This is an American insect.

LAVINIA. Wings tailed, black, barred with green, beneath silvery with fulvous stripes. It inhabits America.

BRUTUS. Wings tailed, white, with a black border; lower pair with a brown band beneath. It inhabits Africa.

DOLICAON. Wings tailed, white, with a common black border; lower ones with marginal white dots on each side. It inhabits America.

ULYSSES. Wings tailed, black, with a blue radiating disk; lower pair with seven ocellate spots beneath. This species is found in Asia.

DIOMEDES. Wings tailed, black; the disk unequally radiate with blue; the lower ones with blue lunules. It inhabits India.

PROTESILAUS. Wings tailed, both surfaces nearly alike, white with brown bands, and a single red one beneath; angle of the tail red. It is found in America.

ANTIOCHUS. Wings tailed, both surfaces alike, yellow, with black bands and margin; the tail is white, and as long as the wings. It is an inhabitant of North America.

* **PODALIRIUS.** Wings tailed, both surfaces nearly alike, yellowish, with double brown bands and margin; lower ones with five blue ocellate spots, and a reddish line beneath. This is found in our own country, and other parts of Europe. Mr. Donovan has given a figure of it.

ANTIPHATES. Wings tailed, white; the margin brown, barred with white; the lower ones beneath yellowish at the base, and barred with black. It inhabits America.

ALCIBIADES. Wings tailed, white; upper ones with black bands on the margin; lower ones beneath ferruginous

PAPILIO.

at the tip, dotted with black. It inhabits Tranquebar. Is less than the *P. podalirius*.

POMPILIUS. Wings tailed, white; the border barred with white; lower ones beneath with ferruginous spots, marked with black. This is an Indian insect.

STIXON. Wings tailed, black, with green entire band, stripes, and dots; lower ones with a red line underneath. It is found in India, and is half the size of the *Podalirius*.

AGAPENOR. Wings tailed, black, with green macular bands; lower ones with a fanguineous line beneath. Found in Africa.

THYASTES. Wings tailed, black, with a yellow band and spots; lower ones with a red line beneath. It inhabits Brazil.

CHIRON. Wings tailed, black, barred with brown; underneath white, on the fore part with ferruginous streaks. It inhabits India.

CRITHON. Wings tailed, above brown, beneath glaucous, with a white band on both sides. It is a small brown insect, and inhabits Surinam.

ORSILOCHUS. Wings tailed; upper ones with two white bands; lower ones with one; beneath white at the base, with a fulvous band. This also is an inhabitant of Surinam.

CURIUS. Wings tailed, both surfaces alike, black; upper pair with two hyaline bands; lower ones with a single white one. It inhabits Siam. A specimen is preserved in Sir Joseph Banks' museum.

OCTAVIUS. Wings tailed, hyaline, with a red margin and stripe. It inhabits Surinam.

LICARSIS. Wings tailed, black, with two white bands; the angle of the tail has two red dots. Found also in Surinam.

MELIBŒUS. Wings tailed, brown; upper pair with a red stripe; lower ones with two; beneath shining blue. It inhabits Surinam.

HOMERUS. Wings tailed, black, with a yellow band; lower ones yellowish underneath, with seven eyes. It inhabits America.

TURNUS. Wings tailed, both surfaces alike, yellow, with black margin, and five abbreviated bands; angle of the tail fulvous. Found in America.

* **MACHAON.** This is an insect of great beauty, and may be considered as the only British species of *Papilio*, excepting the *Podalirius*, belonging to the tribe of Equites. It is commonly known among the English collectors by the title of the Swallow-tailed butterfly, and is of a beautiful yellow, with black spots or patches along the upper edge of the superior wings; all the wings are bordered with a deep edging of black, decorated by a double row of crescent-shaped spots, of which the upper row is blue, and the lower yellow. The under wings are tailed, and are marked at the inner angle or tip with a round red spot, bordered with blue and black. The larva, or caterpillar of this species, feeds principally on fennel, and other umbelliferous plants, and is sometimes found on rue. It is of a green colour, encircled with numerous black bands, spotted with red, and is furnished on the top of the head with a pair of short tentacula of a red colour, which it occasionally protrudes from that part. In the month of July it changes into a yellowish-grey angular chrysalis, affixed to some part of the plant, or other neighbouring substance, and from this chrysalis, in the month of August, proceeds the complete insect. It frequently happens that two broods of this butterfly are produced in the same summer; one in May, having been in the chrysalis state all the winter; the other in August, from the chrysalides of July.

THERSITES. Wings tailed, yellow, with a black border;

lower ones with yellow lunules. It is found in America. A specimen is found in Dr. Hunter's museum.

CODRUS. Wings tailed, above black, underneath brown; upper ones with a macular white band on each side. This is found in Amboyna.

CHALCUS. Wings tailed, black, with two yellow macular bands; lower ones beneath with a yellow fillet and rufous lunules. Found in America.

MENESTHEUS. Wings tailed, black, beneath with whitish spots in streaks; lower ones with rufous and blueish lunules. It inhabits India.

XUTHUS. Wings tailed, black, with white spots in streaks; lower pair underneath with subfasciate blue and fulvous. It inhabits India.

THESANDER. Wings obtusely tailed, brown, with a yellow band and macular streaks; lower ones beneath chestnut-brown, on the disk with black lines. It inhabits Sierra Leone.

THOAS. Wings tailed, black-brown, with ochre yellow bands; lower pair yellow beneath, with a black band and blue lunules. This is found in South America. Dr. Shaw has given a figure of it.

CRESPHONTES. Wings tailed, black, with a green band; lower ones with a blue band beneath. Found in India.

POLYCAON. Wings indented, tailed, black, with a yellow band; lower ones with fulvous blue and yellow lunules beneath. It is found in Surinam.

AJAX. Wings tailed, both surfaces alike, brown with yellow bands, lower ones beneath with red streaks, and fulvous at the angle of the tail. Found in North America.

AGAMEMNON. Wings tailed, black spotted with green; lower ones with three rufous lunules beneath. It inhabits Asia.

ORESTES. Wings slightly tailed, above black, beneath yellowish, all of them with a snowy disk and two black bands. It inhabits Africa.

PYLADES. Wings indented, snowy, with a black border dotted with white; angle of the tail with a rufous eye. This also is an African insect.

DEMOLEUS. Wings indented, black, with yellow spots and bands, the under ones with a blue and rufous eye. It is found in different parts of the East Indies.

EPIUS. Wings indented, brown spotted with yellow; lower ones with a rufous spot at the angle of the tail. It is found in China.

LEONIDAS. Wings indented, both surfaces nearly alike, black spotted with green, lower ones with a green disk. It inhabits various parts of the continent of Africa.

TYNDERÆUS. Wings indented, black spotted with green; lower ones varied beneath with green, brown, and red, the base dotted with black.

ANTHEUS. Wings indented, black barred, and spotted with green; lower ones variegated beneath, with three red lunules. It is found in Amboyna.

NIREUS. Wings indented, black, with a green gilt band, beneath blackish. It is found in India.

LACEDÆMON. Wings indented, black, with whitish marginal lunules; lower ones chestnut brown, with seven black lunules beneath. Inhabits Malabar.

ZENOBIÆ. Wings indented, black, with a common white band, and marginal spots; lower ones beneath yellow at the base, and striate with black. It inhabits Sierra Leona.

CYNORTA. Wings indented, black, with a snowy band; lower ones beneath yellow at the base, dotted and striate with black.

AMPHIMACUS. The wings of this insect are indented, black,

PAPILIO.

black, with a shining blue band; beneath white on the fore part, cinereous behind. It inhabits India.

AMPHITRION. Wings indented, black, with an unequal yellow band; lower ones beneath with a stripe of yellow dots and blue lunules. Inhabits America.

HIPPOCOON. Wings indented, black, spotted with white, the common disk white. It inhabits Sierra Leona.

DISSIMILIS. Wings indented, with dilated veins, black, with white arrow-shaped spots; lower ones with marginal yellow spots beneath. Found in Asia.

ASSIMILIS. Wings slightly scalloped, both surfaces alike, black, with blueish-white dots; lower ones with scarlet dots.

HYPSPYLE. Wings indented, yellow, varied with black and radiate at the tip; lower ones with seven red dots. Found in the southern parts of Europe on the *Aristolochia clematitis*.

TRAPEZUS. Wings entire, fulvous; all of them with four blind eyes. Found in Russia.

FORTUNATUS. Wings entire, brown; lower ones marbled with white; black beneath. It inhabits Lapland.

CLYTUS. Wings very entire, brown; upper pair with a yellow band, lower ones with five eyes. It inhabits Africa.

HYPERBIUS. Wings very entire, brown, with a fulvous patch; upper ones with a bipupillate eye, lower ones blind beneath. It is found in divers parts of Africa.

CASSUS. Wings very entire, brown; upper pair with a double eye; lower ones with three eyes.

FLORIMEL. Wings very entire, brown; under surface of the upper ones with two eyes, of the lower ones with seven.

PHILOCLE. Wings very entire, brown; upper pair with a tripupillate eye, lower ones with transverse wavy lines. It inhabits India.

RENATUS. Wings very entire, both sides alike, black, with a common white band; upper pair with a tripupillate eye. It is found in Surinam.

CRÆSUS. Wings very entire, blue, with numerous black streaks; upper ones with a tripupillate spot above. It is found in Surinam.

* **HYPERANTHUS.** Wings entire, brown; under side of the upper pair with three eyes, the lower ones with five. It is an European insect and found in this country.

CLERIMON. Wings slightly scalloped; upper pair with a black eye above, all of them with four minute eyes beneath.

ZACHÆUS. Wings entire, brown, with two eyes above; under side of the upper pair with four, of the lower ones with six eyes. All the eyes have a white pupil.

ETHUS. Wings very entire, brown; upper pair with a bipupillate eye; lower ones with three eyes above, beneath black, with a white dot in the middle. It is found among the highest mountains of Lapland.

OEDIPUS. Wings very entire, above black, immaculate; beneath brown, with about three eyes on the upper, and five on the lower ones. It inhabits Russia.

ZANGIS. Wings very entire, brown; all of them beneath with a single eye, that on the upper ones bipupillate. It is found in Carolina.

PHOCION. Wings entire, above brown, immaculate; lower ones beneath with yellow streaks, and three oblong eyes. It is preserved in the British Museum.

AREOLATUS. Wings very entire, above brown, immaculate; beneath with a common testaceous streak, margin, and circles, on the upper pair four eyes, on the lower ones

six, the middle ones elongated. It is found in Georgia, and has been supposed to be a variety of the *P. canthus*.

SOSYBIUS. Wings very entire, above brown, immaculate; under surface of the upper ones with five eyes, of the lower ones with six, the middle ones blind.

PERSEUS. Wings very entire, brown; under side of the upper ones with ocellar spots, of the lower ones with seven. It inhabits New Holland.

MARTIUS. Wings very entire, black; under side of the upper pair with four, of the lower ones with seven ocellar spots.

TERMINUS. Wings entire, brown, with a rufous patch; upper pair with a single eye above, lower ones with four. Found in New Holland. A specimen is preserved in the museum of Sir Joseph Banks.

SIRIUS. Wings very entire, dull rufous; upper pair with two eyes above, lower ones with four. This is also a New Holland insect, and is likewise in Sir Joseph Banks' museum.

CORNELIUS. Wings very entire, dull, cinereous; lower ones with four approximate eyes.

DAVUS. Wings very entire, fulvous; upper pair with an eye, and white bands beneath, lower ones with six eyes. It is found in Germany.

* **PAMPHILUS.** Wings very entire, yellow; under side of the upper ones with a single eye, of the lower ones cinereous, with a band and four obliterated eyes. This and the next species are found in England and other parts of Europe.

* **ARCANIUS.** Wings very entire, ferruginous; under surface of the upper ones with a single eye, of the lower ones with five, separated by a band.

LEANDER. Wings very entire, brownish; lower pair beneath cinereous, with fulvous tip and six eyes. Common in the southern parts of Europe.

SABÆUS. Wings entire, brown; upper pair with four blind eyes above, and six pupillate ones beneath.

* **HERO.** Wings very entire, fulvous; under surface of the upper pair with a single eye, of the lower one with six. This is an English insect, and is described and figured by Mr. Donovan.

ARCTUOUS. Wings entire, brown; upper pair with bipupillate eye on both sides; lower ones nearly blind. Found in New Holland. A specimen is in the museum of Sir Joseph Banks.

PHRYNEUS. Wings entire, above white, beneath brown, with white veins and five eyes. Found in Russia.

HYPHEUS. Wings entire, both sides alike, white with brown bands; upper pair with a black eye, lower ones brown. Inhabits the East Indies.

BALDUS. Wings very entire, brown; upper pair with an eye on each surface, the pupil double; lower ones with four eyes above, and six beneath. It is a small insect and a native of India. A specimen is in the museum of Dr. Hunter.

MAGUS. Wings very entire, dull, fulvous; upper pair with an eye on each side, the pupil double; lower ones with two eyes above and three beneath.

DROMUS. Wings very entire, black; upper pair with the disk rufous, in which is a double eye. It inhabits Italy, and is a small insect.

EUMENUS. Wings very entire, half brown; upper ones with a black tripupillate eye on both surfaces. It inhabits the West Indies.

EPHYNEUS. Wings very entire, blue, with purple bands; upper pair with an eye on each side, which is tripupillate beneath. It inhabits Surinam.

TULLIUS.

PAPILIO.

TULLIUS. Wings very entire, dull, cinereous; upper pair brown at the tip, with a tripupillate eye on each side. It inhabits Cayenne.

ACTÆA. Wings scalloped, above brown; upper pair with two eyes and two white dots; lower ones marbled beneath. It inhabits Russia.

FIDIA. Wings indented, above brown; upper pair with two eyes and two white dots; lower ones with an angular black streak beneath. It inhabits Africa.

FERULA. Wings scalloped, black; under side of the upper pair with two eyes, of the lower with cinereous bands. Inhabits Italy.

CORDULA. Wings indented, brown; upper pair with two eyes, and two white dots on both sides, lower ones with two black dots. It inhabits Italy, and is the size of the former ones.

FAUNA. Wings indented, above brown; upper pair with two eyes, and two white dots; lower ones grey beneath. It inhabits Germany.

FERONIA. Wings indented, marbled with blue, brown, and white on the upper surface, all of them with six eyes. It inhabits the East Indies.

* **MÆRA.** Wings indented, brown; upper pair with an eye, including a lesser one on both sides; lower ones with three eyes above, and six beneath. Found in this country, as the asterisk denotes.

ROXELANA. Wings indented, brown; above blind; lower ones waved beneath, with seven eyes, the inner one with a double pupil. It inhabits several parts of Asia.

PROSERPINA. Wings indented, fulvous; upper pair black at the tip, with yellow dots; lower ones marked beneath with four eyes, the middle ones blind. A specimen is in the museum of Sir Joseph Banks.

LYCAON. Wings indented, upper pair brown and spotted with yellow and white; lower ones ferruginous, with six blind eyes; beneath variegated.

ALOPE. Wings indented, brown; upper pair with a yellow band on each side, and two eyes; lower ones with a single eye above, and six beneath. It inhabits India.

CLUERIA. Wings indented, brown; lower ones with a blue band, in which are five black eyes; a brown band beneath, with five eyes.

LACHES. Wings indented, brown, with a blue band beneath; upper pair with five eyes, lower ones with six. Inhabits Guiana.

HERSE. Wings indented, rusty-brown; upper pair dotted with white; lower ones with seven blind eyes.

DEJANIA. Wings indented, brown; upper pair with five eyes on each side; lower ones with six, and a white scalloped band. It is found in Germany.

PEGALA. Wings indented, brown; upper pair with a rufous band and single eye; lower ones with an eye above, and six beneath. This is an American insect, and is found in Dr. Hunter's museum.

BRISEIS. Wings indented, brown, with a green gloss and white band; the upper ones have two eyes; the lower ones none. Found in Germany. The eyes, in this species, are sometimes wanting on the upper surface.

MANTO. Wings slightly indented, brown; with four ocellar dots on the upper and three on the lower wings; the under face of the latter cinereous with brown waves. It is found in Austria.

AUTONOE. Wings indented, brown, subfasciate with yellow and two pupillate eyes; upper ones brown at the base beneath. It is found in Russia.

* **SEMELE.** Wings indented, brown, with a macular fulvous marginal band, in which are two eyes; upper pair

with a fulvous disk at the base beneath. It is found in divers parts of Europe.

ARETHUSA. Wings indented, above brown, with a macular rufous band; upper pair with a single eye on each surface. It is found in Germany.

HERMIONE. Wings indented, brown, with a pale band; upper pair with two eyes above, and one beneath. It is found in France and Germany.

CIRCE. Wings indented, brown, with a white band on both surfaces; upper pair with a single eye. This is an European insect.

* **PHŒDRA.** Wings indented, brown, both sides alike upper pair with two violet eyes.

PERIBŒA. Wings indented, brown; upper pair with an obsolete eye, a yellowish streak beneath; lower ones with ocellar black dots. Inhabits Surinam.

DELILA. Wings scalloped, brown; upper pair with a small eye; under side of the upper one with two eyes, of the lower one with six, the fourth larger. It inhabits Guinea, and is middle-sized.

LIGEA. Wings indented, brown, with a rufous band; upper pair with four eyes, the lower with three on each surface, all spotted with white beneath. Found in Europe.

BATHSEBA. Wings scalloped, brown, with the disk ferruginous; upper pair with a bipupillate eye on both sides, lower ones beneath brown, with a white band. It is found in Barbary.

MEDUSA. Wings slightly scalloped, brown, both surfaces alike, all of them with a yellow macular band, and about four eyes. This is found in Austria.

EPIPHRON. Wings entire, black with a red band; upper pair with two eyes above and three beneath, lower ones with three above and five beneath. It inhabits Germany.

BLANDINA. Wings indented, brown, with a rufous ocellate band; lower ones brown beneath, with a cinereous band. Found in Germany.

GRIELA. Wings slightly indented, black; upper pair with four connected spots on each side. It inhabits the highest mountains of Lapland.

ÆRA. Wings entire, brown with six eyes; lower ones covered with cinereous down. It inhabits Russia.

ERINA. Wings indented, brown, with a macular fulvous band and ocellar black dots. It is found in Germany.

ARACHNE. Wings entire, black, upper pair with a rufous band on each side, containing two eyes; lower ones with an indented cinereous band beneath. It inhabits Austria, and is the size of the last.

PYRRIA. Wings entire, brown, with a red band, which is dotted with black on the upper pair, and macular on the lower ones. It inhabits Austria.

CASSIOPE. Wings entire, brown, with a rufous band, containing three ocellate black spots; the lower ones with only dots beneath.

ARETE. Wings entire, brown with a rufous band; lower ones with a stripe of white dots on each side. It inhabits the mountainous parts of Austria.

SALOME. Upper wings brown, with a rufous band containing a single eye; lower wings with three eyes, beneath an indented white streak, and five eyes. This species is found at Gibraltar.

* **GALATHEA.** Wings indented, varies with brown and yellowish-white; under surface of the upper one with a single eye; of the lower ones with five.

ARGE. Wings indented, white streaked with black; upper

PAPILIO.

upper pair with a single eye, the lower ones with five. Found in Russia.

LIRIA. Wings slightly indented, cinereous, with brown waves; the upper pair has a white band, lower ones with four ocellar white dots. It inhabits India.

PILOSELLÆ. Wings indented, brown, with a yellowish disk; upper pair with a black eye, and double pupil on each side; lower ones with snowy ocellar spots beneath. It is found in many parts of Germany.

IDA. Wings slightly indented, brown, with a yellow disk; the upper pair with a black bipupillate eye on each side, the lower ones varied with grey beneath.

MELUFONA. Wings indented, brown, with a white disk; lower surface whitish, with two eyes on the upper pair, and seven on the lower ones.

CADMA. Wings indented, fulvous; lower ones beneath white on the disk, with two eyes, the pupil double, blue. Inhabits America.

* **JANEIRA.** Wings indented, brown; upper pair beneath yellow, with a single eye on each side; lower ones with three dots beneath. In the female, the upper pair of wings has a yellow patch, including a single eye on each side.

CLYMENE. Wings indented, brown, with a ferruginous patch; lower ones with about three eyes above, and seven beneath. Inhabits Russia.

MIRIAM. Wings indented, brown, beneath cinereous, with two eyes on the upper pair, and seven on the lower. It inhabits India.

EUDORA. Wings indented, brown; upper pair with a ferruginous disk on each side, containing a single eye in the male, and two in the female. It inhabits Germany.

TABITHA. Wings indented, black; upper pair with a single eye; all of them paler beneath, with a streak of ocellate dots. It inhabits the East Indies.

TISIPHONE. Wings indented, brown; upper pair with two eyes on each side, lower ones with six. The pupils all are violet. It is found in Germany.

HALYMA. Wings indented, above brown, immaculate, beneath with yellow bands; upper pair with five eyes, the lower with seven. It inhabits India.

RUMINA. Wings indented, variegated; upper pair with six red dots above, lower ones with four. It inhabits the southern parts of Europe.

FLEGIA. Wings indented, both sides alike, fulvous, with numerous brown dots. It inhabits Cayenne.

ALLICA. Wings indented, both surfaces nearly alike, obscure, fulvous, with numerous black spots, each including a white one. It inhabits Siam.

MELICERTA. Wings indented, both sides alike, black dotted with white; upper pair with a common white interrupted band. This is an African insect.

ACERIS. Wings indented, with black bands, above black, beneath fulvous. This is found in many parts of Europe and Asia.

ACESTE. Wings scalloped; upper pair black, with a yellow band and base, lower ones yellow, with brown bands beneath. Found in India.

SULPITIA. Wings indented, black, with a common white band; lower ones yell. with beneath, with black dots at the base, a white band in the middle, and dots at the tip.

SIBILLA. Wings indented, above brown, beneath ferruginous, spotted with black, and a macular white band on both surfaces. It inhabits Europe.

* **CAMILLA.** Wings indented, dark brown, with a white band, and dots on each side; lower ones silvery blue at the base.

LUCILLA. Wings indented, above brown, beneath

chestnut-brown, with a macular white band both sides. It inhabits Austria.

CÆNOBITA. Wings indented, black; upper pair with a white streak and spots; lower ones with a white band above, beneath white, with four brown bands and marginal spots. It inhabits India.

HERSILIA. Wings indented, white, with a fulvous border, lower ones fulvous, beneath two white bands, and a dot in the middle. It inhabits America.

SOPHIA. Wings indented, varied with yellow, fulvous and black, the margin brown, dotted with black; white lunules on the lower ones. It inhabits India.

DORICLEA. Wings scalloped down; lower ones with a fulvous band dotted with black, and a black dot beneath. It inhabits India.

AUGE. Wings indented, brown; upper pair with three green bands; lower ones with a fulvous band dotted with black, a black dot at the base beneath. It inhabits India.

ETHESIA. Wings indented, black, with a yellow disk; beneath varied with brown and yellow, the base dotted with black. It inhabits Africa.

NARVA. Wings indented, black, with a line of white dots behind; upper pair with yellow spots, lower ones with a yellow disk. This is found in Africa.

MARDANIA. Wings indented, fulvous; upper pair black at the tips, with a white band; lower ones with four ocellar yellow spots.

COCALIA. Wings indented, brown; upper pair spotted with black and yellow; all of them grey beneath, with a line of white dots. It inhabits India.

* **LUCINA.** Wings indented, brown, with testaceous spots; lower ones with two rows of whitish spots beneath. It inhabits Europe.

* **CINXIA.** Wings indented, fulvous, with black spots; lower ones with three whitish bands, dotted with black beneath. It inhabits Europe.

PÆEBE. Wings indented, varied with black and fulvous; lower ones beneath yellowish, waved with black, the base with four black spots, and two fulvous bands, the hinder one composed of spots. This is an European insect.

DIDYMA. Wings indented, fulvous, spotted with black; lower ones beneath yellow, dotted with black, with two continued fulvous bands. It inhabits Russia.

FASCELIS. Wings indented, varied with fulvous and brown; lower ones beneath white, dotted with black, with two fulvous bands, the lower composed of lunules.

ATHALIA. Wings scalloped with fulvous, dotted with black; lower ones beneath white, dotted with black, with two fulvous bands. It inhabits Russia.

HYLLA. Wings indented, fulvous, speckled with black; lower ones brown at the base, beneath whitish. This is found in the East.

* **DICTYNNA.** Wings indented, black, with fulvous spots; lower ones beneath fulvous, with white spots at the base, and band in the middle, the tip with yellow lunules.

CYNTHIA. Wings indented, black, with fulvous and yellow bands; lower ones beneath fulvous, with yellow bands. It inhabits Austria. In the male there are a few white spots.

* **MATURNA.** Wings indented, varied with fulvous and black; lower ones beneath with yellow bands, and waved black streaks, the base impunctured. It inhabits Europe.

ARUINA. Wings indented, fulvous, spotted with black; lower ones beneath white, with two fulvous bands, the lower speckled with black. This is found in Russia.

HECATE. Wings indented, fulvous, spotted with black;

PAPILIO.

all of them with two streaks of black dots at the tip. This is found in Aultria.

* **ARTEMIS.** Wings indented, fulvous, variegated with black; lower ones with a streak of black dots on each side.

AMATHUSIA. Wings indented, fulvous with black spots, and a punctured streak; lower ones variegated beneath, a black dot at the base, and a streak at the tip.

* **DIA.** Wings fulvous, spotted with black; lower ones beneath purple, the base with yellow and silvery spots, and an obsolete silvery band in the middle.

DRYOPE. Wings indented, brown, with rufous spots, the tip fulvous; beneath with rufous spots, furrounded with a white ring. It inhabits Sierra Leona.

* **LEVANA.** Wings denticulated, variegated, beneath reticulate, upper ones with a few white spots.

PRORSA. Wings indented, brown, beneath reticulate with white; the upper pair with a white interrupted band on each side. This is an European insect.

PANDORA. Wings indented, fulvous, spotted with black; lower ones beneath scarlet, immaculate.

PALES. Wings slightly indented; fulvous, with black base and spots; lower ones beneath nut-brown, and variegated with yellow and silvery. This is found in Aultria.

DAPHNE. Wings indented, fulvous, spotted with black; lower ones beneath yellow, with rufous veins, the tip silvery, ferruginous. Inhabits Aultria, and is found on the *Rubus idæus*.

Heliconii.

HORTA. Wings entire, red, upper one hyaline at the tip, lower ones beneath whitish dotted with black. This is an inhabitant of Africa.

QUIRINA. Wings entire, hyaline; disk of the upper pair fulvous, speckled with black. This is found at Madras.

CALLIOPE. Wings entire, yellow; upper pair with three black streaks; lower ones with three black bands. It inhabits India.

MELITE. Wings entire, yellow; upper pair black, with two yellow lines, and a band. Inhabits India.

MOPSA. Wings entire, both surfaces alike, yellow and black, the margin dotted with white. It inhabits India.

MNEME. Wings entire, fulvous, spotted with black; upper pair black at the tip, with yellow spots; lower ones black, with a fulvous band behind. It inhabits India.

LYCASTE. Wings entire, fulvous, tipped with black; upper pair spotted with yellow.

LYSIMNIA. Wings entire, fulvous, with a yellow band, the tip black, with a white spot on the upper pair.

CLARA. Wings scalloped, black, spotted with yellow, and a common testaceous base. It is found in Surinam.

EGENA. Wings entire, upper pair fulvous, with a yellow band, the tip spotted with yellow, and a row of white dots on each side. This is an American species.

EVA. Wings entire, both surfaces alike, black; upper pair with fulvous streaks at the base, and spots at the tip, disk of the lower ones fulvous, with a black band. It inhabits Surinam.

LYBIA. Wings entire, upper pair black, with two fulvous bands; lower ones fulvous, with a marginal black band. It inhabits India.

VESTA. Wings entire, yellowish, the margin dotted with black. It inhabits China.

HYPARTIA. Wings entire, fulvous, dotted with black, the margin black, immaculate. It inhabits Africa.

VIOLÆ. Wings entire, fulvous, dotted with black; mar-

gin of the lower ones black, with seven white dots. It inhabits India.

TERPSICORE. Wings entire, fulvous; lower pair dotted with black. It inhabits Asia.

SERENA. Wings entire, fulvous; base of the lower pair beneath dotted with black. Found in India.

POLYMNIA. Wings entire; upper pair with black spots, and tip and yellow band; lower ones with three black bands, the middle one ferrate. This is found in America.

HIPPODAMIA. Wings entire, upper pair black, with three hyaline bands; the lower ones are likewise hyaline.

IRENE. Upper wings black, with yellow spots, and a fulvous line at the base; lower ones fulvous, edged with black. It inhabits America.

SAPPHO. Wings entire, both surfaces alike, black-blue; upper pair with a white band; lower ones edged with white. Inhabits Jamaica.

URANIA. Wings entire, brown, with a white disk; lower ones with two eyes each. This is found in India.

DORIS. Wings entire, black; upper pair spotted with yellow; lower ones radiate, with blue at the base above. It is found in Surinam.

OLYMPIA. Wings entire, black; upper pair with an oblong fulvous spot at the base, and white ones at the tip, lower ones fulvous at the base.

CRISIA. Wings entire, black; upper pair acuminate with a yellow band; lower pair with a yellow disk. It inhabits America.

HECALE. Wings entire, black; upper pair with a white band; lower pair with white marginal dots beneath. Found in Surinam.

RICINI. Wings entire, brown; upper pair with two yellow bands on each side; lower ones rufous at the base. It inhabits America.

SARA. Wings scalloped, black, with a blue base; upper pair with two yellow bands; lower ones with red beneath. It inhabits Guiana.

ARANEA. Wings black; upper pair with a yellow streak at the base, and two bands; lower ones with a red band beneath.

BRASSOLIS. Wings entire, brown; upper pair spotted with yellow; lower ones beneath with red rays. It inhabits Surinam.

THALES. Wings nearly entire, and alike on both surfaces, black, with red rays at the base; the upper pair is spotted with yellow. It inhabits Surinam.

MYRTI. Wings entire, black; upper pair with two yellow bands; lower ones with a rufous disk. It inhabits Surinam.

NASICA. Wings entire, black; upper pair with two yellow bands; lower ones with a yellow disk.

CEPHA. Wings entire, black; upper pair with an abbreviated white band; lower ones fulvous at the base, and radiate beneath. It inhabits Cayenne.

PSIDI. Wings entire, brown; upper pair with three hyaline bands, lower ones with two. It is found in India.

ASPASIA. Wings entire, black, with hyaline streaks and spots; lower ones yellow at the base. It inhabits Tranquebar.

ÆGLE. Wings entire, black; upper pair with hyaline spots; lower ones with a hyaline disk.

CHARITONIA. Wings entire, black, upper pair with three yellow bands, lower ones with two. Inhabits America.

MELPOMENE. Wings entire, black; upper pair with a red band; lower ones with red dots at the base beneath. It inhabits America.

PAPILIO.

PHYLLIS. Wings entire, black; upper pair with a red band; lower ones with a yellow one. It inhabits Brazil.

CLIO. Wings entire, brown; upper pair spotted with white; lower ones with a white band. It inhabits America.

THALIA. Wings entire, brown; upper pair spotted with yellow; lower ones striate. It inhabits India.

ROSALIA. Wings entire, both surfaces alike, fulvous; upper pair with a yellow spot; lower ones with two black streaks. Inhabits Surinam.

EURYTA. Wings entire, both surfaces alike brown, with a white band; lower ones striate, the base is dotted with black.

UMBERA. Wings entire, brown, with a testaceous base; lower ones speckled with black.

AEDEA. Wings entire, spotted with white; upper pair greenish; lower ones with a yellow band. It inhabits India.

THALLO. Wings entire, black; upper pair with two yellow bands; lower pair with a single one. It inhabits China.

ANTICHA. Wings entire, black; upper pair with two white bands. It is found in India.

CAMOENA. Wings nearly entire, brown, dotted with black; lower ones with a red band. It inhabits Africa.

MACARIA. Wings entire, brown; upper pair with a black base, and broad rufous band in the middle; lower ones dotted with black at the base.

ZETES. Wings brown, dotted with black; lower pair with a fulvous band, dotted with black, the margin beneath with pale dots. It inhabits Guinea.

PERSIPHONE. Wings entire, brown, dotted with black; upper pair with a white spot, margin of the lower ones black, immaculate.

GEA. Wings entire, black; upper pair with two spots; disk of the lower ones fulvous, striate with black, the base beneath is striate with black. This species inhabits Africa.

JODUTTA. Wings entire, black, upper pair with two white spots, disk of the lower ones white, striate with black, the base beneath dotted with black.

PARRHASIA. Wings entire, black; upper pair with a four-cleft fulvous and hyaline spot; lower ones with a fulvous band, beneath yellow with black dots and lines.

LYCIA. Wings entire, both surfaces alike, brown, spotted with white; disk of the lower ones white, with black dots. It inhabits Sierra Leona. There is a specimen in Sir Joseph Banks' Museum.

PYRRHA. Wings entire, both surfaces alike, brown, spotted with yellow; disk of the lower ones ferruginous, striate with black. It inhabits Brazil.

PASIPHLE. Wings entire, brown, varied with white, with black spots and margin. It inhabits Guinea.

MARCIA. Wings entire; upper pair brown, immaculate; lower ones yellowish, dotted with black. This, and also the two next, are found in Africa, and specimens are preserved in Sir Joseph Banks' Museum.

COECILIA. Wings white, in the middle dotted with black; margin of the lower ones black, beneath it is dotted with white.

BONASIA. Wings entire, brown, with a common fulvous band; base of the lower ones dotted with black.

EUTERPE. Wings entire, black, with a fulvous band and white dots. It inhabits America.

SUSANNA. Wings entire, black, dotted with white, a fulvous spot at the base and band behind. It is found in Africa. A specimen is in Sir Joseph Banks' Museum.

HYPARETE. Wings entire, white, with black veins; lower ones beneath yellow, the margin spotted with red. It inhabits India.

PASITHOE. Wings black, slightly radiate, with white, and a central white dot; lower ones beneath sulphur, with black margin and veins; the base is red. There is a variety, in which the wings are entire, black, spotted with white; lower ones beneath yellow on the disk, with a red band at the base.

ERYTHREA. Wings black; upper pair with two red bands; lower ones with six red streaks. Found in Surinam.

ERATO. Wings entire, black; upper pair spotted with yellow and red at the base; lower ones are striate with red. This is found in India.

BELLADONA. Wings entire, black; upper pair with hyaline dots; lower ones with yellow spots.

JULIA. Wings indented, fulvous; upper pair with two black streaks; lower ones black on the hind margin.

HIPPONA. Wings indented, tail varied with yellow and black; lower ones with four white dots. It inhabits India.

Parnassii.

APOLLO. Wings entire, white, spotted with black; lower ones with four eyes above and six beneath. This is a native of many parts of Europe, but has not been observed in these islands. It is something larger than the common great cabbage butterfly. The caterpillar is black, with small red spots, and a pair of short retractile tentacula in front; it feeds on orpine and some other succulent plants, and changes into a brown chrysalis, covered with a kind of violet-coloured powder.

PHOEBUS. Wings entire, both surfaces alike, white, spotted with black; lower ones with three red spots, circled with black. It is found in the wilds of Siberia.

MNEMOSYNE. Wings entire, white, with black nerves; upper pair with two black marginal spots. It inhabits Europe.

* **CRATÆGI.** Wings entire, white, with black veins. This is sometimes called the hawthorn butterfly, and is well known in this country. It is of the size of the common cabbage butterfly, and is seen in the months of June and July.

ANDROMACHIA. Wings entire, both surfaces alike, dotted with black; the upper pair is dusky and naked; the lower ones yellowish. It is found in New Holland.

MANDANE. Wings oblong, entire; the upper pair is hyaline, with black veins; the lower ones black, with a white band. It inhabits Africa.

PIERA. This species has semitransparent wings, with the lower pair marked by two ocellated black spots, with a yellow ring and centre. It is a native of South America.

ANACARDII. Wings entire, hyaline, greenish; lower ones brown at the tip, with two eyes. It is found in America.

NEREIS. Wings scalloped, brown; lower ones with a snowy band, the disk is fulvous, with two black eyes. It inhabits America.

ANDROMEDA. Wings hyaline white; lower ones red at the tip, with a single eye in each. It is found in India.

DIAPHANUS. Wings entire, hyaline, white, the margins brown. It inhabits Jamaica.

HYALINUS. Wings entire, both surfaces alike, upper pair hyaline, with black bands and margin; lower ones testaceous.

OBSCURATUS. Wings testaceous hyaline; upper pair with a yellow band.

IDEA. Semitransparent wings, white, with black spots and veins. It inhabits India.

Eflivi.

PAPILIO.

Festivi.

CYPARISSUS. Wings entire, black, with two white bands, those of the upper pair oblique, of the lower ones punctate. It inhabits America.

MIDAMUS. Wings entire, black, dotted with white; upper pair above blueish; lower ones with a row of white dots. A native of India.

DRYASIS. Wings entire, brown; upper pair with two white dots, all of them with numerous ones beneath. A specimen of this is in the British Museum.

DIOCLETIANUS. Wings entire, black; upper pair with an interrupted white band; lower ones with white lines at the base, and a double row of dots at the tip. A native of the East Indies.

CLAUDIUS. Wings entire, black; upper pair with a blue gloss, and dotted with white; lower ones with white lines. It inhabits Tranquebar.

NAVIUS. Wings entire, black; upper pair with a white band; lower ones with a common white spot at the base. A native of Sierra Leona.

DAMOCLES. Wings entire; upper pair black; lower ones brown with a white disk. It inhabits Asia and Africa.

CORUS. Wings entire, black, all of them with a double row of white dots. A native of India, as is also

TULLIOLUS. Wings entire; upper pair black, with a macular white band; lower ones brown, above immaculate, beneath dotted with white.

SYLVESTER. Wings entire, brown, with a macular white band.

COCHRUS. Wings entire, both surfaces alike, black, with a macular white band; abdomen red, with black belts. In Dr. Hunter's Museum.

LIBERIUS. Wings entire, lead colour, under surface of the upper pair green, of the lower ones fulvous. It inhabits Amboyna.

RADAMANTHUS. Wings entire, black, with a blue gloss; upper pair with a marginal white spot; the lower ones with a white spot and four lines. It is a native of Asia.

ZOILUS. Wings entire, black; upper pair with three white spots, lower ones with a white disk. It is a native of New Holland.

CYNTHEUS. Wings entire, black with testaceous veins, and a white band, which in the upper pair is interrupted. It inhabits Africa.

ARETHEUSUS. Wings entire, black with blue spots; lower ones with red dots beneath. It is found in Surinam.

CLYMENUS. Wings entire, with a blue band; upper pair beneath, fanguneous; lower ones beneath, white with black rings and dots. It is a native of Brazil.

SISAMNUS. Wings entire, black dotted with white and a common white band, which is interrupted in the upper pair.

JASSUS. Wings entire, brown with black streaks; upper pair with a marginal white spot, beneath paler with brown streaks. It inhabits Cayenne.

ANTIOCHUS. Wings entire, black with a common fulvous band above. It is a native of China.

SYPHAX. In this the wings are entire and black; the upper pair has a white band; the lower ones with a marginal red one.

EVALTHE. The wings are entire, black; upper pair with two yellow bands; the lower ones are marked with a yellow band and red spots, beneath red with a yellowish macular band. It is a native of India.

LICAS. Wings entire, brown; upper pair with two white bands; lower ones with a single white band and red spots, beneath cinereous with white bands. It is a native of Surinam.

PHALARIS. The wings of this species are entire and brown; the lower pair with two macular white streaks.

PELASGUS. The wings are entire, both surfaces alike; upper pair greenish with a fulvous band; lower ones immaculate. It inhabits Surinam.

PHICTON. In this the wings are entire, black, with white and rufous spots. It is a native of America.

SOPHUS. The wings are entire; upper pair black, the disk fulvous, spotted with black; the lower ones brown, with a black streak and dots.

GALANTHUS. Wings entire; above black, with sanguineous bands; upper pair with two white dots at the tip.

CENÆUS. Wings entire, brownish; lower ones beneath with a red orb of nine spots. It inhabits India.

CHERMES. Wings entire, dusky; lower ones red, with black bands above, and a snowy dot, in the middle beneath. It is a native of Africa.

HESPERUS. The wings of this are scalloped, brown with black waves, upper pair with white dots.

MIRUS. The wings are scalloped, brown, slightly fasciate with testaceous; lower ones beneath brown at the base, and variegated at the tip.

TYTIUS. Wings entire, brown spotted with white; upper pair with ocellar black dots. It inhabits Surinam.

EUPALUS. The wings are entire, brown; lower ones with a blue band, beneath green, with a black dot. It inhabits Africa.

PINTHEUS. Wings entire, both surfaces alike, brown; upper pair with three yellow spots; lower ones white on the lower half. It is a native of India.

ARCHIPPUS. Wings scalloped, fulvous, with black veins, the margin black, dotted with white; upper pair with fulvous spots at the tip. It is a native of America.

PLEXIPPUS. Wings entire, fulvous, with dilated black veins, the margin black, with white dots; upper pair with a white band at the tip. It inhabits America.

ERIPPUS. Wings entire, dull testaceous, the edge black dotted with white; disk of the lower ones immaculate, beneath with black veins, and white dots. A native of China.

MISIPPUS. The wings of this are scalloped, and fulvous, the edge black, dotted with white, lower ones with a black curve. Found in America.

CHRYSIPPUS. Wings entire, fulvous, the margin black, dotted with white; disk of the lower ones white, with black dots.

ALCIPPUS. Wings entire, fulvous, the margin black, dotted with white; disk of the lower ones white, with black dots. This and the two following are natives of America.

ELEUS. The wings are entire, fulvous; the margin black, of the upper pair with a white band, of the lower ones with white dots.

ERESIMUS. The wings scalloped, testaceous, the tip and margin black dotted with white; lower ones beneath with an obsolete macular whitish band.

DIOCIPPUS. Wings scalloped, fulvous, with a common black border dotted with white; lower ones beneath with three black dots, and a streak of white ones behind. It inhabits India.

GILIPPUS. Wings entire, both surfaces alike, fulvous, spotted with white, the margin black, with white dots. It inhabits America.

HEGESIPPUS. Wings entire, both surfaces alike, black, spotted

PAPILIO.

spotted with white; base of the upper pair fulvous, of the lower ones with white lines.

DARIUS. The wings are entire, brown; upper pair spotted with white, lower ones with a black curve beneath. It inhabits Brazil.

DÆDALUS. Wings entire, brown spotted with white; beneath nut-brown. It is a native of Guinea.

NICÆUS. Wings entire; upper pair with a black eye; lower ones above with a red marginal band and black ocellar spots. It inhabits India.

NUMILIUS. Wings entire, black; upper pair with two fulvous spots, lower ones with a single one. A native of Brazil.

CODOMANNUS. The wings entire, black, with red bands, lower ones beneath with angular yellow lines and blue dots. It inhabits Brazil.

POLYMENUUS. Wings entire, rusty-brown, dotted with black; beneath yellowish, waved with black. It inhabits Surinam.

HYDASPES. Wings entire, brown, with a blue gloss; lower ones beneath yellow, with annular black lines, and three blue dots. A native of Brazil. A specimen is preserved in Sir Joseph Banks' museum.

JAIUS. Wings entire, brown; disk of the lower ones white, with a blue eye above, and two beneath. A native of India.

HAQUINUS. Wings nearly entire, brown; beneath orange, with blueish-silvery spots, marked with black. Found at Tranquebar.

ORION. Wings scalloped; upper pair falcate, rufous, the tip black, with a marginal white spot. Found at Surinam.

COCYTUS. Wings falcate; above black, the hind margin cinereous. It inhabits Siam; and a specimen is in Sir Joseph Banks' museum.

DRUSIUS. Wings entire, fulvous, tip with black; lower ones beneath with white dots and two eyes. This is a native of Rotterdam island.

THYMETUS. Wings entire; yellow, with a common brown border. In the museum of Dr. Hunter.

ABSOLON. Wings fulvous, with brown bands, beneath orange, with brown waves. It inhabits Guinea.

ODIN. Wings entire, dusky, with a single angle; lower ones beneath with a pair of black sub-ocellate dots on each side. It inhabits China.

CELLINE. Wings indented, oblong, fulvous; upper pair with a black lunule. It is a native of America.

DIDO. Wings indented, oblong, black, spotted with green; lower ones with a blueish band, and seven transverse spots. It is a native of America.

EURINOME. Wings indented, black, spotted with white; lower ones white at the base. It inhabits India: so also do the two following.

PHILOMELA. Wings scalloped, black, spotted with white; lower ones radiate, with yellow at the base.

SIMILIS. Wings slightly scalloped, both surfaces alike, with blueish-white dots lineate towards the base.

AFFINIS. Wings indented, black, spotted with white; border of the lower ones beneath black, spotted with yellow and white. A native of New Holland.

LAIUS. Wings indented, black, with blueish stræ, beneath brown. Found in India.

ENOTHIREA. Wings indented, black, with a green disk, beneath black, with a white costal dot. It inhabits Sierra Leona.

DIRTEA. Wings indented, both surfaces alike, black, dotted with yellow. A native of Bengal.

HIPPJA. Wings scalloped, greenish-white, with black border and veins.

PANOPE. Wings indented, brown, both surfaces alike, the outer margin spotted with white, angle of the tail fulvous. This and the next are natives of India.

JACINTHA. Wings scalloped, toothed, brown; upper pair with a streak of white dots; lower ones white at the tip.

MICALIA. Wings falcate, toothed, black, spotted with yellow, middle of the lower ones fulvous, spotted with black. This and the following are natives of America.

PASSIFLOREÆ. Wings indented, fulvous, spotted with black; beneath with thirty silvery spots.

JUNO. Wings angular, indented, oblong, fulvous, with a black border; lower ones beneath black, with fulvous and silvery spots. Found at Surinam.

Danai.

* **BRASSICÆ.** The wings of this insect are rounded, entire, white; tip of the upper pair brown. This is the common large white butterfly known in our gardens: it proceeds from a yellowish caterpillar freckled with blueish and black spots, and which changes during autumn into a yellowish-grey chrysalis, affixed in a perpendicular direction to some wall, tree, or other object, some filaments being drawn across the thorax, in order the more conveniently to secure its position. The fly appears early in the spring, and is seen almost through the summer.

* **RAPÆ.** Wings entire, white; upper pair tipped with brown; male with a brown spot on each, female with three brown spots on the upper, and one on the lower pair. This is common in our own country.

* **NAPI.** Wings entire, with dilated green veins beneath. It inhabits Europe and Asia.

* **SINAPIS.** Wings entire, white; upper pair tipped with brown. This and the three preceding are the insects which in the caterpillar or grub state commit such ravages in our gardens.

NARICA. Wings snowy; upper pair with a brown spot before the tip. It inhabits Guinea.

RAPHANI. Wings entire, white, the tip black, spotted with white; the lower ones beneath with black veins, and covered with yellowish meal.

CASTALIA. Wings entire, white; above immaculate, beneath yellowish at the base. A native of India.

POPPÆA. Wings entire, white; the margin dotted with black; upper pair with a ferruginous spot at the base. It is found at Sierra Leona.

SYLVIA. Wings entire, white; tip of the upper pair brown, with a fulvous spot beneath. Inhabits Sierra Leona. A specimen is in Sir Joseph Banks' museum.

PAULLINA. Wings entire, white, edged with black; lower surface of the upper pair with a yellow spot at the base, of the lower ones immaculate. It is found in India.

ARGANTE. Wings entire, fulvous; beneath speckled with ferruginous. It inhabits Brazil.

MONUSTE. Wings entire, white, edged with brown. Found in America.

AMARYLLIS. Wings entire, both surfaces alike, dull white, upper pair with a black lunule. A native of India.

ARGIA. Wings entire, white; upper pair black at the tip. It inhabits Sierra Leona.

NEPITE. Wings scalloped, white; upper pair with a black dot above, all of them with a brown one beneath. It inhabits China.

AMATHONTE. Wings rounded, white at the tip with black;

PAPILIO.

black; margin of the upper pair beneath nut-brown. Inhabits America.

PHILETA. Wings entire, grey; upper pair above white, tip with brown. It is a native of America.

LIBYTHEA. Wings entire, white; upper pair brown at the base of the rib, and at the tip. Found in India.

CALYPSO. Wings entire, upper pair with a black dot and tip; lower ones beneath yellowish, the margin dotted with black. This is a native of Sierra Leona.

* **DAPLIDICE.** Wings entire, white, with a brown margin, beneath marked with yellowish-white and green. It inhabits Europe and Africa, and is common here.

CNEORA. Wings entire, white, the margin black, with a streak of dots. It inhabits India.

NERISSA. Wings entire, white, with a black margin; beneath with black veins. It is a native of China.

DEMOPHILE. Wings white, with two brown bands and margin; lower ones beneath flesh-colour. It inhabits India.

VANESSA. Wings entire, white; upper pair with a brown exterior margin and black dot; lower ones with brown streaks. It inhabits America.

HECABE. Wings entire, yellow, the outer margin black; beneath dotted with brown. A native of India.

AGAVE. Wings entire, yellow; tip of the upper pair above black; beneath chestnut-brown. It is found at Cayenne.

* **CARDUMINES.** Wings entire, white; upper pair, of the male, with a large bright orange patch at the tip, including two black dots; the lower ones beneath marbled with green; the female is without the orange tip.

GENUTIA. Wings falcate, entire, white; upper pair fulvous at the tip; lower ones marbled with green. It is found in India, as is the next.

DOROTHEA. Wings entire, white; upper pair black at the tip; lower ones beneath with yellow bands, speckled with black.

FLOREA. Wings entire, white; upper pair black at the tip; lower ones with a black spot and marginal dot.

NINA. Wings entire, white; upper pair with a black spot and tip; lower ones beneath speckled with green. This is an Indian insect, but a specimen may be seen in Sir Joseph Banks' museum.

ECHARIS. Wings entire, white; upper pair fulvous at the tip, with a black margin; the lower ones are immaculate. A native of the East Indies.

NYSA. The wings of this species are entire, and white; the lower ones beneath brown, with a white dot and six yellow lunules. It is a native of New Holland. A specimen is in Sir Joseph Banks' museum.

MUTA. Wings entire, white; lower ones with a black dot in the middle, beneath yellow, with two black dots. It is found in many parts of India.

CHLORIS. Wings entire, white, tip with black; lower ones beneath fulvous with a broad black margin. This is an African insect.

RHOPE. Wings entire, white, both surfaces nearly alike; upper pair yellow; lower ones white; all black on the outer margin. It is found in Sierra Leone.

ELATHEA. Wings entire; upper pair yellow; lower ones white; all black on the outer margins; beneath it is cinereous. It inhabits Tranquebar.

ALCMEONE. Wings with both surfaces alike, yellow at the base, and white at the tip. It is found at Tranquebar.

PHRYNE. Wings entire, white, edged with black;

lower ones beneath yellow. It is found in various parts of America.

LICINIA. Wings entire, white, edged with black; lower ones beneath immaculate. It is found in India.

AUROTA. Wings entire, white, the margin black, spotted with white; lower ones beneath yellow. This is a native of Coromandel.

ZELMIRA. Wings white, with a common brown border; upper pair with a white costal band, lower ones with a brown streak beneath. This is found common at Tranquebar.

PYRANTHE. Wings white, with a black dot and tip; beneath with cinereous waves and a fulvous dot. Found on the Cassia in the East Indies.

LEUCIPPE. Wings entire; upper pair red, edged with black; lower ones yellow. It is a native of Amboyna.

GLAUCIPPE. Wings entire, white; upper pair tip with black; lower ones beneath cinereous, with brown waves. It is found in Asia.

CORONIS. Wings entire, with black veins; above white, beneath greenish. It inhabits China.

EUDONIA. Wings entire, white, edged with black; beneath fulvous at the base and spotted with black at the margin. This is found in Sierra Leona.

IPHIGENIA. Wings entire, white, tip with black; the lower ones beneath are yellowish, with a black band in the middle, and an abbreviated fulvous streak. It is found in Surinam.

TEUTONIA. Wings entire, white; lower ones beneath with black veins and yellow spots. It is found in New Holland.

MYISIS. Wings entire, white; margin of the lower ones beneath black with a red band. This is a native of New Holland; and a specimen is in the museum of Sir Joseph Banks.

ARGENTHONA. Wings entire, white, the border black spotted with yellow; the lower ones are yellow, the tip black with a rufous macular band.

NIGRINA. Wings entire, white tip with black; beneath black with a sanguineous flexuous streak on the lower ones. It inhabits New Holland. A specimen is in Sir Joseph Banks' museum.

MARIA. Wings white; upper pair brown with a broad white band. This is found in the East Indies.

SABA. Wings entire, black with a common white band. It inhabits Sierra Leona. Sir Joseph Banks has a specimen.

CORONEA. Wings entire, white edged with black; beneath black radiate with fulvous at the base. Found at Surinam.

MELANIA. Wings entire, white tip with black; lower ones dull glaucous beneath. It inhabits New Holland. There is a specimen in Sir Joseph Banks' museum.

SCYLLA. Wings entire, yellow; upper pair white with a black border; all of them clouded beneath. It is found in the East Indies.

FLIPPANTHA. Wings entire; upper pair white with a black spot and tip; lower ones yellow; beneath nut-brown at the tip.

JUDITH. Wings entire, both surfaces alike; upper pair white with black veins and margin; lower ones fulvous edged with black. This is a native of Poulicandor: a specimen is in Sir Joseph Banks' museum.

AMATA. Wings fulvous, bordered with black, beneath they are greenish. This and the three following are natives of the East Indies.

CYPRÆA.

PAPILIO.

CYPRÆA. Wings entire, fulvous, the margin is black, with fulvous spots; beneath greenish, with a fulvous dot and moniliform streak.

DANAE. Wings white; upper pair saffron at the tip, with a black band and margin; beneath with an abbreviated moniliform streak.

PYRENE. Wings rounded, yellow, with a fulvous spot in the middle, the tip black; lower ones beneath with seven ocellar white spots. It is found in America.

RAHEL. Wings entire, yellow; above edged with black; beneath immaculate. This and the following are natives of India.

MESSALINA. Wings entire, white tipped with black; beneath yellow, with a marginal chefnut-brown spot. It inhabits India.

ÆNIPPE. Wings yellow; underneath they have yellow ocellar brown dots; on the upper pair six; on the lower ones seven. It inhabits China.

EVIPPE. Wings entire, yellowish; upper pair tipped with black; lower ones white beneath. It is found in Asia.

CHARMIONE. Wings entire, both surfaces alike, white with a black border; which on the upper wings has two yellow spots, and one on the lower. A native of Johanna island.

TRITO. Wings entire, yellow; upper pair white above the margin; all of them with a ferruginous streak beneath. It is found in Africa, and also in Europe.

* **EDUSA.** Wings entire, fulvous with a black dot and margin; beneath greenish; upper pair with a black dot; lower with a silvery one. It inhabits Europe.

EUPHENO. Wings entire, yellow; tip of the upper pair black, fulvous in the middle; lower ones with three brown streaks beneath. Found in the southern parts of Europe.

BELIA. Wings entire, white; lower ones subfasciate with grey beneath. It is a native of Barbary.

PHRONIMA. Wings entire, white; base of the rib and tip black; lower ones beneath yellowish, with two darker bands. This and the next are natives of America.

PSAMATHE. Wings entire, white; tip of the upper pair black spotted with white; lower ones beneath greenish with two darker bands, the foremost incurved.

PALÆNO. Wings entire, yellow, with a black tip and fulvous margin; lower ones with a silvery dot beneath. It is found in Europe, as is the next.

* **HYALE.** Wings entire, yellow, the tip black, spotted with white; lower ones with a fulvous spot, a silvery dot with a smaller contiguous one beneath. In the male, the margin of the wings is immaculate; in the female it is spotted.

AURORA. Wings entire, fulvous; upper pair with an ocellar dot beneath; lower ones with a double silvery one. Thought to be a variety of the last.

NICIPPE. Wings entire, fulvous, tipped with brown; upper pair with a black lunule on each side; the lower ones beneath speckled with red. This is found in Virginia.

LESBIA. Wings entire, fulvous; upper pair with a brown dot, all of them beneath pale with a snowy dot. It is found in Patagonia. Sir Joseph Banks has a specimen.

SENNÆ. Wings yellow, each of them beneath with a double ferruginous dot. This is a native of America.

MARCELLINA. Wings entire, yellow; each of them beneath has a double silvery dot. It inhabits Surinam.

EUBULE. Wings entire, yellow, the margin dotted

with black; the lower ones beneath with a double silvery ferruginous dot. A native of Carolina.

CATILLA. Wings yellow; upper pair with a black dot and margin; all of them beneath with a chefnut spot, which on the lower ones contains a double silvery dot. It inhabits Tranquebar.

PROTERPIA. Wings entire, angular, fulvous; upper pair with a black exterior margin. It inhabits Jamaica. There is a specimen in Dr. Hunter's museum.

GNOMA. Wings white; upper pair with a black dot, all of them beneath with a silver dot. Found in India.

DRYA. Wings yellow; lower surface of the upper pair with a ferruginous dot, of the lower ones with a silvery one. It inhabits America.

PHILIPPA. Wings entire, yellow; upper pair acuminate, varied with black, and with a black dot; lower ones with a red dot; all have a silvery one beneath.

* **RHAMNI.** Wings entire, angular, yellow; each with a ferruginous dot in the middle. Inhabits Europe.

PHILEA. Wings entire, angular, yellow; upper pair with a pale spot, lower ones with a pale border. It is a native of India.

CYPRIS. Wings slightly tailed, yellow, the margin dotted with black.

MÆRULA. Wings entire, angular, yellow; upper pair with a black spot and ferruginous one beneath; lower ones with a ferruginous spot on both sides. Inhabits India.

POMONA. Wings subangular, white; upper pair with a black dot; beneath yellow with two silvery dots on the lower ones. A native of New Holland, and is in Sir Joseph Banks' museum.

FLORELLA. Wings subangular, white; upper pair with a brown dot; lower ones beneath with three silvery dots. Native of Africa, and is among Sir J. Banks' collection.

CLEOPATRA. Wings entire; upper pair with a fulvous disk above, and ferruginous dot beneath; lower ones with a ferruginous dot on each side. Found in Europe and Africa.

Nymphales.

JASIUS. Wings two-tailed, brown, yellowish behind; beneath with a white band. Found in different parts of Africa.

PYRRHUS. Wings tailed, brown, with a common white band, reaching half way on the upper pair. It is a native of India.

CAMILLUS. Wings two-tailed, white, with fulvous bands, edged with black; lower ones with a black caudal spot. It is found in Africa, and is in Sir Joseph Banks' museum.

SEMPRONIUS. Wings two-tailed, white, the margin black, dotted with white.

TIRIDATES. Wings indented, two-tailed, above black, spotted with blue; the margin is dotted with white. It inhabits Amboyna.

CASTOR. Wings indented, two-tailed, fulvous, edged with black; beneath with a white band and white spots, including a black one. This and the next are found in Guinea.

POLLUX. Wings indented, two-tailed, brown, with a yellow band; beneath with a white band and spots, including a black one.

ÆCLUS. Wings indented, two-tailed; above black; beneath cinereous, with black waves, and an ocellar fulvous spot. It inhabits Amboyna.

PAULUS. Wings indented, two-tailed, fulvous, tipped with

PAPILIO.

with black; lower ones beneath variegated with a white spot at the base. A native of Jamaica.

ETHEOCLES. Wings two-tailed, blue-brown, with a white band on each side; the lower ones edged with green. It inhabits Sierra Leona.

FABIUS. Wings indented, two-tailed, brown, with yellow bands; the base beneath with black waves; the tip with fulvous dots. It inhabits India, and is in the museum of Sir Joseph Banks.

HORATIUS. Wings indented, two-tailed, black; lower ones fanguineous at the tip, with black ocellar dots.

EUDOXUS. Wings tailed, with a common red band; beneath with silvery spots, including some black ones. It inhabits Africa.

CÆLES. Wings slightly tailed, streaked with white and yellowish, and a white band in the middle; lower ones beneath with a streak of ocellate dots. It is a native of Siam, and is among Sir Joseph Banks' collection.

MILTIADES. Wings tailed, brown; lower ones with a white spot, all beneath with a white band and single eye.

VARANES. Wings tailed, above brown, with fulvous and black spots; the base is white. It is an Indian insect.

THEMISTOCLES. Wings tailed, chestnut-brown, with brown bands; lower ones with black dots.

PERIANDER. Wings tailed, both surfaces alike, white, with yellow bands; the tip brown, streaked with white. It is a native of India, and is in the collection of Sir Joseph Banks.

LYCURGUS. Wings tailed, black, with blue marginal lunules; behind these are five white dots on the lower ones. It is a native of Africa.

DECIUS. Wings tailed, with a common white band; lower ones rufous at the tip, with two eyes and two white dots. It is found in Guinea.

SABINUS. Wings tailed, brown, with a fulvous band; beneath grey, with a white band and ocellar dots. It inhabits Amboyna.

DOREUS. Wings tailed, with a green band above, and a white one beneath. It inhabits Africa, and is in the collection of Sir Joseph Banks.

PALAMEDES. Wings tailed, black, with yellow marginal lunules; upper pair with a yellow band; lower ones with a macular rufous band. It is found in America, and is in the collection of Dr. Hunter.

ORONTES. Wings tailed, black, with two greenish bands; the tail is white and distant. It is a native of India, as is also the next.

ÆGISTUS. Wings tailed, undulate with brown and yellow, and about three caudal eyes.

SOLON. Wings tailed, black, with yellowish bands, brown at the base.

EMPEDOCLES. Wings tailed, brown; upper pair with an abbreviated macular green band; lower ones beneath with two black spots, and a rufous lunule at the angle of the tail. It is a native of India, and in the collection of Sir Joseph Banks.

EURYALUS. Wings tailed, black; lower ones blue before the margin, with black spots, including a white pupil. It inhabits Amboyna, as does the next.

NISUS. Wings tailed, black; upper pair with a fulvous band; lower pair with a submarginal white one.

PHIDIPPUS. Wings slightly tailed, brown; beneath with white biocellate bands, and two blind eyes at the tail. It inhabits India.

XIPHARES. Wings indented, tailed, black; upper pair

with white spots; lower ones with a yellow band. Found in Africa.

AURELIUS. Wings slightly tailed, brown; the tip black, spotted with white; lower ones with two eyes beneath. It inhabits India.

BERNARDUS. Wings tailed, fulvous; upper pair black at the tip, with a yellow band; lower ones with a streak of ocellate dots. It is found in China.

GERDRATUS. Wings tailed, brown; upper pair with an ocellate spot at the tip, beneath ferruginous, with a white dot on the upper, and two on the lower ones.

CHORINÆUS. Wings tailed, brown; upper pair falcate, with a fulvous band. It inhabits Surinam.

LAERTES. Wings tailed, brown, blue at the base; lower ones above with five white dots, beneath with four ocellar dots. Found in Surinam.

MORVUS. Wings tailed, above brown, with a blue base; beneath greenish-grey. A native of India, as are the two following.

OCTAVIUS. Wings tailed, black, with an abbreviated green band; beneath grey, with a brown streak.

ERIBOTES. Wings slightly tailed, fulvous, with a blueish base; beneath grey.

ITYS. Wings slightly tailed, fulvous, tipped with yellow; beneath variegated at the base; the lower ones are blue at the base. This and the two following are inhabitants of Surinam.

CYMODOCE. Wings slightly tailed, brown, the base shining blue; lower ones with a single eye on each side.

BASALTIDE. Wings slightly tailed, fulvous, tipped with black; under surface of the upper pair with two ocellate dots, of the under ones with three.

ARSINOË. Wings indented, tailed, fulvous, spotted with black; lower ones with two eyes beneath. It inhabits Amboyna.

PANTHERA. Wings indented, tailed, brown, beneath waved; lower ones with two eyes on the disk, and five blueish ones on the margin. It inhabits Tranquebar.

ROHRIA. Wings indented, tailed, brown; upper pair with a white band; lower ones with seven eyes beneath, most of them dotted with white. It inhabits India.

REBECCA. Wings indented, tailed, brown, immaculate; beneath paler, with two nut-brown streaks and white sub-ocellar dots. Found in Guinea.

EROTA. Wings slightly tailed, brown, with black waves, and a common white band in the middle; lower ones with two eyes on each side. A native of Africa.

EUROPA. Wings slightly tailed, brown; lower ones beneath with a whitish ocellar band. Found in America.

ACHERONTA. Wings indented, tailed; upper pair red at the base; the tip is black, spotted with white. It inhabits Brazil.

TROGLODYTA. Wings indented, tailed, rufous, with a brown streak and hind margin. It inhabits America, and is in the collection of Dr. Hunter.

THETYS. Wings indented, tailed, fulvous, with black streaks; lower ones beneath glaucous, dotted with black. It inhabits South America.

PORTIA. Wings indented, tailed; beneath grey, speckled with black. It inhabits the South American islands.

C. AUREUM. Wings indented, tailed, fulvous, spotted with black; lower ones marked with a gold C beneath. It is found in Asia.

ISIDORE. Wings falcate, tailed, fulvous; upper pair with two pale dots in the middle, and black at the tip. It is found in India.

BELLA.

PAPILIO.

- BELLA.** Wings slightly tailed, testaceous; upper pair black at the tip, with a yellow band and white spots; margin of the lower ones yellow, with black streaks. This and the six following species are all inhabitants of India.
- FURCULA.** Wings tailed, brown, fulvous at the base; upper pair with a blue band.
- EUROCILIA.** Wings indented, tailed, brown, with a common fulvous disk; lower ones variegated beneath.
- PHORCYS.** Wings slightly tailed, indented, brown; beneath with darker streaks, and two cinereous dots on the lower ones.
- CHIELYS.** Wings indented, tailed, brown; beneath variegated, with a streak of yellowish dots.
- LETHE.** Wings indented, tailed, fulvous; upper pair black at the tip, with a yellow band and spots.
- AFLINA.** Wings tailed, brown, with a common fulvous disk; upper pair with a black lunule. It inhabits St. Thomas's island.
- FATIMA.** Wings slightly tailed, black, with a common yellow band; lower wings with the band abbreviated, and four rufous spots. It is found in India.
- ACHILLES.** Wings indented, black, with a broad blue band; beneath brown, with three or five eyes. Found in America.
- MEDON.** Wings above black; upper pair with a yellow band, and white at the tip; lower ones with a blueish disk. It is found in India.
- ERITHRONIUS.** Wings indented, black; lower ones with a blue band; beneath green, with a streak of white dots. It inhabits Africa, and is in the museum of Dr. Hunter.
- CERES.** Wings indented, black; upper pair with a white band; disk of the lower ones blueish, with a black dot. It inhabits Sierra Leona.
- URSULA.** Wings indented, black; hind ones with a blueish border, and marginal black band; beneath they are marked with fulvous spots. It is a native of America.
- CATO.** Wings indented, black, with a common greenish disk beneath, dotted with black, with a rufous spot at the base of the lower ones. It inhabits Sierra Leona.
- PHILOCTETES.** Wings indented, brown; lower ones with two eyes, the pupil black, and three white dots. It is found in India, as is the next.
- MENETHO.** Wings indented, brown, the margin spotted with yellow; the lower ones have three eyes beneath.
- LUCRETIUS.** Wings indented, black, with fulvous bands; beneath with black spots, surrounded with a blue line. Found in Guinea.
- EPISTROPHIUS.** Wings indented, grey-white; upper pair black at the tip; lower ones with a streak of yellow eyes beneath. It is a native of America.
- HELENES.** Wings indented, brown, with two greenish bands; one on the lower wings entire. It inhabits America.
- GAMBRICIUS.** Wings indented, above black spotted, and streaked with green; upper pair with a macular snowy band. A native of India.
- DEMOPHON.** Wings indented, above black, with a green band; beneath grey, streaked with white. Inhabits Cayenne.
- NESTOR.** Wings indented, brown, with a bright blue common disk, and white spots; beneath with three or four eyes. This species inhabits America.
- PERSEUS.** Wings indented, pale blue, the tip black, with ferruginous spots; beneath they are waved with three or four eyes. Inhabits Surinam.
- ARISTIDES.** Wings indented, brown, spotted with yellow; lower ones with two eyes beneath. Found in India.
- TELEMACHIUS.** Wings indented, brown, with a common blue radiate area, each with eyes beneath. A native of America, as are the two following.
- MENELAUS.** Wings indented, above highly polished, blue; beneath clouded brown, with ferruginous eyes.
- TEUCER.** Wings scalloped, livid brown; beneath clouded, and on the lower ones three eyes, the last very large.
- AUTOMEDON.** Wings angular, scalloped, brown; beneath livid, with an eye at the angle of the tail. Inhabits Surinam.
- HECUBA.** Wings indented; upper pair red, edged with black; lower ones black; all of them ocellate beneath. It inhabits Cayenne.
- METELLUS.** Wings indented, fulvous, the hind part black; under surface of the upper pair with three eyes, of the lower ones five. This is a native of Surinam.
- IDOMEUS.** Wings indented, blue; upper pair with a broad brown upper margin, and abbreviated white band; lower ones with a large yellowish eye beneath. Inhabits America.
- * **Io; Peacock Butterfly,** so called on account of its great beauty. It is rather a common species in this country. The wings are angular, indented, fulvous, spotted with black, and on each there is a large blue eye. "The ground colour of this insect," says Dr. Shaw, "is orange-brown, with black bars, separated by yellow intermediate spaces, on the upper edge of the superior wings; while at the tip of each is a most beautiful large eye-shaped spot, formed by a combination of black, brown, and blue, with the addition of whitish specks; on each of the lower wings is a still larger eye-shaped spot, consisting of a black central patch, varied with blue, and surrounded by a zone of pale brown, which is itself deeply bordered with black. The caterpillar is black, with numerous white spots, and black ramified spines: it feeds principally on the nettle, changing to a chrysalis in July, and the fly appearing in August."
- POLYNICE.** Wings angular, indented, fulvous, tipped with black; beneath brown, with blue streaks and eyes, six on the upper, and five on the lower ones. A native of Sumatra.
- ALMANA.** Wings angular, fulvous, spotted with black; lower ones with a larger eye, and a double pupil, all nut-brown beneath. It inhabits Asia.
- ASTERIE.** Wings indented, varied with yellow; lower ones with a larger eye and double pupil; beneath pale, with about three eyes. This inhabits India.
- OENONE.** Wings denticulate, yellow, edged with black; lower ones blue at the base. This is an Asiatic insect.
- FLIRTEA.** Wings subangular, brown, with fulvous spots, and two eyes; lower ones beneath ferruginous, with about three eyes. This and the next are found in India.
- LEMONIAS.** Wings indented, brown, dotted with yellow, all of them with a single eye.
- VELLIDA.** Wings indented, brown, with a fulvous band behind, and two eyes. It inhabits Amsterdam island. A specimen is in Sir Joseph Banks' museum.
- ORYTHIA.** Wings indented, brown; all with two eyes above, upper pair with a single eye beneath. This inhabits Jamaica.
- CLELIA.** Wings indented, black; upper pair with an interrupted white band and spot at the tip; lower ones with a blue spot on the disk. It is a native of Guinea.
- PENLEA.** Wings indented, above brown; all with two eyes beneath. A native of Surinam.

PAPILIO.

ZELMA. Wings angular, yellow, subfasciate with brown; lower ones with six eyes on each side, and a white streak beneath. It inhabits New Holland, and is in Sir Joseph Banks' collection.

TEREA. Wings angular, indented, above brown, with a fulvous band and streak of white dots on the upper pair, and of ocellate ones on the lower. A native of Sierra Leona.

LAODICE. Wings angular, above black with a greenish band on each side, including a streak of ocellar dots. Found in Guinea.

LAMPETIA. Wings indented, brown; upper pair with a fulvous band; lower ones with six blind eyes. This and the next are natives of India.

GLYCERIE. Wings indented, brown; upper pair with a fulvous band, under surfaces of the upper pair with one, of the lower with two blind eyes.

* **MEGERA.** Wings indented, yellowish-brown with dark bands; upper pair with a single eye; lower ones with five eyes above, and six beneath. This is found in our own country, and has been described and figured by Mr. Donovan.

ÆGERIA. Wings indented, brown, spotted with yellow, upper pair with an eye on each side; lower ones with four eyes above, and dots beneath. This belongs to England, and is described in Lewin's butterflies.

XIPHIA. Wings indented, brown, spotted with yellow; upper pair with an eye on each side; lower ones with three eyes above and four beneath. Found in the island of Madeira, and is in the collection of Sir Joseph Banks.

MINERVA. Wings indented, fulvous, the tip black, spotted with white; lower ones with five blind eyes above, and seven pupillate ones beneath. It is a native of America.

OCYPETE. Wings indented; above brown, immaculate; beneath glaucous, with three dark streaks; lower ones with five eyes. It inhabits Surinam.

OCIRRHŒ. Wings indented; above white tipped with brown; beneath brown with two white bands; lower ones with five eyes. A native of Surinam.

PENELOPE. Wings slightly indented, brown, with a single eye; lower ones with two beneath. It is found in Surinam.

ARANEA. Wings slightly indented, brown; lower ones blueish with five eyes beneath. This is found in Surinam.

ATLITA. Wings indented, brown with a blue gloss; beneath fulvous, with waved glaucous streaks, and five blind eyes on the lower ones. It is middle-sized, and a native of the East Indies.

JATROPHÆ. Wings angular, pale with waved brown streaks; upper pair with a single eye, lower ones with two. This is a native of America.

LAOMEDIA. Wings indented, grey; upper pair with five eyes; lower ones with five, some of them are blind. It inhabits India, as does the next also.

LIBYA. Wings indented, brown; beneath lineate, with six eyes on the lower ones, the pupil silvery.

HEDONIA. Wings indented, both sides alike, grey; each with six ferruginous eyes. An Asiatic insect.

TULLIA. Wings indented, brown, with ocellar spots, beneath with a violet band, which on the lower ones has two eyes. It inhabits China.

MEROPE. Wings indented, fulvous, with a single eye, and black tip; lower ones beneath cinereous with three mi-

nute eyes. It inhabits New Holland, a specimen of it is in the museum of Sir Joseph Banks.

JOLE. Wings indented, fulvous, dotted with black; lower ones with five eyes beneath, the last with a double pupil. It inhabits Guinea.

HESIONE. Wings indented, brown, with an oblique white streak beneath; upper pair with two eyes; lower ones including others within them. It inhabits Surinam.

EGÆA. Wings indented, above black, with a common white band; lower ones with two eyes beneath. This and the two following inhabit America. Dr. Hunter's museum contains a specimen.

SERINA. Wings slightly indented, above green; lower ones beneath with a white disk and two eyes.

POSTUERTA. Wings indented, green with brown spots and margin; lower ones beneath with white bands, and two eyes.

MYLITTA. Wings indented, black, with three macular white bands, lower ones with two eyes. A native of India.

ARTEMISIA. Wings indented, black; upper pair with white spots, lower ones with white bands, and two silvery eyes beneath. It inhabits America.

DORIMENE. Wings indented, brown; beneath blue with black bands, and three pair of eyes. This inhabits Surinam.

JANTHE. Wings indented, above brown, slightly barred with white, lower ones with five blind eyes. It inhabits Cayenne.

LAOTHOE. Wings angular, indented; lower ones above brown, with a white dot, and six blue eyes. This is a native of Surinam.

GENERILLA. Wings indented, black, spotted with white, and a common rufous band; lower ones with four eyes. This is an inhabitant of New Zealand.

ITEA. Wings indented, black; upper pair with a yellow band and dot; disk of the lower ones rufous, with four eyes. It inhabits New Zealand, and is thought to be a variety of the last.

PORTLANDIA. Wings indented, brown; lower ones with five blind eyes above, and seven pupillate ones beneath. It is a native of America.

* **CARDUI.** Wings indented, fulvous, variegated with white and black; the lower ones have four eyes beneath. This is an English insect, and is described by Mr. Donovan.

HUNTERA. Wings subangular, fulvous, varied with white and black; lower ones beneath reticulate with white, and with two eyes.

ALLIONA. Wings indented, brown; upper pair with two eyes, the posterior one blind. Inhabits Portugal.

TULBAGHIA. Wings indented, both surfaces nearly alike, brownish, with a yellow band; lower ones with five eyes. It inhabits the Cape of Good Hope.

PIPLEIS. Wings crenate, both surfaces alike, black; disk of the lower ones fulvous, with seven eyes. It inhabits India, as does the next.

CLAUDIA. Wings crenate, black, with a sanguineous patch; lower ones fulvous with seven eyes.

BLOMFILDIS. Wings indented, yellow, tipped with black; lower ones beneath brown, waved with white, with four eyes, the middle ones blind. It inhabits Brazil. Specimens of this and the two next are in the museum of Sir Joseph Banks.

BANKIA. Wings angular, above brown; disk of the upper pair yellowish, with a black eye, in which is a double pupil. It inhabits New Holland.

PAPILIO.

SOLANDRA. Wings angular, brown; upper pair with an eye, and also a contiguous one that is smaller; lower ones with two above, and four beneath. It inhabits Orabeite.

POLYDECTA. Wings indented, brown; upper pair with an eye; lower ones with two above and seven beneath. It inhabits Tranquebar.

TOLUMNIA. Wings indented, black; lower ones beneath with ferruginous and blue streaks and five eyes, the posterior one very large. This and the next inhabit India.

MORNA. Wings indented, brown; lower ones with two eyes on each side, and three white dots. A specimen may be seen in Dr. Hunter's museum.

JULIANA. Wings indented, brown, spotted with white; lower ones with two eyes on each side. This is a native of Amboyna.

LEDA. Wings angular, brown, upper pair with a double eye above; beneath reticulate with grey, and six eyes on the lower ones. It inhabits Sierra Leona.

LENA. Wings slightly indented, brown; lower ones black behind, with white and blue dots, and eyes beneath. There is a variety with brown hyaline wings, the lower ones with five ocellar white spots. It is found at Cayenne.

DYNDIMENE. Wings indented, brown; lower ones above violet, with four white dots. It inhabits Surinam.

LUNA. Wings indented, brown, with darker streaks; lower ones with two eyes, and they all have underneath four white dots.

IPHITA. Wings angular, indented, brown, with darker bands; all with five eyes beneath. It inhabits China.

CALLISTO. Wings indented, black; lower ones with a red band, and five eyes above, seven beneath. This is an African insect.

* **IRIS.** Wings indented, brown, with a blue gloss, and whitish interrupted band on each side; all with a single eye, those on the upper pair above blind. This is described and figured by Donovan and Lewin.

ILIA. Wings indented, with a blue gloss, and interrupted white band on each side; they have all a single eye. It inhabits Germany, and is probably a variety of the former.

BEROE. Wings entire, brown, with a blue gloss; lower ones with a single eye; beneath chestnut-brown with reddish margin. It inhabits Austria.

AVIA. Wings indented, both surfaces nearly alike, black, with a streak of pale dots, and a macular pale marginal band. It inhabits Africa.

POPULI. Wings indented, brown, with white bands and spots; beneath yellow, with white bands and blueish spots. This is an European insect.

CHRYSIPPE. Wings indented, black, with a common rufous patch; lower ones beneath brown, spotted with black. This is a native of New Holland, and is preserved in Sir Joseph Banks' collection.

CYDIPPE. Wings indented, black, with white spots, and a common rufous patch; the base beneath is testaceous, varied with black and blue. A native of India.

MARICA. Wings indented, testaceous, the tip black, with a white band on the upper, and blue spots on the lower pair. It inhabits Africa.

ALTHEA. Wings indented, brown, with an angular indented white band and streak. It inhabits Guinea.

AMPHICEDA. Wings indented, brown, the common disk cinereous, with brown waves; beneath grey at the tip with black lunules. It inhabits Guinea.

PENTHESILIA. Wings indented, black, with white spots, and a common rufous patch; lower ones beneath with yellow

bands, and a white one spotted with black. It is a native of India.

BERENICE. Wings indented, black, with a common red band; lower ones beneath spotted with black, white, ferruginous and yellow. This and the next inhabit Sierra Leona.

SEMIRE. Wings indented, both surfaces nearly alike, with a green band, and fulvous spots, the base fulvous, dotted with black.

CYANE. Wings indented, black; upper pair with a white band; disk of the lower ones white, dotted with black. Found in India.

VITILLIA. Wings indented, black; beneath spotted with white. This species inhabits Amboyna.

ZENOBIA. Wings indented, black, with a common white band, and marginal spots; base of the lower ones beneath yellow, streaked with black. It inhabits Sierra Leona.

* **ANTIOPA.** Wings angular, indented, black-brown, with a whitish border, behind which is a row of blue spots.

CACTA. Wings angular, indented, upper pair black, the base purple, with a fulvous spot. It inhabits India.

PYTHIA. Wings angular, indented, brown with a white spot on the upper pair; beneath grey, with a streak of black dots on the lower ones. It inhabits Guinea.

ZINGHA. Wings angular, indented, brown, the tip black, with blue streaks, and a macular fulvous one. It inhabits Sierra Leona.

PROTOGENIA. Wings indented, fulvous, the border black spotted with white. It inhabits Java.

AMESTRIS. Wings angular, indented, black with rufous and blue lunules, beneath darker. It inhabits India, as does the next also.

LAMINA. Wings angular, black with a common white band on each side, beneath spotted with rufous.

* **ATALANTA.** Wings indented, black; upper pair with a red band and white spots, the lower ones bordered with red behind. This, as the admirable butterfly, has been described and figured by Donovan, Lewin, and Dr. Shaw; the latter says "it is of the most intense velvet-black colour, with a rich carmine-coloured bar across the upper wings, which are spotted towards the tips with white; while the lower wings are black, with a deep border of carmine colour, marked by a row of small black spots; the under surface of the wings also presents a most beautiful mixture of colours; the caterpillar is brown and spiny, feeds on nettles, and changes into a chrysalis in July, the fly appearing in August."

ARCHESIA. Wings indented, brown with a common fulvous band, which on the upper pair is half blue. It is a native of Java.

CIARONIA. Wings indented, black, with a blueish band. It inhabits India.

BIBLIS. Wings indented, both surfaces alike, black; lower ones with a macular red band. It inhabits America.

HYPERIA. Wings indented, black spotted with white; lower ones beneath with yellow spots, and a rufous band in the middle. Inhabits India. A specimen is in the British Museum.

PROSOPE. Wings indented, brown with a common fulvous band, which on the upper pair has two black dots. It inhabits New Holland, and is in the museum of Sir J. Banks.

ECHIO. Wings indented, brown, all beneath with a row of white dots. It inhabits Surinam.

OCTAVIA. Wings indented, brown, the disk angular, fulvous,

PAPILIO.

fulvous, dotted with black, beneath with yellow spots at the base. This is a native of Sierra Leona.

LUBENTINA. Wings indented, obscure green, spotted with white, black, and rufous. Found in China.

JANASSIA. Wings scalloped, green, bronzed, with black dots on the upper pair; beneath yellowish, with black dots at the base.

* **POLYCHLORIS.** Wings indented, fulvous, spotted with black; upper pair with four black dots above. This is found in England, and divers parts of Europe.

V. ALBUM. Wings angular, fulvous, spotted with black; all with a white spot above; lower ones with a white lunule beneath. Found in several parts of Europe.

* **URTICÆ.** Wings angular, fulvous, spotted with black; upper pair with three black dots, the inner one square. It inhabits this country, and has been described and figured by Donovan and Lewin. The larva is spinous, varied with brown and green, head black; pupa toothed, brown, with gold dots. This insect and many others of the same genus, as the *Atalanta*, *Polychloris*, *Io*, &c. soon after their enlargement from the chrysalis state, discharge a few drops of reddish coloured fluid, which, in places where they have appeared in large numbers, has had the appearance of a shower of blood, and having of course been greatly magnified, the fact has been recorded by writers as a prodigy ominous of some extraordinary event.

CLYTEMNESTRA. Wings angular, black; beneath spotted with white; upper pair with a yellow band on each side. Inhabits Surinam.

DIRCE. Wings angular, brown; upper pair with a yellowish band, beneath undulate with black. Found in various parts of India; as are the two following.

ISIS. Wings indented; upper pair black, with a red spot on the disk; all of them with green lines beneath.

OISIS. Wings angular, blue; upper pair with a black spot and margin; beneath dusky.

PROGNE. Wings indented, fulvous, with black dots and margin, the latter dotted with white; beneath grey. Found in South America.

* **C. ALBUM.** Wings angular, fulvous, spotted with black; lower ones beneath marked with a white C. This is found in England, and other European countries.

TRIANGULUM. Wings angular, fulvous, the disk dotted with black; lower ones beneath cinereous with white waves, and a white angle in the middle. It is a native of Italy.

MERIONE. Wings indented, fulvous, edged with brown; lower ones beneath brown, with white and blue spots and streaks. It inhabits Surinam.

ARIADNE. Wings angular, fulvous, with undulate black streaks; upper pair with a white marginal dot. Found in the island of Java.

BOLINA. Wings indented, black; upper pair with two, lower ones a single blue-white spot; beneath ferruginous, with a white band. Found in the East Indies.

THECLA. Wings indented, black, with a white-blue spot, all of them have a streak of white dots; beneath brown, with a white band. Found in India.

LASINASSA. Wings indented, black, with a shining blue spot; beneath brown, with white lunules. It inhabits Asia.

CLYTIA. Wings indented, black; outer margin of the upper pair spotted with white; lower ones with a triple row of white and yellow spots. This and the next are natives of India.

COCYTA. Wings scalloped, indented, brown; lower ones blueish at the tip. It inhabits India.

UNDULARIS. Wings indented, above brown; lower ones

ferruginous at the tip, with a white dot beneath. It inhabits Coromandel.

MONIMA. Wings indented, brown; lower ones pale chestnut, blueish at the angle of the tail, with a black streak. It inhabits the East Indies.

HIARBA. Wings indented, black, with a common white band, which is abbreviated on the upper pair. It inhabits India.

AMATHEA. Wings angular, indented; above brown, with white dots, a red band, and waved black line. It inhabits Cayenne.

MELEAGRIS. Wings slightly indented, dotted with white, above brown, beneath yellowish. It inhabits Africa.

MELANTHA. Wings indented, above brown, dotted with white, beneath pale chestnut. It inhabits Guinea. A specimen is to be seen in Sir J. Banks' museum.

LEUCOTHOE. Wings indented, above brown, with three white bands; beneath yellow, with three white bands marked with black. It is found in divers parts of Asia.

MEDEA. Wings indented, falcate, black, with three macular yellow bands; angle at the tail red. A native of Surinam.

BLANDINA. Wings indented, above brown, beneath yellow, with two blue streaks, and dots marked with black on the lower ones. This and the next are found in Sierra Leona.

HOSTILIA. Wings indented, brown; the base fulvous dotted with black; upper pair spotted with yellow at the tip.

NAUPLIA. Wings slightly indented, both surfaces nearly alike, black; upper pair with four white spots above, lower ones with a white band. It inhabits South America.

HELIODORE. Wings indented, fulvous, with three black bands. It is found at Siam, and may be seen in the museum of Sir Joseph Banks.

OPHIONE. Wings indented, brown spotted with white; beneath with numerous black ocellar spots. It inhabits Guinea.

ILITHURIA. Wings indented, fulvous, with black bands; lower ones beneath with white bands, spotted with black. It inhabits India.

AMPHIONE. Wings indented, black, clouded with blue; upper pair with a white band on each side; lower ones beneath radiate with red. It inhabits South America.

OPIS. Wings indented, brown; upper pair reticulate, lower ones barred with yellow. This and the next are found at Sierra Leona.

CRITHEA. Wings indented, brown, with ocellar spots; lower ones beneath cinereous, with two brown spots and a streak.

PHEGEA. Wings indented, brown; upper pair with a ferruginous or white band; disk of the lower ones ferruginous or white; beneath paler, waved with black. It is found in India.

SALMASIS. Wings indented, black, radiate with blue; beneath brown, with a white band. It inhabits Africa.

PELEA. Wings indented, black; upper pair with arrow-shaped white and black spots; beneath cinereous, with black lunules. It is a native of the East Indies.

NERINA. Wings indented, black, with a white band, which on the upper pair ends in a rufous spot. It inhabits New Holland, and may be seen at Sir J. Banks.

VENILIA. Wings indented, brown, with a common white curved band, blueish at the edges. This and the three following are natives of India.

ALCMENA. Wings indented, black, with an interrupted blue band, each with seven white marginal dots.

PAPILIO.

PHERUSA. Wings indented, fulvous, with three brown bands, those on the upper pair longitudinal, on the lower ones transverse.

AGATHA. Wings indented, above fulvous, beneath glaucous, lower ones with one black dot above, and three beneath.

LAURA. Wings angular, indented, brown, with a common band, which is fulvous on the upper half, and snowy on the lower; lower ones beneath silvery with a snowy band. It inhabits Jamaica.

LYDIA. Wings indented, yellow, black above the margin; beneath with a streak of black dots. It inhabits Surinam.

IPHICLA. Wings indented, above brown, with a common white ferruginous spot at the angle of the tail. Found in South America.

LIBERIA. Wings indented, fulvous; upper pair with a black curve at the tip; lower ones with a black dot above, and three ocellar ones beneath. It inhabits India.

AMASIA. Wings indented, green; lower pair with marginal black dots above, and eyes beneath. Found at Surinam.

ÆTHIOPIA. Wings indented, blue; tip of the upper pair black, dotted with white. A native of Africa.

VERONICA. Wings indented, above greenish, beneath ferruginous, with a paler band. It is found in Guinea.

GNIDIA. Wings indented, testaceous, upper pair brown at the tip, with a white band; lower ones with a fulvous streak and black lunules. It is found in India.

PERSEA. Wings indented, oblong, black, spotted with yellow, and with a common red disk. It inhabits India.

NÆRREA. Wings indented, above brown, spotted with white beneath, with white spots surrounded with a red line. There is a variety of this species, wings slightly tailed, black; upper pair with two red spots, disk of the lower ones edged with red. Natives of India.

PROCRIS. Wings indented, fulvous, with black spots and a white band, beneath variegated. Inhabits China.

MAJA. Wings indented, brown; upper pair spotted with white, lower ones immaculate. It is found in Brasil.

ERYMANTHIS. Wings indented, fulvous; upper pair black at the tip, with a yellow band; lower ones with black lunules above, and a streak of ocellate dots beneath. Inhabits China.

CARIMENTA. Wings falcate, indented, brown, spotted with yellow; upper pair black at the tip, with four white spots. Found in Surinam.

MARTHA. Wings indented, varied with brown and fulvous; upper pair with three rows of white lunules; lower ones with a white band. It is found in Siam, and a specimen is in Sir Joseph Banks' museum.

CELTIS. Wings angular, indented, brown, with fulvous spots, and a single white one; lower ones beneath grey. Found in Southern Europe.

F. ALBUM. Wings angular, indented, fulvous, spotted with brown; lower ones with a snowy line beneath. It is found in Russia.

HARPYJA. Wings falcate, indented, brown, with a common blueish band, dotted with black.

MELISSA. Wings indented, brown; lower ones beneath marbled with grey. It is found in America.

ELEA. Wings indented, brown; upper pair with a fulvous band, lower ones with a white one. Found in India.

MESENTERIA. Wings indented, brown; upper pair with a fulvous band above, and blue central spots beneath. Inhabits Surinam.

NIPHE. Wings indented, yellow; tip of the upper pair

black, with a white band; lower ones beneath silvery with five eyes. It inhabits China. There is a variety, of which the wings above are fulvous, spotted with black, without the black tip and white band.

THYELIA. Wings indented, fulvous, spotted with black; lower ones beneath, with a white band and two scarlet dots at the base. It is a native of India.

PAPHIA. This is a highly elegant insect, of a fine orange-chestnut colour above, with numerous black spots and bars; beneath greenish, with narrow silvery undulations on the lower wings, and black spots on the upper. It proceeds from a yellowish-brown spiny caterpillar, living principally on nettles. This insect is generally found in the neighbourhood of woods. There is a variety cinereous, spotted with black, peculiar to Russia.

CYNARA. Wings indented, green spotted with black; lower ones beneath green, with three silvery spots and two bands. An inhabitant of the East.

CETHOSIA. Wings indented, fulvous, spotted with black; lower ones beneath brown at the tip, with a glaucous gloss, and ending in an interrupted silvery band. It inhabits Russia.

CYTHEREA. Wings crenate, brown; upper pair with a fulvous band; lower ones with a common silvery one; beneath with a lanceolate silvery band. It is found in India.

* **AGLAJA.** Wings indented, fulvous, spotted with black; beneath it has twenty-one silvery spots. This is found in England and other parts of Europe.

APHRODITE. Wings indented, fulvous, spotted with black; lower ones beneath brown, with twenty-four silvery spots. A native of South America.

MYRINA. Wings indented, fulvous, spotted with black; beneath with thirty silvery spots. It inhabits North America, as do the two following.

CYBELE. Wings indented, fulvous, spotted with black; beneath thirty-four silvery spots.

IDALIA. Wings indented, fulvous, spotted with black; beneath with thirty-seven silvery spots.

DIANA. Wings indented, brown, with a common black disk; lower ones beneath with nine silvery spots.

* **ADIPPE.** Wings indented, fulvous, spotted with black; beneath there are twenty-eight silvery spots. This is an English insect.

* **LATHONIA.** Wings slightly indented, pale, fulvous, spotted with black; beneath with thirty-seven silvery spots. This and the next, like the last, are English insects.

* **EUPHYROSYNE.** Wings indented, pale, fulvous, spotted with black; beneath with nine silvery spots.

SELENE. Wings indented, fulvous, with black; lower ones beneath, with twelve silvery spots; a distinct black dot at the base and streak behind. This is found at Kiel.

NIobe. Wings indented, fulvous, spotted with black; beneath with pale spots, and three silvery ocellate ones. Found in various parts of Europe.

COLUMBINA. Wings indented, fulvous, spotted with black; lower ones beneath with two silvery streaks. It is found in America, as is the next.

BELLONA. Wings indented, fulvous, spotted with black; lower ones beneath silvery at the tip, with six ocellar spots.

PHALANTA. Wings indented, fulvous, spotted with black; lower ones beneath; glaucous at the tip, with three fulvous ocellar spots. Found in the East Indies.

THAIS. Wings indented, fulvous, the margin streaked with black; beneath glaucous; lower ones with a silvery band and ocellar dots. Native of America.

GRIPUS. Wings entire, brownish; beneath a streak of white dots. It is found in India.

POSTHUMOUS.

PAPILIO.

POSTHUMOUS. Wings falcate, entire, brown, with a blue disk; lower ones beneath grey immaculate.

SOPHORÆ. Wings entire, brown, with a ferruginous band; lower ones beneath chestnut-brown, with two eyes. It inhabits America.

XANTHUS. Wings entire, brown, with a ferruginous band; lower ones beneath marbled with grey and two eyes. It inhabits Asia.

CASSIÆ. Wings scalloped, brown, with a ferruginous band, bifid at the tip; lower ones beneath cinereous, with two eyes. It inhabits America.

BEIRECYNTHUS. Wings entire, above black, with a marginal yellow band; lower ones beneath with six ocellar spots. Found at Surinam.

ARCADIUS. Wings entire; upper pair black, spotted with blue and white; lower ones brown; beneath chestnut-brown. It inhabits Africa.

HONORIUS. Wings entire, blue; upper pair black at the tip, with a brown rib; lower ones dotted, with black at the base and striate at the tip.

OETHON. Wings entire, brown, with a fulvous marginal streak; lower ones beneath, nearly naked, with seven eyes. Found at Surinam.

POLIXENES. Wings entire, brown; lower ones beneath clouded with brown and grey. It inhabits North America, and is in the museum of Sir Joseph Banks.

CAPAVIUS. Wings entire, black, spotted with white; lower ones beneath grey, with a white band on each side. It is found on the Guinea coast of Africa.

CONSTANTIUS. Wings entire, dull, cinereous, with a marginal streak of brown dots.

MARTHESIUS. Wings entire, black; upper pair with a fulvous disk; lower ones with a streak of white dots. It is a native of Surinam.

ARCESILAUS. Wings entire, above ferruginous, immaculate, beneath brown, with two darker streaks. It is found in Siam; a specimen is preserved in Sir Joseph Banks' museum.

NERO. Wings entire, fanguineous, with a brownish margin; lower ones orange beneath. This is a native of Asia. It is in the British Museum.

POLYCARMES. Wings entire, above black, beneath chestnut-brown, immaculate. This is found in Surinam.

ÆROPIUS. Wings entire, brown with a yellow band; upper pair beneath, with a single eye at the base. It inhabits India, as does the next.

OBRINUS. Wings entire, above brown, with a blue band and ferruginous spot, beneath green, with a whitish band.

LUCINDUS. Wings entire, barred with black, above blue, beneath fulvous. It inhabits Surinam.

LIRIOPE. Wings entire, fulvous, the border brown, with fulvous spots; lower ones yellowish, with fulvous waves. It is a native of Guiana.

ARMINIUS. Wings entire, both surfaces alike; fulvous, with reddish lunules and dots.

MORPHEUS. Wings entire, fulvous, spotted with black; lower ones with a streak of black dots on each side.

LYSIDICE. Wings entire, blue, with a black border above, and bands beneath. Found at Surinam.

EUMENUS. Wings entire, brown, with a white band, which in the lower ones is terminated on each side by a fulvous spot. Native of Cayenne.

DARDUS. Wings entire, brown; upper pair with a blue eye in the middle of each side; all beneath with two ocellar streaks. This and the next are found at Surinam.

ARCAS. Wings entire, blue; upper pair spotted with

white; lower ones with a black and white marginal spot. It inhabits Surinam.

CANTHUS. Wings entire, above brown, immaculate; lower ones with six eyes beneath. Found in North America.

EURYTHIS. Wings entire, brown; upper pair with two eyes on each side; lower ones with a single pupil, one above and four beneath; all of them with a double pupil. It is found in the island of Jamaica.

HERMES. Wings entire, above brown; immaculate, with six eyes on the upper pair, three of which are blind. Found at Brazil.

IRIUS. Wings entire, with a yellow disk; lower ones with a single eye above and one beneath. A native of New Holland. Preserved in Sir Joseph Banks' museum.

MINEUS. Wings entire, brown; upper pair with a single eye above; lower ones with seven beneath and a white band. It inhabits China.

CRANTOR. Wings entire, brown; lower ones with a single bipupillate eye above, and five beneath, the first and fourth bipupillate. It inhabits India.

MERGUS. Wings entire, brown, both surfaces alike; upper pair with four eyes, the anterior one with a double pupil; lower ones with five. It is an African insect.

Hesperia. Rurales.

CUPIDO. Lower wings six-toothed; tailed; beneath whitish, with silvery spots. It inhabits America.

CNIDUS. Wings six-toothed, tailed, white, with a black border; lower ones with silvery spots beneath. A native of Surinam.

AGRIPPA. Wings three-tailed, blue with a black border, beneath cinereous, with a white streak and two rufous spots at the angle of the tail. It is a native of America.

HELIUS. Wings three-tailed; upper pair black, lower ones blue; beneath cinereous, with two brown streaks and two eyes at the angle of the tail. This is an inhabitant of Africa.

JANIAS. Wings three-tailed, blue, with a black border; beneath green. It inhabits Surinam.

PYTHAGORAS. Wings three-tailed, with a yellow border; beneath black, varied with white, and a white band in the middle. It inhabits India.

AMOR. Wings three-tailed, brown, the disk beneath variegated, and a golden streak behind on the lower ones. It inhabits India.

HESIODUS. Wings three-tailed, black with a blue disk, beneath white, with a common greenish streak, and two silvery dots at the angle of the tail. It is found in India.

TIMON. Wings three-tailed, greenish at the base; beneath white, with an abbreviated red band on the lower ones. It inhabits America; a specimen is in Dr. Hunter's museum.

MONOUS. Wings three-tailed, brown; beneath snowy, slightly barred with brown; the lower ones with two gilt eyes. This is a native of Africa, and preserved in Sir Joseph Banks' collection.

FAUNUS. Wings three-tailed, brown; beneath white, with two fulvous streaks. It inhabits Africa.

LISIAS. Wings three-tailed; upper pair brown, with a fulvous spot; lower ones beneath white, spotted with black. It inhabits Poulicandor, and is in Sir Joseph Banks' museum.

HYMEN. Wings three-tailed, brown, spotted with white beneath; upper pair white above. It inhabits Africa, and like the last is to be seen in Sir Joseph Banks' museum.

GABRIELIS. Wings nearly three-tailed, glossy blue; lower

PAPILIO.

lower ones beneath brown, with white bands before the tip. It is found in divers parts of America.

PINDARUS. Wings nearly three-tailed, blue, with a black border; beneath brown, with silvery and fulvous spots. Inhabits India.

CHITON. Wings three-tailed, blue with a brown border; beneath yellowish-white, with black bands.

PELION. Wings nearly three-tailed, blue, with gold dots and a brown border. It inhabits America.

AUNUS. Wings nearly three-tailed, blue, with a black border; beneath black, with white bands. It is an American insect.

PETUS. Wings nearly three-tailed, blue, with a black border; beneath brown; the base rufous dotted with white. It inhabits Surinam.

FREJA. Wings two-tailed, brown; the disk beneath brown, with a wavy streak, which on the upper pair is fulvous, on the lower ones black. It inhabits Tranquebar.

ETOLUS. Wings two-tailed, upper pair black; lower ones blueish, beneath whitish, with a black dot at the base, and two at the tip. Native of India.

VULCANUS. Wings two-tailed, above brown, with fulvous spots; beneath variegated with fulvous yellow and silvery streaks. It is a native of India.

GANYMEDES. Wings two-tailed, blueish, with a brown border; beneath greenish, at the base with gold dots. It inhabits India.

MARS. Wings two-tailed, brown; lower ones with a rufous spot and two white dots, and an oblique band beneath. A native of America.

CELERIO. Wings two-tailed, white; beneath with alternate brown and white bands, and a triple rufous eye at the angle of the tail. It inhabits Surinam, as do the two next.

EMATHEON. Wings two-tailed, glossy blue, beneath black speckled with blue.

DIDYMAON. Wings two-tailed, brown, the base beneath red with white ocellar dots.

EROSINE. Wings two-tailed, brown, upper pair with seven red dots, lower ones with three; upper pair with three silvery dots. It inhabits the Cape of Good Hope.

ISOCRATES. Wings two-tailed, brown, two approximate, wavy, darker streaks, and a double black spot at the angle of the tail. This, and the two following, are found in India.

ATYS. Wings two-tailed, brown, with a blue disk; beneath cinereous with brown veins, the base with a fulvous spot, and white dots.

SOPHOCLES. Wings two-tailed, black, with a common blue disk; beneath white, with wavy yellowish streaks, the lower ones with a fulvous dot at the tip.

EURIPIDES. Wings two-tailed, with a blue disk; beneath brown, with an abbreviated white streak on the upper pair, and two angular rufous streaks and marginal ocellar spots on the lower ones.

PHOLEUS. Wings two-tailed, blue; beneath black, with green and blue bands. A native of Surinam.

ANACREON. Wings two-tailed, brown, beneath wavy with white, and a macular fulvous streak behind. This and the next species are natives of India.

THALES. Wings two-tailed, black, with blue lunules beneath, lower ones beneath with an abbreviated sub-marginal gold band.

ENDYMION. Wings two-tailed; beneath green, with rufous and gold specks, lower ones with a black streak and red band.

VENUS. Wings two-tailed; lower surface of the upper

pair green, speckled with gold; of the lower ones gold, spotted with green and black. There is a variety of this species, of which the wings are three-tailed, blueish, tipped with black; beneath golden, speckled with black.

ECHEON. Wings two-tailed, above brown, beneath palish, with a rufous band, and terminal red eye. Found in America.

TELEMUS. Wings two-tailed, shining blue; lower ones with a marginal angular black streak beneath. Found in America.

DINDUS. Wings two-tailed, black, the thinner margin blue; beneath cinereous, with white spots, and a double rufous spot at the angle of the tail. It is found in India, as is the next.

CECROPS. Wings two-tailed, black, with a red band beneath.

HEMON. Wings two-tailed, above brown, immaculate; lower ones beneath with three blueish bands at the angle of the tail. A native of Surinam.

SPHINX. Wings two-tailed, blueish; beneath cinereous, with a double black spot at the angle of the tail. This and the next are natives of India.

MELIBÆUS. Wings two-tailed, blueish, with a brown border; beneath yellowish, with brown streaks on the upper pair, and black ones on the lower, angle of the tail black, with blue rings.

MÆCENAS. Wings two-tailed, black, with a blue disk beneath, with chestnut-brown clouds. It inhabits China.

TYRTÆUS. Wings two-tailed, brown; lower ones beneath with a wavy white streak, and black marginal lunules, the middle ones rufous. This and the next are natives of India.

XENOPHON. Wings two-tailed, brown, with a yellow disk; beneath cinereous, with a white streak in the middle, joined to a brown one.

MARSYAS. Wings two-tailed, above blue, beneath blueish with black dots. A native of America.

BATHIS. Wings two-tailed, blue, with a black eye; beneath brown, with white bands, angle of the tail rufous.

CYANUS. Wings two-tailed, shining blue; beneath with a white disk. Native of Surinam.

HYACINTHUS. Wings two-tailed, shining blue; under surface of the lower ones black in the middle, with a white band. It is found in India.

HALESUS. Wings two-tailed, blue, edged with black; lower ones each side spotted with gold at the tip. It is found in America.

ACHÆUS. Wings nearly two-tailed, brown fulvous spots, beneath yellow, with gold spots. It inhabits India, as does the next.

PERICLES. Wings two-tailed, black; beneath brown, wavy with white, angle of the tail with a double silvery spot.

FORMOSUS. Wings two-tailed, brown; beneath yellowish, with red and gold spots. It inhabits Surinam, as does the next.

METON. Wings two-tailed, white, with a brown border; upper pair with an ocellar gold spot.

THERO. Wings indented, nearly two-tailed, blackish, with fulvous spots, beneath with silvery spots. A native of Africa.

LIGER. Wings two-tailed, white, tipped with black, beneath brown, with white streaks, and lunules. An inhabitant of Surinam.

HARPAX. Wings tailed, fulvous, spotted with black, beneath cinereous, with gold dots. A native of America.

VALENS. Wings tailed, brown; beneath yellowish, with

PAPILIO.

with spots including gold ones. A native of Surinam, and so is the next.

PERION. Wings tailed, fulvous, with a brown border and bands, beneath dotted with gold.

AUGUSTUS. Wings tailed, white, with a brown border; beneath varied with ferruginous and yellow, the lower ones with two cinereous streaks. It inhabits America.

CENTAURUS. Wings tailed, blueish, with a brown border, beneath cinereous, with ocellar spots at the base. It inhabits New Holland, and is, with the next two, in the museum of Sir Joseph Banks.

GERONTES. Wings tailed, black, with a common transverse white spot; upper pair with an eye, lower ones with a double eye. Native of Africa.

JARBUS. Wings tailed, fulvous, with a brown border; beneath cinereous, with a white streak, lower ones with two black dots. It inhabits Siam.

CERANUS. Wings tailed, blueish; beneath chestnut-brown, at the base spotted with white. It inhabits India.

PANN. Wings tailed, brown; upper pair with a fulvous spot; lower ones with a black sub-marginal one; beneath cinereous, with two eyes at the angle of the tail. Found in Africa.

PHORBAS. Wings tailed, brown, with a white disk; beneath white, with cinereous streaks, and two black dots at the angle of the tail. It inhabits India.

* **BETULÆ.** Wings slightly tailed, brown; beneath yellowish, with two white streaks on the lower ones.

* **PRUNI.** Wings slightly tailed, above brown, with a red spot at the tip of the lower ones; lower wings beneath, with a fulvous marginal band dotted with black. This and the last species are found in this country.

SPINI. Wings tailed, brown; beneath cinereous, with fulvous marginal lunules, and a blueish spot near the tail. It is found in Germany, on the *Prunus spinosa*, hence its specific name.

FAVONIUS. Wings slightly tailed, brown, with fulvous spots; beneath cinereous, with two white streaks; lower ones with a sub-marginal fulvous band, and blueish at the angle of the tail. It is found in America.

* **QUERCUS.** Wings slightly tailed, blueish; beneath cinereous, with a white streak, and double fulvous dot near the tail. A native of England, and other parts of Europe.

LINCEUS. Wings tailed, brown, immaculate; lower ones beneath with a lunulate white and rufous streak. Inhabits Russia, resembles the *P. spini*.

CERASI. Wings tailed, brown, immaculate; beneath a white streak, and fulvous lunules marked with a black dot on the lower ones. Inhabits Austria.

ACACIÆ. Wings tailed, brown; beneath blueish, with a white streak, and fulvous lunules near the tail. This is a Russian insect.

SYMETHUS. Wings slightly tailed, brown, with a white spot on the disk, upper pair tipped with black. Found in America.

BETICA. Wings tailed, blueish; beneath cinereous, with white waves, angle of the tail with a double gilt spot. Found in Europe and India.

APIDANUS. Wings tailed, blue; lower ones beneath brown, varied with blue, angle of the tail with a double gilt spot. Inhabits Surinam.

ÆLIANUS. Wings tailed, white; beneath cinereous, with white streaks, angle of the tail with a black eye. Found in the East Indies, as are the two following.

STREPHON. Wings tailed, brown, with a blueish disk; beneath cinereous, with a white band, and a double rufous eye at the angle of the tail.

ERICUS. Wings tailed, blueish; beneath varied with white and brown, the lower ones with two dots at the angle of the tail.

THEOPHRASTUS. Wings tailed, brownish; beneath white, spotted with black; lower ones with five marginal gilt dots. It is found in Morocco.

COLUMELLA. Wings tailed, brownish; beneath cinereous, with a streak of black and white dots, and two fulvous spots on the lower ones. Found in the South American islands.

CLEON. Wings tailed, brown; beneath cinereous, with a red streak on the upper pair, and band on the lower ones, angle of the tail with a double rufous eye. A native of Brazil; a specimen is in the museum of Sir Joseph Banks.

PHOCIDES. Wings tailed, above brown; lower ones white, with two black dots. It is found in Africa.

ALCIDES. Wings tailed, black, with a blue gloss, beneath ferruginous, with a yellow streak. It inhabits Sierra Leona.

PHILIPPUS. Wings tailed, brown; beneath white, with two fulvous streaks, and two sub-ocellar black dots at the angle of the tail. It is a native of India.

ATYMNUS. Wings tailed, fulvous; upper pair tipped with black. Found at Siam.

ERYX. Wings tailed, black; beneath green, with a slightly indented and spotted margin on the lower ones. It inhabits China.

ÆOLUS. Wings tailed, blue, with a black spot on the upper pair; all beneath with a white band streaked with black. This and the two following inhabit India.

CORIOLANUS. Wings indented, tailed, dull cinereous, with a common ferruginous streak.

PLINIUS. Wings tailed, varied with white and brown; lower ones beneath with a double gilt spot at the angle of the tail.

ACMON. Wings tailed, blue; lower ones beneath black, with green-gold streaks at the tip. Found in Surinam.

DEMOCRITUS. Wings tailed, shining blue; beneath black, spotted with white. Inhabits India.

AMYNTAS. Wings tailed, blue, with a black margin; beneath cinereous, with black dots, and two ferruginous ones on the lower pair at the angle of the tail. It inhabits Austria.

TIMEUS. Wings tailed, varied with fulvous and brown; upper pair beneath with ocellar black dots. It inhabits Surinam, as does the next.

SIMETHIS. Wings tailed, brown; beneath green with a silvery stripe.

SEDI. Wings tailed, blue, the margin spotted with white; beneath white, with square black spots and a rufous band. Inhabits Germany.

PHIDIAS. Wings tailed, blueish, with a brown border; beneath cinereous, all with a black dot at the angle of the tail. This is an Indian insect.

HERODOTUS. Wings tailed, blue; beneath green, with a streak of black and white dots on the lower ones. This and the next are inhabitants of India.

STRABO. Wings tailed, blue; beneath cinereous, with white waves; lower ones with two marginal dots, and two at the angle of the tail.

* **RUBI.** Wings slightly tailed; above brown; beneath green. This is found in our own country, and other parts of Europe.

PLATO. Wings tailed, blue, with a brown border; beneath cinereous, with white waves; lower ones with a black bipupillate eye. This and the six following are natives of India.

ROSIMON.

PAPILIO.

ROSIMON. Wings tailed, white, with a black border, and dots on the disk; beneath dotted with black, angle of the tail with three gold dots.

HIPPOCRATES. Wings tailed, brown, tip with white; beneath white, dotted with black.

THEOCRITUS. Wings tailed, greenish, with a darker rib; beneath black, dotted with yellow.

LINCUS. Wings tailed, white, tip with brown; beneath with white and black bands, angle of the tail with three white dots.

PARRHASIUS. Wings tailed, blue; beneath cinereous, with white streaks; lower ones with marginal gold dots.

AMYNTOR. Wings indented, tailed, black, with a fulvous spot at the base, the tip with a yellow band.

NARCISSUS. Wings indented, brown, with a blueish disk; beneath with red spots and bands with silvery edges. Inhabits New Holland, as does the next.

APELLES. Wings indented, fulvous, with a border; lower ones beneath with rufous bands and silvery edges.

HERACLITUS. Wings indented, black, with a fulvous spot on the upper pair; lower wings with a blue spot above, and yellowish streaks and blue dots beneath. It is a native of America.

PLAUTUS. Wings indented, brown, above immaculate, beneath with transverse black and white lines. It inhabits India.

THYSBE. Wings denticulate, fulvous, spotted with black; lower ones beneath friate, black spotted with gold. Inhabits Africa.

NAIS. Wings indented, the base silvery, with gold streaks. A native of the Cape of Good Hope.

MELEAGER. Wings indented, blue, with a black border, beneath grey, with black ocellar dots. It inhabits Germany.

EPULUS. Wings entire, brown, with fulvous spots; beneath variegated. Inhabits Surinam.

* **ARIGN.** Wings above blue, edged with brown, and spotted with black, beneath grey, with numerous small eyes. This inhabits our own and other countries of Europe.

EREBUS. Wings entire, brown; all with a streak of ocellate dots beneath. It inhabits Germany.

ALCON. Wings entire, blue, edged with brown, beneath grey-brown, with numerous eyes. Inhabits Austria.

DAMON. Wings entire, blue, beneath grey-brown, with numerous dots and a white band on the lower ones.

CYLLARUS. Wings entire, blue edged with black; beneath grey-brown, with a streak of ocellate dots, the hind ones blue at the base. This is an European insect.

* **ARGIOLUS.** Wings entire, blue edged with black, beneath blueish-grey, spotted with black. This species is common to this and other European countries.

ACIS. Wings entire, blue, beneath grey-blue, with oblong, black simple dots. It inhabits Austria.

* **ALSUS.** Wings entire, brown, immaculate, beneath cinereous, with a streak of ocellate dots. Found in England.

CAJUS. Wings entire, brown, with a blueish disk, beneath varied, cinereous and white, with brown ocellar dots. It inhabits India.

OTIS. Wings entire, brown, with a blue base, beneath cinereous, with a dot in the middle, and streak on the upper pair, and numerous ocellar dots on the lower ones. Found in China.

* **ARGUS.** Wings entire, lower ones beneath with a ferruginous border, and silvery blue eyes. This and the

three following are found in England, and other European countries.

* **HYACINTHUS.** Wings entire, blue, lower wings beneath with a marginal row of red eyes, and a circle of black ones on the disk.

* **ARTAXERXES.** Wings entire, brown, upper pair with a white dot in the middle; lower ones with rufous marginal lunules, beneath with rufous and white dots on the margin.

* **TITUS.** Wings entire, brown, immaculate; lower ones ocellate beneath, and a macular fulvous streak behind.

OPILETE. Wings entire, blueish, with a blackish edge; lower ones beneath cinereous, with ocellar black dots, and two fulvous lunules. It inhabits Russia, as does the next.

TRITON. Wings entire, blueish, beneath a ferruginous streak, and numerous black dots.

* **CORYDON.** Wings entire, blue edged with black; beneath cinereous with black ocellar dots, lower ones with a central white spot. This and the next are found in England.

* **ADONIS.** Wings entire, blue, with a black marginal streak, beneath cinereous, with numerous ocellar dots, and a white central one on the lower ones.

DORYLAS. Wings entire, blue, beneath cinereous, with a dot in the middle of the upper pair, and streak of ocellar dots behind. It is found in Austria.

HYLUS. Wings entire, with a black lunule in the middle, and marginal dots; beneath cinereous, with ocellar dots. It inhabits Austria.

BATTUS. Wings entire, blackish-blue beneath, whitish with numerous black dots; lower ones with a continued fulvous band. Found in Germany.

ARGIADES. Wings entire, blue, with a brown edge, beneath grey-brown, with a lunule in the middle, and two streaks of ocellated dots. It inhabits Saxony.

AMPHION. Wings entire, blue edged with black; beneath cinereous, ocellate with black; lower ones with red lunules, marked before with a white lunule, behind with a black gold dot. It inhabits Germany.

ACREON. Wings entire, brown, beneath paler, with black ocellate dots; lower ones with a white and red band and streak of gold dots. It is found in Russia.

HEBRUS. Wings entire, brown, varied with blue; lower ones blue, with a white inner margin. It inhabits Surinam.

AVIUS. Wings entire, both surfaces alike, brown, with two blue streaks at the tip. It is a native of the West Indies.

ACANTHUS. Wings entire, brown, immaculate, beneath pale ferruginous, with blue bands and yellow border. It is found at Surinam, as is the next.

CENEUS. Wings entire, black, with blue waves; the margin dotted with white.

ERINUS. Wings entire, brown, beneath cinereous, with a double black dot on the hind angle of the lower ones. It inhabits New Holland; a specimen is in the museum of Sir Joseph Banks.

ICARUS. Wings entire, above with brown bands, beneath with alternate white and black bands. Found at Surinam.

PARCIMON. Wings entire, brown, beneath cinereous, with white waves; lower ones with ocellar black dots at the base and eye of the tip. It inhabits Africa.

DAMOETES. Wings entire, brown, beneath with cinereous waves, lower ones with a double gilt eye. Inhabits

New

PAPILIO.

New Holland. Specimens of this and the last are in Sir J. Banks' museum.

CERAUNUS. Wings entire, brown, with a blue gloss; beneath cinereous, lower ones with ocellar black dots at the base, and an eye and dot at the tip. This species and the next inhabit the South American islands.

CATILINA. Wings entire, brown, with a blue gloss; beneath with white bands and two blue eyes at the angle of the tail.

MINEREUS. Wings entire, brown, lower ones beneath with ocellar red dots, and an eye at the angle of the tail. It inhabits America.

HYLAX. Wings entire, above brown, immaculate, beneath cinereous, dotted with black. It inhabits the East Indies.

TELEPIUS. Wings entire, black; upper pair dotted with white; lower ones above rufous at the base, beneath blue, varied with black. It inhabits America.

EMYLUS. Wings entire, black dotted with white; upper pair with a yellow band; all beneath variegated. It inhabits Surinam.

CARICÆ. Wings entire, brown, with a common white disk, the border cinereous, subocellate. It inhabits America.

PELOPS. Wings entire, white, with a common brown border, on which are a few fulvous spots, and a streak behind. It inhabits Cayenne.

LAMIS. Wings entire, brown, with a common abbreviated white and fulvous band. It inhabits Cayenne, as does the next.

CACHRYS. Wings entire, blue, with a double white spot on the upper pair, beneath cinereous, with black lines.

LAGUS. Wings entire, blue, with a double white spot on the upper pair, beneath cinereous, with black lines. It inhabits Surinam.

MÆCENAS. Wings oblong, both surfaces alike, black, with a common red band and line on the upper pair. Found at Guadaloupe.

MANTUS. Wings oblong, entire, variegated blue and brown, with a common white band. It inhabits Africa.

MIDAS. Wings subangular, brown, with a whitish spot, beneath white at the base, with a rufous streak. It inhabits India, as do the three following.

BIBULUS. Wings entire, brown; beneath white, with a silvery band dotted with brown on the lower pair.

ÆSOPUS. Wings entire, above brown, with a white spot, beneath white, immaculate.

PHÆDRUS. Wings entire, fulvous, with a brown margin, beneath white, immaculate.

BIAS. Wings entire, black, with a blue gloss, beneath brown, with a white hind margin. Inhabits Cayenne.

PHAREUS. Wings entire, both surfaces nearly alike, red, with a black border. This and the next species inhabit Surinam.

TACITUS. Wings entire, fulvous, outer margin of the upper pair black, spotted with yellow.

CÆNUS. Wings entire, white, outer margin of the upper pair brown spotted with white. A native of India.

PROCAS. Wings entire, both surfaces alike, black, with yellow disk, on the upper pair a yellow spot. This and the following inhabit Surinam.

ALPHONSUS. Wings entire, black; upper pair with two yellow spots, lower ones with a single one at the base.

* **HIPPOTHOE.** Wings entire, orange edged with black and white; beneath cinereous, with numerous black ocellar dots. Found in England.

* **VIRGAURÆ.** Wings subangular, fulvous, edged with

black; beneath with black and white dots. Found in this and other European countries.

CIRYSEIS. Wings gold, with a bluish margin, lower ones slightly indented, beneath dull grey, with numerous ocellar dots. It inhabits Austria.

SALUSTIUS. Wings entire, fulvous, varied with black; upper pair beneath dotted with black, lower cinereous, with brown spots. This and the next inhabit India.

FLORUS. Wings entire, fulvous, edged with black, the base beneath dotted with black.

HIERE. Wings brown, dotted with black, beneath cinereous, with numerous ocellar dots. It inhabits Austria.

* **PHILÆAS.** Wings entire, fulvous, dotted with black, beneath blueish. It inhabits England.

ARCAS. Wings entire, fulvous, with black margin and dots, lower ones beneath grey, immaculate. Inhabits the Cape of Good Hope.

BALLUS. Wings entire, fulvous, with a brown margin; lower surface of the upper pair dotted with black, of the lower ones green, edged with brown. It inhabits Spain.

HELLE. Wings entire, dusky, with a blue gloss; all beneath with numerous ocellar dots. It is found in Germany.

XANTHE. Wings entire, brown, with black dots, and a marginal fulvous band, beneath yellowish, with numerous dots. It is found in Russia.

GARBUS. Wings brown, dotted with black, and edged with white, beneath greenish, with numerous dots. It inhabits Austria. Probably the other sex of the last.

THERSAMON. Wings slightly tailed, fulvous, with numerous ocellar dots beneath; upper pair beneath fulvous, lower ones cinereous. It inhabits Russia.

LUCIANUS. Wings entire, dotted with black, above fulvous, beneath cinereous. Inhabits Guadaloupe.

PENTHEUS. Wings entire, fulvous, spotted with black; tip of the lower ones white, dotted with black. It inhabits Surinam, as well as the next.

ULRICUS. Wings entire, glossy-blue, beneath pale chestnut-brown at the base, upper pair with a tripupillate eye.

THYRA. Wings indented, the disk fulvous, dotted with black, beneath purplish, with silvery spots. It is found in Guinea.

ZEUXO. Wings entire, the disk fulvous, dotted with black; upper pair with silvery dots. This and the two next are found in different parts of Africa.

JUBA. Wings entire, black, with a fulvous disk, beneath with a white band, and abbreviated streaks.

LARA. Wings entire, subtestaceous; upper pair with one eye above, and the lower ones with two.

CEPHUS. Wings entire, brown, beneath with blue bands and a single eye on the upper pair, and two on the lower ones. It inhabits India.

DOMITIANUS. Wings entire, brown, upper pair with a green spot; lower ones with a green band; beneath pale ferruginous, with silvery dots, and marginal streak. It inhabits Guadaloupe.

LIVIUS. Wings entire, black, with a blue spot on the disk; lower ones beneath cinereous, with rufous bands that are silvery at the edge. This and the next inhabit India.

ROMULUS. Wings entire, brown, beneath green, with a rufous spot on the lower ones.

ACTORIS. Wings entire, both surfaces alike, brown dotted with white. Inhabits Surinam.

CASSIUS. Wings entire, above white, with a brown border on the upper pair, and five white dots on the hind margin of the lower ones. This is a native of Surinam.

PAPILIO.

ISARCHIUS. Wings entire, blue, with a white band on the lower ones, beneath varied with white and black. This and the next are of America.

CARACTACUS. Wings entire, brown, with a white spot on the disk; beneath variegated, a brown band with a silvery edge on the lower ones.

OURANUS. Wings entire, both surfaces alike, black with a common white band, ending in a red spot behind. Found at Surinam.

HARALDUS. Wings entire, blue, with a black border, beneath white, the margin dotted with black. It inhabits the East Indies.

TALUS. Wings entire, with brown and blue bands, and an abbreviated red band beneath. Found at Surinam.

NELEUS. Wings entire, both surfaces alike, black; upper pair with ten white dots; lower ones with a white disk. Found in India.

ATHEMON. Wings entire, brownish, with a common white disk, and a brown half band behind. It inhabits America.

REGULUS. Wings entire, black, with two yellow bands, the posterior one on the upper wings interrupted. Found in America.

HISRON. Wings entire, black, with three yellowish bands, the hind one interrupted. Inhabits India.

TARQUINIUS. Wings entire, black; upper pair with an oblong yellow spot at the base, lower ones yellow, spotted with black at the angle of the tail. Found also in India.

GEMELLUS. Wings entire, yellowish, with a brown border, beneath white, with a red streak in the middle and marginal lunules. Inhabits Cayenne.

PTOLOMÆUS. Wings entire, ferruginous, with brown streaks; beneath blue, paler at the base. This, and the four that immediately follow, are natives of India.

ARCHIMEDES. Wings entire, black, with a blue disk, beneath brown, immaculate.

LUCIUS. Wings entire, both surfaces nearly alike, fulvous, with black waves.

OVIARIUS. Wings entire, dotted with gold; above fulvous, beneath yellowish.

SUETONIUS. Wings entire, yellow, with a brown border; under surface of the upper pair with silvery black dots; of the lower pair cinereous.

ELECTRON. Wings entire, both surfaces alike, black, with a yellow band and sanguineous dot at the tip. It inhabits Cayenne.

SAGARIS. Wings entire, black, with a common transverse fulvous spot. This and the next inhabit Surinam.

EURITEUS. Wings entire, black, with a blue spot; beneath rufous in the middle, with white bands.

PHERECLUS. Wings entire, both surfaces alike, black; upper pair with a linear red band. This and the next are natives of America.

LYSIPPUS. Wings angular, brown, all of them with a red streak, beneath with cinereous dots.

ÆMULIUS. Wings entire, cinereous, spotted with brown and white; the lower ones pale above; beneath all dotted brown. Inhabits India.

GEMINUS. Wings rounded, blue, with a black border, in which is a blue streak; lower ones beneath subfasciate, with brown. A native of America.

LUCANUS. Wings entire, black, with a yellow disk; lower ones beneath red, with square brown spots. Inhabits India.

PERDITUS. Wings entire, both surfaces alike, black,

with a fulvous band. It inhabits Cayenne, as does the next.

PYRAMIS. Wings entire, brown, with a blue gloss, and a fulvous band; lower ones beneath grey.

PRIASSUS. Wings entire, both surfaces alike, black; upper pair with a double fulvous band. This and the four following inhabit India.

THUCYDIDES. Wings entire, black, with a fulvous spot on the disk, beneath cinereous, with rufous waves.

VIRGILIUS. Wings entire, black, with a blue thinner margin, beneath grey, with three whitish lunules, including a black dot on the lower ones.

PETRONIUS. Wings entire, blue streaked with black, beneath brown, cinereous, dotted with black.

NUMITOR. Wings entire, brown, with a yellow disk on the lower ones, beneath yellow, immaculate.

PHILLIASUS. Wings entire, brown, spotted beneath; lower ones with two eyes above on the hind part, and one beneath. It inhabits Africa.

GYAS. Wings entire, brown, beneath fulvous, with punctured gold streaks. A native of Surinam.

ÆGON. Wings entire, brown, with numerous macular fulvous bands. Inhabits Jamaica.

Hesperia. Urbicole.

EXCLAMATIONIS. Wings entire, divaricate, brown; upper pair with a yellowish line and dots under it. Inhabits India.

* **COMMA.** Wings entire, divaricate, fulvous, with a black line on the upper pair; beneath spotted with white. This is found in England.

PROPERTIUS. Wings divaricate, black, spotted with yellow; lower ones beneath with alternate, rufous, and yellow bands. This and the next are natives of India.

TIBULLUS. Wings entire; upper pair black, spotted with yellow; lower ones yellow, with a black border.

LINEA. Wings entire, divaricate, fulvous, edged with black. It inhabits Aultria.

* **SYLVANUS.** Wings divaricate, dark orange, with square yellow spots above, and whitish ones beneath. This is an English butterfly, as well as the next.

* **THAUMAS.** Wings divaricate, orange, with a darker patch at the base, the upper pair, in the male, with a black line in the middle.

OTHO. Wings divaricate, brown, with fulvous spots at the base, and nearly square yellow ones each side on the disk.

AUGIAS. Wings divaricate, fulvous, with an oblique black band and hind margin. This is a native of India.

VITELLIUS. Wings divaricate, fulvous; upper pair with a brown margin and spot in the middle; lower ones with a brown border. Inhabits the South American islands.

COLON. Wings divaricate, fulvous, with a brown striate margin and spot in the middle. It inhabits India.

* **PANISCUS.** Wings divaricate, dark brown, with fulvous spots. Inhabits England, and has been described and figured by Mr. Donovan.

HELIRIUS. Wings entire, divaricate, brown, edged with black; upper pair with a central yellow dot. It inhabits Surinam.

SATURNUS. Wings divaricate, brown; upper pair dotted with white; lower ones striate beneath with white. Inhabits Cayenne.

ORIGENES. Wings divaricate, both surfaces alike, brown, with a streak of white dots; upper pair testaceous at the base. It is a native of India.

PAPILIO.

NOSTRODAMUS. Wings divaricate, brown; upper pair with a macular whitish band above; lower ones cinereous beneath. Inhabits Barbary.

PIITNEUS. Wings subangular, divaricate, brown, with an interrupted yellow band on the upper pair. This and the next are natives of Surinam.

HELIUS. Wings subdivaricate, brown; lower ones fulvous at the inner margin.

METIS. Wings entire, brown, with scattered fulvous spots; lower ones beneath, immaculate. Inhabits the Cape of Good Hope.

DIOSCORIDES. Wings entire, brown, spotted with yellow; lower ones beneath yellow with brown waves. It inhabits Tranquebar.

PLUTARGUS. Wings entire, brown, speckled with gold; upper pair with a testaceous spot at the tip above, and testaceous outer margin. This and the next are natives of India.

EPICTETUS. Wings entire, black, with a yellow disk; upper pair with a brown spot, including a yellow lunule; lower ones beneath yellow, immaculate.

SILENUS. Wings tailed, brown, beneath pale chestnut, with a yellowish streak. It inhabits Africa.

ORION. Wings tailed, brown; upper pair with semi-transparent spots; lower ones with white tails. This and the next are inhabitants of Surinam.

EUDOXUS. Wings tailed, brown; upper pair with a white band on each side; lower ones on the under surface only.

PROTEUS. Wings tailed, brown, with transparent spots; antennæ hooked. A native of America.

CHEMNIS. Wings slightly tailed, brown, with hyaline spots and yellow hind margin. It inhabits India.

TITYRUS. Wings slightly tailed, brown; upper pair with a yellow band on each side; lower ones with a silvery streak beneath. A native of America.

MURETUS. Wings slightly tailed, brown, with hyaline spots. This and the next are natives of India.

MEATUS. Wings slightly tailed, black; upper pair with hyaline spots; lower ones beneath brown, with a white band at the base.

EPITUS. Wings slightly tailed, brown, spotted with yellow; lower ones beneath with a silvery band. A native of Surinam.

LYCIDAS. Wings slightly tailed, brown, with black teeth; upper pair with a yellow band on each side; lower ones beneath clouded with brown at the base, and afterwards white. It inhabits America.

NICIAS. Wings slightly tailed, fulvous; upper pair brown at the tip, with a yellow hyaline spot. It is found at Cayenne, as is the next.

MERCURIUS. Wings slightly tailed, brown, yellow at the base, with hyaline dots on the upper pair; lower ones beneath black, with a cinereous band.

THYRSIS. Wings slightly tailed, brown, with a yellow band on the upper pair, beneath all of them purple, speckled with yellow. It is found in America.

ALPHÆUS. Wings slightly tailed, black, with a red band; beneath variegated. A native of the Cape of Good Hope.

PRETUS. Wings slightly tailed, black, spotted with green, beneath ferruginous, spotted with yellow. This also is a native of the Cape.

PHOCAS. Wings slightly tailed, brown, with diaphanous spots; lower ones beneath with a black dot at the base. A native of America.

MOMUS. Wings slightly tailed, brown, with hyaline streaks at the base, and spots at the tip. It inhabits Cayenne.

VESPASIVS. Wings slightly tailed, rusty-brown; upper pair with yellowish dots at the tip. Found in India.

RHETUS. Wings slightly tailed, fulvous; outer margin of the lower ones blue-black. This and the three next inhabit Surinam.

CLONIAS. Wings slightly tailed, black; upper pair with a snowy band; lower ones beneath blueish, tail fanguineous.

ACASTUS. Wings slightly tailed, black; upper pair with a snowy band; lower ones beneath greenish, with abbreviated yellow streaks.

PALÆMON. Wings slightly tailed, blueish; upper pair with a rufous dot in the middle; lower ones rufous at the angle of the tail.

JULIANUS. Wings slightly tailed, brown; upper pair spotted with yellow; lower ones beneath varied with brown and glaucous. It inhabits Jamaica.

BRONTES. Wings slightly tailed, both surfaces alike, brown; upper pair with a snowy band; lower ones with a snowy margin. It inhabits America.

ARINUS. Wings tailed, both surfaces alike, black; upper pair with a transverse snowy spot; tail ferruginous.

ALEXIS. Wings tailed, brown; lower ones with a blueish band beneath. This and the next are natives of India.

MITHRIDATES. Wings rounded, black, with a purple spot and band behind, including paler lunules.

JUPITER. Wings without tails, black with a green gloss, beneath green, with black veins and margin; head and tail fanguineous. It inhabits Africa.

CASSANDER. Wings without tails, both surfaces alike brown, immaculate.

POLYBIUS. Wings without tails, black; upper pair with a fulvous spot; lower ones yellow at the angle of the tail. This and the three following are natives of India.

THRAX. Wings without tails, brown, with a few diaphanous spots; antennæ hooked.

ENNIUS. Wings brown; upper pair with hyaline spots; lower ones above black, with a yellow disk, beneath brown, with a white disk.

SCYPIO. Wings without tails; upper pair with a hyaline white band on each side, above black, beneath green.

MARCUS. Wings without tails, brown, with hyaline spots; lower ones beneath with two yellowish fillets; the thinner margin fulvous. It inhabits Cayenne.

FLESUS. Wings without tails, brown; upper pair with diaphanous spots; disk of the lower ones white, dotted with black. A native of Africa.

CICERO. Wings rounded, brown; upper pair with white hyaline spots; lower ones with a white hyaline disk. It inhabits the East Indies.

ATTICUS. Wings rounded; upper pair brown, with black spots and hyaline dots; lower ones hyaline, with black spots. It is found in India.

CLERICUS. Wings rounded, brown, subfasciate, with black; upper pair with hyaline dots. This and the next four inhabit different parts of the continent of America.

LUCAS. Wings without tails, brown; upper pair with yellow hyaline spots on both surfaces.

JUVENALIS. Wings without tails, brown; upper pair spotted with black, and dotted with white.

BATHYLLUS. Wings without tails, brown; upper pair with

PAPILIO.

with diaphanous square white spots; lower ones beneath with clouded waves.

AECIUS. Wings without tails, brown; upper pair with white diaphanous spots; all of them beneath palish purple at the tip.

NEPOS. Wings rounded, black; upper pair dotted with white; lower ones white at the angle of the tail above and beneath, with a white disk. It inhabits India, as do the next five species.

NERVA. Wings entire; upper pair brown, spotted with white; lower ones above black immaculate.

CÆSAR. Wings entire; upper pair brown, with diaphanous spots; lower ones black, with a snowy spot in the middle.

TERTULIANUS. Wings entire, rounded, blueish, spotted with black; the upper pair with white dots.

ORCUS. Wings rounded, brown; upper pair spotted with yellow; lower ones beneath blueish.

DAN. Wings without tails, dull cinereous, dotted with brown; upper pair with hyaline spots.

NOTHUS. Wings without tails, brown; upper pair with hyaline dots; lower ones beneath white; the margin brown, with six ocellar dots. Inhabits America.

SILVIUS. Wings without tails, brown; the disk yellowish, spotted with brown; lower ones beneath cinereous, with brown waves. Inhabits the Cape of Good Hope.

SALUS. Wings indented, fulvous, with black bands; upper pair with hyaline spots; lower ones hyaline in the centre. Inhabits Surinam.

JACCHUS. Wings without tails, spotted with yellow; lower ones with six snowy dots. Inhabits New Holland.

GNETUS. Wings indented, both surfaces nearly alike, black; upper pair with three hyaline spots; lower ones with blue bands. This and the next are natives of India.

ALSARIUS. Wings indented, black; upper pair with yellow and white spots; disk of the lower ones yellow, with black dots.

ANAPHUS. Wings entire, both surfaces alike, brown; lower ones yellow at the tip. Inhabits Surinam.

SEBALDUS. Wings without tails, varied with brown and black; lower ones beneath yellow at the angle of the tail. It is found in America.

EVADRUS. Wings without tails, brown, with a yellow disk; upper pair with subocellar silvery dots beneath. Inhabits the Cape of Good Hope.

BIXÆ. Wings rounded, brown, greenish at the base; lower ones beneath with a yellow band. Inhabits America.

POLYCLETUS. Wings slightly tailed, green-brown, with a white spot on the upper pair; beneath with fulvous silvery spots on the margin. Native of India.

ARACINTHUS. Wings rounded, entire, brown; lower ones beneath grey, with ocellar spots. It inhabits Austria.

BUSIRIS. Wings oblong, entire, black; upper pair with two yellow spots and dots; lower ones with a yellow disk. This is a native of India.

PISISIRATUS. Wings entire, brown; lower ones with a yellow disk above, and a snowy band, dotted with black beneath. It is a native of America.

HEMES. Wings rounded, entire, black; upper pair with a white spot; lower ones with a white band. This and the next are natives of Surinam.

EUMELUS. Wings rounded, entire, black; upper pair spotted with white; lower ones fulvous, with black veins.

PHILEMON. Wings rounded, entire, black, immaculate. Native of America.

THRASIBULUS. Wings entire, black, with blue lunules;

lower ones beneath at the angle of the tail cinereous, dotted with brown. This and the two following are natives of India.

CELSUS. Wings entire, both surfaces alike, black; upper pair with a yellow band.

ZELEUCUS. Wings entire, both surfaces alike, black; lower ones edged with white; head and tail sanguineous.

MÆNAS. Wings entire, glossy green, black, edged with white; lower ones beneath with a white band; mouth and tail red. A native of America.

PHIDIAS. Wings entire, glossy black, edged with white; mouth and tail red. Inhabits Asia.

AMIATUS. Wings entire, black, with a yellow hind-margin; head and tail red. A native of America, and so is the next.

ÆSCULAPIUS. Wings entire, black, with fulvous spots, the margin dotted with yellow.

LYCAGUS. Wings rounded, entire, blue-green, immaculate; tail red. Inhabits Surinam.

CATULLUS. Wings rounded, entire, black; upper pair dotted with white; lower ones with a streak of white dots. This and the two following species are natives of India.

JOVIANUS. Both surfaces of the wings alike, black; lower ones radiate with blue and white.

SALVIANUS. Wings entire, brown, spotted with green; lower ones beneath white, with a marginal streak of brown dots.

OILEAS. Wings rounded, entire, varied with black and white; lower ones beneath cinereous, with wavy black streaks. It is found in America.

MAIMON. Wings entire, white, with black margin and spots. Inhabits Cayenne.

TALAUUS. Wings entire, both surfaces alike, brown; upper pair with white dots and red base; lower ones with a white disk. Found in India.

MIMAS. Wings entire, brown, with a ferruginous margin; beneath with a streak of black dots. This and the next inhabit Surinam.

GENTIUS. Wings entire, both surfaces alike, yellow, with a black border; upper pair with yellow bands.

PELOPIDAS. Wings entire; upper pair dull cinereous, with a brown line in the middle; lower ones cinereous. This and the next species are natives of India.

GALENUS. Wings entire, both surfaces alike, brown, spotted with yellow.

* **MELVÆ.** Wings indented, divaricate, brown, with cinereous waves; upper pair with hyaline dots; lower ones with white dots beneath. Inhabits this country.

ALCÆE. Wings divaricate, varied with brown and cinereous; upper pair with hyaline dots; lower ones beneath cinereous, immaculate. Inhabits Russia.

SIDÆ. Wings entire, divaricate, black, with square white spots; lower ones beneath cinereous, with two yellow bands. Inhabits Russia.

* **FRITILLUM.** Wings entire, divaricate, black, dotted with white. It inhabits Europe.

GALBA. Wings entire, divaricate, black, dotted with white; lower ones beneath grey, with two white bands. It inhabits Tranquebar.

MÆVIUS. Wings entire, above black, beneath greenish, with white lines and spots on both surfaces. Inhabits the East Indies.

LAVATERÆ. Wings entire, brown; upper pair with white spots; lower ones with white dots; all with a snowy lunule in the middle. It inhabits Germany.

MENALCAS.

MENALCAS. Wings entire, both surfaces alike, white edged with black. It inhabits India.

MENIPPUS. Wings entire, striate, brown, with a broad white band, in the middle of which is a brown dot. It inhabits Surinam.

CLITO. Wings entire, both surfaces alike, black; upper pair dotted with white; lower ones with a white band. It inhabits Cayenne.

VIBRIUS. Wings entire, black; upper pair with three white dots; lower ones tipped with white. Inhabits Surinam, as do the two next.

CURTIVS. Wings entire, both surfaces alike, black; upper pair with four white dots; lower ones immaculate.

PHOREUS. Wings entire; upper pair brown; lower ones yellow.

* **TAGES.** Wings entire, denticulate, brown, with obsolete white dots. A native of England and other parts of Europe.

NISO. Wings entire, sub-reversed, brown; upper pair with four white scattered dots above. This and the two remaining species are natives of India.

SHIO. Wings entire, reversed, blackish, every where spotted with white.

PYGMÆUS. Wings entire, brown, immaculate.

PAPILIO-Musca, a name given by some authors to a series of small insects, which seem to be of a middle nature between the fly and the butterfly classes. Its wings are in part covered with those scales in form of dust, which render the wings of the butterfly kinds opaque, and in part are transparent and glassy. Reaumur has called the wings *alies vitrées*, *glassy wings*. Reaumur's Hist. of Insects.

PAPILION-BOURDON, a name given by the French authors to a sort of butterflies, which while they feed keep upon the wing with a humming noise like that of the humble-bee. Reaumur. See **EPERVIERS** and **PAPILIO**.

PAPILION-a-quene, tailed butterflies, a name given by the French naturalists to a sort of butterfly, of which there are several species. The sides of the wings of these butterflies are jagged, and one of the jags run out so far beyond the rest as to represent a sort of tail issuing from the creature. Reaumur.

PAPILIONACEÆ, in *Botany*, the 32d among the natural orders of Linnæus, composing a principal part of the **LEGUMINOSÆ** of Jussieu; see that article, and **PAPILIONACEOUS Flowers**; see also **DIADELPHIA**. In addition to what is to be found under the last-named article, respecting the qualities and uses of these plants, it may be mentioned that Linnæus, in his *Prædicationes*, has observed that scarcely any of them are medicinal, except *Glycyrrhiza*, the Liquorice, for *Galega*, though recommended against the plague, is scarcely to be trusted, which we can readily believe. He asserts moreover that they have scarcely any scent. If this be intended of the flowers, the *Spartium junceum* and *Lathyrus odoratus* are powerful exceptions, indicated by his editor; to which Mr. Salisbury has added *Coronilla valentina*, *Lupinus luteus*, *Vicia Faba*, and various species of *Trifolium*. The herbage of some *Papilionaceæ* acquire a very penetrating durable scent, of a peculiar kind, in drying; as the common and blue Melilot, *Trifolium officinale* and *ceruleum*; with most of the genus *Trigonella*. The seeds of this family are of a flatulent quality, and best suited for the food of hard-working people.

Some of this order are very remarkable for their occasionally subterraneous mode of fructifying. *Lathyrus amphicarpos*, as well as *Vicia amphicarpa* of Dortnes, see Willd. Sp. Pl. v. 3. 1105, bear some flowers from their roots, considerably below the surface of the ground, which are pale

and deformed, but having perfect anthers and stigmas, produce good seed. The same individual plants have abundance of flowers and seeds upon their stems above, like those of their natural order. Others, after flowering, bury their flower-stalks and ripening germens in the ground, in a very curious manner. Such are *Glycine subterranea*, *Arachis hypogæa*, and our English *Trifolium subterraneum*, which last fixes itself by supplementary radicles from the tops of the buried stalks.

PAPILIONACEOUS FLOWERS, *Flores papilionacæ*, are so termed from a fancied resemblance in their form to a *Papilio*, or Butterfly, see the last article. This denomination appears, as Tournefort suggests, to have originated with the ingenious and learned Valerius Cordus, who in his *Historia Sturpium*, chap. 162, applies it to the flowers of the Bean. The word does not occur in the *Lexicon* of David Kyber, published in 1553, by the care of their common friend the great Conrad Gesner, eight years before the latter printed the works of Cordus.

Linnæus has very particularly described such flowers in his *Genera Plantarum* 358, at the head of his class *Diadelphia*, which is composed of them.

“**CALYX.** Perianth inferior, of one leaf, bell-shaped, withering; its base gibbous, attached by its lower side to the flower-stalk, obtuse and containing honey at the upper; its mouth with five acute, erect, oblique, unequal teeth, of which the lowermost is longest, and has no fellow; the upper pair shortest and furthest asunder: the bottom is internally moist with honey, including the receptacle.

COROLLA, called *papilionaceous*, is unequal; each *petal* being distinguished by an appropriate name, as follows.

The *standard* is one petal, larger than the rest, which it lies over and covers, in a flattish horizontal position. Its claw is inserted into the upper margin of the receptacle; and what projects beyond the calyx approaches to a roundish, almost entire, figure, having an elevated longitudinal line, especially towards the extremity, as if the petal were depressed at the sides. That part of the petal nearest the base, approaches to a semicylindrical shape, embracing the parts beneath. The border of the petal is depressed at each side, but a portion near the margin is reflexed upwards where the halved tube, or claw, ends; where the halved limb, or border, begins to expand, are two posterior concave impressions, prominent beneath, which compress the wings lying under them.

Wings two equal petals, one at each side of the flower, under the standard, incumbent at the margin, parallel, roundish-oblong, broadest outwards, straightest at their upper edge, more dilated into a roundish form at the lower. The base of each is divided, the lower portion thereof elongated into a claw, inserted at the side of the receptacle, and about the length of the calyx; the upper portion being shorter and inflexed.

Keel, the lowest petal, is usually deeply divided, situated under the standard, within the wings, boat-shaped, concave, compressed at the sides, in the position of a boat upon the water, mutilated at its base, whose lower part is extended into a claw, as long as the calyx, inserted into the receptacle, its lateral and upper segments being shorter, and twisted together with the corresponding parts of the wings. The sides of the keel agree with the wings in form, and nearly in situation, except in being interior to them, and somewhat lower. The outline of this petal, constituting the actual keel, extends half way in a straight line, then it gradually ascends, in a segment of a circle; but the margin, or upper edge, is straight to the end, where it unites in a blunt angle with the other.

STAMENS for the most part united, in two sets; their *filaments* of different shapes; one inferior, embracing the pistil; the other superior, lying upon that part.

The inferior *filament*, sheathing the germen, is in its lower half membranous, cylindrical, with a longitudinal slit above; the upper portion consists of nine awl-shaped divisions, having the same length and curvature as the keel of the corolla which incloses them, the intermediate or lower ones longer than the others in alternate pairs.

The superior *filament* is of a slender awl-shaped figure, lying over, and covering, the suture in the former, to which it answers in situation, being simple, and rather less permanent, so that, separating at its base from the former, it allows of the escape of the honey at each side.

Anthers small, equal, terminal, ten in all; one upon the upper *filament*; nine on the respective divisions of the lower.

PISTIL one, superior.

Germen oblong, somewhat cylindrical, slightly compressed, straight, the length of the cylinder, formed by the inferior *filament*, by which it is embraced.

Style awl-shaped, slender, ascending, the length and position of the segments of the lower *filament*, among which it is stationed, withering.

Stigma downy, at the upper part, immediately beneath the anthers.

PERICARP an oblong, compressed, obtuse *legume*, of two valves, having a longitudinal suture above as well as below, both straight, except that the upper slopes downwards towards the base, and the lower upwards near the extremity; it bursts finally along the upper suture.

SEEDS several, roundish, smooth, fleshy, pendulous, marked with the slightly prominent embryo, near the insertion of the scar. In germination the cotyledons retain the form of the two halves of the seed, (but do not always rise above ground.)

RECEPTACLES of the seeds minute, very short, taper at the base, attached to the seeds by an obtuse oblong disk, all inserted along the upper suture only, but in an alternate order, so that when the valves are separated they adhere alternately to each valve."

Such is the character of the diadelphous papilionaceous flowers, composing the third order of the 17th class in the Linnæan system; see DIADELPHIA. There are however many papilionaceous genera which have flowers with ten separate and distinct stamens, and which therefore range in the class DECANDRIA; see that article. Of the plants so circumstanced Linnæus knew but few, chiefly his *Sophora*, *Anagyris* and *Cercis*; but recent discoveries, especially in New Holland, have greatly added to the list; see DAVIESIA, DILLWYNIA, GOMPHOLOBIUM, MIRELIA, PULTENÆA. Neither are the *stamens* of the diadelphous tribe uniformly constructed in the precise manner above described. Some few, like *Smithia*, have them in two equal sets, five anthers to each; in others five of the anthers are occasionally imperfect. The *corolla* itself is liable to exceptions. In *Amorpha* it consists of a standard only, the wings and keel being deficient; in some species of *Erythrina* the wings are scarcely discernible, however conspicuous the other petals. In *Trifolium* the *corolla* is often really monopetalous, the standard, wings, and keel, though retaining much of the form and aspect proper to papilionaceous flowers, being all firmly united below into a tube. So in many genera of the *Diadelphia Decandria*, the two sets of *stamens* are really united into one, by a tubular base; thus becoming properly monadelphous. Yet the rest of their structure is such, as to evince their inseparable affinity with the others, like which they are to all appearance perfectly diadelphous.

Linnæus thought too much stress had been laid upon the figure of the *legume*, in characterizing the genera of this tribe, and he recommends the *calyx* as leading to very solid distinctions. He has also recourse to the *stigma*, which is certainly, in many cases, a very important part. He recommends, in his Gen. Pl. 360, according to the usual principles which justly guided him, that the foliage should not be referred to for generic characters; yet in his *Systema Vegetabilium* he very commodiously indicates certain distinctions in the habit of the class *Diadelphia*, by which the genera differ from each other; some having twining stems, as *Phaseolus*, *Dolichos*, *Crotalaria* and *Glycine*; some abruptly pinnate leaves, as *Orobanchus*, *Pisum*, *Lathyrus*, *Vicia*, *Ervum*, *Arachis* and *Abrus*; while in others the leaves are pinnate with an odd leaflet, as *Biserrula*, *Astragalus*, *Phaca*, *Hedysarum*, *Glycyrrhiza*, *Indigofera*, *Galega*, *Colutea*, *Amorpha*, &c. and in a third tribe the leaves are ternate, as *Trifolium*, *Lotus*, *Medicago*, *Erythrina*, *Genista*, *Cytisus*, *Ononis*, *Trigonella*, and most of the climbing genera. Yet some species of *Hedysarum* have simple, others pinnate leaves, and several *Genista* have simple ones.

PAPILLÆ, in *Anatomy*, small prominences on various organs of the body, particularly the skin and tongue. (See INTEGUMENTS and TONGUE.) The word papilla is also applied technically to the nipple of the breast.

PAPILLARIS, in *Botany*, a name used by some authors for the common *lampyris*, or nipple-wort.

PAPILLARY, PAPILLARIS, in *Anatomy*. See PAPPILLÆ.

PAPILLARY *Processes*, is a name which the ancients gave to the olfactory nerves, from the place of their origin, to the os cribriform. See NERVOUS *System*.

PAPILLON, PHILIBERT, in *Biography*, an industrious man of letters, the son of an eminent advocate at Dijon, where he was born in 1666. He was brought up to the profession of the law, but he afterwards embraced the ecclesiastical state, and received priests' orders in 1694. Previously to this he had obtained a canonry of no great revenue, but sufficient for his wants, since his great ambition was to be possessed of a good library, in order that he might devote himself to the cultivation of literature. His researches went chiefly to literary history, especially that of his own province, and the works of several other writers were enriched by his collections. He supplied P. Le Long with memoirs inserted in his "Bibliothèque des Historiens de France," and also with materials for his "Bibliothèque Sacrée." To M. P. Desmolets he communicated a number of critical and biographical articles for the use of his "Mémoires d'Histoire et de Littérature;" and in Niceron's memoirs, the lives of Peter Abelard and James Amyot are by his hand. The principal work of the abbé Papillon was his "Bibliothèque des Auteurs de Bourgogne," which appeared after his death in two volumes folio. He died at Dijon in the year 1738. He was endeared to all his acquaintance by his modest, frank, and amiable disposition. Moreri.

PAPILLOSUM FOLIUM, in *Botany*, is a leaf covered with soft succulent tubercles or granulations, of which the Ice Plant, *Mesembryanthemum cressifolium*, is a striking example; see LEAF. *Papulifolium* is nearly equivalent, and is sometimes used by Linnæus for the same thing, though he errs in ever making it synonymous with *verrucosum*. The latter character consists in hard cartilaginous warts, equally perceptible in the dried specimen and in the living one; the former, depending on succulency, changes its appearance greatly by drying, yet is clearly discernible to an experienced eye, even in that state, in the foliage of many species of
Mesem-

Mesembryanthemum, on which it then forms minute orbicular depressions.

PAPIMOUAGON, in *Geography*, a lake of Canada, 70 miles N.N.E. of Quebec. N. lat. 50°. W. long. 69 20'.

PAPIN, DENYS, in *Biography*, an ingenious physician, the son of Nicholas Papin, also a physician, was born at Blois. He took the degree of doctor, and travelled to England, where he was elected a fellow of the Royal Society, in December 1680. He passed the following year in London, and published an account of a machine which he had invented, and which still bears his name; this was "The New Digester, or Engine for the softening of Bones," 4to. 1681. It soon appeared in French, with the title of "La Manière d'Amollir les Os, et de faire cuire toutes sortes de Viandes en peu de tems et à peu de fraix." Paris 1682. The machine consists of a very strong metal boiler, with an air-tight cover screwed down with great force; hence the contained matter, being incapable of escaping either by evaporation or by bursting the machine, may be heated to a degree far beyond that of boiling water, so as to dissolve the gluten of bones and cartilages. He afterwards improved this digester, and it has since been much employed in chemical and philosophical experiments. He assisted Boyle in various experiments, of which an account is given in the history of the Royal Society. Papin was a Calvinist, and was therefore prevented from returning home by the revocation of the edict of Nantes. He afterwards resided at Marburg, where he taught the mathematics, and published a "Fasciculus Dissertationum de quibusdam Machinis Physicis," 12mo. 1696, and in 1707, he published at Francfort an account of a machine which he had invented for raising water by the action of fire, entitled "Ars nova ad aquam ignis adminiculo efficacissimè elevandam."

His father, Nicholas Papin, was author of several works, which, however, are nearly forgotten. Two of them related to the powder of Sympathy, which he defended; and one to the discovery of Harvey, which he opposed. Eloy Dict. Hist. de la Med. Gen. Biog.

PAPINACHOIS, in *Geography*, a river of Canada, which runs into the Saguenay; N. lat. 48 24'. W. long. 70° 50'.—Also, Indians of Canada, so named from the river. N. lat. 50° to 51°. W. long. 69° to 71°.

PAPINIANUS, in *Biography*, a celebrated Roman lawyer, who attained to the rank of pretorian prefect under the emperor Severus, in the year 194. His profound knowledge of the law, and his incorruptible integrity, gave him great influence during this reign, the rigours of which he softened by his counsels as much as lay in his power. On his death-bed, Severus recommended his sons Caracalla and Geta to the care and protection of this faithful servant; and he accordingly used all his efforts to preserve that fraternal union between them, which soon appeared in danger of dissolution. Caracalla deprived the prefect of his post, but did not banish him from his person, and when he had perpetrated the execrable murder of his brother, he earnestly solicited him to compose a paper in justification of it, to which he replied, that it was easier to commit a murder than to defend, and that it was a second murder to vilify the memory of the innocent. A man so honest was not likely to exist long, he was probably sacrificed to the emperor's repentment, in 212. Papinianus composed a great number of works, and formed several illustrious disciples. His authority as a lawyer rose beyond that of any of his predecessors; the emperor Valentinian III. made a decree, that in cases in which the opinions of judges should be divided, the preponderance should be given to that which should have the sup-

PAPIO, PAPIONES, in *Zoology*, the name of those species of monkeys which we call *baboons*; which see.

These are all species of the *simia* in the Linnæan system. See SIMIA.

PAPIRA, or POPYRA, in *Ancient Geography*, a town of Asia, in Galatia, upon the route from Palsinuum to Ancyra, between Vindia and Ancyra; according to the Itinerary of Antonine.

PAPIRE-MASSON, JOHN, in *Biography*, an historian, was born, in 1544, at Saint-Germain-Laval, in Forez. He was brought up among the Jesuits, and for some time taught in their seminaries in Italy and France. He afterwards quitted the society, studied the law at Angers, and was admitted an advocate in the parliament of Paris; it was on this occasion he changed his family name of Masson into Papire-Masson. His works are "Annalium, l.b. iv." relating to the history of France: "Notitia Episcoporum Galliarum:" "Vita Joannis Calvini:" "Elogia Virorum Illustrium:" "De Episcopis Urbis Romæ:" "Descriptio Fluminum Galliarum:" "Agobardi, Episcopi Lugdunensis, Opera." All his works are said to display considerable learning and research, but they are not so well esteemed with regard to accuracy. He distinguished himself by his learning and integrity, and obtained the post of substitute to the procureur-general. He died in 1611, much regretted by men of letters, of whom the principal were his particular friends. His life was composed by De Thou. Moreri.

PAPIRIA, in *Botany*, a name originally given by Thunberg, in the Lund Transactions, to the genus which he and all other botanists have subsequently called *GETHYLIS*; see that article.

PAPIRIAN CODE, a collection of imperial constitutions, &c. made by a private lawyer, whose name was Papius. See CODE.

PAPIRIUS CURSOR, the elder, in *Biography*, an eminent Roman commander, was master of the horse to Papius Crassus, when dictator, in the year 339 B. C. He was consul for the first time in the year 333 B. C., and was nominated dictator in the war with the Samnites B. C. 324. Having appointed Quintus Fabius Rullianus to be his master of the horse, he marched against the enemy, strictly enjoining Fabius not to engage during his absence. A favourable opportunity, however, occurred, and his master of the horse disobeyed the injunction, and gave the Samnites a total defeat, for which breach of discipline he was condemned to death by the dictator, but the sentence was not executed. Papirius, during the remainder of the campaign, applied himself to the recovering of the affections of his soldiers, which had been alienated by his severity, and then he attacked the enemy, who were reduced to sue for peace. He was chosen consul a second time in the year 320: and again a third time in the following year, when he reduced Satricum, which had revolted, and put all the Samnite garrison to the sword. For his exploits in this and the preceding campaign, triumphal honours were decreed him. In the consulate of Fabius Rullianus and Marcus Rutilius, B. C. 310, the latter having sustained great loss in an engagement with the Samnites, it was determined again to raise Papirius to the dictatorship, as the commander most to be relied on in the public danger. A decree was accordingly passed, enjoining Fabius to nominate Papirius to that high office. He was again successful, and received a third triumph. This was probably his last public service, as his name occurs no more in history. He surpassed all his contemporaries in military talents. In person he was tall and majestic, of great bodily strength and vigour, and so swift

of foot, that he obtained the surname from that circumstance. He kept his troops, as well as himself, in constant exercise, and maintained strict discipline. Univer. Hist. Livy.

PAPIRIUS CURSOR, the younger, son of the preceding, was created consul B. C. 293, in conjunction with Spurius Carvilius. In his contests with the Samnites he was very successful, and gave a proof of superiority to that superstition which was so prevalent among the early Romans. Being informed, as he was about to advance to battle, that the keeper of the sacred chickens had falsely given a favourable report of the augury derived from their eating, and that in fact the preface was inauspicious; he replied, that he should understand the report as it was given, and that if the keeper had deceived him, the vengeance of the gods would fall on him alone. He therefore placed the man in the front of the battle, where he was killed by an unknown hand before the armies came to a close engagement. The battle terminated in favour of the Romans: the Samnites were not only totally defeated, but lost their camp. For this and some subsequent success he obtained a triumph at the end of the campaign. Papirius, in his second consulate with the same colleague, was equally successful against the same people, which put an end to a war that had lasted for seventy-two years. The consuls next subdued the Lucanians and Bruttians, and proceeding to Tarentum, invested that city which had been the first to invite Pyrrhus into Italy. Papirius, by the offer of favourable terms, gained possession of the citadel, and the town soon surrendered, and became tributary. From this period nothing more occurs relating to this valiant commander. Univer. Hist.

PAPIRIUS, in *Botany*, see PAPIRIUS; also the misprinted name BROUSONNETRA.

PAPIST. Under this head, we shall present the reader, I. *With an account of the difference between Papists, reputed Papists, Popish Recusants, and Popish Recusants Convict*, in the legal acceptation of those words. II. *With a short view of the tenets of the Roman Catholic religion*, as distinguishable, 1st, into those which they consider as articles of their faith; 2dly, those which regulate their discipline; and, 3dly, the opinions of their private divines. III. *The laws enacted against them*, 1st, for the exercise of their own religious worship; 2dly, for not conforming to the religious worship of the state; 3dly, for their refusal to take the oath of supremacy; 4thly, for their refusal to take the sacrament of our Lord's supper; 5thly, for their refusal to take the declaration against transubstantiation; 6thly, for their refusal to take the declaration against popery; and, 7thly, the laws which affect their landed property. IV. The partial repeal of those acts, 1st, by act of the 18th; and, 2dly, by the act of the 31st of his present majesty. And, V. We shall close the article by a short mention of the penal laws, the effect of which is felt by the Roman Catholics, but the effect of which is not felt by the Protestant dissenters.

I. The word *Papist* came into use soon after the Reformation. From that time, the word "Protestant" was used to denote all descriptions of Christians, who were not in communion with the church of Rome; and the word "Papist" was used to denote that description of Christians, which remained in communion with her. It is to be observed, that, before the laws passed in the present reign, to repeal the principal penal laws in force against the Roman Catholics, the word "Papist" had a very extensive signification. In the language of the law, Papists are divided into five classes: *the mere Papist* was a person who had done those

acts, which amounted to legal evidence of Popistry; *the reputed Papist* was a person generally considered to have done such acts; *the Popish recusant* was a Papist, who absented himself from the Protestant church; *the Popish recusant convict* was a Papist legally convicted of such absence. Several statutes inflicted the penalties, legally incident to Popish recusancy, on the commission of certain acts, and the omission of others, into which the religious principles of Roman Catholics frequently led them; and thus constituted an *indirect recusancy*, the fifth and last species of Popistry, if it can be justly called by that name. But "Papist" was the general appellation given to the particular denomination of Christians, who are the subject of the present article. It was always considered by them to be a term of reproach, and they affected the appellation of Roman Catholics. In the oath, which passed in the year 1791, for the relief of the Roman Catholics, the person who takes it is made to say, "I. A. B., do hereby declare, that I do profess the Roman Catholic religion." Since the passing of that act, the name of Roman Catholic has been generally given them, and it now seems to be their proper legal appellation.

II. We shall now present the reader with a short view of the *tenets of the Roman Catholic religion*. They are distinguishable into, 1st, those which Roman Catholics consider to be the articles of their faith; 2dly, those which regulate their general discipline; and, 3dly, the opinions of their private divines.

All of them are thus stated and explained by the Rev. Joseph Berrington, a Roman Catholic priest, in his "State and Behaviour of the English Catholics, from the Reformation to the year 1780."

II. 1. "The following rule," says this intelligent writer, "is the grand criterion by which each article of our faith may be distinctly ascertained.

"This rule is:—All that, and only that, belong to Catholic belief, which is revealed in the word of God, and which is proposed by the Catholic church to all its members, to be believed with divine faith.

"Guided by this certain criterion, we profess to believe,

1. "That Christ has established a church upon earth; and that this church is that which holds communion with the see of Rome, being one, holy, Catholic, and apostolical.

2. "That we are obliged to hear this church; and therefore, that she is infallible, by the guidance of Almighty God, in her decisions regarding faith.

3. "That St. Peter, by divine commission, was appointed the head of this church, under Christ its founder; and that the pope or bishop of Rome, as successor to St. Peter, has always been, and is at present, by divine right, head of this church.

4. "That the canon of the Old and New Testament, as proposed to us by this church, is the word of God; as also such traditions, belonging to faith and morals, which, being originally delivered by Christ to his apostles, have been preserved, by constant succession, in the Catholic church.

5. "That honour and veneration are due to the angels of God, and his saints; that they offer up prayers to God for us; that it is good and profitable to have recourse to their intercession; and that the relics or earthly remains of God's particular servants are to be held in respect.

6. "That no sins ever were, or can be remitted, unless by the mercy of God, through Jesus Christ; and, therefore, that man's justification is the work of divine grace.

7. "That the good works which we do, receive their whole

PAPIST.

whole value from the grace of God; and that by such works we not only comply with the precepts of the divine law, but that we thereby likewise merit eternal life.

8. "That by works done in the spirit of penance, we can make satisfaction to God for the temporal punishment, which often remains due, after our sins, by the divine goodness, have been forgiven us.

9. "That Christ has left to his church power of granting indulgencies; that is, a relaxation from such temporal chastisements only, as remain due after the divine pardon of sin; and that the use of such indulgencies is profitable to sinners.

10. "That there is a Purgatory, or middle state; and that the souls of imperfect Christians, therein detained, are helped by the prayers of the faithful.

11. "That there are seven sacraments, all instituted by Christ: baptism, confirmation, eucharist, penance, extreme unction, holy orders, matrimony.

12. "That in the most holy sacrament of the eucharist, there is truly, really, and substantially, the body and blood, together with the soul and the divinity of our Lord Jesus Christ.

13. "That in this sacrament there is, by the omnipotence of God, a conversion or change of the whole substance of the bread into the body of Christ, and of the whole substance of the wine into his blood: which change we call transubstantiation.

14. "That, under either kind, Christ is received whole and entire.

15. "That in the mass or sacrifice of the altar is offered to God a true, proper, and propitiatory sacrifice for the living and the dead.

16. "That by the sacrament of penance, the sins we fall into, after baptism, are by the divine mercy forgiven us.

"These are the great points of Catholic belief, by which we are distinguished from other Christian societies; and these only are the real and essential tenets of our religion. We admit also of the other grand articles of revealed and natural religion, which the gospel and the light of reason have manifested to us. To these we submit, as men and as Christians; and to the former, as obedient children of the Catholic church.

II. 2. "There are *points of discipline* also, which regulate conduct, and to which we pay obedience; as fasting on particular days, communion in one kind, celibacy of churchmen, use of the Latin language in public service, and other similar practices. But as these vary, and may be either altered or suppressed by due authority, they belong not to what is properly styled the faith of Catholics.

III. 3. "*Opinions* also, whether regarding belief or practice, of particular schools, or of particular divines, constitute a distinct and separate object. Great latitude in the forming such opinions is allowed, and consequently it will be often abused. It has been in the power of some men to give an undue weight to such opinions, whereby Catholics themselves have been too often imposed on.

"They have ignorantly confounded the inventions of fallible men with the unerring declarations of heaven. Of this circumstance our enemies have many times taken an unfair advantage, and the faith of Catholics has suffered from the false representation. Some opinions may deserve respect, but others should be despised and reprobated.

"And it should be noticed, that most of the charges brought against us are founded on this false supposition, that the opinions of private men, or of whole societies, are as much a part of our real creed, as the articles I have mentioned. When all this extraneous matter, whether of dis-

cipline or of opinion, is brought to a proper test, by the rule of faith I so much insist on, it will soon appear in what light it is to be considered. Were I to reject every opinion, hitherto discovered, and solely adhere to the articles of doctrine as above stated, I should be a Catholic in the strict and accurate acceptation of the word. Divines might censure me, casuists might defame me, and the pope might deny me the name of Papist; but my faith would still be pure, unimpaired, and Catholic."

Thus far Mr. Berrington.—We trust that the passage which we have cited from his work, gives a correct view of the religious creed and opinions of the Roman Catholics. Those, who wish to be more fully acquainted with them, should peruse Bossuet's "Exposition of the Catholic Faith," and the Rev. Mr. Gotter's "Papist misrepresented and represented on a twofold Character of Popery." The last work was first published in 1685: it is become scarce; but an abridgment of it, now in its 17th edition, is very common, and is generally referred to by Roman Catholics, as an excellent epitome of their religious tenets, and a complete exposure of the misrepresentations of them.

III. The history of the English Catholics, as a distinct body of Dissenters, begins with the reign of Elizabeth. In the course of her reign many oppressive, and even sanguinary laws were enacted against them. The justice and policy of those laws scarcely find at this time a single advocate. But when they were enacted they found their defenders; and none among them, none more able than lord treasurer Burleigh, who published, or rather caused to be published, in their defence, a book entitled "The Execution of Justice," in which he attempted to shew, that the Catholic priests, executed in the reign of queen Elizabeth, were not executed for their religion, but for treasonable practices. In answer to it cardinal Allen published his true modest "Defence of the English Catholics." The subject was revived in our times by Dr. Sturges' "Reflections on Popery." To those, Dr. Milner opposed his "Letters to a Prebendary;" one of the most successful works that has appeared in defence of the Roman Catholics. A discussion of this controversy would be misplaced in a work like the present. We shall only mention that, by a succession of legislative enactments during the reigns of queen Elizabeth, of the three first Stuart monarchs, and of the three monarchs who filled the throne from the abdication of king James II. to the accession of king George II. the Catholics were subjected to the heaviest pains, penalties, and disabilities. The laws by which they were inflicted may be reduced under five heads.

III. 1. The first are those which subjected them to penalties and punishments for exercising their religious worship; under which head may be ranked the laws respecting their education, and the ministers of their church. By these laws, if an English priest of the church of Rome, born in the dominions of the crown of England, came to England from beyond the seas, or tarried in England three days without conforming to the church, he was guilty of high treason; and those incurred the guilt of high treason, who were reconciled to the see of Rome, or procured others to be reconciled to it. By these laws also, Papists were totally disabled from giving their children any education in their own religion; for if they educated their children at home; then, for maintaining the school-master, if he did not repair to church, or was not allowed by the bishop of the diocese, they were liable to forfeit 10*l.* a-month, and the school-master was liable to forfeit 40*l.* a-day. And if they sent their children for education to any school of their persuasion abroad, they were liable to

forfeit 100*l.* and the children, so sent, were disabled from inheriting, purchasing, or enjoying any lands, profits, goods, debts, duties, legacies or sums of money. Saying mass was punishable by a forfeiture of 200 marks; hearing it by a forfeiture of 100. See 1 Eliz. c. 2. 23 Eliz. c. 1. 27 Eliz. c. 2. 29 Eliz. c. 6. 35 Eliz. c. 2. 2 Jac. I. c. 4. 3 Jac. I. c. 4. 5. 7 Jac. I. c. 6. 3 Car. I. c. 2. 25 Car. II. c. 2. 7 & S.W. 3. c. 27. 1 Geo. I. c. 13.

III. 2. Under the second head, were those laws which punished the English communicants with the church of Rome, for not conforming to the established church. These are generally called the Statutes of Recusancy. It should be observed, that absence from church alone, and unaccompanied by any other act, constituted recusancy, in the true sense of that word. Till the statute of 35 Eliz. c. 2, all nonconformists were considered as recusants, and were all equally subject to the penalties of recusancy. That statute was the first penal statute made against Popish recusants by that name, and as distinguished from other recusants. From that statute arose the distinction between Protestant and Popish recusants; the former were subject to such statutes of recusancy as preceded that of the 35th of queen Elizabeth, and to some statutes against recusancy made subsequently to that time; but they were relieved from them all by the Act of Toleration in the first year of king William's reign. From 35 Eliz. c. 2, arose also the distinction between Papists, and persons professing the Popish religion, and Popish recusants, and Popish recusants convicted.

By the statutes against Popish recusants convicted, they were punishable by the censures of the church, and by a fine of 20*l.* for every month, during which they absented themselves from church; they were disabled from keeping arms in their houses; from maintaining actions, or suits at law, or in equity; from being executors or guardians; from presenting to advowsons; from practising in the law, or physic; and from holding offices, civil or military; they were subject to the penalties attending excommunication; were not permitted to travel five miles from home, unless by licence, upon pain of forfeiting all their goods; and might not come to court under pain of 100*l.* A married woman, when convicted of recusancy, was liable to forfeit two-thirds of her dower or jointure: she could not be executrix or administratrix to her husband, or have any part of his goods, and during her marriage she might be kept in prison, unless her husband redeemed her at the rate of 10*l.* a-month, or the third part of his lands. Popish recusants convicted were, within three months after conviction, either to submit and renounce their religious opinions, or, if required by four justices, to abjure the realm; and, if they did not depart, or if they returned without a licence, they were guilty of felony, and were to suffer death as felons. See the statutes referred to under the former head.

III. 3. As to the penalties or disabilities attending the refusal of Roman Catholics to take the oath of supremacy, the declaration against transubstantiation, and the declaration against Popery; it must be premised, that the Roman Catholics make no objection to take the oath of allegiance (1 Geo. II. c. 13.), or the oath of abjuration (6 Geo. III. c. 53.) With respect to the oath of supremacy, by 1 Eliz. c. 1, the persons therein mentioned were made compellable to take the oath of supremacy, contained in that act. By the third of king James I. c. 4, another oath was prescribed to be taken, commonly called the "Oath of Allegiance and Obedience." These oaths were abrogated by the first of king William and queen Mary sess. 1. c. 8, and a new oath of allegiance, and a new oath of supremacy, were introduced

and required to be taken in their stead. The statute made in the second session of the first year of king George I. c. 13. contains an oath of supremacy, in the same words as the oath of supremacy, required to be taken by the first of king William and queen Mary. By that oath persons are made to swear, "That no foreign prince, person, prelate, state, or potentate, hath, or ought to have, any jurisdiction, power, supremacy, pre-eminence or authority, ecclesiastical or spiritual, within the realm." It was required to be taken by the persons therein named; it might be tendered to any person, by any two justices of the peace, and persons refusing the oath so tendered, were adjudged to be Popish recusants convicted, and to forfeit and be proceeded against, as such. This was the constructive recusancy referred to above. It was not the offence itself of recusancy, which, as we have already observed, consisted merely in the party's absenting himself from church; it was the offence of not taking the oath of supremacy, and the other oaths prescribed by the act of 1 Geo. I. the refusal of which was, by that statute, placed on the same footing as a legal conviction on the statutes of recusancy, and subjected the party refusing to the penalties of those statutes. This was the most severe of all the laws against Papists.

The punishment of recusancy was penal in the extreme; and the persons objecting to the oath in question, might be subjected to all the penalties of recusancy, merely by their refusing the oath when tendered to them. It added to the penal nature of these laws, that the oath in question might be tendered at the mere will of two justices of peace, without any previous information or complaint before a magistrate or any other person. Thus, by refusing to take the oath of supremacy, when tendered to them, they became liable to all the penalties of recusancy; and the same refusal, by 7 & S.W. III. c. 4. and 1 Geo. I. st. 2. c. 13, restrained them from practising the law as advocates, barristers, solicitors, attorneys, notaries, or proctors, and from voting at elections.

III. 4. With respect to receiving the sacrament of our Lord's supper; by 13 Car. II. (commonly called the Corporation Act,) no person can be legally elected to any office relating to the government of any city or corporation, unless, within a twelvemonth before, he has received the sacrament of the Lord's supper according to the rites of the church of England; and he is also enjoined to take the oaths of allegiance and supremacy, at the same time that he takes the oath of office, or in default of either of these requisites such election shall be void.

III. 5. As to the declaration against transubstantiation, by 25 Car. II. c. 2. (commonly called the Test Act,) all officers, civil or military, are directed to take the oath, and make the declaration against transubstantiation, in the court of King's Bench or Chancery, the next term or at the next quarter sessions, or, (by subsequent statutes,) within six months after their admission; and also, within the same time, to receive the sacrament of the Lord's supper, according to the usage of the church of England, in some public church immediately after divine service and sermon; and to deliver into court a certificate thereof, signed by the minister and churchwardens, and also to prove the same by two credible witnesses, upon forfeiture of 500*l.* and disability to hold the office.

III. 6. With respect to the declaration against Popery; the act passed in the 30th year of Car. II. stat. 2. c. 1. contains the declaration, and prescribes it to be made by members of either house of parliament, before they take their seats; by it they declare their disbelief of the doctrine of transubstantiation; and their belief that the invocation of saints and the sacrifice of the mass are idolatrous.

III. 7. With respect to the *laws affecting their landed property*. How this was affected by the laws against recusancy has been already mentioned. By the 11 & 12 W. III. c. 4. it was enacted that a person educated in the Popish religion, or professing the same, who did not, in six months after the age of sixteen, take the oaths of allegiance and supremacy, and subscribe the declaration of 30 Car. II., should, in respect of himself only, and not of his heirs, or posterity, be disabled to inherit or take lands by descent, devise, or limitation, in possession, reversion, or remainder: and that during his life, till he took the oaths, and subscribed the declaration against popery, his next of kin, who was a Protestant, should enjoy the lands without accounting for the profits, and should be incapable of purchasing; and that all estates, terms, interests, or profits, out of lands, made, done, or suffered, to his use, or in trust for him, should be void. By 3 Jac. I. c. 5. 1 W. & M. c. 26. 12 Anne stat. 2. c. 14. 11 Geo. II. c. 17. Papists, or persons professing the Popish religion, were disabled from presenting to advowsons, and other ecclesiastical benefices, and to hospitals and other charitable establishments. By annual acts of the legislature, Papists, being of the age of eighteen years, and not having taken the oaths of allegiance and supremacy, were subjected to the burthen of the double land tax.

By a statute made in the second session of the first year of Geo. I. c. 55, they were required to register their names and estates in the manner and under the penalties therein mentioned; and by 3 Geo. I. c. 18. continued by several subsequent statutes, an obligation of enrolling their deeds and wills was imposed on them. Such were the principal penal laws against Roman Catholics, "*imensus aliarum super alias acervatarum legum cumulus*," (Liv. 3. 34.) at the time of the accession of the house of Brunswick.

IV. To the enlightened and humane temper of the times during the reign of his present majesty, his Roman Catholic subjects are wholly indebted for any repeal of this large and grievous code. *Two acts have been already passed for their relief.*

IV. 1. *The first of those acts was passed in the 18th year of his majesty's reign.* It enacted, that so much of the 11 & 12 W. III. as related to the prosecution of Popish priests and Jesuits, and imprisoning Papists who keep schools, or to disable Papists from taking by descent or purchase, should be repealed as to all Papists, or persons professing the Popish religion, who, within six months after the passing of the act, or their coming of age, should take the oath prescribed by the act.

This act was an essential benefit to Roman Catholics; but its best effect in their regard, was its operation on the public mind, by lessening the prejudices generally entertained against them, and bringing them and their fellow-subjects into habits of social intercourse and amity, which the penal code had too much interrupted. It can only be conceived by those who witnessed it, what a sudden and extensive effect, in this regard, was produced by this single act of parliament.

IV. 2. A more extensive relief from the penal laws was granted to the English Roman Catholics by an act of the 31st year of the reign of his present majesty. The extent and the conditions of this relief will be stated under the article TOLERATION.

V. It remains to give some account of the penal laws, the effect of which is felt by Roman Catholics, but the effect of which is not felt by Protestant dissenters.

V. 1. It has been already shewn, how the law stands on

the Corporation and Test Acts. The statute of the 1st William and Mary, (commonly called the Toleration Act), exempts all Dissenters, except Papists, and such as deny the Trinity, (with regard to whom an alteration has lately taken place, see TRINITY,) from all penal laws relating to religion, provided they take the oaths of allegiance and supremacy, and subscribe the declaration against popery, and repair to some congregation registered in the bishop's court or at the sessions. But there is nothing in this act which dispenses, either with the Test Act or the Corporation Act, so far as they impose the obligation of receiving the Lord's supper on persons serving in offices, or elected to serve in corporations. With respect, therefore, to the Test Act and the Corporation Act, these are the only acts which subject the Protestant dissenters to any penalties or disabilities. To these the Roman Catholics are subject, equally with the Protestant dissenters. There is, therefore, no penalty or disability that affects the Protestant dissenters, to which Roman Catholics are not subject equally; but there still remain several penal laws, the effect of which is most severely felt by Roman Catholics, but the effect of which is not, in any manner, felt by Protestant dissenters.

V. 2. The first of these is the 30th Car. II. stat. 2. c. 1. which provides that no person should sit or vote in the house of peers, or be a member of, or sit or vote in the house of commons, till he has taken the oaths of allegiance and supremacy, and made and signed the declaration against popery.

V. 3. By the 7th and 8th of W. III. c. 27, those, who refuse to take the oath of supremacy, tendered to them at the requisition of a candidate, are disabled from voting at elections.

V. 4. By several statutes, Roman Catholics are disabled from presenting to advowsons. This disability is peculiar to them; Quakers, and even Jews, having the full enjoyment of the right of presentation.

V. 5. Lastly, Roman Catholics alone feel the penal operation of 1 Geo. I. stat. 2. c. 13, which requires all persons, bearing offices, civil or military, or holding command or place of trust, or receiving pay or wages, by reason of any patent or grant from his majesty, to take the oath of supremacy under the penalty of 500*l.* and under other penalties.

Such are the penal laws under which the Roman Catholics of England still labour. They have presented petitions to both houses of parliament for their repeal, and we wish them success: but we still more anxiously wish for that time, when the imperial parliament of the united empire will see the injustice and impolicy of every restriction on religious opinion, and at once abolish the whole religious penal code.

The Declaration and Protestation signed by the English Catholics in 1789.

We, whose Names are hereunto subscribed, CATHOLICS of ENGLAND, do freely, voluntarily, and of our own accord, make the following solemn DECLARATION and PROTESTATION.

Whereas sentiments unfavourable to us, as citizens and subjects, have been entertained by English Protestants, on account of principles which are asserted to be maintained by us and other Catholics, and which principles are dangerous to society, and totally repugnant to political and civil liberty; — it is a duty that we, the English Catholics, owe to our country as well as to ourselves, to protest, in a formal and solemn manner, against doctrines that we condemn, and that constitute no part whatever of our principles, religion, or belief.

We are the more anxious to free ourselves from such imputations, because divers Protestants, who profess themselves to be real friends to liberty of conscience, have, nevertheless, avowed themselves hostile to us, on account of certain opinions which we are supposed to hold. And we do not blame these Protestants for their hostility, if it proceeds (as we hope it does) not from an intolerant spirit in matters of religion, but from their being misinformed as to matters of fact.

If it were true, that we, the English Catholics, had adopted the maxims that are erroneously imputed to us, we acknowledge that we should merit the reproach of being dangerous enemies to the state; but, we detest those unchristianlike and execrable maxims: and we severally claim, in common with men of all other religions, as a matter of natural justice, that we, the English Catholics, ought not to suffer for or on account of any wicked or erroneous doctrines that may be held by any other Catholics, which doctrines we publicly disclaim, any more than British Protestants ought to be rendered responsible for any dangerous doctrines that may be held by any other Protestants, which doctrines they, the British Protestants, disavow.

First, We have been accused of holding, as a principle of our religion, that princes excommunicated by the pope and council, or by authority of the see of Rome, may be deposed or murdered by their subjects, or other persons.

But, so far is the above mentioned unchristian-like and abominable position from being a principle that we hold, that we reject, abhor, and detest it, and every part thereof, as execrable and impious: and we do solemnly declare, that neither the pope, either with or without a general council, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, can absolve the subjects of this realm, or any of them, from their allegiance to his majesty king George the Third, who is, by authority of parliament, the lawful king of this realm, and of all the dominions thereunto belonging.

Second, We have also been accused of holding, as a principle of our religion, that implicit obedience is due from us to the orders and decrees of popes and general councils; and that therefore if the pope, or any general council, should, for the good of the church, command us to take up arms against government, or by any means to subvert the laws and liberties of this country, or to exterminate persons of a different persuasion from us, we (it is asserted by our accusers) hold ourselves bound to obey such orders or decrees, on pain of eternal fire:

Whereas, we positively deny that we owe any such obedience to the pope and general council, or to either of them; and we believe that no act that is in itself immoral or dishonest can ever be justified by or under colour that it is done either for the good of the church, or in obedience to any ecclesiastical power whatever. We acknowledge no infallibility in the pope; and we neither apprehend nor believe that our disobedience to any such orders or decrees (should any such be given or made) could subject us to any punishment whatever. And we hold and insist, that the Catholic church has no power that can, directly or indirectly, prejudice the rights of Protestants, inasmuch as it is strictly confined to the refusing to them a participation in her sacraments and other religious privileges of her communion, which no church (as we conceive) can be expected to give to those out of her pale, and which no person out of her pale will, we suppose, ever require.

And we do solemnly declare, that no church, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, hath, have, or ought

to have, any jurisdiction or authority whatsoever within this realm, that can, directly or indirectly, affect or interfere with the independence, sovereignty, laws, constitution, or government thereof; or the rights, liberties, persons, or properties of the people of the said realm, or of any of them, save only and except by the authority of parliament; and that any such assumption of power would be an usurpation.

Third, We have likewise been accused of holding, as a principle of our religion, that the pope, by virtue of his spiritual power, can dispense with the obligations of any compact or oath taken or entered into by a Catholic: that therefore no oath of allegiance, or other oath, can bind us; and, consequently, that we can give no security for our allegiance to any government.

There can be no doubt but that this conclusion would be just, if the original proposition upon which it is founded were true; but, we positively deny that we do hold any such principle. And we do solemnly declare, that neither the pope, nor any prelate, nor any priest, nor any assembly of prelates or priests, nor any ecclesiastical power whatever, can absolve us, or any of us, from, or dispense with, the obligations of any compact or oath whatsoever.

Fourth, We have also been accused of holding, as a principle of our religion, that not only the pope, but even a Catholic priest, has power to pardon the sins of Catholics at his will and pleasure; and therefore, that no Catholic can possibly give any security for his allegiance to any government, inasmuch as the pope, or a priest, can pardon perjury, rebellion, and high treason.

We acknowledge also the justness of this conclusion, if the proposition upon which it is founded were not totally false. But, we do solemnly declare, that, on the contrary, we believe that no sin whatever can be forgiven at the will of any pope, or of any priest, or of any person whomsoever; but that a sincere sorrow for past sin, a firm resolution to avoid future guilt, and every possible atonement to God and the injured neighbour, are the previous and indispensable requisites to establish a well-founded expectation of forgiveness.

Fifth, And we have also been accused of holding, as a principle of our religion, that 'no faith is to be kept with heretics;' so that no government which is not Catholic can have any security from us for our allegiance and peaceable behaviour.

This doctrine, that 'faith is not to be kept with heretics,' we reject, reprobate, and abhor, as being contrary to religion, morality, and common honesty: — and we do hold and solemnly declare, that no breach of faith with any person whomsoever can ever be justified by reason of or under pretence that such person is an heretic or an infidel.

And we further solemnly declare, that we do make this Declaration and Protestation, and every part thereof, in the plain and ordinary sense of the words of the same, without any evasion, equivocation, or mental reservation whatsoever.

And we appeal to the justice and candour of our fellow citizens, whether we, the English Catholics, who thus solemnly disclaim, and from our hearts abhor, the above mentioned abominable and unchristian-like principles, ought to be put on a level with any other men who may hold and profess those principles?

The above Declaration and Protestation was signed by one thousand seven hundred and forty persons; including several peers, and two hundred and forty-one clergymen of the Catholic religion.

PAPIUCHI, in *Geography*, a town of Mexico, in the province of Mayo; 150 miles N. of Santa Cruz.

PAPLAH, a town of Asia, and capital of a small country, dependent upon Thibet; governed by a rajah; 90 miles N. of Fyzabad. N. lat. 28° 10'. E. long. 82° 53'.

PAPOUL, ST., a town of France, in the department of the Aude, before the revolution the see of a bishop; four miles E. of Castelnaudary. N. lat. 43° 20'. E. long. 2° 7'.

PAPOZZE', a town of Italy, in the department of the Lower Po; 22 miles N.E. of Ferrara.

PAPPAW, a town of Prussia, in the palatinate of Culm; 10 miles S.E. of Culm.

PAPPENBURG, a sea-port town of East Friesland, on a canal which communicates with the Ems. Although it has been lately erected, it contains 19 yards for ship-building, 2 churches, 400 houses, and 3000 inhabitants. To this port belong 160 vessels, the largest of which carry 160 lasts, with about 100 small craft; 20 miles S. of Emden. N. lat. 53°. E. long. 7° 28'.

PAPPENHEIM, a town of Bavaria, and capital of a county, in the bishopric of Aichstatt, on the Altmuhl. The established and universal religion is Lutheranism; 12 miles N.W. of Aichstatt.

PAPPON, JOHN PETER, in *Biography*. was born in the year 1736, at Pujes, near Nice. He entered while he was young into the congregation of the Oratory, and became a distinguished member. He passed life in tranquillity, exempt from ambition and intrigue, and his spirits were scarcely affected by the loss of pension, which constituted his chief support, at the commencement of the revolution. During the reign of the infamous Robespierre, he took refuge in the department of the Puy-de-Dôme, whence he afterwards returned to Paris. He died in 1801, in the sixty-fifth year of his age. His principal works are as follow; "An Ode to Death," inserted in the collection of the Floral Games of Toulouse; "L'Art du Poete et de l'Orateur;" "Voyage de Provence," 2 vols. 12mo.; "Histoire de Provence," 4 vols. 4to. He wrote some pieces relative to the French revolution, and a work entitled "Epoques memorables de la Peite," in two vols. 8vo. To the history of Provence many ancient documents were annexed; and for the purpose of discovering new authorities the author took a journey to Naples, and procured, among other pieces, the Quittance given by queen Joan to pope Clement VI. for the price of Avignon, which she sold him.

PAPPOPHORUM, in *Botany*, a genus first established by Schreber, and named by him from *παππος*, *thistle down*, and *φειω*, *to bear*, in allusion to the peculiar resemblance of the fine aggregate awns of this grass, to the seed-down of many Syngenesious plants. Schreb. 787. Willd. Sp. Pl. v. 1. 458. Mart. Mill. Dict. v. 3. Brown Prodr. Nov. Holl. v. 1. 184. Lamarck Dict. v. 5. 3. Clafs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two long, linear, somewhat compressed, very thin, pointed, awnless valves, containing two florets; the outermost valve a little shorter. *One floret* below the other, larger, sessile, bearded at the base, perfect; the *second* raised upon a short stalk, smaller, pressed close to the back of the former, beardless, neuter; above these is the rudiment of a third, sometimes of a fourth. *Cor.* Glume of two valves, shorter than the calyx; the outermost ovate, swelling, angular, terminated by numerous, nine to thirteen, very long, straight, unequal, feathery or rough, spreading awns, its edges embracing the inner glume, which is lanceolate, acute, rather longer and narrower than the outer. Nectary minute, of two linear leaves. *Stam.* Filaments three, capillary; anthers oblong. *Pist.* Germen ovate, superior; styles two, short; stigmas villous. *Peric.*

none, except the corolla, which encloses the seed, but is not united to it. *Seed* solitary, ovate, compressed, pelucid.

Ess. Ch. Calyx of two linear, nearly equal, valves, containing two florets, with the rudiments of more. Corolla of two valves, the outermost with numerous awns.

Obf. The outer glume of the lowermost floret is villous at the back and sides; the inner glume is hollowed out at the back, for the reception of the upper, or neuter, floret. The awns have the appearance of the down of the seeds of syngenesious flowers. Schreb.

1. *P. alopecuroideum*. Vahl. Symb. v. 3. 10. t. 51. (Saccharum pappiferum; Lamarck Illustr. v. 1. 155.)—Awns thirteen, minutely toothed.—Native of South America. *Root* perennial. *Stem* branched, three or four feet high, smooth. *Leaves* convoluted, acute, striated, shorter than the stem. *Panicle* or *spike* erect, compound, eighteen inches long, resembling that of *Agrostis panicea*, Willd. Sp. Pl. v. 1. 363. Engl. Bot. t. 1704. Willd. The calyx, according to Vahl, contains sometimes four florets, though only one is perfect.

2. *P. nigricans*. Brown n. 1.—Awns nine, feathery. *Spike* compound, somewhat cylindrical, with imbricated lobes. *Glumes* very finely downy. *Leaves* and sheaths naked, roughish. Gathered by Mr. Brown, in the tropical as well as southern parts of New Holland, and at Port Jackson.

3. *P. pallidum*. Br. n. 2.—Awns nine, feathery. *Spike* compound, somewhat cylindrical, with imbricated lobes. *Glumes* and *leaves* villous.—Native of the tropical part of New Holland, as well as the two following, Mr. Brown having gathered them all in that country.

4. *P. purpurascens*. Br. n. 3.—Awns nine, feathery, coloured. *Spike* lanceolate, lobed; its branches alternate, racemose. *Glumes* and *leaves* downy.

5. *P. gracile*. Br. n. 4.—Awns nine, feathery. *Spike* divided in the lower part; simple above. *Glumes* downy. *Leaves* involute, smooth, as well as the stems.

We have taken the specific characters of all the five species from Mr. Brown, having seen no specimen of any of them.

PAPPOSE PLANTS, in *Gardening*, are all those which have a downy kind of flowers, or a sort of feathery crown of the same nature, which adheres to the seeds of many of them, as are exemplified in the lettuce, the dandelion, the sow-thistle, groundsel, and some other sorts. A great many of these kinds of plants also produce compound flowers, the seeds of which are furnished with a portion of this downy substance adhering to the top part of each, so as in some degree to resemble a shuttle-cock, being naturally framed for flying, in order to spread and disseminate the seed, and transport it to considerable distances by the wind, so that it may be sown and deposited in different soils and situations, instead of being confined to a single spot.

Among this class of plants are some of the most troublesome weeds, the seeds of which are, by the means which they thus possess, carried and scattered in the gardens and fields, to the great inconvenience and trouble of the gardener and farmer.

These are likewise frequently called winged seeds. See the following article, and WEEDS.

PAPPUS, in *Botany* and *Vegetable Physiology*, Seed-down; the hairy or feathery, sometimes chaffy, radiating crown of the seed, in the natural order of Compound Flowers, or Syngenesious class, such being the true classical acceptation of this Latin word, as well as of the Greek *παππος*, from whence it comes. The use of this part is to waft the seed to a distance, in dry and windy weather, when the *pappus* is most light and expanded; by which means such

such plants are widely dispersed. Finally it either slips off, by the drying and contraction of the summit of the seed, as in Thistles; or the seed having fixed itself in the earth, the down is broken off by the wind, or some other accidental cause; in either case the seed is left behind, to germinate without further disturbance. The down, having fulfilled its primary destination, often serves a secondary purpose in the economy of nature; being hoarded up by birds, and the smaller quadrupeds, to compose or to line their nests, or winter retreats. Its texture is not such as to render it fit for being woven, by human art, for any use.

Gærtner properly restrains the term *pappus* to compound flowers; though Linnæus and others use it indiscriminately for such, and for the hairy appendages to the top, sides, or base, of other seeds, even when they are enclosed in a capsule; witness *Epilobium*, *Aselepias*, and many others of the *Contortæ*, *Salix*, *Eriophorum*, &c. Gærtner uses the word *Coma*, when such an appendage is situated at the top of the seed; *Pubes* when it originates from the base or sides, as in *Gossypium*, the Cotton plant.

The proper *Pappus* of syngenesious compound flowers is either stalked, as in the Common Dandelion, or sessile, as in the Thistle; in both which examples its rays are of a feathery structure. In *Hieracium* the rays are, or ought to be, simple; but such a structure is very rare, what are so described being for the most part rough or toothed, at least, if not more or less branched or feathery. In *Cichorium*, and several other genera, the *pappus* consists of dilated chaffy teeth, or leaflets, either separate or combined at their base, which clearly shews the affinity of the part to a calyx. This more strikingly appears in *Scabiosa*, in which the term is admitted, even by Gærtner, that genus having compound, though not syngenesious, flowers. Here the *pappus* is double, very variously and curiously constructed in the different species. *Bidens* has a *pappus* of two, three, or four rigid barbed bristles, evidently contrived so for the purpose of attaching the seeds to the coats of animals, or to any thing else that may come in the way, in order to aid in their dispersion by that means, instead of their being wafted on the wings of a light feathery seed-down. The variety of structure in the part in question is indeed highly curious, some plants having two sorts of *pappus* to the different florets of the same flower; see HEDYPSOIS. A judicious, but not indiscriminate, attention to its differences, affords one of the best clues to a knowledge of the syngenesious genera; but in this as well as other cases no difference must be considered as absolute; the genus always being required to give the character, not the character the genus.

PAPPUS, in *Biography*, a very eminent Greek mathematician of Alexandria, who flourished in the fourth century, during the reign of Theodosius the Great, who presided over the empire from the year 379 to 395. Such of his works as are still extant, prove that he was profoundly skilled in the mathematical sciences: the greater part of his productions are probably lost, among which are a "Commentary upon Ptolemy's Almagest;" "A Description of the Rivers of Lybia;" "An Universal Chorography;" a treatise "On Military Engines;" "Commentaries upon Aristarchus of Samos, concerning the Magnitude and Distance of the Sun and Moon." Reference is made by Marinus, a disciple of Proclus, to his "Mathematical Collections," in eight books, of which the last six, and part of the second remain. They were among the manuscripts presented by sir Henry Saville to the Bodleian library at Oxford. To this work, Marcus Meibonius annexed some *lemmata*, from the seventh book, in Greek, with a version of his own, to his "Dialogue on Proportions," published at Copenhagen in the year 1665;

and Dr. Wallis printed the last twelve propositions in Greek, from the Savilian MS. with a Latin version and notes at the end of his edition of Aristarchus' treatise "On the Magnitude and Distance of the Sun and Moon;" and also in the third volume of his "Mathematical Works." In the year 1703, Dr. David Gregory gave part of the preface to the seventh book, in which the author treats of the geometrical analysis of the ancients, &c. in Greek, accompanied with the Latin version of Commandini, in the *Prolegomena* to his edition of Euclid; and in 1706 Dr. Edmund Halley printed the whole preface, in Greek and Latin, in the *Prolegomena* to his edition of the *Conics* of Apollonius. And, to mention no other instances of a like kind, we may observe, that the whole of what remains of the "Mathematical Collections," was published at Bologna in 1660. For an analysis of these collections, we refer to Hutton's dictionary, art. *Pappus*.

PAPRA, in *Geography*, a town on the W. coast of Siam. N. lat. 8° 10'. E. long. 98° 30'.

PAPREMIS, or PAPIRIMIS, in *Ancient Geography*, a town of Egypt, and the capital of the Papremite nome. In this place the hippopotamus was regarded as a sacred animal; and Mars was honoured with a singular ceremony. Upon the festival appropriated to this deity, the priests bore upon a four-wheeled chariot the statue of the god, which was enclosed in a small chapel of gilt wood; and while they endeavoured to force the chariot and statue into the temple of that divinity, men armed with clubs stood in the way to hinder it; and as the priests who accompanied the procession had likewise arms, there ensued an engagement, when naturally many people must have lost their lives. The Egyptians, however, maintained that nobody died of the wounds they received upon that occasion.

PAPS, in *Geography*, the two remarkable mountains of the county of Kerry, Ireland, about eight miles E. by S. from Killarney.—Also, two remarkable hills of Upper Canada, on the N. shore of lake Superior.

PAPUA. See *New GUINEA*.

PAPUDA BAY, a bay on the coast of Chili, in the South Pacific ocean, five leagues N. of the shoals of Quintaro and four from port Liga; the water is deep, the anchorage good, and the entrance safe.

PAPULA, in *Medicine*, a diminutive of *papa*, the *nipple*, signifies a small, hard, and acuminate elevation of the surface of the skin, which has an inflamed base, but seldom contains a fluid, or tends to suppurate. It is synonymous with the English term *pimple*.

This appellation has been applied by medical writers to a considerable variety of eruptions; but, in the more accurate nomenclature of cutaneous diseases, adopted by the late Dr. Willan, its signification is limited, as above, to a minute tumour, which appears to originate in an inflammation of the papillæ of the skin, by which these are enlarged, elevated, and indurated, and made to assume more or less of a red colour; they do not end in suppuration like pustules, but commonly terminate in a scurfy exfoliation of the cuticle. The most accurate nosologists, indeed, seem to have agreed in restricting the meaning of the word to this sense. Thus Sauvages defines *papula*, "Phyma parvulum, desquamari solitum." (Nosol. Method. c. 1. i. Synopf. ord. ii. 6. See also Linnæi, Gen. Morbor. class. xi. ord. 4.) Among the ancients, Celsus seems to have understood the term in the same acceptation, although he applies it generically, apparently to the lichen. De Medicina, lib. v. cap. 28.

The *papular* eruptions constitute the first order in Dr. Willan's ingenious classification of diseases of the skin; and of these he has described three distinct genera; namely, the STROPHULUS, *red-gum*, or *tooth rash*, of children; the LI-

CHEN,

CHEN, and the PRURIGO, which see respectively. See also Willan on Cutaneous Diseases; and Bazeman's Practical Synopsis of Cutaneous Diseases, p. xx.

PAPULARIA, in *Botany*, so termed by Forskall, in his *Fl. Ægypt. Arab.* 69, on account of the crystalline soft granulations sprinkled over its leaves, is no other than *Triantenna monogyna*. See PAPPILLOSUM *folium*, and TRIANTHEMA.

PAPYRIUS, from *papyrus*, Lamarck *Illustr.* t. 762, a name given by that author to the Paper Mulberry, in allusion to the use made of its bark, from which most of the East Indian, Japanese, and Chinese paper is prepared, as well as the cloth of Otaheite, &c. This plant, confounded by Linnæus under *Morus*, was separated from thence, as a distinct genus, by l'Heritier, who called it *Broussonetia*, in honour of his friend P. M. Augustus Broussonet, M. D. an excellent botanist and ichthyologist, who first introduced this valuable tree alive into the French gardens. He was also one of the most zealous disciples of the Linnæan school in that country, and an undisguised opponent of those, who, from envy or prejudice, depreciated the merits of the great naturalist of Sweden. Hence it seems that Lamarck was not inclined to adopt the name l'Heritier had proposed, if he was actually acquainted therewith, and he retaliated that sort of neglect or opposition which he had, in many instances, received from his rival. Ventenat, however, and Willdenow, have restored *Broussonetia*, which has every claim to preference, and it is adopted in this country, where the merits and amiable character of Dr. Broussonet are well known to several, who have sincerely deplored the misfortunes which, like many good Frenchmen, he experienced under Robespierre, and his subsequent untimely death. One of our predecessors has passed over this name; see BROUSSONNETIA, as it is very erroneously printed. We beg leave here to assert its just claims, though out of its alphabetical place.

BROUSSONETIA. l'Herit. MSS.—Venten. *Tabl.* v. 3. 547. *Andr. Repof.* v. 7. 488. *Willd. Sp. Pl.* v. 4. (Papyrus; *Lam. Illustr.* t. 762. *Poiret in Lam. Dict.* v. 5. 3.)—Class and order, *Diacia Tetrandria*. *Nat. Ord. Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth in four deep, ovate, concave segments. *Cor.* none. *Stam.* Filaments four, awl-shaped, erect, much longer than the calyx, opposite to its segments; anthers oval, of two cells.

Female, on a separate plant, *Cal.* Perianth inferior, tubular, of one leaf, with four, rarely but three, segments, permanent. *Cor.* none. *Pist.* Germen somewhat stalked, ovate, compressed; style lateral, awl-shaped, elongated, permanent; stigma simple. *Peric.* none, except the elongated, pulpy, coloured, forked, club-shaped receptacle, on which the seed is elevated as on a stalk, and enclosed between its points. *Seed* solitary, ovate, partly covered by the forks of its pulpy supporter, and accompanied by the capillary withered style. *Common receptacle* globose, very densely covered with flowers spreading every way, and interspersed bristly permanent scales.

Ess. Ch. Male, Calyx in four deep segments, Corolla none.

Female, Calyx tubular, in four segments. Corolla none. Style one, lateral. Seed solitary, elevated on a pulpy, club-shaped, forked receptacle. Common receptacle globose, bristly.

t. B. *papyrifera*. Paper Mulberry. *Andr. Repof.* t. 488. (*Morus papyrifera*; Linn. *Sp. Pl.* 1399. *M. fativa, foliis urticæ mortuæ, cortice papyrifera*; Kämpf. *Am. Exot.*

471. t. 472.)—Native of Japan; probably also of China, and the South Sea islands. At least it is cultivated in all those countries. It appears from Miller to have been introduced into England before the year 1759, by the late duke of Northumberland. Dr. Broussonet saw the female tree in fruit at London, and possibly, as Poiret indicates, at Edinburgh, in 1782, and carried it with him to Paris, where the male only had previously been known, and consequently no suspicion could have arisen of its not being, as Linnæus supposed, a *Morus*, though dioecious. (See MORUS) It there bore fruit, which it continually does at Kew, and in other gardens, being quite hardy, and blossoming all summer long. This is a deciduous tree, of a moderate size, with the aspect of a mulberry, or rather of some arborefcient *Urticæ*. Branches alternate, round, downy, leafy at the extremities. Leaves alternate, stalked, ovate or somewhat heart-shaped, acute, serrated, deeply lobed and sinuated without any regularity, so that scarcely two can be found precisely alike; their upper side of a dull hoary green, very rough with minute cartilaginous tubercles; the under paler and downy, with numerous veins. Stipulas in pairs, ovate, pointed, downy. Flowers axillary, stalked; the male in very dense, cylindrical, blunt, drooping, greyish spikes, which have the aspect of catkins; female on a distinct tree, in equally dense, green, globular heads, about an inch in diameter. As the fruit advances, numerous scarlet, juicy, club-shaped, incurved bodies are protruded, in every direction, in whose summits the seed is lodged. These have a sweet flavour, but are not of consequence sufficient to render the fruit an object of cultivation, though it is not destitute of beauty.

The chief importance of this tree, consists in the uses made of its bark. The clothing of the inhabitants of the South Sea islands, in their primeval simplicity, was almost entirely prepared from it, several layers of the bark being laid over each other, and incorporated by beating, aided with some slight cement; and so elegantly coloured with the natural productions of the country, as to excite the admiration of our most intelligent voyagers. Kämpfer gives a particular account of the preparation of the Japanese paper from this bark. For this purpose the branches of the present year, after the leaves are fallen, in December, are chosen, and being cut into pieces about a yard long, are boiled, till the bark shrinks, and is easily separable from the wood, which is then thrown away. The bark being dried, is preserved till it is wanted. In order to make paper, it is soaked for three or four hours in water, after which the external skin, and the green internal coat, are scraped off. At the same time the stronger and firmer pieces are selected, the produce of the youngest shoots being of an inferior quality. If any very old portions present themselves, they are, on the other hand, rejected as too coarse. All knotty parts, and every thing which might impair the beauty of the paper, is also removed. The chosen bark is boiled in a lixivium, till its downy fibres can be separated by a touch of the finger. The pulp so produced is then agitated in water, till it resembles tufts of tow. If not sufficiently boiled, the paper will be coarse, though strong; if too much, it will be white indeed, but deficient in strength and solidity. Upon the various degrees and modes of washing the pulp, much also depends, as to the quality and beauty of the paper. Mucilage obtained from boiling rice, or from a root called *Oreni*, Kämpf. 474, one of the mallow tribe, is afterwards added to the pulp. The paper is finished much after the European mode, except that stalks of rushes are used instead of brass wires. See PAPER.

PAPYRUS. See CYPERUS.

PAPUASHE

PAQUASHE LAKE, in *Geography*, a lake of North America. N. lat. $50^{\circ} 48'$. W. long. $93^{\circ} 30'$.

PAQUILIGASTA, a town of South America, in the province of Tucuman; 40 miles S.S.W. of S. Miguel de Tucuman.

PAR, a term of nobility. See PEER.

PAR, CATHERINE, in *Biography*, sixth wife of Henry VIII. was daughter of sir Thomas Par, and received, according to the custom of the age, a learned education. She was known to be friendly to the reformation, and on that account bishop Gardiner, and others, whose zeal and bigotry were ever displayed against the reformers, endeavoured to effect her ruin, but by her prudence she preserved the king's favour till his death. In the year 1544 she was so much in the confidence of her royal spouse, that he made her regent while he went with a great army into France. After this she had a narrow escape from impeachment, of which Mr. Hume has given an interesting account. Immediately after the death of the monarch she married lord Seymour: the ceremony was, indeed, performed with so much haste, that the historian already quoted, says, "had she soon proved pregnant, it might have been doubtful to which husband the child belonged." She was extremely ill-treated by this second husband, which so much affected her, that she died in child-bed in the year after her marriage. Hume, vol. iv. Walpole's Royal and Noble Authors.

PAR of Exchange. This subject, which is so very familiar in the mouths of commercial men, yet so little understood, has been already incidentally noticed under the article EXCHANGE; but as what was said of it there refers more to its practical nature, than to the general principles on which it is founded, and by a knowledge of which alone it can be satisfactorily and fully ascertained, we shall enter more regularly and systematically into the discussion of it in this article. Most of the difficulties, and much of the obscurity, which encompass that part of the science of political economy, which relates to the commerce between nations, would be removed, if we were to consider this commerce as exactly the same in its nature, operations and effects, as the trade that is carried on between different parts of the same kingdom, or even between two individuals: by bringing the subject thus within a narrower compass, and placing it in a point of view more familiar and more within the reach of our observation and experience, we should be enabled to examine it more attentively, and to render ourselves acquainted with it more accurately, not only in its general principles, but in its minute and complicated details. These remarks will apply with peculiar force and propriety to the subject which we are about to discuss: in entering upon it, if we take our illustrations and examples, not from what passes in the commercial intercourse of two distinct nations, the denomination and value of whose currency differs, but from what occurs in the commercial transactions that are carried on between different parts of the same kingdom, we shall clear the way so completely, as to be enabled to proceed without impediment, confusion, or difficulty.

Let us take, as an example, the commercial intercourse between London and York; and suppose that in the former city, there are merchants who owe to their correspondents in London the sum of 2000*l.*, and merchants who have demands on their correspondents in London to the same amount. The obvious and natural mode of settling these claims, would be for the merchants who have money to pay in London, to pay the amount to the merchants who have money to receive in London: by this mode the York merchants, so far as they alone were concerned, would have their business settled; but there would yet remain to be arranged the pecu-

niary business of the London merchants, who either were indebted to the York merchants, or had money to receive from them: the mode of adjusting their business would be equally obvious and natural. The York merchant who had received the 2000*l.* from his brother merchant in the same city, as a settlement of the debt to that amount due to him in London, would in return give him an order for that sum on the London merchant his debtor; which order, transmitted to London, would serve to discharge the debt that the York merchant owed in the capital. It is easy to perceive what trouble and expence are saved by this arrangement: were it not adopted, the York merchant who owed 2000*l.* in London, must have been at the expence of transmitting this sum to London; and a similar expence must have been incurred by the other York merchant, or by his debtor in London, in transmitting the 2000*l.* from London to York. When the general plan of adjusting the debts in this mode was once arranged, there would be no difficulty in carrying it into execution, as the currency in York and London were exactly the same; but the case, in this respect, would be altered, if Dublin and London were concerned, instead of York and London. The currencies of England and Ireland differ in real value, though they are exactly the same in denomination. Let us now suppose that a merchant in London owes 2000*l.* in Dublin, and another merchant has 2000*l.* to receive in London. They would respectively save the freight and insurance of this sum, if in London they could adjust what they have respectively to receive or pay in Dublin: had the currencies of Ireland and England been exactly the same in real value, as they are in denominative value, there could not be the slightest difficulty in making this arrangement; but as there is a difference in the real value of the currencies of these two countries, this difference must be satisfactorily and exactly ascertained before any arrangement can take place. When this difference in the real value is determined, the par of exchange is said to be fixed; or in other words, the sums in the currencies of the two countries, which contain exactly the same quantity of the precious metals, are ascertained. In the case we are now supposing, *viz.* that between England and Ireland, the currency of the latter country is about eight *per cent.* worse than the currency of England; or in other words, the denominative value of the currency of the two countries being the same, there is about eight *per cent.* less of the precious metals in the coins of Ireland of the same denomination as those of England: a debt of 2000*l.* in Ireland, therefore, could be discharged for eight *per cent.* less of real value, than the same nominal debt could be discharged for in England: on this account the English merchant, who owes this sum in Ireland, and who wishes to discharge his debt by paying a sum of money to the other English merchant, who has owing to him 2000*l.* in Ireland, will only pay to the latter 2000*l.* minus eight *per cent.*; and the latter, if he receives this sum, will receive the full amount of his debt. It may perhaps be thought that the latter will refuse to accede to this mode of settling his debt: but a little reflection will convince us that in this, as in the former case between York and London, both merchants are accommodated in an equal degree by this arrangement; for let us see how they must proceed, if they did not accede to it. The merchant who owed the 2000*l.* in Ireland would be obliged to transmit there as much bullion as would be equal in value to 2000*l.* Irish currency; and the merchant, who had money to that amount to receive from Ireland, could get from that country only as much bullion, as that sum of Irish currency would purchase: hence, as the expence of freight, insurance, &c. would be the same in each case, it would evidently be for
their

PAR OF EXCHANGE.

their mutual advantage to settle their debts and payments in the manner which has been described.

The general rules, therefore, in fixing the par of exchange between any two countries, is by ascertaining the real value of the coin of these countries: if the same quantity of gold or silver is contained in two coins of two countries, these coins are equal in value to each other; if there is more gold or silver contained in the coin of one country, than in the coin compared with it of the other country, the values are not equal, but proportional: and these proportions can always be accurately expressed by the smaller coins, of which the larger ones that are compared are composed. Thus, let us suppose that the ruble of Russia, and the half-crown piece of Britain, contain exactly the same quantity of silver of the same fineness: then the par of exchange between Britain and Russia will be the ruble and the half crown piece; but as the intrinsic value of either or both of them may be changed, though their denominations remain the same, the par is more commonly expressed by the smaller coins which form them, as in the case of the half-crown, by the pence which compose it: and the par of exchange between England and Russia, is said to be, when the ruble of the latter country is at thirty pence. Again, let us suppose that the crown piece of Great Britain and the dollar of Spain are compared, and that it is found that the former contains more silver of the same purity than the latter: the difference can easily be ascertained, and as the crown piece is divided into, or composed of, smaller coins, this difference, when ascertained, can as easily be expressed. The crown piece is equal to sixty pence: the dollar, we shall suppose, contains one-tenth less silver than the crown piece; if the par between Spain and England, therefore, is measured by a reference to these two coins, it will be expressed, by stating it at four shillings and sixpence British for the Spanish dollar. The advantage, and even necessity, of supposing the coins thus compared divided into their component parts, will be further illustrated when we come to consider the circumstances that affect the real or nominal par of exchange.

It may seem superfluous to enquire upon what principle equal quantities of the precious metals are supposed to be of equal value in different countries; yet this requires investigation. Let us suppose that a merchant of London, who owes 2000*l.* in Dublin, is not able to obtain a bill on that city, and has no other mode of discharging his debt but by transmitting the money. Let us farther suppose, that for this purpose he cannot transmit English money to Ireland: how is he to proceed? The only mode he can adopt, is to purchase in London as much bullion as will sell for, or may be coined into, 2000*l.* in Dublin; he cannot discharge his debt by the mere bullion he transmits; could he do this in all cases, the principle, that equal weights of bullion were always of equal value in all countries, would be without exception, and would be a fundamental principle, beyond which we could not proceed in illustrating the doctrine of the par of exchange. But if cases may occur, in which the bullion and the mint value of the precious metals differ, then, in these cases, we must look beyond this principle, for a principle more steady on which to ground the doctrine of the par of exchange. Let us suppose that the merchant who owes 2000*l.* in Dublin, being perfectly well acquainted with the quantity of the precious metals contained in this sum of Irish currency, purchases that quantity in London, and transmits it to Dublin: in the mean time, a difference has taken place in this city, between the bullion and the mint value of the precious metals; the bullion value has fallen, so that the quantity of bullion trans-

mitted will not sell for 2000*l.* Irish currency. In this case we perceive, that by fixing the par merely by a reference to the quantity of the precious metals in the coins of any two countries, we should fix it inaccurately; it may, indeed, be alleged, that the bullion and mint value of the metals can never differ much, nor for a long continuance; but as they may, and do differ, though to ever so trifling an amount, and for ever so short a time, we must correct the principle on which the par of exchange is fixed: thus corrected, it will stand thus;—the par of exchange must be estimated, not by a comparison between the quantities of bullion contained in the coins of any two countries, but by a comparison between the quantities of bullion which these coins will purchase: this is the accurate principle; but as in most cases the bullion and mint value are equal; and as, where an inequality does exist, it is very trifling, and continues but for a very short period, the usual manner of computing the par of exchange is, in most instances, sufficiently just and accurate.

It must, however, be observed, that the comparison of the coins of different countries has not been made with all that skill and attention which ought to have been employed upon it: indeed the par seems to have been fixed at a time when the art of assaying metals and determining their positive and relative purity was comparatively but little known.

But the loose and inaccurate mode in which the par of exchange has been fixed, as well as the unfoundness of the principle, which would infer an equality of value in the coins of two countries from the circumstance of their containing the same quantity of the precious metals, will be further confirmed and illustrated by a reference to the coinage of France before the revolution. At that time a duty, or seignorage of eight *per cent.* was paid on all bullion brought to the mint for the purpose of being coined. Let us suppose that a Louis d'or, and an English guinea, contained each the same quantity of gold, of the same purity, and that that quantity was a quarter of an ounce, according to the principle that we are examining, the exchange between England and France would be said to be at par, when a guinea in London purchased a bill on Paris for one Louis d'or, since, in this case, a quarter of an ounce of gold in London purchased neither more nor less than a quarter of an ounce of gold in Paris. But a little reflection will serve to convince us, that when a guinea in London purchased a bill for a Louis in Paris, the exchange, instead of being at par, was in fact favourable to England eight *per cent.*: for, let us suppose that the merchant who had to pay the Louis in Paris could not obtain a bill in London, but was obliged to send bullion to Paris to discharge his debt; how much bullion must he send for that purpose? if a quarter of an ounce of gold would serve to discharge his debt; then, on the supposition that he procured a bill, and paid for it only a guinea, or a quarter of an ounce of gold, the exchange would be at par; but he would find, if he sent only a quarter of an ounce of gold to Paris, that it would not discharge his debt of a Louis. When his gold is brought to Paris, it must either be coined, or sold, before the debt can be discharged: if it is taken to the mint, eight *per cent.* will be kept to pay the expences of coinage; consequently, when converted into money, it will not discharge his debt by eight *per cent.*: if the gold is sold, it will not procure a Louis, or a coin of a quarter of an ounce of the same metal, by eight *per cent.*; for no person will give the same weight of coined gold for uncoined gold, when the coinage cost eight *per cent.* The merchant in London, therefore, who has a Louis to pay in Paris, must pay for a bill to that amount the quantity of bullion contained in a Louis, and

PAR OF EXCHANGE.

eight *per cent.* more; or, in other words, he must pay a guinea, and eight *per cent.* more; and by purchasing a bill on Paris at this rate, he loses nothing, nor does the person who sells the bill gain any thing by the transaction; for let us suppose that he can find no merchant to take his bill, but is obliged to get the money due to him in Paris, or in the best manner he is able: with the Louis due to him there, he purchases bullion; and as coined gold is eight *per cent.* more valuable in Paris than uncoined, he gets for his Louis, (all along supposed to weigh an ounce,) an ounce and one-eighth of uncoined gold, which, when brought to England and taken to the mint, will procure him a guinea, and one-eighth *per cent.* On the suppositions, therefore, which we have proceeded upon, that a guinea and a Louis contained the same quantity of gold, and that the duty on coinage in France was eight *per cent.*, the par of exchange between England and France would not be a guinea for a Louis, but a guinea and one-eighth *per cent.* for a Louis; or, in other words, a bill for an ounce of coined gold in Paris, would be worth in London an ounce of gold, and one-eighth *per cent.* Hence it is obvious, that the par of exchange ought not to be fixed by a reference merely to the quantity of the precious metals contained in the coins of two countries; and that the exchange between any two countries is actually at par, when no more is paid for a bill on one of these countries, than would be necessary to procure the bullion that could be sold for, or coined into the sum expressed in the bill, though the sum paid, and the bullion it could procure, were really greater than the sum expressed in the bill.

There is yet another case, which will require to be considered, before we proceed to state and examine those circumstances which affect the nominal and real par of exchange. The currency of almost all countries consists of two different kinds of metals, gold and silver, (for copper, though forming part of the currency, need not enter into our investigation.) The gold and silver currency of all countries is fixed by the proportionate value of these two metals: let us suppose the proportionate value of gold and silver to be as 1 to 15, *i. e.* that one ounce of gold is worth fifteen ounces of silver. There may be some little difference in this proportionate value in different countries; but the great bullion market of the world keeps it nearly the same, and generally pretty steady. What would be the effect on the par of exchange, on the supposition, that in one of two countries which trade with each other, the proportionate value changed; let us suppose, for instance, that in England the proportionate value continued as stated above, 1 to 15, while in France silver became so much more abundant, that the proportionate value was 1 to 16. Would the par of exchange be affected by this circumstance? and if it were affected, in what mode, and to what extent would it be affected? In the case supposed, the price of silver would fall in France while it continued steady in England; or, in other words, if we suppose no duty on coinage to exist in either of these countries, the bullion price of silver in France would fall below its mint price, and silver bullion would exchange for less gold bullion than it did before; but the proportionate value between coined gold and silver would remain the same. It might, at first sight, appear, that a merchant in London, who had a debt to discharge in Paris, would be benefited by this circumstance; as, it may be said, he might transmit gold bullion, which, in Paris, would command a larger quantity of silver than formerly: undoubtedly this would be the case, for every ounce of gold transmitted to Paris, he would get sixteen ounces of silver instead of fifteen, as formerly; and if his object were to bring

this silver to England, and there exchange it for gold, he would profit by the alteration in the proportionate value of the two metals, since in England he would obtain an ounce of gold for fifteen ounces of silver, and thus have a profit of one ounce of silver in the transaction; but in the case here supposed, that he has a debt to discharge in Paris, he would not be benefited by the alteration in the proportionate value of the two metals, unless he took the sixteen ounces of silver to the mint, for if he sold the silver bullion, he would get as much less for it as its value had fallen in proportion to gold: if, however, he took sixteen ounces, instead of fifteen, to the mint, it is obvious that he would get more silver coin, and consequently that his ounce of gold, by this variation in the proportionate value of the two metals, would enable him to discharge his debt on easier terms, provided it could be discharged in silver. But if the amount of the debt were very great, payment of it in silver could not legally be enforced. This circumstance, joined to the consideration that the proportionate value of the gold and silver currency of any country must always be kept as nearly as possible the same as the proportionate value of gold and silver bullion in that country, will always prevent the par of exchange being much, or for any length of time, affected by a change in the relative value of gold and silver in any two countries. On the contrary supposition, that gold falls and silver rises, so that, for instance, one ounce of the former metal is worth only fourteen ounces of the latter, it is obvious that the comparatively greater expence of the freight of silver will prevent a merchant from taking advantage of this circumstance, and consequently will keep it from having any material influence on the exchange.

In treating on this subject, it is of the utmost importance to distinguish accurately and clearly between the nominal and the real par of exchange: they are often confounded both in theoretical and practical writings. The cause of this confusion will be best explained by a consideration of the circumstances that affect the nominal par of exchange as separate and distinct from those circumstances which affect the real par of exchange. The most obvious circumstance that has influence on the nominal par of exchange, is the depreciation of the currency of a country, or a diminution of its real and intrinsic value; as the denomination of the currency continues the same, though its real and intrinsic value is lessened, the par of exchange will also continue the same. Thus, let us suppose, that when the par between Russia and England was fixed, the ruble of the former country, and the half-crown of the latter country, each contained exactly the same quantity of silver, of the same purity, and that that quantity was half an ounce. When, therefore, a ruble, exchanged for half a crown, the exchange was at par: let us now suppose, that the ruble of Russia, though still retaining that denomination, no longer contains half an ounce of silver, but only a quarter of an ounce of that metal. In this case it will not exchange for half a crown, or thirty pence, but only for half that sum, or fifteen pence; but the par between the two countries being still considered as fixed at thirty pence the ruble, the rate of exchange will appear to be very much against Russia, when the ruble is quoted as only worth fifteen pence, whereas, in fact, when the ruble will purchase a bill on England for fifteen pence, it purchases its full value: all this is very clear and obvious; but the mode in which this difference in the power of the ruble over British currency takes place, requires some illustration; and this illustration will confirm the position we laid down, that in considering the par of exchange between the two countries, we ought to look beyond the quantity of the precious metals contained in the coins of these countries

PAR OF EXCHANGE.

to the power of the metals over these coins, when sold for them. Instead of supposing that the ruble was all at once lowered so much, as to contain only a quarter of an ounce of silver, instead of half an ounce, let us suppose that the diminution in the quantity of silver contained in this coin was very trifling, and did not produce a correspondent rise in the nominal price of silver or bullion; or, in other words, that a ruble, though less by one, two, or three *per cent.* than half an ounce of silver, still would purchase half an ounce of silver bullion. In this case, would the nominal par of exchange between England and Russia be changed? We apprehend not; and for this reason, if a merchant in London, who wished to purchase a bill on Petersburg, refused to give at the rate of half a crown a ruble, on the ground that the ruble no longer contained the same quantity of silver as half a crown, that is, half an ounce, and not being able to obtain the bill on lower terms, determined to transmit bullion, he would soon be convinced, that to discharge his debt, he must pay as much as if he had bought the bill at the rate of half a crown the ruble; for, on the supposition made, that the nominal price of silver in Petersburg had not risen in proportion to the debasement of the ruble, but that this coin, though containing one, two, or three *per cent.* less silver, still purchased as much silver bullion, he would be obliged to transmit as many half ounces of silver as he had rubles to pay, and consequently it would have been more advantageous for him to have purchased the bill on Petersburg, at the rate of half a crown the ruble.

Thus, we perceive, that unless the power of the coin of any country over bullion is diminished, the mere circumstance of the diminution of the intrinsic value of that coin will not affect its exchangeable value, with the unaltered coin of another country, for so long as it can purchase the same quantity of bullion as formerly, it will exchange on equal terms with the same foreign coin as formerly. It may, indeed, be objected, that the coined precious metals will always purchase, neither more nor less, than the same quantity of the uncoined metal, which they respectively contain; and consequently, if they contain less than formerly, they will purchase less than formerly: but this, though undoubtedly true in general, is not true universally. Where confidence and credit are great in any country, and where the coin has its intrinsic value slowly and gradually diminished, merely by the circumstance of its being worn, the nominal value of bullion will not always correspond with the actual depreciation in the value of the coin. Indeed, setting aside the consideration of confidence and credit, there is a great difference between coin worn by use, and coin reduced in the same degree, when it first comes from the mint: in the latter case, no person in possession of bullion will sell it for the same number of coined pieces of gold or silver, as he did before their debasement, because, by taking his bullion to the mint, he can get a greater number of coined pieces out of it; he will, therefore, no longer sell his silver at five shillings *per ounce*, if these five shillings contain only half an ounce of silver, because at the mint he can get his ounce of silver coined into ten shillings; this price, therefore, he will ask for his silver *per ounce*; and, as has been often remarked, if the price of bullion rises in nominal value, the nominal rate of exchange will rise in the same proportion; so that a foreign coin, containing an ounce of silver, will exchange for ten shillings, instead of five, and thus the exchange will appear to be unfavourable, when, in fact, it is not so, no more being given for the foreign coin than would be necessary to purchase the silver that would sell for it. But it is different, when the coin of a country has undergone a slow and gradual diminution by wear;

in this case, if the bullion merchant refuses to sell his bullion at the old price, what alternative has he: he refuses, for instance, to take five worn shillings for an ounce of silver: but if he carries his ounce of silver to the mint, he gets from it, when coined, only five shillings, which, in the purchase of commodities, are of no more value than the five worn shillings that he refused for his ounce of bullion. In this case, the rate of exchange cannot be even nominally altered; since the coin, though worn, will still sell for as much bullion as formerly, and consequently a debt to be paid in that coin will require as much bullion to discharge it as formerly.

Hitherto we have confined our remarks and illustrations entirely to those cases, in which the metallic currency of a country is supposed to be debased or worn; we shall now examine what effect on the par of exchange will be produced by a paper currency. So long as this paper currency is not depreciated, the nominal par of exchange will be precisely the same as the real one: this position will easily be made out. Let us suppose, as formerly, that the ruble of Russia is the par of the half-crown of England; and that in the former country a paper currency is issued, and that paper rubles circulate as well as metallic ones: so long as these paper rubles are equivalent to the metallic ones, so long will the real and nominal par of exchange be precisely the same. For, as we have already explained, the metallic ruble of Russia is deemed the par of the half crown of England, not (strictly speaking) because each coin contains the same quantity of silver of the same standard, but because the one coin will purchase as much silver, as if sold, or coined, will be equivalent to the other coin; while, therefore, the paper ruble will exchange for the silver ruble, it must have the same command over silver bullion as the silver ruble, and consequently must indirectly have the same command over the half-crown of England. Let us now suppose that the paper currency of Russia is depreciated, from whatever cause: and that, in consequence of this depreciation, a paper ruble will no longer exchange for a silver ruble, nor purchase the quantity of silver bullion contained in a silver ruble. In this case the nominal par of exchange will no longer coincide with the real par of exchange, but will rise above it in the same ratio precisely as the paper ruble has fallen in value below the metallic ruble: if it require a paper ruble, and one-tenth of a ruble, to purchase the silver contained in a silver ruble, or if a silver ruble, by the depreciation of paper currency, become equivalent to one paper ruble, and one-tenth of a paper ruble, then the real par between England and Russia will be a half-crown of the former country for a paper ruble and one-tenth of a paper ruble of the latter country. This will be the real par of exchange; but as the par is still supposed to continue as it was, that is, a half-crown of England for a ruble of Russia, the exchange will appear to be conformable to Russia, when in fact it is at par.

From these remarks and illustrations, it is sufficiently evident, that the real par of exchange between two countries must be ascertained by the following process: the object of the merchant who has a debt to discharge in a foreign country, is to pay no more, in his own country, for the means of discharging that debt, than it would cost him to effect it in the foreign country. If he were obliged to pay the debt in the foreign country, he must of course procure the coin of that country; and, therefore, for the purpose of discharging it in his own country, he must consent to give as much as would be necessary to procure the sum which he owes. If, in the foreign country, the precious metals in bullion and in coin are exactly of the same value, he could discharge his debt there by transmitting the precise quantity of bullion contained in the sum he owed; but if, as was the case in

PAR OF EXCHANGE.

France before the revolution, the precious metals in bullion were not equivalent to the precious metals when coined, he would be obliged to transmit as much more bullion as was necessary to make them equivalent, and consequently, if in his own country he paid no more than the price of this bullion for a bill to discharge his foreign debt, he, in fact, bought his bill at par. The same general illustration might be pursued with respect to a bill bought with a depreciated paper currency; if no more were given for the bill, than would have been sufficient to have purchased the bullion necessary to discharge the debt; the bill, in this case, was bought at par, though nominally much more was given for it.

There is only one other case, in which the nominal and real rate of exchange can differ, and this case is thus explained by Smith in his *Wealth of Nations*: we shall give his explanation, and then offer some remarks on it, as at first sight the fact which it unfolds may seem to militate against the doctrine we have laid down on this subject.

“In some places, as at Amsterdam, Hamburg, Venice, &c. foreign bills of exchange are paid in what they call bank money; while in others, as at London, Lisbon, Antwerp, Leghorn, &c. they are paid in the common currency of the country. What is called bank money is always of more value than the same nominal sum of common currency. A thousand guilders, of the bank of Amsterdam, for example, are of more value, than a thousand guilders of the bank of Amsterdam currency. The difference between them is called the *agio* of the bank, which at Amsterdam is generally about five *per cent.* Supposing the current money of the two countries equally near to the standard of their respective mints, and that the one pays foreign bills in this common currency, while the other pays them in bank money, it is evident that the computed exchange may be in favour of that which pays in bank money, though the real exchange should be in favour of that which pays in current money; for the same reason that the computed exchange may be in favour of that which pays in better money, or in money nearer to its own standard, though the real exchange should be in favour of that which pays in worse. The computed exchange before the late reformation of the gold coin, was generally against London with Amsterdam, Hamburg, Venice, and, I believe, with all other places which pay in what is called bank money. It will by no means follow, however, that the real exchange was against it. Since the reformation of the gold coin, it has been in favour of London, even with those places. The computed exchange has generally been in favour of London, with Lisbon, Antwerp, Leghorn, and if you except France, I believe with most other parts of Europe that pay in common currency, and it is not improbable that the real exchange was so too.”

The cause of this difference between bank money and the common currency of Amsterdam, &c. is explained by Smith himself, in his digression concerning banks of deposit. In Amsterdam, &c. the coin in circulation consisted of the currency of different countries; and consequently differed very much in its intrinsic value, and was also liable to great variations of value. Hence, even if there had been no banks of deposit, these various coins must have passed in exchange for bullion, not according to their denominative, but according to their real value, and, as we have already explained, the rate of exchange is fixed by the command which the respective currencies of two countries, that trade with each other, possess over bullion. This difference between the bullion and the mint value of the various coins circulated in Amsterdam, would be confirmed by the circumstance, that the bank of deposit, when a sum of money in these coins was paid into it, gave credit only for the actual quantity of

bullion which they contained. A merchant in London, therefore, who gave five *per cent.* above the nominal par for a bill on Amsterdam, to be paid in bank money, gave no more than the real value of the bullion which he was to receive, and consequently, in fact, bought his bill at par.

Having thus considered, at sufficient length, the different circumstances which affect the nominal rate of exchange, we shall now advert to those circumstances which have a tendency to raise or lower the rate of exchange, actually, above or below par.

Let us suppose that the merchants in London have bought goods in Paris to the amount of 2000 Louis d'ors; while other merchants in London have sold goods in Paris to the same amount: the latter draw bills for that sum, and the former become purchasers of these bills. At what rate will these bills be purchased? Undoubtedly at the real par of exchange, whatever that may be, since the supply and demand are exactly equal. If, therefore, the par of exchange be a guinea for a Louis, the merchants who have drawn bills upon Paris to the amount of 2000 Louis, will receive for them 2000 guineas; and thus each party will be accommodated, and save the expence of freight and insurance in transmitting or receiving what they owe, or what is owing to them. Let us now suppose that the bills in London on Paris are still for 2000 Louis, but that, owing to the London merchants having purchased fewer goods in Paris, there is a demand for bills on Paris only to the amount of 1500 Louis: in this case it is evident that the price of bills on Paris will fall, as the proportion between the demand and the supply is altered; the supply is the same, but the demand is become less; hence a bill on Paris for a certain number of Louis, will no longer command in the London market the same number of guineas; that is, it will no longer be sold at par; but at two, three, or five *per cent.* below par. In this case the exchange is said to be unfavourable to France, because French money in the London market, or what is the same thing, a bill for French money, will no longer bring its real and intrinsic value. On the other hand, let us suppose the amount of the bills in London on Paris to be still 2000 Louis, but the demand for these bills increased from 2000 to 2500 Louis; on this supposition it is equally plain that the exchange between London and Paris will rise above par; or, in other words, that for a bill for a certain number of Louis, more than the same number of guineas will be paid. In this case the exchange is said to be favourable to Paris, and unfavourable to London, because for French money, or a bill for French money in London, more than its equivalent in British money is paid.

There are several points to be investigated, connected with a *real* variation in the rate of exchange between two countries; in the first place, to what amount can the exchange become unfavourable to any country; in the second place, what effects does a favourable or unfavourable exchange produce on the commercial transactions of two countries; thirdly, by what process is the exchange, when it varies from the real par, brought back to that par; and, lastly, can the exchange between any given country, and all the other countries with which it trades, be, on an average, for any length of time, either above or below the real par.

In the first place, to what amount can the exchange become really unfavourable to any country? Let us suppose that a merchant in London wishes to purchase a bill on Paris for 500 Louis, but that owing to the small supply of such bills, or the great demand for them, he finds he must pay for it ten *per cent.* above par. He will, before he agrees to these terms, enquire whether he cannot discharge his debt in Paris at a cheaper rate; the most obvious and simple mode is by the purchase and transmission of bullion; and if he finds that

PAR OF EXCHANGE.

he can purchase bullion at the mint price, and can send it over to Paris at a cheaper rate than ten *per cent.*, he will naturally prefer this mode of settling his debt, to giving such a high premium for a bill on Paris. In fact, therefore, the exchange can never become unfavourable to any country, to a greater amount *per cent.* than will pay for the transmission of bullion: it may, indeed, be alleged that where the price of bullion has risen, the exchange may become unfavourable to the amount of that rise, added to the amount of the charges of transmission; but from what has been already said respecting the nominal rate of exchange, it will be sufficiently apparent, that the rate *per cent.* above the computed par, which is paid for a bill, must not be considered as indicating or measuring a really unfavourable exchange, but that this must be considered as indicated and measured solely by the amount of the sum paid for the bill above the price of the bullion which it would purchase. It is not easy to fix the rate *per cent.* which the transmission of bullion to any particular country would cost; it must vary from the different causes. In the circumstances of Europe, since the French revolutionary wars, the difficulty and risk of transmitting bullion to any part of the continent, subject or exposed to the French arms, must have been greatly increased; and consequently, from this cause, independently of the operation of other causes affecting the nominal rate of exchange, the real rate of exchange between Great Britain and the continent may have become unfavourable to a greater degree than it would otherwise have been.

In the second place, what effects does a favourable or unfavourable exchange produce on the commercial transactions of two countries trading with each other? It is abundantly clear and evident, that if the exchange between England and France is unfavourable to the former country, she must pay a higher price for all the commodities she imports from France. The British merchant indeed purchases them in France at the same rate as formerly: he gives, we will suppose, ten Louis for a pipe of wine; but let us consider what in fact he will pay for this wine, when the exchange is at par, and when it is unfavourable to England. In the former case, he will pay for a bill for ten Louis, exactly ten guineas (on the supposition that a guinea and a Louis form the *real par*), while, in the latter case, he must pay for a bill for ten Louis, ten guineas, and one, two, or three *per cent.* more, according as the exchange is more or less unfavourable to England; consequently, though he purchases the wine at the same rate in Paris, it costs him more in London, French money, or a bill for French money, being there worth more than its real and intrinsic value; or, in other words, the demand for these bills being greater, or the supply of them less, than formerly.—Let us now reverse the case, and suppose that the exchange is favourable to England; that in the London market there are more bills than formerly on Paris, while the demand for them is the same; under these circumstances, bills on Paris may be purchased under par; and consequently the price of wine still continuing the same in that city, the English merchant, by purchasing bills under par, will in reality purchase it at a cheaper rate. The general conclusion is, that when the exchange between London and Paris is favourable to the former city, *i. e.* when a certain sum of English money is worth more than its *par*, in the purchase of bills on Paris, then, in this case, French goods may be brought into England at a cheaper rate; whereas, if bills in London on Paris are above par, or in other words, if the exchange is unfavourable to England, so that for a bill for a certain sum on Paris, more than its *par* in English money is given, then, in this case, French goods will be bought at a dearer rate.

We are now, in the third place, to examine by what process the exchange, when it varies from the real par, is brought back to it: what we have unfolded and illustrated under the second head, will, in some degree, explain this process. Let us suppose that the exchange between London and Paris is unfavourable to the former place one, two, or three *per cent.*, or that one, two, or three *per cent.* must be given in London, as a premium for a bill on Paris. It is abundantly evident that in this case, the supply of bills is not equal to the demand; this is indicated by the rise in the price of them above par; but it is well known, what takes place when the demand for any commodity, becoming greater than the supply of it, raises its price: capital and industry are withdrawn from other sources of employment, and directed to the commodity, of which there is an inadequate supply. The same will take place with respect to bills of exchange; as it has become a profitable concern to deal in them, more of them will be brought into the market, but it is evident that no man can draw a bill of exchange, unless he has property or credit in the country on which the bill is drawn. Bullion, therefore, or goods, will be sent into France from England, when bills on France bear a premium in England; and though they sell in the former country for no more than they would have done when the exchange was at par, yet as a bill for the sum at which they are sold bears a premium, that premium secures a profit to the exporter of the bullion or merchandise. By this exportation more bills on France are presented in the London market, and the price of them is reduced, till it reaches par. On the other hand, let us suppose that there are more bills on France in the London market than there is a demand for; or, in other words, that the exchange is favourable to London; in this case, by what process will the exchange be brought to par? The quick-sighted interest of commercial men will soon effect this: in the first place, the English merchant, finding that his bills are at a discount, will lessen his exports to France; and in the second place, as has been already stated and explained, the low price of bills on France will act as a motive to the importation of more French commodities, which, of course, will create a demand for more bills, and thus bring the exchange back to par.

Hitherto we have considered the unfavourable exchange, or (to speak more correctly) the exchange, when either above or below par, as brought back to par, solely by the transactions of merchants, and by the actual transmission of commodities; but perhaps it is more frequently brought back to par by other means. There are, in all commercial countries, merchants who deal principally in bullion and bills of exchange: a correspondence is kept up among these merchants; and they accommodate and benefit each other, according as the rate of exchange rises or falls in their respective countries. Thus, let us suppose that two merchants, one in Paris and the other in London, have entered into a correspondence of this nature; and that in London, bills on Paris bear a large premium. In this case, the London merchant draws bills on his Paris correspondent, which are duly honoured; and the latter divides the premium or profit on them with the former. If, on the contrary, bills in Paris on London bear a premium, the Paris merchant draws on his London correspondent, who in his turn duly honours them, and divides the profit. Thus it is evident, that an unfavourable exchange may be brought back to par, without the transmission of bullion or goods, and solely, as we observed, by credit: but it is also evident, that if the exchange continues unfavourable to England, for example,

for

for a considerable length of time, the kind of transaction we have been describing cannot go on, without the transmission of bullion or commodities.

There is another mode by which, when the exchange deviates from par, it is brought back to it. Let us suppose that bills in London on Paris bear a high premium, and that bills in America on Paris are at a considerable discount. In this case, bills, like all other commodities under similar circumstances, will leave the place where they are cheap, and seek the place where they are dear; or, in other words, the American merchant will bring his bill on Paris to the London market. He will be the more induced to do this, if, in addition to the circumstances that bills on Paris are cheap in America and dear in London, it should happen that bills in America on London are dear; and this was exactly the case during the earlier years of the second French revolutionary war. England imported more from France than she exported to it; America exported more to France than she imported from it, and imported more from England than she exported to it: the consequence was, that in London bills on Paris bore a premium, while bills on Paris in America were at a discount, and bills in America on London at a premium. Under these circumstances, let us suppose an American merchant who had imported goods from England: he wishes to purchase a bill in America on England, to pay for these goods; but he finds that for it he must pay a premium, while, at the same time, bills in America on Paris are at a discount: he therefore purchases a bill on Paris, instead of a bill on England; and this bill, which he purchases at a discount in America, he sells at a premium in London; thus discharging his English debt for less than its real value; whereas, if he had discharged it by purchasing in America a bill on England, he must have discharged it for more than its real value. Let us now consider the effect of this transaction on the rate of exchange in America and England. In the former country, the exchange with England was unfavourable, or, in other words, there was a greater demand for bills than could be supplied; consequently they were at a premium, or the exchange was below par: but the American merchant, by purchasing a bill on Paris, instead of a bill on England, lessens the demand, and thus brings the exchange nearer to par. By the same operation, he increases the demand for bills on Paris, which before were in too large a supply, and consequently at a discount; or, in other words, the exchange between America and Paris was above par, or favourable to the former. Thus we perceive that in America, by a very simple process, a process to which interest will always be a sufficient motive and guide, the rate of exchange with two distinct countries is brought back to par. Let us now follow the effects of the same transaction in England: the American merchant pays his English debts with a bill on Paris, and consequently, by increasing the supply of these bills, reduces the premium on them; or, in other words, reduces the exchange between England and France nearer to par.

The concluding inquiry is, whether the exchange between any given country, and all the other countries with which it trades, can, on an average, for any length of time, be above or below the real par? This question is one of more importance than difficulty; and we shall probably arrive at its true and satisfactory solution, by the following considerations.

In the first place, it has been abundantly shewn, that the interest of the merchant prompts him to take advantage, either of a favourable or unfavourable rate of exchange, in such a manner as most certainly, and in no long space of

time, to reduce it to par. If it were, therefore, even possible for any nation to have an unfavourable rate of exchange with all the other nations with which it trades, this would soon be rectified by the commercial transactions of its merchants.

But in the second place, such an event could not take place at all, even for the shortest space of time: for let us consider what it implies, and would produce. It implies that the nation, supposed to be so circumstanced, purchases more commodities than it sells. Let us even for a moment suppose this to be the case: the overplus of its purchases must be paid for; but by the hypothesis, only its bullion and coin can be employed for that purpose; and if they are exported, commodities must become cheap; if commodities become cheap, buyers will flock into it; or, in other words, its exports will increase, and consequently the rate of exchange will be restored to par, or perhaps raised above it.

In the whole of this discussion, and in most discussions on the par of exchange, it is supposed to be affected only when the trade between any two countries is not balanced or equal; that is to say, when one country imports more commodities from the other country than it exports to it. But there are several other circumstances which affect the par of exchange, though it was not necessary, in discussion, and explaining the general principles of this subject, to enter upon them: the most material and common of them may, however, be noticed.

In the first place, besides the merchants who require bills on any particular country, to pay for the commodities they may have purchased there, government has frequently occasion for these bills, for the purposes of subsidy, civil and military expenditure, &c. The history of the present and of the last war affords many striking instances of this fact, and of the consequences produced on the rate of exchange, by the increased demand for foreign bills on the part of government.

In the second place, all persons who are leaving the country to settle abroad, or who have money to transmit abroad, though not for mercantile purposes, naturally prefer purchasing bills of exchange; and consequently, from this cause, the rate of exchange is affected.

Lastly, another source of demand for bills of exchange arises in England from the dividends on the stock held by foreigners, as these dividends are usually transmitted by means of bills of exchange.

When, therefore, the rate of exchange is unfavourable to a country, it by no means follows that that country is importing goods to a greater amount than it exports. If bills of exchange were sought after, and employed solely to pay for goods imported, this would be a legitimate inference; but as they are employed for other purposes, such a conclusion is erroneous.

We have thus endeavoured to illustrate the doctrine of commercial exchanges, on the general principles of political economy; and if, in some parts of this article, we may seem to have been too minute, and to have descended to details too familiar, our apology must be derived from the anxiety we felt not to leave obscure any part of the subject, and from our conviction that political economy, more than any other science, requires ample and familiar illustration.

PAR, in *Geography*, a river of Bavaria, which runs into the Danube, four miles below Ingoldstadt.

PAR *Vagum*, in *Anatomy*, the eighth pair of nerves. See *NERVOUS System*.

PARA, in *Commerce*, a small Turkey coin, 40 of which are equal to a piastre, and contains three aspers.

PARA,

PARA, *Grand Para*, in *Geography*, the most northern of the colonies or governments of Brasil, in South America. This government comprehends that part of Guiana which belongs to the Portuguese, on the north side of the river Amazons, extending from the union of the river Madeira to the Atlantic, about 600 miles from east to west, and 200 from north to south. It produces abundance of cotton, sugar, vanilla, chocolate, coffee: a fleet laden with these articles has usually sailed every year for Lisbon. The climate is extremely hot; and the woods abound with valuable timber of great solidity and brilliant colours, and some trees that yield odorous balsams. (See **BALSAM**.) The capital Para, situated at the mouth of the great river Tocantin, which receives that called dos Bocas, into which a natural canal from the Maranon (called Tagipuru) has been opened by the violent tides. This is a rich and handsome town, with two parish churches, and a college. Besides a citadel, it has a fortress, with a strong train of artillery, and a garrison of four companies. S. lat. $1^{\circ} 45'$. W. long. 50° .

PARA, a large river of Brasil, formed by the union of the Tocantin and the Guanapa, which runs about 120 miles in a north-easterly direction, separating the island of Marajo from the continent, and discharging itself into the Atlantic, about 20 miles S. of the Line.—Also, a river of Brasil, which rises about 150 miles W. of Villarica, and runs into the S. Francisco, S. lat. $16^{\circ} 50'$.—Also, a town of Turkish Armenia; 90 miles N.N.E. of Cars.

PARA Hotun, a town of Chinese Tartary, on the river Kerlon. N. lat. $48^{\circ} 6'$. E. long. $113^{\circ} 14'$.

PARA, in *Mythology*, is the name of the Hindoo goddess Parvati, in her character of *Prakriti*; which see. It means first, or greatest.

PARABITTA, in *Geography*, a town of Naples, in the province of Otranto; 10 miles N.W. of Alessano.

PARABLE, παραβολη, formed from παραβαλλειν, to oppose, or compare, a fable, or allegorical instruction, founded on something real, or apparent, in nature, or history; from which a moral is drawn, by comparing it with some other thing, wherein the people are more immediately concerned. (See **ALEGORY**.) Or, it is that figure of sentences, which illustrates a thing by comparing it with some other, to which it bears a resemblance.

Such are those parables of the ten virgins, of Dives and Lazarus, of the prodigal son, &c. in the New Testament.

Aristotle defines parable, a similitude drawn from form to form. Cicero calls it a collation, others a simile. F. de Colonia calls it a rational fable.

The Hebrews call it חש"ב, from a word which signifies either to predominate, or to assimilate: the Proverbs of Solomon are by them also called חש"ב, parables, or proverbs.

Glossius defines parable a simile, by which a fictitious thing is related as real, and compared with some spiritual thing, or accommodated to signify it.

Some make parable differ from fable; Grotius and others use the two terms promiscuously. Kircher derives the use of parables from the Egyptians.

Parable, according to the eminently learned bishop Lowth, (Lectures on the Sacred Poetry of the Hebrews,) is that kind of allegory which consists of a continued narration of a fictitious event, applied by way of simile to the illustration of some important truth. The Greeks call these allegories αἰοι (or apologues,) the Latins fabulæ, or fables; and the writings of the Phrygian sage, or those composed in imitation of him, have acquired the greatest celebrity.

Nor has our Saviour himself disdained to adopt the same method of instruction, of whose parables it is doubtful, whether they excel most in wisdom and utility, or in sweetness, elegance, and perspicuity. As the appellation of parable has been applied to his discourses of this kind, the term is now restricted from its former extensive signification to a more confined sense. This species of composition occurs very frequently in the prophetic poetry, and particularly in that of Ezekiel. If to us they should sometimes appear obscure, we must remember, that in those early times, when the prophetic writings were indited, it was universally the mode throughout all the eastern nations, to convey sacred truths under mylterious figures and representations. In order to our forming a more certain judgment upon this subject, Dr. Lowth has briefly explained some of the primary qualities of the poetic parables; so that, by considering the general nature of them, we may decide more accurately on the merits of particular examples.

It is the first excellence of a parable to turn upon an image well known and applicable to the subject, the meaning of which is clear and definite; for this circumstance will give it perspicuity, which is essential to every species of allegory. If the parables of the sacred prophets are examined by this rule, they will not be found deficient. They are in general founded upon such imagery as is frequently used, and similarly applied by way of metaphor and comparison in the Hebrew poetry. Examples of this kind occur in the parable of the deceitful vineyard (Isa. v. 1—7.), and of the useless vine (Ezek. xv. and xix. 10—14.); for under this imagery the ungrateful people of God are more than once described. (See also Ezek. xix. 1—9. Ezek. xxxi. Ezek. xvi. and xxiii.) Moreover, the image must not only be apt and familiar; but it must be also elegant and beautiful in itself; since it is the purpose of a poetic parable, not only to explain more perfectly some proposition, but frequently to give it some animation and splendour. As the imagery from natural objects is in this respect superior to all others, the parables of the sacred poets consist chiefly of this kind of imagery. It is also essential to the elegance of a parable, that the imagery should not only be apt and beautiful, but that all its parts and appendages should be perspicuous and pertinent. Of all these excellencies, there cannot be more perfect examples than the parables that have been just specified: to which we may add the well-known parable of Nathan (2 Sam. xii. 1—4.) although written in prose, as well as that of Jotham (Jud. ix. 7—15.) which appears to be the most ancient extant, and approaches somewhat nearer to the poetical form. It is also the criterion of a parable, that it be consistent throughout, and that the literal be never confounded with the figurative sense: and in this respect it materially differs from that species of allegory, called the continued metaphor. (See Isaiah, v. 1—7.) It should be considered that the continued metaphor and the parable have a very different view. The sole intention of the former is to embellish a subject, to represent it more magnificently, or at the most to illustrate it; that, by describing it in more elevated language, it may strike the mind more forcibly; but the intent of the latter is to withdraw the truth for a moment from our sight, in order to conceal whatever it may contain ungraceful or disgusting, and to enable it secretly to insinuate itself, and obtain an ascendancy as it were by stealth. There is, however, a species of parable, the intent of which is only to illustrate the subject; such is that remarkable one of Ezekiel (chap. xxxi.), of the cedar of Lebanon; than which, if we consider the imagery itself,

PARABOLA.

itself, none was ever more apt or more beautiful: of the description and colouring, none was ever more elegant or splendid; in which, however, the poet has occasionally allowed himself to blend the figurative with the literal description, (see ver. 11, 14—17.): whether he has done this because the peculiar nature of this kind of parable required it, or whether his own fervid imagination alone, which disdained the stricter rules of composition, was his guide, our learned author can scarcely presume to determine.

In the New Testament, the word parable is used variously. In Luke, iv. 23. for a proverb, or adage: in Matt. xv. 15. for a thing darkly and figuratively expressed: in Heb. ix. 9, &c. for a type: in Luke, xiv. 7, &c. for a special instruction: Matt. xxiv. 32. for a similitude or comparison.

Parables, or similitudes, are of two sorts, simple and compound. Those are called simple, in which one thing only is likened or compared to another in this manner: as swallows appear in summer, but in winter retreat; so false friends shew themselves in prosperity, but fly all away, when adversity approaches. Compound similitudes are such wherein one thing is likened or compared to several others, as thus: what light is to the world, physic to the sick, water to the thirsty, and rest to the weary; that is knowledge to the mind. The more exact the agreement is between the things compared, they give the greater beauty and grace to the figure. Ward's Orat. vol. ii. p. 76.

PARABOLA, in *Geometry*, is a curve line made by the common intersection of a conic surface and a plane which cuts it, and is parallel to another plane that touches the same conic surface.

A conic section made by a plane ever so little inclined to the parabola on the one side, is an ellipse; and a section made by a plane inclined ever so little on the other side, is an hyperbola: thus the parabola is the limit between these two curves, to which they both continually approach, while their transverse axes increase more and more; being, as it were, the passage from one of them to the other.

While all the planets move round the sun in orbits of a small, or a moderate degree of excentricity, the comets describe ellipses so astonishingly excentric, that they cannot be distinguished from parabolas during the short time those bodies continue visible.

If a heavy body be projected from the earth's surface, and if we abstract from the resistance of the air, and suppose gravity to act in parallel directions, the path described by the projectile will be a parabola.

Again, if we wish to collect parallel rays of light in a single point by reflecting them from a curve surface; we must employ for this purpose the concave curve generated by the revolution of a parabola about its axis, which will reflect all the parallel rays incident upon it to the focus of the generating parabola.

On all these accounts the parabola merits much attention. We have already treated of it along with the other conic sections; and it only remains that we add here those properties deserving notice which are peculiar to this curve.

PROP. I. Ordinates drawn to two diameters of a parabola from one another's vertices, will cut off equal abscissas. See *Plate of Conics*, (*Parabola*), *fig. 1.*

Let A E be an ordinate to the diameter whose vertex is B, and B D an ordinate to the diameter whose vertex is A: then the abscissas A D and B E will be equal. Draw the tangents A F and B F meeting in F; join A B; draw F K, cutting the curve in H, parallel to A D and B E; also draw H M and K N parallel to B D.

Then (Cor. 31. CONICS)

$$H M^2 : B D^2 :: A M : A D;$$

but on account of the similar triangles K A N, B A D,

$$K N^2, \text{ or } H M^2 : B D^2 :: A N^2 : A D^2;$$

therefore (11. 5. E.)

$$A M : A D :: A N^2 : A D^2;$$

consequently A D is a third proportional to A M and A N; or to F H and H K.

And in like manner it may be shewn that B E is a third proportional to F H and F K;

$$\text{therefore } A D = B E.$$

PROP. II. The part of the diameter of a parabola intercepted between an ordinate (*fig. 2.*), and a tangent drawn from the same point in the curve, is bisected in the vertex of the diameter.

Let the ordinate M A, and the tangent M D, meet the diameter, whose vertex is V: then A V = D V. Draw V L parallel to M D to meet the diameter passing through M: then V L will be an ordinate of that diameter (19. CONICS); therefore (1) M L = D V = V A.

PROP. III. A diameter of a parabola drawn through the intersection of two tangents will bisect the chord that joins the two points of contact.

Let T P and T Q (*fig. 3.*) be two tangents of a parabola; then T K, a diameter drawn through their intersection, will bisect the line drawn between the points of contact. Let P M be an ordinate drawn to the diameter which passes through Q, and let P T meet the same diameter in L. Then (2) M Q = Q L: but T Q is parallel to P M (CONICS, 19.): therefore also P T = T L, and P K = K Q.

PROP. IV. A tangent of a parabola makes equal angles with a diameter and a straight line drawn from the point of contact to the focus.

Let M P (*fig. 4.*) touch a parabola in M, it will make equal angles with a diameter M K, and the line M F drawn to the focus from the point of contact. Let K G be the directrix of the parabola, M K perpendicular to K G, M Q perpendicular to the axis, and let the tangent meet the axis in P. Then (CONICS, Def. 24.) G V = V F; and (2) V P = V Q; therefore P F = G Q = M K = (CONICS, 43.) M F: therefore (5. 1. E.) the angle F M P = the angle F P M = the angle P M K.

PROP. V. A straight line drawn from the intersection of two tangents of a parabola to the focus, will bisect the angle contained by two lines drawn from the focus to the points of contact of the tangents.

Let T P and T Q (*fig. 5.*) be two tangents of a parabola, having its focus at F: then, having drawn T F, P F, Q F, the angle P F T will be equal to the angle T F Q. Draw P M and Q N perpendicular to the directrix, and join T M, T N. In the two triangles T P M, T P F, T P is common; P M is equal to P F (CONICS, 43.); and (4) the angle T P M is = the angle T P F: therefore (4. 1. E.) T M = T F, and the angle T M P = the angle T F P. In like manner, the two triangles Q T N, Q T F, have Q T common; Q N = Q F; and the angle T Q N = angle T Q F: therefore T N = T F, and the angle T F Q = T N Q. And because T M = T F, and T N = T F; therefore T M = T N, and the angle T M N = T N M (5. 1. E.) Now it was shewn that T F Q = T N Q = complement of T N M; and T F P = T M P

PARABOLA

$= T M P =$ complement of $T M N$; therefore $T F Q = T F P$.

Cor.—If a diameter, $O R$, be drawn through T , that diameter, and the line $T F$, will make equal angles with the tangents $T P$ and $T Q$. For the triangle $N T Q$, having been proved equal to the triangle $Q T F$; and the triangle $M P T$ equal to the triangle $F P T$; therefore $2 N T Q + 2 P T F + N T M =$ four right angles (*Cor.* 2. 15. 1. E.): but, $N T M$ being an isosceles triangle, $R O$, perpendicular to the base $M N$, will bisect the vertical angle $N T M$: therefore $2 N T Q + 2 P T F + 2 N T O =$ four right angles, consequently $N T Q + P T F + N T O =$ two right angles. But $N T Q + Q T R + N T O =$ two right angles: consequently $Q T R = P T F$, and $P T R = Q T F$.

Cor. 2.—If two tangents of a parabola (*fig.* 6.), drawn from the extremities of a chord passing through the focus, intersect in T ; then $T F$ is perpendicular to the chord $P Q$. For the angles $Q F T$ and $P F T$ being in all cases equal, they will become right angles when $Q F$ and $F P$ are in one straight line.

PROP. VI.—If from a point in a parabola there be drawn an ordinate to the axis, and likewise a perpendicular to the line touching the curve at that point, the part of the axis which those lines intercept will be equal to half the parameter of the axis.

Let $P M$ (*fig.* 7.) be an ordinate to the axis of a parabola, and $P N$ a perpendicular to the tangent $P Q$; then $M N = \frac{1}{2}$ parameter of the axis. For (*Def.* 20. CONICS) $P M^2 = V M \times \text{param.}$; but (*Cor.* 8. 6. E.) $P M^2 = Q M \times M N$ now $Q M = 2 V M$: therefore $P M^2 = 2 V M \times M N = V M \times \text{param.}$ Consequently $M N = \frac{1}{2}$ param.

PROP. VII.—If $M N$ (*fig.* 8.) be any chord drawn through the focus of a parabola, and $P Q$ likewise drawn through the focus be ordinately applied to the axis: then four times the rectangle $M F \times F N$ will be equal to the rectangle $M N \times P Q$.

Draw $M H$, $N K$ perpendicular to the axis, and $M L$, $N R$, $Q O$ perpendicular to the directrix: then the triangles $F M H$, $F N K$ are equiangular; consequently,

$$M F : F N :: F H : F K.$$

Now $G F = F Q = Q O$, $H G = L M = M F$, and $G K = N R = N F$; therefore, $F H = F Q - M F$; and $F K = N F - F Q$. Consequently, the proportion above will become

$$M F : F N :: F Q - M F : N F - F Q.$$

$$\text{Therefore } 2 M F \times F N = M N \times F Q;$$

$$\text{and } 4 M F \times F N = M N \times P Q.$$

PROP. VIII.—The square of the perpendicular drawn to a tangent of a parabola from the focus, is equal to a rectangle under one-fourth of the parameter of the axis, and the line drawn from the focus to the point of contact of the tangent.

Let $F P$ (*fig.* 9.) be drawn from the focus of a parabola, perpendicular to a tangent, and $M F$ to the point of contact. Then $F P^2 = M F \times F V$, $F V$ being one-fourth part the parameter of the axis. Let the tangent $M P$ meet the axis in R ; draw $M S$ an ordinate of the axis; join $P V$, and make $P G$ perpendicular to $M F$; draw $M O$ parallel to the axis. Then (4) the angle $O M P = F M P = F R P$; therefore $M F R$ is an isosceles triangle, and $F P$, a perpendicular from the vertex upon the base, will bisect the base $M R$: but $R S$ is also bisected in V (2): therefore $P V$ is parallel to $M S$ (2. 6. E.), perpendicular to the axis, and a tangent of the curve at V : therefore $P F$ will bisect the angle $M F V$ (5): hence it is plain, that the

VOL. XXVI.

right-angled triangles $P V G$ and $P F G$ are equal in all respects, and that $F G = F V$. Now $P F^2 = M F \times F G = M F \times F V$ (8. 6. E.).

Of the Description of a Parabola in Plano.—1. When the parameter of the axis is given, any number of points in the curve may be found as follows. Let $A B$ (*fig.* 10.) be the parameter; continue it indefinitely towards B , and draw a perpendicular from B , which prolong indefinitely; bisect $A B$ in C ; then if a series of points, 1, 2, 3, &c. be assumed on the same side of C with B , and from these points, as centres, circles be described through A , to cut the perpendicular in the points $N, N', N'', \&c.$ and the prolongation of $A B$, in $D, D', D'', \&c.$; the perpendiculars $B N, B N', B N'', \&c.$ will be the ordinates of the parabola that belong to the abscissas $B D, B D', B D'', \&c.$; which is manifest, since, from the nature of the circle, we have, $B N^2 = A B \times B D$; $B N'^2 = A B \times B D'$, &c. Hence, if we complete the parallelograms $B M, B M', B M'', \&c.$ the several points $M, M', M'', \&c.$ will be in the curve of the parabola.

2. When the directrix $A B$ (*fig.* 11.), and the focus are given, the curve may be described by finding points in the following manner. Through F draw $G P$ perpendicular to the directrix, then $G P$ will be the axis of the parabola: through any point P of the axis, draw $M m$ parallel to $A B$, and from the centre F , with the distance $G P$, describe a circle to intersect $M m$ in the points M and m ; then will M and m be points of the curve. (CONICS, 43.)

3. When the directrix and the focus are given (*fig.* 12.), the curve may be thus described by a continued motion. Let the ruler $E D H$ be so applied, that the edge $E D$ may be upon the directrix $A B$, and the edge $D H$, which is perpendicular to $E D$, on the same side of $A B$ with the focus F : take a thread or string, exactly equal in length to the part of the ruler $D H$, and fix one end of it in the focus F , and the other end to the extremity of the ruler H : then if a pencil is kept upon the edge $D H$, so as to stretch the thread tight, while the edge $E D$ is made to slide along the directrix, the pencil will describe a parabola. (CONICS, 43.)

But although the curve of a parabola cannot be constructed by very convenient or very simple means; yet it is expressed by an equation of a more simple form than any other curve. If we denote by y the ordinate which corresponds to the absciss x in a parabola, having p for the parameter of its axis; then the equation of the parabola will be $y^2 = p x$. This equation is less complicated than even that of the circle, which curve is on a footing in this respect with the ellipsis and hyperbola. If then the circle be admitted into elementary geometry, while the kindred curves of the conic sections are classed as a higher branch of that science; the reason of this preference of the circle in the construction of geometrical problems is to be sought for in the more easy and simple description of the curve, not in the nature of its equation. But this is a point so well discussed by the admirable sir Isaac Newton, in his "Arithmetica Universalis," when treating of the linear construction of equations, that we must refer our readers to that work.

Quadrature of the Parabola.—The quadrature of the parabola is a discovery that will always be interesting to geometers. It is still the most remarkable instance in the history of mathematical learning, of the exact equality of a curvilinear to a rectilinear space. We are indebted for it to Archimedes, the most inventive geometer of antiquity. The original work in which this discovery is contained, has happily been preserved; and it is the most curious monument extant of the power of inventive genius to employ in the search of truth means the most unconnected with the subject in con-

H h

templation,

templation, and the least likely to be successful. The treatise of Archimedes on the quadrature of the parabola consists of two parts: in the first part the author details the reasonings, founded on mechanical considerations, and the nature of the lever, by which his discovery was originally made: in the second part, he demonstrates the same thing more naturally from principles purely geometrical. The whole treatise is well worth the attention of mathematicians: but in this place we must confine ourselves to demonstrate concisely the discovery of Archimedes. This we shall do in a manner strictly rigorous, and not differing essentially from the mode of investigation traced out by the illustrious inventor.

We call equidistant parallel lines those that cut any straight line that crosses them into equal parts.

PROP. I. If a triangle ACB (*fig. 13.*) be inscribed in a segment of a parabola, by drawing a diameter DC to bisect the base; and if a polygon $AMCNB$ be likewise inscribed in the same segment by drawing four equidistant diameters which will divide the base into four equal parts; the excess of the polygon above the triangle will be one-fourth part of the triangle.

At A draw a tangent of the curve to meet the diameters EM and DC in H and K . Because AD is bisected in E , AC will be bisected in S ; therefore $HM = MS$ and $DC = CK$ (2). Therefore the triangle $AHS =$ twice the triangle $AMS =$ the triangle AMC ; but the triangle $AHM = \frac{1}{2}$ of the triangle ACK (19. 6. E.) $= \frac{1}{2}$ of the triangle ACD . For like reasons the triangle $CNB = \frac{1}{2}$ of the triangle CDB . Therefore the sum of the two triangles AMC and CNB , which is the excess of the polygon $AMCNB$ above the triangle ACB , is equal to one-fourth part of the triangle ACB .

PROP. II. If a triangle ACB (*fig. 14.*) be inscribed in a segment of a parabola by drawing a diameter AB to bisect the base of the segment; the excess of the segment above the triangle will be less than the triangle.

Because AB is ordinately applied to the diameter DC , therefore AB is parallel to FG , a tangent of the curve at C ; draw AF and BG parallel to CD : then these lines will be diameters, and the part of each above the vertex being without the curve, the parallelogram $AFGD$ will contain the segment of the parabola. Now the excess of the parallelogram above the triangle ACB , is exactly equal to the triangle; therefore the excess of the segment above the triangle is less than the triangle.

PROP. III. To investigate the area of a segment of a parabola.

Let ACB be a segment of a parabola, and let the triangle ACB (*fig. 16.*) be inscribed in it by drawing the diameter DC to bisect the base of the segment; the area of this triangle we shall denote by a .

Draw the diameters EN, FQ , to bisect the parts AD, BD ; by which means the base AB will be divided into 4, or 2^2 , equal parts, and a polygon $ANCQB$ will be inscribed in the segment, the excess of which polygon above the triangle ACB is equal to one-fourth part of the triangle (first prop.); consequently the area of the same polygon will be equal to

$$a + \frac{a}{4},$$

which space is less than the segment. Again, the excess of the segment ANC above the triangle ANC , is less than the triangle ANC (2d prop.); and the excess of the segment CQB above the triangle CQB , is less than the triangle CQB ; therefore the sum of these two excesses, which

is equal to the excess of the segment ACB above the polygon $ANCQB$, will be less than the sum of the two triangles ANC and CQB ; that is, it will be less than $\frac{a}{4}$ (first prop.) Hence the space

$$a + \frac{a}{4} + \frac{a}{4}$$

will be greater than the segment ACB .

And if we inscribe another polygon $AMNOCQRB$ in the segment, by drawing diameters to bisect the intervals between the diameters of the last polygon, so as to divide the base of the segment into 8, or 2^3 , equal parts; then the excess of this polygon above the last polygon will be equal to the sum of the triangles AMN, NOC, CQB, QRB ; but the sum of the triangles AMN and NOC is equal to one-fourth part of the triangle ANC ; and the sum of the triangles CQP and QRB is equal to one-fourth part of the triangle CQB (first prop.); therefore the excess above-mentioned is equal to one-fourth part of the sum of the triangles ANC and CQB ; that is, it is equal to $\frac{1}{4}$ of $\frac{a}{4}$; or to $\frac{a}{4^2}$. Therefore the area of the polygon formed by dividing the base into 8, or 2^3 , equal parts, will be equal to

$$a + \frac{a}{4} + \frac{a}{4^2};$$

which space is less than the segment ACB . Again, the excess of the segment ACB above the same polygon, is less than the sum of the triangles AMN, NOC, CPQ, QRB ; that is, it is less than $\frac{a}{4^2}$; therefore the space

$$a + \frac{a}{4} + \frac{a}{4^2} + \frac{a}{4^2}$$

is greater than the segment ACB .

In like manner, if we continue to inscribe new polygons in the segment, by drawing diameters which shall bisect the intervals between the diameters of the preceding polygons, after n bisections, which will divide the base of the segment into 2^n equal parts, we shall come to an inscribed polygon whose area is equal to

$$a + \frac{a}{4} + \frac{a}{4^2} + \frac{a}{4^3} \dots \dots \frac{a}{4^{n-1}};$$

which is therefore less than the segment ACB . But we can prove, as is done above, that the excess of the segment

above the polygon is less than $\frac{a}{4^{n-1}}$; therefore the space

$$a + \frac{a}{4} + \frac{a}{4^2} + \frac{a}{4^3} \dots \dots + \frac{a}{4^{n-1}} + \frac{a}{4^{n-1}}$$

will be greater than the segment.

Now, if from the area of the polygon, *viz.*

$$a + \frac{a}{4} + \frac{a}{4^2} + \frac{a}{4^3} \dots \dots + \frac{a}{4^{n-1}},$$

we subtract its fourth part, the three-fourths which remain will be equal to $a - \frac{a}{4}$; therefore the area of the polygon

will be equal to $\frac{4a}{3} - \frac{1}{3} \cdot \frac{a}{4^{n-1}}$, which is less than the segment; and the space proved above to be greater than the

segment will be equal to $\frac{4a}{3} + \frac{2}{3} \cdot \frac{a}{4^{n-1}}$. Between these

PARABOLA.

two limits the area of the parabolic segment is contained, how great soever may be the number of bisections denoted by n .

But $\frac{4a}{3}$ is the only quantity which, for every value of n , is contained between the foregoing limits, *viz.*

$$\frac{4a}{3} - \frac{1}{3} \cdot \frac{a}{4^{n-1}}$$

$$\frac{4a}{3} + \frac{2}{3} \cdot \frac{a}{4^{n-1}}$$

For it is manifest that n may be taken so great, that the difference between the two limits shall be less than any assignable space. Therefore the area of the segment of the parabola is equal to $\frac{4a}{3}$; that is, it is equal to four third parts

of the triangle inscribed in it, by drawing a diameter to bisect the base: or, which is the same thing, it is equal to four third parts of the triangle that has the same base and altitude with the segment.

The area of a parallelogram circumscribed about a segment of a parabola (*fig. 15.*), being double of the triangle inscribed in the segment; the area of the segment will be two-third parts of the parallelogram.

The modern analysis furnishes a much shorter way of determining the area of a parabola than the prolix though elegant method of the ancient geometers. Let p denote the parameter of a diameter of a parabola; y an ordinate; x the corresponding absciss; and m the sine of the angle in which the ordinate cuts the diameter; then the fluxion of the area of the semi-segment of the parabola will be $my\dot{x}$; but $y^2 = px$, and $y = p^{\frac{1}{2}}x^{\frac{1}{2}}$; therefore the fluxion of the semi-segment is $m p^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$; and the fluent, or the area itself, is $\frac{2}{3} m p^{\frac{1}{2}} x^{\frac{3}{2}}$; and by substituting y for $p^{\frac{1}{2}} x^{\frac{1}{2}}$, the semi-segment of the parabola is $\frac{2}{3} m y x$; and the whole segment is equal to $\frac{2}{3} \times 2 m y x$, that is, to two-thirds of the circumscribing parallelogram.

Rectification of the Parabola.—About the year 1659, Van Heuraet, a Dutch mathematician, invented a method of reducing the rectification of any proposed curve to the quadrature of another curve derived from the former by a geometrical construction; and in this way he shewed that the rectification of the parabola could be accomplished by the quadrature of the hyperbola. This discovery is explained by the author in a letter to Francis Schooten, inserted by that mathematician in the edition of Des Cartes' geometry, which he published in 1659. Inventions of this kind, although they might be very interesting at the time they were first made known to the public, are now only objects of curiosity to such as wish to inquire into the history of mathematical learning; we shall therefore proceed to investigate the length of an arc of a parabola, by the general method now in use.

Let $4p$ denote the parameter of the axis of a parabola; y an ordinate to the axis; x the corresponding absciss; s the length of the arc estimated from the vertex; then, as is proved in the method of fluxions, $\dot{s} = \sqrt{\dot{x}^2 + \dot{y}^2}$; but the equation of the curve is $y^2 = 4px$; therefore $y = 2\sqrt{px}$;

consequently $\dot{y} = \dot{x} \sqrt{\frac{p}{x}}$; and $\dot{y}^2 = \dot{x}^2 \cdot \frac{p}{x}$; therefore, by

substitution, $\dot{s} = \dot{x} \sqrt{1 + \frac{p}{x}} = \frac{x\dot{x} + p\dot{x}}{\sqrt{x^2 + px}}$.

Suppose $z = \sqrt{x^2 + px}$; then by taking the fluxions

$$\dot{z} = \frac{x\dot{x} + \frac{1}{2}p\dot{x}}{\sqrt{x^2 + px}}; \text{ hence } \dot{s} = \dot{z} + \frac{1}{2}p \cdot \frac{\dot{x}}{\sqrt{x^2 + px}}; \text{ and}$$

by taking the fluents, and restoring the value of z , we get

$$s = \sqrt{x^2 + px} + \frac{1}{2}p \times \text{hyp. log.} \frac{x + \frac{1}{2}p + \sqrt{x^2 + px}}{\frac{1}{2}p};$$

which is the expression of the length of an arc of a parabola estimated from the vertex, cut off by an ordinate corresponding to the absciss x . I.

The area of a frustum, or zone, of a parabola, included by two parallel right lines, and the intercepted curves of the parabola, may be found by the following rule; *viz.* To one of the parallel ends add the quotient arising from the division of the square of the other by the sum of the said ends; multiply the sum by the altitude of the frustum, or distance of the ends; and $\frac{2}{3}$ ds of the product will be the area. Or, divide the difference of the cubes of the diameters by the difference of their squares, and multiply the quotient by $\frac{2}{3}$ ds of

the altitude. Then, $D + \frac{DD}{D+d} \times \frac{2}{3}a$, or $d + \frac{DD}{D+d}$

$$\times \frac{2}{3}a, \text{ or } \frac{D^3 - d^3}{D^2 - d^2} \times \frac{2}{3}a = \text{the area; } D, d \text{ being the two}$$

ends and a the altitude. For by a property of the parabola,

$$DD - dd : a :: \left\{ \begin{array}{l} DD : \frac{aDD}{DD - dd} \\ dd : \frac{add}{DD - dd} \end{array} \right\} = \text{the altitudes}$$

of two complete segments, whose bases are the ends D, d of the frustum; and consequently their difference, or the

$$\text{frustum, is } \frac{2}{3}a \times \frac{D^3 - d^3}{D^2 - d^2} = \frac{2}{3}a \times \frac{DD + Dd + dd}{D + d} =$$

$$\frac{2}{3}a \times D + \frac{dd}{D+d} = \frac{2}{3}a \times d + \frac{DD}{D+d}.$$
 Hence a pa-

rabolic frustum is equal to a parabola of the same altitude, and whose base is equal to the end of the frustum, increased by a third proportional to the sum of the ends and the other. Consequently in the one end DC (*Plate XXIII. Miscellany, fig. 9.*) produced of a parabolic frustum ABCD, take CE = the other end AB; raise EF perpendicular to EC and = CD; draw DF, and perpendicular to it FG meeting CE produced in G; then, if upon the base CG be described any parabola CHG, touching the line ABH, it will be equal to the frustum ABCD. For

$$CG = CE + EG = AB + EG = AB + \frac{EF^2}{DE} =$$

$$= AB + \frac{DC^2}{DC + AB}. \text{ Hutton's Mensuration.}$$

PARABOLA, *Quadrature of the.* See QUADRATURE, and the article PARABOLA *supra*.

PARABOLA, *Rectification of the.* See RECTIFICATION, and PARABOLA.

PARABOLA, *Centre of gravity of a.* See CENTER of Gravity.

PARABOLA, *Centre of oscillation of the.* See CENTER of Oscillation.

PARABOLAS of the higher kinds, are algebraic curves, defined by $a^m - 1 x = y^m$. *E. gr.* by $a^2 x = y^2$, $a^3 x = y^3$, $a^4 x = y^4$, $a^5 x = y^5$, &c. See CURVE.

Some call these paraboloids: more particularly, if $a^2 v = y^2$, they call it a *cubical* paraboloid. If $a^2 x = y^2$, &c. they call it a *biquadratic* paraboloid, or a *surfolidal* paraboloid. And in respect of these, the *parabola of the first kind*, above explained, they call the *Apollonian*, or *quadratic* parabola. Those curves are likewise to be referred to parabolas, in which $a x^{m-1} = y^m$; as *e. gr.* $a x^2 = y^2$, $a x^3 = y^3$, which some call *semi-parabolas*. They are all comprehended under the common equation, $a^m \times x^m = y^m$, which also extends to other curves, *v. gr.* to those in which $a^2 x^2 = y^2$, $a^2 x^3 = y^3$, $a^2 x^4 = y^4$.

Since in parabolas of the higher kinds, $y^m = a^{m-1} x$; if any other semi-ordinate be called v , and the abscissa corresponding to it z , we shall have $v^m = a^{m-1} z$, consequently $y^m : v^m :: a^{m-1} x : a^{m-1} z$, *i. e.* $x : z$. It is a common property, therefore, of these parabolas, that the powers of the ordinates are in the ratio of the abscissas. But in semi-parabolas, $y^m : v^m :: a x^{m-1} : a z^{m-1} :: x^{m-1} : z^{m-1}$. Or the powers of the semi-ordinates are as the powers of the abscissas, one degree lower. *E. gr.* In cubical semi-parabolas the powers of the ordinates y^3 and v^3 are as the squares of the abscissas x^2 and z^2 .

PARABOLA, *Helicoid*. See HELICOID.

PARABOLA, *Osculatory*, in *Geometry*, is used particularly for that parabola which not only osculates or measures the curvature of any curve at a given point, but also measures the variation of the curvature at that point. See M'Laurin's Appendix to his Algebra, p. 17. Cramer, *Analys. des Lignes Courbes*, p. 559. See also CURVATURE.

A curve, strictly speaking, may have an indefinite number of osculatory parabolas at any of its points; but the appellation may be restrained to that particular parabola which meets the curve so closely, that no other parabolic arc can be drawn between them; and this parabola will measure the variation of curvature of the curve at that point. See VARIATION of Curvature.

PARABOLA, *Resistance of a*. See RESISTANCE.

PARABOLAN, PARABOLANUS, among the *Ancients*, was a sort of gladiator, called also the *confessor*.

The name was given them from the Greek, $\piαραβολοι$, of $\betaαλλω$, to throw, *precipitate*; because they threw themselves on danger and death.

PARABOLANI, or PARABOLARI, is also used in *Church History*, for a set of people, especially in Alexandria, who devoted themselves to the services of churches and hospitals.

The parabolani were not allowed to withdraw themselves from their function, which was the attendance on the sick. They made a kind of fraternity, amounting sometimes to six hundred persons, dependent on the bishop.

The design of their institution was that the diseased, especially those infected with the plague, might not be without attendance.

PARABOLIC ASYMPTOTE, in *Geometry*, is used for a parabolic line approaching to a curve, so that they never meet; yet by producing both indefinitely, their distance from each other becomes less than any given line.

There may be as many different kinds of these asymptotes as there are parabolas of different orders.

When a curve has a common parabola for its asymptote, the ratio of the subtangent to the abscissa approaches continually to the ratio of two to one, when the axis of the parabola coincides with the base; but this ratio of the subtangent to the abscissa approaches to that of one to two, when the axis is perpendicular to the base. And by observing the limit to which the ratio of the subtangent and

absciss approaches, parabolic asymptotes of various kinds may be discovered. See M'Laur. Flux. art. 337. See also ASYMPTOTE.

PARABOLIC CONOID, or PARABOLOID, a solid figure generated by the rotation of a parabola about its axis.

The circles conceived to be the elements of this figure, are in an arithmetical proportion, decreasing towards the vertex.

A parabolic conoid is to a cylinder of the same base and height as 1 to 2; and to a cone of the same base and height, as $1\frac{1}{2}$ to 1. See CONOID.

I. The curve surface of a paraboloid may be found by the following rules.

Rule 1.—To the square of the ordinate, or semi-diameter of the base, add four times that of the axis; and the square root of the sum will be the tangent to the curve at the base, and intercepted by the axis produced; call this tangent t ; then we shall have $t = \sqrt{yy + 4xx}$, x being the axis, and y the ordinate. Then by the rule at the close of the article PARABOLA, find the area of the frustum of a parabola, whose parallel ends are t and y , and its altitude $= y$, and this area multiplied by 3.14159 will be the curve surface of the paraboloid ABC required. Plate XXIII. *Miscellany*, fig. 10.

Calling the ordinate y , the absciss x , the curve z , and the parameter p ; also $a = 3.14159$; the equation of the generating parabola will be $px = yy$; hence $p\dot{x} = 2y\dot{y}$, and the fluxion of the surface $\dot{s} = 2ay\dot{z} = 2ay\sqrt{\dot{y}^2 + \dot{x}^2} = \frac{4ay\dot{y}}{p}\sqrt{\frac{1}{4}pp + yy}$; and, by taking the correct fluents,

the surface s will be $= \frac{4a}{3p} \times (\frac{1}{2}pp + yy)^{\frac{3}{2}} - \frac{1}{2}app = \frac{2}{3}ay \times \frac{(yy + 4xx)^{\frac{3}{2}} - y^3}{4xx}$

$= \frac{2}{3}ay \times \frac{t^3 - y^3}{t^2 - y^2} = \frac{2}{3}ay \times \frac{t + y}{t + y} = \frac{2}{3}ay \times t$

$= \frac{2}{3}ay \times \left(t + \frac{yy}{t+y}\right) = \frac{2}{3}ay \times \left(y + \frac{ty}{t+y}\right)$; putting

$t = \sqrt{yy + 4xx} = BE$, the tangent to the curve at the extremity of the ordinate, and intercepted by the axe produced. Q. E. D.

Corol. 1.—In CB produced take BG = the tangent BE; erect GH perpendicular to GB and equal to BD; join DH, and perpendicular to it HI, meeting BG produced in I; take BK = $\frac{1}{2}$ BI; and upon KC describe a circle meeting BL perpendicular to BC in L. And the circle whose radius is BL, will be equal to the curve surface of the paraboloid BAC.

For, by the construction, $BL^2 = KB \times BC = BC \times \frac{1}{2}BI = \frac{2}{3}BD \times (BG + GI) = \frac{2}{3}BD \times \left(BE + \frac{GH^2}{GD}\right) = \frac{2}{3}BD \times \left(BE + \frac{BD^2}{BE + BD}\right) = \frac{2}{3}y \times \left(t + \frac{yy}{t+y}\right)$.

Corol. 2.—The curve surface of the paraboloid is to the area of its circular base, as IK is to BD.

For the base is $= a \times BD^2$, and the curve surface $= a \times \frac{2}{3}IB \times BD = a \times IK \times BD$.

Corol. 3.—If M be the focus of the generating parabola, and there be taken AN = MC = AD + AM, and the double

PARABOLIC CONOID.

double ordinates P N O, Q M R be drawn; the surface generated by B A C, will be to the area P Q R O, as $a = 3.14159$, to 1, or as the circumference of a circle to its diameter.

For the surface is $= \frac{4a}{3p} \times (\frac{1}{4}pp + yy)^{\frac{3}{2}} - \frac{1}{6}app = \frac{4a}{3p} \times (\frac{1}{4}pp + px)^{\frac{3}{2}} - \frac{1}{6}app = \frac{4}{3}a \times (\frac{1}{4}p + x) \sqrt{\frac{1}{4}pp + px} - \frac{1}{6}app = \frac{4}{3}a \times MC \sqrt{MC} \times p - \frac{1}{6}app = \frac{4}{3}a \times AN \times NO - \frac{1}{6}a \times AM \times MR = a \times (PAO - QAR) = a \times PQRO.$

Rule 2.—Divide the difference between the cube of the tangent and the cube of the ordinate, by four times the square of the axis; multiply the quotient by $\frac{1}{3}$ ds of the ordinate, and the product again by 3.14159 for the surface. Thus, $\frac{t^3 - y^3}{4x} \times \frac{1}{3}cy =$ the surface; where $t = \sqrt{yy + 4xx}$ is the tangent, x the absciss or axis, y the ordinate or semi-diameter of the base, and $c = 3.14159$.

II. The curve surface of the frustum of a paraboloid, having its altitude and the diameters of its ends given, may be thus found.

Divide the difference of the squares of the semi-diameters of the ends, by their distance, or by the altitude of the frustum; or divide the difference of the squares of the whole diameters, by four times the altitude; and the quotient will be the parameter of the axis of the generating parabola.

Find the two sums arising from the addition of the square of the parameter and the square of each diameter; multiply each sum by its root, and divide the difference of the products by the parameter; multiply the quotient by 3.14159, and $\frac{1}{6}$ th of the product will be the surface of the frustum.

That is, $\frac{(pp + DD)^{\frac{3}{2}} - (pp + dd)^{\frac{3}{2}}}{p} \times \frac{1}{6}c =$ the surface; D and d being the diameters of the ends, $p =$ the parameter $= \frac{DD - dd}{4a}$, $a =$ the altitude, and $c = 3.14159$.

In the investigation of rule 1. of the last problem, it appears that $\frac{4a}{3p} \times (\frac{1}{4}pp + yy)^{\frac{3}{2}} - \frac{1}{6}c p p$ or $\frac{c}{6p} \times (pp + DD)^{\frac{3}{2}} - \frac{1}{6}c p p$ is the surface of the segment whose base diameter is D ; and $\frac{c}{6p} \times (pp + dd)^{\frac{3}{2}} - \frac{1}{6}c p p =$

that whose diameter is d ; and, by taking the difference, $\frac{1}{6}c \times \frac{(pp + DD)^{\frac{3}{2}} - (pp + dd)^{\frac{3}{2}}}{p}$, will express the surface of the frustum, the diameters of whose ends are D, d .

And that the parameter is $= \frac{DD - dd}{4a}$, appears thus: Since $pX = YY$, and $px = yy$, therefore $pX - px = YY - yy$, and $p = \frac{YY - yy}{X - x} = \frac{DD - dd}{4a}$.

III. The solidity of any segment of a paraboloid, whose base is either perpendicular or oblique to the axis, may be found by the following rule. For both right and oblique segments, multiply the base by half the altitude, and the product will be the content. Let b denote the base, a the altitude, x any variable absciss, or part of the diameter drawn through

the middle of the base, and s the sine of the angle formed by this diameter and its ordinate, to the radius 1.

Then as $a : sx :: b : \frac{bsx}{a}$ the section corresponding to the absciss x . Therefore $\frac{sx}{a} \times bsx$ is the fluxion of the

solid; and, by taking the fluent, the solid itself will be $\frac{bssxx}{2a}$; which, when $sx = a$, becomes $\frac{1}{2}ab$ for the whole

solid, whose base is b and altitude a . *Q. E. D.*

Corol. 1.—A paraboloid is equal to half a prism of the same base and altitude. Also a prism, a semi-spheroid or semi-sphere, a paraboloid, and a pyramid, all of equal bases and altitudes, are to one another as the numbers 1, $\frac{2}{3}$, $\frac{2}{3}$, $\frac{1}{3}$, or as 6, 4, 3, 2; and are, therefore, in a discontinued geometric proportion, whose ratio is that of 3 to 2. Which will appear by comparing the above value of the paraboloid with those of the other solids.

When the base of the paraboloid is perpendicular to the axis, or when the paraboloid is right, the semi-spheroid, or semi-sphere, will also be right; and the prism and pyramid will be the right or common cylinder and cone, the common base being a circle. But if the paraboloid be oblique, by having its base oblique to the axis, the common base of all the solids will be an ellipse; the semi-spheroid will also be oblique, by having its base oblique to the axis; and the prism and pyramid may be either right or oblique.

Corol. 2.—If upon the diameter NP = BC = the conjugate axis of the section AB, be described a circle; (*Plate XXIII. Miscellany, fig. 11*) the oblique paraboloid, or segment AHB, will be equal to the right paraboloid whose base is that circle, and its altitude MH. For, the diameter of the circle being the conjugate axis of the base of the oblique paraboloid, the circle will be to that base, as the conjugate is to the transverse axis, that is, as CB to AB; but HK is to HM in the same proportion of CB to AB; consequently HK \times elliptical base AB will be = HM \times circular base NP or BC.

It is also evident, that all segments, right or oblique, having the same vertex H, and the transverse axes of whose bases pass through the same point M, and terminate in A, C, O, P, parallel to and equidistant from HM, will be equal to one another.

Corol. 3.—If B, b denote the two bases, or parallel ends, of the frustum of a paraboloid, either right or oblique; and d the distance of the ends, or the altitude of the frustum; then $\frac{1}{2}d \times (B + b)$ will be the solidity of the frustum.

For, by this problem, $\frac{1}{2}AB$ is the segment whose base is B and altitude A ; and $\frac{1}{2}ab$ is that whose base is b and altitude a ; therefore the frustum, or the difference of the segments, is $\frac{1}{2}AB - \frac{1}{2}ab$. But, by the nature of the

paraboloid, $B - b : d$ or $A - a :: B : A = \frac{Bd}{B - b}$, and

$B - b : d :: b : a = \frac{bd}{B - b}$; which values of A and a

being substituted for them, we obtain $\frac{1}{2}AB - \frac{1}{2}ab = \frac{dB^2 - db^2}{2B - 2b} = \frac{1}{2}d \times (B + b)$.

Corol. 4.—Let A G B b be a right frustum, HI the diameter to the double ordinate AB, and HK perpendicular to AB, that is, HK the altitude of the oblique segment AHB. Then the value of the oblique segment AHB is $\frac{1}{2}n \times AB \times BC \times HK$, putting $n = .785398$.

But,

But, by the property of the figure, $DB^2 - DC^2 : DB^2 - DI^2 :: AC : HI = \frac{DB^2 - DI^2}{DB^2 - DC^2} \times AC$;
 hence $HM = HI - IM = HI - \frac{1}{2} AC = \frac{DB + DC}{DB - DC}$
 $\times \frac{1}{4} CA = \frac{BC \times CA}{8 DI}$; and, by similar triangles,
 $AB : CB :: HM : HK = \frac{HM \times CB}{AB} = \frac{AC \times CB^2}{AB \times 8 DI}$;
 therefore the oblique segment AHB , or $\frac{1}{2} n \times AB \times CB \times HK$, will be $\frac{CB^3}{8 DI} \times \frac{1}{2} AC \times n = \frac{CB^3}{bB^2 - AG^2}$
 $\times AC \times \frac{1}{2} n$.

Or, by substituting the value of AC , viz. $\frac{DB^2 - DC^2}{DB^2}$
 $\times DE = \frac{CB \times 2 DI}{DB^2} \times DE$, instead of it, the same
 segment AHB will be $\frac{CB^3}{8 DB^2} \times DE \times n = \frac{CB^3}{bB^2} \times$
 $DE \times \frac{1}{2} n$.

Corol. 5.—If from $DE \times bB^2 \times \frac{1}{2} n$, the value of the
 right segment DEB , be taken the above value of the ob-
 lique segment AHB , there will remain $\frac{bB^3 - CB^3}{bB^2} \times$
 $DE \times \frac{1}{2} n$, or $\frac{bB^3 - CB^3}{bB^2 - AG^2} \times AC \times \frac{1}{2} n$ for the value
 of the greater ungula AB .

Corol. 6.—And if from the said value of the oblique seg-
 ment AHB , be taken that of the right segment AEG ,
 viz. $\frac{AG^3}{bB^2} \times DE \times \frac{1}{2} n$, or $\frac{AG^3}{bB^2 - AG^2} \times AC \times \frac{1}{2} n$,
 there will remain $\frac{CB^3 - AG^3}{bB^2} \times DE \times \frac{1}{2} n$, or $\frac{CB^3 - AG^3}{bB^2 - AG^2}$
 $\times AC \times \frac{1}{2} n$ for that of the less ungula AGB . Hut-
 ton's Mensuration.

PARABOLIC Cuneus, a solid figure, formed by multiplying
 all the DB 's, (*Plate XIII. Analysis, fig. 3.*) into the D 's:
 or, which amounts to the same, on the base APB erect a
 prism, whose altitude is AS : this will be a parabolical
 cuneus, which of necessity will be equal to the parabolical
 pyramidoid; inasmuch as the component rectangles in one are
 severally equal to all the component squares in the other.

PARABOLIC Pyramidoid, a solid figure, generated by
 supposing all the squares of the ordinate applicates in the
 parabola so placed, as that the axis shall pass through all
 their centres at right angles; in which case the aggregate
 of the planes will form the parabolic pyramidoid.

The solidity of this body is had by multiplying the base
 by half the altitude; the reason of which is obvious; for
 the component planes being a series of arithmetical pro-
 portionals beginning from 0, their sum will be equal to the
 extremes multiplied by half the number of terms, that is,
 in the present case, equal to the base multiplied by half the
 height.

PARABOLIC Space, the space or area contained between
 any entire ordinate, and the curve of the parabola.

The parabolic space is to the rectangle of the ordinate
 into the abscissa, as 2 to 3: to a triangle inscribed on

the ordinate as a base whose altitude is the abscissa, the
 parabolic space is as 4 to 3.

The segment of a parabolic space, is that space included
 between two ordinates. See **PARABOLA**.

Quadrature of a parabolical segment. See **QUADRATURE**,
 and **PARABOLA** *Supra*.

PARABOLIC Speculum or Mirror. See **MIRROR**.

PARABOLIC Spindle. See **PYRAMOID** and **SPINDLE**.

PARABOLIC Spiral, in Conics. See **HELICOID Parabola**.

PARABOLIFORM CURVES, a name sometimes given
 to the parabolas of a higher kind.

PARABOLOIDES, parabolas of the higher kinds.
 See **PARABOLAS of the higher kind**.

PARABOLOID, Centre of gravity of a. See **CENTER**.

PARABOLOID, Quadratic. Cubical paraboloid, surfolidal
paraboloid. See **PARABOLAS of the higher kinds**.

PARABOSCO, GIROLAMO, in *Biography*, organist of
 St. Mark's cathedral at Venice, and according to Crefcembeni
 (Stor. del Vulg. Poef.) a most admirable performer. "Who-
 ever," says Ant. Fran. Doni, (*Libraria Tratt. imo.*) "is en-
 dowed by heaven with the power of receiving and communicat-
 ing pleasure, should imitate Parabosco; who, not content with
 that musical excellence, with which he has given such delight,
 both in public and private, and acquired such fame, has
 afforded equal pleasure by his literary and poetical talents,
 in the publication of works, that are as much esteemed for
 their wit and learning, as originality." He then gives a list
 of his tragedies, comedies, miscellaneous poems, and letters;
 adding, that "he hoped his novels would soon appear in
 print, which, for their invention and style, he thought the
 most admirable productions of the kind that he had ever
 read." They were afterwards published under the title of
 "Gli Disporti," &c. 1586; and we purchased them at an
 extravagant price, as curiosities, at the sale of the late Hon.
 Topham Beauclerc's books; but find, on perusal, that Doni
 spoke of them as he did, perhaps, of his musical abilities,
 with the partiality of a friend. Several of the motets and
 madrigals of Parabosco are inserted in the collections that
 were published about the middle of the sixteenth century,
 some of which we took the trouble to score, but found in
 them no subject; and but little design or contrivance. And
 if his literary character did not impose on his friends, and on
 the writers who speak of his musical productions, his fame
 as a composer must have been established on works superior
 to these, which are mere *remplissage*, or notes heaped on each
 other totally devoid of meaning with respect to melody.

PARABRAMA, in *Mythology*, is a name given to the
 first of the gods of India.

PARABYSTE was one of the five principal civil tri-
 bunals of Athens.

PARAC, in *Geography*, a town of the island of Borneo;
 200 miles N. of Banjar-Massim.

PARACA, a town of Peru, in the audience of Lima;
 12 miles S. of Pisco.

PARACELS, or PRACELS, a chain of small islands,
 with rocks and shoals, in the Chinese sea, parallel to, and
 about 60 miles E. of the coast of Cochinchina. This range
 is about 300 miles long, and 60 broad from N. lat. $11^{\circ} 40'$
 to $16^{\circ} 10'$, and E. long. 110° to 111° . The navigation is
 dangerous, on account of several currents among them.

PARACELSISTS. See *Fire Philosophers*.

PARACELSUS, in *Biography*, an extraordinary ad-
 venturer in chemistry and physic, in the early part of the
 sixteenth century, is said to have been born at Einsidlen, a
 little village near Zurich, in Switzerland, in 1493; and his
 father, called William de Hohenheim, is supposed to have
 been the natural son of a grand master of the Teutonic
 order,

PARACELSUS.

order, and a practitioner in medicine in Carinthia, in the beginning of the following century. With a view of dignifying himself and his family, his son assumed the names of *Philippus*, *Aureolus*, *Theophrastus*, *Paracelsus*, *Bombastus de Hohenheim*. But Thomas Erastus affirms, that there was no family bearing any of these names in that part of Switzerland, either noble or ignoble; and Haller was credibly informed, that Paracelsus was a native of Gais, in the canton of Appenzel, and of an obscure family of the name of Hochener, which was still existing there. His father gave him early a turn for his own pursuits, and put him under the care of John Trithemius, abbot of Spanheim, at that time eminent for his knowledge of the spagiric art, as chemistry in its infancy was called. He afterwards followed another master of the art, Sigismund Fugger, and from both these he learned many secrets. If any credit is due to his own statements, he received instructions from several other tutors, whom he has named; although in one of his treatises, he denies having had any instructors at all. He very soon commenced a sort of rambling life; for he says, he had examined the principles of the medical art with great attention, and found them defective and erroneous in all points, and therefore he resolved, after having visited the schools of France, Italy, and Germany, to travel in pursuit of medical truth, and not only to search for it among physicians, and other learned persons, but among barber-surgeons, monks, conjurers, old women, and quacks of every description. He makes a pompous display of the names of all the countries which he thus visited, during a peregrination of several years, and of the important acquisitions in science which he thus collected, with the view of impressing on the world the highest opinion of his superiority; for he seems to have possessed the talents of imposing and successful quackery in an eminent degree. Even the learned Erasmus appears to have consulted him, especially after a fortunate cure of his friend Frobenius, the celebrated printer of Basle, in an attack of gout, (although the latter died of apoplexy a few months afterwards,) and Oporinus, an eminent citizen of that place, left his family to follow him. In the course of his travels he had doubtless collected much information concerning metallic chemistry; which, however, he perverted to the vain search of the philosopher's stone; and by the bold use of some active medicines, especially mercury and opium, the administration and properties of which were not understood by medical men, he had certainly effected many cures, where ordinary medicine had failed; and while these successful cases were blazoned forth with the usual exaggeration, the unsuccessful ones, and the mistakes were long passed over in silence. To such a height, however, his reputation had been raised in Switzerland, that the magistrates of Basle were induced to engage him, at a large salary, to fill the chair of medicine in their university. In the years 1527 and 1528, he gave lectures daily, sometimes in barbarous Latin, but more frequently in German; and although he at first acquired several enthusiastic adherents, yet the barbarism, vanity, and extravagance of his lectures at length disgusted the students, and he was soon left without an audience. Indeed nothing could exceed the ridiculous pride and bombast, with which he assumed the supremacy, the monarchy of medicine, and the contempt which he affected towards all the teachers and universities in the world. Seated in his professorial chair, at his first lecture, he publicly burnt the works of Galen and Avicenna, averring that his cap contained more knowledge than all physicians, and that the hair of his beard had more experience than all the universities. "Greeks, Romans, French, and Italians," he exclaimed; "you Avicenna, you Galen, you Rhazes, you

Mesue; you doctors of Paris, you of Montpellier, you of Swabia, you of Misnia, you of Cologne, you of Vienna; and all you throughout the countries that are washed by the Danube and the Rhine, and you who inhabit the islands of the sea, Athenian, Greek, Arab, and Jew; you shall follow and obey me, I am your king, the monarchy of physic is mine," &c. That such an extravagant enthusiast should not long retain his professorial chair might be anticipated. A quarrel with the magistrates of Basle, on account of a decision against him in respect to a demand of fees, which was deemed exorbitant, increased his displeasure, and he suddenly quitted that place in 1528. From this time he resided chiefly in Alsace, and in different parts of Germany, leading a life of extreme intemperance, in the lowest company, being frequently in a state of continued intoxication for many days and nights in succession. Nevertheless he still maintained his reputation by extraordinary cures, occasionally effected by his powerful remedies, though his failures were equally conspicuous. But the most signal failure of his boasted remedies occurred in his own person; for after pretending to the power of extending human life to an indefinite limit, by virtue of his *elixir*, he died in 1541, at an inn at Saltzburg, in the forty-eighth year of his age, in consequence of an attack of fever, and was buried in the hospital of St. Sebastian, to which he bequeathed the little property that he possessed.

Notwithstanding the reputation, and the numerous eulogies bestowed on this singular man, it can scarcely be said, that either scientific chemistry or medicine is much indebted to him for its advancement. The fundamental doctrines of his chemistry, which resolved every thing into three elements, salt, sulphur, and mercury, and which were for a long time received, were, in fact, borrowed from his predecessor, Basil Valentine. And as to his medical skill, it consisted principally in the bold administration of some powerful remedies, which had been heretofore thought too dangerous to be used. His most favourite medicine was opium, a drug with which, it is obvious, he would be able in many instances to afford great and speedy relief; but with which also few permanent cures could be effected, and much mischief would necessarily be produced, when it was misapplied. Antimony and mercury were also medicines which he liberally prescribed, and he used various preparations of them of the most active kind. He was indeed one of the first to employ mercury for the cure of the venereal disease, and of course he must, in this severe and newly distinguished malady, have been successful in a degree, to which none of his contemporaries, who did not resort to that remedy, could attain: and this success was a source of considerable emolument. In fact, he must be allowed to have conferred a substantial benefit on mankind, by the introduction of mercury as a cure of this malady: and in this point consists his principal merit in respect to medicine. For his total ignorance of anatomy and rational physiology, his inability from want of literature to investigate the doctrines of the ancients, which he so boldly impugned, and his employment of a barbarous jargon, as well as his infatuated notions of magic, astrology, geomancy, and all the other branches of mythical imposture, are totally adverse to any claim on his part to the improvement of medical science; and indeed he appears to have been entirely destitute of clear and methodical views upon any subject. We shall not pretend therefore to enter into any detail of the unintelligible jargon and absurd hypotheses which he employed, or to enumerate the immense farrago of treatises, which made their appearance under his name after his death, the notices of which occupy above nine quarto pages in the Bibliotheca of Haller: for the first

first we are unable to comprehend, and the latter would be a waste of time. The most complete edition is that of Geneva, in three volumes folio, 1658. He published little while he lived. See Sennert. de Consensu et Dissensu Galenicorum, &c. cum Chymicis, cap. iv. De Paracelsi. Eloy Dist. Hist. de la Med. Gen. Biog.

PARACENTESIS, from *παρὰ* and *κέντησις*, to make a perforation, a term in Surgery, signifying the operation of tapping, or making an opening into the thorax, abdomen, or bladder, for the purpose of discharging the fluid confined in these parts in cases of empyema, hydrothorax, ascites, and retention of urine. Effused blood may also require an opening to be made into the chest. For an account of paracentesis thoracis, in different cases, we refer to EMPHYSEMA, EMPYEMA, EXTRAVASATION, HYDROTHORAX, and WOUNDS of the CHEST.

Paracentesis of the Abdomen, or Tapping — The belly is subject to two kinds of dropsy; one has received the name of *ascites*; the other is termed *empysemal*. In the first, the fluid is effused in the general cavity of the peritoneum; in the second, it is contained in a pouch, or cyst; whence the name of the disorder is derived. The first case is the most common, and affects indiscriminately both sexes; the second is more rare, and presents itself oftener in women than men.

The treatment of these two species of dropsy belongs to the physician; but when they have made considerable progress, they demand the aid of surgery, an operation of which may facilitate the action of the medicines exhibited, procure a degree of relief, which would be in vain expected from physic, and tend to prolong the life of the patient. The operations alluded to, are the puncture, or paracentesis, which consists in letting out the collected fluid, by piercing the abdomen with an instrument expressly constructed for the purpose, called a *trocar*.

In cases of ascites, the abdomen cannot be prudently or safely tapped, unless the quantity of water be considerable. By this observation, however, we are far from meaning to dissuade practitioners from deferring the operation as a last resource. On the contrary, we are decidedly advocates for the performance of paracentesis at an earlier period than it is usually done; and we would earnestly recommend the faculty to give their patients a better chance of recovery, by having them tapped before their constitutional strength is too much reduced. The operation is no hindrance to the trial and continuance of such medicines as are likely to prove beneficial. Hence, as soon as paracentesis can be done, without risk of injuring the viscera, or rather as soon as the abdomen is sufficiently distended with fluid to render the introduction of the trocar safe, the operation appears to be advisable.

There is much reason for believing that paracentesis would in numerous instances be something more than a palliative measure, if it were resorted to at an earlier period of the disease. Le Blanc, in his "Precis d'Operations," assures us, that he was constantly in the habit of practicing the operation immediately when he distinctly felt the fluctuation of the fluid in the abdomen, and that the success of the treatment was very great. Even in the ordinary mode of practice, the operation of paracentesis sometimes effects a radical cure, and the fluid never accumulates again. (See Journal de Médecine, tom. lxxvi.) It is highly probable, that this would be the case more frequently, if the operation were properly practised. (Fothergill in Med. Observations and Enquiries, vol. iv.) There appear to be two causes which tend to hinder the salutary effect of the ope-

ration. The first is, that if the disease recur after it has been once practised, all hope of radical cure is generally renounced. The second cause is, that the operation is almost always repeated too late, not until the belly is again prodigiously distended. But, in order to give the best chance of a radical cure, the operation should be repeated frequently and at short intervals. Dehaen used to tap dropical patients once a week, and in many cases, after he had performed the operation two or three times, the disease was stopped.

Even when the operation does not itself accomplish a radical cure of ascites, it at least promotes and facilitates this desirable event. There cannot exist a doubt, that it is impossible for the means, which the physician prescribes with a view of cure, to produce their free and full effect while the abdomen is distended with water, and the functions of the viscera thereby more or less disturbed. Experience has proved, that medicines, which were found to be ineffectual previously to the operation, have frequently had the desired effect after the water has been evacuated.

Serious and even fatal symptoms have sometimes followed the operation of paracentesis, and hence it has been considered by certain practitioners as a proceeding attended with danger. But the foregoing unpleasant consequences are not to be ascribed to the operation; but either to the physician, who has recommended it to be performed too late, or at an improper period, or else to the surgeon, who has executed it without the requisite skill and caution. For, how frequently it happens, that it is not undertaken until the abdomen is swelled with a prodigious quantity of water, and the patient is in an extreme state of disorder and debility, partly from the long duration and high degree of the disease, and partly from the effect of the large quantities of violent medicines which have been exhibited. The operation is here plainly unseasonable and too late. If the sudden discharge of the fluid should now give rise to alarming consequences, the occurrence would prove nothing more, than that the operation, like every other means, is not proper at every time, and under any circumstances. In such cases the right opportunity of doing it is past. It ought to have been resorted to at an earlier period. It is a certain fact, that the sooner dropical patients are tapped, the less dangerous and the more beneficial is the operation. Immediately when there is a sufficient quantity of fluid in the abdomen to produce a manifest fluctuation, paracentesis is practicable; and no sooner do medicines begin to debilitate the patient, or become ineffectual, than the operation is indicated as a measure which should not be deferred. But even in those very instances in which paracentesis has been improperly delayed, modern surgery is furnished with a method of obviating the perilous symptoms, which are liable to arise from the sudden evacuation of the large quantity of fluid, as we shall presently have occasion to explain.

The following are the ordinary symptoms of ascites. A smooth uniform swelling extending over the whole abdomen, but most prominent at that part which happens to be the most dependent. A shining or glossy appearance of the integuments, which is particularly observable in the early stage of the disorder, and becomes obvious when the complaint has attained a high degree, and the abdomen is exceedingly tense and distended. An œdematous swelling of the feet and scrotum, especially when the disease is making progress. Thirst, dry skin, costive bowels, and hardened stools; a scanty secretion of thick dark-coloured urine; difficulty of breathing, especially in the recumbent posture; and, lastly, the fluctuation of the fluid in the abdomen. The latter symptom can be distinctly felt by the surgeon, when he places the palm of one of his hands upon one side

PARACENTESIS.

of the patient's belly, and taps gently with two fingers upon the opposite side.

There is one case, which bears considerable resemblance to dropsy of the belly, and may easily lead a careless surgeon to commit a serious mistake. We here allude to a retention of urine, that has existed a considerable time, and has attained a very high degree. In this instance, the bladder is sometimes so enormously distended, that it produces an uniform swelling of the whole belly, attended with a fluctuation and protuberance at the most dependent part of the abdomen. As, in this case, the bladder has lost its power of contraction, it always remains full and distended; but while the pressure of the abdominal muscles and viscera resists a still greater expansion of this organ, it also occasions an evacuation of a certain quantity of urine every day. This circumstance prevents the retention from proving fatal, and is apt to lead the practitioner into the error of mistaking the case for dropsy.

The instrument with which the paracentesis of the abdomen is performed, is called a trocar, of which there are several kinds. The celebrated Richter thinks the common one the best. Most of the modern alterations, which have been made in the construction of trocars, have only tended, says he, to render the employment of these instruments more difficult. There is no reason for the ordinary objection, that the common trocar cannot be introduced without considerable force. If the part into which it is about to be passed be made tense, very little force will be necessary, especially if care be taken to rotate the instrument gently as well as push it forward. Hence, all the inventions, which have originated from this supposed imperfection, are, according to Richter, entirely useless. He represents the trocar with a double edged point as needles. The proposal of Mr. Cline, to make a puncture with a lancet first, and then to introduce into the opening a blunt-pointed trocar, is alleged to be superfluous. Nay, these innovations are stated to be worse than useless. A cutting instrument is liable to injure the blood-vessels, and bring on a weakening degree of hemorrhage; and it is said, that the wound, thus made, does not so readily heal as that made with a common trocar. That cutting edged instruments are attended with the inconvenience of being apt to wound enlarged veins, and produce a disagreeable degree of hemorrhage, is a truth, of which the writer of this article has recently met with a convincing example. A female, who had strong aversion to being tapped with a trocar, prevailed upon him to make the opening with a lancet. The puncture was made in the linea alba, about three inches below the navel. A stream of dark-coloured venous blood continued to run from the wound the whole time the water was flowing out of the cannula, and did not cease until a compress was applied. The quantity of blood lost could not be less than a pint, or a pint and a half. In many cases, the loss of so much blood would prove fatal to a dropical patient, and is a thing which one must always feel anxious to avoid.

It was the general plan, a few years ago, to introduce the trocar at the middle of a straight line drawn from the navel to the anterior superior spinous process of the os ilium, or at the central point of the space between the navel, the spine, the crilla of the ilium, and the lower false ribs, and the puncture was made on the left side, in order to run no risk of injuring the liver, in the event of this viscus happening to be enlarged. In operating in the first of these situations, the intention of the surgeon was to make an opening into the abdomen at the linea semilunaris. Modern practitioners usually prefer making the puncture in the linea

alba, for several weighty reasons. The first is, that in the old method, you are not sure of introducing the trocar in the exact situation of the linea semilunaris, and consequently may unnecessarily wound the thick muscular parietes of the abdomen, instead of merely a thin tendinous part. Another still more important objection is, that the epigastric artery has sometimes been wounded by very skilful men, even by professed anatomists, in the attempt to tap in the linea semilunaris. In dropical cases, the rectus muscle is frequently much broader than in a healthy subject; and as it always yields to the distention of the fluid in a greater proportion than the lateral layers of muscles, the above-mentioned measurement is very likely to cause the wound to be made near the course of the epigastric artery.

When the operation is to be performed in the linea alba, (and, except in cases of encysted dropsy, we would always recommend this mode,) the trocar should be introduced about three inches below the navel. As soon as the instrument meets with no farther resistance, it is not to be pushed more deeply, without any object, and with a possibility of injuring the viscera. The cannula alone is now to be conveyed a little further into the opening, at the same instant that the fillet is withdrawn, in order to allow the fluid to run out.

Notwithstanding the fluctuation of the water may be plainly felt at the part where the puncture is about to be made, the surgeon must refrain from being too bold with the trocar, lest he wound some of the viscera. A bowel may lie very near the peritoneum, when a manifest fluctuation is perceptible at the part, the intervention of a very small quantity of fluid sufficing to cause such a sensation to the fingers of an examiner. Caution, therefore, in this operation is a most prudent and necessary virtue.

Sometimes the surgeon feels a fluctuation over the whole abdomen, but in a weak and indistinct way. In this circumstance, when the patient is not at the same time affected with anasarca, which of course must tend to weaken the sensation of a fluctuation, the surgeon has reason for suspecting, either that the disease may be encysted dropsy, or that the fluid contained in the abdomen may be thick, or else that the tumour of the belly may be occasioned by hydatids.

In performing paracentesis, the practitioner should always be careful to avoid wounding the cutaneous vein, which, in dropical persons, frequently attain a vast size, and become capable of emitting a large quantity of blood.

In dropical patients, the navel swells in such a manner, that it puts on the appearance of a bladder of water. In this case, a proposal has been started to open the tumour of the navel with a lancet, taking care to make only a small aperture, so that the fluid may not be all discharged suddenly, but may be some days in dribbling away. It is said, that in performing paracentesis in this way, there is not only no bleeding, but no risk of any perilous symptoms, so gradually does the water make its escape. The alarming disposition, which often immediately arises from the sudden discharge of the fluid in the ordinary operation, is a source of considerable uneasiness both to the patient and the surgeon; and the avoidance of it is undoubtedly a desideratum of importance. Another advantage of the plan, which we have just now been speaking of, is, that the little opening does not directly close up, so that the continuance of the oozing from it prevents for some time any re-accumulation of fluid in the abdomen. The practitioner may the more readily make up his mind to this operation, by considering, that if a puncture be not made into the swelling of the navel, a spontaneous opening is in time generally produced; that

PARACENTESIS.

when this has happened, and the fluid been thus discharged, no bad consequences have ensued; and, lastly, that the method has been already practised with success. (See Sims's *Obf.* in the *Memoirs of the Medical Society*, vol. iii.) The apprehension of an umbilical hernia being the consequence, which Garengot and others entertained, is, as Mr. Samuel Sharp conjectured, quite unfounded, especially when the puncture is small, as it always ought to be. (Richter's *Anfangsgr. der Wundarzn.* Band 5, § 143.) Sometimes the water descends into the empty sac of a scrotal hernia, and distends it in a considerable degree. Here we may without hesitation adopt the plan of discharging the water from the cavity of the peritoneum, by puncturing the hernial sac. Frequently, in the female subject, the fluid of ascites presses upon the vagina in such a manner, as to produce a kind of prolapsus of the latter part, which has the appearance of a pouch filled with water. In a case of this description, the fluid has been evacuated from the abdomen, by puncturing the tumour of the vagina with a trocar, and the wound healed very favourably. Bishop on *Medical Communications*, vols. i, ii.

The plan of tapping males from the rectum, and women from the vagina, has been suggested as one deserving of general imitation. In 1788, Macarn, a surgeon at Turin, addressed a letter upon this subject to the secretary of the French Academy of Surgery, mentioning three examples, in which the operation had been done in the foregoing way, and requiring such further information as could be given him. Allan, a member of the academy, was the only one who knew any thing about the method. He recollected having, in 1767, presented to the society a memoir, in which he discussed the question, whether paracentesis from the bladder and rectum might not have advantages. (See Sabatier's *Médecine Opératoire*, tom. i. p. 173.) We join Richter in the opinion, that, as a general practice, this does not deserve recommendation, and that it should only be pursued, when nature indicates it, by presenting a tumour either in the vagina or rectum.

In the operation of paracentesis, it is prudent to employ an assistant in compressing both sides of the abdomen; by which means, the contained fluid will be urged in larger quantity towards the place where the trocar is to be introduced; the integuments will be rendered tense, so that the instrument will penetrate with greater ease; the determination of the water towards the part about to be punctured, will increase the distance between the peritoneum and the viscera of the abdomen; and, of course, the likelihood of these being touched with the point of the trocar will be diminished. As such compression should be maintained till the end of the operation, the assistant ought to put himself in a position, in which he will be able to do what is required of him without the least remission.

It is customary with many operators to oil the trocar, just before using it; and this plan has come into vogue from a supposition, that the instrument will now pierce the flesh with greater facility. For our own part, we have always regarded this fashion as equally useless and harmless: its omission is far more proper than that of many other circumstances, which are too frequently neglected. The patient is mostly tapped as he sits in a chair, or upon the edge of his bed. The surgeon is to hold the trocar in his right hand, in such a manner that the handle of the instrument is exactly in the hollow of the palm, while the fore-finger is applied along the cannula to within an inch and a half of the point of the trocar. The end of the finger prevents the instrument from piercing too far, which it would otherwise be apt to do in a very sudden way.

If it be a common round trocar that is used, its entrance will be greatly facilitated by rotating it a little, at the moment it is pushed forward. The sudden cessation of all resistance apprises the operator of the point of the instrument having passed through the peritoneum. The trocar, or stilet, is now to be immediately withdrawn, care being taken to keep back the cannula with the left thumb and fore-finger. Sometimes the fluid suddenly ceases to flow, which circumstance is generally owing to a part of the omentum, or intestines, having fallen against the inner opening of the cannula. In this case, the part causing the stoppage must be pushed back by means of a probe, passed through the tube. Frequently the obstruction is produced by membranous flakes, which the water sometimes contains: here the introduction of a probe will also remove the stoppage.

When most of the fluid has been discharged, the viscera often come directly into contact with the inner end of the cannula, which, if moved about, will bruise and injure the parts. Hence, towards the end of the operation, the tube should always be held entirely motionless. Although it is always proper to draw off as much of the water as possible, yet the practitioner must be careful not to press and handle the lower part of the abdomen too forcibly, with a view of squeezing out the whole of the fluid, lest he press the bowels against the cannula, and excite inflammatory symptoms.

Sometimes swooning, extreme prostration of strength, and violent pain, occur during and after the operation. These evils are imputed to the sudden evacuation of the water, the consequent sudden relaxation of the distended parts, and the copious influx of blood into the containing and contained parts of the abdomen from the rest of the circulation. Experience has proved, that this alleged cause of the indisposition and even danger, which are apt to take place upon the discharge of the water, is founded in reality. A patient died during the operation: upon examination of the body, all the vessels of the brain were found quite empty, while those of the abdomen were turgid with blood. (Richter's *Anfangsgr.* Band 5, p. 147.) Several plans have been suggested, with the view of preventing the dangerous consequences under consideration. Some writers advise us not to let out all the fluid at once; but, after discharging only a part of it, to stop up the cannula secure in its place, and let out a certain quantity of the water every day. There is too great reason to apprehend, however, that the cannula, being a hard extraneous body, if left long in the wound, with a portion of it in the abdomen, would rub against and irritate the bowels, so as to excite inflammation, and other dangerous effects, especially when the quantity of fluid in the cavity of the peritoneum has been reduced to a small quantity. Others have recommended a repetition of the operation from time to time, and discharging on each occasion only a part of the fluid. The objections which have been urged against this plan are, that the water, which is left after the first performance of paracentesis, would ooze through the puncture, so as to prevent it from healing; and that if the operation were to be repeated a certain number of times, the quantity of fluid would be so small, that the abdomen could not be again punctured, without risk of the intestines being wounded by the trocar.

The means, commonly resorted to for the prevention of the bad symptoms apt to be produced by the operation, is making pressure with a bandage, or towel, applied round the body, as soon as the fluid has been discharged. The method seems, indeed, to be a rational one, and well calculated to answer the end proposed; but, unfortunately, if

PARACENTESIS.

it be not adopted till after the fluid has been let out, it is not likely to be of much service. After the water has been discharged, the bad symptoms have in general already come on. It was observed by Bertrandi, that a patient became faint in the operation every time the assistant remitted the pressure of his hands on the abdomen; a fact which proves, in Richter's opinion, that, in proportion as the parts cease to be compressed by the evacuation of the water, the blood is determined into them.

The celebrated Dr. Alexander Monro was the inventor of a sort of belt, for making the necessary pressure on the abdomen, during the operation of paracentesis; and it is certainly well adapted to the purpose. It is furnished with straps and buckles, which are fastened behind the patient; while in front it is provided with an aperture at the place where the trocar is to pass. It is applied before the operation, and, in proportion as the water escapes, the straps are drawn more and more tightly; so that when the whole of the fluid has been let out, the abdominal viscera are just as much compressed as they were before the performance of the operation. This belt, being applied previously to the puncture, the water is more particularly urged towards that point which is left uncompressed, namely, the place where the opening in the bandage is situated, and where the surgeon means to introduce the trocar. Here the integuments become prominent and tense, so that the instrument penetrates more easily, and without risk of injuring any of the internal parts. When Monro's belt or girdle is not at hand, a very good way of keeping up the requisite pressure, during the operation, is by means of a sheet, which is to be put round the abdomen, and to be gradually tightened by the assistants, in proportion as the fluid escapes. Immediately after the water has been discharged, a piece of lint and the emplastrum saponis are to be applied to the wound; a flannel compress, sprinkled with camphorated spirit or brandy, is to be laid over the abdomen; and a tight flannel roller put round the body. The patient is to be got into bed as quickly as possible, and may take the following draught: \mathcal{R} Ammoniz Muriat. gr. x. Mist. Camph. ζ iss Tinct. Opii \mathcal{M} xxx ft. haust.

In operating at the middle of the fore part of the abdomen, that is, at the linea alba, the surgeon cannot wound any artery of magnitude; though it is possible for him even here to have hemorrhage from a varicose enlarged vein, should he happen to wound such a vessel. The writer of this article, as already related, had a patient, who lost a very large quantity of blood, after being tapped in the linea alba with a lancet. But the most perilous kind of bleeding is that which proceeds from a wound of the epigastric artery, and which must ever be regarded as a serious objection to tapping at the side of the abdomen; because, in this method, no surgeon can be sure of not producing it. As the epigastric artery lies deeply, the blood may become extravasated in the abdomen, and the patient die of the consequences, without any continuance of external hemorrhage from the wound. When the wound bleeds profusely, the preceding artery having been injured, surgical authors advise us to introduce into the opening a cylinder of wax, of sufficient diameter to fill up completely the track of the trocar. Bellecq, a French surgeon, first adopted this plan with success; but in withdrawing the wax, after it had answered its purpose, it broke, and the part of it left behind did not come away till some time afterwards. Hence this practitioner was led to give the preference to the employment of a piece of a narrow wax-candle, the wick of which would render the whole stronger, and more certain of being drawn out again entire. Sabatier very properly thinks a piece of

a thick bougie might be still better. (Sabatier, Médecine Opératoire, tom. i. p. 178.) Thus far we have been speaking of paracentesis, as performed in cases of ascites: it is next proper to say a few words on the subject of encysted dropsies, and describe the mode of operating for them.

Sometimes the fluid is not contained in the cavity of the peritoneum itself, but in a preternatural cystus, the disease being then termed encysted dropsy. Various parts in the abdomen may be the seat of this disorder. The left lobe of the liver has been found distended into a sort of pouch, that was filled with an aqueous fluid. It is more common, however, for the omentum to be affected; but the ovaries and the cellular substance of the peritoneum are the parts, in which the disease takes place the most frequently of all.

Dropsy of the ovary makes its appearance first as a circumscribed moveable swelling on one side of the abdomen, and, in the beginning, is not uncommonly supposed to be a solid tumour. In general, the swelling enlarges very slowly, and the patient suffers no particular inconveniences from it. At length, however, it undergoes a rapid increase of size, and distends equally every part of the belly, so that it may now be easily mistaken for an ordinary case of ascites. Dropsy of the ovary may be discriminated from the latter disease, by paying attention to the following circumstances. Both in the early and more advanced stage, the feel of a fluctuation is never so plain as in ascites. Sometimes the fluid is contained in a large number of cysts, which have no communication with each other; and sometimes it is very thick and viscid; in which circumstances, scarcely any fluctuation at all is usually distinguishable. In particular instances, even when the whole abdomen appears, on a cursory view, to be every where uniformly distended, the prominences and inequalities caused by the separate cysts may be felt on more careful examination. The swelling of the abdomen hardly ever sinks downward to the most depending part, as it does in ascites. The urine is generally secreted in the ordinary quantity, and is of a natural quality. Even when the tumour has attained considerable magnitude, the patient has fewer complaints than in common dropsy; she breathes more freely, moves about easily, looks better, and is less troubled with thirst. In numerous instances, the patient suffers no inconveniences whatsoever, excepting such as are directly produced by the size and weight of the swelling. The menses of many patients are also quite regular, notwithstanding the disease is advanced. The navel never swells, as it occasionally does in ascites.

But although these are the usual symptoms of encysted dropsy, the disease is subject to several varieties, which sometimes facilitate the diagnosis, sometimes render it more difficult. For example, in certain cases, the fluctuation is as plain as in ascites. In others, the urine is thick, and secreted only in small quantities, and the feet swell, as is common in this latter disease. The swelling may increase with great rapidity, or it may only enlarge from time to time, and at length remain a good while stationary. Sometimes, as the disorder advances, pains occur in the cyst, and the patient is afflicted with colic, constipation, fever with emaciation, &c.

The fluid found in a dropsical ovary is never of a bright yellow colour, and transparent, as the water of ascites commonly is; but is always more or less discoloured, fetid, and blended with matter, blood, or a thick sediment. When, therefore, the exact nature of the case is not known before the operation is done, it is always ascertained then by the quality of the discharged fluid. Sometimes the fluid contained in the ovary is of a gelatinous kind. In other instances, this viscus is found filled with hydatids. In most

PARACENTESIS.

cases, the ovary is at the same time in a scirrhus state, and the inner surface of the cavity which it forms is ulcerated. Numerous patients live a considerable time with this disease. Twenty and even thirty years have been known to elapse, ere the disorder proved fatal.

Dropsy of the ovary is mostly observed to afflict women who have either had many children, or repeated abortions. It is generally incurable. Internal means avail little; the operation by which the fluid is let out is the only useful proceeding, and even this procures merely temporary relief, for, in general, the sac soon becomes filled with fluid again. Sometimes, indeed, the operation proves hurtful, and hastens the patient's dissolution. In the first performance of it, a clear fluid is usually discharged; but when it is repeated, the water is turbid, and mixed with blood and matter. The more frequently the operation is done, the more quickly does the water continue to accumulate again. Paracentesis seems not only to promote the ulceration of the cyst, but also to lower the patient, and bring her to the grave sooner than she would otherwise have arrived at it. Certain it is, at all events, that numerous patients, who have not been operated upon, have lived a long while with disease, while reiterated operations have in general been soon followed by a fatal termination.

Hence, when the swelling is not very large, and not productive of great inconvenience, we are advised by Richter to refrain from every means, and from the operation itself. He acknowledges, however, that there are cases where the operation may be judiciously and advantageously practised; namely, when the swelling is exceedingly large, and attended with much inconvenience. That it may be usefully done in certain instances, seems to be proved by examples, in which it was repeated forty-one times, (Medical Communications, vol. ii.), sixty-five times (Mead), and even 155 times (Philos. Transact. vol. lxxix.)

When it is known beforehand, that the disease is an encysted dropsy, one should choose rather a large trocar, because the fluid is usually thick, flaky, and viscous, and will not readily flow out through a narrow cannula. The place for making the puncture is not so determinate as in cases of ascites. The trocar is to be introduced where the tumour is not prominent, where the fluctuation is most distinct, where there is no obvious induration, and where there is no risk of wounding the epigastric artery. Dropsical enlarged ovaries are generally adherent to the peritoneum; but when they are not so, the performance of the operation may not be followed by any bad effects. Sometimes, both the ovaries are at the same time distended with fluid. In this case, after an ovary has been tapped, the operation may be practised on the other. When the water is contained in several different cysts, it is sometimes necessary to make no less than four or five punctures, in order to discharge a sufficient quantity of the fluid. In particular examples the fluid is so gelatinous, that it will not pass through the cannula, and, in this circumstance, it has been usual to dilate the puncture by an incision, so as to let out the contents of the swelling; but the cases have commonly had a fatal termination. Richter decidedly recommends us not to imitate the practice, but to withdraw the cannula, and abandon all thoughts of evacuating the fluid.

Since the discharge of the water, by means of a trocar, as in ascites, only palliates the disease for a short time, the question has been started whether any thing can be done with a view of effecting a radical cure? With this design, several plans have been suggested, the merit or demerit of which can only be determined by future and repeated experience. Le Dran has advised us to make an incision into the swelling,

so as to let the fluid which is daily secreted into the sac, have constantly a ready issue, and to keep the diseased cavity continually empty, in order that it may have an opportunity of contracting. (See Mem. de l'Acad. de Chirurgie, tom. vi.) The operation is done in two ways; viz. either a trocar is first introduced, and, after the water has been let out, and a director has been passed in through the cannula, the latter is taken away, and an incision four inches long made on the director; or else a trocar with a cannula having a fissure in it, is employed, through which fissure the puncture is enlarged with a bistoury.

After the operation, emollient injections are to be employed until the matter is of good quality, and then an attempt must be made to promote the closure of the aperture with injections of an astringent nature. Le Dran assures us, that such an operation has been actually practised with success. In cases where the cavity of the ovary is divided into several cysts, or where it is filled with a gelatinous fluid, or hydatids, and where, consequently, the palliative method is inapplicable, this operation is the only practicable undertaking.

There are so many things to be taken into consideration, however, that the surgeon will hardly be inclined to adopt such practice in ordinary cases. The uncertainty whether the ovary is adherent to the peritoneum, is often an unpleasant circumstance. A dropsical ovary is also commonly in a scirrhus state, a thing that must render the radical cure difficult, and even impossible. Before attempting it, we are advised by Le Dran always to let out the water with a trocar, and then examine whether any scirrhus induration can be felt, and, if it be perceptible, not to think of undertaking the radical cure. Le Dran also assures us, that scirrhus swellings, which may sometimes be felt at first, frequently subside during the continuance of the suppuration. This desirable event Richter thinks cannot be expected to happen often, and he apprehends that after the water has been discharged, the indurated part of the ovary will not always admit of being felt. The strongest argument against this operation, however, arises from the ill success which has hitherto attended it. In general, the suppuration soon afterwards becomes more copious and degenerated, and the patient dies of a lingering fever, at an earlier period than she would probably have done, had the operation not been done at all. In one example, Le Dran converted the wound into a fistula, by which means the patient lived a long while in a very tolerable condition.

Other practitioners, fearful of the free entrance of the air into a large incision, have suggested the plan of letting out the water with a trocar, and then introducing through the cannula a flexible hollow bougie, which is to be kept in the opening, until either a complete cure, or a fistula is produced.

Richter represents this operation as attended with several advantages, and no hazard. It has always been observed, that patients who have submitted to the palliative operation, always find themselves very well, until the fluid has accumulated again in considerable quantity. This last radical operation has at least the advantage, that while it keeps the sac empty, it also keeps the patient in the same tranquil state as is generally enjoyed for some days after the palliative method. When an incision has been made, it generally heals up again very soon, so that it becomes necessary to introduce a cannula. Thus, even supposing a large opening were useful, it is only of short duration. A few days after an incision has been made, the patient is in the same state as if a mere puncture had been practised, and a necessity arises for dilating the wound to its original size. We have noticed, that

PARACENTESIS.

that the incision has been known to change into a fistula, with which the patient survived a long while with tolerable health. By means of the puncture and flexible tube, an artificial fistula is immediately made. There is also only this difference between the incision and the puncture, that by the latter, the patient is at once placed in a state, in which experience proves that she mostly finds herself well, and capable of living a considerable time. On the contrary, the operation by incision always puts the patient's life at first into imminent danger.

There can be no doubt that paracentesis, and the employment of a flexible tube, will be more likely to prove successful the sooner they are tried. Experience shews, that the more frequently the water is drawn off by the palliative operation, the more blended with matter, the more bloody, and the more turbid it becomes, and the more rapidly it collects again. It appears also, that the repeated emptying and filling of the cyst again, always render the patient's condition worse, and promote ulceration within the dropsical cavity. A flexible tube should always be introduced directly after the first palliative operation, so as never to suffer the cyst to be filled again. The more the cyst is dilated before it is the first time punctured, the more likely is it to be in a morbid state, and the more improbable is the attempt at a radical cure to succeed: the water, therefore, should always be discharged as early as possible, and a flexible tube be immediately introduced. By observing this rule, we may rationally expect to accomplish in many instances a radical cure, and, when this success does not attend the plan, we may rest certain that the state of the patient will at all events be meliorated, and her life prolonged. During the first few days, the operation is occasionally followed by vomiting, fever, &c. which symptoms, however, are commonly unattended with danger, and soon give way to proper treatment. Richter's *Anfangsgrunde*, &c. band 5, kap. 6.

Some practitioners have recommended repeating the palliative operation from time to time, with a view of effecting a radical cure. Unfortunately, however, the cyst of a dropsical ovary cannot, in general, be safely tapped until considerably distended, and hence the plan does not promise much success; but in those kinds of encysted dropsy which lie more superficially, the method may answer better.

The encysted dropsy of the peritoneum is commonly seated in the cellular substance, between this membrane and the peritoneum. Here the cyst, which contains the fluid, is formed of condensed cellular substance. The prognosis must evidently be more favourable than in dropsy of the ovary. The surgeon detects the existence of the disease at an earlier period, and with greater facility, while the things to be considered, and the dangers to be feared in the treatment, are much fewer, and the hope of a radical cure far stronger than in a dropsical affection of the ovary. The cyst may be formed at any point of the circumference of the abdomen. Sometimes several cysts present themselves at the same time, forming at first so many separate tumours, which, as they enlarge, at length make one general swelling, in which, however, some irregularities may always be distinguished. The appearances and gradual changes of this sort of encysted dropsy resemble those which accompany dropsy of the ovary, with the exception of such symptoms as depend upon the different situations of the two diseases. When the cyst is situated at the lower and anterior part of the abdomen, the case may at first be easily mistaken for pregnancy; but a little attention to the different circumstances which characterise encysted dropsy and pregnancy, will soon dispel the error. In this kind of dropsy, a fluctuation may in general be more plainly felt, than in dropsy of the ovary. The sac is sometimes filled

with hydatids, and the disease is most frequent in women who have had many children.

As the swelling is soon obvious, and lies under the integuments and muscles, the palliative operation may be safely undertaken at a very early period, and be repeated when the cyst becomes at all prominent again. Here there is no possibility of an extravasation in the abdomen, nor of any of the viscera being wounded. A radical cure is frequently effected, as the case is not complicated with any scirrhus induration, and the attempt may be made early, before the cyst is of large size. The best mode of performing the operation is as follows: a puncture is first to be made, and a flexible tube introduced, which is to be kept in until the cavity of the cyst is as much contracted as possible; the wound is then to be dilated, and the cavity allowed to suppurate and fill up by the granulating process. Sometimes a fistula will after all remain, but it is attended with still less inconvenience than such a consequence usually is in cases of dropsical ovaries. See Richter's *Anfangsgrunde der Wundarzneeykunst*, band 5, kap. 6.

Paracentesis of the Bladder.—This operation becomes indispensable, when the symptoms of a retention of urine are urgent, and this fluid cannot be voided through the natural channel so soon as the circumstances of the case absolutely require. The operation is proper also, only where all other means of promoting the evacuation of the urine have failed, and where there is reason to hope that the natural passage for this secretion will be in a moderate length of time re-established: for it is to be regarded merely as a palliative measure. Such a case is not very frequent. The operation itself is not the occasion of much danger, and the chief peril mostly arises from the puncture having been too long deferred.

Although, however, it appears to us, that the operation of puncturing the bladder ought not to be long postponed, after milder methods have decidedly failed, we believe that these methods will almost always prove successful under skilful hands, and that the operation may generally be avoided. In the opinion of Default, there are very few instances in which a surgeon, expert at introducing the catheter, cannot pass this instrument into the bladder, and consequently the cases in which paracentesis is absolutely necessary, must be exceedingly unfrequent. This assertion, says Bichat, might be confirmed by a multitude of cases. During the years of the time when Default was principal surgeon of the Hôtel-Dieu at Paris, where diseases of the urinary passages, and more especially obstructions of the urethra, are constantly numerous, this distinguished practitioner never had occasion to puncture the bladder, except in one example. This case happened soon after his appointment to the hospital, and he used to declare, subsequently, that if he had then had as much experience, and had possessed as much skill in introducing the catheter as he had afterwards acquired, he might, perhaps, have extricated this individual patient from the necessity of submitting to the operation. But, as Bichat observes, since it is not every practitioner that is skilful enough to make the catheter surmount the various obstacles which may present themselves to its passage, without risk of producing a false passage, or doing other serious mischief; and since the urethra may sometimes be totally obstructed, so that no catheter nor bougie, though introduced as far as the stoppage, can serve to give exit to the urine; the operation, in these circumstances, becomes positively indispensable, for the purpose of relieving the urgent symptoms arising from the retention, and in order to prevent the bladder from bursting. *Cœuvres Chirurg. de Default*, par Bichat, tom. iii. p. 316.

PARACENTESIS.

The circumstances in which puncturing the bladder becomes necessary and proper, will be hereafter noticed again. See URINE, *Retention of*.

There are three situations in which the surgeon may tap the bladder; *viz.* from the perineum; above the os pubis; and from the rectum. As the first mode of operating is nearly exploded, and has nothing to make it preferable to the two others, we shall omit a description of it in this work.

Paracentesis of the Bladder above the Pubes.—There are some practitioners who prefer making a perpendicular incision, about two inches in length, through the integuments and fat, covering the lower part of the linea alba. When this plan is followed, the wound ought not to be made, as some authors direct, with its lowest part full an inch above the os pubis. There is no great reason for keeping so far from this bone, and the lower the incision is made, the nearer it is to that part of the bladder which is the most desirable to puncture, and the further it is from the peritoneum. Hence, the lower angle of the incision should nearly meet the upper part of the symphysis pubis. A cut of the same length is next to be made between the pyramidal muscles, and, this being done, the surgeon will be able to feel with his finger the prominent distended bladder. A trocar, the curvature of which forms the segment of a circle seven inches in diameter, is now to be introduced into the exposed part of this viscus. When this instrument is held with its convexity upward, that is, towards the patient's navel, it can be more conveniently introduced obliquely downward, and backward, into the bladder, in the direction of the axis of this organ, than any straight trocar can possibly be set. M. Sabatier observes, a curved instrument of this kind is also much less likely to penetrate the back part of the bladder and wound the rectum, besides having this advantage, that when the urine is discharged, and the bladder collapsed, the cannula will not be so apt, as that of a straight trocar, to slip out of the part into which it has been introduced. *De la Médecine Opératoire*, tom. ii. p. 128, 129.

However, there can be no doubt, that when the bladder is certainly distended with urine, and the swelling distinct and prominent, it is perfectly safe to introduce the trocar at once into the bladder, without any preliminary division of the integuments, fat, &c.

When the operator perceives, by the want of resistance, that the point of the instrument is in the bladder, he is to take hold of the mouth of the cannula, and while he pushes the tube further inward, he is to withdraw the stylet. The cannula is to be allowed to remain in the wound after the urine is evacuated. Its mouth may be closed with any kind of stopper, which cannot insinuate itself into the bladder, and it may be kept from slipping out by means of two pieces of tape, which are to be passed through the two little rings at the sides of the instrument.

There are surgeons who recommend an elastic gum catheter to be passed into the bladder through the cannula, and then taking the latter away. The advantage of this practice is not at all obvious, and, as for ourselves, we are positively adverse to the practice. An elastic gum catheter does not fill the wound; consequently, the urine is discharged, not only through the tube, but also between the sides of the wound and the circumference of the instrument, so that the chance of the urine becoming diffused into the cellular membrane is not guarded against, as it is by allowing the cannula to remain in the wound, at least two or three days, until the inflammation has closed the interstices of the surrounding cellular substance, and removed

the possibility of the urine becoming extravasated. It is now known, that, after the above period, the cannula may be safely taken out, and easily introduced as occasion may require.

Another objection to introducing an elastic gum catheter is the length of such an instrument, the end of which would produce irritation in the bladder. The use of long, straight silver cannulae has been known to form a communication between the bladder and rectum, in consequence of ulceration, or sloughing, produced by the pressure of the points of these instruments on the back part of the bladder. Mr. Samuel Sharp mentions his having seen this accident. *Critical Enquiry*, &c. p. 127, edit. 4.

It is obvious, that the outlet made for the urine by the operation of paracentesis, is merely designed as a temporary one, and that as soon as the impediment to the passage of the urine through the urethra is removed, the wound ought to be allowed to heal.

Whenever the prostate gland is known to be very much enlarged, one would certainly prefer this mode of operating to puncturing the bladder through the rectum. The wound is made in a situation where there is no risk of injuring any part of importance; but, in this method, little as the chance may be of an extravasation of urine taking place, it is undoubtedly a possible event, and the opening is not made in a depending place, so that the whole of the urine cannot very well be voided through it.

Paracentesis of the Bladder from the Rectum.—The patient is to be put in the posture which is usually chosen for the lateral operation for the stone. (See LITHOTOMY.) An assistant is to make pressure on the abdomen, just above the os pubis, in order to make the prominence of the bladder plainer to the surgeon's finger in the rectum. A curved trocar, with its point drawn within the cannula, is to be introduced with the right hand, and conveyed upon the left fore-finger, as high as the surgeon can reach up the intestine, along the swelling formed by the distended bladder. The instrument should be kept exactly in the central line of the front portion of the rectum, and, when conveyed sufficiently beyond the prostate gland, the point of the trocar is to be pushed into the bladder, through the interior part of the intestine.

This operation is so easy and safe, that it must be allowed to merit a general preference. The coats of the rectum and bladder are here almost in immediate contact, and the instrument has to penetrate no thickness of substance. The operation is not more painful than venesection, and the distended bladder is so distinctly perceptible to the finger, that no mistake can well be made. The only chance of doing mischief arises from the situation of the vesiculæ feminales; but all risk may be avoided, by introducing the finger very high up the rectum, and making the puncture exactly in the central part of the swelling. The trocar must, of course, be of a length sufficient to admit of the operation being done according to these principles.

The only inconvenience following the operation, is the necessity of keeping the cannula introduced through the anus until the urine resumes its natural course. This circumstance is not only very troublesome when the patient is walking, or sitting down, but is particularly incommode when he goes to stool. The difficulty of voiding hardened feces, however, while the instrument is introduced, may always be obviated by injecting a clyster. Whenever the patient has a motion, it is, of course, necessary for him to hold the cannula with his fingers, or else it would be protruded.

We have no facts on record, however, which justify the conclusion,

conclusion, that any serious harm would result from withdrawing the cannula immediately after paracentesis of the bladder from the rectum. If the urethra were not pervious at the time, the frequent passage of the urine through the puncture would probably be sufficient to keep it from becoming closed, and the occasional passage of this fluid, through the lower part of the rectum, would be far less annoying, than the continual presence of the cannula. There is one instance in which the cannula was inadvertently withdrawn forty-eight hours after the operation, and could not be introduced again. The urine was discharged into the rectum, through the puncture, for six days afterwards, and, as soon as it began to pass out through the urethra, the wound healed, without leaving any filulous communication between the bladder and the intestine. (Bentley in Med. Communications, vol. i.) Richter, indeed, assures us, that the cannula has even been taken out immediately after the operation without any ill consequences. (Anfangsgr. &c. band 6 p. 328.) Women seldom require the performance of paracentesis of the bladder. Retroversio uteri, however, is one case, which may render such proceeding absolutely necessary. The operation may be done in two ways, viz. from the vagina, and above the pubes. See Sabatier's Médecine Opératoire, tom. ii. Sharp's Critical Enquiry, &c. Richter's Anfangsgrunde, &c. band 6. First Lines of the Practice of Surgery, by Samuel Cooper, edit. 3. &c. &c.

PARACENTRIC MOTION, in *Astronomy*, a term used for so much as a revolving planet approaches nearer to, or recedes farther from, the sun, or centre of attraction.

Thus, if a planet in A, (*Plate XVIII. Astronomy, fig. 2.*) move to B, then SB — SA = bB, is the paracentric motion of that planet.

PARACENTRIC Solicitation of Gravity amounts to the same with the *vis centripeta*; and in astronomy, is expressed by the line AL, (*Plate XVIII. fig. 3.*) drawn from the point A parallel to the ray SB (infinitely nearer SA) till it intersects the tangent BL.

PARACHO, in *Geography*, a town of Hindoostan, in the cirçar of Gohud; 15 miles N. of Narwa.

PARACHUETEAS, a town of West Florida, near the Apalachicola. N. lat. 31° 24'. W. long. 85°.

PARACHURECOLL, a town of Hindoostan, in Marwar; 7 miles N.W. of Tripatore.

PARACHUTE, a machine in the form of an umbrella, sometimes annexed to a balloon, and sometimes used separately, and serving to buoy up a heavy body in its ascent, or to prevent its precipitate fall (as its name imports) in the atmosphere. (See *AEROSTATION*). Umbrellas have been used for this purpose from remote times in various parts of the East Indies. In the "Historical Relation of the Kingdom of Siam," by M. de la Loubere, who visited that country in the years 1687 and 1688, we have an account of the manner in which umbrellas were employed in the diversions of the court of Siam. "There died one," says this writer, "some years since, who leaped from a hoop, supporting himself only by two umbrellas, the hands of which were firmly fixed to his girdle: the wind carried him accidentally sometimes to the ground, sometimes to trees or houses, and sometimes into the river. He so exceedingly diverted the king of Siam, that this prince had made him a great lord, he had lodged him in the palace, and had given him a great title, or, as they say, a great name." See *UMBRELLA*.

PARACLET, a name which the church has given to the

Holy Spirit; from the Greek Παράκλησις, q. d. *comforter*, or *advocate*.

PARACME, Παράκμη, a Greek word signifying *declension*, or a thing's being past its height.

PARACOPE, or **PARACRUSIS**, a word used by Hippocrates to express a slight delirium in fevers.

PARACUSIS, from Παράκουσις, *non recte audio*, signifies, in the language of the nosologists, *depraved hearing*. The term is not applied to simple deafness, that is, to a mere diminution or abolition of the sense of hearing; but to those varieties of imperfect hearing, in which all sounds are heard incorrectly; as for instance, with hissing, ringing, or other noises; and to over-acute as well as obtuse powers of hearing. See Cullen, *Nofol. Meth. Gen.* 97.

PARACYNANCHE. See *CYNANCHE*.

PARADANGA, in *Geography*, a town of Bengal; 25 miles E.N.E. of Rungpour.

PARADE, the show, or exposure of any thing to view, in all its advantages and ornaments.

Bed of parade, is that in which a person lies in state.

PARADE, in *War*, a place where troops assemble, or draw together, in order to exercise or go on any service.

PARADE is more properly the appearance of the officers and soldiery at a post assigned them, to put themselves under arms, in the best order they can; either to mount, or break up the guard, or to form a battalion, or on some other occasion.

PARADE, in *Fencing*, is the action of parrying or turning off any push or stroke.

There are as many kinds of parades, as of strokes and attacks; as the parade inward, outward, above, below, feigned, &c.

PARADE is used in France for a species of farce, which was merely designed to amuse, and to excite mirth.

PARADE de Bouro, in *Geography*, a town of Portugal, in the province of Entre Duero e Minho; 16 miles N.N.E. of Braga.

PARADELLA, a town of Portugal, in the province of Beira; 12 miles S.E. of Lamego.

PARADES, a town of Spain, in the province of Seville; 5 miles S. of Carmona.

PARADIAZEUXIS, near a disjunction, was in the ancient Greek music, according to Bucehnius Senior, the interval only of a tone between the strings of the two tetrachords; such is the disjunction, for instance, which occurs between the tetrachord *fynemenon*, and the tetrachord *diezeugmenon*. See these several words.

PARADIES, DOMENICO, in *Biography*, a Neapolitan, arrived in England in 1742, at the beginning of lord Middlesex's opera regency. In 1747 he set "Fetonte," or Phaeton, for the theatre in the Haymarket. The drama was written by Vaneschi, afterwards manager of that theatre. In examining the airs of this opera, as set by Paradies, that were printed, the first seems very common and ill-phrased, nor is there much *glro*, or grace, in any of his songs that we have seen. Indeed he seems to have had no great experience as an opera composer. And during his residence in England he acquired more reputation by the lessons he published for the harpsichord, and the scholars he made on that instrument, for which he was an admirable master, than by his vocal compositions. His little scholar, Frederica, afterwards Mrs. Wynne, gained him so much reputation as a harpsichord master, that he was appointed to instruct the young princesses at Leicester-House; and had soon the offer of more scholars elsewhere than he could undertake.

His book of 12 lessons has great merit: steering between

tween Scarlatti and Alberti, and adding many new passages of brilliant execution, strung together in a mallyerly manner; yet they seem detached, and to form no style, or unity of melody.

PARADIGM, PARADIGMA, formed from *παράδειγμα*, *exemplar*, of *παρά*, and *δεικνυμι*, *ostendo*, q. d. *justa ostendo*, an example, or instance, of something said or done. See EXAMPLE.

Grammarians have appropriated the word paradigm to examples of declension and conjugations, which may serve as models for other words of the like kind.

PARADIGRAMMATICE, is used by some for the art of making all sorts of figures in plaiter. The artists in this are called *gyfsochi*.

PARADIN, WILLIAM, in *Biography*, an industrious French author, who flourished in the 16th century, but of whose personal history little more is known than that he was living about the year 1581. His most important works were "The Chronicle of Savoy," divided into two parts: the first part treats of the counts, and the second of the dukes of that country: "Aristeus's History of the Sepuagint:" "History of his own Times:" "Memoirs of the City of Lyons."

PARADIS, *Mademoiselle* THERESA, a young person, equally distinguished by her talents and misfortunes, was the daughter of M. Paradis, secretary to his imperial majesty, in the Bohemian department, and god-daughter to the late empress queen.

At the age of two years and eight months, she was suddenly deprived of sight by a paralytic stroke, or palsy in the optic nerves.

At seven years old, she began to listen with great attention to the music she heard in the church, which suggested to her parents the idea of having her taught to play on the piano forte, and, soon after, to sing. In three or four years' time she was able to accompany herself on the organ in the "Stabat mater" of Pergolesi, of which she sung the first *soprano*, or upper part, in the church of St. Augustin, at Vienna, in the presence of the late empress queen; who was so touched with her performance and misfortune, that she settled a pension on her for life.

After learning of several masters at Vienna, she pursued her musical studies under the care of Kozeluch, who has composed many admirable lessons and concertos on purpose for her use, which she played with the utmost neatness and expression.

At the age of thirteen she was placed under the care of the celebrated empyric, Dr. Mesmer, who undertook to cure every species of disease by animal magnetism. He called her disorder a perfect *gutta serena*, and pretended, after she had been placed in his house as a boarder for several months, that she was perfectly cured; yet refusing to let her parents take her away, or even visit her, after some time, till, by the advice of the barons Stoërk and Wenzel, Dr. Ingenhous, professor Barth the celebrated anatomist, and the express order of her late imperial majesty, she was taken out of his hands by force; when it was found that she could see no more than when she was first admitted as Mesmer's patient. However, he had the diabolical malignity to assert that she could see very well, and only pretended blindness, to preserve the pension granted to her by the empress queen; and since the decease of this princess, the pension of Mad. Paris was withdrawn, indiscriminately, with all other pensions granted by her imperial majesty.

Mad. Paradis quitted Vienna, in order to travel, accompanied by her mother, who treated her with ex-

treme tenderness, and was a very amiable and interesting character. After visiting the principal courts and cities of Germany, where her talents and misfortunes procured her great attention and patronage, she arrived at Paris, and remained there five or six months, and received every possible mark of approbation and regard in that capital, both for her musical abilities, and innocent and engaging disposition.

When she arrived in England, she brought letters from persons of the first rank to her majesty, the prince of Wales, the imperial minister, count Kageneck, lord Stormont, and other powerful patrons, as well as to the principal musical professors in London. Messrs. Cramer, Abel, Salomon, and other eminent German musicians, interested themselves very much in her welfare; not only as their countrywoman, bereaved of sight, but as an admirable performer.

She went to Windsor, to present her letters to the queen, and had the honour of playing there to their majesties, who were extremely satisfied with her performance, and treated her with that condescension and kindness, which all who are so happy as to be admitted into the presence of our gracious sovereigns, in women's of domestic privacy, experience, even when less intitled to it by merit and misfortunes than Mad. Paradis. Her majesty was not only graciously pleased to promise to patronize and hear her frequently again in the course of the winter, but to afford her all the protection in her power; as did his royal highness the prince of Wales, to whom she since performed, at a grand concert at Carlton house, to the entire satisfaction and wonder of all who heard her.

Besides her musical talents, which were indisputable for neatness, precision, and expression, particularly in the great variety of admirable pieces she executed of her maller, Kozeluch, Mad. Paradis was extremely well educated, and was very ingenious and accomplished; as she was able, with printing types, to express her thoughts on paper, almost as quick as if she could write. She understood geography, by means of maps prepared for her use, in which she could find and point out any province, or remarkable city in the world; and was likewise able, by means of tables formed in the manner of draught-boards, to calculate, with ease and rapidity, any sums or numbers in the first five rules of arithmetic. She is likewise said to have distinguished many colours and coins by the touch; played at cards, when prepared for her by private marks unknown by the company; and in her musical studies, her memory and quickness were wonderful: as she learned in general the most difficult pieces for keyed instruments, however full and complicated the parts, by hearing them played only on a violin: and since her arrival in this kingdom, she was enabled, in this manner, to learn to perform some of Handel's most elaborate and difficult organ fugues and movements in his first book of Lessons, as well as his Coronation Anthem, and more popular compositions.

Since her arrival in England she received a cantata, written for her in the German language, by the celebrated professor of mathematics, M. Pfeffel, of Colmar, who is himself blind. This cantata has been admirably set to music for her own voice and accompaniment on the piano forte, and she executed it in a truly pathetic and able manner. Her voice was not so powerful as her hand; but it is touching in itself, and her knowledge of music and circumstances rendered it doubly interesting.

Madame Paradis having entreated Dr. Burney, who has had letters from Germany in behalf of her ingenious daughter,

ter, and was very zealous in her service, to translate this cantata; we have procured the following copy of his version :

Cantata, written in German for Mad. Paradis, by her blind friend M. Pfeffel, of Colmar, and set to music by her music-maſter, M. Leopold Kozeleuch, of Vienna, November 11, 1784.

Imitated by Dr. Burney.

- “ The new-born infant sporting in the fun,
Is the true ſemblance of my infant ſlave,
When ev’ry prize for which life’s race is run
Was hidden from me by malignant fate.
- “ Infant deſtruction quench’d each viſual ray,
No mother’s tears, no objects were reveal’d !
Extinguiſh’d was the glorious lamp of day,
And ev’ry work of God at once conceal’d !
- “ Where am I plunged ? with trembling voice I cried,
Ah ! why this premature, this ſudden night !
What from my view a parent’s looks can hide,
Thoſe looks more cheering than celeftial light !
- “ How ſhould I wander through the gloomy maze,
Or bear the black monotony of woe,
Did not maternal kindneſs gild my days,
And guide my devious footſteps to and fro !
- “ Thereſa ! great in goodneſs as in power,
Whoſe fav’rite uſe of boundleſs ſway,
Was benefits on all to ſhower,
And wipe the tear of wretchedneſs away.
- “ When firſt my hand and voice eſſay’d,
Sweet Pergoleſi’s pious ſtrains,
Her pitying goodneſs ſhe diſplayed,
To cheriſh and reward my pains.
- “ But now, alas ! this friend to woe,
This benefactreſs is no more !
And though my eyes no light beſtow
They’ll long with tears her loſs deplore !
- “ Yet ſtill wher’er my footſteps bend,
My helpleſs ſtate has found a friend.
- “ The wreathes my feeble talents ſhare,
The balmy ſolace friends employ,
Lifting the ſoul above deſpair,
Convert calamity to joy.”

PARADIS. See PLATE *Forme*.

PARADISE, in *Geography*, a townſhip of America, in Pennſylvania, in the county of York, containing 1275 inhabitants.

PARADISE, a term primarily uſed for the place in which Adam was ſeated, during his innocence ; and from which he was expelled for diſobeying God : this is called, in a ſtricter manner, the *Terreſtrial Paradise*.

The word is formed of *παρδειſος*, *orchard*, a place ſtored with apples, and all kinds of fruits. Moſes calls it the *Garden of Eden*, q. d. garden of delight, from *עֵדֶן*, *edem*, *voluptas*, *pleaſure*.

The critics are in diſpute about the precise place of Paradise. Some, as Hardouin, &c. will have it in Judea, in the place where now is the lake Genefareth ; others, as Le Clerc, &c. in Syria, towards the ſprings of the Orontes, and Chryſorrhoe : but in neither of thoſe places do we diſcover any track of the rivers with which the Paradise in Moſes’s deſcription was watered. Calmet, and ſome other ingenious critics, have placed the terreſtrial Paradise in Ar-

menia, near mount Ararat, where Noah’s ark was left ; and imagine they there diſcover the ſources of the four rivers which watered the garden of Eden, *viz.* Euphrates ; Hiddekel, now the Tigris ; Gihon, now Araxes ; and Piſon, now Phazzo. But ſir J. Chardin aſſures us in his travels, that the Phazzo ſprings out of the mountains of Caucaſus, northward of the kingdom of Imereti, and far enough from mount Ararat : beſides, that in Armenia we have no ſigns of the countries of Havila and Ethiopia, which thoſe rivers waſhed after their departure from Eden.

There are various other opinions, as to this point : Poſtellus will have Paradise placed under the north pole ; grounding his notion upon an ancient tradition of the Egyptians and Babylonians, that the ecliptic or ſun’s way was at firſt at right angles to the equator ; and ſo paſſed directly over the north pole. Others are againſt limiting it to any one place, and contend, that it included the whole face of the earth, which was then, as it were, one continued ſcene of pleaſures, till altered upon Adam’s tranſgreſſion.

However, both theſe opinions are equally incompatible with the account in the book of *Genesis* ; others, as Origen, Philo, &c. interpret the ſcripture relation of Paradise allegorically.

But the moſt common and probable opinion is that of Hopkinſon, Huet, Bochart, &c. who place Paradise between the confluence of the Euphrates and Tigris, and their ſeparation. Theſe rivers are two of thoſe with which the garden of Eden was watered : Piſon was a branch ariſing out of one of them after their ſeparation ; and Gihon another branch ariſing from the other, on the ſide of Armenia, or the weſt : accordingly Ethiopia, one of the countries which theſe rivers waſhed, was inconteſtably Arabia Deſerta ; for Moſes calls his wife, who was of this country, an Ethiopian ; and Havilah, the other country, muſt have been the Chuiſtan in Perſia ; where were anciently found gold, bdellium, the onyx, &c. mentioned in Moſes’s deſcription.

The great difficulty in this ſyſtem is, that Moſes ſpeaks expreſſly of four rivers, each of which had its ſource in the garden of Eden ; whereas this gives us only two rivers, which were ſeparated into four branches. See EDEN.

PARADISE is alſo uſed in the New Teſtament, and by Chriſtian writers, for the final habitation of the bleſſed, or HEAVEN : which ſee.

PARADISE *Loſt*, a poem, which, whether it be referred or not to the claſs of thoſe poems that are denominated *Epic* (ſee that article), is juſtly deemed one of the higheſt efforts of poetical genius, and in one great characteristic of the epic poem, majeſty and ſimplicity, fully equal to any which bear that name. With reſpect to the choice of his ſubject, it has been queſtioned whether Milton was altogether happy ; and it has been ſuggeſted, that, if it had been more human, and leſs theological, and more connected with the occurrences of life, ſo as to have afforded a greater diſplay of the characters and paſſions of men, his poem would have been more acceptable and pleaſing to the bulk of readers. However, his ſubject was ſuited to the daring ſublimity of his genius. To this purpoſe Dr. Johnſon aſſures us, (*Life of Milton*,) that “ he ſeems to have been well acquainted with his own genius, and to know what it was that nature had beſtowed on him more beautifullly than upon others ; the power of diſplaying the vaſt, illuminating the ſplendid, enforcing the awful, darkening the gloomy, and aggravating the dreadful. He therefore choſe a ſubject, on which too much could not be ſaid ; on which he might tire his fancy, without the cenſure of extravagance.”

In the conduct of the ſubject which he has ſelected, he has ſhewn a very wonderful ſtretch of imagination and in-

vention, and he has admirably sustained the various characters—he has assumed, and made the most of the scanty materials which he derived from the sacred scriptures. Some, indeed, have lamented that he has added to these a variety of incidents, which have served to perpetuate erroneous doctrines in theology, and a system of demonology of his own creation, without sufficient warrant from the sacred writings. However this be, “the general tenor of his work is interesting; he seizes and fixes the imagination: engages, elevates, and affects us as we proceed; and this is always a sure test of merit in an epic composition. The artful change of his objects: the scene laid now in earth, now in hell, and now in heaven, affords a sufficient diversity, while unity of plan is at the same time perfectly supported. We have still life and calm scenes, in the employments of Adam and Eve in Paradise; and we have busy scenes, and great actions, in the enterprise of Satan, and wars of the angels. The innocence, purity, and amiableness of our first parents, opposed to the pride and ambition of Satan, furnish a happy contrast, that reigns throughout the whole poem:” though the conclusion is, in Dr. Blair’s opinion, too tragic for epic poetry. Although the nature of Milton’s subject did not admit any great display of characters, those which he has introduced are supported with much propriety. Satan is the best drawn character in the poem, inasmuch that some have said, either seriously or jocularly, that he was the hero of his poem. (See HERO.) The different characters of Beelzebub, Moloch, and Belial, are well painted in their eloquent speeches. Among the good angels, always described with propriety, though with greater uniformity than the infernal spirits in their appearance, the dignity of Michael, the mild condescension of Raphael, and the tried fidelity of Abdiel, form characteristic distinctions. In the adventurous attempt to describe God Almighty himself, and to recite dialogues between the Father and the Son, Milton, as we might naturally expect, has been most unsuccessful. With regard to human characters, the innocence of our first parents, and their love, are finely and delicately painted. Eve is more distinctly characterized than Adam. Her gentleness, modesty, and frailty, very expressively mark a female character.

Milton’s distinguishing excellence is his sublimity, in which he far surpasses Virgil, and every other poet, and is thought by some to excel even Homer. The prospect of hell, and of the fallen host, the appearance and behaviour of Satan, the consultation of the infernal chiefs, and Satan’s flight through chaos to the borders of this world, manifest the most lofty ideas that ever entered into the conception of any poet. Indeed, the first and second books are continued instances of the sublime. In the sixth book there is also much grandeur, particularly in the appearance of the Messiah; but in this book, the witticisms of the devils upon the effect of their artillery, form an intolerable blemish. It is observed that Milton’s sublimity is different from that of Homer. That of the latter is generally accompanied with fire and impetuosity; while Milton’s possesses more of a calm and amazing grandeur. Homer warms and hurries us along; Milton fixes us in a state of astonishment and elevation. Homer’s sublimity is most conspicuous in the description of actions; Milton’s in that of wonderful and stupendous objects. Milton also unites with his sublimity, much of the beautiful, the tender, and the pleasing, in many parts of his works. Milton’s language and versification possess high merit. His style is full of majesty, and wonderfully adapted to his subject. His blank verse is harmonious and diversified, and affords the most complete example of the elevation, which our language is capable of attaining by the force of numbers. “Upon the whole,” as Dr. Blair observes in the conclusion of his criti-

cism upon this poem, “Paradise Lost is a poem that abounds with beauties of every kind, and that justly entitles its author to a degree of fame not inferior to any poet; though it must be also admitted to have many inequalities. It is the lot of almost every high and daring genius, not to be uniform and correct. Milton is too frequently theological and metaphysical; sometimes harsh in his language; often too technical in his words, and affectedly ostentatious of his learning. Many of his faults must be attributed to the pedantry of the age in which he lived. He discovers a vigour, a grasp of genius equal to every thing that is great; if at some times he falls much below himself, at other times he rises above every poet, of the ancient or modern world.” Blair’s Lectures, vol. iii.

Mr. Addison’s criticisms on the Paradise Lost contained in the “Spectator,” are in every body’s hands. They comprehend the fable, the characters, the sentiments, and the language of this poem. See ACTION, EPIC Poem, FABLE, &c. &c. See also the biographical article of MILTON.

PARADISE, *Birds of*, in *Ornithology*. See PARADISEA.

PARADISE, *Golden Bird of*. See ORIOLUS Aureus.

PARADISE Sound, in *Geography*, a bay on the S.W. part of Placentia, on the coast of Newfoundland. N. lat. 47° 30'. W. long. 54° 15'.

PARADISEA, the Bird of Paradise, in *Ornithology*, a genus of birds of the order Picæ, of which the generic character is; bill covered with a belt of downy feathers at the base; feathers of the sides very long; two of the tail-feathers naked; legs and feet very large and strong. These birds chiefly inhabit New Guinea, from which they migrate in the dry season into the neighbouring islands. Their feathers are used in these countries as ornaments for the head-dress; and the Japanese, Chinese, and Persians import them for the same purpose. Among the latter, the principal people attach these brilliant collections of plumage, not only to their own turbans, but to the housings and harness of their horses. They are seldom found many degrees beyond the equator. Gmelin enumerates twelve species, Shaw fifteen, and Latham only eight. We shall give those of Gmelin.

Species.

APODA; Greater Bird of Paradise. Chestnut; neck beneath gold-green; feathers on the sides longer than the body; the two middle tail-feathers are long and bristly. There is a variety which is less, and the body above is yellow; the feathers on the sides are yellowish-white. The two long tail-feathers are naked, straight, and tapering to the tip; the tail, as it is improperly called, is nothing more than the long feathers of the back and flanks. These birds are found in the Molucca islands, and those surrounding New Guinea, particularly in Aroo, where they arrive with the westerly or dry monsoon, and whence they return to New Guinea, when the easterly or wet monsoon sets in. They are seen going and returning in flights of thirty or forty, conducted by a leader, which flies higher than the rest. During this flight they cry like starlings. By a sudden shifting of the wind, their long scapular feathers are sometimes so dishevelled as to preclude flying, when they fall to the ground, or are lost in the water. In the former case they cannot rise again into the air, without gaining an eminence, and are secured by the natives, and killed on the spot, as they cannot be preserved alive by art. They are likewise caught with bird-lime, or shot with blunt arrows, or are sometimes intoxicated with the berries of *Menispermum cocculus* put into the water which they are accustomed to drink. Their real food is not known with certainty. According to some authors, they feed on the red berries of the *Waringa-tree*, the *Ficus benjamina*; according

ording to others they are particularly fond of nutmegs; some assert that they live on large butterflies and moths, and others that they chase and devour small birds.

REGIA; King's Bird of Paradise. This is of chestnut-purple, whitish beneath; two middle tail-feathers filiform, feathered, and femilunar at the tips; the breast is blueish; the cirri of the tail are very long; the feathers under the wings are longer than the rest; the tail is short and truncate; from five to seven inches long, and about the size of a lark. It is said not to associate with any other birds of Paradise, but shifts in a solitary state from bush to bush in quest of red berries, and never gets on tall trees. It is found on the islands of the Indian ocean, and returns to New Guinea in the rainy season.

TRISTIS; Grakle Bird of Paradise. This has a triangular naked space behind the eyes; the head and neck are brown. It inhabits the Philippine islands; is nine inches and a half long; feeds on fruit, insects, mice, and every kind of grain; builds twice a-year in the forked branches of trees; it lays four eggs; when young it is easily tamed, and becomes docile and imitative. The bill and legs are yellow; the body is brownish; the first quill-feathers are white from the base to the middle; tail-feathers, except the middle ones, are tipped with white. This bird has a great affinity in all its habits to the grakle genus, yet, on account of the downy feathers at the base of the bill, it is placed among the birds of Paradise.

MAGNIFICA; Magnificent Bird of Paradise. Chestnut-brown above; chin green, with golden lunules; crown with a tuft of yellow feathers. It inhabits New Guinea, and is about nine inches long. This is a singularly beautiful species, and a figure of it is given by Latham. The first quill-feathers are brown, secondary deep yellow; middle tail-feathers very long, with a short fringe; legs and bill yellow, the latter black at the base and tip.

CIRATA; Crested Bird of Paradise. Head, neck, and wings black; tuft of hairs near the crown and frontlet yellow. It inhabits New Guinea, and is eighteen inches long.

NIGRA; Gorget Bird of Paradise. Black; beneath slight green; hind head, nape, crown, and band on the middle of the belly fine green, under the chin a splendid gold-coloured crescent. It inhabits the islands of the Indian ocean, and is twenty-eight inches long. There are twelve unequal tail-feathers, the outer ones five inches long, and the two in the middle about twenty-two inches.

LEUCOPTERA; White-winged Bird of Paradise. Black; crown shining copper; quill-feathers white, edged with black on the outside; the tail is very long and wedged.

SUPERBA; Superb Bird of Paradise. This species is crested; the head, crown, and belly are green; the chin is violet, silky; wings black; tail with a shade of green. It is found in New Guinea, and is about ten inches long. The bill is black; the legs are brown; under the wings a tuft of loose, black, silky feathers, as long as the wings when folded.

FURCATA. This is black; under the wings is a downy tuft; feathers in the middle of the belly like a forked tail; shining-green.

AUREA; Gold-breasted Bird of Paradise. Crested, black; crown, cheeks, and chin violet-black; throat, spot on the neck, and breast shining-green; at the region of the ears, on each side, are three long bristly feathers. It inhabits New Guinea, and is the size of a turtle dove.

VIRIDIS; Blue-green Bird of Paradise. Sea-green; back, belly, rump, and tail steel-blue. It inhabits New Guinea, and is sixteen inches long. The bill is thick and

black; the plumage on the head is silky, and on the body it appears as if it were crisp at the tips.

ALBA; White Bird of Paradise. This is entirely white, and is the rarest of all the species. It is found in the Papuan islands. A variety of it is black on the fore-part, and white on the hind-part.

"In the second edition of Pennant's Indian Zoology," says Dr. Shaw, "may be found a good general description from Valentyn, of this remarkable genus, by Dr. J. Reinhold Forster, preceded by a very learned dissertation on the fabulous phoenix of antiquity, a bird of the size of an eagle, decorated with gold and purple plumes, and more particularly described by Pliny, as having the splendour of gold round the neck, the rest of the body purple, the tail blue, varied with rose-colour, the face adorned with wattles, and the head furnished with a crest. This imaginary bird, Dr. Forster supposes to have been no other than a symbolical Egyptian illustration of the annual revolution of the sun, and the conversion of the great year, which corresponds with the supposed life of the phoenix, and from which period the same course of seasons and positions of the heavenly bodies is renewed." These notions, then, says Dr. Forster, are to be explained by the theology of Egypt. Though the birds of Paradise were never known to the ancients, and though what has been said by the Egyptian priests concerning the fabulous phoenix, has but little agreement with the bird of Paradise, yet it is remarkable that the names applied both by the Indian and European nations to these birds, appear to attribute something of a supposed celestial origin to them. In all probability, says Dr. Shaw, this notion has arisen merely from their transcendent beauty, and the singular disposition and delicacy of their plumage.

PARADISIACA, in *Botany*, a name given by some authors to the *arbor vite*, or *thuya*.

PARADISUS, among *Ancient Church Writers*, denoted a square court, before cathedrals, surrounded with piazzas, or porticos for walking under, supported by pillars. Matthew Paris calls it *parvifus*.

PARADOX, Παράδοξον, formed from παρά, *against*, and δοξα, *opinion*, in *Philosophy*, a proposition seemingly absurd, because contrary to the received opinions; but yet true in effect.

The Copernican system is a paradox to the common people; but the learned are all agreed as to its truth.

Geometricians have been accused of maintaining paradoxes; and it must be owned, that some use very mysterious terms in expressing themselves about asymptotes, the sums of infinite progressions, the areas comprehended between curves and their asymptotes, and the solids generated from these areas, the length of some spirals, &c. But all these paradoxes and mysteries amount to no more than this: that the line or number may be continually acquiring increments, and those increments may decrease in such a manner, that the whole line or number shall never amount to a given line or number.

The necessity of admitting this is obvious from the nature of the most common geometrical figures: thus, while the tangent of a circle increases, the area of the corresponding sector increases, but never amounts to a quadrant. Neither is it difficult to conceive, that if a figure be concave towards a base, and have an asymptote parallel to the base (as it happens when we take a parallel to the asymptote of the logarithmic curve, or of the hyperbola, for a base), that the ordinate in this case always increases while the base is produced, but never amounts to the distance between the asymptote and the base. In like manner, a curvilinear area may increase while the base is produced, and approach continually

tinually to a certain finite space, but never amount to it; and a solid may increase in the same manner, and yet never amount to a given solid. See LOGARITHMIC Curve.

A spiral may in like manner approach to a point continually, and yet in any number of revolutions never arrive at it; and there are progressions of fractions which may be continued at pleasure, and yet the sum of the terms shall be always less than a given number. See Maclaurin's Fluxions, book i. ch. 10. seq. where various rules are demonstrated, and illustrated by examples, for determining the asymptotes and limits of figures and progressions without having recourse to those mysterious expressions which have of late years crept into the writings of mathematicians. For, as that excellent author observes elsewhere, though philosophy has, and probably always will have, mysteries to us, geometry ought to have none.

PARADOXES, *Hydrostatical*. See FLUID.

PARADOXI, or PARADOXOLOGI, among the *Ancients*, were a kind of mimes or buffoons, who diverted the people with their drolling.

They were also called *ordinarii*, for this reason apparently, that, as they spoke without study or preparation, they were always ready.

They had another denomination, *viz. nianicologi, q. d. tellers of children's tales*: and beside were called *aretalogi*, of *αρετα*, *virtue*, or talking much of their own rare talents and qualifications.

PARÆA, in *Zoology*, the name of a species of serpent, called also *anguis Æsculapii*. It is a perfectly innocent and harmless creature, and is so little dreaded by the inhabitants, that it is common about their houses, and even sometimes gets into their beds. Its mouth is full of very small teeth, and when much provoked, it is sometimes known to bite, though without any bad symptoms attending the wound; it is a very long kind, and is of a yellowish-green colour on the sides, and blackish on the back; it has two small eminences on the neck, and between them two small sinews. It is very common in Spain, Italy, and most other of the warm countries.

PARÆNESIS, *παραινσις*, formed of *παρα*, and *αινω*, *I praise*, a Greek term, signifying adoration or exaltation.

PARAGAUDÆ, among the Romans, a sort of wreaths, either wholly of gold, or of silk adorned with gold, which were interwoven in garments and not sewed to them. The garment was sometimes of one colour, in which was woven one paragauda; others were of two colours, and had two paragaudæ; and some had three colours, and three paragaudæ. They were worn both by men and women.

PARAGE, PARAGIUM, in *Law*, an equality of blood or dignity, but more especially of land, in the partition of an inheritance between coheirs.

PARAGE, *Paragium*, is more properly used, in ancient customs, for an equality of condition among nobles, or persons holding nobly.

Thus, when a fief is divided among brothers; in this case, the younger hold their part of the elder by parage, *i. e.* without a y homage or service.

This still obtains, in some measure, in Scotland, where the husbands of the younger sisters are not obliged to any faith or homage to the husband of the elder; nor their children to the second degree.

This parage being an equality of duty or service among brothers and sisters, some have called it *fratriage* and *parentage*.

The Customary of Normandy defines enure by parage to be, when a noble fief being divided among daughters, the eldest does homage to the chief lord for all the rest, and the

youngest hold their parts of the rest by parage, *i. e.* without any homage or fealty.

Parage ceases at the sixth degree inclusively. It likewise ceases when any of the sisters sell their part.

PARAGLOSSA, from *παρρα*, and *γλωσσα*, *the tongue*, in *Surgery*, a prolapsus of the tongue; or a protrusion of it from the mouth.

PARAGOGE, *παρρωγιη*, in *Grammar*, a figure whereby a word is lengthened out by adding a syllable at the end of it: as in *dicier* for *dici*.

PARAGOGE is also a word used by medical writers to express a reduction of luxated bones.

PARAGOGIC, formed of *παραγω*, *I prolong*, compounded of *παρα* and *γω*, in *Grammar*, denotes something added to a word without adding any thing to its sense.

In the Hebrew, the ה is frequently paragogic; as in אברכה, for אברך, *I will praise*. The paragogic letters are the five following, *viz. ו י ה ה א*; to which some add the ה.

The use of paragogic letters is only to give a more full and agreeable sound to words, either for the sake of the verse, or the smoothness of the period. As in the Hebrew letters are sometimes added "euphonia gratia," so likewise the four following letters, *viz. ה ו י ו*, which, according to the grammatical rules, ought to be present, are omitted.

PARAGON, in *Geography*, one of the largest of the Calamianes islands, in the East Indian sea.

PARAGONE, in *Natural History*, the name given by many to the basaltas, a black marble, used as a touchstone.

PARAGRAPH, *Παραγραφος*, a term in *Jurisprudence*, signifying a section or division of the text of a law: otherwise called an *article*.

Such a law is said to be divided into so many paragraphs.

The character of a paragraph in quotation, is ¶.

Among the Greek poets, paragraphs, *παραγραφοι*, were a species of critical notes, serving to mark the couplets, strophes, and other divisions of odes, and other poetical compositions. This paragraph, as described by the scholiast of Aristophanes, was a short line, with a dot at the extremity of it.

PARAGUA, in *Ornithology*, the name of a Brazilian parrot, of the size of our common green parrot; but its back is all black, and its breast and the forepart of its belly are of a beautiful red; its eyes are black, with a red circle round them; its beak brown, or a very dusky grey, and legs and feet grey. See PSITTACUS *Paraguanus*.

PARAGUARE, in *Geography*, a town of Brazil, on the river of the Amazons. S. lat. 3° 10'. W. long. 65° 56'.

PARAGUAY, or PALAWAN, the most westerly of the Philippine islands, about 180 miles in length, and 21 in breadth; 190 miles E.N.E. of Mindanao. N. lat. 8 12' to 11° 31'. E. long. 117° 21' to 119° 40'.

PARAGUAY, a river of South America, which rises about W. long. 58 between the 5th and 6th degrees of S. lat. After pursuing an almost due S. course, it joins the Plata in S. lat. 28°. W. long. 60° 36'. The word "Paraguay" means "the crown," or a kingly stream.

PARAGUAY, a province of the viceroyalty of La Plata or Buenos Ayres, called the "Government of Paraguay." This government lies S. of Santa Cruz de la Sierra and E. of Tucuman. Southward it joins to that of Buenos Ayres, and eastward it is terminated by the captainship of St. Vicente in Brazil, the capital of which is the city of St. Pablo. These countries were first discovered by Sebastian Gaboto or Cabot (see CABOT), who, coming to the river of Plata in the year 1526, sailed up the Parana in small barks,

PARAGUAY.

barks, and thence entered that of Paraguay. In 1536 he was succeeded by Juan de Ayolas, to whom Don Pedro de Mendoza, the first governor of Buenos Ayres, had given a commission, together with a body of troops, military stores, and other necessaries; and, afterwards, by his orders, Juan de Salinas founded the city of Nuestra Señora de la Assumption, the capital of the province; but the discovery of the whole, and consequently the conquest of the people who inhabited it, being still imperfect, it was prosecuted by Alvar Nunez, surnamed Cabeza de Baca, or Cowhead, whose eminent services, on the death of Don Pedro de Mendoza, procured for him the government of Buenos Ayres. The only settlements, in the whole extent of this government, is the city of Assumption, Villa Rica, and some other towns, inhabited by converted Indians, who were once entirely under the administration of the Jesuits. The province is distinguished by its fertility, and though it produces none of the precious metals, it is the most opulent in the new viceroyalty, on account of its various vegetable productions, and the prodigious herds of horses, mules, cattle and sheep, which enliven its extensive plains. The northern parts, however, of Paraguay have been little explored, as the settlements of the Jesuits were chiefly in the southern skirts, and among the adjacent Abipons and Guaranis. It was in the year 1580 that the Jesuits were first admitted into these fertile regions, where they afterwards, in the reign of Philip III., founded the famous Missions, which in Europe have been known under the name of Paraguay, but in America Uruguay, from the river of that name on which they were situated. Actuated by motives of religion and of interest, they were diligent and zealous in the service assigned them of converting the Indians to the Catholic faith; and by a gradual progress their labours were attended with very considerable success. The Jesuit missionaries had previously stipulated with the court of Spain, that for the more effectual accomplishment of their purposes in converting and civilizing the Indians, they should be independent of the governors of the province, and that they should annually receive from the royal treasure 60,000 piastres for defraying the expences of cultivation; on condition that as colonies were formed and the lands cultivated, the Indians should pay yearly a piastre *per* head to the king, from the age of eighteen to sixty. The Jesuits thus encouraged embarked in the execution of their enterprize with singular resolution and ardour, and notwithstanding the difficulties with which they had to contend, succeeded in civilizing the barbarous Indians, introducing among them useful and polite arts, and forming them into a state of mutual association and amity, of profitable labour and domestic comfort. Their missions extended over a country, which contained about 200 leagues N. and S. and about 150 E. and W.; and the number of inhabitants was about 300,000. From the immense forests they derived all kinds of wood, and the extensive pastures were covered with at least two millions of cattle.

The country was divided into parishes, and each parish was under the direction of two Jesuits, who officiated, the one as rector, and the other as curate. The establishment was supported at an expence, which, comprehending the magnificent structure and ornaments of the churches, was not very considerable; as the Indians supported themselves by their own labour. The products of the ground and cattle belonged to the Jesuits, who provided instruments of various trades, for glass, knives, needles, chaplets of beads, gunpowder, and muskets. Their annual revenues consisted in cotton, tallow, leather, honey, and more especially *Mathe*, or herb of *Paraguay* (which see,) monopolized by the society, and yielding, according to the statement of

Dr. Robertson in his "History of America," 500,000 pesos, at 4s. 6d each. The whole system of administration, planned and conducted by the Jesuits, was so formed as to keep the Indians in perfect subordination to the rectors; whilst they were provided with means of instruction in various departments of science, such as music, painting, sculpture, and architecture, and also of manufacture and trade; and at the same time their attention was directed to the regular performance of religious ceremonies and duties.

The society of Jesuits was thus employed in extending its missions, and establishing its authority, when their designs and labours were entirely terminated by the Spanish court, which decreed their expulsion throughout its widely spread dominions. The missions upon the Uruguay, of which we have above given a concise account, were not the only ones founded by the Jesuits in South America; northward and southward they made progress in carrying their plans of government into effect, and multiplying their establishments. When their effects in this province were confiscated, it was expected that large sums of hoarded money would have been found; but these, in their whole amount, were very trifling. Their magazines, indeed, were furnished with all sorts of merchandize, consisting of the products of the country, and of goods imported from Europe; the number of their slaves was also very considerable, inasmuch, that at Cordova alone they reckoned 3500. In detailing botanical notices, with respect to the province of Paraguay, by the assistance of Dobrizhoffer's communications, in the first volume of his work, we shall cursorily mention the tree, which bears the quinquina or Jesuits' bark, the sarsaparilla, rhubarb, jalap, saffaras, the guayacur, the zamu, called from its form the drunkard, the mangay, yielding the elastic juice applied in Europe to various purposes, the caa, from which is obtained the resin called dragon's blood, the cupay, whose precious oil is used in medicine, the nux vomica, the vanilla, the tree which yields chocolate, the timbabi, which supplies store of a beautiful golden gum, that is run into moulds and formed into crosses, necklaces, and ear-rings, straight and lofty cedars, and the American pine called cury, harder than the European, and marked with red veins, of the knots of which exuding a red juice, and appearing varnished, the Guaranis make elegant images; several species of the algarobba or carob tree, of which are made a bread by pounding it in a mortar, and a wholesome drink by infusing it in cold water, which is said to be a radical cure for consumptions, and to possess a strong diuretic virtue: the paraguay already mentioned, numerous and beautiful species of palm, figs, peaches, pomegranates, lemons, and large oranges. Among the native fruits are the jujub, the chanar, the yacani, the quabyra, of a species of which candles are made for divine service, the passion-flower plant, the fruit called quembe, yielding a delicious pulp, the mammon growing on the trunk of a tree, and approaching to the melon, the tatay, producing a fruit like the mulberry, the alaba, whose fruit is delicious and refreshing, the anguay, the pips of which are of a splendid violet colour, and triangular shape, used by the Indian women for making necklaces, the tarumay, resembling the olive, the molle, yielding a copious and fragrant gum, the bacoba, banana, and anana, the manioc, the cotton-tree, which is a common plant, the zevil, yielding a bark useful in tanning, the seibo, bearing flowers of a violet colour, the izapi, whose leaves distil a copious supply of water, the ant-tree, the chosen haunt of these insects, the umbu, which might cover 50 men with its thick shade, the willow, the ambay, used in striking fire, the urucuy, a shrub yielding a strong scarlet dye, indigo, cochineal, nakalie, whose beautiful yellow is used by dyers and painters, the

caraquata

caraquata of the Guaranis, or maguey of the Mexicans, resembling an aloe, reeds of a prodigious size, the sugar-cane, various species of rosemary, rue, mint, sage, borragé, &c.; maize, or Indian corn, of which is made the favourite drink of the Indians, called chicha, or alloja, potatoes of large size, white, red, and yellow, which latter are the best, the mani, resembling the almond in taste and form, of which there are several kinds, the oil of which is superior to that of the olive; European beans, peas, melons, cucumbers, lettuce, turnip, mustard, cresses, leeks, and onions, asparagus found wild in the fields, wheat in large quantities, and the vine. Paraguay in particular produces a generous and healthy wine, but the roots are destroyed by the prodigious number of ants. Of quadrupeds it has been said, that here are the glama or lama, the guanoco, the macmorro, or chilibueque of the Chikea, the vicuna, and the paco or alpaco. (See CAMELUS.) But a late author, Azara, has omitted them in his work, and it has been accordingly affirmed, that they are totally unknown in Brazil, a town in Paraguay. The American tiger or jaguar is chiefly known in Paraguay, and the forests to the north. Other animals are the wild cat, the elk, the ant-bear, a kind of deer, &c. A species of ostrich is found in the wide plains of Paraguay. Dobrizhoffer counted nine kinds of picafior, or humming-bird, in this province; and here are also about 20 kinds of serpents, among which the rattle-snake is not uncommon. See LA PLATA.

PARAGUAY, or *Paragoué*, in *Natural History*, a celebrated plant of the shrub kind, growing in some provinces in South America, especially in that of Paraguay, whence its name, though better known among us under the denomination of *South-sea tea*. See *ILEX Vomitoria*.

This plant, which does not rise above a foot and a half high, has very slender branches, and leaves somewhat like those of fenna; it may be looked on as a kind of occidental tea, which, like the oriental, is taken infused in hot water, to which it communicates a colour and smell nearly like those of the best tea seen in Europe.

There are two kinds of paraguay, the one called simply *paraguay*; the other *caamini*, (which see,) by the Spaniards, *yervacamini*; which last is most esteemed, and sold for a third more than the other.

The first the Spaniards called the *yerva-con-palos*, i. e. *herb with little sticks*, because full of broken branches: this is chiefly used by domestics and slaves: the latter is the drink of the richest. But both are of so much use, and esteemed of such absolute necessity, that nobody in that part of America will live without them. The works of the mines of Potofi would stand still, but that the masters take care to supply the slaves that labour therein with paraguay, which is their constant remedy against those mineral steams, with which they would otherwise be suffocated. Nor will a servant engage himself with any master, but upon this among other conditions, that he have nothing but paraguay for drink.

The paraguay makes one of the most considerable articles of the South American commerce. At Peru, Chili, and Buenos Ayres, there are above two millions worth sold *per annum*; which used to pass almost altogether through the hands of the Jesuits.

The preparation of the plant, and the making it into drink, is much the same with that of tea, except that they infuse both the leaves and the wood, that they drink it immediately out of the vessel it is made in, without letting it have time to infuse, by reason of the black tincture it gives; and that, to prevent leaves and all from coming, they suck it through a silver or glass pipe, which goes round the company one after another. Frezier.

Beside all the virtues which the eastern people ascribe to their tea, as to be good in diseases of the head, breast, and stomach against phlegm, and to restore sleep; the Americans attribute to their's this likewise, of purifying all kinds of water, how foul and corrupt soever, by only infusing it therein, either hot or cold. Thus, having always some of it with them, if they meet with none but the worst waters in the vast deserts to be crossed in going from Buenos Ayres to Peru and Chili, they are not afraid to drink them, after steeping some of the plant a little while therein. It is also held sovereign against the scurvy and putrid fevers.

PARAGUR, in *Geography*, a ruined town of Hindoostan, in the circar of Gohud; 25 miles S. of Narwa.

PARAH, in *Commerce*, a corn measure in the East Indies. At Madras, the garee, corn-measure, contains 80 parahs, or 400 marcals, and the marcal, 64 o'locks. The marcal should measure 750 cubic inches, and weigh 27 lb. 2 oz. 2 dr. avoirdupois of fresh spring water; hence, 43 marcals = 15 English bushels, and the garee = 17½ English quarters nearly. When grain is sold by weight, 9256½ lbs. are reckoned for 1 garee, being 18 candies 12¾ marcals.

At Bombay, the candy, dry measure, contains 8 parahs; the parah, 16 adowlies, 64 seers, or 128 tiprees. This serves for wheat and all grain but rice, or batty, which is sold by the batty measure, as follows; the morah contains 4 candies, or 25 parahs; the parah, 20 adowlies, 150 seers, or 300 tiprees.

PARAH, in *Geography*, a town of Bengal; 10 miles W. of Rogonapour. N. lat. 23° 3'. E. long. 86° 39'.

PARAIBA, or PARA-IBA, a town of Brasil, and capital of a province or captaincy of the same name, which it derives from that of a river, on the S. bank of which it is situated, about 10 miles from the sea; the river being navigable above the town for ships loaded with 600 or 700 hogfheads of sugar. The harbour is large, but rather dangerous on account of the sand-banks. The town has many stately houses, decorated with marble pillars, besides large warehouses and magazines for the accommodation of the merchants. The mouth of the river is defended by three forts. The Portuguese, who took possession of this town and territory in 1584, after having expelled the French, have increased its buildings, planted sugar-canes, and erected sugar-mills. The whole territory is fertile in sugar-canes, and abounds in Brasil wood, cattle, tobacco, cotton, &c.; 60 miles N. of Fernambuco. S. lat. 7° 15'. W. long. 34° 3'.

PARA-IBA *de Sul*, a river of Brasil, which runs into the Atlantic. S. lat. 7° 15'. There is another river in the south, of the same appellation.

PARAKIN, a town of Servia; 32 miles N.N.W. of Nissa.

PARALAMPSIS, from *παρὰ λαμπρῶν*, *to shine a little*, in *Surgery*, a white opacity of the cornea of the eye.

PARALAPUTTY, in *Geography*, a town of Hindoostan, in Myfore; 10 miles from Sankeridurgum.

PARALEA, in *Botany*, so called by Aublet from the Caribbean word *parala*, a genus of that author's, of which the characters, as far as concerns the female parts of fructification, and the nature of the fruit itself, are unknown. It belongs to the *Polyandria*, or rather *Dodecandria*, of Linnæus, and is ranged by Jussieu among his *Guaiaacanz* with indefinite stamens, between *Ciponima* of Aublet, and *Hopea* of Garden and Linnæus, both which are now known to belong to the *Symplocos* of Jacquin and Linnæus, as l'Heritier first suggested. We may therefore presume to reduce the *Paralea* to the same genus; even though no such collection of its stamens into parcels has been observed, as is found in various species of *Symplocos* already known; for that might easily

easily escape detection in such small flowers as these are represented. See Aubl. Guian. t. 231. Lamarck Illustr. t. 454. Juss. 157.

The tree is said to be lofty, with a hard white wood. Leaves alternate, on short stalks, oval, entire, coriaceous, dark green, smooth, except a fringe of white hairs in their early state, which are deciduous. Flowers pleasantly scented, in little axillary tufts, accompanied by small, downy, reddish scales or bractæas. Calyx of one leaf, downy, reddish, with four sharp teeth. Corolla with a short inflated quadrangular tube, and a limb in four small, fleshy, red lobes. Stamens 18, shorter than the corolla. A little prismatic body, covered with red hairs, is found in the centre of the flower. This tree blossoms in October. The natives of Guiana, where it grows, about 50 miles from the sea-coast, bathe themselves with a decoction of its bark when they are attacked with fevers.

PARALEPSIS, Παραλεψις, in Rhetoric, a pretence of omitting or passing over a thing, and yet expressing it by the way.

The design of this figure, according to Hermogenes, is to possess the minds of the audience with more than the words express, and it is principally made use of on three occasions: either when things are small and yet necessary to be mentioned; or well known, and need not be enlarged on; or ungrateful, and therefore should be introduced with caution, and not set in too strong a light. When the imagination is warmed, and reasons and arguments present themselves in abundance, the orator would willingly lay them all down, in form; but for fear of wearying his audience, he only produces some of them *en passant*, and without dwelling on them: and this is called a *paralepsis*, by the Latins *præteritio*, by the Greeks *apospopefsis*.

For instance, I pass over in silence the many injuries I have received, &c. I won't insist on this last outrage. See Ep. to Philemon, v. 19.

PARALIA, Παραλία, in Antiquity, a day kept in memory of an ancient hero, called Paralus.

PARALIA was also the name of one of the Athenian tribes.

PARALIPOMENA, Παραλιπομείνα, a supplement of things omitted and forgot, in some preceding work, or treatise. The word is formed from the Greek παραλειπω, *prætermitto*, I pass by. Some authors use the word *subreclitum* instead of *paralipomenon*.

In the canon of Scripture, there are two books of Paralipomena, called in the English version Chronicles; being a supplement to the four books of kings, the two first of which are also called books of Samuel.

Quintus Calabar has a work, entitled the Paralipomena of Homer.

PARALLACTIC ANGLE, called also simply *parallax*, is the angle made in the centre of a star by two right lines, drawn, the one from the centre of the earth, T B, (Plate XVIII. Astron. fig. 4.) the other from its surface, E B.

Or, which amounts to the same, the parallactic angle is the difference of the angles C E A, and B T A, under which the real and apparent distances from the zenith are seen.

The sines of the parallactic angles A L T and A S T, (fig. 5.) at the same or equal distances from the zenith S Z, are in a reciprocal ratio of the distances of the stars from the centre of the earth, T L and T S.

PARALLAX, Παραλλαξις, in Astronomy, an arc of the heavens intercepted between the true place of a star, and its apparent place.

The true place of a star is that point of the heavens B, (fig. 4.) in which it would be seen by an eye placed in the centre of the earth as at T. The apparent place is that point of the heavens C, in which the star appears to an eye on the surface of the earth as at E. Now, as, in effect, we view a celestial body not from the centre, but from the surface of our earth, which is a semi-diameter distant from the centre; we see it by a visual ray, which passing through the centre of the star, and proceeding thence to the surface of the mundane sphere, marks out another point C, which is its apparent place.

The difference of places, is what we call absolutely the *parallax*; παραλλαξις, or the *parallax of altitude*; by Copernicus it is called the *commutation*; which, therefore, is an angle formed by two visual rays, drawn the one from the centre, the other from the circumference of the earth, and traversing the body of the star; and is measured by an arc of a great circle intercepted between the two points of the true and apparent place, C and B.

The nature and effects of the parallax may be otherwise familiarly illustrated by adverting to Plate XVIII. fig. 9. Let C be the centre of the earth, A the place of the spectator on its surface, S any object, Z H the sphere of the fixed stars, to which the places of all the bodies in our system are referred; Z the zenith, H the horizon; draw C S M, A S n, and m is the place of S seen from the centre, and z from the surface. As the plane S A C passes through the centre of the earth, it must be perpendicular to its surface, and consequently pass through the zenith Z; and the points m, n, lying in the same plane, the arc of parallax, m n, must lie in a circle parallel to the horizon; and hence the azimuth is not affected, if the earth be a sphere. Now the parallax, m n, is measured by the angle m S n, or A S C; and (by trigonometry) C S : C A :: sin. S A C or sin. S A Z its supplement : sin. A S C the parallax = $\frac{C A \times \sin. S A Z}{C S}$.

But C A being constant, on the supposition of the earth's being a sphere, the sine of the parallax varies as the sine of the apparent zenith distance directly, and the distance of the body from the centre of the earth inversely. Hence, a body in the zenith has no parallax, and at s in the horizon it is the greatest. If the object be at an indefinitely great distance, it has no parallax; and therefore the apparent places of the fixed stars are not altered by it. As n is the apparent place, and m is called the true place, the parallax depresses an object in a vertical circle. For different altitudes of the same body, the parallax varies as the sine, s, of the apparent zenith distance; therefore, if p = the horizontal parallax, and radius be unity, we have 1 : s :: p : p s, the sine of the parallax. In order, therefore, to determine the parallax at all altitudes, we must first find it at some given altitude. Vince's Elem. of Astronomy, 1810.

PARALLAX of Declination, is an arc of a circle of declination S I, (fig. 6.) whereby the parallax of altitude diminishes the declination of a star.

PARALLAX of Right Ascension and Descension, is an arc of the equator D d, (fig. 6.) whereby the parallax of altitude increases the ascension, and diminishes the descension.

PARALLAX of Longitude, is an arc of the ecliptic T t, (fig. 7.) whereby the parallax of altitude increases or diminishes the longitude.

PARALLAX of Latitude, is an arc of a circle of latitude S I, whereby the parallax of altitude increases or diminishes the latitude.

PARALLAX, Mensural, of the Sun, is an angle formed by two right lines, one drawn from the earth to the sun, and another

PARALLAX.

another from the sun to the moon, at either of their quadratures.

PARALLAX of the annual orbit of the earth, is the difference between the heliocentric and geocentric place of a planet, or the angle at any planet, subtended by the distance between the sun and earth.

PARALLAX is also used for the angle made in the centre of the star by two right lines, drawn, the one from the centre, the other from the surface of the earth.

This is also called *parallactic angle*. Hence the parallax diminishes the altitude of a star, or increases its distance from the zenith; and has, therefore, a contrary effect to the refraction.

The parallax of altitude C B, (*fig. 4.*) is, strictly, the difference between the true distance from the zenith C A, and the apparent distance B A.

The parallax is greatest in the horizon; in the zenith, or meridian, a star has no parallax at all; the true and apparent places then coinciding.

The horizontal parallax is the same, whether the star be in the true, or the apparent horizon.

Few, if any, of the fixed stars have any sensible parallax, by reason of their immense distance, to which the semi-diameter of the earth is but a mere point. See STAR.

Hence also, the nearer a star is to the earth, the greater is its parallax, at an equal elevation above the horizon; and Saturn is so high, that it is difficult to observe in him any parallax at all.

The parallax increases the right and oblique ascension, diminishes the descension; diminishes the northern declination and latitude in the eastern part, increases them in the western; increases the southern in the eastern and western part; diminishes the longitude in the western part, increases it in the eastern. The parallax, therefore, has just opposite effects to the refraction.

Hence the parallax of the remoter star S (*fig. 5.*) is less than the parallax of the nearer L, at the same distance from the zenith; as before observed.

The sines of the parallactic angles M and S, of stars equally distant from the centre of the earth T, are as the sines of the distances seen from the vertex Z M, and Z S. Hence, the distances from the vertex decrease, *i. e.* as the altitudes decrease, the parallax increases; and hence, also, the parallax affects the altitude of the star, from the horizon to the zenith.

The doctrine of parallaxes is of the utmost importance, in astronomy, for determining the distances of planets, comets, and other phenomena of the heavens; for the calculation of eclipses, and for finding the longitude. Methods of finding the parallaxes of the celestial phenomena are various: some of the principal and easier follow.

To observe the PARALLAX of a celestial Phenomenon.—Observe when the phenomenon is in the same vertical with a fixed star which is near it, and measure its apparent distance from the star; observe, again, when the phenomenon and fixed star are at equal altitudes from the horizon; and again measure their distance. The difference of those distances will be, very nearly, the parallax sought. The parallax of a phenomenon may be likewise found by observing its azimuth and altitude; and by marking the time between the observation, and its arrival at the meridian.

All required to find the parallax of the moon is, the parallax of right ascension: to find the effect of the magnitude of the semi-diameter of the earth, with regard to the phenomena of its motion, it is sufficient to know how far the meridian, to which the eye refers it, deviates from the true meridian. This is what M. Cassini found and practised with

regard to Mars; and what M. Maraldi has since practised with regard to the moon. The whole mystery here consists in having the moon's true motion, which refers to the centre of the earth; and its apparent motion, which refers to the place of observation: the difference of these, which is greatest in the horizon, or horary circle of six o'clock, gives the horizontal parallax for that latitude; whence the general parallax, or that under the equator, is easily found: the parallax of any parallel being to that of the equator, as the semi-diameter of this parallel is to that of the equator. See the practice of this method exemplified in finding the parallax of Mars.

PARALLAX, *to observe the Moon's.* Observe the moon's meridian altitude, with the greatest accuracy, and mark the moment of time: this time being equated (see EQUATION), compute her true longitude and latitude, and from these find her declination, and from her declination, and the elevation of the equator, find her true meridian altitude: if the observed altitude be not meridian, reduce it to the true altitude for the time of observation; take the refraction from the observed altitude, and subtract the remainder from the true altitude; and the remainder is the moon's parallax.

By this means Tycho, in 1583, Oct. d. 12 hor. 5. 19'. from the moon's meridian altitude observed, 13° 38', found her parallax to be 54 minutes.

To observe the Moon's PARALLAX in an Eclipse.—In an eclipse of the moon, observe when both horns are in the same vertical circle; in that moment take the altitudes of both horns; the difference of the two being halved, and added to the least, or subtracted from the greatest, gives nearly the visible altitude of the moon's centre: but the true altitude is nearly equal to the altitude of the centre of the shadow at that time. Now we know the altitude of the centre of the shadow, because we know the sun's place in the ecliptic, and its depression under the horizon, which is equal to the altitude of the opposite point of the ecliptic in which the centre of the shadow is: thus have we both the true and apparent altitude, the difference whereof is the parallax.

PARALLAX, *in order to find the Moon's.* Let a graduated instrument, as D A E (the larger the better), *Plate XVIII. Astronomy, fig. 8.* having a moveable index with sight-holes, be fixed in such a manner, that its plate surface may be parallel to the plane of the equator, and its edge A D in the meridian; so that when the moon is in the equinoctial, and on the meridian A D E, she may be seen through the sight-holes, when the edge of the moveable index cuts the beginning of the divisions at O, on the graduated limb D E; and when she is so seen, let the precise time be noted. Now, as the moon revolves about the earth from the meridian to the meridian again, in about 24 hours, 48 minutes, she will go a fourth part round it in 6 hours, 12 minutes, as seen from C, or from the earth's centre or pole. But as seen from A, the observer's place on the earth's surface, the moon will seem to have gone a quarter round the earth when she comes to the sensible horizon at O; for the index, through the sights of which she is then viewed, will be at *d*, 90° from D, where it was when she was seen at E. Now, let the exact moment when the moon is seen at O, in or near the sensible horizon, be carefully noted, (allowance being made for the horizontal refraction, which is about 34', so that the moon's centre will appear 34 minutes above the horizon, when her centre is really in it); that it may be known in what time she has gone from E to O; which time subtracted from 6 hours 12 minutes, (the time of her going from E to L), leaves the time of her going from O to L, and affords an easy method for finding the angle O A L, or the moon's horizontal

horizontal parallax, which is equal to the angle ALC , by the following analogy: as the time of the moon's describing the arc EO is to 90° , so is 6 hours 12 minutes to the degrees of the arc DdE , which measures the angle EAL ; from which subtract 90° , and there remains the angle $OAL = ALC$, under which the earth's semi-diameter AC is seen from the moon.

Astronomers have proposed the following method, for more accurately determining the moon's parallax; let two observers be placed under the same meridian, one in the northern hemisphere, and the other in the southern, at such a distance from each other, that the arc of the celestial meridian included between their two zeniths, may be at least 80 or 90 degrees. Let each observer take the distance of the moon's centre from his zenith, by means of an exceeding good instrument, at the moment of her passing the meridian: add these two zenith distances of the moon together, and their excess above the distance between the two zeniths, will be the distance between the two apparent places of the moon. Then as the sum of the natural sines of the two zenith distances of the moon is to the radius, so is the distance between her two apparent places to her horizontal parallax. If the two places be not exactly under the same meridian, their difference of longitude must be accurately taken, that proper allowance may be made for the moon's declination, while she is passing from the meridian of the one to the meridian of the other. Ferguson's Astr. p. 307. quarto, 1773.

Otherwise: take the meridian altitudes of the moon, when it is at its greatest north and south latitudes, and correct them for refraction: then the difference of the altitudes, thus corrected, would be equal to the sum of the two latitudes of the moon, if there were no parallax; consequently the difference between the sum of the two latitudes and the difference of the altitudes, will be the difference between the parallaxes at the two altitudes. To find from them the parallax itself, let S, s , be the sines of the greatest and least apparent zenith distances; P, p , the sines of the corresponding parallaxes: then as, when the distance is given, the parallax varies as the sine of the zenith distance, as we have shewn at the beginning of the article PARALLAX,

$$S : s :: P : p; \text{ hence } S - s : s :: P - p : p = \frac{s \times P - p}{S - s},$$

the parallax at the greatest altitude. This supposes that the moon is at the same distance in both cases; but as this will not necessarily happen, we must correct one of the observations, in order to reduce it to what it would have been, had the distance been the same, the parallax at the same altitude being inversely as the distance. If the observations be made in those places where the moon passes through the zenith of one of the observers, the difference between the sum of the two latitudes and the zenith distance at the other observation will be the parallax at that altitude.

Since, from the moon's theory, we have the ratio of her distances from the earth in the several degrees of her anomaly; those distances being found by the rule of three in semidiameters of the earth, the parallax is thence determined to the several degrees of the true anomaly.

De la Hire makes the greatest horizontal parallax $1^\circ 1' 25''$, the smallest $54' 5''$. The moon's distance, therefore, when in her perigee, is, according to his calculation, $55,197\frac{7}{8}$, that is, almost 56 semidiameters; in her apogee $63,107\frac{5}{8}$, that is, $63\frac{1}{2}$ semidiameters of the earth.

M. le Monnier determined the mean parallax of the moon to be $57' 12''$. Others have made it $57'.18''$.

According to the Tables of Mayer, the greatest parallax

of the moon (or when she is in her perigee and in opposition) is $61' 32''$; the least parallax (or when she is in her apogee and conjunction) is $53' 52''$, in the latitude of Paris: the arithmetical mean of these is $57' 42''$. But this is not the parallax at the mean distance, because the parallax varies inversely as the distance; and therefore the parallax at the mean distance is $57' 24''$, an harmonic mean between the two. M. de Lambre re-calculated the parallax from the same observations from which Mayer calculated it, and found it did not exactly agree with Mayer's. He made the equatorial parallax $57' 11''.4$ M. de la Lande makes it $57' 5''$ at the equator, $56' 53''.2$ at the pole, and $57' 1''$ for the mean radius of the earth, supposing the difference of the equatorial and polar diameters to be $\frac{1}{100}$ of the whole. From the formula of Mayer, the equatorial parallax is $57' 11''.4$.

From the Moon's PARALLAX AST, Plate XVIII. Astronomy, fig. 5, and Altitude SR , to find her Distance from the Earth. By her apparent altitude given, we have her apparent distance from the zenith, i. e. the angle ZAS ; or, by her true altitude, the angle ATS ; wherefore, since at the same time we have the parallactic angle S ; and the semi-diameter of the earth AT is reputed as 1; by plane trigonometry we shall have the moon's distance in semidiameters of the earth, thus: as the sine of the angle S is to the opposite side given, so is the sine of the other angle T to the side AS : or so is the sine of $TAS (= 180^\circ - T + S)$ to the side TS , the distance from the centre.

Hence, according to Tycho's observation, the moon's distance at that time from the earth was 62 semi-diameters of the earth.

Otherwise: for finding the mean distance, Cs (fig. 9.) of the moon, we have AC , the mean radius (r) of the earth: Cs , the mean distance (D) of the moon from the earth: $\sin. 57' 1'' = AsC : \sin. 90^\circ$ or radius :: $1 : 60.3$; consequently $D = 60.3 r$; but $r = 3964$ miles; and therefore $D = 239029$ miles. According to M. de la Lande, the horizontal semi-diameter of the moon: its horizontal parallax for the mean radius (r) of the earth :: $15' : 54' 57''.4$, or very nearly as $3 : 11$; hence, the semi-diameter

$$\text{of the moon is } \frac{3}{11} r = \frac{3}{11} \times 3964 = 1081 \text{ miles; and as}$$

the magnitudes of spherical bodies are as the cubes of their radii, we have the magnitudes of the moon and earth as $3^3 : 11^3 :: 27 : 1331 :: 1 : 49$ nearly. Vince, ubi supra.

Another Method of observing the Parallax of a celestial Body.—Let the body, P , (fig. 10.) be observed from two places, A and B , in the same meridian, then the whole angle APB is the sum of the parallaxes of the two places. The parallax $APC = \text{hor. par.} \times \sin. PAL$, (as appears in the beginning of this article,) taking APC for $\sin. APC$, and the parallax $BPC = \text{hor. par.} \times \sin. PBM$; hence $\text{hor. par.} \times \sin. PAL + \sin. PBM = APB$; therefore $\text{hor. par.} = APB$ divided by the sum of these two sines. If the two places be not in the same meridian, it does not signify, provided we know how much the altitude varies from the change of declination of the body, in the interval of the passages over the meridians of the two observers.

Ex. On October 5, 1751, M. de la Caille, at the Cape of Good Hope, observed Mars to be $1' 25''.8$ below the parallel of λ in Aquarius, and at the distance of 25° from the zenith. On the same day, at Stockholm, Mars was observed to be $1' 57''.7$ below the parallel of λ , and at $68^\circ 14'$ zenith distance. Hence the angle APB is $31''.9$, and the sines of the zenith distances being 0.4226 and 0.9287 ,

the horizontal parallax was $23''.6$. Hence, if the ratio of the distance of the earth from Mars to its distance from the sun be found, we shall have the sun's horizontal parallax, the horizontal parallaxes being inverfely as their distances from the earth.

To observe the PARALLAX of Mars.—1. Suppose Mars in the meridian and equator, in H, (*fig. 11.*) and that the observer, under the equator in A, observes him culminating with some fixed star. 2 If now the observer was in the centre of the earth, he would see Mars constantly in the fame point of the heavens with the star; and therefore, together with it, in the plane of the horizon, or of the sixth horary; but since Mars here has some sensible parallax, and the fixed star has none, Mars will be seen in the horizon, when in P, the plane of the sensible horizon; and the star, when in R, the plane of the true horizon: observe, therefore, the time between the transits of Mars and of the star through the plane of the sixth hour. 3. Convert this time into minutes of the equator; by this means we shall have the arc PM, to which the angle PAM, and consequently the angle AMD, is nearly equal; which is the horizontal parallax of Mars.

If the observer be not under the equator, but in a parallel IQ, that difference will be a less arc QM: wherefore, since the little arcs QM and PM are as their sines ID and AD; and since ADG is equal to the distance of the place from the equator, *i. e.* to the elevation of the pole; and therefore AD to ID, as the whole sine to the co-sine of the elevation of the pole; say, as the co-sine of the elevation of the pole ID is to the whole sine AD; so is the parallax observed in I, to the parallax to be observed under the equator.

Since Mars and the fixed star cannot be commodiously observed in the horizon; let them be observed in the circle of the third hour: and since the parallax there observed, TO, is to the horizontal one PM, as IS to ID; say, as the sine of the angle IDS, or 45° , (since the plane DO is in the middle between the meridian DH and the true horizon DM.) is to the whole sine; so is the parallax TO to the horizontal parallax PM.

If Mars be likewise out of the plane of the equator, the parallax found will be an arc of a parallel; which must, therefore, be reduced, as above, to an arc of the equator.

Lastly, if Mars be not stationary, but rather direct, or retrograde, by observations for several days; find out what his motion is every hour, that his true place from the centre may be assigned for any given time.

By this method Cassini, to whom we owe this noble invention, observed the greatest horizontal parallax of Mars to be twenty-five seconds, or a little less: but, by the same method, Mr. Flamsteed found it near thirty seconds. By the same method, the same author, Cassini, observed also the parallax of Venus.

It must be here noted, that the observation is to be made with a telescope, in whose focus are strained four threads, cutting each other at right angles, A, B, C, D, *fig. 12*, and the telescope is to be turned about, till some star near Mars be seen to pass over some of the threads, that the threads AB and CD may be parallel to the equator, and therefore AC and BD may represent circles of declination: thus, by means of the perpendicular threads, the situations of the star, and of Mars, in the meridian, and circle of three o'clock, will be determined.

Another Method of finding the Parallax of a celestial Body. Let EQ be the equator (*fig. 13.*), P its pole, Z the zenith, v the true place of the body, and r the apparent place, as depressed by parallax in the vertical circle ZK,

and draw the secondaries, Pva , Prb ; then ab is the parallax in right ascension, and rs in declination. Now,

$$vr : vs :: 1 \text{ (rad.)} : \sin. vrs, \text{ or } ZvP$$

$$vs : ab :: \text{cof. } va : 1 \text{ (rad.)}$$

$$\therefore vr : ab :: \text{cof. } va : \sin. ZvP;$$

therefore $ab = \frac{vr \times \sin. ZvP}{\text{cof. } va}$; but $vr = \text{hor. par.} \times$

$\sin. vZ$, and $\sin. vZ : \sin. ZP :: \sin. ZPv : \sin. ZvP =$
 $\frac{\sin. ZP \times \sin. ZPv}{\sin. vZ}$; therefore, by substitution, $ab =$

$\frac{\text{hor. par.} \times \sin. ZP \times \sin. ZPv}{\text{cof. } va}$. Hence, for the same

star, where the hor. par is given, the parallax in right ascension varies as the sine of the hour angle. Also, the hor. par.

$= \frac{ab \times \text{cof. } va}{\sin. ZP \times \sin. ZPv}$. For the eastern hemisphere, the

apparent place, b , lies on the equator to the east of a , the true place, and therefore the right ascension is increased by parallax; but in the western hemisphere, b lies to the west of a , and therefore the right ascension is diminished. Hence, if the right ascension be taken before and after the meridian, the whole change of parallax in right ascension between the two observations, is the sum (s) of the two parts before and

after the meridian, and the hor. par. $= \frac{s \times \text{cof. } va}{\sin. ZP \times S}$. On

the meridian there is no parallax in right ascension, for $ab =$
 $\frac{vr \times \sin. ZvP}{\text{cof. } va}$, and on the meridian, the angle ZvP , and

consequently its sine, vanishes.

To apply this rule, observe the right ascension of the planet when it passes the meridian, compared with that of a fixed star, at which time there is no parallax in right ascension; about six hours after, take the difference of their right ascensions again, and observe how much the difference, d , between the apparent right ascensions of the planet and fixed star has changed in that time. Next, observe the right ascension of the planet for three or four days when it passes the meridian, in order to get its true motion in right ascension; then, if its motion in right ascension, in the above interval of time, between the taking of the right ascensions of the fixed star and planet on and off the meridian, be equal to d , the planet has no parallax in right ascension; but if it be not equal to d , the difference is the parallax in right ascension; and hence the horizontal parallax will be known. Or one observation may be made before the planet comes to the meridian, and one after, by which a greater difference will be obtained.

Ex. On Aug. 15, 1719, Mars was very near a star of the fifth magnitude, in the eastern shoulder of Aquarius; and at $9^h 18'$ in the evening, Mars followed the star in $10' 17''$; and on the 16th, at $4^h 21'$ in the morning, it followed it in $10' 1''$; therefore, in that interval, the apparent right ascension of Mars had increased $16''$ in time. But, according to observations made in the meridian for several days after, it appeared that Mars approached the star only $14''$ in that time, from its motion; therefore $2''$ in time, or $30''$ in motion, is the effect of parallax in the interval of the observations. Now the declination of Mars was 15° , the co-latitude $41^\circ 10'$, and the two hour angles $49' 15''$, and $56' 39''$;

therefore the hor. par. $= \frac{30'' \times \text{cof. } 15^\circ}{\sin. 41^\circ 10' \times \sin. 49^\circ 15' + \sin. 56^\circ 39'}$
 $= 27\frac{1}{2}''$. But at that time, the distance of the earth from Mars

PARALLAX.

Mars was to its distance from the sun, as 37 to 100; and therefore, the sun's horizontal parallax comes out 10".17.

Besides the effect of parallax in right ascension and declination, it is manifest that the latitude and longitude of the moon and planets must also be affected by it; and as the determination of this, in respect to the moon, is in many cases, particularly in solar eclipses, of great importance, we shall proceed to shew how to compute it, supposing that we have given the latitude of the place, the time, and consequently the sun's right ascension, the moon's true latitude and longitude, with her horizontal parallax.

Let H Z R (fig. 14.) be the meridian, φ E Q the equator, p its pole; φ C the ecliptic, P its pole; φ the first point of Aries, H Q R the horizon, Z the zenith, Z L a secondary to the horizon passing through the true place r , and apparent place, t , of the moon; draw P t, P r, which produce to s , drawing the small circle ts , parallel to ov ; then rs is the parallax in latitude, and ov the parallax in longitude. Draw the great circles, φ P, P Z A B, P p d e, and Z W, perpendicular to pe ; then, as φ P = 90° , and φp = 90° , φ must be the pole of P p d e, and therefore $d \varphi$ = 90° ; consequently d is one of the solstitial points, \oplus or \ominus ; also, draw Z x perpendicular to P r, and join Z φ , $p \varphi$. Now φ E, or the angle φp E, or Z p φ , is the right ascension of the mid-heaven, which is known; P Z = A B (because A Z is the complement of both) the altitude of the highest point, A, of the ecliptic above the horizon, called the nonagesimal degree, and φ A, or the angle φ P A, is its longitude; also, Z p is the co-latitude of the place, and the angle Z p W is the difference between the right ascension of the mid-heaven φp E, and φ E. Now, in the right-angled triangle Z p W, rad. \times cof. p = tan. p W \times cot. p Z; therefore,

$$\log. \tan. p W = 10, + \log. \text{cof. } p - \log. \text{cot. } p Z;$$

hence, P W = $p W \pm p P$, where the upper sign takes place when the right ascension of the mid-heaven is less than 180° ; and the lower sign, when greater. Also, in the triangles W Z p, W Z P, we have fin. W p : fin. W P :: tan. W P Z : tan. W p z :: cot. W p Z : cot. W P Z, or, tan. A P φ ; therefore,

$$\log. \tan. A P \varphi = \text{ar. co. log. fin. W p} + \log. \text{fin. W P} + \log. \text{cot. W p Z} - 10;$$

and as we know φ o, or φ P o, the true longitude of the moon, we know A P o, or Z P x. Also, in the triangle W P Z, we have cof. W P Z, or fin. A P φ , : rad. :: tan. W P : tan. Z P; therefore,

$$\log. \tan. Z P = 10, + \log. \tan. W P - \log. \text{fin. A P } \varphi.$$

Again, in the triangle Z P r, we know Z P, P r, and the angle, P, from which the angle Z r P, or $t r s$, may be thus found. In the right-angled triangle Z P x, we know Z P, and the angle P; hence, rad. \times cof. Z P x = cot. P Z \times tan. P x; therefore,

$$\log. \tan. P x = 10, + \text{cof. Z P x} - \log. \text{cot. P Z};$$

therefore we know r x; hence, fin. r x : fin. P x :: tan. Z P x : tan. Z r x, or $t r s$; therefore,

$$\log. \tan. Z r x = \text{ar. co. log. fin. r x} + \log. \text{fin. P x} + \log. \text{tan. Z P x} - 10;$$

also, in the right-angled triangle Z r x, we have rad. \times cof. Z r x = cot. Z r \times tan. r z; therefore,

$$\log. \text{cot. Z r} = 10, + \log. \text{cof. Z r x} - \log. \text{tan. r x}.$$

With this true zenith distance Z r, find the parallax, as if it were the apparent zenith distance, and it will give you the true parallax nearly; add this, therefore, to the true zenith

distance, and you will get nearly the apparent zenith distance, to which compute again the parallax, and thus you will get the true parallax, r t, extremely nearly; then, in the right-angled triangle r s t, which may be considered as plane, we have rad. : cof. r :: r t : r s, the parallax in latitude; therefore,

$$\log. r s = \log. r t + \log. \text{cof. r} - 10, = \log. \text{par. latitude}.$$

Also, rad. : fin. r :: r t : t s; therefore,

$$\log. t s = \log. r t + \log. \text{fin. r} - 10,$$

hence, cof. t v : rad. :: t s : o v, the parallax in longitude, therefore,

$$\log. o v = 10, + \log. t s - \log. \text{cof. t v} = \log. \text{par. long.}$$

Ex. On January 1, 1771, at 9^h apparent time, in lat 53° N., the moon's true longitude was $3^\circ 18' 27'' 35''$, and latitude $4^\circ 5' 30''$ S., and its horizontal parallax $61' 9''$; to find its parallax in latitude and longitude.

The sun's right ascension was $282^\circ 22' 2''$ by the Tables, and its distance from the meridian 135° ; also, the right ascension φ E, of the mid-heaven, was $57^\circ 22' 2''$; hence, the whole operation for the solution of the triangles will stand thus:

Tri. Z p W	Z p W = $32^\circ 37' 58''$	-	10, + cof.	19.9253864

The value of *tv* is *ro* - or + *rs*, according as the moon has N. or S. latitude.

The order of the signs being from west to east, from A towards C is eastward, and from A towards φ is westward: now the parallax depressing the body from *r* to *t*, increases the longitude from *o* to *v*; but if the point *o* had been on the other side of A, *ov* would have lain the contrary way; hence, when the body is to the east of the nonagesimal degree, the parallax increases the longitude; and when it is to the west, it diminishes the longitude. Vince, ubi supra.

PARALLAX, To find the Sun's. — The great distance of the sun renders its parallax too small to fall under even the nicest immediate observation; indeed, many attempts have been made, both by the ancients and moderns, and many methods invented for that purpose. The first was that of Hipparchus, followed by Ptolemy, who made the sun's horizontal parallax 2' 50", and Tycho, who made it 3', &c.; this was founded on the observation of lunar eclipses: the second was that of Aristarchus, whereby the angle subtended by the semidiameter of the moon's orbit, seen from the sun, was sought from the lunar phases: but these both proving deficient, astronomers are now forced to have recourse to the parallaxes of the planets nearer us, as Mars and Venus; for, from their parallaxes known, that of the sun, which is inaccessible by any direct observation, is easily deduced. For, from the theory of the motions of the earth and planets, we know, at any time, the proportion of the distances of the sun and planets from us; and the horizontal parallaxes are in a reciprocal proportion to those distances: knowing, therefore, the parallax of a planet, that of the sun may be found from it.

Thus Mars, when opposite to the sun, is twice as near as the sun is: his parallax, therefore, will be twice as great as that of the sun; and Venus, when in her inferior conjunction with the sun, is sometimes nearer us than he is; her parallax, therefore, is greater in the same proportion. Thus, from the parallaxes of Mars and Venus, Cassini found the sun's parallax to be ten seconds; which implies his distance to be 22,000 semidiameters of the earth.

The most accurate method of determining the parallaxes of these planets, and deducing from thence the true parallax of the sun is, that of observing their transit: however, Mercury, though frequently to be seen on the sun, is not fit for this purpose; because it is so near the sun, that the

difference of their parallaxes is always less than the solar parallax required. But the parallax of Venus, being almost four times as great as the solar parallax, will cause very sensible differences between the times in which she will seem to be passing over the sun at different parts of the earth. With a view of engaging the attention of astronomers to this method of determining the sun's parallax, Dr. Halley communicated to the Royal Society in 1691, a paper containing an account of the several years in which such a transit may happen, computed from the tables which were then in use: those at the ascending node occur in the month of November, O. S. in the years 918, 1161, 1396, 1631, 1639, 1874, 2109, 2117: and at the descending node in May, O. S. in the years 1048, 1283, 1291, 1518, 1526, 1761, 1769, 1996, 2004. Phil. Transf. Abr. vol. i. p. 435, &c.

Dr. Halley even then concluded, that if the interval in time between the two interior contacts of Venus with the sun could be measured to the exactness of a second, in two places properly situated, the sun's parallax might be determined within its 500th part. But this conclusion was explained more fully in a subsequent paper, (Phil. Transf. N^o 348, or Abr. vol. iv. p. 213.) concerning the transit of Venus in the year 1761. It does not appear that any of the preceding transits had been observed; except that of 1639, by our illustrious countryman Mr. Horrox, and his friend Mr. Crabtree, of Manchester. But Mr. Horrox died on the 3d of January, 1640—1, about the age of twenty-five, just after he had finished his treatise, intitled "Venus in Sole Visa," in which he discovered a more accurate knowledge of the dimensions of the solar system than his learned commentator Hevelius.

In order to give our readers, not much conversant with subjects of this kind, a general idea of this method of determining the horizontal parallax of Venus, and from thence, by analogy, the parallax and distance of the sun, and of all the planets from him; it may be briefly illustrated in the following manner: let DBA, (Plate XVIII. Astronomy. fig. 15.) be the earth, V, Venus, and T S R the eastern limb of the sun. To an observer at B the point *t* of that limb will be on the meridian, its place referred to the heaven will be at E, and Venus will appear just within it at S. But, at the same instant, to an observer at A, Venus is east of the sun, in the right line A V F; the point *t* of the sun's limb appears at *e* in the heavens, and if Venus were then visible, she would appear at F. The angle C V A is the horizontal parallax of Venus; and is equal to the opposite angle F V E, measured by the arc FE. A S C is the sun's horizontal parallax, equal to the opposite angle e S E, measured by the arc e E; and F A e, or V A v, is Venus's horizontal parallax from the sun, which may be found by observing how much later in absolute time her total ingrefs on the sun is, as seen from A, than as seen from B, which is the time she takes to move from V to v, in her orbit O V v. If Venus were nearer the earth, as at U, her horizontal parallax from the sun would be the arc f e, which measures the angle f A e; and this angle is greater than the angle F A e, by the difference of their measures f F. So that as the distance of the celestial object from the earth is less, its parallax is the greater. Now it has been already observed, that the horizontal parallaxes of the planets are inversely as their distances from the earth's centre; therefore as the sun's distance at the time of the transit is to Venus's distance, so is her horizontal parallax to that of the sun: and as the sun's mean distance from the earth's centre is to his distance on the day of the transit, so is his horizontal parallax on that day to his horizontal parallax at the time of his mean distance from the earth's centre

centre. Hence his true distance in semidiameters of the earth may be obtained by the following analogy: as the sine of the sun's parallax is to radius, so is unity or the earth's semidiameter to the number of semidiameters of the earth in the sun's distance from the centre; which number multiplied by 3985, the number of miles in the earth's semidiameter, will give the number of miles in the sun's distance. Then from the proportional distances of the planets, determined by the theory of gravity (see DISTANCE), we may find their true distances. And from their apparent diameters at these known distances, their real diameters and bulks may be found. See PLANETS.

Mr. Short, with great labour, deduced the quantity of the sun's parallax from the best observations that were made of the transit of June 6th, 1761, (for which see Phil. Transf. vol. li. and lii.) both in Britain and abroad, and found it to have been $8''.52$ on the day of the transit, when the sun was very nearly at his greatest distance from the earth; and, consequently, $8''.65$ when the sun is at his mean distance from the earth. (See Phil. Transf. vol. lii. art. 100. p. 611, &c.) Whence we shall have radius, or $10.0000000 - 5.621914$, or sine of $8''.65$ taken out of Gardiner's tables = 4.3780860 , the logarithm of the number 23882.84 , or the number of semidiameters of the earth contained in its distance from the sun: and multiplying 23882.84 by 3985 , the number of English miles contained in the earth's semidiameter, we shall have $95,173,127$ miles for the earth's mean distance from the sun. And from the analogies under the article DISTANCE, we shall find the mean distances of all the rest of the planets from the sun in miles to be as follows, viz. Mercury's distance, $36,841,468$; Venus's distance, $68,891,486$; Mars's distance, $145,014,148$; Jupiter's distance, $494,990,976$; and Saturn's distance, $907,956,130$. In another paper, (Phil. Transf. vol. liii. p. 169.) Mr. Short states the mean horizontal parallax of the sun at $8''.69$. Mr. Hornsby, from several observations of the transit of June 3d, 1769, (for which see Phil. Transf. vol. lix. &c.) deduces the sun's parallax for that day equal to $8''.65$, and the mean parallax $8''.78$, whence he makes the mean distance of the earth from the sun to be $93,726,900$ English miles; Mercury's distance, $36,281,700$; Venus's distance, $67,795,500$; Mars's distance, $142,818,000$; Jupiter's distance, $487,472,000$; and Saturn's distance, $894,162,000$ miles. (Phil. Transf. vol. lxi. part ii. p. 579.) Others, however, by taking the results of those observations that were most to be depended on, have made the sun's parallax at his mean distance from the earth to be $8''.6045$; and others again make it $8''.54$. According to the former of these, the sun's mean distance from the earth is $95,109,736$ miles; and, according to the latter, it is $95,834,742$ miles. Upon the whole, there seems reason to conclude, that it may be fairly reckoned at more than ninety-five millions of miles, and less than ninety-six. Ferguson's Astr. p. 354. See PLANETS.

The PARALLAX of the Stars, with regard to the Earth's natural Orbit; called their annual parallax. The stars have no parallax, with regard to the earth's semidiameter; yet, with regard to the earth's annual orbit, it is justly expected, that some parallax may be found.

The axis of the earth, in its natural motion, describes a kind of cylinder, which, being prolonged to the heaven of the fixed stars, there draws a circular circumference; each point of which is the pole of the world for its respective day: so that the situation of the apparent pole, with regard to any of the fixed stars, changes very considerably in the course of a year.

Could this be found by observation, it would irrefragably evince the annual motion of the earth round the sun, and remove that only objection which lies against it, urged by Ricciolus, from no such parallax being observed.

Accordingly, Dr. Hook attempted to find it by observing the various distances of a fixed star from the zenith, in different parts of the earth's orbit; and Mr. Flamsteed, from the access and recess of a fixed star from the equator at different times of the year, and with imagined success; the result of his observations being, that a fixed star, near the pole, was found 40 or 45 seconds nearer it at the winter solstice, than at the summer one, for seven years successively.

Mr. Cassini the younger allows the observations of Flamsteed to agree with those made at the Royal Observatory; but he denies the consequences: he says that the variations in the distance of the pole-star are not such as they should be, supposing the motion of the earth. Fontenelle accounts for them from a supposition, that the stars, like the sun, turn or revolve on their centres; and that some of them have their hemispheres equally luminous: whence, when the more shining hemisphere is turned towards us, the stars appear bigger, consequently nearer the neighbouring stars, than when the darker is towards us.

Dr. Bradley has accounted for this supposed parallax in another way; and conceives it to proceed from the progressive motion of the star's light. (See Motion of the EARTH and LIGHT.) For the result of later observations, see STARS.

PARALLAX is also used, in Levelling, for the angle contained between the line of true level, and that of apparent level.

PARALLAXIS, among Medical Writers, expresses a natural change in the situation of the parts of a broken bone, as when the two fragments slip to the sides of one another.

PARALLEL, in Geometry, is applied to lines, figures, and bodies, which are every where equidistant from each other; or which, though infinitely produced, would never either approach nearer, or recede farther from, each other.

PARALLEL Right Lines, are those which, though infinitely produced in the same plane surface, would never meet.

Thus the line O P, (Plate X. Geometry, fig. 10.) is parallel to Q R.

Parallel lines stand opposed to lines converging, and diverging.

Some define an inclining or converging line that which will meet another at a finite distance; and a parallel line, that which will only meet it at an infinite distance.

A perpendicular is by some said to be the shortest of all lines that can be drawn to another; and a parallel the longest.

Geometricians demonstrate, that two right lines, perpendicular to one and the same right line, are parallel to each other, and hence they infer the possibility of parallel lines: that perpendiculars to one of two parallel lines, terminated by those lines, are equal to each other, and also perpendicular to the other of the two parallels: that two lines, parallel to the same third line, are also parallel to one another; and that if two parallels, O P and Q R, be cut by a transverse line S T in A and B; 1. The alternate angles x and y are equal: 2. The external angle u is equal to the internal opposite one y : 3. That a line intersecting two parallel lines, make the angles on the same side equal to each other: and,

4. That

PARALLEL MOTION.

4. That the two internal opposite ones, z and y , are also equal to two right ones.

It is shewn, on the principles of optics, that if the eye be placed between two parallel lines, they will appear to converge towards a point opposite to the eye, because the apparent magnitudes of their perpendicular intervals are perpetually diminished; for the same reason they appear to converge towards an imaginary line, drawn parallel to them from the eye: and if they run to such a length, as that the distance between them be but as a point thereto, they will there appear to coincide.

This is the reason that the remoter parts of a walk or floor appear to ascend gradually, and the ceiling to descend towards the horizontal line; and that the surface of the sea, seen from an eminence, appears to ascend gradually in going from the shore; and that the upper parts of very high buildings seem to lean forward over the eye below.

Parallel lines are described by letting fall equal perpendiculars, and drawing lines through their extremes, by sliding the compasses open to the desired width, along a line, &c. or, by drawing two lines, which shall make the alternate angles with a line intersecting them equal.

Parallel Motion, is a term used among practical mechanics to denote the rectilinear motion of a piston-rod, &c. in the direction of its length; and contrivances, by which such alternate rectilinear motions are converted into continuous rotatory ones, or *vice versa*; for pumps, steam-engines, saw-mills, &c. are usually called parallel motions, or parallel levers. In the modern improved steam-engines and pumps, close cylinders are generally used for the pistons to act in, which being worked by polished rods sliding through collars or stuffing-boxes in the lids of the cylinders, it has become necessary to contrive methods for causing the piston-rod to move accurately up and down in the same right line. The different combinations of levers used to produce this effect are worthy of our notice, as exhibiting some ingenious applications of geometrical principles. The object of the parallel motion is, to convert the motion of the end of a reciprocating beam or lever, into a vertical or rectilinear motion; or the continuous motion of a crank at once into a reciprocating motion.

The simplest and most obvious method of producing either of these effects, is to connect the end of the piston-rod to the beam, or the crank, by means of joints, with a connecting rod of a proper length between them, and confine the former, to preserve its rectilinear movement, by sliding through a collar, or in grooves. Friction-wheels may be used to make it work easily; but in machines which have great strains, the constant wear of the grooves or wheels would soon produce looseness, and destroy the parallelism of the motion: recourse must, therefore, be had to parallel levers.

Plate III. of Steam-engines, contains three different constructions of levers, which are in common use in steam-engines, to produce parallel motions. Two of them, *figs. 1, 2, 3, and 4*, were, we believe, first introduced by Messrs. Boulton and Watt, as appendages to their patent steam-engine, in lieu of the sectors, or arch heads with chains, formerly applied to the beams of the old atmosphere engines. The most simple of these two is represented in *figs. 3 and 4*, where the pump, or piston-rod T , is required to move always in the line $T T$, when actuated by the beam, or lever, $H B$, whose centre of motion is A , and the point I , from which the rod receives its motion, of course moves in an arc of a circle. To this point, one end of a bar, or link $I K$, of any convenient length, is joined, and to the opposite end, K , the

extremity of a lever, $K L$, is attached by the joint or centre-pin K , the other end, L , moving on a fixed centre of motion. The lever, $K L$, is exactly equal in length to the acting radius, $A I$, of the beam, and its centre of motion, L , is attached to a fixed support, so situated, that when the beam, $A I$, is horizontal, or at right angles to the line $T T$, the lever, $K L$, will also be horizontal, and therefore parallel to $A I$; at the same time the link, $I K$, which connects them, must hang perpendicular. A centre-pin is fixed at M , exactly in the middle of $I K$, and to this centre the top of the piston-rod, T , is attached. Now the effect of the combination is, that the point, M , will always move in the vertical line $T T$, when the beam or the point, I , describes an arc of a circle round the centre A ; for it is evident, that when the levers, by the motion of the beam on its centre, are brought into the position shewn by the dotted lines A, I, K, L , (*fig. 3.*) either above or below the horizontal, the upper end of the link, $I K$, is drawn as much out of the line, $T T$, on one side, by the curved motion, or sweep of the beam, as the lower end is drawn out of that line, on the opposite side, by the sweep of the lever $K L$; consequently, its middle point, M , continues always in that line, and prevents the piston-rod deviating from it. The movement may be readily traced by inspection of the diagram, *fig. 3*, which exhibits the levers in three different positions.

Figs. 1 and 2 represent another of Boulton and Watt's parallel motions, and is that now most commonly used by themselves and other engine-makers. This, as before described, has two fixed centres, A and F , and rods connected by moveable joints C, B, D and E , forming a parallelogram.

In setting out of these centres, the line $G G$, in which the piston is to move, should fall as much short of the end of the beam, or point B , when in the horizontal position, as it will be beyond the end of the same at the two extremes of the movement, which positions are represented by dotted lines, *fig. 1*: the link, $B D$, connects the end of the beam with the top of the piston-rod, and about half way to the centre of the beam, another link, $C E$, of the same length, is joined, being always kept parallel to the former by a connecting rod, $D E$, which is equal in length to $C B$, so that $C B, D E$, may form a parallelogram, in whatever position it may be placed by the motion of the beam, and the consequent motion of the links and coupling-rod on their moveable centres.

The parallelism of the point, D , is produced by means of the lever, $E F$, which is connected to the point, E , of the parallelogram, and the other end moves on the fixed centre, F ; therefore the end, E , of the rod, $E D$, moves in an arc of a circle, round the centre F ; the other end, D , will be found to traverse the right line $G G$.

The proportions of the levers of this motion admit of great variation: the simplest case is, when the radius, $A C$, is exactly half of $A B$, then $E F$ must be equal to $A C$ or $C B$. Considerable latitude is allowed to the workman in the length of the links $B D$ and $C E$, without sensibly deranging the parallelism of the point D , and piston-rod attached to it. With these proportions, the centre, F , will fall upon the line $G G$, which is often inconvenient; for as there are two of the parallelograms, $C E$ and $D B$, one on each side of the beam, the centres of the lever, $E F$, cannot be made on one common axis. Eleven different proportions for these levers will appear by the following table of dimensions, in inches, taken from some of the best steam-engines, by various makers in or near the metropolis.

The principle on which parallel motion, or what is insensibly near to one, is produced in all these different cases, will best appear, after explaining a different construction for the same purpose by Mr. Freemantle.

Fig. 6. represents this parallel motion, which is effected by means of two fixed centres, D and E. and the three moveable ones B, C and A. In this case the beam-centre, A, is not stationary, but has a small motion on its support D A, which is moveable on the fixed centre D: the centre C, which unites the lever, E C, to the beam, is in the middle of the beam, (*i. e.* BC = CA, and E C is also of the same length,) the support, D A, being of any convenient length; but the longer the better, since the construction requires, in strictness, that the point, A, should slide horizontally in the dotted lines E, A, instead of descending in each end of its course in the arc of the radius D A. The piston-rod, G, is jointed immediately to the end of the beam at B. The parallelism of the motion in this contrivance is effected by the lever, E C, compelling the middle point of the beam, A B, to move upon the arc C C, as it librates upon its centre, whilst that point traverses upon the top of the bar, A D, to such an extent, that the extremity, B, will always traverse upon the line G G, and of course carry the piston-rod with it. This may be demonstrated thus: supposing E A to be a horizontal line, let the dotted line, B A, represent any position whatever of the beam, and E C the corresponding position of the lever; then B C E and A C E will form two isosceles triangles, because of the equal sides B C and C E, and E C and C A: their opposite angles are equal, as E B C = B E C, and C E A = C A E; and because the angle, B E A, is made up of the angles B E C and C E A, the same, (B E A,) is equal to the sum of the two angles, B and A, of the triangle B A E, which shew the third angle, E, to be a right angle; therefore the point, B, will be perpendicular over E, or perpendicular beneath it, as a similar construction, below the line E A, would shew. As the demonstration is equally true of every other part of the movement, as well as its extremes, the angle, B E A, will in all cases be a right angle, and consequently produce a parallel motion. We have here supposed the centre, A, to be confined to slide along the line E A; but in practice it has been found, that the point, A, may be allowed to move in the arc of a circle, described on the centre D, instead of the right line E A, without producing sensible deviation in the parallelism of the point B, and the piston-rod, G, attached to it. The fixed centre, E, may also be moved out of the line B B, either towards or from the centre A, within certain limits, making proportionate alteration in the lengths of the lever E C, and radius A C, as will be evident on making the fol-

lowing comparison between the constructions in fig. 2. and fig. 6. If in figs. 1. and 2. we produce the line D E, and from A draw a line parallel to C E and B D, intersecting it in Y, then suppose the figures turned upside down, and end for end, we can compare the fixed centre D, fig. 6, with A, fig. 2; and the fixed centre E, fig. 6, with F; also the beam A B, fig. 6, with the produced coupling rod Y D; the support D A, fig. 6, with A Y; and the lever E C, fig. 6, with F E: it will then appear that the two constructions are essentially the same in principle, supposing the fixed centre, E, moved out beyond the line B B, as has been mentioned above to be practicable.

The dimensions, given in our table above, will shew what considerable variations in the proportion of lengths, particularly with regard to the lever E F, fig. 2, may be made in practice, without sensibly impairing this admirable contrivance for producing a vertical motion from a power moving up and down, in the arc of a circle described by the end of the beam.

A very ingenious parallel motion is represented in fig. 5, which converts the rectilinear motion of a piston-rod at once to a rotatory motion for a crank or axis. This contrivance has been ascribed to an American, named White; and has been adopted in steam-engines by Mr. Murray, of Leeds. It is founded on a well-known property of epicycloidal curves, *viz.* that if within any given fixed circle another circle rolls round, which is just half the diameter of the fixed circle, any point in the circumference of the rolling circle describes a right line, which crosses the longer circle, as a diameter thereto. The mode of construction is easily understood from the figure, in which A B is a fixed circle, or hoop of cast iron, whose internal diameter is equal to the stroke of the piston; it is supported externally by standards G and H, and furnished with small teeth all round the interior part of its circumference; C is a toothed wheel, whose diameter is only half that of the ring; the axis of the wheel, which is to have the rotatory motion, passes through the centre of the ring, and has a circular iron plate, or wheel E, fixed upon the extremity of it; from this plate, a pin or bolt, R, projects, and is by the motion of the axis carried round in a circle, in the manner of a crank. This pin forms the centre-pin of the small wheel C, and therefore compels it to roll round within the great circle, and keep the teeth always in contact. The upper extremity of the piston-rod is attached to a pin, F, fixed on the circumference of the small wheel, at the point where the two wheels will be in contact, when at the lowest and highest points of the motion.

The pin F, at the circumference of the small wheel, is adjustable by a slider and screw, so as exactly to suit the diameter of the outer circle; and the piston-rod, being attached to it, is moved truly up and down in the line I K, in a very regular manner, when the axis of the plate, E, is turned round; or *vice versa*, if the impelling power is applied to the piston-rod, in which case a fly-wheel must be applied upon the central axis to regulate the motion.

The extremity of the piston-rod will be confined to move in the vertical diameter of the ring, because it is made to describe an epicycloid of that kind, which is formed by a circle rolling round within the inside of another circle of double diameter, in which case, it is well known the epicycloid becomes a diameter of the larger circle, and the smaller circle makes two complete revolutions, while it is revolving from any one point of the larger circle to the same point again.

In all the motions we have described, the conversion of the reciprocating motion to a rotative, is effected by means

of a crank, which communicates with the beam by a connecting rod at the opposite end of the beam, in the manner of H K, *fig. 4*; usually at the end opposite to the parallel levers. Some mechanics have supposed it desirable, in a parallel motion, to give the piston-rod, the saw, or the like, an uniform velocity through the whole of its progress; then to bring it at once to rest again, and to give it instantaneously its intended velocity in the opposite direction, and so on. This the crank will not do, as its motion, at the point where the change or reciprocation of motion takes place, is imperceptible; they have therefore sought other means.

One method of producing this effect is, to make the piston-rod consist of two parallel bars, having teeth in the side, which front each other. Let a toothed wheel be placed between them, having only the half of its circumference furnished with teeth. It is evident, without any further description, that if this wheel be turned uniformly round its axis, the piston-rod will be moved uniformly up and down without intermission. This has often been put in practice, and the piston-rod made to work between grooved rollers, but the machine always went by jolts, and seldom lasted a few days. Unskilful mechanics attributed this to defects in the execution, but the fault is essential, and lies in the principle. The machine could not perform a single stroke without breaking, if the first mover did not slacken a little, or the different parts of the machine did not yield by bending, or by compression, and no strength of materials could withstand the violence of the strains at every reciprocation of the motion. This is chiefly experienced in great works, which are put in motion by a water-wheel, or some other equal power, exerted on the mass of matter of which the machine consists. The water-wheel, being of great weight, moves with considerable steadiness, or uniformity; and when an additional resistance is opposed to it by the beginning of a new stroke of the piston, its great quantity of motion is but little affected by this addition, and it proceeds with very little loss of motion. The machine must either yield a little by bending, and compression, or go to pieces, which is the common event. Cranks are free from this inconvenience, because they accelerate the piston gradually, and bring it gradually to rest, while the water-wheel moves round with almost perfect uniformity. The only inconvenience attending this slow motion of a piston at the beginning of its stroke, is, that the valves do not shut with rapidity, so that some water gets back through them. But when they are properly formed and loaded, this is but trifling.

PARALLEL Planes are those planes which have all the perpendiculars drawn betwixt them equal to each other. And it is demonstrated, that two right lines perpendicular to the same plane are parallel to each other; and that if one of two parallel right lines be perpendicular to any plane, the other will also be perpendicular to the same plane; that planes, to which one and the same right line is perpendicular, are parallel to each other; that all right lines, perpendicular to one of two parallel planes, are perpendicular to the other; that right lines parallel to one and the same right line, though not in the same plane with it, are also parallel to each other; that if two right lines, meeting each other, be respectively parallel to two other right lines, also meeting each other, and not being in the same plane with them, the angles contained by those lines will be equal; that if two right lines, meeting each other, be respectively parallel to two other right lines, also meeting each other, and not being in the same plane with them, the planes extended by those lines will be parallels; and that the sections, made by a plane cutting two parallel planes, are also parallel the one to the

other: and hence parallel lines, terminated by the same parallel planes, are equal to each other.

PARALLEL Rays, in *Optics*, are those which keep at an equal distance in respect to each other, from the visible object to the eye, which is supposed to be infinitely remote from the object.

PARALLEL Ruler, called also *Parallelism*, an instrument consisting of two wooden, brass, or steel rulers, A B and C D, (*Plate X. Geom. fig. 11.*) equally broad every where, and so joined together by the cross blades E F and G H, as to open to different intervals, and accede and recede, yet still retain their parallelism. The use of this instrument is obvious; for one of the rulers being applied to R S, and the other withdrawn to a given point V; a right line A B, drawn by its edge through V, is a parallel to R S; and thus, having given only one line, and erected a perpendicular upon it, we may draw any number of parallel lines, or perpendiculars to them; by only observing to set off the exact distance of every line with the point of the compasses.

But the best parallel rulers are those whose bars cross each other, and turn on a joint at their intersection; one end of each bar moving on a centre, and the other ends sliding in grooves as the rulers recede. See *fig. 12.*

PARALLELS, or *Places of Arms*, in a siege, are deep trenches fifteen or eighteen feet wide, joining the several attacks together; and serving to place the guard of the trenches in, to be at hand to support the workmen when attacked. There are generally three in an attack; the first is about three hundred toises from the covert-way, the second one hundred and sixty, and the third near or on the glacis. They are said to have been first invented or used by M. Vauban.

Thus, in *Plate VII. Fortification, fig. 2*, let A, B be the bastions to be attacked, whose capitals, as well as that of the ravelin C, being indefinitely produced towards the field, set off three hundred fathoms from the salient angles, *r, s*, of the covert-way to the points *l, m*; and from the centre, *o*, of the place, describe an arc of a circle through the points *l, m*, whose intersections with the capitals will terminate the several parts of the first parallel E, which is terminated at twenty fathoms beyond the faces produced of the two adjacent ravelins *z, X*, next to the front attacked. Take *ln, m q*, each equal to one hundred and forty fathoms, and describe from the centre, *o*, another part of a circle through the points *n, q*; and its intersection with these capitals will terminate the several parts of the second parallel F, which extends only ten fathoms beyond the faces of the ravelins *z, X*. Lastly, draw lines through the salient angles of the glacis, and they will give the third parallel G. When this is done, take the points *d, e*, in the capitals of the bastions, at about eight hundred fathoms from the salient angles, *r, s*, of the covert-way, and join them by a right line, which will express the beginnings of the attacks. From the point *f*, in *de*, at about twenty-four or twenty-six fathoms from the point *e*, draw a line *fg* or H of any length, as one hundred and twenty or one hundred and twenty-six fathoms, for the first approach, but so as, when produced, to fall ten or twelve fathoms from the farthest salient angle of the covert-way: from the point *g* draw *gh*, so as to fall as much from the farthest salient angle on the other side of the place; and the point *h* is taken, so as to be nearly at the same distance from the capital *se* as the point *g*; and from the point *h* draw the line *hi*, so as to fall again as far from the farthest salient angle in the first side, and that the point *i* be equally as distant from the capital *se* as the point *h*; and thus continue the approaches to the third parallel. The approaches are traced after the same manner as the capital *d e*, and also

on the capital of the ravelin C, from the second parallel to the third; always observing that no part of them is to be seen or enfiladed from any part of the fortification, nor to defile too much, which would occasion unnecessary labour. As the approaches advance nearer the place, they become shorter, as they make smaller angles with each other. Between the second and third parallels, at the returns of the approaches, are made places of arms, such as I, about thirty or forty fathoms long, nearly parallel to the third parallel, which serve to receive the troops that are to cover the workmen, till the third parallel is quite finished. When the principal or outlines of the trenches are thus traced, parallels are drawn to them on the side towards the field, at twelve feet distance in the approaches, fifteen in the first and second parallels, and at eighteen in the third; and the intervals between these and the former lines will express the width of the trenches. At the ends of the second parallel are made square redoubts, as K, K, of about ten or twelve fathoms on each side, to protect it more effectually from the sallies of the besieged. The first part, *de*, of the trenches is an epaulement of about ten feet high to cover the horse designed to guard the trenches. Muller's *Attack and Def. of Fortified Places*, p. 21, &c.

PARALLELS, or *Parallel Circles*, in *Geography*, called also *parallels of latitude*, and *circles of latitude*, are lesser circles of the sphere, conceived to be drawn from west to east, through all the points of the meridian; commencing from the equator, to which they are parallel, and terminating with the poles.

They are called *parallels of latitude*, &c. because all places lying under the same parallel have the same latitude.

PARALLELS of *Latitude*, in *Astronomy*, are lesser circles of the sphere parallel to the ecliptic, imagined to pass through every degree and minute of the colures.

They are represented on the globe by the divisions of the quadrant of altitude, in its motion round the globe, when screwed over the poles of the ecliptic.

PARALLELS of *Altitude*, or *Almucantars*, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith; having their poles in the zenith.

On the globe these are represented by the divisions on the quadrant of altitude, in its motion about the body of the globe, when screwed to the zenith.

PARALLELS of *Declination*, are the same with parallels of latitude in geography.

PARALLELS, *Anti*. See ANTI-PARALLELS.

PARALLEL *Sphere*, that situation of the sphere in which the equator coincides with the horizon, and the poles with the zenith and nadir.

In this sphere, all the parallels of the equator become parallels of the horizon; consequently no stars ever rise or set, but all turn round in circles parallel to the horizon; and the sun, when in the equinoctial, wheels round the horizon the whole day.

After his rising to the elevated pole, he never sets for six months; and after his entering again on the other side of the line, he never rises for six months longer.

This position of the sphere is their's who live under the poles, if any such there be; their sun being never above $23^{\circ} 30'$ high.

PARALLEL *Sailing*, in *Navigation*, is the sailing under a parallel of latitude.

Of this there are but three cases. 1. Given the departure, and distance; required the latitude. The canon for

which is, as the difference of longitude is to the radius, so is the distance to the cosine of latitude.

2. Given the difference of longitude between two places under the same parallel; required their distance. The canon is, as radius to difference of longitude, so is cosine of latitudes to distance.

3. Given the distance between two places in the same latitude; required their difference of longitude. The canon is, as the cosine of latitude to distance, so is radius to difference of longitude. See SAILING.

PARALLEL *Cut*, in *Inland Navigation*, is a counter-drain to carry off water, and prevent the adjoining lands from being flooded.

PARALLELA, a word used by medical writers to express a sort of scurf or leprous appearance, affecting only the palms of the hands. It is a symptom of the pox.

PARALLELEPIPED, in *Geometry*, one of the regular bodies, or solids, comprehended under six parallelograms, the opposite ones of which are similar, parallel, and equal; as in *Plate X. Geometry*, fig. 13.

A parallelepiped is by some defined an upright prism, whose base is a parallelogram, and the planes of whose sides are perpendicular to the plane of the base. A rectangular parallelepiped is that whose bounding planes are all right angles, and which stand at right angles one to another; and every rectangular parallelepiped is said to be contained under the planes that are its length, breadth, and altitude.

It is demonstrated, that if from one of the angular points of any parallelogram, a right line be elevated above the plane of the parallelogram, so as to make any angles with the contiguous sides of it, and there be also drawn, from the three remaining angular points, three other right lines parallel and equal to the former, and the extremes of these lines be joined, the figure thus described will be a parallelepiped. If the angle of the parallelogram be right, and the elevated line be erected perpendicular to the plane of the base, then will the parallelepiped be a rectangular one.

PARALLELEPIPED, *Properties of the*. All parallelepipeds, prisms, and cylinders, &c. whose bases and heights are equal, are themselves equal.

Every upright prism is equal to a rectangular parallelepiped of equal base and altitude.

A diagonal plane divides the parallelepiped into two equal prisms: a rectangular prism, therefore, is half a parallelepiped upon the same base, and of the same altitude.

All parallelepipeds, prisms, cylinders, &c. are in a ratio compounded of their bases and altitudes: wherefore, if their bases be equal, they are in proportion to their altitudes; and conversely.

All parallelepipeds, cylinders, cones, &c. are in a triplicate ratio of the homologous sides; and also of their altitudes.

Equal parallelepipeds, prisms, cones, cylinders, &c. are in the reciprocal ratio of their bases and altitudes.

Rectangular parallelepipeds, contained under the corresponding lines of three ranks of proportionals, are themselves proportionals.

To measure the Surface and Solidity of a Parallelepiped.—Find the areas of the parallelograms I L M K, L M O N, and O M K P (see PARALLELOGRAM); add these into one sum, and multiply that sum by 2: the product will be the surface of the parallelepiped.

If, then, the base I L M K be multiplied by the altitude M O, the product will be the solidity.

Suppose, *v. gr.* L M = 56, M K = 15, M O = 12. Then
 $L I K M = 36 \times 15 = 540$; $L M O N = 36 \times 12 = 432$;
 M m M O K P

$MOKP = 15 \times 12 = 180$. The sum of which is $= 1152$, which multiplied by 2, gives the superficies equal to 2304. And 540×12 gives the solidity equal to 6480. Or the solid content of a parallelepiped may be obtained by multiplying the area of the base by the altitude of the parallelepiped. *E. g.* If the two dimensions of the base be 16 and 12 inches, and the height of the solid 10 inches; then the area of the base being 192, the content of the solid will be 1920 cubical inches.

The parallelepiped with oblique angles is a figure very common to many kinds of stones, especially of the softer sort. The common crystallizations of grottos break naturally into fragments of this shape; and the stalactites which hang down from their roofs in form of icicles, are originally small hollow pipes formed by the water which continually trickles down drop by drop; and whose outer surfaces, fixing themselves by their small bases, form by degrees a sort of blunted pyramids, which like so many rays from the axis, which is the hollow pipe, grow hollow at last. This axis seems to be composed of plates, almost cylindrical, laid one over another; but, if broken, the whole divides into fragments of a parallelepiped figure: the blunted pyramids that are about the axis divide themselves at first into other blunted pyramids; but afterwards almost all these fragments divide of themselves into other fragments of a parallelepiped figure, this seeming every where the ultimate shape of the particles.

In the mountain of Berege there is found a vast quantity of asbestos; the stone upon which this grows, though in itself of no determinate figure externally, always breaks into regular parallelepipeds: nor is this peculiar to these stones found naturally concentered on the surface or within the bowels of the earth, but it is also found in such as are concentered by means of art out of the water in which they are originally suspended.

The water of the fountain de Salut, near Bagneres in Gascony, when evaporated to a certain degree, yields a scum on the surface, which also adheres to the sides of the vessel; and this scum, examined by the microscope, is found to be composed of many regular parallelepipeds. If the same waters, and those of several other springs, be evaporated to a dryness, there remains a white shining powder, out of which the microscope can direct us to several the like regular figures. *Phil. Trans. N^o 472. p. 32.*

PARALLELISM, the quality of a parallel, or that which denominates it such: or it is that whereby two things, *v. gr.* lines, rays, or the like, become equidistant from one another.

Thus, we say, remote objects are scarcely perceptible, by reason of the parallelism of their rays.

PARALLELISM of the Earth's Axis, in *Astronomy*, or motion of parallelism, is that invariable situation of the earth's axis, in its progress through its orbit, whereby it still looks nearly to the same point of the heavens, *viz.* towards the pole-star; so that if a line be drawn parallel to its axis, while in any one position; the axis, in all other positions or parts of the orbit, will always be nearly parallel to the same line. This parallelism is the necessary result of the earth's double motion; the one round the sun, the other round its own axis. Nor is there any necessity to imagine a third motion, as some have done, to account for this parallelism.

It is to this parallelism that we owe the vicissitudes of seasons, and the inequality of day and night.

PARALLELISM of Rows of Trees. The eye placed at the end of an alley bounded by two rows of trees, planted in parallel lines, never sees them parallel, but always inclining to each other, towards the farther extreme.

Hence mathematicians have taken occasion to enquire, in what lines the trees must be disposed, to correct this effect of the perspective, and make the rows still appear parallel? To this purpose parallel they must not be, but diverging; but according to what law must they diverge? The two rows, in fine, must be such, as that the unequal intervals of any two opposite or corresponding trees may be seen under equal visual angles.

On this principle, F. Fabry has asserted, without any demonstration; and F. Tacquet, after him, has demonstrated by a long and intricate synthesis; that the two rows of trees must be two opposite semi-hyperbolas.

M. Varignon has since, in the Memoirs of the Royal Academy, ann. 1717, found the same solution by an easy and simple analysis. But he renders the problem much more general, and requires not only that the visual angles be equal, but to have them increase, or decrease, in any given ratio: provided the greatest do not exceed a right angle. The eye he requires to be placed in any point either just at the beginning of the ranges, or beyond, or on this side.

All this laid down, he supposes the first row to be a right line, and seeks what line the other must be, which he calls the *curve of the range*. This he finds must be an hyperbola, to have the visual angles equal. The straight and hyperbolic rows will be seen parallel to infinity; and if the opposite semi-hyperbola be added, we shall have three rows of trees (the straight one in the middle), and all three parallel.

Nor is it required this second hyperbola be the opposite of the first, *i. e.* of the same kind, or have the same transverse axis: it is enough, if it have the same centre, its vertex in the same right line, and the same conjugate axis. Thus the two hyperbolas may be of all the different kinds possible; yet all have the same effect.

Again, the straight row being laid down as before; if it be required to have the trees appear under decreasing angles, M. Varignon shews, that if the decrease be a certain ratio, which he determines; the other line must be a parallel straight line.

But he goes yet farther, and supposing the first row any curve whatever, he seeks for another that shall make the rows have any effect desired, *i. e.* be seen under any angles equal, increasing, or decreasing.

Notwithstanding the ingenuity of this speculation, it has been satisfactorily demonstrated by M. D'Alembert, and M. Bouguer, that in order to produce the effect proposed, the trees are to be ranged merely in two diverging right lines. *Encyclopedie.*

PARALLELISM, in *Hebrew Poetry*, is a term used by bishop Lowth for expressing the correspondence of one verse, or line, with another. When a proposition is delivered, and a second is subjoined to it, or drawn under it, equivalent, or contrasted with it in sense, or similar to it in the form of grammatical construction; these the learned prelate calls *parallel* lines; and the words, or phrases, answering one to another in the corresponding lines, are denominated *parallel* terms. Parallel lines, he says, may be reduced to three sorts; parallels synonymous, parallels antithetic, and parallels synthetic. Of these the author has given a variety of examples, exhibiting their various forms, from the books universally acknowledged to be poetical; the correspondent examples from the prophet Isaiah; and sometimes also from the other prophets; in order to shew, that the form and character of the composition are in all the same. It is observed, that the several sorts of parallels are perpetually

mixed with one another; and that this mixture gives a variety and beauty to the composition.

Parallel lines synonymous are those which correspond one to another by expressing the same sense in different, but equivalent terms; when a proposition is delivered, and is immediately repeated, in the whole or in part, the expression being varied, but the sense entirely or nearly the same. Examples occur in the following passages: *viz.* Pf. xxi. 1, 2. Prov. i. 24—32. Isaiah, lv. 6, 7. If. liv. 4. If. li. 7, 8. Joel, xi. 7. Pf. cxii. 1. If. xlvi. 3. Prov. iii. 9. If. lv. 3. In the foregoing examples there are different degrees of synonymous parallelism. The parallel lines sometimes consist of three or more synonymous terms; sometimes of two, which is generally the case, when the verb, or the nominative case of the first sentence, is to be carried on to the second, or understood there; sometimes of one only, as in the four last examples. Among the foregoing there are a few instances, in which the lines consist of double numbers, or two propositions. The author has subjoined one or two more of these, very perfect in their kind, occurring in Pf. cxliv. 5, 6. If. lxxv. 21, 22.

Parallels are also sometimes formed by a repetition of part of the first sentence; as in Pf. lxxvii. 1. 11. 16. If. xxvi. 5, 6. Hosea, vi. 4.

Sometimes in the latter line a part is to be supplied from the former to complete the sentence; as in 2 Sam. xxii. 41. Job, xxvi. 5. If. xli. 28.

There are also parallel triplets; when three lines correspond together, and form a kind of stanza, of which, however, only two commonly are synonymous: Pf. cxii. 10. Job, iii. 4. 6. 9. If. ix. 20. Joel, iii. 13. There are likewise parallels consisting of four lines; two distichs being so connected together, by the sense and the construction, as to make one stanza. Such is the form of the xxxviii. Psalm. See particularly Pf. xxxvii. 1, 2. If. i. 3. If. xlix. 4. Amos, i. 2.

Some periods may be considered as making stanzas of five lines, in which the odd line, or number, either comes in between two distichs, or after two distichs making a full close: as in Job, viii. 5, 6. If. xlvi. 7. Hof. xiv. 9. Joel, iii. 16. If. xlv. 26. In stanzas of four lines sometimes the parallel lines answer to one another alternately; the first to the third, and the second to the fourth; as in Pf. ciii. 11, 12. If. xxx. 16. If. l. 16.

The second parallels are the antithetic; when two lines correspond with one another by an opposition of terms and sentiments; when the second is contrasted with the first, sometimes in expressions, sometimes in sense only. Accordingly the degrees of antithesis are various, examples of which occur in Prov. x. 1. Prov. x. 7. Prov. xi. 24. Prov. xxix. 26. Prov. xvi. 33. See also Pf. xx. 7, 8. Pf. xxx. 5. Pf. xxxvii. 10, 11. If. liv. 10. If. ix. 10.

The third sort of parallels comprehends those, which are called synthetic, or constructive; where the parallelism consists only in the similar form of construction; in which word does not answer to word, and sentence to sentence, as equivalent or opposite; but there is a correspondence and equality between different propositions, in respect of the shape and turn of the whole sentence, and of the constructive parts; such as noun answering to noun, verb to verb, number to number, negative to negative, interrogative to interrogative. See Pf. cxlviii. 7—13. Job, xii. 13—16. If. lviii. 5—8. The following passages are constructively parallel, *viz.* Pf. cxxxv. 6, 7. If. l. 5, 6. Micah, vi. 15. See also Prov. xxx. Prov. vi. 16—19. Eccl. xi. 2. If. li. 19. Cantic. i. 5. If. xv. 3.

Of the three different sorts of parallels, above-enumerated, every one has its peculiar character and proper effect;

and therefore they are differently employed on different occasions; and that sort of parallelism is chiefly made use of, which is best adapted to the nature of the subject and of the poem. Synonymous parallels have the appearance of art and concinnity, and a studied elegance; they prevail chiefly in shorter poems; in many of the psalms; in Balaam's prophecies; frequently in those of Isaiah, which are most of them distinct poems of no great length. The antithetic parallelism gives an acuteness and force to adages and moral sentences; and therefore abounds in Solomon's proverbs, and elsewhere is not often to be met with. The poem of Job, being on a large plan, and in a high tragic style, though very exact in the division of the lines, and in the parallelism, and affording many fine examples of the synonymous kind, yet consists chiefly of the constructive. A happy mixture of the several sorts gives an agreeable variety; and they serve mutually to recommend and set off one another. Lowth's Preliminary Dissertation to his "New Translation of Isaiah."

PARALLELOGRAM, in *Geometry*, a quadrilateral right-lined figure, whose opposite sides are parallel, and equal to each other.

A parallelogram is generated by the equable motion of a right line always parallel to itself.

When the parallelogram has all its four angles right, and only its opposite sides equal, it is called a *rectangle*, or an *oblong*.

When the angles are all right, and the sides are all equal, it is called a *square*, which some make a species of parallelogram, others not.

If all the sides are equal, and the angles unequal, it is called a *rhombus*, or *lozenge*.

If both the sides and angles be unequal, it is called a *rhomboides*.

Every other quadrilateral whose opposite sides are neither parallel nor equal, is called a *trapezium*. See each of these, under their respective names.

PARALLELOGRAM, *Properties of the*. In every parallelogram, what kind soever it be of, *e. gr.* A B C D, *Plate X. Geometry, fig. 14.* a diagonal D A divides it into two equal parts; the angles diagonally opposite B, C, and A, D, are equal; the opposite angles of the same side, C, D, and A, B, &c. are, together, equal to two right angles; and each two sides together are greater than the diagonal. Every quadrilateral whose opposite sides are equal, is a parallelogram.

Two parallelograms A B C D, and E C D F, on the same, or on an equal base C D, and of the same height A C, or between the same parallels A F, C D, are equal. And hence two triangles C D A, and C D F, on the same base, and of the same height, are also equal; and all parallelograms or triangles whatever, whose bases and altitudes are equal among themselves.

Hence, also, every triangle C F D is half a parallelogram A C D B upon the same, or an equal base C D, and of the same altitude, or between the same parallels. Hence also a triangle is equal to a parallelogram, having the same base, and half the altitude, or half the base, and the same altitude.

Parallelograms, therefore, are in a given ratio, compounded of their bases and altitudes. If then the altitudes be equal, they are as the bases; and conversely.

In similar parallelograms and triangles, the altitudes are proportional to the homologous sides; and the bases are cut proportionably thereby. Hence, similar parallelograms and triangles are in a duplicate ratio of their homologous sides, also of their altitudes, and the segments of their bases: they

are, therefore, as the squares of the sides, altitudes, and homologous segments of the bases.

In every parallelogram, the sum of the squares of the two diagonals is equal to the sum of the squares of the four sides; and the two diagonals bisect each other. For the triangles AEB , DEC , (*fig. 15.*) being equi-angular, on account of the equal vertical and alternate angles, and having one side $AB =$ one side DC , will have $AE = CE$, and $BE = DE$. Moreover, because the double of the square of a line drawn from the vertex to the middle of the base of any triangle, together with double of the square of the semi-base, is equal to the squares of both the sides taken together, $2AE^2 + 2ED^2 = AD^2 + CD^2$, and by doubling these, we shall have, because four times the square on half a line is equal to the square on the whole line (see SQUARE), $4AE^2 + 4ED^2 = AD^2 + CD^2 + 4AE^2 + 4ED^2 = AD^2 + BC^2 + CD^2 + AB^2$.

This proposition, M. de Lagny takes to be one of the most important in all geometry; he even ranks it with the celebrated forty-seventh of Euclid, and with that of the similitude of triangles; and adds, that the whole first book of Euclid is only a particular case of it. For if the parallelogram be rectangular, it follows, that the two diagonals are equal; and, of consequence, the square of a diagonal, or, which comes to the same thing, the square of the hypotenuse of a right angle, is equal to the squares of the sides.

If the parallelogram be not rectangular, and of consequence, the two diagonals be not equal, which is the most general case, the proposition becomes of vast extent; it may serve, for instance, in the whole theory of compound motions, &c.

There are three ways of demonstrating this proposition; the first by trigonometry, which requires twenty-one operations; the second geometrical and analytical, which requires fifteen. M. de Lagny gives a more concise one, in the Mémoires de l'Acad. which only requires seven.

To find the area of the right-angled parallelogram $ABCD$, (*fig. 14.*) Find the length of the sides AB and AC ; multiply AB into AC , the product will be the area of the parallelogram. Suppose, *e. gr.* AB to be 345; AC 123; the area will be 42435.

Hence, 1. Rectangles are in a ratio compounded of their sides AB and AC . 2. If, therefore, there be three lines continually proportional; the square of the middle one is equal to the rectangle of the two extremes: and if there be four proportional lines, the rectangle under the two extremes is equal to that under the two middle terms.

Other parallelograms, not rectangular, have their areas found by resolving them, by diagonals, into two triangles, and adding the areas of the separate triangles into one sum; or by multiplying their bases into their altitudes.

PARALLELOGRAM, *Complement of a* See COMPLEMENT.

PARALLELOGRAM, *Centre of Gravity of a*. See CENTER of Gravity, and CENTROBARYC Method.

PARALLELOGRAM, *Newtonian or Analytic*, in Algebra, an appellation used for an invention of sir Isaac Newton, to find the first term of an infinite converging series.

This is sometimes called the method of the parallelogram and ruler; because a ruler or right line is also used in it.

This analytic parallelogram is formed by dividing any parallelogram into equal squares or parallelograms, by lines drawn horizontally and perpendicularly through the equal divisions of the sides of the parallelogram. The cells, thus formed, are filled with the dimensions of the quantities x and y , and their products.

The powers, $y^0 = 1$, y , y^2 , y^3 , y^4 , &c. of y , for instance

being placed in the lowest horizontal range of cells, and the powers of x , or $x^0 = 1$, x , x^1 , x^2 , &c. in the vertical column to the left, or *vice versa*; so that these powers and their products will stand as in *Plate XVII. Analysis, fig. 4.*

Thus, when any literal equation is proposed, mark such of the parallelograms or cells as correspond to all its terms; and let a ruler be applied to two, or perhaps more of the parallelograms so marked, of which let one be the lowest in the left-hand column at AB , the other touching the ruler towards the right hand; and let all the rest not touching the ruler lie above it. Then select those terms of the equation which are represented by the parallelograms that touch the ruler, and from them find the quantity to be put in the quotient.

This is sir Isaac Newton's famous rule, of the application of which he has left us some examples in his Method of Fluxions and Infinite Series, p. 9 and 10, but without demonstration; which has been since supplied by others. See Mr. Colson's Comment on that treatise, p. 192, seq. MacLaurin's Algebra, p. 251, seq. and particularly Mons. Cramer's *Analyf. des Lignes Courbes*, chap. vii. p. 148, seq.

This learned author observes, that this invention, which is the true foundation of the method of series, was but imperfectly understood, and not valued as it deserved for a long time. He thinks it more convenient in practice to use the analytic triangle of the abbé de Gua, which takes in no more than the diagonal cells lying between A and C , and those which lie between them and B .

PARALLELOGRAM, or *Parallelism*, also denotes a machine used for the ready and exact reduction or copying of designs, schemes, prints, &c. in any proportion; which is done hereby without any knowledge or habit of *designing*; which see.

The parallelogram is also called pentagraph. See its description and use under PENTAGRAPH.

PARALLELOGRAM of the Hyperbola, in Geometry, is used for the parallelogram formed by the two asymptotes of an hyperbola, and the parallels to them, drawn from any point of the curve. A parallelogram thus formed is of an invariable magnitude in the same hyperbola; and the rectangle of its sides is equal to the power of the hyperbola. L'Hôpital, *Señ. Coniq. Art. 99—101.* See POWER.

This parallelogram is the modulus of the logarithmic system; and if we take it as unity, the hyperbolic sectors and segments will correspond to Napier's, or the natural logarithms. If the parallelogram be taken $= 0.43429$, &c. these sectors and segments will represent Briggs's logarithms. See LOGARITHM.

Huygens has made use of this term, *De Caus. Gravitat. in fin.* See LOGARITHMIC Curve.

PARALLELOGRAM *Protractor*, a mathematical instrument, consisting of a semicircle of brass, with four rulers in form of a parallelogram, made to move to any angle: one of these rulers is an index, which shews on the semicircle the quantity of any inward or outward angle.

PARALLELOPIPEDIA, in *Natural History*, the name of a genus of spars, thus called, because regularly of a parallelepiped or paralepiped form.

They are pellucid crystalline spars, externally of a determinate and regular figure, always found loose, detached, and separate from all other bodies, and in form an oblique paralepiped, with six parallelogram sides and eight solid angles, easily fissile, either in an horizontal or perpendicular direction, being composed of numbers of thin plates, and those of very elegantly and regularly arranged bodies, each of the same form with the whole mass, except that they are thinner in proportion to their horizontal planes; and naturally

rally fall into these and no other figures, on being broken with a slight blow.

Of this genus Hill has enumerated four known species. 1. The hard, pellucid, and colourless one, called the island crystal of authors. (See *Island CRYSTAL*.) 2. A dull and whitish kind, found in France, Germany, and England, particularly in the Derbyshire and Yorkshire lead-mines, and about Scarborough. This has the same property with the former, of giving a double refraction; but it is so dull and opaque, that it does not shew it so elegantly. 3. A soft, whitish, and very bright one, found principally in the lead-mines of Yorkshire, and about the sea-shores of that county. And, 4. A dull, hard, and pale brown one: this is found in the lead-mines of the same county, and in some parts of Ireland. All these species have the same power of double refraction with the first, but are too opaque to shew it so beautifully, and often have not transparency enough to make it at all distinguishable.

PARALLELOPLEURON, a term used by some writers for an imperfect parallelogram, or a kind of trapezium, having unequal angles and sides, but which observe a certain regularity and proportion.

PARALOGISM, *παραλογισμὸς*, in *Logic*, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false, or, though true, are not proved; or when a proposition is passed over, which should have been proved by the way.

A paralogism differs from a sophism in this, that the sophism is committed out of design and subtlety; and paralogism out of mistake, and for want of sufficient light and application.

Yet Messieurs du Port Royal do not seem to make any difference between them.

PARALOPHIA, a word used by Keil, and some other anatomical writers, to express the lower and lateral part of the neck.

PARALOURGES, *παραλουργῆς*, among the ancients, a kind of garment, with a purple clavus on each side. See **CLAVUS**.

PARALYSIS, in *Botany*. See **PRIMROSE**.

PARALYSIS, in *Medicine*. See **PALSY**.

PARALYTIC, a person afflicted with the paralysis, or palsy.

PARAMARIBO, or **PARAMAIRAMBA**, in *Geography*, a considerable town of South America, and capital of Surinam, or Dutch Guiana, occupying a pleasant gravelly situation, on the banks of the river Surinam, which is here about a mile in breadth. The number of houses, chiefly constructed of timber, is about 1400. and that of the inhabitants is about 5000; the town contains two churches, and two Jewish synagogues: the streets are all perfectly straight, and lined with trees, such as oranges, lemons, shaddocks, and tamarinds. It is about 18 miles from the sea, and has a good harbour. N. lat. 5° 48'. W. long. 55° 11'.

PARAMBAH, a town of Hindoostan, in Bahar; 17 miles E. of Bahar.

PARAMECIUM, in *Vermeology*, a genus of worms of the order Infusoria, of which the generic character is this; an invisible, simple, pellucid, flattened worm. There are seven species mentioned by Gmelin, which are as follow:

Species.

* **AURELIA**. This is compressed, longitudinally plaited towards the fore part, behind it is acute. This, says Mr. Adams, is rather a large animalculum, four times longer than it is broad; the fore part is obtuse, transparent, and apparently without intestines; the hind part is filled with

molecules of various sizes; the fold that goes from the middle to the apex is a striking characteristic of the species, forming a kind of triangular aperture, and giving it somewhat the appearance of a gimblet. Its motion is rectilinear, reeling, or staggering, and generally vehement. This species is frequently found in ditch-water, and in infusions, cohering lengthwise; the lateral edges of both bodies appear bright. They may sometimes be seen lying on one another alternately, at others adhering by the middle. They will live many months in the same water, without its being renewed. They are to be found in the month of June, in ditches where there is plenty of duck-weed.

* **CHIRYSALIS**. This is cylindrical, longitudinally plaited on the fore part, and obtuse behind. It is an inhabitant of salt water, is very like the last, but is more obtuse behind. The margins are filled with black globules.

* **OVIIFERUM**. Depressed, with large oval molecules within: the body is oval, pellucid, with black grains towards one end.

MARGINATUM. This is depressed, is grey, and has a double margin. It is, says Mr. Adams, one of the largest of the genus, flat, elliptical, and every part filled with molecules, except in the lower end, where there is a pellucid vesicle. This animalculum is surrounded by a broad double margin, and at the moment of its expiring, a bright spiral intestine is observable.

CAUDATUM. This species is pointed at both ends, the middle is the broader, and filled with molecules. It is found in waters among duck-weed; its motion is very slow.

ANCEPS. The tail of this species is two-edged, and the head is obtuse. The motion of this animalculum is very slow; it is found in the water, in which the plant hydrocharis is produced.

ACUTUM. Tail two-edged, head acute; inhabits stagnant water; is slow in its motions, continually agitating its tail.

VERSUTUM. This species, mentioned by Adams, is cylindrical, the lower part thick, and both ends very obtuse. It has an oblong green gelatinous body, filled with molecules; the lower part is thick, the fore part is smaller, both ends are obtuse, and they may be seen to propagate by division. It is found in ditches.

PARAMESE, *παραμῆσον*, in the *Ancient Music*, the ninth chord or sound in the diagramma, or scale of music.

The word is Greek, and signifies *juxta medium*, next to the middle; its situation in the first state of the scale, being next the mese, or middle chord.

It was the note above the mese, which answers to *a-la-mi-re* of Guido's scale. Hence, as the paramese was the first of the diazeugmenon tetrachord, it will be equivalent to Guido's highest \sharp mi. See **DIAGRAM**.

PARAMESOS, a word used by some to express the ring-finger, that next the little one.

PARAMESWARA, in *Mythology*, a name given to the Hindoo deity Siva by his sectaries. Hindoos of some sects give this name exclusively to Brahm, the supreme ruler; others apply it to the deity whom they more particularly worship. In one of the Puranas, Lakshmi is invoked under the name of Paramaiswarya-rupini, meaning with the countenance of Parameswara; but in strictness it seems more applicable to the supreme ruler, as noticed under the article **MAYA**.

PARAMETER, in *Geometry*, a constant right line in each of the three conic sections; called also *latus rectum*. In the parabola the rectangle of the parameter, and an abscissa, is equal to the square of the correspondent semi-ordinate. See **PARABOLA**.

In an ellipsis and hyperbola, the parameter is a third proportional to a conjugate, and transverse axis. See ELLIPSIS and HYPERBOLA.

PARAMO, LUIZ DE, in *Biography*, a native of Borox, in the diocese of Toledo, archdeacon and canon of Leon, and afterwards inquisitor in Sicily, is author of a most extraordinary work, entitled "De Origine et Progressu Officii Sanctæ Inquisitionis, ejusque Dignitate et Utilitate," which was undertaken under the patronage of D. Gaspar de Quiroga, then archbishop of Toledo, and inquisitor-general, and which was pronounced by Nicholas Antonio, to be a work full of various learning. It was printed in folio at Madrid in 1598, and afterwards at Antwerp, in 1614, and a copy of the first edition is in Dr. Williams' library in Redcross-street, London. Mr. Southey, in the *General Biography*, has given an analysis of this book, from whose account we shall give a short extract, to shew the inquisitor's mode of reasoning.

Paramo begins by proving God to have been the first inquisitor, who convicts Adam and Eve of heresy, infidelity, apostasy, and blasphemy. God cited Adam, otherwise the process would have been null. On Adam's appearance, he made inquisition into the crime. The man accused his wife, and then the judge questioned her: he did not examine the serpent, because of his obstinacy. The examinations were secret and separate, that there might be no collusive lying. He calls no witnesses, and affirms that confession and confession are as a thousand witnesses, and save the judge all the trouble, except that of condemning. The whole, he says, was done secretly, that it might be a precedent for the holy office; and so closely does this holy office observe the precedent, that they make the dress of penitent offenders after the very pattern of the clothes which God made for Adam and Eve, and confiscate all the property of a heretic, because Adam and Eve were turned out of paradise. The author then goes on to shew that Abraham was an inquisitor, so were David and Solomon, Christ, and a multitude of others, but our readers will easily believe, after the specimen we have given, he can prove any thing. It had been well had Paramo stopped here, but he was one of the most savage practical inquisitors that ever existed. In proof of this it is sufficient to observe, that, he himself says, in the course of one hundred and fifty years, the inquisition had burnt thirty-thousand witches, and he claims great part of the merit for himself, saying he had punished very many of them. We cannot help saying, that unless the British government insist upon the abolition, not only of the existing inquisition in Spain, but also of the laws (which we know on good authority still remain) which sanction so savage a court, they cannot with any degree of propriety be said to be contending for the liberties of mankind. We hope the noble marquis, the hero of the times, will immortalize his name by destroying every vestige of it.

PARAMORES, in *Geography*, a small island in the Atlantic, near the coast of Virginia. N. lat. $37^{\circ} 36'$. W. long. $75^{\circ} 44'$.

PARAMOUNT, in our *Law*, signifies the supreme lord of the fee.

There may be a tenant to a lord, who holdeth himself of another lord; in respect whereof the former lord is called *lord mesne* (see MESNE), and the latter *lord paramount*.

All honours, which have manors under them, have the lord paramount.

But even the term lord paramount is only comparative; for as one man may be great, compared to a less; and little, being compared with a greater; so none truly seems to be

lord paramount but the king, who is patron paramount to all the benefices in England. See MANOR and TENANT.

PARAMOUSIR, or POROMASHIR, in *Geography*, the second of the Kurile or Kurilskoi islands; between which and Shoombshu, the Irait is but two versts broad. It extends from N.E. to S.W., and is twice as large as Shoombshu, and, according to Capt. Cook, is the largest of the Kuriles under the dominion of Russia. The land is very high, and when visited by Capt. Cook's navigators, in his Third Voyage, Oct. 13, 1779, it was entirely covered with snow. It is richly furnished with roots and minerals, but destitute of wood. Here is no scarcity of red foxes, wolves, and all kind of mice. Mr. King places the S. end of this island in N. lat. $49^{\circ} 58'$, and the N. end in lat. $50^{\circ} 46'$. E. long. $156^{\circ} 14'$.

PARAMUTTY, a town of Hindoostan, in the Carnatic, taken by the British in 1790; 10 miles S.W. of Coveriporum.

PARANA, the longest and most considerable stream of the Rio de la Plata, which rises in the grand mineral mountains of Brasil, S. lat. 19° , and bending S., then W. till it receives the Iba Parana, after which it bends S.W. till it is joined by the Paraguay; while the conjunct rivers are still called the Parana by the natives, and the Rio de la Plata by the Spaniards. Yet the length of the Paraguay, according to the map of La Cruz, does not yield above half a degree to that of the Parana; and the straightness of its course gives it the appearance of the principal river. The grand cataract of the Parana is in lat. 24° , not far from the ruined town of Cuayra; but is rather a series of rapids, for a space of 12 leagues, amidst rocks of tremendous and singular forms. Dobrizhoffer asserts that the Parana is the chief stream, which receives the Paraguay and Uruguay. The inundations are chiefly in December and January, rising about five or six yards above the islets. This noble river is studded with numerous islands; and Spanish vessels navigate to the town of Assumption, about 400 leagues from the sea. On the shores are often found geods, inclosing crystals; but the natural history of the Parana is almost as obscure as that of the true Maranon. The breadth of the estuary is such, that the land cannot be discovered from a ship in the middle of the stream. Pinkerton.

PARANA, a town on the W. coast of the island of Samar. N. lat. $11^{\circ} 54'$. W. long. $124^{\circ} 48'$.—Also, a town of Brasil, on the coast of the island of Marajo. S. lat. $0^{\circ} 12'$. W. long. $51^{\circ} 36'$.

PARANAGUA, a river of Brazil, which runs into the Atlantic, S. lat. $25^{\circ} 30'$.

PARANA-MERIN, a river of Brazil, which runs into the Atlantic, S. lat. $2^{\circ} 50'$. W. long. $42^{\circ} 46'$.

PARANAPANEMA, a river of Paraguay, which runs into the Parana.

PARANETE, in the *Ancient Music*, was a name sometimes used to signify the next note or chord to the nete, or last note of a tetrachord.

Hence it might be called the penultimate chord. It was otherwise, and more properly called the *lichanos*, or index.

PARANETE *Diezeugmenon*, in the *Greek Music*, was the penultimate note of the diezeugmenon tetrachord, and answers to Guido's *de-la-fol-re*. See DIAGRAM.

PARANETE, *Hyperbolæon*, was the penultimate note of the hyperbolæon tetrachord, and answers to Guido's *g-fol-re-ut*. See DIAGRAM.

PARANOMASIA, is a figure that occurs when two words, very near in sound, but different in sense, respect each

each other in the same sentence; this is usually called a pun.

PARANOO, in *Geography*, a river of Malacca, which runs into the sea, N. lat. 4° 40'. E. long. 103° 25'.

PARANYMPH, PARANYMPHUS, among the ancients, the person who waited on the bride-groom, and directed the nuptial solemnities; called also *pronubus* and *auspex*, because the ceremony begun with taking auspicious.

In strictness, the paranymph, *παρὰνυμφος*, only officiated on the part of the bride-groom; on the part of the bride a woman officiated, who was called *pronuba*.

The Jews had likewise a kind of paranymphs, which the Talmud and rabbins call *ששׁבׁים*, *schuschelim*, q. d. *companions of the spouse*.

The fourth council of Carthage appoints, that when the married couple come to ask the priest's blessing, they be presented either by their fathers and mothers, or by their paranymphs.

PARAPET, BREASTWORK, in *Fortification*, a defence, or screen, on the extreme of a rampart, or other work, serving to cover the soldiers and the cannon from the enemy's fire. See *Plate VII. Fortification, fig. 3.*

Borel gives us, from Jos. Maria Surenhus, a curious collection of names, which the ancients and moderns have given to this kind of parapet: the Latins call them *subarra*, and *bastia*, whence the names bastion and bastille. They also call them *paginematata*, *lorica*, and *antemuralia*. The Spaniards call them *barbacanes*; the Italians, *parapetti*, because of their defending the breast, *petto*; whence our parapet.

Parapets are raised on all works, where it is necessary to cover the men from the enemy's fire; both within and without the place, and even in the approaches. See *Mr. Vauban's Method of Fortification*, under the article *Military CONSTRUCTION*.

The thickness of the parapet should be about eighteen or twenty feet, in order to be cannon-proof, and it should be about seven or eight feet high, when the enemy has no command above the battery; otherwise it should be raised high enough to cover the men while they load the guns. Its length depends on the number of guns to be employed in the battery: for one gun, it is common to allow eight yards in length, and six yards more for every other gun. The parapet consists of two parts, the wall contained in one piece from end to end, and about two and a half or three feet high, and the merlons, which are detached pieces of the parapet, leaving openings, called embrasures, through which the cannon deliver their shot.

The parapet of the wall is sometimes of stone. The parapet of the trenches is either made of the earth dug up; or of gabions, fascines, barrels, sacks of earth, or the like.

PARAPET is also a little wall, breast-high, raised on the brinks of bridges, quays, or high buildings; to serve as a stay, and prevent people's falling over.

PARAPH, a particular character, knot, or flourish, which people habituate themselves to make always in the same manner at the end of their name, to prevent their signature from being counterfeited.

The paraph of the kings of France used to be a grate, which the secretaries always place before their own, in all letters, &c. Menage derives the word from *paragrapheus*. See PARAGRAPH.

PARAPHERNALIA, or PARAPHERNA, in the *Civil Law*, those goods which a wife brought her husband, besides her dower, and which were still to remain at her disposal, exclusive of her husband, unless there was some provision made to the contrary in the marriage-contract.

The word is formed from the Greek *παρα*, *beyond*, or *over*, and *φερν*, *dos*, *dower*. "In his rebus quas extra dotem mulier habet, & quas Greci *παρὰφερνα* vocant, nullam, uxore prohibente, vir habeat communionem." Cod. de Pactis.

The Grand Customary of Normandy gives a different sense to the word; it calls paraphernalia the moveables, linen, and other female necessaries, which are adjudged to a wife, in prejudice to the creditors, when she renounces the succession of her husband.

Some of our English lawyers give a still different sense to the word paraphernalia, defining it to be such goods as a wife challengeth over and above her dower, or jointure after her husband's death; as furniture for her chamber, wearing apparel, and jewels, which are not to be put in the inventory of her husband's goods.

Accordingly the apparel and ornaments of a wife, suitable to her rank and degree, are paraphernalia; and even the jewels of a peeress, usually worn by her, have been held to be paraphernalia. (Moor, 213.) These she becomes entitled to at the death of her husband, over and above her jointure or dower, and preferably to all other representatives. (Cro. Car. 347. 1 Roll. Abr. 911. 2 Leon. 166.) Neither can the husband devise by his will such ornaments and jewels of his wife; though during his life perhaps he hath the power (if unkindly inclined to exert it) to sell them or give them away. (Noy's Max. c. 49. *Grahme v. lord Londonderry*, 24 Nov. 1746. *Caſt*.) But if she continues in the use of them till his death, she shall afterwards retain them against his executors and administrators, and all other persons except creditors, where there is a deficiency of assets. (1 P. Wins. 730.) And her necessary apparel is protected even against the claim of creditors. Noy's Max. c. 49.

PARAPHIMOSIS, or PARAPHYMOSIS, from *παρα*, *back*, and *σιμων*, *to bridle*. This term, in *Surgery*, is applied to the case, in which the prepuce is drawn backward, behind the glans penis, and cannot be brought forward again. The complaint is the very reverse of phymosis, which is attended with a contraction of the opening of the prepuce, so that the glans cannot be uncovered. Both these diseases are mostly the consequence of an inflammatory thickening of the prepuce, arising from the irritation of gonorrhœa, a chancre, or simple excoriations. Paraphymosis very frequently follows phymosis, by the thickened prepuce being very improperly drawn back behind the glans. In this circumstance, the constricted part of the prepuce acts as a ligature round the body of the penis, and retards the return of blood from the glans, and the portion of the prepuce beyond the stricture. Hence, œdematous inflammation attacks the latter part, while the former becomes prodigiously distended, and, it is evident, that mortification of the glans and part of the prepuce may be produced by the complaint.

Paraphymosis frequently admits of being expeditiously relieved, by compressing as much of the blood as possible out of the glans penis, and then pushing this part back again through the stricture. In order to perform this operation skilfully, the surgeon should first make continued pressure on the glans, by placing it between the ends of the thumb, index, and middle fingers of each hand. The whole surface of the part should thus be gradually compressed at the same time for the space of four or five minutes. Then the two thumbs are to be employed, both in pushing backward the diminished glans, and, together with the fingers, in drawing forward the prepuce. The cases, which cannot thus be relieved, are extremely few. When the plan fails, however, leeches should be applied to the glans, and the flow of blood be afterwards promoted by immersing the part in warm water.

In almost every case, the preceding method will now be found completely effectual. But, if it should not do so, as much blood must be taken away by venesection, as the state of the patient will well bear, and the part is either to be covered with a cold saturnine poultice, or the lotio plumbi superacetatis. When, notwithstanding every exertion, and the strict observance of antiphlogistic means, the œdematous swelling increases instead of subsiding, the only way to prevent a mortification of the glans and prepuce is to make an incision, just behind the former part, through that portion of the prepuce which forms the constriction. A small scalpel is the best instrument, and care must be taken to cut to a sufficient depth. In most surgical books, paraphymosis is represented as a venereal complaint, and demanding the exhibition of mercury; but the history, which we have here given of it, must convey a different, and, we trust, a more accurate notion of the complaint. When paraphymosis originates from the irritation of a chancre, mercury is indeed necessary for the cure of the sore; but the paraphymosis does not itself absolutely require this medicine, and may be at once cured by compressing the glans and pushing it back through the constricted part of the prepuce. Paraphymosis from gonorrhœa never stands in need of mercury. See First Lines of Practice of Surgery, by S. Cooper, edit. 3.

PARAPHONIA, from *παρὰ*, and *φωνή*, *the voice*, signifies a depraved sound of the voice in speaking, and of course is not applicable to dumbness. Dr. Cullen makes six species of *morbid voice*, viz. 1. Paraphonia *puberum*, or the harsh and rough voice of males about the period of puberty. 2. *P. rauca*, or hoarseness, connected with dryness or swelling in the fauces. 3. *P. resonans*, or nasal tone, from obstructed nostrils. 4. *P. palatina*, or the change of voice arising from a less or division of the uvula, or pendulous palate. 5. *P. clangens*, when the voice acquires a shrill, acute, and small sound. And, 6. *P. comatosa*; when, from relaxation of the palate and glottis, a stertorous sound is made during inspiration. Cullen, Nosol. Meth. Gen. 112.

PARAPHONIA, in *Musical*, is that species of concord which results from different sounds, as the fifth and fourth: and thus it differs from *homophonia*, which is produced by the same sounds, as in the unison, and from *antiphonia*, or the replication of the same sounds, as in the octave.

PARAPHORA, a word used by the ancients to express a slight kind of delirium, or light-headedness in a fever: some have made it to signify a delirium in general.

PARAPHRASE, *παρὰφρασις*, an explanation of some text in clearer and more ample terms, whereby we supply what the author might have said or thought on the subject. See TEXT.

Colomesius looks on Erasmus's Paraphrase on the New Testament as so extraordinary a work, that he makes no scruple to declare, he thinks the author to have been divinely inspired when he penned it.

PARAPHRASE, *Chaldee*, is a phrase frequent among the critics and divines, denoting an ancient version of the bible, in Chaldee. There are three Chaldee paraphrases on the Pentateuch: that of Onkelos, whom some take to be the same with Aquila, and whom others take to have been that Onkelos whom the Talmudists, in the treatise "Gittin," make a nephew of the emperor Titus. The second is the paraphrase of Jonathan. The third is called the Targum of Jerusalem. See TARGUM.

The Chaldee paraphrase on the prophets is that of Jonathan son of Uziel, whom some confound with Theodotus.

The author of the Chaldee paraphrase on the Hagiographers is unknown. Some attribute it to one Joseph, fur-

named the Squinter; others to rabbi Akiba. Others say there is so much difference in the style, that no one person can have been the author of the whole.

The paraphrase of Onkelos is that which is most esteemed by the modern Jews, and read in their synagogues. See Walton Pref. Polyglott.

PARAPHRENTIS, *παρὰφρενίτις*, in *Medicine*, sometimes written *paraphrensis*, is not derived, it would appear, from *φρην*, *mens*, and therefore synonymous with *phrenitis*, or *phrensy*, but from *φρενες*, *præcordia*; and it is synonymous with *diaphragmitis*, which signifies an inflammation of the diaphragm. The disease, indeed, is described as accompanied by severe delirium, but its seat is in the diaphragm, and consequently the pain and most distressing symptoms are referred to the præcordia.

Authors who have described the paraphrenitis, have mentioned the symptoms attendant upon pleurisy, together with constant delirium and a *risus sardonicus*, or convulsive laughter, as characterizing the disease. They describe the respiration as exceedingly short and quick, being performed entirely by the motion of the ribs, the tender state of the diaphragm not admitting of its motion, and therefore preventing the expansion of the cavity of the chest in that direction. They mention also other symptoms, indicative of the inflammatory soreness of the diaphragm, especially an extreme increase of the pain of the chest upon coughing, sneezing, reaching, vomiting, straining at stool, &c. See Boerhaave, Aphorism 909.

But there appears to have been some mistake, in referring such a fever, with delirium, and convulsive laughter, to an inflammation of the diaphragm: and every practitioner will now accord with the observation of Dr. Cullen, when he observes, (First Lines, par. cccxlii.) "an inflammation of the pleura covering the upper surface of the diaphragm has been distinguished by the appellation of *paraphrenitis*, as supposed to be attended with the peculiar symptoms of delirium, risus sardonicus, and other convulsive motions; but it is certain, that an inflammation of that portion of the pleura, affecting also even the muscular substance of the diaphragm, has often taken place without any of these symptoms; and I have not met with either dissections, or any account of dissections, which support the opinion, that an inflammation of the pleura covering the diaphragm is attended with delirium more commonly than other pneumonic inflammation." The result of modern investigation of disease, by dissection after death, is in fact demonstrative of the error of referring such a fever to inflammation of the diaphragm; and when it does occur, it must be obviously ascribed to a morbid affection of the sensorium itself. See FEVER and PLEURISY.

PARAPHROSYNE, or *Alienation of Mind*, signifies, in the writings of some physicians, a slight and transitory derangement of the intellect, or non-febrile delirium, especially the temporary delirium occasioned by intoxicating and narcotic substances, such as spirituous liquors, opium, stramonium, hyoscyanus, hemp or bang, nightshade, hemlock, the betel leaf, &c. &c. Sauvages Nosol. Meth. class. viii. gen. 17.

PARAPITE, in *Geography*. See MADEIRA.

PARAPLEGIA, and PARAPLEXIA, from *παρὰ*, and *πλησσω*, *I strike*, signify, in the writings of the older authors, a palsy affecting the whole body below the neck. Dr. Cullen and the moderns confine it to a palsy, affecting half the body *transversely*, in contradistinction from the hemiplegia, which affects one side, or half the body *longitudinally*. See PALSY.

PARAPOTAMIA, in the *Materia Medica of the Ancients*, a word used at first as an epithet of distinction for a kind

kind of œnanthe, from which the œnanthine ointment of the Greeks was made; but afterwards used simply as the name of that plant. This kind of œnanthe was the most fragrant of all the kinds, and was therefore used for making the ointment preferably to the rest.

Theophrastus makes a very great difference in the œnanthe of different places, observing that the Cyprian kind was fragrant, and fit for making this sweet ointment; but that the Grecian had no smell at all: and thence it probably arose, that the Greeks used afterwards the flowers of the wild vine for this purpose, and called them by the same name.

Pliny's account of this ointment is by no means to be depended upon. The whole passage where he names it, and the others of the like kind, is taken from the account of Apollodorus, in Athenæus; but it is so carelessly translated by Pliny, that the author's sense can scarcely any where be made out.

PARAPROSDOCIA, παραπροσδοκία, in *Rhetoric*, the same with paradox. See PARADOX.

PARARYTHMOS, an epithet used by the ancients to express any kind of pulse, which did not seem suitable to the age and state of the person.

PARASANG, παρασαγγήνη, or FARSANG, an ancient Persian measure different at different times, and in different places; being usually thirty, sometimes forty, and sometimes sixty stadia or furlongs.

The word, according to Littleton, has its rise from *parafch, angarius, q. d.* the space a postman rides from one station, *angaria*, to another.

Cassaubon cites a fragment of the architect Julian, who says, that the most common measure of the parasang, in his time, was forty stadia; and reckoning each stadium at one hundred and twenty-five geometrical paces, they would hereby avoid fractions in the computation of distances; forty stadia, of one hundred and twenty-five paces each, making five thousand Roman paces. The authors of the Universal Dictionary, vol. ii. p. 19, fol. ascribe the introduction of this measure to Keykobod, one of the Persian kings of the second race, who employed his soldiers in making great roads through the empire, setting up public marks at the end, as they say, of every four thousand paces, which space was called by the Persians, *pherfength*, and from thence by the Greeks, *parasang*.

PARASÄOLI, in *Geography*, a town of Hindooftan, in the circle of Jyenagur; 15 miles N.N.E. of Jyepour. N. lat. 27° 10'. E. long. 76° 48'.

PARASCENIUM, among the Romans, was a place behind the theatre, whither the actors withdrew to dress, undress, &c. more frequently called *postscenium*.

PARASCEVE, παρασκευη, the sixth day of the last week of Lent, popularly called *Good Friday*.

St. John says, our Saviour was crucified on the parasceve of the Passover, *i. e.* on the eve or day of preparation of the Passover: for Isidore and Papias observe, that the word in the original Greek signifies preparation, and was applied among the Jews to Friday, because on that day they used to prepare what was necessary for the celebration of the sabbath. Exod. xv. 23. xxxv. 2, 3.

Hence, what our translation of the New Testament renders preparation of the sabbath, M. Simou, and some others, call *parascova*.

PARASCHE, from פֶּרַשׁ, *to divide*, a name which the Jews give to that portion of the Pentateuch which they read every sabbath. They divide their five books of the law, not into chapters, as we do, but into fifty-four parts, which they call *parasche*: and thus go through the whole in a

VOL. XXVI.

year. To these they have added some verses of the prophets, which they made use of under the persecution of Antiochus Epiphanes, when they were prohibited the use of the law.

PARASCHIDES, a word used by chirurgical writers to express the splinters of fractured bones, or the fragments of bones corroded by sharp humours.

PARASEISMA, a sort of exercise prescribed by the Greek physicians in many cases. It was a general concussion of the body.

PARASELENE, formed from παρα, *near*, and σεληνη, *moon*, in *Physiology*, a mock moon: a meteor, or phenomenon encircling or adjacent to the moon, in form of a luminous ring; in which are sometimes observed one, sometimes two apparent images of the moon.

The paraselenes are formed after the same manner as the parhelia, or mock-suns, by reflections of the moon from zones of dense vapours that happen to be collected in the sky.

Pliny mentions three moons, which were seen in the year of Rome 632. Eutropius also informs us, that he saw three moons at Rimini, in the year 234 before Christ. Hevelius also saw three moons at Dantzic, in 1660. And similar phenomena have been observed at different times, by many others. These paraselenes have been seen, accompanied with tails and coloured circles, like those which accompany the parhelia. An account of several, and a particular description of a fine appearance of this kind, may be found in Muschenbroeck's Introduction, p. 1046. See HALO and PARIELIUM.

PARASEMUM, παρασημον, among the ancients, a sign painted or carved on the prow of ships, by which they were distinguished from one another. The sign was commonly the figure or picture of some animal, as the bull, lion, &c. or of any other thing, as a mountain, tree, flower, &c.

PARASIOPEISIS, παρασιωπησις, in *Rhetoric*. See PARALEPSIS.

PARASITE, παρασιτης, among the Greeks, was originally a very reputable title: the parasites being a kind of priests, or at least ministers of the gods; in the same manner, as at Rome were the epulones.

They took care of the sacred corn; or the corn destined for the service of the temples, and the gods; *viz.* sacrifices, feasts, &c. They had even the intendance over sacrifices, and took care that they were duly performed. At Athens there was a kind of college of twelve parasites; each people of Attica furnishing one, who was always chosen out of one of the best families.

Polybius adds, that parasite was also an honourable name among the ancient Gauls, and was given to their poets; but of late it has been made a term of reproach, and used for a flatterer and mean dependant.

PARASITE Plants, in *Gardening*, are all those which are produced upon the trunks, branches, or any other parts of other plants or roots: and which, in some instances, will not take their growth in the ground, as in the cases of mistletoe, various mosses, and the fungus tribe in general, but not always.

The particular manner in which these sorts of plants attach themselves to those of other kinds is not by any means constant or uniform. Some, such as the mistletoe, mosses, and fungi, are produced originally upon the plants on which they are found growing; the first of which grows upon the branches of large trees, principally from the under sides of them multiplying and extending its roots underneath the bark; and its top branches or spreads out into a large head, which, for the most part, grows downwards in a hanging position,

position, being nourished wholly at the expence of the tree or plant upon which it grows: the mosses, on the contrary, are in general dispersed all over the surfaces of the stems and branches; and the fungi sometimes fix themselves upon the upper roots of old trees, and at others upon their trunks or stems.

There are other plants of this nature which arise from the ground, and the stems of which fix on and attach themselves to the first plants which they meet with, or that come in their way, into which they strike root, in consequence of which the first or ground roots die, or are decayed, the plants continuing to live and nourish themselves upon the plants into which they have struck, and on which they are fixed.

And there are still other kinds of this sort of plants, which first root in the ground, their stems attaching themselves to the bodies of trees or other substances within their reach, striking their roots into their barks, or other matters, as they rise or grow upon them; but still continuing their ground roots, and drawing their chief nourishment from the earth. This is the case in the ivy kind of plants, and some others of a similar nature and habit of growth.

Several of these plants are highly injurious and mischievous to garden, fruit, and other trees, as the mistletoe and moss, to those of the apple kind; and the ivy, as well as sometimes the funguses, both to fruit and forest trees. They should therefore be constantly removed from them by the gardener as soon as they are perceived to have fixed or established themselves on them.

This, in the first or mistletoe kind, should be done by cutting away the top parts, and then completely destroying the roots, while the plants are in an early state of growth. And, in the moss forts, by means of rubbing and scraping them off from the trunks and branches in a complete manner by a stiff brush, or some other way, afterwards washing them well with soft soap and water, then keeping the trees sufficiently thinned out in their different parts.

The fungi about the roots of trees may be easily removed and destroyed by any sort of slight digging of the ground near them.

PARASITEUM, among the ancients, a granary or place where the sacred corn, designed for religious purposes, was preserved. See PARASITE.

PARASO, in *Geography*, a town of France, in the department of Golo (or isle of Corsica,) and chief place of a canton, in the district of Calvi. The canton contains 2471 inhabitants.

PARASOL, a little moveable, in manner of a canopy, borne in the hand to screen the head from the sun, rain, &c. more usually called *umbrella*.

It is made of leather, taffety, oil-cloth, &c. mounted on a stick, and opened or shut at pleasure, by means of pieces of whalebone that sustain it. The East Indians never stir without a parasol.

The word is French; and that used against rains is sometimes called *parapluie*.

PARASOPIAS, in *Ancient Geography*, a country of Greece, in Thessaly, between Asopus and Sparchius, and above Heraclea. Strabo.

PARASPHAGIS, a word used by some anatomical writers to express that part of the neck which is contiguous to the clavicles.

PARASTATA, in *Ancient Architecture*, a kind of pier, or piedroit, serving as a defence or support to a column or arch.

Mr. Evelyn makes the parastata the same with pilaster.

Barbaro, and others, the same with anta; and Daviler, the same with piedroit. See PILASTER.

PARASTATÆ, EPIDYDIMIDÆ, in *Anatomy*. See GENERATION.

PARASTREMMA, a name given by medical writers to a convulsive distortion of the mouth, or of any part of the face.

PARASU RAMA, in *Hindoo Mythology*, is one of the ten grand incarnations of their deity Vishnu. On this occasion he was born the son of a pious Brahman named Jamadagni, and his wife Runeka. (See these articles.) This incarnation or avatara is said to have taken place in Agra, for the purpose of relieving mankind from a military government, which had become insupportably oppressive. Parasu Rama fought twenty battles with one of the oppressive rajas, slew him, and extirpated the race. After a life spent in mighty and holy deeds, Rama gave his whole property in alms, and retired to the Kokan, or Concan, the low country between Surat and the Southern Cape, though not the whole extent of this tract, (see CONCAN,) where the Hindoos say he is still living. In pictures, this Rama (for there are three of this name whose exploits form the subject of the Ramayana, to which article, and to Rama, the reader is referred,) is usually represented two-armed, holding a battle axe and a lotus, combating his twenty-armed foe Raja Diruj. The epithet *parasu*, distinguishingly prefixed to the name of this hero, means a *sword*, and denotes his warlike character. Some authorities say that Rama was educated by Siva, and going one day to pay his respects on Kailasa, he was prevented from entering by Ganefa, whom he knew not. Enraged at his insolence, he wrenched a scimeter from his hand, and cut off his head, and was hence surnamed *Parasu*, the *cutter-off*. Ganefa is a name of Pollear. See the latter article.

PARATECA, in *Geography*, a town of Brazil, in the Francisco; 240 miles W. of St. Salvador.

PARATELLA, a town of Hindooostan, in the circar of Condapilly; 5 miles N. of Condapilly.

PARATHENAR, in *Anatomy*, a name given by Winslow to two muscles of the foot. His parathenar major is that part of the abductor minimi digiti, which arises from the os calcis: the parathenar minor is the flexor brevis minimi digiti.

PARATHESIS, in the *Greek Church*, the prayer which the bishop rehearses over the catechumens, stretching his hands over them to give them benediction; and which they receive, bowing their heads under his hands.

PARATHESIS (popularly called *brackets* or *crotchets*) is also the name of a kind of point or mark, as [], used in writing, chiefly to include synonyma, explicatives, and the like matters, not essential to the discourse. See PARENTHESIS.

PARATHESIS, in *Grammar*, *opposition*; or a figure whereby two or more substantives are put in the same case.

PARATHREMA, from *παρα*, and *αρθρον*, a *joint*, in *Surgery*, a luxation, or dislocation. Also, a tumour caused by a protrusion of parts; a rupture, or hernia.

PARATI, in *Ichthyology*, the name of a Brasilian fish of the mullet kind, much resembling that species called *curema*, or *taintra*, in all respects but size, and in the colour of its eyes, the iris of which, instead of the silvery colour it has in the curema, is of a fine yellow. Its flesh also, when dressed, is drier than that of the curema, which see.

PARATIANÆ, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis, on the route from Lemna to Hippona, between Ruficades and Calucitena, according to the Itin. of Antonine.

PARATILMUS, in the *Ancient Greek Jurisprudence*, a name

a name given to a sort of punishment imposed on adulterers, who were poor, and unable to stand the common penalty.

It consisted either in making them run a horse-radish up the anus, which they called *απορίσσανδρασις*; or in tearing up by the roots the hair about the pudenda, which they called *παράτιλος*, of *παρτίλλειν*, to *tear, pluck up*.

PARATINGA, in *Geography*. See XINGU.

PARATITLES, PARATITLA, in *Jurisprudence*, short notes, or summaries of the titles of the Digest and Code; which have been made by several lawyers, in order to compare and examine the connexion of the several parts with one another.

We have paratitles of Cujas, of Maran, &c. Chaffaucus has a second comment on the paratitles of Cujas.

PARATOLA, in *Geography*, a town of Bengal; 8 miles S.S.E. of Islamabad.

PARATOUNKA, an ostrog of Kamtschatka, on a river which runs into the Avatcha; 10 miles W. of St. Peter and St. Paul.

PARAVAIL, PARAVAILLE, in *Law*, the lowest tenant of a fee; or he that is immediate tenant to the land.

He is called *tenant paravail*, because, it is presumed, he hath profit and avail by the land. See TENANT.

PARAVANGAH, in *Geography*, two small islands near the coast of Bengal. N. lat. 22° 50'. E. long. 89° 35'.

PARAVANI, a town of Turkish Armenia; 50 miles S.S.E. of Akalziké.

PARAUTE, a town of South America, in the province of Venezuela, on lake Maracaybo; 80 miles S. of Venezuela.

PARAWA, a town of India, on the route from Agra to Oujein; 14½ miles N.W. from Soofneer. The soil in its vicinity is black and spongy, like most of Malava or Malwa, but little cultivated. The district dependent on this town yields one lack of rupees annually. Asiatic Ref. vol. vi. p. 62.

PARAY-le-Monias, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Charolles, near the river Bourbinec; 6 miles W. of Charolles. The place contains 2848, and the canton 7258 inhabitants, on a territory of 235 kilometres, in 12 communes. N. lat. 46° 27'. E. long. 4° 12'.

PARAZONIUM, *παράζωνιον*, or *Scipio*, among *Medicists*, a sceptre rounded at the two ends in manner of a truncheon, or commander's staff; or a kind of poignard, or short sword, represented as worn at the girdle, on several ancient medals.

Antiquaries are much divided on the explication of the parazonium; as, indeed, the form and manner of bearing it are very different. It is sometimes thrown across the shoulders in manner of a quiver.

PARBOILING, in *Pharmacy*, &c. a term applied to fruits, herbs, &c. which are boiled a little while, to draw out the first juices, in order to be afterwards inspissated or thickened. See BOILING.

PARBOSENA, in *Ancient Geography*, a town of Asia, in the environs of Cappadocia, upon the route from Tavia to Sebaste, between Sibora and Carniana, according to the Itinerary of Antonine.

PARBUCKLE, in *Seamanship*, a contrivance used by sailors as a substitute for a crane or tackle. It is formed by fastening the *bight* of a rope to the place from whence the weight, such as a cask or bale, is to be raised or lowered; the two parts of the rope are then passed under the quarters of the cask, and bringing them back again over it, the ends of the rope are hauled upon to raise the weight, or gradually

slackened together, and the cask or bale suffered to roll easily downwards to whatsoever may receive it below.

PARCÆ, so called, says Servius, on the fourth eclogue of Virgil, by antiphrasis, because they spare nobody, *quod nemini parcant*, goddesses who, according to the ancient Pagan theology, preside over the periods or durations of human lives. These the ancients frequently confounded with the Fates, or Destinies; and, in effect, the Parcæ, according to Plato, were the daughters of Necessity and Destiny. According to Hesiod, they were the daughters of Jupiter and Themis, by whom he had also the Seasons; but in another place he says, they were the offspring of Night and Erebus.

The Parcæ were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us, the Parcæ spun the thread of men's lives; that Clotho held the distaff, and drew the thread; Lachesis twirled the spindle, and spun it; and Atropos cut it:

“Clotho eolum retinet, Lachesis net, & Atropos occat.”

The ancients represent the Parcæ divers ways: Lucian, in the shape of three poor old women, having large locks of wool, mixed with daffodils, on their heads; one of which holds a distaff, the other a wheel, and the third a pair of scissars, with which to cut off the thread of life. Others represent them otherwise; Clotho appearing in a long robe of divers colours, wearing a crown upon her head, adorned with seven stars, and holding the distaff in her hand; Lachesis in a robe beset with stars, with several spindles in her hand; and Atropos, clad in black, cutting the thread with large scissars.

The ancients imagined, that the Parcæ used white wool for a long and happy life; and black for a short and unfortunate one.

Pausanias says, that these goddesses had some temples in Greece, and statues in several places. He informs us, that in the city of Olympia, there was an altar consecrated to Jupiter, the inventor of the Parcæ, near which these goddesses had another; and from the same author we learn, that among the other figures upon Cypselus's chest, was to be seen that of a kind of monster, with a wild and savage air, great tusks, and crooked hands, which was known to be a Parca from an inscription upon it.

PARCAS, in *Geography*, a town of Walachia; 16 miles S. of Brancovani.

PARCAY, a town of France, in the department of the Mayne and Loire; 12 miles S.E. of Baugé.

PARCE', a town of France, in the department of the Sarthe; 6 miles E. of Sablé.

PARCEL-MAKERS, two officers in the exchequer, who make parcels of the excheator's accounts, wherein they charge them with every thing that they have levied for the king's use, within the time of their office, and deliver the same to one of the auditors of the court to make their accounts therewith.

PARCELS, *Bill of*. See BILL.

PARCELLING, RIGGING, in *Ship Building*, long narrow slips of canvas payed or dipt in soft tar, which are bound round the surface of ropes in spiral turns, as smoothly as possible, before it is *served*, that the rope may not be uneven, or full of ridges, and to further preserve it from the injuries of weather, &c.

PARCELLING a *Scam*, is laying a slip of canvas, prepared as above, over the seam, first paying under it, and then over it, with soft tar or melted pitch. This should be always per-

formed when seams are covered by the cheeks of the leads, &c. or, what is better, covered with sheet copper.

PARCELOR, in *Geography*, a mountain of Asia, on the coast of Salengore, near the straits of Malacca. N. lat. 2° 45'. E. long. 101° 29'.

PARCENERS, quasi *Parcellers*. See CO-PARCENERS.

Parceners are so called, says Littleton (§ 309.), because they may be constrained to make *partition*, of which there are several kinds. (See PARTITION.) The properties of parceners are, in some respects, like those of *joint-tenants* (see that article); as they have the same unities of interest, title, and possession. They may sue and be sued jointly for matters relating to their own lands (Co. Litt. 164); and the entry of one of them shall, in some cases, enure as the entry of them all. (Ibid. 188, 243.) They cannot have an action of trespass against each other; but herein they differ from joint-tenants, that they are also excluded from maintaining an action of waste (2 Inst. 403); for co-parceners could at all times put a stop to any waste by writ of partition, but till the statute of Henry VIII. joint-tenants had no such power. Parceners also differ materially from joint-tenants in other points. 1. They always claim by descent, whereas joint-tenants always claim by purchase. 2. There is no unity of time necessary to an estate in co-parcenary. 3. Parceners, though they have an unity, have not entirety, of interest.

PARCHIM, in *Geography*, a town of the duchy of Mecklenburg, on the Elda, which divides it into New and Old Town, in each of which is a church. The number of inhabitants is about 3000; 34 miles S. of Wismar. N. lat. 53° 28'. E. long. 11° 55'.

PARCHMENT, in *Commerce*, &c. sheep or goats' skin prepared after a peculiar manner, which renders it proper for several uses; particularly for writing on, and for the covering of books, &c.

The word comes from the Latin *Pergamena*, the ancient name of this manufacture; which it is said to have taken from the city of Pergamos, to Eumenes, king whereof, its invention is usually ascribed; though, in reality, that prince appears rather to have been the improver than the inventor of parchment; for the Persians of old, according to Diodorus, wrote all their records on skins; and the ancient Ionians, as we are told by Herodotus, made use of sheep-skins and goat-skins in writing, many ages before Eumenes's time. Nor need we doubt, that such skins were prepared and dressed for that purpose, after a manner not unlike that of our parchment, though, probably, not so artificially. Vide Diod. Sicul. lib. ii. p. 84. Herodot. lib. v. Prid. Connect. part i. lib. vii. p. 708.

Dr. Prideaux is a strenuous advocate for the antiquity of parchment; and he imagines that the authentic copy of the law which Hilkiah found in the Temple, and sent to king Josiah, was formed of this material; because no other used for writing, parchment excepted, could be of so durable a nature as to last from the time of Moses till that period, for eight hundred and thirty years. But it has been replied to this argument, that the Egyptians wrote on linen those things which they designed for long duration; and those who have examined mummies with attention, assure us, that the characters so written continue to this day. It is not, therefore, improbable, that a copy of the law of Moses, written after this manner, might have lasted eight hundred and thirty years. Besides, it is not very likely that those skins which were used, according to the testimony of Diodorus and Herodotus, by the Persians and Romans for writing, long before the time of Eumenes, were dressed like parchment. They must have been prepared in a much

runder manner, and have little resembled the parchment, of which Eumenes is said to be the inventor; because, if it had been found out before, it would have rendered the want of the Egyptian papyrus no inconvenience to that prince. Such skins might do for records, and for some occasional writings, but would have been by no means proper for books. Hence some writers have concluded, that parchment was a later invention than the Egyptian paper.

Parchment constitutes a very considerable article in the French commerce; it is made in most of their cities; and, besides the consumption at home, they send vast quantities abroad, particularly to England, Flanders, Holland, Spain, and Portugal.

That called *virgin* parchment is somewhat thinner and finer than the rest; and is most proper for certain purposes, as fans, &c. and made of the skin of an abortive lamb, or kid.

PARCHMENT, *Manufacture of*. The skin having been stripped of its wool, and having passed the lime-pit (after the manner described under the article SHAMMY), the skinner stretches it on a kind of frame, consisting of four pieces of wood, mortised into each other at the four angles, and perforated lengthways from distance to distance, with holes furnished with wooden pins, that may be turned at pleasure, like those of a violin.

To stretch the skin on this frame, they make little holes all around it, and through every two holes draw a little skewer; to this skewer they tie a small piece of pack-thread, and tie that over the pins; so that coming to turn the pins equally the skin is strained tight every way, like that of a drum.

The skin being thus sufficiently stretched on the frame, the flesh is pared off with a sharp instrument for that purpose; this done, it is moistened with a rag; and a kind of white stone, or chalk, reduced to a fine dust, is strewed over it: then, with a large pumice-stone, flat at bottom, much after the manner of a mullet for grinding colours, they rub over the skin as if about to grind the chalk; and thus they scour off the remains of the flesh. Then they go over it again with the iron instrument; again moisten it as before, and again rub it with the pumice-stone without any chalk underneath; this smoothens and softens the flesh-side very considerably. They then drain it again, by passing over it the iron instrument as before.

The flesh-side being thus drained, they pass the iron on the wool or hair-side; then stretch it tight on the frame, by means of the pins, and go over the flesh-side again with the iron; this finishes its draining; and the more the skin is drained, the whiter it always becomes.

They now throw on more chalk, sweeping it over with a piece of lamb-skin that has the wool on; this smoothens it still farther, and gives it a white down or knap. It is now left to dry, and when dried it is taken off the frame, by cutting it all round.

The skin, thus far prepared by the skinner, is taken out of his hands by the parchment-maker, who first scrapes or pares it dry on the summer with an iron instrument like that above-mentioned, only finer and sharper; with this, worked with the arm from top to bottom of the skin, he takes away about one-half of its thickness. The skin, thus equally pared on both sides, they pass the pumice-stone over both sides, to smoothen it. This last preparation is performed on a kind of form or bench covered with a sack stuffed with straws, and it leaves the parchment in a condition for writing on.

The paring of the skin dry on the summer is the most difficult preparation in the whole process of parchment-making; for which reason, the skimmers seldom dare meddle with

with it, but usually leave it to those more experienced in it; the summer, whereon it is performed, is a calf-skin well-stretched on a frame, serving as a support to the skin, which is fastened a-top of it with a wooden instrument, that has a notch cut in it. Lastly, that the iron knife may pass the easier between the summer and the skin to be pared, they put another skin, which they call the counter-summer. The parings, thus taken off the skin, are used in making glue, size, &c.

What we call *vellum*, is only parchment made of the skins of abortive calves, or, at least, of sucking calves; it is finer, whiter, and smoother, than the common parchment; but it is prepared in the same manner as that, except that it is not passed through the lime-pit.

PARCHMENT, To make a green transparent. Wash the parchment in cold ley, till it come clear from it; then squeeze out the liquor as much as possible; and if you would have it of a fine green colour, take distilled verdigris, ground with vinegar, and add a little sap-green to it; temper it neither too thick nor too thin; then soak your parchment in this colour thoroughly a whole night; rinse it afterwards in water, strain it immediately on a frame, and set it to dry; take clear varnish, lay it on both sides, set it in the sun to dry; after this cut the parchment out of the frame into leaves, as large as you please, and lay them in a book under press, to keep them fine and straight. The effect of this parchment is to make a small letter, when put over it, appear as big again; and it is a great preserver of the eyes, especially to those that read much by candle-light. The varnish must be prepared of linseed-oil, and boiled with frankincense, mastich, and sandarac.

If you would have the parchment of a clear, transparent, and white colour, only wash, strain, and varnish it, as above. If you would colour it yellow, steep your parchment, after it has been washed, in a yellow liquid, made of saffron; for which purpose, tie saffron in a thin linen rag, hang it in a weak ley, and warm it over a slow fire; and when you see the ley tintured yellow, it is fit for use.

For a transparent red.—Take brazil, as much as you will: put it into a hot ley, which is clear, and not too strong, and it will tincture the ley of a fine red; then pour to it about half an egg-shell full of clean wine; draw the parchment through the colour; and when it is as deep as you would have it, strain it as before.

For a blue.—Take Lombard indigo, grind it with vinegar on a stone, and mix sal ammoniac among it, to the quantity of a pea; with this wet your parchment, and proceed as has been directed for the green.

For a violet or purple Colour.—Temper two-thirds of the above red, and one-third of the blue, and use it as before directed.

For a black Colour.—Take Roman alum, beat it into powder, and boil it in rain-water to a fourth part; add Roman vitriol, or atrament, with some Roman galls, and boil them together: with this stain your parchment twice or three times over; and, when dry, lay the Spanish varnish over it.

N. B. With these transparent parchments you may make curious bindings. One sort, used at Rome, is made thus: lay the board or pasteboard over with leaf-gold, leaf-silver, staniel, metal-leaves, &c. then binding the parchment over it, it will give it an uncommon lustre and beauty.

Dr Lewis informs us, that, in order to render the ink durable on parchment, a thick piece of it should be steeped in water, with some oak-bark, for three or four days, and then pressed smooth and dried. When the surface of this parchment was pared off, and the internal part written upon,

the characters continued of a good black, while those made with the same ink, on unprepared parchment, were changed into a yellowish-brown. Vellum may also be treated in the same manner.

It is said, that writing upon parchments decayed by time, may be recovered, and rendered legible, by dipping the obliterated parchment into a vessel of cold water, fresh drawn from the well; let it be taken out in about a minute, and pressed between two papers, in order to prevent its crumpling up in drying. As soon as it is moderately dry, if it be not legible, repeat the operation two or three times.

PARCHMENT, Roll of. See ROLL.

PARCHOUR, in *Geography*, a town of Hindoostan, in the circar of Guntoor; 18 miles S. of Guntoor.

PARCHWITZ, a town of Silesia, in the principality of Liegnitz, and capital of a prefecturate, containing two Lutheran churches, and a Roman Catholic chapel, and also a manufacture of cloth; 10 miles N.E. of Liegnitz. N. lat. 51° 15'. E. long. 16° 20'.

PARCIEUX, ANTHONY DE, in *Biography*, a French mathematician, and member of the Academy of Sciences, was born in the diocese of Uzes in 1703. He taught the mathematics at Paris with great reputation, and died there in 1768. His works are “A Treatise of Trigonometry,” “Essays on the Probability of the Duration of Life,” and “Memoirs on the Practicability of bringing to Paris the Water of the River d’Yvette.” Of the tables of M. Parcieux on the probability of life, great use has been made by the writers on the doctrine of annuities. He had a nephew of the same name, who was educated at the college of Navarre at Paris, where he studied mathematics and philosophy, and, at the age of 24, gave public lectures. In 1779 he began a course of experimental philosophy, in the military school of Brienne; after which, he occupied the philosophical professorship at the Lyceum in Paris, where he died in 1798. He wrote an elementary book on Geometrical and Astronomical Calculations; and in his youth he is said to have composed a tragedy, entitled “Ozorio.”

PARCO FRACTO, or *Pound-break*, in *Law*, a writ which lies against him who violently breaks open a pound, and takes out beasts thence, which, for some trespass done, were lawfully impounded. See POUND.

PARCOL, or **PARCOUL**, in *Geography*, a lake of Thibet; 25 miles in circumference. N. lat 43° 22'. E. long. 92° 42'.

PARCOS, a town of Peru, in the diocese of Guamanga; 25 miles N.E. of Guancavelica.

PARCOU, a town of France, in the department of the Lower Charente; 12 miles E. of Montlien.

PARCOW, a town of Austrian Poland, in Galicia; 36 miles N.N.E. of Lublin.

PARDALIS, in *Zoology*. See *FELIS Pardalis*.

PARDALUS, in *Ornithology*. See *TRINGA Squatarola*.

PARDANTHUS, in *Botany*, so named by Mr. Ker, from *παρδος*, a panther, and *ανθος*, a flower; in allusion to the beautifully spotted tawny-coloured corolla. Ker (late Gawler) in *Ann. of Bot.* v. 1. 246. *Ait. Hort. Kew.* ed. 2. v. 1. 122.—Class and order, *Triandria Monogynia*. Nat. Ord. *Enfatæ*, Linn. *Irides*, Juss.

Gen. Ch. *Cal.* none, unless the bractæ be taken for spathas. *Cor.* of one petal, superior, wheel-shaped, regular, divided to the base into six equal segments, spirally twisted in decay. *Stam.* Filaments three, shorter than the corolla, inserted into the base of three of its segments, nearly straight, spreading; anthers oblong, vertical, somewhat approaching each

each other. *Pist.* Germen roundish; style thread-shaped, ascending, the length of the filaments; stigmas three, spreading, dilated, involute, two-lipped. *Peric.* Capsule obovate-oblong, coriaceous, obscurely triangular, of three cells and three valves, the valves at length revolute. *Seeds* numerous, globose, pulpy, inserted in three double rows upon the edges of a triangular, central, unconnected *receptacle*.

Ess. Ch. Corolla regular, divided to the base into six equal spreading segments. Capsule with many globose, pulpy seeds, inserted into a central, unconnected, triangular receptacle.

1. *P. chinensis.* Chinese Panther-flower. (*Ixia chinensis*; Linn. Sp. Pl. 52. Curt. Mag. t. 171. Gært. t. 13. Trew Ehret. t. 52. Moræa chinensis; Thunb. Mor. n. 19. Willd. Sp. Pl. v. 1. 245. Belamcanda chinensis; Redout. Liliac. t. 121.)—Native of the East Indies, China, and Japan. Hardy with us in the open ground, flowering in June and July. *Root* tuberous, perennial. *Stems* several, about three feet high, round, leafy, smooth, paniced at the summit. *Leaves* equitant, sword-shaped, pointed, striated, light green, about a foot long. *Flowers* several, terminal, erect, stalked, with sheathing tumid bractæas, very short-lived, inodorous, an inch and half wide, of a pale tawny orange, elegantly speckled with a deeper or reddish colour. This flower appears to be a favourite with the Chinese, and is often represented on their paper-hangings and screens.

PARDELA, in *Ornithology*. See PROCELLARIA *Capensis*.

PARDIES, IGNATIUS-GASTON, in *Biography*, a French Jesuit, and ingenious mathematician and philosopher. was born in Bearn in the year 1636. He entered the society of Jesuits when he was about the age of 16, and applied himself so diligently and successfully to his studies, that he was appointed tutor in polite literature, and composed many pieces in prose and verse, distinguished by delicacy of thought and elegance of style, while he was very young. The bent of his mind was, however, turned to philosophical and mathematical studies; and to these he devoted himself with so much ardour, that in a short time he made himself master of the principles of the Peripatetic and Cartesian philosophy, and became highly esteemed as a professor of them. Having displayed great skill in the speculative sciences, in different provinces, he was called to Paris, to be professor of rhetoric in the college of Lewis the Great. Here he acquired celebrity, and the most sanguine hopes were formed of him, which, however, were blasted by his early death in 1673, when he was only in the 37th year of his age. This melancholy event was attributed to a malignant disorder, which he caught while zealously discharging the duties of preacher and confessor at the Bicêtre, during the festival of Easter. He wrote with neatness and conciseness, and in a very good style. His principal works are "Horologium Thaummaticum Duplex;" "Dissertatio de Motu et Natura Cometarum;" "A Discourse on local Movement;" "Elements of Geometry;" "A Discourse concerning the Knowledge of Beasts;" "Statistics, or the Science of moving Forces;" "Description and Explanation of two Machines, for facilitating the Construction of Sun-dials." The greatest part of Pardies' works was printed in a collective form at the Hague, in 1691; and afterwards at Lyons, in 1725. He had a dispute with sir Isaac Newton, concerning his "New Theory of Light and Colours;" and his Letters are preserved in the Philosophical Transactions for the year 1672.

PARDISIUM, in *Botany*, Burm. Prodr. Fl. Capenf. 26. Juss. 190, is corrected by Linnæus in his copy

of Burmann into *Perdisium*. It seems on examination to be his own *Perdicium semiflosculare*, Sp. Pl. 1248, of which Jussieu had no suspicion.

PARDO, or PARDAO, in *Commerce*, a silver coin, and money of account, at Goa. A pardo is worth four good tangas, or five bad. The pardo is divided into 300 reas. The silver coins are the pardo xeraphim of five good tangas, and the common pardo of four good tangas.

PARDO, in *Geography*, a river of Paraguay, which runs into the Parana.

PARDON, in *Law*, a remission or forgiveness of a felony or other offence, against the king, or the laws.

This, our lawyers make twofold: the one, *ex gratia regis*; the other, *per cours de ley*. The first is that which the king, out of some special regard to the person, or some other circumstance, grants, by his absolute prerogative or power, either before conviction of the offender, or after.

This power of pardoning is the most amiable prerogative of the crown. It was said by our Saxon ancestors, (L.L. Edw. Conf. c. 18.) to be derived "a lege sua dignitatis;" and it is declared in parliament by statute 27 Hen. VIII. c. 24, that no other person hath power to pardon or remit any treason or felonies whatsoever; but that the king hath the whole and sole power thereof, united and knit to the imperial crown of this realm.

Judge Blackstone observes, that this is one of the great advantages of monarchy in general, above any other form of government; that there is a magistrate, who has it in his power to extend mercy, wherever he thinks it is deserved; holding a court of equity in his own breast, to soften the rigour of the general laws, in such criminal cases as merit exemption from punishment. Some theorists, however, maintain, that pardons should be excluded in a perfect legislation, where punishments are mild, but certain; because the clemency of the prince seems to be a tacit disapprobation of the laws. But the exclusion of pardons must necessarily introduce a very dangerous power in the judge or jury, that of construing the criminal law by the spirit instead of the letter (see Beccaria, ch. 4. and 46.); or else it must be holden, what no man will seriously avow, that the situation and circumstances of the offender, though they alter not the essence of the crime, ought to make no distinction in the punishment. In democracies, however, this power of pardon can never subsist; for there nothing higher is acknowledged than the magistrate who administers the laws; and it would be impolitic for the power of judging and of pardoning to centre in one and the same person. This, as Montesquieu observes, (Sp. of Laws, book vi. c. 5.) would oblige him very often to contradict himself, to make and unmake his decisions: it would tend to confound all ideas of right among the mass of the people; as they would find it difficult to tell, whether a prisoner were discharged by his innocence, or obtained a pardon through favour. In monarchies, the king acts in a superior sphere; and though he regulates the whole government as the first mover, yet he does not appear in any of the disagreeable or invidious parts of it. Whenever the nation sees him personally engaged, it is only in works of legislature, magnificence, or compassion. To him, therefore, the people look up as the fountain merely of bounty and grace; and these repeated acts of goodness, proceeding immediately from himself, endear the sovereign to his subjects, and contribute more than any thing to root in their hearts that filial affection, and personal loyalty, which are the sure establishment of a prince. In the exercise of this prerogative, however, the sovereign should be directed by a sound discretion and impartial judgment, and also by wise and upright counsellors;

fellors; and the occasions for the exercise of it should be rendered as few and unfrequent as possible, by mitigating the severity of our criminal laws, and lessening their number, and making the penalties annexed to the violation of them more definite and certain.

A pardon may be pleaded in arrest of judgment; in which case it has the same advantage, as when pleaded upon arraignment, *viz.* the saving the attainder, and of course the corruption of blood, which nothing can restore but parliament, when a pardon is not pleaded till after sentence. And certainly, on all accounts, when a man hath obtained a pardon, he is in the right to plead it as soon as possible.

With regard to the object of pardon, judge Blackstone observes, that the king may pardon all offences merely against the crown, or the public; excepting, 1. That, to preserve the liberty of the subject, the committing any man to prison out of the realm is, by the habeas corpus act, made a *præmunire*, unpardonable even by the king. Nor, 2. Can the king pardon, where private justice is principally concerned in the prosecution of offenders; therefore, in *appeals* (which see,) of all kinds, (which are the suit not of the king, but of the party injured,) the prosecutor may release, but the king cannot pardon. (3 Inst. 237.) Neither can he pardon a common nuisance, while it remains unredressed, or so as to prevent an abatement of it; though afterwards he may remit the fine. (2 Hawk. P. C. 391.) Neither, lastly, can the king pardon an offence against a popular or penal statute, after information brought; for thereby the informer hath acquired a private property in his part of the penalty. (3 Inst. 238.) Nor, farther, can the king's pardon be pleaded to any parliamentary impeachment, so as to impede the enquiry, and stop the prosecution of great and notorious offenders. It was enacted by the act of settlement (12 & 13 W. III. c. 2.), that no pardon under the great seal of England shall be pleadable to an impeachment by the commons in parliament. But after the impeachment has been solemnly heard and determined, it is not understood, that the king's royal grace is farther restrained and abridged.

As to the manner of pardoning, it must be under the great seal, and it is a general rule, that wherever it may be reasonably presumed the king is deceived, the pardon is void; so that any suppression of truth, or suggestion of falsehood, in a charter of pardon, will vitiate the whole; for the king was misinformed. (3 Inst. 238.) Generally, words have also a very imperfect effect in pardons. A pardon of all felonies will not pardon a conviction or attainder of felony, but these must be particularly mentioned. (2 Hawk. P. C. 383.) Nor will a pardon of felonies include piracy, which is not punishable at the common law. (1 Hawk. P. C. 94.) It is also enacted by 13 Ric. II. it. 2. c. 1. that no pardon for treason, murder, or rape, shall be allowed, unless the offence be particularly specified; and in murder it shall be expressed, whether it was committed by lying in wait, assault, or malice prepense.

A pardon may be conditional, or the king may extend his mercy upon what terms he pleases. (2 Hawk. P. C. 394.) It may also be observed, that a pardon, by act of parliament, is more beneficial than by the king's charter; for a man is not bound to plead it, but the court must *ex officio* take notice of it (Inst. 43.): neither can he lose the benefit of it by his own laches or negligence, as he may of the king's charter or pardon. (2 Hawk. P. C. 397.) The effect of such pardon by the king, is to make the offender a new man; to acquit him of all corporal penalties and forfeitures annexed to that offence, for which he ob-

tains pardon, and to give him a new credit and capacity. Blackst. Com. book iv.

PARDON by course of Law, is that which the king grants as the law and equity persuades, for a slight offence; as homicide, casual, &c.

PARDON, Charter of. See CHARTER.

PARDON for discovering Accomplices, &c. See APPROVER and DISCOVERY of Accomplices.

PARDON, in the *Canon Law*, is an indulgence which the pope grants to supposed penitents, for remission of the pains of purgatory, which they have merited for the punishment of their sins.

The grand time for the dispensation of pardons is the jubilee.

In this sense, pardon is properly the angelic salutation, said to the Virgin at the found of three little strokes of a bell, rung in the morning, at noon, and night, in order for the person to be entitled to indulgences.

PARDONERS, in our *Ancient Customs*, were persons who carried about the pope's indulgences, and sold them to the best bidders.

PARDOS, or *POMPENNY*, in *Geography*, a town of Africa, in the district of Anta, on the Gold Coast.

PARDOUX, St., a town of France, in the department of the Two Sevres; five miles S.S.W. of Partenay.

PARDOUX la Rivière, St., a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Nontron; four miles S.E. of Nontron. The place contains 1273, and the canton 7860 inhabitants, on a territory of 217½ kilometers, in seven communes.

PARDUBITZ, a town of Bohemia, in the circle of Chrudim, situated on the Elbe, well-built and fortified, in which is a manufacture of knives and sword-blades; five miles N. of Chrudim. N. lat. 49° 55'. E. long. 15° 40'.

PARDUS, in *Zoology*. See *FELIS Pardus*.

PARDUS, in *Conchology*, a name given by authors to a kind of shells, of the genus of the volutæ. We have three kinds of this shell. 1. A voluta spotted with black. 2. Another spotted with yellow. And, 3. A very elegant one spotted with a reddish-colour. They are called *pardis*, or leopard-shells, from their distinct spots resembling those on the skin of a leopard.

PARÉ, AMBROSE, in *Biography*, a French surgeon of eminence, was born at Laval, in the district of the Maine, in the year 1509. He commenced the study of his profession early in life, and practised it with great zeal both in hospitals and in the army; in the latter he held an appointment, under the captain-general of infantry, in 1536. Subsequently his reputation rose very high, and he was appointed surgeon in ordinary to king Henry II. in 1552; and he held the same office under the succeeding kings, Francis II., Charles IX., and Hen. III. To Charles IX. especially he is said to have conferred great professional benefits, especially on one occasion, when some formidable symptoms had been produced by the accidental wound of a tendon in venesection, which he speedily removed. His services appear to have been amply acknowledged by the king; for as Paré was a Huguenot, he would have been included in the horrible massacre of St. Bartholomew's, had not the king sent for him on the preceding night, and ordered him not to leave the royal chamber. After having been long esteemed as the first surgeon of his time, and beloved for his private virtues, he died in the year 1590, at the age of eighty-one.

Paré was not a man of learning, and was even obliged to request a physician to make a French translation of some of the books of Galen, which he wished to consult. Nevertheless

thelſs there are an affectation of much learned reference, and numerous quotations from the ancients, in his writings, which have added nothing to his reputation. There is ſome juſtice in the remark of Van Hoorne, that Paré would have done better, if he had limited his publication to a ſmall volume, containing only the records of his own obſervation and experience. He muſt be conſidered, however, as a man of original mind, and a real improver of his art; and as having greatly facilitated and extended the application of ſeveral principles of practice, which, according to his own acknowledgment, he derived from the Italian writers and practitioners. Though he did not invent, he greatly promoted the practice of tying divided arteries, which he effected by drawing them out naked, and paſſing a ligature over them. He was the author of a great improvement in the treatment of gun-ſhot wounds, by adopting a lenient method, and rejecting irritants and cauterizations, which were employed by his contemporaries. He was alſo a bold and ſucceſſful operator, and records many inſtructive caſes, in which he diſplayed all the reſources of an enlightened ſurgeon. He did not, however, greatly excel in anatomy, though he had practiſed diſſections; and was chiefly a borrower from the works of Veſalius in this department of ſcience, though not without ſome obſervations of his own.

Paré was the author of ſome works, which were univerſally read and translated into moſt of the languages of Europe. His firſt treatiſe, "Manière de traiter les playes faites par harquebuſes, fleches, &c." was published at Paris in 1545, and again in 1552 and 1564. He afterwards laboured ſtrenuouſly to put his brethren in poſſeſſion of a body of ſurgical ſcience in their native tongue; and in 1561 published the firſt edition of his works, in folio. Numerous editions were afterwards printed at Paris and alſo at Lyons; and his pupil, Guillemeau, who was alſo ſurgeon to Charles IX. and Henry IV., translated theſe works into Latin. This translation has been frequently reprinted at various places, with the title of "Ambroſii Paræi, Opera, novis iconibus elegantiſſimis illuſtrata, et Latinitate donata." This volume contains twenty-fix treatiſes, and there is no branch of ſurgery which is not touched upon in the collection. Eloy Dict. Hiſt. Gen. Biog.

PARÉ, or PARÆUS, DAVID, a celebrated German Proteſtant divine of the reformed communion, was born at Francoſtein, in Sileſia, in the year 1548. He was put apprentice to a ſhoe-maker, but this ſituation did not repreſs the early inclination which the youth had diſcovered for learning, and at length his father permitted him to follow the bent of his inclination. At the age of ſixteen years he was ſent to Hirschberg, where was a college, of which Chriſtopher Schilling was the principal. By his tutor he was converted from Lutheraniſm, in which he had been educated, to the principles of the reformed church, on the ſubject of the *real preſence*, a circumſtance that involved the maſter and the pupil in conſiderable difficulties. In 1566 he was ſent, with ten of his ſchool-fellows, to Heidelberg, and they carried with them ſuch effectual recommendations from their common maſter, that they were all admitted into the college of Wiſdom, of which Zachary Uſinus, profeſſor of divinity, was director. At Heidelberg, Paré made great proficiency in all the branches of learning taught in that place, and in 1571 he was admitted to the miniſtry, in which he officiated many years with great reputation. In 1598, he was nominated divinity profeſſor of Heidelberg. He died in June 1622, and was buried with all the funeral honours which the univerſities of Germany are accuſtomed to beſtow on their moſt diſtinguiſhed members. He wrote ſeveral treatiſes againſt Bellarmine; and

commentaries on the ſcriptures. That on the epiſtle to the Romans, being translated into Engliſh, was burnt by order of James I. for containing ſeditious principles. He had a ſon, John Philip, who was born in 1576, at Hembach, in the dioceſe of Worms; and who ſtudied at Neuſtadt and Heidelberg. In 1610 he was made rector of the college at Neuſtadt, where he continued till the town fell into the hands of the Spaniards in 1622, on which occaſion his library was plundered. He died in 1650. He was author of "Lexicon Criticon;" "Lexicon Plautinum, or A Vocabulary to the Comedies of Plautus;" "Calligraphia Romana," and other works. He left a ſon, Daniel, who published "Melliſcium Atticum;" "Hiſtoria Palatina;" "Medulla Hiſtoriæ Eccleſiaſticæ."

PARÉ, in the *Manege*. To pare a horſe's foot is to cut his nails; *i. e.* the horn and ſole of his foot; which is done with a buttrefs in order to ſhoe him.

In England, the ſmith or farrier holds the horſe's foot between his knees, in which poſture he pares the foot, ſets on the ſhoe, drives the nails, and rivets them, and this all alone, without any aſſiſtance from the groom.

PARECALA, in *Geography*, a fertile province of the iſland of Luçon, rich in mines of gold and precious ſtones. The Spaniards receive tribute from about 7000 perſons.

PARECBASIS, παραβάσις, in *Rhetoric*, is uſed to ſignify the exaggeration of a crime, and not a digreſſion from the queſtion in hand, as ſome have thought.

PARECHAMPA, in *Geography*, a town of Bootan; five miles N. of Taſſafudon.

PARECHESIS, παραχρησις, in *Rhetoric*, the too frequent repetition of the ſame ſyllable, thus *perire me malis malim modis*.

PARECHIA, in *Geography*, a ſmall town of the iſland of Paros, built on the ruins of the ancient Paros, on the W. coaſt of the iſland, facing Antiparos; but it preſents no idea of the ancient city, unleſs by the beautiful ruins, which are employed equally without reſerve and without taſte in its conſtruction. Off Parechia, the ſea forms a bight, and a harbour, whoſe entrance is difficult, on account of the ſhoals by which it is obſtructed on the oppoſite coaſt. N. lat. 37° 5'. E. long. 25° 10'.

PAREDES, a town of Spain, in Aſturia; 25 miles N.W. of Oviedo.—Alfo, a town of Spain, in Leon; 13 miles N.W. of Leon.—Alfo, a town of Spain, in New Caſtile; eight miles N. of Siguença.

PAREDES, a town of Portugal, in Eſtramadura; 12 miles N.W. of Layria.

PAREDON *del Eſte*, a ſmall iſland near the N. coaſt of Cuba. N. lat. 22° 16'. W. long. 77° 80'.

PAREDON *del Medios*, a ſmall iſland near the N. coaſt of Cuba. N. lat. 22° 16'. W. long. 77° 50'.

PAREDRI, παραδρι, among the *Athenians*. When the archon, baſileus, or polemarchus, by reaſon of their youth happened not to be ſo well ſkilled in the laws and cuſtoms of their country as might have been wiſhed, it was cuſtomary for each of them to make choice of two perſons of age, gravity, and reputation, to fit with them upon the bench, and direct them as there was occaſion. And theſe aſſeſſors, or paredri, were obliged to undergo the ſame probation in the ſenate-houſe and public forum with the other magiſtrates; and like them too, to give an account how they had behaved themſelves in their reſpective truſts, when their office was expired.

PAREDRIA, a term uſed by Hippocrates to expreſs an aſſociation of two or more diſeaſes in the ſame patient, making, what we call, a complicated illneſs.

PAREGORICS, παραγορικα, formed of παραγορεω, *I apprehenſe*,

peafe, or mitigate, in Medicine, remedies which affuage pain. The fame with what we otherwife call anodynes and opiates.

PAREGORIC Elixir. See ELIXIR Paregoricum.

PAREJA, JUAN DE, in *Biography*, was a Mestizo, (a Spanish name given to thofe who are born of a Spanish father, and a mother a native Indian,) whose love for the art of painting was fuch, that though the flave of Velafquez, and employed by him to prepare his colours, and attend upon him while painting, yet he contrived in feeret to obtain very confiderable proficiency in the art. He died at the age of 60, in 1670.

PAREIRA BRAVA, the root of a plant which is a fpecies of Ciffampelos, growing in the Weft Indies, chiefly in Mexico and Brazil; formerly efteemed a fpecific for the cure of the ftone and gravel.

The name, which, in the original Portuguefe, fignifies *wild wine, or balfard wine*, bears a good deal of analogy to the plant which bears branches loaden with leaves perfectly like thofe of the vine; and which, like them, creep along walls and trees. The Portuguefe value this root on an equal footing with the ipecacuanha. Some druggifts call it, by corruption, *parada prava*.

The root has no remarkable fmell; but to the tafte it manifefts a remarkable fweetnefs of the liquorice kind, together with a confiderable bitternefs, and a flight roughnefs covered by the fweet matter. It gives out great part both of the bitter and fweet fubftance to watery and fpirituons menftrua; in evaporating the watery decoction, a confiderable quantity of refinous matter feparates, which does not mingle with the remaining extract, nor difsolve in water, but is readily taken up by fpirit; whence fpirit appears to be the moft perfect difsolvent of its active parts. Both the fpirituons tincture and extract are in tafte ftronger than the watery.

The Portuguefe were informed of the virtues of this root by the natives of the Brafil, who infufed it in water, which they drank freely in all obftructions of the urinary paffages; and on trial extolled it above all the medicines in ufe. According to Browne, it is ftill ufed with this intention by the negroes in Jamaica. Towards the end of the 17th century, fome of thefe roots were brought over to Europe by the Portuguefe, who recommended them to phyficians as the moft effectual remedy hitherto difcovered in all calculous and gravelly complaints, and various accounts of their efficacy werefoon after publifhed. The Portuguefe accounts were too exaggerated to gain credit with the judicious part of the world; but Mr. Geoffroy's experiments fet its virtues in a much modefter light, and yet fhewed them to be very great; and that the root deferved to be for ever continued in ufe in medicine, and reckoned among the moft valuable fimples. The Portuguefe pretended that it difolves the ftone in the bladder; but though this is not true, Mr. Geoffroy found that it was admirable for breaking the common weaker fabulous concretions in the kidnies and ureters; and that the taking it was always attended with the voiding of large quantities of gravel. He gave it alfo with great fuccefs to perfons afficted with ulcers in the kidnies and bladder, and whose urine was purulent, and at many times totally fuppreffed; thefe fuppreffions of urine were always cured by it, and their urine became lefs thick and purulent; many alfo were perfectly cured of thefe complaints by a courfe of it, with the addition of balfam of capivi toward the end of the courfe.

This property of the pareira brava, of difolving thick humours, gave Mr. Geoffroy an opinion of trying it in humorous afthmas; and thefe obftinate cafes often were greatly abated, and fometimes perfectly cured by it. The

ufual way of taking it was in decoction, fweetening it in the manner of tea. Of the root in fubftance he prefcribed from twelve grains to half a dram, and in decoction or infufion, two or three drams: this quantity of the root bruifed he directed to be boiled in a pint and a half of water, till only a pint remains, which is to be ftrained off, fweetened with a little fugar, divided into three portions, and drank as tea at intervals of half an hour. Mem. Acad. Par. 1710.

The facts alleged to evince the utility of the radix pareiræ bravæ in nephritic and calculous cafes, were principally thofe of Geoffroy, Helvetius, and Lochner. It has alfo been recommended in ifchuria, jaundice, afthma, and fome other chronic difeafes. The accounts given of the fuccefsful employment of this root by French writers induced phyficians to try its effects in this country; but British praftitioners have recorded no remarkable inftances of its efficacy; and as a proof of its being funk into difrepute, it has no place in our pharmacopeias. Lewis's Mat. Med. Woodville's Med. Bot.

PARELCON, in *Grammar*, a figure, whereby a word or fyllable is added to the end of another.

PARELLA, in *Geography*, a town of France, in the department of the Dora; 20 miles N. of Turin.

PARELLONES, a cluster of fmall iflands in the Spanish Main, near the coaft of Darien. N. lat. 9° 37'. W. long. 79° 30'.

PAREMBOLE, παραμβολή, in *Rhetoric*, a figure wherein fomething relating to the fubject is inferted in the middle of a period. All the difference between the parembole and parenthefis, according to Voffius, is, that the former relates to the fubject in hand, whereas the latter is foreign to it. An example of each we have in Virgil, and firft of the parembole.

“Æneas (neque enim patrius confistere mentem
Paffus amor) rapidum ad naves præmitit Achatem.”

The following is an inftance of the parenthefis:

“———— ipfique fuos jam morte fub ægrâ
(Di meliora piis, erroremque hoftibus illum)
Disciffos nudis laniabant dentibus artus.”

See PARENTHESIS.

PARENCEPHALIS, a name given by fome authors to the cerebellum.

PARENCHYMA, in *Anatomy*, is generally applied to the fubftance of glands, and denotes that part of them, which conftitutes the peculiarity of the organ, the bafis, which would remain, if the veffels and nerves were removed. It is often ufed more generally, and in application to other parts, and fignifies the arrangement of the general tiffues, which is common to all the body, and in which the peculiar matter producing the differences of the organs is depofited. See FIBRE.

PARENCHYMA of Plants. Dr. Grew gives the name parenchyma to the pith or pulp, or that inner part of a fruit or plant, through which the juice is fupposed to be diftributed.

This, when viewed with a microfcope, appears to refemble marrow, or rather a fponge, being a porous, flexible, dilatible fubftance.

Its pores are innumerable, and exceedingly fmall; receiving as much humour as is requifite to fill and extend them; which difpofition of pores it is, that is fupposed to fit the plant for vegetation and growth.

The parenchyma of roots is white at firft; but it changes its colour, in proportion as the root grows thicker. Thus

it becomes yellow in the root of the bastard rhubarb, and red in that of the bistort.

PARENT, PARENS, a term of relation, applicable to those from whom we immediately receive our being. See FATHER and MOTHER.

The duties of parents to legitimate children consist in three particulars; *viz.* their maintenance, their protection, and their education.

The first of these duties is a principle of natural law; its obligation results from their having been voluntarily instrumental in giving them existence, which existence they should endeavour, as far as in them lies, to support and preserve. Children have, therefore, a perfect right of receiving maintenance from their parents. Montesquieu observes (*Sp. of Laws*, b. xxiii. c. 2.) that the establishment of marriage in all civilized states is founded on this natural obligation of the father to provide for his children; for that ascertains and makes known the person who is bound to fulfil this obligation. Moreover, the affection of parents to their children, which is too powerful to be totally suppressed or extinguished by any deformity of person or mind, or by the ingratitude, rebellion, and wickedness of children, and the provision which nature has prepared in the person of the mother for the sustentation of the infant, concerning the existence and design of which there can be no doubt, are manifest indications of the divine will. We may hence infer the guilt of those, who run away from their families, and by mere idleness or drunkenness, throw them upon a parish, or leave them, at their death, destitute of that provision for their subsistence, which, by diligence and frugality, they might have laid up for them; and also of those, who refuse or neglect the care of their bastard offspring, abandoning them to a condition, in which they must either perish, or become burdensome to others; for, though it be often not properly regarded, the duty of maintenance, like the reason upon which it is founded, extends to bastards, as well as to legitimate children. The Christian scriptures have declared, in explicit terms, the obligation of this duty: "If any provide not for his own, especially for those of his own household, he hath denied the faith, and is worse than an infidel" (1 Tim. v. 8.), that is, he hath disgraced the Christian profession, and fallen short in a duty which even infidels acknowledge. We may further observe, that the municipal laws of all well-regulated states have taken care to enforce this duty. The civil law (*Ff.* 25. 3. 5.) obliges the parent to provide maintenance for his child; and if he refuses, "*judex de ea re cognoscat.*" It even carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing, and there are fourteen such reasons enumerated (*Nov.* 115), which may justify such disinherison. If the parent alleged no reason, or a bad, or a false one, the child might set the will aside, "*tanquam testamentum inofficiosum,*" a testament contrary to the natural duty of the parent.

It is also a principle of law, as well as of nature, that every man is obliged to provide for those descended from his own loins. By 43 Eliz. cap. 2. the father, mother, grandfather, and grand-mother of poor impotent persons, shall maintain them at their own charges, if of sufficient ability, according as the quarter-sessions shall direct; and by 5 Geo. I. cap. 8. if a parent runs away, and leaves his children, the churchwardens and overseers of the parish shall seize his rents, goods, and chattels, and dispose of them towards their relief. But no person is bound to provide a maintenance for his issue, unless where the children are unable to work, through infancy, disease, or accident: and then is only obliged to find them with necessaries, the penalty on

refusal being no more than 20*s.* a month. (See *Jews*.) Our law has made no provision to prevent the disinheriting of children by will; but by the custom of London, formerly universal, the children of freemen are entitled to one third of their father's effects, to be equally divided between them; of which he cannot deprive them. Farther, a parent, by our laws, may protect his children by supporting them in their law-suits, without being guilty of the legal crime of maintaining quarrels (2 *Inst.* 564.); and a man may justify assault and battery in defence of the persons of his children. (1 *Hawk. P. C.* 131.) With regard to the education of children, parents are bound to perform this part of their duty in a manner suitable to their station in life. This is a duty obviously reasonable, and unquestionably important. If this duty be not discharged with proper attention and assiduity, children must be miserable, and probably will be vicious, when they grow up, either from want of the means of subsistence, or from want of rational and inoffensive occupation. Besides, a person left in this condition will be useless, and at the same time he will be generally mischievous to the community. So that to launch an uneducated child into the world, is injurious to the rest of mankind; it is little better than to turn out a mad dog, or a wild beast into the streets. In the inferior classes of the community, this kind of reasoning condemns the neglect of parents, who do not betimes inure their children to labour and restraint, and fit them, as they have ability and opportunity, for some honest employment, by which they may be preserved from beggary, vice, and infamy. The municipal laws of most countries seem to be defective in this point, by not constraining the parent to bestow a proper education upon his children. The charity of the well-disposed has provided assistance for those parents, whose lot is so hard, that they cannot by labour provide for their children the means both of subsistence and education; and although our laws are defective, yet in one instance they have made a wise provision for breeding up the rising generation; since by the statutes for apprenticing poor children, such children may be apprenticed out by the overseer, &c. (See *APPRENTICE*.) And, in the case of religion, all parents are under peculiar restrictions.

Among the Athenians, if the parent did not put his child into a way of getting a livelihood, the child was not bound to make provision for the parent when old and necessitous. In the middle orders of society, those parents are most reprehensible, who neither qualify their children for a profession, nor enable them to live without one; and those in the highest, who, from indolence, indulgence, or avarice, omit to procure for their children those liberal attainments, which are necessary to make them useful in the stations to which they are destined. A man of fortune, who permits his son to consume the season of education, in hunting, shooting, or frequenting horse-races, assemblies, or other unedifying, if not vicious diversions, defrauds the community of a benefactor, and bequeaths them a nuisance. As some preparation for future life is necessary for youth of every description, those who leave the education of their bastards to chance, contenting themselves with making provision for their subsistence, desert half their duty. Archdeacon Paley observes, that a reasonable provision for the happiness of a child in respect of outward condition, requires three things; a situation suited to his habits and reasonable expectations; a competent provision for the exigencies of that situation; and a probable security for his virtue. The two first articles will vary with the condition of the parent. A situation somewhat approaching in rank and condition to the parent's own; or, if that be not practicable,

ble, similar to what other parents of like condition provide for their children, bounds the reasonable, as well as (generally speaking) the actual expectations of the child, and therefore contains the extent of the parent's obligation. By virtue of this rule, a parent is justified in making a difference between his children, according as they stand in greater or less need of the assistance of his fortune, in consequence of the difference of their age or sex, or of the situations in which they are placed, or the various success which they have met with. Daughters, on account of their peculiar circumstance, which it is needless to specify, should be the particular objects of a parent's care and fore-sight; and as an option of marriage is not presented to every female who deserves it, especially in a country and at a period of time in which a licentious celibacy is fashionable with the men, a father should endeavour to enable his daughter to lead a single life with independency and decorum, even though he subtract more from the portions of his sons, than is agreeable to modern usage, or than they expect. A parent, having provided for the exigencies of his children's conditions, next considers how to satisfy their just expectations: and upon this principle he prefers the eldest son to the rest, and the sons to daughters; which constitutes the right, and the whole right of primogeniture, as well as the only reasons for the preference of one sex to the other. The preference of the first born, indeed, has one public good effect: that if the estate were divided equally among the sons, it would probably make them all idle; whereas, by the present rule of descent, it makes only one so; which is the less evil of the two. And on the part of sons it may be observed, that if the rest of the community make it a rule to prefer sons to daughters, an individual of that community ought to guide himself by the same rule, upon principles of mere equality. For as the son suffers by the rule in the fortune he may expect in marriage, it is but reasonable, that he should receive the advantage of it in his own inheritance. Indeed, whatever the rule be, as to the preference of one sex to the other, marriage restores the equality. And as money is generally more convertible to profit, and more likely to promote industry in the hands of men than of women, the custom of this country may properly be complied with, when it does not interfere with the very plain reason already explained. The actual expectations of children, together with the expediency of subjecting the illicit commerce of the sexes to every discouragement which it can receive, makes the difference between the claims of legitimate children and of bastards. But neither reason will, in any case, justify the leaving of bastards to the world, without provision, education, or profession: or, what is more cruel, without the means of continuing in the situation to which the parent has introduced them; which last is to leave them to inevitable misery.

After the exigencies of a child's situation are provided for, a parent may diminish his portion, in order to punish any flagrant crime, or to punish contumacy and want of filial duty in instances not otherwise criminal; for a child who is conscious of bad behaviour, or of contempt of his parent's will and happiness, cannot reasonably expect the same instances of his munificence. In case of vicious habits that are incorrigible, or of such a disposition to waste or misemploy the fortune put into his power, as if he were made an idiot, the parent may treat the child as such; and provide for his support by an annuity equal to his wants and innocent enjoyments, and which he may be restrained from alienating: and this, says Dr. Paley, is the only case in which a disinherison, nearly absolute, is justifiable. But in order to justify an inofficious disposition of his for-

tune, no parent should be allowed to plead, that "every man may do what he will with his own." For though his will, in this case, however capricious, will be valid; yet his conscience will not be absolved from the obligations of a parent. Nor, on the other hand, when he sits down to make his will, should any partialities for a favourite child over-rule and mislead more manly deliberations. When a parent, in order to make suitable provision for his children by frugality and industry, has gained a sufficiency for this purpose, the plea of children furnishes no just excuse for parsimony. A parent should consider, that children gain not so much as we are apt to imagine, in the chance of this world's happiness, or even of its external prosperity, by setting out in it with large capitals. With respect to those who have died rich, many began with little; and with regard to enjoyment, there is no comparison between a fortune, which a man acquires himself by a fruitful industry, or a series of successes in his business, and one found in his possession, or received from another. It remains to mention another principal part of a parent's duty, which is that of using proper precautions and expedients, in order to form and preserve his children's virtue. But this is a subject which is amply discussed under the several articles of EDUCATION.

The rights of parents result from their duties; and the authority with which they are invested, is given them, partly to enable them more effectually to perform these duties, and partly as a recompence for their care and trouble in the faithful discharge of them. The relation between a parent and his children infers no property in their persons, or natural dominion over them.

By the ancient Roman laws, the father had a power of life and death over his children; but the rigour of these laws was softened by subsequent constitutions. By our English laws, parental authority is much more moderate, but still sufficient to maintain order and obedience. A parent may lawfully correct his child, being under age, in a reasonable manner. The consent or concurrence of the parent to the marriage of his child under age was also directed by our ancient law to be obtained; but now it is absolutely necessary, and without it the contract is void. A father has no other power over his son's estate than as a trustee or guardian; for though he may receive the profits during the child's minority, yet he must account for them when he comes of age. He may, indeed, have the benefit of his children's labour while they live with him, and are maintained by him: but this is no more than he is intitled to from his apprentices or servants. Moreover, the legal power of a father (for a mother, as such, is entitled to no power, but only to reverence and respect) over the persons of his children ceases at the age of twenty-one. Yet, till that age arrives, this empire of the father continues even after his death; for he may by his will appoint a guardian to his children. He may also delegate part of his authority, during his life, to tutors and school-masters.

As it is necessary to determine the destination of children, before they are capable of judging of their own happiness, parents have a right to elect professions for them. Parents, having no natural dominion over their children, or property in their persons, have no right to sell them into slavery. Accordingly, the children of slaves are not, by the law of nature, born slaves; for as the master's right is derived to him through the parent, it can never be greater than the parent's own. Parents not only pervert, but exceed their just authority, when they consult their own ambition, interest, or prejudice, at the manifest expence of their children's happiness. Many instances might be mentioned of this abuse of parental power;

power; but some of them belonging to countries where Catholic establishments prevail, we shall select that of urging children to marriages from which they are averse, with a view of exalting or enriching the family, or for the sake of connecting estates, parties, or interests, or the opposing of a marriage, in which the child would probably find happiness, from a motive of pride or avarice, of family hostility, personal pique, or diversity of religious opinions. Blackst. Com. b. 1. ch. 16. Paley's Princ. of Moral and Political Philosophy, vol. i. ch. 9 and 10. See CHILD.
